Current calculation type	Current route calculation type: • SPF calculation. • **Intra router calculation**—Intra-area route calculation. • **ASBR calculation**—Inter-area ASBR route calculation. • **Inc intra router**—Incremental intra-area route calculation. • **Inc ASBR calculation**—Incremental inter-area ASBR route calculation. • **7to5 translator**—Type-7-to-Type-5 LSA calculation. • **Full intra AS**—Calculation of all intra-AS prefixes. • **Inc intra AS**—Calculation of incremental intra-AS prefixes. • **Full inter AS**—Calculation of all AS-external prefixes. • **Inc inter AS**—Calculation of incremental AS-external prefixes. • **Forward address**—Forwarding address calculation. • **N/A**—Route calculation is not triggered.
Current calculation phase	Current route calculation phase: • **Calculation area topology**—Calculating area topology. • **Calculation router**—Calculating routes on routers. • **Calculation intra AS**—Calculating intra-AS routes. • **7to5 translator**—Calculating Type-7-to-Type-5 LSAs. • **Forward address**—Calculating forwarding addresses. • **Calculation inter AS**—Calculating AS-external routes. • **Calculation end**—Ending phase of calculation. • **N/A**—Route calculation is not triggered.

Process reset state	Process reset state: • **N/A**—The process is not reset. • **Under reset**—The process is in the reset progress. • **Under RIB smooth**—The process is synchronizing the RIB.
Current reset type	Current process reset type: • **N/A**—The process is not reset. • **Normal**—Normal reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPF process.
Next reset type	Next process reset type: • **N/A**—The process is not reset. • **Normal**—Normal reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPF process.
Reset prepare message replied	Modules that reply reset prepare messages: • **P**—Neighbor maintenance module. • **L**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.
Reset process message replied	Modules that reply reset process messages: • **P**—Neighbor maintenance module. • **L**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.

Reset phase of module	Reset phase of each module:
	• Main control module:
	  ○ **N/A**—Not reset.
	  ○ Delete area.
	  ○ Delete process.
	• Neighbor maintenance (P) module:
	  ○ **N/A**—Not reset.
	  ○ Delete neighbor.
	  ○ Delete interface.
	  ○ **Delete vlink**—Delete virtual link.
	• LSDB synchronization (L) module:
	  ○ **N/A**—Not reset.
	  ○ Stop timer.
	  ○ **Delete ASE**—Delete all ASE LSAs.
	  ○ **Delete ASE maps**—Delete ASE LSA maps.
	  ○ Clear process data.
	  ○ **Delete area LSA**—Delete LSAs and maps from an area.
	  ○ **Delete area interface**—Delete interfaces from an area.
	  ○ **Delete process**—Delete process-related resources.
	  ○ **Restart**—Restart process-related resources.
	• Route calculation (C) module:
	  ○ **N/A**—Not reset.
	  ○ **Delete topology**—Delete area topology.
	  ○ **Delete router**—Delete routes of routers.

	○ **Delete intra AS**—Delete intra-AS routes ○ **Delete inter AS**—Delete AS-external routes. ○ **Delete forward address**—Delete forwarding address list. ○ **Delete advertise**—Delete advertising router list. • Route redistribution (R) module: ○ **N/A**—Not reset. ○ **Delete ABR summary**—Delete summary routes of the ABR. ○ **Delete ASBR summary**—Delete summary routes of the ASBR. ○ **Delete import**—Delete redistributed routes.
Area	Area ID in the IP address format.
MPLS TE not enabled	Status of MPLS TE for the OSPF area, which can be **MPLS TE not enabled** or **MPLS TE enabled**.
Authtype	Authentication type of the area: • **None**—No authentication. • **Simple**—Simple authentication. • **MD5**—MD5 authentication.
Area flag	Type of the area: • Normal. • Stub. • StubNoSummary (totally stub area). • NSSA. • NSSANoSummary (totally NSSA area).
7/5 translator state	State of the translator that translates Type-7 LSAs to Type-5 LSAs: • **Enabled**—The translator is specified through commands. • **Elected**—The translator is designated through election. • **Disabled**—The device is not a translator.
7/5 translate stability timer interval	Stability interval for Type-7 LSA-to-Type-5 LSA translation.
SPF scheduled Count	SPF calculation count in the OSPF area.
Interface	Interface in the area.
Cost	Interface cost.
State	Interface state.
Type	Interface network type.
MTU	Interface MTU.
Priority	Router priority.
Timers	OSPF timers: • **Hello**—Interval for sending hello packets. • **Dead**—Interval within which the neighbor is down. • **Poll**—Interval for sending hello packets. • **Retransmit**—Interval for retransmitting LSAs.
FRR backup	Whether Loop Free Alternate (LFA) calculation is enabled on an interface.
Enabled by interface configuration (including secondary IP addresses)	OSPF is enabled on the interface. **including secondary IP addresses** indicates that OSPF advertises the direct routes

	to the primary and secondary addressess of the interface.
Simple authentication enabled	Simple authentication is enabled.
MD5 authentication enabled	MD5/HMAC-MD5 authentication is enabled.
The last key is *xx*	The most recent MD5/HMAC-MD5 authentication key ID is *xx*.
The rollover is in progress, *xx* neighbor(s) left	Key rollover for MD5/HMAC-MD5 authentication is in progress. The number of neighbors that have not completed rollover is *xx*.
Packet size	Maximum length of OSPF packets that can be sent by the interface.

display ospf abr-asbr

Use **display ospf abr-asbr** to display routes to the ABR or ASBR.

Syntax

display ospf [*process-id*] **abr-asbr** [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays routes to the ABR and ASBR for all OSPF processes.

verbose: Displays detailed information. If you do not specify this keyword, the command displays brief information.

Usage guidelines

If you use this command on routers in a stub area, the commands displays no ASBR information.

Examples

Display brief information about routes to the ABR or ASBR.

```
<Sysname> display ospf abr-asbr

          OSPF Process 1 with Router ID 192.168.1.2
                  Routing Table to ABR and ASBR

                 Topology base (MTID 0)
 Type        Destination       Area       Cost  Nexthop         RtType
 Inter       3.3.3.3           0.0.0.0    3124  10.1.1.2        ASBR
 Intra       2.2.2.2           0.0.0.0    1562  10.1.1.2        ABR
```

Display detailed information about routes to the ABR or ASBR.

```
<Sysname> display ospf abr-asbr verbose

          OSPF Process 10 with Router ID 101.1.1.11
```

```
                  Routing Table to ABR and ASBR

                Topology base (MTID 0)

Destination: 1.1.1.1            RtType     : ASBR
Area       : 0.0.0.1            Type       : Intra
Nexthop    : 150.0.1.12         BkNexthop  : 0.0.0.0
Interface  : Vlan10             BkInterface: N/A
Cost       : 1000
```

Table 2 Command output

Field	Description
Type	Type of the route to the ABR or ASBR: • **Intra**—Intra-area route. • **Inter**—Inter-area route.
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
Destination	Router ID of an ABR or ASBR.
Area	ID of the area of the next hop.
Cost	Cost from the router to the ABR or ASBR.
Nexthop	Next hop address.
BkNexthop	Backup next hop address.
RtType	Router type: ABR or ASBR.
Interface	Output interface.
BkInterface	Backup output interface.

display ospf abr-summary

Use **display ospf abr-summary** to display ABR summary route information.

Syntax

display ospf [*process-id*] [**area** *area-id*] **abr-summary** [*ip-address* { *mask-length* | *mask* }] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about ABR summary routes for all OSPF processes.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays information about ABR summary routes for all OSPF areas.

ip-address: Specifies a summary route by its IP address.

mask-length: Specifies the mask length in the range of 0 to 32.

mask: Specifies the mask in dotted decimal notation.

verbose: Displays detailed ABR summary route information. If you do not specify this keyword, the command displays brief ABR summary route information.

Usage guidelines

If you do not specify an IP address, this command displays information about all summary routes on the ABR.

Examples

Display brief information about summary routes on the ABR.

```
<Sysname> display ospf abr-summary

          OSPF Process 1 with Router ID 2.2.2.2
                  ABR Summary Addresses

                Topology base (MTID 0)
                        Area: 0.0.0.1
 Total summary address count: 1
 Net             Mask            Status        Count      Cost
 100.0.0.0       255.0.0.0       Advertise     1          (Not Configured)
```

Table 3 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
Area	Area to which the summary routes belong.
Total summary address count	Total number of summary routes.
Net	Address of the summary route.
Mask	Mask of the summary route address.
Status	Advertisement status of the summary route: **Advertise** or **Non-Advertise**.
Count	Number of summarized routes.
Cost	Cost of the summary route.

Display detailed information about summary routes on the ABR.

```
<Sysname> display ospf abr-summary verbose

          OSPF Process 1 with Router ID 2.2.2.2
                  ABR Summary Addresses

                Topology base (MTID 0)
```

```
                        Area: 0.0.0.1
 Total summary address count: 1

 Net         : 100.0.0.0
 Mask        : 255.0.0.0
 Status      : Advertise
 Cost        : (Not Configured)
 Routes count: 1
   Destination            NetMask                Metric
   100.1.1.0              255.255.255.0          1000
```

Table 4 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
Destination	Destination address of a summarized route.
NetMask	Network mask of a summarized route.
Metric	Metric of a summarized route.

display ospf asbr-summary

Use **display ospf asbr-summary** to display ASBR summary route information.

Syntax

display ospf [*process-id*] **asbr-summary** [*ip-address* { *mask-length* | *mask* }]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about ASBR summary routes for all OSPF processes.

ip-address: Specifies an IP address in dotted decimal notation.

mask-length: Specifies the mask length in the range of 0 to 32.

mask: Specifies the mask in dotted decimal notation.

Usage guidelines

If you do not specify an IP address, this command displays information about all ASBR summary routes.

Examples

Display ASBR summary route information in OSPF process 1.

```
<Sysname> display ospf 1 asbr-summary

          OSPF Process 1 with Router ID 2.2.2.2
                  Summary Addresses

               Topology base (MTID 0)
 Total summary address count: 1

                  Summary Address

 Net         : 30.1.0.0
 Mask        : 255.255.0.0
 Tag         : 20
 Status      : Advertise
 Cost        : 10 (Configured)
 Route count : 2

 Destination     Net mask        Proto      Process   Type     Metric

 30.1.2.0        255.255.255.0   OSPF       2         2        1
 30.1.1.0        255.255.255.0   OSPF       2         2        1
```

Table 5 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
Total summary address count	Total number of summary routes.
Net	Address of the summary route.
Mask	Mask of the summary route address.
Tag	Tag of the summary route.
Status	Advertisement status of the summary route.
Cost	Cost of the summary route.
Route count	Number of summarized routes.
Destination	Destination address of a summarized route.
Net mask	Network mask of a summarized route.
Proto	Routing protocol from which the route was redistributed.
Process	Process ID of the routing protocol from which the route was redistributed.
Type	Type of a summarized route.
Metric	Metric of a summarized route.

display ospf event-log

Use **display ospf event-log** to display OSPF log information.

Syntax

display ospf [*process-id*] **event-log** { **lsa-flush** | **peer** | **spf** }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF log information for all processes.

lsa-flush: Specifies LSA aging log information.

peer: Specifies neighbor log information.

spf: Specifies route calculation log information.

Usage guidelines

Route calculation logs show the number of routes newly installed in the IP routing table.

Neighbor logs include information about the following events:

- The OSPF neighbor state goes down.
- The OSPF neighbor state goes backward because the local end receives BadLSReq, SeqNumberMismatch, and 1-Way events.

Examples

Display OSPF LSA aging log information for all processes.

```
<Sysname> display ospf event-log lsa-flush

          OSPF Process 1 with Router ID 1.1.1.1
                  LSA Flush Log

 Date: 2013-09-22 Time: 14:47:33 Received MaxAge LSA from 10.1.1.1
 Type: 1   LS ID: 2.2.2.2         AdvRtr: 2.2.2.2           Seq#: 80000001

 Date: 2013-09-22 Time: 14:47:33 Flushed MaxAge LSA by the self
 Type: 1   LS ID: 1.1.1.1         AdvRtr: 1.1.1.1           Seq#: 80000001

 Date: 2013-09-22 Time: 14:47:33 Received MaxAge LSA from 10.1.2.2
 Type: 1   LS ID: 2.2.2.2         AdvRtr: 2.2.2.2           Seq#: 80000001

 Date: 2013-09-22 Time: 14:47:33 Flushed MaxAge LSA by the self
 Type: 1   LS ID: 1.1.1.1         AdvRtr: 1.1.1.1           Seq#: 80000001
```

Table 6 Command output

Field	Description
Date/Time	Time when the device receives an LSA that has reached the maximum age.
Received MaxAge LSA from *X.X.X.X*	The device received an LSA that has reached the maximum age from *X.X.X.X*.
Flushed MaxAge LSA by the self	The device flushed the LSA that has reached the maximum age.
Type	LSA type.
LS ID	LSA link state ID.
AdvRtr	Advertising router.
Seq#	LSA sequence number.

Display OSPF route calculation log information for all processes.

```
<Sysname> display ospf event-log spf

          OSPF Process 1 with Router ID 1.1.1.2
                  SPF Log

               Topology base (MTID 0)

Date       Time     Duration   Intra Inter External Reason
2012-06-27 15:28:26 0.95       1     1     10000    Intra-area LSA
2012-06-27 15:28:23 0.2        0     0     0        Area 0 full neighbor
2012-06-27 15:28:19 0          0     0     0        Intra-area LSA
2012-06-27 15:28:19 0          0     0     0        external LSA
2012-06-27 15:28:19 0.3        0     0     0        Intra-area LSA
2012-06-27 15:28:12 0          1     0     0        Intra-area LSA
2012-06-27 15:28:11 0          0     0     0        Routing policy
2012-06-27 15:28:11 0          0     0     0        Intra-area LSA
```

Table 7 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
Date/Time	Time when the route calculation starts.
Duration	Duration of the route calculation, in seconds.
Intra	Number of intra-area routes newly installed in the IP routing table.
Inter	Number of inter-area routes newly installed in the IP routing table.
External	Number of external routes newly installed in the IP routing table.
Reason	Reasons why the route calculation is performed: • **Intra-area LSA**—Intra-area LSA changes. • **Inter-area LSA**—Inter-area LSA changes. • **External LSA**—External LSA changes. • **Configuration**—Configuration changes.

	• **Area 0 full neighbor**—Number of **FULL**-state neighbors in Area 0 changes. • **Area 0 up interface**—Number of interfaces in up state in Area 0 changes. • **LSDB overflow state**—Overflow status changes. • **AS number**—AS number changes. • **ABR summarization**—ABR summarization changes. • **GR end**—GR ends. • **Routing policy**—Routing policy changes. • **Others**—Other reasons.

Display OSPF neighbor log information for OSPF process 1.

```
<Sysname> display ospf 1 event-log peer

          OSPF Process 1 with Router ID 1.1.1.1
                  Neighbors Log

Date       Time     Local Address   Remote Address  Router ID       Reason
2012-12-31 12:35:45 197.168.1.1     197.168.1.2     2.2.2.2         IntPhyChange
2012-12-31 12:35:19 197.168.1.1     197.168.1.2     2.2.2.2         ConfNssaArea
2012-12-31 12:34:59 197.168.1.1     197.168.1.2     2.2.2.2         SilentInt
```

Table 8 Command output

Field	Description
Date/Time	Time when the neighbor state changes.
Local Address	Local address of the neighbor relationship.
Remote Address	Peer address of the neighbor relationship.
Router ID	Neighbor router ID.
Reason	Reasons for neighbor state changes: • **ResetConnect**—The connection is lost due to insufficient memory. • **IntChange**—The interface parameter has changed. • **VlinkChange**—The virtual link parameter has changed. • **ResetOspf**—The OSPF process is reset. • **UndoOspf**—The OSPF process is deleted. • **UndoArea**—The OSPF area is deleted. • **UndoNetwork**—The interface is disabled. • **SilentInt**—The interface is configured as a silent interface. • **IntLogChange**—The logical attribute of the interface has changed. • **IntPhyChange**—The physical attribute of the interface has changed. • **IntVliChange**—The virtual link attribute of the interface has changed. • **VlinkDown**—The virtual link goes down. • **DeadExpired**—The dead timer expires. • **ConfStubArea**—The interface is configured with stub area parameters. • **ConfNssaArea**—The interface is configured with NSSA area parameters. • **AuthChange**—The authentication type has changed. • **OpaqueChange**—The Opaque capability has changed. • **Retrans**—Excessive retransmissions. • **LLSChange**—The LLS capability has changed.

	• **OOBChange**—The OOB capability has changed. • **GRChange**—The GR capability has changed. • **BFDDown**—The interface is shut down by BFD. • **BadLSReq**—The interface receives BadLSReq events. • **SeqMismatch**—The interface receives SeqNumberMismatch events. • **1-Way**—The interface receives 1-Way events. • **LocalNoLSA**—The requested LSA does not exist. • **SameLSAReq**—The received LSA is in the local request queue. • **OldLSAReq**—The received LSA has a larger aging time than the requested LSA in the local request queue. • **DdTimerOut**—Receives a DD packet after the hello timer expires. • **EAChange**—The External Attribute bit has changed. • **RecvNoDupPkt**—Receives a non-duplicate DD packet in loading or full status. • **EbitChange**—The E bit has changed. • **MSbitChange**—The MS bit has changed. • **IbitChange**—The I bit has changed. • **MSeqNumError**—The primary router receives an unexpected serial number from the secondary router. • **SSeqNumError**—The secondary router receives an unexpected serial number from the primary router. • **RecvOpqIntf**—A DD packet that contains a type 9 LSA is received when the opaque LSA reception and advertisement capability is disabled. • **RecvOpqArea**—A DD packet that contains a type 10 LSA is received when the opaque LSA reception and advertisement capability is disabled. • **RecvOpqAs**—A DD packet that contains a type 11 LSA is received when the opaque LSA reception and advertisement capability is disabled. • **RecvNSSA**—A DD packet that contains a type 7 LSA is received in a non-NSSA area. • **InvalidLSA**—A DD packet that contains an invalid LSA is received. • **RecvASE**—A DD packet that contains a type 5 LSA is received on a virtual link or in a stub area.

Related commands

`reset ospf event-log`

display ospf event-log hello

Use **`display ospf event-log hello`** to display OSPF log information about received or sent hello packets.

NOTE:

This command is supported only in Release 6342 and later.

Syntax

`display ospf` [*`process-id`*] **`event-log hello`** { **`received`** [**`abnormal`** | **`dropped`**] | **`sent`** [**`abnormal`** | **`failed`**] } [*`neighbor-id`*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF log information for all processes.

received: Specifies log information for received hello packets.

sent: Specifies log information for sent hello packets.

abnormal: Specifies log information for abnormal hello packets received or sent at intervals greater than or equal to 1.5 times the hello interval.

dropped: Specifies log information for received hello packets that were dropped.

failed: Specifies log information for hello packets that failed to be sent.

neighbor-id: Specifies a neighbor by its ID. If you do not specify this argument, the command displays hello packet log information for all neighbors.

Examples

Display log information about sent hello packets.

```
<Sysname> display ospf event-log hello sent

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Interface: Vlan10
Neighbor address: 10.1.1.2, NbrID: 1.0.0.2
First 4 hello packets sent:
  2019-09-05 20:10:10:121, failed, errno: 132
  2019-09-05 20:10:20:121, succeeded
  2019-09-05 20:10:30:121, succeeded
  2019-09-05 20:10:40:121, succeeded
Last 4 hello packets sent before Full->Down at 2019-09-06 14:52:10:121
  2019-09-06 14:51:40:021, succeeded
  2019-09-06 14:51:50:021, succeeded
  2019-09-06 14:52:00:021, failed, errno: 132
  2019-09-06 14:52:10:010, failed, errno: 132

Interface: Vlan10
Neighbor address: 10.1.1.2, NbrID: 1.0.0.2
First 4 hello packets sent:
  2019-09-05 20:10:10:121, failed, errno: 132
  2019-09-05 20:10:20:121, succeeded
  2019-09-05 20:10:30:121, succeeded
  2019-09-05 20:10:40:121, succeeded
Last 4 hello packets sent before Full->Init at 2019-09-06 11:16:20:171
  2019-09-06 11:15:20:121, succeeded
  2019-09-06 11:15:30:121, succeeded

```

```
  2019-09-06 11:15:50:121, succeeded
```

Table 9 Command output

Field	Description
Interface	Interface that sent the hello packets.
Neighbor address	IP address of the neighbor.
NbrID	Router ID of the neighbor.
First 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the first four hello packets. For a packet failed to be sent, an error code is displayed in the **errno** field.
Last 4 hello packets sent before Full->Down at 2018-01-06 14:52:10:121	Time and result (**succeeded** or **failed**) for sending the last four hello packets before neighbor state change. For a packet failed to be sent, an error code is displayed in the **errno** field.

Display log information about the hello packets that failed to be sent.

```
<Sysname> display ospf event-log hello sent failed

          OSPF Process 1 with Router ID 5.5.5.5
                  Hello Log

Date: 2019-09-06 Time: 14:51:20:121 Interface: Vlan10
Destination address: 224.0.0.5, sent failed, errno: 132

Date: 2019-09-06 Time: 11:20:20:116 Interface: Vlan11
Destination address: 10.1.1.2, sent failed, errno: 132
```

Table 10 Command output

Field	Description
Date	Date for the hello packet sending failure, in the format of YYYY-MM-DD. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for the hello packet sending failure, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that sent the hello packet.
Destination address	Destination IP address of the hello packet.
error	Error code for the hello packet sending failure.

Display log information about the abnormal hello packets sent.

```
<Sysname> display ospf event-log hello sent abnormal

          OSPF Process 1 with Router ID 5.5.5.5
                  Hello Log

Date: 2019-09-06 Time: 11:21:12:121 Interface: Vlan11
Destination address: 224.0.0.5, last one sent: 2019-09-06 11:20:51:916
```

```
Date: 2019-09-06 Time: 11:56:21:312 Interface: Vlan11
Destination address: 10.1.1.2, last one sent: 2019-09-06 11:56:02:691
```

Table 11 Command output

Field	Description
Date	Date for sending the abnormal hello packet, in the format of YYYY-MM-DD. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for sending the abnormal hello packet, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that sent the abnormal hello packet.
Destination address	Destination IP address of the abnormal hello packet.
last one sent	Time for sending the last hello packet before sending the abnormal hello packet.

Display log information about received hello packets.

```
<Sysname> display ospf event-log hello received

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Interface: Vlan10
Neighbor address: 10.1.1.2, NbrID: 1.0.0.2
First 4 hello packets received:
  2019-09-05 20:11:10:121
  2019-09-05 20:11:20:121
  2019-09-05 20:11:30:121

Last 4 hello packets received before Exchange->Down at 2019-09-06 14:52:10:121
  2019-09-06 14:51:10:121
  2019-09-06 14:51:20:121
  2019-09-06 14:51:30:121
  2019-09-06 14:51:40:121

Interface: Vlan10
Neighbor address: 10.1.1.1, NbrID: 1.0.0.1
First 4 hello packets received:
  2019-09-06 19:11:15:121
  2019-09-06 19:11:25:121
  2019-09-06 19:11:35:121
  2019-09-06 19:11:45:121
Last 4 hello packets received before Full->Init at 2019-09-06 21:16:20:171
  2019-09-06 21:15:45:121
  2019-09-06 21:15:55:121
  2019-09-06 21:16:05:121
  2019-09-06 21:16:15:121
```

Table 12 Command output

Field	Description
Interface	Interface that received the hello packets.
Neighbor address	IP address of the neighbor.
NbrID	Router ID of the neighbor.
First 4 hello packets received	Time for receiving the first four hello packets.
Last 4 hello packets received before Full->Init at 2019-09-06 21:16:20:171	Time for receiving the last four hello packets before neighbor state change, in the format of YYYY-MM-DD hh:mm:ss:xxx. YYYY represents the year, MM represents the month, and DD represents the day. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.

Display log information about the received hello packets that were dropped.

```
<Sysname> display ospf event-log hello received dropped

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Date: 2019-09-06 Time: 14:51:22:791 Interface: Vlan10
Source address: 10.1.1.1, NbrID: 1.0.0.1, area: 0.0.0.1
Drop reason: Hello-time mismatch

Date: 2019-09-06 Time: 14:51:20:121 Interface: Vlan10
Source address: 10.1.1.2, NbrID: 1.0.0.2, area: 0.0.0.1
Drop reason: NP-bit mismatch
```

Table 13 Command output

Field	Description
Date	Date for dropping the received hello packet, in the format of YYYY-MM-DD. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for dropping the received hello packet, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that received the hello packet.
Source address	Source IP address of the received hello packet.
NbrID	Router ID of the neighbor.
area	Area to which the neighbor interface belongs.
Drop reason	Reason for dropping the hello packet: • **Area under reset**—The area is in the reset progress. • **Router ID conflict**—Route ID conflict. • **Area mismatch**—Area ID mismatch. • **Unknown virtual router**—The hello packet is from an unknown virtual link. • **Authentication failure**—Authentication check failure. • **Peer address check**—Neighbor address check failure.

	• **Not DR or BDR**—The destination IP address of the hello packet is 224.0.0.6, but the interface is not a DR or BDR. • **Unknown unicast peer**—The hello packet is from an unknown unicast neighbor. • **Option mismatch**—Option mismatch. • **Netmask mismatch**—Subnet mask mismatch. • **Address mismatch**—Address range mismatch. • **Hello-time mismatch**—Hello timer mismatch. • **Dead-time mismatch**—Dead timer mismatch. • **Peer changed**—The source IP address or router ID has changed.

Display log information about the abnormal hello packets received.

```
<Sysname> display ospf event-log hello received abnormal

         OSPF Process 1 with Router ID 5.5.5.5
                 Hello Log

Date: 2019-09-06 Time: 10:12:22:121 Interface: Vlan10
Source address: 10.1.1.2, NbrID: 1.0.0.2, area: 0.0.0.1
Last one received: 2019-09-06 10:12:04:212

Date: 2019-09-06 Time: 14:51:20:121 Interface: Vlan10
Source address: 10.1.1.2, NbrID: 1.0.0.2, area: 0.0.0.1
Last one received: 2019-09-06 14:51:05:113
```

Table 14 Command output

Field	Description
Date&Tme	Date for receiving the abnormal hello packet, in the format of YYYY-MM-DD. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time for receiving the abnormal hello packet, in the format of hh:mm:ss:xxx. hh represents the hours, mm represents the minutes, and ss represents the seconds, and xxx represents the milliseconds.
Interface	Interface that received the abnormal hello packet.
Source address	Source IP address of the received abnormal hello packet.
NbrID	Router ID of the neighbor.
area	Area to which the neighbor interface belongs.
Last one received	Time for receiving the last hello packet before receiving the abnormal hello packet.

Related commands

`reset ospf event-log hello`

display ospf fast-reroute lfa-candidate

Use **`display ospf fast-reroute lfa-candidate`** to display OSPF FRR backup next hop information.

Syntax

display ospf [*process-id*] [**area** *area-id*] **fast-reroute lfa-candidate**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays FRR backup next hop information for all processes.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays FRR backup next hop information for all OSPF areas.

Examples

Display OSPF FRR backup next hop information.

```
<Sysname> display ospf 1 area 0 fast-reroute lfa-candidate

          OSPF Process 1 with Router ID 2.2.2.2
                  LFA Candidate List

                Topology base (MTID 0)

 Area: 0.0.0.0
 Candidate nexthop count: 2
 NextHop          IntIP            Interface
 10.0.1.1         10.0.1.2         Vlan10
 10.0.11.1        10.0.11.2        Vlan20
```

Table 15 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
Area	Area to which the backup next hops belong.
Candidate nexthop count	Number of backup next hops.
NextHop	Backup next hop address.
IntIP	IP address of the output interface.
Interface	Output interface.

display ospf graceful-restart

Use **display ospf graceful-restart** to display GR information.

Syntax

display ospf [*process-id*] **graceful-restart** [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays GR information for all processes.

verbose: Displays detailed GR information. If you do not specify this keyword, the command displays brief GR information.

Examples

Display detailed GR information.

```
<Sysname> display ospf graceful-restart verbose

          OSPF Process 1 with Router ID 1.1.1.1
              Graceful Restart information

4.4.4.4         20.2.0.4        Normal       Reset neighbor
```

Table 16 Command output

Field	Description
OSPF Process 1 with Router ID 1.1.1.1 Graceful Restart information	GR information for OSPF process 1 with router ID 1.1.1.1.
Graceful Restart capability	Whether GR is enabled: • **Enable(IETF)**—IETF GR is enabled. • **Enable(Nonstandard)**—Non-IETF GR is enabled. • **Disable**—GR is disabled.
Graceful Restart support	GR modes that the process supports (displayed only when GR is enabled): • **Planned and unplanned**—Supports both planned and unplanned GR. • **Planned only**—Supports only planned GR. • **Partial**—Supports partial GR. • **Global**—Supports global GR.
Helper capability	Helper capability that the process supports: • **Enable(IETF)**—Supports IETF GR helper capability. • **Enable(Nonstandard)**—Supports non-IETF GR helper capability. • **Enable(IETF and nonstandard)**—Supports both IETF GR helper capability and non-IETF GR helper capability. • **Disable**—Does not support GR helper capability.
Helper support	Policies that the helper supports (displayed only when GR helper is enabled): • **Strict lsa check**—The helper supports strict LSA checking. • **Planned and unplanned**—The helper supports planned and unplanned GR. • **Planned only**—The helper supports only planned GR.
Current GR state	GR state: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in process. • **Under Helper**—The process is acting as GR helper.
Last exit reason	Last exit reason: • **Restarter**—Reason that the restarter exited most recently. • **Helper**—Reason that the helper exited most recently.
Area	Area ID in IP address format.
Authtype	Authentication type of the area: • **None**—No authentication. • **Simple**—Simple authentication. • **MD5**—MD5 authentication.

Field	Description
Area flag	Type of the area: • Normal. • Stub. • StubNoSummary (totally stub area). • NSSA. • NSSANoSummary (totally NSSA area).
Area up Interface count	Number of up interfaces in the area.
Interface	Interface in the area.
Restarter state	Restarter state on the interface.
State	Interface state.
Type	Interface network type.
Neighbor count of this interface	Neighbors of an interface.
Neighbor	Neighbor router ID.
IP address	Neighbor IP address.
GR state	Neighbor GR state: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in process. • **Under Helper**—The process is acting as GR helper.
Last Helper exit reason	Reason that the helper exited most recently.
Virtual-link Neighbor-ID	Router ID of the virtual link's neighbor.
Neighbor-State	Neighbor state: Down, Init, 2-Way, ExStart, Exchange, Loading, and Full.
Interface	Output interface of the virtual link.

display ospf interface

Use **`display ospf interface`** to display OSPF interface information.

Syntax

`display ospf` [*`process-id`*] **`interface`** [*`interface-type interface-number`* | **`verbose`**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`process-id`: Specifies an OSPF process ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPF interface information for all OSPF processes.

`interface-type interface-number`: Specifies an interface by its type and number.

`verbose`: Displays detailed OSPF information for all interfaces.

Usage guidelines

If you do not specify the *interface-type interface-number* argument or the **verbose** keyword, this command displays OSPF brief information for all interfaces.

Examples

Display all OSPF interface brief information.

```
<Sysname> display ospf interface

          OSPF Process 1 with Router ID 192.168.1.1
                  Interfaces

 Area: 0.0.0.0
 IP Address      Type         State    Cost  Pri   DR              BDR
 192.168.1.1     PTP          P-2-P    1562  1     0.0.0.0         0.0.0.0

 Area: 0.0.0.1
 IP Address      Type         State    Cost  Pri   DR              BDR
 172.16.0.1      Broadcast    DR       1     1     172.16.0.1      0.0.0.0
```

Table 17 Command output

Field	Description
Area	Area ID of the interface.
IP Address	Interface IP address (regardless of whether TE is enabled or not).
Type	Interface network type: PTP (P2P), PTMP (P2MP), Broadcast, or NBMA.
State	Interface state: • **Down**—No protocol traffic can be sent or received on the interface. • **Loopback**—The interface is in loopback state and it cannot forward traffic. • **Waiting**—The interface starts sending and receiving Hello packets. The router is trying to determine the identity of the (Backup) designated router for the network. • **P-2-P**—The interface will send Hello packets at the hello interval, and try to establish an adjacency with the neighbor. • **DR**—The router is the designated router on the network. • **BDR**—The router is the backup designated router on the network. • **DROther**—The router is a DR Other router on the attached network.
Cost	Interface cost.
Pri	Router priority.
DR	DR on the interface's network segment.
BDR	BDR on the interface's network segment.

Display detailed information about VLAN-interface 10.

```
<Sysname> display ospf interface vlan-interface 10

          OSPF Process 1 with Router ID 192.168.1.1
                  Interfaces

 Area: 0.0.0.0
```

```
Interface: 172.16.0.1 (Vlan-interface10)
Cost: 1       State: DR        Type: Broadcast    MTU: 1500
Priority: 1
Designated router: 172.16.0.1
Backup designated router: 0.0.0.0
Timers: Hello 10, Dead 40, Poll  40, Retransmit 5, Transmit Delay 1
FRR backup: Enabled
Primary path detection mode: BFD ctrl
Enabled by interface configuration (including secondary IP addresses)
BFD: echo
MD5 authentication enabled.
   The last key is 3.
   The rollover is in progress, 2 neighbor(s) left.
LDP state: No-LDP
LDP sync state: Achieved
Packet size: 1000
```

Table 18 Command output

Field	Description
Interface	Information about the interface, such as the IP address.
Timers	OSPF timers (in seconds): **Hello**, **Dead**, **Poll**, and **Retransmit**.
Transmit Delay	LSA transmission delay on the interface, in seconds.
FRR backup	Whether LFA calculation is enabled on an interface.
Primary path detection mode	Primary link detection mode: • **BFD ctrl**—BFD control packet mode. • **BFD echo**—BFD echo packet mode.
Enabled by interface configuration (including secondary IP addresses)	OSPF is enabled on the interface (including secondary IP addresses).
BFD	BFD session mode enabled on the interface: • **ctrl**—BFD control packet mode. • **echo**—BFD echo packet mode.
Simple authentication enabled	Simple authentication is enabled.
MD5 authentication enabled	MD5/HMAC-MD5 authentication is enabled.
The last key is *xx*	The most recent MD5/HMAC-MD5 authentication key ID is *xx*.
The rollover is in progress, *xx* neighbor(s) left.	Key rollover for MD5/HMAC-MD5 authentication is in progress. The number of neighbors that have not completed rollover is *xx*.
LDP state	LDP state: • **Init**—Initialization state. LDP has not been delivered. • **No-LDP**—LDP is not configured. • **Not ready**—LDP sessions have not been established. • **Ready**—LDP sessions have been established.

Field	Description
LDP sync state	LDP IGP synchronization state: • **Init**—Initialization state. • **Achieved**—LDP has been synchronized. • **Max cost**—OSPF advertises the maximum cost in LSAs.
Packet size	Maximum length of OSPF packets that can be sent by the interface.

display ospf interface hello

Use **display ospf interface hello** to display information about hello packets sent by OSPF interfaces.

NOTE:

This command is supported only in Release 6342 and later.

Syntax

display ospf [*process-id*] **interface** [*interface-type interface-number*] **hello**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process ID in the range of 1 to 65535. If you do not specify this argument, the command displays hello packet information for all OSPF processes.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays information about the hello packets sent by all OSPF interfaces.

Usage guidelines

This command displays information for only the hello packets sent in multicast.

Examples

Display hello packet information for all OSPF interfaces.

```
<Sysname> display ospf interface hello

          OSPF Process 1 with Router ID 192.168.1.1
                 Interfaces

 Area: 0.0.0.0

 Interface: 172.16.0.1 (Vlan-interface10)
 First 4 hello packets sent:
   2019-09-05 11:05:10:121, succeeded
   2019-09-05 11:05:20:121, succeeded
```

```
  2019-09-05 11:05:30:121, succeeded
  2019-09-05 11:05:40:121, succeeded
Last 4 hello packets sent:
  2019-09-06 11:15:10:121, succeeded
  2019-09-06 11:15:20:121, succeeded
  2019-09-06 11:15:30:121, succeeded
  2019-09-06 11:15:40:121, succeeded
```

Table 19 Command output

Field	Description
Area	Area to which the interface belongs.
Interface	IP address of the interface.
First 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the first four hello packets.
Last 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the last four hello packets when the command is executed.

display ospf lsdb

Use **display ospf lsdb** to display OSPF LSDB information.

Syntax

display ospf [*process-id*] **lsdb** [**brief** | **originate-router** *advertising-router-id* | **self-originate**]

display ospf [*process-id*] **lsdb** { **ase** | **opaque-as** } [*link-state-id*] [**originate-router** *advertising-router-id* | **self-originate**]

display ospf [*process-id*] **lsdb** { **asbr** | **network** | **nssa** | **opaque-area** | **opaque-link** | **router** | **summary** } [*link-state-id*] [**originate-router** *advertising-router-id* | **self-originate**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays LSDB information for all OSPF processes.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays LSDB information for all OSPF areas.

brief: Displays brief LSDB information.

asbr: Displays Type-4 LSA (ASBR Summary LSA) information in the LSDB.

ase: Displays Type-5 LSA (AS External LSA) information in the LSDB.

network: Displays Type-2 LSA (Network LSA) information in the LSDB.

nssa: Displays Type-7 LSA (NSSA External LSA) information in the LSDB.

opaque-area: Displays Type-10 LSA (Opaque-area LSA) information in the LSDB.

opaque-as: Displays Type-11 LSA (Opaque-AS LSA) information in the LSDB.

opaque-link: Displays Type-9 LSA (Opaque-link LSA) information in the LSDB.

router: Displays Type-1 LSA (Router LSA) information in the LSDB.

summary: Displays Type-3 LSA (Network Summary LSA) information in the LSDB.

link-state-id: Specifies a link state ID in the IP address format.

originate-router *advertising-router-id*: Specifies an advertising router by its ID.

self-originate: Displays information about self-originated LSAs.

Examples

Display OSPF LSDB information.

```
<Sysname> display ospf lsdb
         OSPF Process 1 with Router ID 192.168.0.1
                 Link State Database

                         Area: 0.0.0.0
 Type      LinkState ID    AdvRouter          Age  Len   Sequence   Metric

Table 21 Command output

Field	Description
Type	LSA type.
LS ID	DR IP address.
Adv Rtr	Router that advertised the LSA.
LS age	LSA age time.
Len	LSA length.

Field	Description
Options	LSA options: • **O**—Opaque LSA advertisement capability. • **E**—AS External LSA reception capability. • **EA**—External extended LSA reception capability. • **DC**—On-demand link support. • **N**—NSSA external LSA support. • **P**—Capability of an NSSA ABR to translate Type-7 LSAs into Type-5 LSAs.
Seq#	LSA sequence number.
Checksum	LSA checksum.
Net mask	Network mask.
Attached router	ID of the router that established adjacency with the DR, and ID of the DR itself.

display ospf nexthop

Use **display ospf nexthop** to display OSPF next hop information.

Syntax

display ospf [*process-id*] **nexthop**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays next hop information for all OSPF processes.

Examples

Display OSPF next hop information.

```
<Sysname> display ospf nexthop

          OSPF Process 1 with Router ID 1.1.1.2
                  Neighbor Nexthop Information

 NbrID           Nexthop         Interface               RefCount   Status
 192.168.12.1    0.0.0.0         Vlan10                  4          Valid
 192.168.12.2    192.168.12.2    Vlan10                  3          Valid
 192.168.12.1    0.0.0.0         Loop100                 1          Valid
```

Table 22 Command output

Field	Description
NbrID	Neighbor router ID.

Field	Description
Nexthop	Next hop address.
Interface	Output interface.
RefCount	Reference count (routes that use the next hop).
Status	Next hop status: valid or invalid.

display ospf non-stop-routing status

Use **display ospf non-stop-routing status** to display OSPF NSR information.

Syntax

display ospf [*process-id*] **non-stop-routing status**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF NSR information for all OSPF processes.

Examples

Display OSPF NSR information.

```
<Sysname> display ospf non-stop-routing status

                  OSPF Process 1 with Router ID 192.168.33.12
                        Non Stop Routing information

Non Stop Routing capability : Enabled
Upgrade phase : Normal
```

Table 23 Command output

Field	Description
Non Stop Routing capability	NSR status: enabled or disabled.
Upgrade phase	Upgrade phase: • **Prepare**—Upgrade preparation phase. • **Restore Smooth**—Upgrade phase. • **Preroute**—Route pre-calculation phase. • **Calculating**—Route calculation phase. • **Redisting**—Route redistribution phase. • **Original and age**—LSA generation and aging phase. • **Normal**—Normal status.

display ospf peer

Use **display ospf peer** to display information about OSPF neighbors.

Syntax

display ospf [*process-id*] **peer** [**hello** | **verbose**] [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF neighbor information for all OSPF processes.

hello: Displays information about the hello packets sent to and received from neighbor routers. In scenarios where hello packets are sent in multicast, the command displays information only about the hello packets received from neighbor routers.

verbose: Displays detailed neighbor information. If you do not specify this keyword, the command displays brief OSPF neighbor information.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays neighbor information for all interfaces.

neighbor-id: Specifies a neighbor router ID. If you do not specify this argument, the command displays all neighbor information.

Examples

Display detailed OSPF neighbor information.

```
<Sysname> display ospf peer verbose

          OSPF Process 1 with Router ID 1.1.1.1
                  Neighbors

 Area 0.0.0.0 interface 1.1.1.1(Vlan-interface100)'s neighbors
 Router ID: 1.1.1.2          Address: 1.1.1.2          GR state: Normal
   State: Full  Mode: Nbr is master  Priority: 1
   DR: 1.1.1.2  BDR: 1.1.1.1  MTU: 0
   Options is 0x02 (-|-|-|-|-|-|E|-)
   Dead timer due in 33  sec
   Neighbor is up for 02:03:35
   Authentication sequence: [ 0 ]
   Neighbor state change count: 6
   BFD status: Disabled

 Last Neighbor Down Event:
 Router ID: 22.22.22.22
 Local Address: 11.11.11.11
```

```
Remote Address: 22.22.22.22
Time: Apr  9 03:18:19 2014
Reason: Ospf_ifachange
```

Table 24 Command output

Field	Description
Area *areaID* interface *IPAddress*(*InterfaceName*)'s neighbors	Neighbor information for the interface in the specified area: • **areaID**—Area to which the neighbor belongs. • **IPAddress**—Interface IP address. • **InterfaceName**—Interface name.
Router ID	Neighbor router ID.
Address	Neighbor router address.
GR state	GR state: • Normal. • Restarter. • Complete. • Helper.
State	Neighbor state: • **Down**—Initial state of a neighbor conversation. • **Init**—The router has received a Hello packet from the neighbor. However, the router has not established bidirectional communication with the neighbor. The router did not appear in the neighbor's hello packet. • **Attempt**—Available only in an NBMA network. In this state, the OSPF router has not received any information from a neighbor for a period. The router can send Hello packets at a longer interval to keep the neighbor relationship. • **2-Way**—Communication between the two routers is bidirectional. The local router appears in the neighbor's Hello packet. • **Exstart**—The goal of this state is to decide which router is the master, and to decide upon the initial Database Description (DD) sequence number. • **Exchange**—The router is sending DD packets to the neighbor, describing its entire link-state database. • **Loading**—The router sends LSRs packets to the neighbor, requesting more recent LSAs. • **Full**—The neighboring routers are fully adjacent.
Mode	Neighbor mode for LSDB synchronization.
Priority	Neighboring router priority.
DR	DR on the interface's network segment.
BDR	BDR on the interface's network segment.
MTU	Interface MTU.

Field	Description
Options	LSA options: • **O**—Opaque LSA advertisement capability. • **E**—AS External LSA reception capability. • **EA**—External extended LSA reception capability. • **DC**—On-demand link support. • **N**—NSSA external LSA support. • **P**—Capability of an NSSA ABR to translate Type-7 LSAs into Type-5 LSAs.
Dead timer due in 33 sec	This dead timer will expire in 33 seconds.
Neighbor is up for 02:03:35	The neighbor has been up for 02:03:35.
Authentication sequence	Authentication sequence number.
Neighbor state change count	Count of neighbor state changes.
BFD status	BFD status: • Disabled. • Enabled (Control mode). • Enabled (Echo mode).
Last Neighbor Down Event	The most recent neighbor down event.
Time	Time when the neighbor went down.
Reason	Reason for the neighbor down event.

Display brief OSPF neighbor information.

```
<Sysname> display ospf peer

          OSPF Process 1 with Router ID 1.1.1.1
               Neighbor Brief Information

 Area: 0.0.0.0
 Router ID       Address         Pri Dead-Time  State             Interface
 1.1.1.2         1.1.1.2         1   40         Full/DR           Vlan10
```

Table 25 Command output

Field	Description
Area	Neighbor area.
Router ID	Neighbor router ID.
Address	Neighbor interface address.
Pri	Neighboring router priority.
Dead-Time	Dead interval remained.
Interface	Interface connected to the neighbor.
State	Neighbor state: Down, Init, Attempt, 2-Way, Exstart, Exchange, Loading, or Full.

Display detailed information about the hello packets sent to and received from neighbor routers.

```
<Sysname> display ospf peer hello
```

```
          OSPF Process 1 with Router ID 1.1.1.1
                  Neighbors

 Area 0.0.0.0 interface 1.1.1.1(Vlan-interface10)'s neighbors
 Router ID: 1.1.1.2          Address: 1.1.1.2
 First 4 hello packets received:
   2019-09-06 09:12:10:121
   2019-09-06 09:12:20:121
   2019-09-06 09:12:30:121
   2019-09-06 09:12:40:121
 Last 4 hello packets received:
   2019-09-06 11:15:10:121
   2019-09-06 11:15:20:121
   2019-09-06 11:15:30:121
   2019-09-06 11:15:40:121
 First 4 hello packets sent:
   2019-09-06 09:12:12:121, failed, errno:132
   2019-09-06 09:12:22:121, succeeded
   2019-09-06 09:12:32:121, succeeded
   2019-09-06 09:12:42:121, succeeded
 Last 4 hello packets sent:
   2019-09-06 11:15:12:121, succeeded
   2019-09-06 11:15:22:121, succeeded
   2019-09-06 11:15:32:121, failed, errno:132
   2019-09-06 11:15:42:121, failed, errno:132
```

Table 26 Command output

Field	Description
Router ID	Router ID of the neighbor.
Address	IP address of the neighbor interface.
First 4 hello packets received	Time for receiving the first four hello packets from neighbors.
Last 4 hello packets received	Time for receiving the last four hello packets from neighbors.
First 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the first four hello packets to neighbors. For a packet failed to be sent, an error code is displayed in the **errno** field. This field is not displayed in scenarios where hello packets are sent in multicast.
Last 4 hello packets sent	Time and result (**succeeded** or **failed**) for sending the last four hello packets to neighbors when the command is executed. For a packet failed to be sent, an error code is displayed in the **errno** field. This field is not displayed in scenarios where hello packets are sent in multicast.

display ospf peer statistics

Use **display ospf peer statistics** to display OSPF neighbor statistics.

Syntax

display ospf [*process-id*] **peer statistics**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF neighbor statistics for all OSPF processes.

Examples

Display OSPF neighbor statistics.

```
<Sysname> display ospf peer statistics
          OSPF Process 1 with Router ID 10.3.1.1
                    Neighbor Statistics
  Area ID         Down Attempt Init 2-Way ExStart Exchange Loading Full Total
  0.0.0.0         0    0       0    0     0       0        0       1    1
  0.0.0.2         0    0       0    0     0       0        0       1    1
  Total           0    0       0    0     0       0        0       2    2
```

Table 27 Command output

Field	Description
Area ID	The state statistics for all the routers in the area to which the router belongs is displayed.
Down	Number of neighboring routers in Down state in the same area.
Attempt	Number of neighboring routers in Attempt state in the same area.
Init	Number of neighboring routers in Init state in the same area.
2-Way	Number of neighboring routers in 2-Way state in the same area.
ExStart	Number of neighboring routers in ExStart state in the same area.
Exchange	Number of neighboring routers in Exchange state in the same area.
Loading	Number of neighboring routers in Loading state in the same area.
Full	Number of neighboring routers in Full state in the same area.
Total	Total number of neighbors in the same state: Down, Attempt, Init, 2-Way, ExStart, Exchange, Loading, or Full.

display ospf request-queue

Use **display ospf request-queue** to display OSPF request queue information.

Syntax

display ospf [*process-id*] **request-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPF request queue information for all OSPF processes.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays the OSPF request queue information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify this argument, the command displays the OSPF request queue information for all OSPF neighbors.

Examples

Display OSPF request queue information.

```
<Sysname> display ospf request-queue

          OSPF Process 100 with Router ID 192.168.1.59
                  Link State Request List

  The Router's Neighbor is Router ID 2.2.2.2         Address 10.1.1.2
  Interface 10.1.1.1         Area 0.0.0.0
  Request list:
       Type       LinkState ID      AdvRouter         Sequence   Age
       Router     2.2.2.2           1.1.1.1           80000004   1
       Network    192.168.0.1       1.1.1.1           80000003   1
       Sum-Net    192.168.1.0       1.1.1.1           80000002   2
```

Table 28 Command output

Field	Description
The Router's Neighbor is Router ID	Neighbor router ID.
Address	Neighbor interface IP address.
Interface	Local interface IP address.
Area	Area ID.
Request list	Request list information.
Type	LSA type.
LinkState ID	Link state ID.
AdvRouter	Advertising router.
Sequence	LSA sequence number.
Age	LSA age.

display ospf retrans-queue

Use **display ospf retrans-queue** to display retransmission queue information.

Syntax

display ospf [*process-id*] **retrans-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays retransmission queue information for all OSPF processes.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays retransmission queue information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify this argument, the command displays retransmission queue information for all neighbors.

Examples

Display OSPF retransmission queue information.

```
<Sysname> display ospf retrans-queue

          OSPF Process 100 with Router ID 192.168.1.59
                  Link State Retransmission List

  The Router's Neighbor is Router ID 2.2.2.2         Address 10.1.1.2
  Interface 10.1.1.1         Area 0.0.0.0
  Retransmit list:
       Type       LinkState ID      AdvRouter         Sequence   Age
       Router     2.2.2.2           2.2.2.2           80000004   1
       Network    12.18.0.1         2.2.2.2           80000003   1
       Sum-Net    12.18.1.0         2.2.2.2           80000002   2
```

Table 29 Command output

Field	Description
The Router's Neighbor is Router ID	Neighbor router ID.
Address	Neighbor interface IP address.
Interface	Interface address of the router.
Area	Area ID.
Retransmit list	Retransmission list.
Type	LSA type.
LinkState ID	Link state ID.

Field	Description
AdvRouter	Advertising router.
Sequence	LSA sequence number.
Age	LSA age.

display ospf routing

Use **display ospf routing** to display OSPF routing information.

Syntax

display ospf [*process-id*] **routing** [*ip-address* { *mask-length* | *mask* }] [**interface** *interface-type interface-number*] [**nexthop** *nexthop-address*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the routing information for all OSPF processes.

ip-address: Specifies a destination IP address.

mask-length: Specifies mask length in the range of 0 to 32.

mask: Specifies the mask in dotted decimal notation.

interface *interface-type interface-number*: Displays routes passing the specified output interface. If you do not specify this option, the command displays OSPF routing information for all interfaces.

nexthop *nexthop-address*: Displays routes passing the specified next hop. If you do not specify this option, the command displays all OSPF routing information.

verbose: Displays detailed OSPF routing information. If you do not specify this keyword, the command displays brief OSPF routing information.

Examples

Display OSPF routing information.

```
<Sysname> display ospf routing

          OSPF Process 1 with Router ID 192.168.1.2
                  Routing Table

                Topology base (MTID 0)

Table 31 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
Priority	Prefix priority: critical, high, medium, and low.
Type	Route type: intra-area, transit, stub, inter-area, Type-1 external, and Type-2 external.
AdvRouter	Advertising router.
Area	Area ID.
SubProtoID	Sub protocol ID.
Preference	OSPF route preference.
NextHop	Primary next hop IP address.
BkNextHop	Backup next hop IP address.
IfType	Type of the network to which the primary next hop belongs.
BkIfType	Type of the network to which the backup next hop belongs.
Interface	Output interface.
BkInterface	Backup output interface.
NibID	Next hop ID.
Status	Route status: • **Local**—The route is on the local end and is not sent to the route management module. • **Invalid**—The next hop is invalid. • **Stale**—The next hop is stale. • **Normal**—The route is available. • **Delete**—The route is deleted. • **Host-Adv**—The route is a host route. • **Rely**—The route is a recursive route.
Cost	Cost to destination.

display ospf spf-tree

Use **display ospf spf-tree** to display SPF tree information.

Syntax

display ospf [*process-id*] [**area** *area-id*] **spf-tree** [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify a process, this command displays SPF tree information for all OSPF processes.

area *area-id*: Specifies an OSPF area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify an area, this command displays SPF tree information for all OSPF areas.

verbose: Displays detailed SPF tree information. If you do not specify this keyword, the command displays brief SPF tree information.

Examples

Display brief SPF tree information for Area 0 in OSPF process 1.

```
<Sysname> display ospf 1 area 0 spf-tree

          OSPF Process 1 with Router ID 100.0.0.4

        Flags: S-Node is on SPF tree       R-Node is directly reachable
               I-Node or Link is init      D-Node or Link is to be deleted
               P-Neighbor is parent        A-Node is in candidate list
               C-Neighbor is child         T-Node is tunnel destination
               H-Nexthop changed           N-Link is a new path
               V-Link is involved          G-Link is in change list

```

Table 32 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.

Field	Description
SpfNode	SPF node, represented by a router ID when the node type is **Router**, or the IP address of the DR when the node type is **Network**. Node flag: • **I**—The node is in initialization state. • **A**—The node is on the candidate list. • **S**—The node is on the SPF tree. • **R**—The node is directly connected to the root node. • **D**—The node is to be deleted. • **T**—The node is the tunnel destination. This flag is not supported in the current software version.
SpfLink	SPF link, representing the peer node. Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network. Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **G**—The link is on the area change list.

Display detailed SPF tree information for Area 0 in OSPF process 1.

```
<Sysname> display ospf 1 area 0 spf-tree verbose

Table 33 Command output

Field	Description
Topology	Topology name. The topology name for base topology is **base**.
MTID	Topology ID. The value of 0 indicates the base topology.
LsId	Link state ID.
AdvId	ID of the advertising router.
NodeType	Node type: • **Network**—Network node. • **Router**—Router node.
Mask	Network mask. Its value is 0 for a router node.
SPFLinkCnt	Number of SPF links.
Distance	Cost to the root node.
VlinkData	Destination address of virtual link packets.
ParentLinkCnt	Number of parent links.
NodeFlag	Node flag: • **I**—The node is in initialization state. • **A**—The node is on the candidate list. • **S**—The node is on the SPF tree. • **R**—The node is directly connected to the root node. • **D**—The node is to be deleted. • **T**—The node is the tunnel destination. This flag is not supported in the current software version.
NextHop	Next hop.
Interface	Output interface.
BkNextHop	Backup next hop.
LinkId	Link ID.
LinkType	Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network.
LinkCost	Link cost.

Field	Description
NextHopCnt	Number of next hops.
LinkData	Link data.
LinkNewCost	New link cost.
LinkFlag	Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **G**—The link is on the area change list.

display ospf statistics

Use **display ospf statistics** to display OSPF statistics.

Syntax

display ospf [*process-id*] **statistics** [**error** | **packet** [**hello** | *interface-type interface-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPF statistics for all OSPF processes.

error: Displays error statistics. If you do not specify this keyword, the command displays OSPF packet, LSA, and route statistics.

packet: Displays OSPF packet statistics.

hello: Displays statistics of the sent and received hello packets. If you do not specify this keyword, the command displays statistics of all types of sent and received OSPF packets.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays statistics for all interfaces.

Examples

Display OSPF statistics.

```
<Sysname> display ospf statistics

          OSPF Process 1 with Router ID 2.2.2.2
                  Statistics
```

```
I/O statistics
 Type                    Input     Output
 Hello                   61        122

```

Table 34 Command output

Field	Description
I/O statistics	Statistics about input/output packets and LSAs.
Type	OSPF packet type.
Input	Packets received.
Output	Packets sent.
Hello	Hell packet.
DB Description	Database Description packet.
Link-State Req	Link-State Request packet.
Link-State Update	Link-State Update packet.
Link-State Ack	Link-State Acknowledge packet.
LSAs originated by this router	LSAs originated by this router.
Router	Number of Type-1 LSAs originated.
Network	Number of Type-2 LSAs originated.
Sum-Net	Number of Type-3 LSAs originated.
Sum-Asbr	Number of Type-4 LSAs originated.
External	Number of Type-5 LSAs originated.
NSSA	Number of Type-7 LSAs originated.
Opq-Link	Number of Type-9 LSAs originated.

Field	Description
Opq-Area	Number of Type-10 LSAs originated.
Opq-As	Number of Type-11 LSAs originated.
LSA originated	Number of LSAs originated.
LSA received	Number of LSAs received.
Routing table	Routing table information.
Intra area	Number of intra-area routes.
Inter area	Number of inter-area routes.
ASE/NSSA	Number of ASE/NSSA routes.

Display OSPF error statistics.

```
<Sysname> display ospf statistics error

          OSPF Process 1 with Router ID 192.168.1.112
                  OSPF Packet Error Statistics

 0          : Router ID confusion         0          : Bad packet

 0          : UPD: LSA checksum bad       0          : UPD: Unknown LSA type
 0          : UPD: Less recent LSA
```

Table 35 Command output

Field	Description
Router ID confusion	Packets with duplicate router ID.
Bad packet	Packets illegal.
Bad version	Packets with wrong version.
Bad checksum	Packets with wrong checksum.
Bad area ID	Packets with invalid area ID.
Drop on unnumbered link	Packets dropped on the unnumbered interface.
Bad virtual link	Packets on wrong virtual links.
Bad authentication type	Packets with invalid authentication type.
Bad authentication key	Packets with invalid authentication key.

Field	Description
Packet too small	Packets too small in length.
Neighbor state low	Packets received in low neighbor state.
Transmit error	Packets with error when being transmitted.
Interface down	Shutdown times of the interface.
Unknown neighbor	Packets received from unknown neighbors.
HELLO: Netmask mismatch	Hello packets with mismatched mask.
HELLO: Hello-time mismatch	Hello packets with mismatched hello timer.
HELLO: Dead-time mismatch	Hello packets with mismatched dead timer.
HELLO: Ebit option mismatch	Hello packets with mismatched E-bit in the option field.
HELLO: Mbit option mismatch	Hello packets with mismatched M-bit in the option field.
DD: MTU option mismatch	DD packets with mismatched MTU.
DD: Unknown LSA type	DD packets with unknown LSA type.
DD: Ebit option mismatch	DD packets with mismatched E-bit in the option field.
ACK: Bad ack	Bad LSAck packets for LSU packets.
ACK: Unknown LSA type	LSAck packets with unknown LSA type.
REQ: Empty request	LSR packets with no request information.
REQ: Bad request	Bad LSR packets.
UPD: LSA checksum bad	LSU packets with wrong LSA checksum.
UPD: Unknown LSA type	LSU packets with unknown LSA type.
UPD: Less recent LSA	LSU packets without the most recent LSA.

Display OSPF packet statistics for all processes and interfaces.

```
<Sysname> display ospf statistics packet

          OSPF Process 100 with Router ID 192.168.1.59
                  Packet Statistics

 Waiting to send packet count: 0
        Hello      DD         LSR        LSU        ACK        Total

```
Output: 2          1          19         20         42
```

Table 36 Command output

Field	Description
Waiting to send packet count	Number of packets waiting to be sent.
Total	Total number of packets.
Input	Number of received packets.
Output	Number of sent packets.
Area	Area ID.
Interface	Interface address and interface name.

Display statistics of the sent and received hello packets.

```
<Sysname> display ospf statistics packet hello

        OSPF Process 1 with Router ID 100.1.1.1
                Hello Statistics
 Total sent                            : 4
 Total sent failed                     : 0
 Sent after one and a half intervals   : 0
 Total received                        : 2
 Total received dropped                : 0
 Received after one and a half intervals: 0
```

Table 37 Command output

Field	Description
Total sent	Total number of hello packets sent.
Total sent failed	Total number of hello packets that failed to be sent.
Sent after one and a half intervals	Total number of hello packets sent at intervals greater than 1.5 times the hello interval.
Total received	Total number of hello packets received.
Total received dropped	Total number of received hello packets that were dropped.
Received after one and a half intervals	Total number of hello packets received at intervals greater than 1.5 times the hello interval.

Related commands

`reset ospf statistics`

display ospf troubleshooting

Use **`display ospf troubleshooting`** to display OSPF neighbor relationship troubleshooting information.

NOTE:

This command is supported only in Release 6342 and later.

Syntax

display ospf troubleshooting

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display OSPF neighbor relationship troubleshooting information.

```
<Sysname> display ospf troubleshooting

                OSPF troubleshooting Information
Total count: 3
Time                  Sequence   Description
2019-09-02 19:31:28   101        The state of OSPF 1 peer 1.1.1.1 changed to DOWN because
the interface went down or MTU changed. Please check the interface state and MTU settings
(Interface: Vlan10, neighbor address: 10.1.1.1)
2019-09-02 15:33:28   100       The state of OSPF 1 peer 1.1.1.1 changed to Down because
dead timer expired. Please check the connection to the neighbor (Interface: Vlan10,
neighbor address: 10.1.1.1; ping result: 5 packets in total, 5 packets timed out; CPU usage:
25.37%; memory usage: 36.49%, memory state: normal).
2019-09-02 15:28:00   99        The state of OSPF 1 peer 1.1.1.1 changed to Down because
the BFD session went down. Please check the BFD session information.
```

Table 38 Command output

Field	Description
Total count	Total number of OSPF neighbor relationship troubleshooting entries.
Time	Time when the OSPF neighbor was disconnected. The most recent entry is displayed first.
Sequence	Sequence number of the OSPF neighbor relationship troubleshooting entry.
Description	OSPF neighbor relationship troubleshooting information, including the OSPF process ID, neighbor ID, reason, and recommended action. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because OSPF interface parameters changed. Please check the interface parameters (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the OSPF process was reset. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the OSPF process was deleted. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the OSPF area was deleted. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because OSPF was disabled (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because OSPF packet receiving and sending are disabled (Interface:

	Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the interface address was deleted or OSPF was disabled on interface. Please check the interface settings (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the interface went down or MTU changed. Please check the interface state and MTU settings (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the virtual link was deleted or the route it relies on was deleted. Please check the virtual link and the route it relies on (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the virtual link interface went down or the virtual link settings were deleted. Please check the virtual link and the route it relies on (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the sham link was deleted or the route it relies on was deleted. Please check the sham link and the route it relies on (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the dead timer expired. Please check the connection to the peer (Interface: Vlan10, peer address: 10.1.1.1; ping result: 5 packets in total, 5 packets timed out; CPU usage: 25.37%; memory usage: 36.49%, memory state: normal). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the dead timer expired. Please check the connection to the peer (Interface: Vlan10, peer address: 10.1.1.1; ping result: ping was not executed because of the disabled MTP; CPU usage: 25.37%; memory usage: 36.49%, memory state: normal). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the dead timer expired. Please check the connection to the peer (Interface: Vlan10, peer address: 10.1.1.1; ping result: waitting for the ping to execute; CPU usage: 25.37%; memory usage: 36.49%, memory state: normal). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the stub configuration changed in area 0.0.0.1. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the NSSA configuration changed in area 0.0.0.1. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the Opaque LSA capability configuration changed. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the out-of-band resynchronization capability configuration changed. • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because the BFD session went down. Please check the BFD session information. • The state of OSPF 1 peer 1.1.1.1 changed to INIT because a 1-way hello packet was received. Please check the OSPF peer state on the remote end (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to DOWN because database-filter configuration changed or database-filter ACL configuration changed. Please check the OSPF database-filter and its ACL configuration (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a BadLSReq event was triggered upon the request for a nonexistent LSA. Please check the local OSPF LSDB

	and the OSPF request queue on the remote end (Interface: Vlan10, peer address: 10.1.1.1, LSA type: 5, LSID: 91.1.1.0, AdvRouter: 5.5.5.5). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because the LSA requested and then learned is the same as that in local. Please check the OSPF request queue and the specified LSA on both ends (Interface: Vlan10, peer address: 10.1.1.1; LSA type: 5, LSID: 91.1.1.0, AdvRouter: 5.5.5.5). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because the LSA requested and then learned is older than that in local. Please check the OSPF request queue and the specified LSA on both ends (Interface: Vlan10, peer address: 10.1.1.1; LSA type: 5, LSID: 91.1.1.0, AdvRouter: 5.5.5.5). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a non-retransmitted DD packet from the Loading or Full peer during the DD retransmit interval. Please check the OSPF peer state and LSDB on the remote end (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered by the change of the OSPF peer's capability to external attribute. Please check the DD packets transmitted on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered by the OSPF peer's multi-topology attribute change. Please check the multi-topology capability configuration on the remote end (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a retransmitted DD packet from the Loading or Full peer after the DD retransmit interval expired. Please check the OSPF peer state and LSDB on the remote end (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered by the change of the OSPF peer's capability to receive AS external LSA. Please check the area configuration (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered by the master-slave relationship change. Please check the DD packets transmitted on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of an unexpected initial DD packet after DD transmission started. Please check the DD packets transmitted on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a DD packet with a wrong sequence number from the slave. Please check the DD packets transmitted on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a DD packet with a wrong sequence number from the master. Please check the DD packets transmitted on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART

	because a SeqNumberMismatch event was triggered upon the receipt of a DD packet containing local opaque LSA without enabling the opaque capability. Please check the specified LSA on the remote end and the opaque capability configuration on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a DD packet containing area opaque LSA without enabling the opaque capability. Please check the specified LSA on the remote end and the opaque capability configuration on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a DD packet containing AS opaque LSA without enabling the opaque capability. Please check the specified LSA on the remote end and the opaque capability configuration on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a DD packet containing NSSA external LSA in a non-NSSA area. Please check the specified LSA on the remote end and the area configuration on both ends (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a DD packet containing invalid LSA. Please check the specified LSA on the remote end (Interface: Vlan10, peer address: 10.1.1.1). • The state of OSPF 1 peer 1.1.1.1 changed to EXSTART because a SeqNumberMismatch event was triggered upon the receipt of a DD packet containing AS external LSA in the stub area or on the virtual link. Please check the specified LSA on the remote end and the area configuration on both ends (Interface: Vlan10, peer address: 10.1.1.1).

Related commands

`reset ospf troubleshooting`

display ospf vlink

Use **`display ospf vlink`** to display OSPF virtual link information.

Syntax

`display ospf` [*`process-id`*] **`vlink`**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`process-id`: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPF virtual link information for all OSPF processes.

Examples

Display OSPF virtual link information.

```
<Sysname> display ospf vlink

          OSPF Process 1 with Router ID 3.3.3.3
                  Virtual Links

 Virtual-link Neighbor-ID  -> 2.2.2.2, Neighbor-State: Full
 Interface: 10.1.2.1 (Vlan-interface100)
 Cost: 1562  State: P-2-P  Type: Virtual
 Transit Area: 0.0.0.1
 Timers: Hello 10 , Dead 40 , Retransmit 5 , Transmit Delay 1
 MD5 authentication enabled.
    The last key is 3.
    The rollover is in progress, 2 neighbor(s) left.
```

Table 39 Command output

Field	Description
Virtual-link Neighbor-ID	ID of the neighbor on the virtual link.
Neighbor-State	Neighbor state: Down, Init, 2-Way, ExStart, Exchange, Loading, Full.
Interface	IP address and name of the local interface on the virtual link.
Cost	Interface route cost.
State	Interface state.
Type	Virtual link.
Transit Area	Transit area ID.
Timers	Values of timers (in seconds): **Hello**, **Dead**, and **Retransmit**.
Transmit Delay	LSA transmission delay on the interface, in seconds.
Simple authentication enabled	Simple authentication is enabled.
MD5 authentication enabled	MD5/HMAC-MD5 authentication is enabled.
The last key is *xx*	The most recent MD5 authentication key ID is *xx*.
The rollover is in progress, *xx* neighbor(s) left	Key rollover for MD5/HMAC-MD5 authentication is in progress. The number of neighbors that have not completed rollover is *xx*.

display router id

Use **display router id** to display the global router ID.

Syntax

display router id

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display the global router ID.

```
<Sysname> display router id
         Configured router ID is 1.1.1.1
```

dscp

Use **dscp** to set the DSCP value for outgoing OSPF packets.

Use **undo dscp** to restore the default.

Syntax

dscp *dscp-value*

undo dscp

Default

The DSCP value for outgoing OSPF packets is 48.

Views

OSPF view

Predefined user roles

network-admin

Parameters

dscp-value: Specifies the DSCP value in the range of 0 to 63 for outgoing OSPF packets.

Examples

Set the DSCP value for outgoing OSPF packets to 63 in OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] dscp 63
```

enable link-local-signaling

Use **enable link-local-signaling** to enable the OSPF link-local signaling (LLS) capability.

Use **undo enable link-local-signaling** to disable the OSPF LLS capability.

Syntax

enable link-local-signaling

undo enable link-local-signaling

Default

OSPF link-local signaling capability is disabled.

Views

OSPF view

Predefined user roles

network-admin

Examples

Enable link-local signaling for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] enable link-local-signaling
```

enable out-of-band-resynchronization

Use **enable out-of-band-resynchronization** to enable the OSPF out-of-band resynchronization (OOB-Resynch) capability.

Use **undo enable out-of-band-resynchronization** to disable the OSPF out-of-band resynchronization capability.

Syntax

enable out-of-band-resynchronization

undo enable out-of-band-resynchronization

Default

The OSPF out-of-band resynchronization capability is disabled.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

Before you configure this command, enable the link-local signaling capability.

Examples

Enable the out-of-band resynchronization capability for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] enable link-local-signaling
[Sysname-ospf-1] enable out-of-band-resynchronization
```

Related commands

enable link-local-signaling

event-log

Use **event-log** to set the number of OSPF logs.

Use **undo event-log** to remove the configuration.

Syntax

event-log { **hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } | **lsa-flush** | **peer** | **spf** } **size** *count*

undo event-log { **hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] } | **lsa-flush** | **peer** | **spf** } **size**

Default

The device can generate a maximum of 100 logs for each type.

Views

OSPF view

Predefined user roles

network-admin

Parameters

hello: Specifies the number of logs for received or sent hello packets.

received: Specifies the number of logs for received hello packets.

sent: Specifies the number of logs for sent hello packets.

abnormal: Specifies the number of logs for abnormal hello packets received or sent at intervals greater than or equal to 1.5 times the hello interval.

dropped: Specifies the number of logs for received hello packets that were dropped.

failed: Specifies the number of logs for hello packets that failed to be sent.

lsa-flush: Specifies the number of LSA aging logs.

peer: Specifies the number of neighbor logs.

spf: Specifies the number of route calculation logs.

size *count*: Specifies the number of OSPF logs, in the range of 0 to 65535.

Examples

Set the number of route calculation logs to 50 in OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] event-log spf size 50
```

fast-reroute (OSPF view)

Use **fast-reroute** to configure OSPF FRR.

Use **undo fast-reroute** to restore the default.

Syntax

fast-reroute { **lfa** [**abr-only**] | **route-policy** *route-policy-name* }

undo fast-reroute

Default

OSPF FRR is disabled.

Views

OSPF view

Predefined user roles

network-admin

Parameters

lfa: Uses the LFA algorithm to calculate a backup next hop for all routes.

abr-only: Uses the next hop of the route to the ABR as the backup next hop.

route-policy *route-policy-name*: Uses a routing policy to designate a backup next hop. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

When both OSPF FRR and PIC are configured, OSPF FRR takes effect.

Do not use the **fast-reroute lfa** command together with the **vlink-peer** command.

Examples

Enable FRR to calculate a backup next hop for all routes by using LFA algorithm in OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] fast-reroute lfa
```

filter (OSPF area view)

Use **filter** to configure OSPF to filter inbound/outbound Type-3 LSAs on an ABR.

Use **undo filter** to disable Type-3 LSA filtering.

Syntax

filter { *ipv4-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }

undo filter { **export** | **import** }

Default

Type-3 LSAs are not filtered.

Views

OSPF area view

Predefined user roles

network-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter inbound/outbound Type-3 LSAs.

prefix-list-name: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Type-3 LSAs.

route-policy-name: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Type-3 LSAs.

export: Filters Type-3 LSAs advertised to other areas.

import: Filters Type-3 LSAs advertised into the local area.

Usage guidelines

This command applies only to an ABR.

Examples

Use IP prefix list **my-prefix-list** to filter inbound Type-3 LSAs. Use basic ACL 2000 to filter outbound Type-3 LSAs in OSPF Area 1.

```
<Sysname> system-view
```

```
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] filter prefix-list my-prefix-list import
[Sysname-ospf-100-area-0.0.0.1] filter 2000 export
```

filter-policy export (OSPF view)

Use **filter-policy export** to configure OSPF to filter redistributed routes.

Use **undo filter-policy export** to remove the configuration.

Syntax

filter-policy { *ipv4-acl-number* | **prefix-list** *prefix-list-name* } **export** [*protocol* [*process-id*]]

undo filter-policy export [*protocol* [*process-id*]]

Default

OSPF does not filter redistributed routes.

Views

OSPF view

Predefined user roles

network-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter redistributed routes by destination address.

prefix-list-name: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes by destination address.

protocol: Filters routes redistributed from the specified routing protocol. If you do not specify this argument, the command filters all redistributed routes.

process-id: Specifies a process by its ID in the range of 1 to 65535. This argument is available only when the *protocol* argument is **rip** or **ospf**.

Usage guidelines

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the destination address. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

Configure OSPF process 100 to filter redistributed routes by using basic ACL 2000.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
```

```
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 2000 export
```

Configure advanced ACL 3000 to permit only route 113.0.0.0/16. Configure OSPF process 100 to filter redistributed routes by using advanced ACL 3000.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 3000 export
```

Related commands

import-route

filter-policy import (OSPF view)

Use **filter-policy import** to configure OSPF to filter routes calculated using received LSAs.

Use **undo filter-policy import** to restore the default.

Syntax

filter-policy { *ipv4-acl-number* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **route-policy** *route-policy-name* } **import**

undo filter-policy import

Default

OSPF does not filter routes calculated using received LSAs.

Views

OSPF view

Predefined user roles

network-admin

Parameters

ipv4-acl-number: Specifies an IPv4 ACL by its number in the range of 2000 to 3999 to filter received routes by destination.

gateway *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter received routes by next hop.

prefix-list *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter received routes by destination.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter received routes.

Usage guidelines

To use an advanced ACL (with a number from 3000 to 3999) in the command or in the specified routing policy, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit a route with the specified destination and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the subnet mask of the destination address. For the mask configuration to take effect, specify a contiguous subnet mask.

Examples

Use basic ACL 2000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule deny source 192.168.10.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 2000 import
```

Configure advanced ACL 3000 to permit only route 113.0.0.0/16. Use ACL 3000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule 10 permit ip source 113.0.0.0 0 destination 255.255.0.0
0
[Sysname-acl-ipv4-adv-3000] rule 100 deny ip
[Sysname-acl-ipv4-adv-3000] quit
[Sysname] ospf 100
[Sysname-ospf-100] filter-policy 3000 import
```

graceful-restart (OSPF view)

Use **graceful-restart** to enable OSPF GR.

Use **undo graceful-restart** to disable OSPF GR.

Syntax

graceful-restart [**ietf** | **nonstandard**] [**global** | **planned-only**] *

undo graceful-restart

Default

OSPF GR is disabled.

Views

OSPF view

Predefined user roles

network-admin

Parameters

ietf: Enables IETF GR.

nonstandard: Enables non-IETF GR.

global: Enables global GR. In global GR mode, a GR process can be completed only when all GR helpers exist. A GR process fails if a GR helper fails (for example, the interface connected to the GR helper goes down). If you do not specify this keyword, the command enables partial GR. In partial GR mode, a GR process can be completed if a GR helper exists.

planned-only: Enables only planned GR. If you do not specify this keyword, the command enables both planned GR and unplanned GR.

Usage guidelines

GR includes planned GR and unplanned GR.

- **Planned GR**—Manually restarts OSPF by using the **reset ospf process** command or performs an active/standby process switchover by using the **placement reoptimize** command. Before OSPF restart or active/standby switchover, the GR restarter sends Grace-LSAs to GR helpers.
- **Unplanned GR**—OSPF restarts or an active/standby switchover occurs because of device failure. Before OSPF restart or active/standby switchover, the GR restarter does not send Grace-LSAs to GR helpers.

Before enabling IETF GR for OSPF, enable Opaque LSA advertisement and reception with the **opaque-capability enable** command.

Before enabling non-IETF GR for OSPF, enable OSPF LLS with the **enable link-local-signaling** command and OOB-Resynch with the **enable out-of-band-resynchronization** command.

If you do not specify the **nonstandard** or **ietf** keyword, this command enables non-IETF GR for OSPF.

OSPF GR and OSPF NSR are mutually exclusive. Do not configure the **graceful-restart** command and the **non-stop-routing** command at the same time.

Examples

Enable IETF GR for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] opaque-capability enable
[Sysname-ospf-1] graceful-restart ietf
```

Enable non-IETF GR for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] enable link-local-signaling
[Sysname-ospf-1] enable out-of-band-resynchronization
[Sysname-ospf-1] graceful-restart nonstandard
```

Related commands

enable link-local-signaling

enable out-of-band-resynchronization

opaque-capability enable

graceful-restart helper enable

Use **graceful-restart helper enable** to enable OSPF GR helper capability.

Use **undo graceful-restart helper enable** to disable OSPF GR helper capability.

Syntax

graceful-restart helper enable [**planned-only**]

undo graceful-restart helper enable

Default

OSPF GR helper capability is enabled.

Views

OSPF view

Predefined user roles

network-admin

Parameters

planned-only: Enables only planned GR for the GR helper. If you do not specify this keyword, the command enables both planned GR and unplanned GR for the GR helper.

Usage guidelines

The **planned-only** keyword is available only for the IETF GR helper.

Examples

Enable GR helper capability for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] graceful-restart helper enable
```

graceful-restart helper strict-lsa-checking

Use **graceful-restart helper strict-lsa-checking** to enable strict LSA checking capability for GR helper.

Use **undo graceful-restart helper strict-lsa-checking** to disable strict LSA checking capability for GR helper.

Syntax

graceful-restart helper strict-lsa-checking

undo graceful-restart helper strict-lsa-checking

Default

Strict LSA checking capability for GR helper is disabled.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

When an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Examples

Enable strict LSA checking capability for GR helper in OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
```

```
[Sysname-ospf-1] graceful-restart helper strict-lsa-checking
```

graceful-restart interval (OSPF view)

Use **graceful-restart interval** to set the GR interval.

Use **undo graceful-restart interval** to restore the default.

Syntax

graceful-restart interval *interval*

undo graceful-restart interval

Default

The GR interval is 120 seconds.

Views

OSPF view

Predefined user roles

network-admin

Parameters

interval: Specifies the GR interval in the range of 40 to 1800 seconds.

Usage guidelines

For GR restart to succeed, the value of the GR restart interval cannot be smaller than the maximum OSPF neighbor dead time of all the OSPF interfaces.

Examples

Set the GR interval for OSPF process 1 to 100 seconds.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] graceful-restart interval 100
```

Related commands

ospf timer dead

host-advertise

Use **host-advertise** to advertise a host route.

Use **undo host-advertise** to remove a host route.

Syntax

host-advertise *ip-address cost-value*

undo host-advertise *ip-address*

Default

No host route is advertised.

Views

OSPF area view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the IP address of a host.

cost-value: Specifies a cost for the route, in the range of 1 to 65535.

Examples

Advertise host route 1.1.1.1 with a cost of 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 0
[Sysname-ospf-100-area-0.0.0.0] host-advertise 1.1.1.1 100
```

import-route (OSPF view)

Use **import-route** to redistribute AS-external routes from another routing protocol.

Use **undo import-route** to disable route redistribution from another routing protocol.

Syntax

import-route { **direct** | **static** } [**cost** *cost-value*] | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

import-route { **ospf** | **rip** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo import-route { **direct** | { **ospf** | **rip** } [*process-id* | **all-processes**] | **static** }

Default

OSPF does not redistribute AS-external routes from any other routing protocol.

Views

OSPF view

Predefined user roles

network-admin

Parameters

direct: Redistributes direct routes.

ospf: Redistributes OSPF routes.

rip: Redistributes RIP routes.

static: Redistributes static routes.

process-id: Specifies a process by its ID in the range of 1 to 65535. The default is 1.

all-processes: Redistributes routes from all the processes of the specified routing protocol.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. If you do not specify this keyword, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a route cost in the range of 0 to 16777214. If you do not specify a cost, the cost of a redistributed route is 1.

nssa-only: Limits the route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. If you do not specify this keyword, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit is set to 0. This keyword applies to NSSA routers.

route-policy *route-policy-name*: Specifies a routing policy to filter redistributed routes. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies a tag for external LSAs, in the range of 0 to 4294967295. The default is 1.

type *type*: Specifies a cost type, 1 or 2. The default is 2.

Usage guidelines

This command redistributes routes destined for other ASs from another protocol. AS external routes include the following types:

- **Type-1 external routes**—Have high credibility. The cost of Type-1 external routes is comparable with the cost of OSPF internal routes. The cost of a Type-1 external route equals the cost from the router to the ASBR plus the cost from the ASBR to the external route's destination.
- **Type-2 external routes**—Have low credibility. OSPF considers the cost from the ASBR to the destination of a Type-2 external route is much bigger than the cost from the ASBR to an OSPF internal router. The cost of a Type-2 external route equals the cost from the ASBR to the Type-2 external route's destination.

The **import-route** command redistributes only active routes. To display information about active routes, use the **display ip routing-table protocol** command. The **import-route** command cannot redistribute default external routes.

The **import-route nssa-only** command redistributes AS-external routes in Type-7 LSAs only into the NSSA area.

The **undo import-route** { **ospf** | **rip** } **all-processes** command removes only the configuration made by the **import-route** { **ospf** | **rip** } **all-processes** command, instead of the configuration made by the **import-route** { **ospf** | **rip** } *process-id* command.

Examples

Redistribute routes from RIP process 40 and specify the type, tag, and cost as 2, 33, and 50 for redistributed routes.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] import-route rip 40 type 2 tag 33 cost 50
```

Related commands

default-route-advertise (OSPF view)

ispf enable (OSPF view)

Use **ispf enable** to enable OSPF incremental SPF (ISPF).

Use **undo ispf enable** to disable OSPF ISPF.

Syntax

ispf enable

undo ispf enable

Default

OSPF ISPF is enabled.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

Upon topology changes, ISPF recomputes only the affected part of the SPT, instead of the entire SPT.

Examples

Disable ISPF for OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] undo ispf enable
```

log-peer-change

Use **log-peer-change** to enable logging for OSPF neighbor state changes.

Use **undo log-peer-change** to disable logging for OSPF neighbor state changes.

Syntax

log-peer-change

undo log-peer-change

Default

Logging for OSPF neighbor state changes is enabled.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

This command enables output of OSPF neighbor state changes to the information center. The information center processes the logs according to user-defined output rules (whether and where to output logs). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Disable logging for neighbor state changes for OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] undo log-peer-change
```

lsa-arrival-interval

Use **lsa-arrival-interval** to set the LSA arrival interval.

Use **undo lsa-arrival-interval** to restore the default.

Syntax

lsa-arrival-interval *interval*

undo lsa-arrival-interval

Default

The LSA arrival interval is 1000 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

Parameters

interval: Specifies the LSA arrival interval in the range of 0 to 60000 milliseconds.

Usage guidelines

If an LSA that has the same LSA type, LS ID, and originating router ID as the previous LSA is received within the interval, OSPF discards the LSA. This feature helps avoid overuse of system resources due to frequent network changes.

As a best practice, set the interval with the **lsa-arrival-interval** command to be smaller than or equal to the minimum interval set with the **lsa-generation-interval** command.

Examples

Set the LSA arrival interval to 200 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsa-arrival-interval 200
```

Related commands

lsa-generation-interval

lsa-generation-interval

Use **lsa-generation-interval** to set the OSPF LSA generation interval.

Use **undo lsa-generation-interval** to restore the default.

Syntax

lsa-generation-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo lsa-generation-interval

Default

The maximum interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

Parameters

maximum-interval: Specifies the maximum LSA generation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum LSA generation interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the LSA generation incremental interval in the range of 10 to 60000 milliseconds.

Usage guidelines

When network changes are infrequent, LSAs are generated at the minimum interval. If network changes become frequent, the LSA generation interval is incremented by the incremental interval × 2^{n-2} for each generation until the maximum interval is reached. The value *n* is the number of generation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum LSA generation interval to 2 seconds, minimum interval to 100 milliseconds, and incremental interval to 100 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsa-generation-interval 2 100 100
```

Related commands

lsa-arrival-interval

lsdb-overflow-interval

Use **lsdb-overflow-interval** to set the interval that OSPF exits overflow state.

Use **undo lsdb-overflow-interval** to restore the default.

Syntax

lsdb-overflow-interval *interval*

undo lsdb-overflow-interval

Default

The OSPF exit overflow interval is 300 seconds.

Views

OSPF view

Predefined user roles

network-admin

Parameters

interval: Specifies the interval that OSPF exits overflow state, in the range of 0 to 2147483647 seconds.

Usage guidelines

When the number of LSAs in the LSDB exceeds the upper limit, the LSDB is in an overflow state. In this state, OSPF does not receive any external LSAs and deletes the external LSAs generated by itself to save system resources.

You can configure the interval that OSPF exits overflow state. An interval of 0 indicates that the timer is not started and OSPF does not exit overflow state.

Examples

Set the OSPF exit overflow interval to 10 seconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsdb-overflow-interval 10
```

lsdb-overflow-limit

Use **lsdb-overflow-limit** to set the upper limit of external LSAs in the LSDB.

Use **undo lsdb-overflow-limit** to restore the default.

Syntax

lsdb-overflow-limit *number*

undo lsdb-overflow-limit

Default

The number of external LSAs is not limited.

Views

OSPF view

Predefined user roles

network-admin

Parameters

number: Specifies the upper limit of external LSAs in the LSDB, in the range of 1 to 1000000.

Examples

Set the upper limit of external LSAs to 400000.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] lsdb-overflow-limit 400000
```

network (OSPF area view)

Use **network** to enable OSPF on the interface attached to the specified network in the area.

Use **undo network** to disable OSPF for the interface attached to the specified network in the area.

Syntax

network *ip-address wildcard-mask*

undo network *ip-address wildcard-mask*

Default

OSPF is not enabled for any interface.

Views

OSPF area view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the IP address of a network.

wildcard-mask: Specifies the wildcard mask of the IP address. For example, the wildcard mask of mask 255.0.0.0 is 0.255.255.255.

Usage guidelines

This command enables OSPF on the interface attached to the specified network. The interface's primary IP address must be in the specified network. If only the interface's secondary IP address is in the network, the interface cannot run OSPF.

Examples

Specify the interface whose primary IP address is on network 131.108.20.0/24 to run OSPF in Area 2.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 2
[Sysname-ospf-100-area-0.0.0.2] network 131.108.20.0 0.0.0.255
```

Related commands

ospf

non-stop-routing

Use **non-stop-routing** to enable OSPF NSR.

Use **undo non-stop-routing** to disable OSPF NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

OSPF NSR is disabled.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

This command takes effect only for the current process. As a best practice, enable OSPF NSR for each process if multiple OSPF processes exist.

OSPF NSR and OSPF GR are mutually exclusive. Do not configure the **non-stop-routing** command and the **graceful-restart** command at the same time.

Examples

Enable NSR for OSPF process 100.

```
<Sysname> system-view
[Sysname] ospf 100
```

```
[Sysname-ospf-100] non-stop-routing
```

nssa (OSPF area view)

Use **nssa** to configure an area as an NSSA area.

Use **undo nssa** to restore the default.

Syntax

nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **type** *type*] * | **no-import-route** | **no-summary** | **suppress-fa** | [[[**translate-always**] [**translate-ignore-checking-backbone**]] | **translate-never**] | **translator-stability-interval** *value*] *

undo nssa [**default-route-advertise** [**cost** | **nssa-only** | **route-policy** | **type**] * | **no-import-route** | **no-summary** | **suppress-fa** | [**translate-always** | **translate-never**] | **translator-stability-interval**] *

Default

No area is configured as an NSSA area.

Views

OSPF area view

Predefined user roles

network-admin

Parameters

default-route-advertise: Used on an NSSA ABR or an ASBR only. With this keyword, an NSSA ABR redistributes a default route in a Type-7 LSA into the NSSA area. The ABR redistributes a default route regardless of whether a default route exists in the routing table. With this keyword, an ASBR redistributes a default route in a Type-7 LSA only when the default route exists in the routing table.

cost *cost-value*: Specifies a cost for the default route, in the range of 0 to 16777214. If you do not specify this option, the default cost specified by the **default-cost** command applies.

nssa-only: Limits the default route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. By default, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit is set to 0.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. When a default route exists in the routing table and the routing policy is matched, the command redistributes a default route in a Type-7 LSA into the OSPF routing domain. The routing policy modifies values in the Type-7 LSA.

type *type*: Specifies a type for the Type-7 LSA, 1 or 2. If you do not specify this option, the default type specified by the **default type** command applies.

no-import-route: Used on an NSSA ABR to control the **import-route** command to not redistribute routes into the NSSA area.

no-summary: Used only on an ABR to advertise a default route in a Type-3 summary LSA into the NSSA area and to not advertise other summary LSAs into the area. The area is a totally NSSA area.

suppress-fa: Suppresses the forwarding address in the Type-7 LSAs from being placed in the Type-5 LSAs.

translate-always: Always translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

translate-ignore-checking-backbone: Ignores checking for FULL state neighbors in the backbone area during the translator election in the NSSA area.

translate-never: Never translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

translator-stability-interval *value*: Specifies the stability interval of the translator. During the interval, the translator can maintain its translating capability after another device becomes the new translator. The *value* argument is the stability interval in the range of 0 to 900 seconds and defaults to 0. A value of 0 means the translator does not maintain its translating capability when a new translator arises.

Usage guidelines

All routers attached to an NSSA area must be configured with the **nssa** command in area view.

If you specify the **translate-ignore-checking-backbone** keyword for an ABR, you must also specify the keyword for other ABRs in the NSSA area. This ensures that a translator can be elected among the ABRs.

Examples

Configure Area 1 as an NSSA area.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] nssa
```

Related commands

default-cost (OSPF area view)

opaque-capability enable

Use **opaque-capability enable** to enable opaque LSA advertisement and reception.

Use **undo opaque-capability** to disable opaque LSA advertisement and reception.

Syntax

opaque-capability enable

undo opaque-capability

Default

The feature is enabled.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

After the opaque LSA advertisement and reception capability is enabled, OSPF can receive and advertise Type-9, Type-10, and Type-11 opaque LSAs.

Examples

Disable opaque LSA advertisement and reception.

```
<Sysname> system-view
[Sysname] ospf 100
```

```
[Sysname-ospf-100] undo opaque-capability
```

ospf

Use **ospf** to enable OSPF and enter OSPF view.

Use **undo ospf** to disable OSPF.

Syntax

ospf [*process-id* | **router-id** *router-id*] *

undo ospf [*process-id*]

Default

OSPF is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535.

router-id *router-id*: Specifies an OSPF router ID in dotted decimal notation.

Usage guidelines

You can enable multiple OSPF processes on a router and specify different router IDs for them.

Enable an OSPF process before performing other tasks.

Examples

Enable OSPF process 100 and specify router ID 10.10.10.1.

```
<Sysname> system-view
[Sysname] ospf 100 router-id 10.10.10.1
[Sysname-ospf-100]
```

ospf area

Use **ospf area** to enable OSPF on an interface.

Use **undo ospf area** to disable OSPF on an interface.

Syntax

ospf *process-id* **area** *area-id* [**exclude-subip**]

undo ospf *process-id* **area** [**exclude-subip**]

Default

OSPF is not enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535.

area-id: Specifies an area by its ID, an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format.

exclude-subip: Excludes secondary IP addresses. If you do not specify this keyword, the command enables OSPF also on secondary IP addresses.

Usage guidelines

The **ospf area** command has a higher priority than the **network** command.

If the specified process and area do not exist, the command creates the process and area. Disabling an OSPF process on an interface does not delete the OSPF process or the area.

Examples

Enable OSPF process 1 on VLAN-interface 10 that is in Area 2 and exclude secondary IP addresses.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf 1 area 2 exclude-subip
```

Related commands

network

ospf authentication-mode

Use **ospf authentication-mode** to set the authentication mode and key on an interface.

Use **undo ospf authentication-mode** to remove specified configuration.

Syntax

For MD5/HMAC-MD5 authentication:

ospf authentication-mode { **hmac-md5** | **md5** } *key-id* { **cipher** | **plain** } *string*

undo ospf authentication-mode { **hmac-md5** | **md5** } *key-id*

For simple authentication:

ospf authentication-mode simple { **cipher** | **plain** } *string*

undo ospf authentication-mode simple

Default

No authentication is performed for an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

hmac-md5: Specifies HMAC-MD5 authentication.

md5: Specifies MD5 authentication.

simple: Specifies simple authentication.

key-id: Specifies a key by its ID in the range of 1 to 255.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive.

- In simple authentication mode, the plaintext form of the key is a string of 1 to 8 characters. The encrypted form of the key is a string of 33 to 41 characters.
- In MD5/HMAC-MD5 authentication mode, the plaintext form of the key is a string of 1 to 16 characters. The encrypted form of the key is a string of 33 to 53 characters.

Usage guidelines

To establish or maintain adjacencies, interfaces attached to the same network segment must have the same authentication mode and key.

If MD5 or HMAC-MD5 authentication is configured, you can configure multiple keys, each having a unique key ID and key string. To minimize the risk of key compromise, use only one key for an interface and delete the old key after key replacement.

To replace the key used for MD5 or HMAC-MD5 authentication on an interface, you must configure the new key before removing the old key from each router. OSPF uses the key rollover mechanism to ensure that the routers can pass authentication before the replacement is complete on the interface. After you configure a new key on a router, the router sends copies of the same packet, each authenticated by a different key, including the new key and the keys in use. This practice continues until the router detects that all its neighbors have the new key.

Examples

On VLAN-interface 10, enable MD5 authentication, and set the interface key ID to 15 and the key to **123456** in plaintext form.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf authentication-mode md5 15 plain 123456
```

On VLAN-interface 10, enable simple authentication, and set the key to **123456** in plaintext form.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf authentication-mode simple plain 123456
```

Related commands

authentication-mode

ospf bfd enable

Use **ospf bfd enable** to enable BFD on an OSPF interface.

Use **undo ospf bfd enable** to disable BFD on an OSPF interface.

Syntax

ospf bfd enable [**echo**]

undo ospf bfd enable

Default

BFD for OSPF is disabled.

Views

Interface view

Predefined user roles

network-admin

Parameters

echo: Enables BFD single-hop echo detection. If you do not specify this keyword, the command enables BFD bidirectional control detection.

Examples

Enable BFD for OSPF on VLAN-interface 11.

```
<Sysname> system-view
[Sysname] ospf
[Sysname-ospf-1] area 0
[Sysname-ospf-1-area-0.0.0.0] network 192.168.0.0 0.0.255.255
[Sysname] interface vlan-interface 11
[Sysname-Vlan-interface11] ospf bfd enable
```

ospf cost (interface view)

Use **ospf cost** to set an OSPF cost for an interface.

Use **undo ospf cost** to restore the default.

Syntax

ospf cost *cost-value*

undo ospf cost

Default

An interface computes its OSPF cost according to the interface bandwidth. For a loopback interface, the cost is 0.

Views

Interface view

Predefined user roles

network-admin

Parameters

cost-value: Specifies an OSPF cost in the range of 0 to 65535 for a loopback interface, and in the range of 1 to 65535 for other interfaces.

Usage guidelines

If you do not execute this command, the interface automatically computes its OSPF cost.

Examples

Set the OSPF cost on VLAN-interface 10 to 65.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf cost 65
```

Related commands

bandwidth-reference

ospf database-filter

Use **ospf database-filter** to filter outbound LSAs on an interface.

Use **undo ospf database-filter** to restore the default.

Syntax

ospf database-filter { **all** | { **ase** [**acl** *ipv4-acl-number*] | **nssa** [**acl** *ipv4-acl-number*] | **summary** [**acl** *ipv4-acl-number*] } * }

undo ospf database-filter

Default

The outbound LSAs are not filtered on the interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

all: Filters all outbound LSAs except the Grace LSAs.

ase: Filters outbound Type-5 LSAs.

nssa: Filters outbound Type-7 LSAs.

summary: Filters outbound Type-3 LSAs.

acl *ipv4-acl-number*: Specifies an IPv4 ACL by its number in the range of 2000 to 3999.

Usage guidelines

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL using one of the following methods:

- To deny/permit LSAs with the specified link state ID, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* command.
- To deny/permit LSAs with the specified link state ID and mask, use the **rule** [*rule-id*] { **deny** | **permit** } **ip source** *sour-addr sour-wildcard* **destination** *dest-addr dest-wildcard* command.

The **source** keyword specifies the link state ID of an LSA and the **destination** keyword specifies the subnet mask of the LSA. For the mask configuration to take effect, specify a contiguous subnet mask.

If the neighbor has already received an LSA to be filtered, the LSA still exists in the LSDB of the neighbor after you execute the command.

Examples

Filter all outbound LSAs (except the Grace LSAs) on VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf database-filter all
```

On VLAN-interface 20, configure ACL 2000, 2100, and 2200 to filter outbound Type-5, Type-7, and Type-3 LSAs, respectively.

```
<Sysname> system-view
[Sysname] interface vlan-interface 20
```

```
[Sysname- Vlan-interface20] ospf database-filter ase acl 2000 nssa acl 2100 summary acl
2200
```

Related commands

`database-filter peer` (OSPF view)

ospf dr-priority

Use **`ospf dr-priority`** to set the router priority for DR/BDR election on an interface.

Use **`undo ospf dr-priority`** to restore the default value.

Syntax

`ospf dr-priority` *`priority`*

`undo ospf dr-priority`

Default

The router priority is 1.

Views

Interface view

Predefined user roles

network-admin

Parameters

`priority`: Specifies the router priority for the interface, in the range of 0 to 255.

Usage guidelines

The greater the value, the higher the priority for DR/BDR election. If a device has a priority of 0, it will not be elected as a DR or BDR.

Examples

Set the router priority on VLAN-interface 10 to 8.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf dr-priority 8
```

ospf fast-reroute lfa-backup

Use **`ospf fast-reroute lfa-backup`** to enable LFA on an interface.

Use **`undo ospf fast-reroute lfa-backup`** to disable LFA on an interface.

Syntax

`ospf fast-reroute lfa-backup`

`undo ospf fast-reroute lfa-backup`

Default

LFA is enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

Usage guidelines

An interface enabled with LFA can be selected as a backup interface. After you disable LFA on the interface, it cannot be selected as a backup interface.

Examples

Disable VLAN-interface 11 from calculating a backup next hop by using the LFA algorithm.

```
<Sysname> system-view
[Sysname] interface vlan-interface 11
[Sysname-Vlan-interface11] undo ospf fast-reroute lfa-backup
```

ospf lsu-flood-control

Use **ospf lsu-flood-control** to enable OSPF to limit the LSU transmit rate.

Use **undo ospf lsu-flood-control** to disable OSPF to limit LSU transmit rate.

Syntax

ospf lsu-flood-control [*interval count*]

undo ospf lsu-flood-control

Default

OSPF does not limit the LSU transmit rate.

Views

System view

Predefined user roles

network-admin

Parameters

interval: Specifies the LSU transmit interval in the range of 10 to 1000 milliseconds. The default value is 30.

count: Specifies the maximum number of LSUs that can be sent at each interval, in the range of 1 to 1000. The default value is 50.

Usage guidelines

During LSDB synchronization, if the local router has multiple neighbors, it must send many LSUs to each neighbor. When a neighbor receives excessive LSUs within a short time period, the following events might occur:

- The performance of the neighbor is degraded because too many system resources are occupied for LSU packet processing.
- The neighbor drops hello packets used for maintaining the neighbor relationship because it is busy dealing with the LSUs. As a result, the neighbor relationship is torn down. To reestablish a relationship to the neighbor, the local router must send more LSUs to the neighbor. This exacerbates the performance degradation.

To prevent this problem, execute this command to limit the global LSU transmit rate.

Inappropriate use of this command might cause abnormal routing. As a best practice, execute this command with the default values.

Examples

Enable OSPF to limit the LSU transmit rate, and configure all OSPF interfaces to send 60 LSUs every 40 milliseconds.

```
<Sysname> system-view
[Sysname] ospf lsu-flood-control 40 60
```

ospf mib-binding

Use **ospf mib-binding** to bind an OSPF process to the public MIB.

Use **undo ospf mib-binding** to restore the default.

Syntax

ospf mib-binding *process-id*

undo ospf mib-binding

Default

The public MIB is bound to the OSPF process with the smallest process ID.

Views

System view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535.

Usage guidelines

To access information or data about an OSPF process in **RFC4750-OSPF.MIB**, use this command. To access information or data about an OSPF process in a private MIB for the device, you do not need to use this command. You can access information or data about all OSPF processes in the private MIBs.

If the specified process ID does not exist, a notification is displayed to report that the MIB binding configuration has failed.

Deleting an OSPF process that has been bound to the public MIB unbinds the OSPF process from the MIB, and re-binds the MIB to the OSPF process with the smallest process ID.

Examples

Bind OSPF process 100 to the public MIB.

```
<Sysname> system-view
[Sysname] ospf mib-binding 100
```

ospf mtu-enable

Use **ospf mtu-enable** to enable an interface to add the interface MTU into DD packets.

Use **undo ospf mtu-enable** to restore the default.

Syntax

ospf mtu-enable

undo ospf mtu-enable

Default

The MTU in DD packets is 0.

Views

Interface view

Predefined user roles

network-admin

Usage guidelines

After you configure this command, the interface checks whether the MTU in a received DD packet is greater than its own MTU. If yes, the interface discards the packet.

Examples

Enable VLAN-interface 10 to add the interface MTU value into DD packets.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf mtu-enable
```

ospf network-type

Use **ospf network-type** to specify the network type for an interface.

Use **undo ospf network-type** to restore the default.

Syntax

ospf network-type { **broadcast** | **nbma** | **p2mp** [**unicast**] | **p2p** [**peer-address-check**] }

undo ospf network-type

Default

The network type of an interface is broadcast.

Views

Interface view

Predefined user roles

network-admin

Parameters

broadcast: Specifies the network type as broadcast.

nbma: Specifies the network type as NBMA.

p2mp: Specifies the network type as P2MP.

unicast: Specifies the P2MP interface to unicast OSPF packets. By default, a P2MP interface multicasts OSPF packets.

p2p: Specifies the network type as P2P.

peer-address-check: Checks whether the peer interface and the local interface are on the same network segment. Two P2P interfaces can establish a neighbor relationship only when they are on the same network segment.

Usage guidelines

If a router on a broadcast network does not support multicast, configure the network type for the connected interfaces as NBMA.

When the network type of an interface is NBMA or P2MP unicast, you must use the **peer** command to specify the neighbor.

If only two routers run OSPF on a network, you can configure the network type for the connected interfaces as P2P.

When the network type of an interface is P2MP unicast, all OSPF packets are unicast by the interface.

Examples

Specify the OSPF network type for VLAN-interface 10 as NBMA.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf network-type nbma
```

Related commands

ospf dr-priority

ospf packet-size

Use **ospf packet-size** to set the maximum length of OSPF packets that can be sent by an interface.

Use **undo ospf packet-size** to restore the default.

Syntax

ospf packet-size *value*

undo ospf packet-size

Default

The maximum length of OSPF packets that an interface can send equals the interface's MTU.

Views

Interface view

Predefined user roles

network-admin

Parameters

value: Specifies the maximum length of OSPF packets that can be sent by an interface, in the range of 500 to 10000 bytes.

Usage guidelines

The interface chooses the smaller one between the value set in this command and the interface MTU, and uses it as the maximum length of OSPF packets that can be sent.

Examples

Set the maximum length of OSPF packets that can be sent by VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan 10
[Sysname-Vlan-interface10] ospf packet-size 1000
```

ospf prefix-suppression

Use **ospf prefix-suppression** to disable an OSPF interface from advertising all its IP prefixes, except for the prefixes of secondary IP addresses.

Use **undo ospf prefix-suppression** to restore the default.

Syntax

ospf prefix-suppression [**disable**]

undo ospf prefix-suppression

Default

Prefix suppression is disabled.

Views

Interface view

Predefined user roles

network-admin

Parameters

disable: Disables prefix suppression for an interface.

Usage guidelines

To disable prefix suppression for an interface associated with an OSPF process that has been enabled with prefix suppression, use the **ospf prefix-suppression disable** command on that interface.

Examples

Enable prefix suppression for VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf prefix-suppression
```

Related commands

prefix-suppression

ospf primary-path-detect bfd

Use **ospf primary-path-detect bfd** to enable BFD for primary link failure detection for OSPF.

Use **undo ospf primary-path-detect bfd** to disable BFD for primary link failure detection for OSPF.

Syntax

ospf primary-path-detect bfd { **ctrl** | **echo** }

undo ospf primary-path-detect bfd

Default

BFD is disabled for primary link failure detection for OSPF.

Views

Interface view

Predefined user roles

network-admin

Parameters

ctrl: Enables BFD control packet mode.

echo: Enables BFD echo packet mode.

Usage guidelines

This command enables OSPF PIC or OSPF FRR to use BFD to detect primary link failures.

Examples

On VLAN-interface 10, enable BFD control packet mode for OSPF FRR.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] fast-reroute lfa
[Sysname-ospf-1] quit
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf primary-path-detect bfd ctrl
```

On VLAN-interface 11, enable BFD echo packet mode for OSPF PIC.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] pic additional-path-always
[Sysname-ospf-1] quit
[Sysname] bfd echo-source-ip 1.1.1.1
[Sysname] interface vlan-interface 11
[Sysname-Vlan-interface11] ospf primary-path-detect bfd echo
```

ospf timer dead

Use **ospf timer dead** to set the neighbor dead interval.

Use **undo ospf timer dead** to restore the default.

Syntax

ospf timer dead *seconds*

undo ospf timer dead

Default

The dead interval is 40 seconds for broadcast and P2P interfaces. The dead interval is 120 seconds for P2MP and NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the dead interval in the range of 1 to 2147483647 seconds.

Usage guidelines

If an interface receives no hello packet from a neighbor within the dead interval, the interface considers the neighbor down.

The dead interval on an interface is a minimum of four times the hello interval. Routers attached to the same segment must have the same dead interval.

Examples

Set the dead interval for VLAN-interface 10 to 60 seconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf timer dead 60
```

Related commands

ospf timer hello

ospf timer hello

Use **ospf timer hello** to set the hello interval on an interface.

Use **undo ospf timer hello** to restore the default.

Syntax

ospf timer hello *seconds*

undo ospf timer hello

Default

The hello interval is 10 seconds for P2P and broadcast interfaces, and is 30 seconds for P2MP and NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the hello interval in the range of 1 to 65535 seconds.

Usage guidelines

The shorter the hello interval, the faster the topology converges, and the more resources are consumed. Make sure the hello interval on two neighboring interfaces is the same.

Examples

Set the hello interval on VLAN-interface to 20 seconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf timer hello 20
```

Related commands

ospf timer dead

ospf timer poll

Use **ospf timer poll** to set the poll interval on an NBMA interface.

Use **undo ospf timer poll** to restore the default.

Syntax

ospf timer poll *seconds*

undo ospf timer poll

Default

The poll interval is 120 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the poll interval in the range of 1 to 2147483647 seconds.

Usage guidelines

When an NBMA interface finds its neighbor is down, it sends hello packets at the poll interval.

The poll interval must be a minimum of four times the hello interval.

Examples

Set the poll timer interval on VLAN-interface 10 to 130 seconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf timer poll 130
```

Related commands

ospf timer hello

ospf timer retransmit

Use **ospf timer retransmit** to set the LSA retransmission interval on an interface.

Use **undo ospf timer retransmit** to restore the default.

Syntax

ospf timer retransmit *seconds*

undo ospf timer retransmit

Default

The LSA retransmission interval is 5 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the LSA retransmission interval in the range of 1 to 3600 seconds.

Usage guidelines

After sending an LSA, an interface waits for an acknowledgment packet. If the interface receives no acknowledgment within the retransmission interval, it retransmits the LSA.

To avoid unnecessary retransmissions, set an appropriate retransmission interval. For example, you can set a large retransmission interval value on a low-speed link.

Examples

Set the LSA retransmission interval to 8 seconds on VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf timer retransmit 8
```

ospf trans-delay

Use **ospf trans-delay** to set the LSA transmission delay on an interface.

Use **undo ospf trans-delay** to restore the default.

Syntax

ospf trans-delay *seconds*

undo ospf trans-delay

Default

The LSA transmission delay is 1 second.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the LSA transmission delay in the range of 1 to 3600 seconds.

Usage guidelines

Each LSA in the LSDB has an age that is incremented by 1 every second, but the age does not change during transmission. Adding a transmission delay into the age time is important in low speed networks.

Examples

Set the LSA transmission delay to 3 seconds on VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf trans-delay 3
```

ospf troubleshooting max-number

Use **ospf troubleshooting max-number** to set the maximum number of OSPF neighbor relationship troubleshooting entries.

Use **undo ospf troubleshooting max-number** to restore the default.

NOTE:

This command is supported only in Release 6342 and later.

Syntax

ospf troubleshooting max-number *number*

undo ospf troubleshooting max-number

Default

The maximum number of OSPF neighbor relationship troubleshooting entries is 100.

Views

System view

Predefined user roles

network-admin

Parameters

number: Specifies the maximum number of OSPF neighbor relationship troubleshooting entries, in the range of 0 to 65535. The value 0 means OSPF does not record neighbor relationship troubleshooting entries.

Examples

Set the maximum number of OSPF neighbor relationship troubleshooting entries to 50.

```
<Sysname> system-view
[Sysname] ospf troubleshooting max-number 50
```

ospf ttl-security

Use **ospf ttl-security** to enable OSPF GTSM for an interface.

Use **undo ospf ttl-security** to disable OSPF GTSM for an interface.

Syntax

ospf ttl-security [**hops** *hop-count* | **disable**]

undo ospf ttl-security

Default

OSPF GTSM is disabled for an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

hops *hop-count*: Specifies the hop limit for checking OSPF packets, in the range of 1 to 254. The default hop limit is 1 for packets from common neighbors, and is 255 for packets from virtual link neighbors.

disable: Disables OSPF GTSM for the interface.

Usage guidelines

GTSM protects the device by comparing the TTL value in the IP header of incoming OSPF packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the OSPF packets sent by the device have a TTL of 255. To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

The **hops** keyword configured in interface view takes precedence over the **hops** keyword configured in OSPF area view.

If the **ttl-security** command is not configured, the **undo ospf ttl-security** command disables GTSM for an interface.

If the **ttl-security** command is configured, the **undo ospf ttl-security** command removes the GTSM configuration for an interface. At the same time, the GTSM configuration for the area applies to the interface. The **ospf ttl-security disable** command disables GTSM for an interface.

If a virtual link exists in an area, you can enable GTSM for the interfaces on the virtual link. If you do not know the interfaces on the virtual link, enable GTSM in area view to prevent packet loss.

Examples

Enable OSPF GTSM for VLAN-interface 10 and set the hop limit to 254.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf ttl-security hops 254
```

Enable GTSM in OSPF area view and disable OSPF GTSM for VLAN-interface 10.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] ttl-security
[Sysname-ospf-100-area-0.0.0.1] quit
[Sysname-ospf-100] quit
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospf ttl-security disable
```

Related commands

ttl-security (OSPF area view)

peer (OSPF view)

Use **peer** to specify a neighbor in an NBMA or P2MP network.

Use **undo peer** to remove a neighbor in an NBMA or P2MP network.

Syntax

peer *ip-address* [**cost** *cost-value* | **dr-priority** *priority*]

undo peer *ip-address*

Default

No neighbor is specified.

Views

OSPF view

Predefined user roles

network-admin

Parameters

ip-address: Specifies a neighbor by its IP address.

cost *cost-value*: Specifies the cost to reach the neighbor, in the range of 1 to 65535.

dr-priority *priority*: Specifies the DR priority for the neighbor, in the range of 0 to 255. The default neighbor DR priority is 1.

Usage guidelines

In an NBMA or P2MP network, OSPF packets are sent in unicast, so you must use this command to specify neighbors.

The cost set with the **peer** command applies only to P2MP neighbors. If no cost is specified, the cost to the neighbor equals the local interface's cost.

A router uses the priority set with the **peer** command to determine whether to send a hello packet to the neighbor rather than for DR election. The DR priority set with the **ospf dr-priority** command is used for DR election.

Examples

Specify the neighbor 1.1.1.1.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] peer 1.1.1.1
```

Related commands

ospf dr-priority

pic (OSPF view)

Use **pic** to enable OSPF PIC.

Use **undo pic** to disable OSPF PIC.

Syntax

pic [**additional-path-always**]

undo pic

Default

OSPF PIC is enabled.

Views

OSPF view

Predefined user roles

network-admin

Parameters

additional-path-always: Allows the indirect suboptimal route as the backup route.

Usage guidelines

Prefix Independent Convergence (PIC) enables the device to speed up network convergence by ignoring the number of prefixes. PIC applies only to inter-area routes and external routes.

When both OSPF PIC and OSPF FRR are configured, OSPF FRR takes effect.

Examples

Configure OSPF PIC to support the suboptimal route as the backup route.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] pic additional-path-always
```

preference (OSPF view)

Use **preference** to set a preference for OSPF.

Use **undo preference** to remove the configuration.

Syntax

preference [**ase**] { *preference* | **route-policy** *route-policy-name* } *

undo preference [**ase**]

Default

The preference is 10 for OSPF internal routes and 150 for OSPF external routes (ASE routes).

Views

OSPF view

Predefined user roles

network-admin

Parameters

ase: Specifies a preference for OSPF external routes. If you do not specify this keyword, the command sets a preference for OSPF internal routes.

preference: Specifies the preference value in the range of 1 to 255. A smaller value represents a higher preference.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to set a preference for the specified routes.

Usage guidelines

If multiple routing protocols find routes to the same destination, the router uses the route found by the protocol with the highest preference.

When the **route-policy** *route-policy-name* option is specified, the following preferences take effect:

- For routes matching the routing policy, the preference set in the routing policy takes effect.
- For other routes, the preference set with the **preference** command takes effect.

Examples

Set a preference of 200 for OSPF external routes.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] preference ase 200
```

Set a preference of 100 for OSPF internal routes matching the specified routing policy, and set a preference of 150 for other routes.

```
<Sysname> system-view
[Sysname] ip prefix-list test index 10 permit 100.1.1.0 24
[Sysname] route-policy pre permit node 10
[Sysname-route-policy-pre-10] if-match ip address prefix-list test
[Sysname-route-policy-pre-10] apply preference 100
[Sysname-route-policy-pre-10] quit
[Sysname] ospf 100
[Sysname-ospf-100] preference route-policy pre 150
```

prefix-priority (OSPF view)

Use **prefix-priority** to enable prefix prioritization.

Use **undo prefix-priority** to disable prefix prioritization.

Syntax

prefix-priority route-policy *route-policy-name*

undo prefix-priority

Default

Prefix prioritization is disabled.

Views

OSPF view

Predefined user roles

network-admin

Parameters

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to set a priority for the specified route prefixes.

Usage guidelines

Prefix prioritization enables the device to install prefixes in descending priority order: critical, high, medium, and low. The prefix priorities are assigned through routing policies. When a route is assigned multiple prefix priorities, it uses the highest priority.

By default, the 32-bit OSPF host routes have a medium priority and other routes have a low priority.

Examples

Use a routing policy to assign the medium priority to the specified route prefixes.

```
<Sysname> system-view
[Sysname] ip prefix-list test index 10 permit 100.1.1.0 24
[Sysname] route-policy pre permit node 10
[Sysname-route-policy-pre-10] if-match ip address prefix-list test
[Sysname-route-policy-pre-10] apply prefix-priority medium
[Sysname-route-policy-pre-10] quit
[Sysname] ospf 100
[Sysname-ospf-100] prefix-priority route-policy pre
```

prefix-suppression

Use **prefix-suppression** to disable an OSPF process from advertising all IP prefixes except for the prefixes of loopback interfaces, secondary IP addresses, and passive interfaces.

Use **undo prefix-suppression** to restore the default.

Syntax

prefix-suppression

undo prefix-suppression

Default

An OSPF process advertises all prefixes.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

By default, an OSPF interface advertises all of its prefixes in LSAs. To speed up OSPF convergence, you can suppress interfaces from advertising all their prefixes. This feature helps improve network security by preventing IP routing to the suppressed networks.

As a best practice, configure prefix suppression on all OSPF routers if you want to use prefix suppression.

To disable an OSPF process from advertising the prefixes of loopback and passive interfaces, configure prefix suppression on the interfaces by using the **ospf prefix-suppression** command.

When prefix suppression is enabled:

- On P2P and P2MP networks, OSPF does not advertise Type-3 links in Type-1 LSAs. Other routing information can still be advertised to ensure traffic forwarding.
- On broadcast and NBMA networks, the DR generates Type-2 LSAs with a mask length of 32 to suppress network routes. Other routing information can still be advertised to ensure traffic forwarding. If no neighbors exist, the DR also does not advertise the primary IP addresses of interfaces in Type-1 LSAs.

Examples

Enable prefix suppression for OSPF process 1.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] prefix-suppression
```

Related commands

ospf prefix-suppression

reset ospf event-log

Use **reset ospf event-log** to clear OSPF log information.

Syntax

reset ospf [*process-id*] **event-log** [**lsa-flush** | **peer** | **spf**]

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears OSPF log information for all OSPF processes.

lsa-flush: Clears LSA aging log information.

peer: Clears neighbor log information.

spf: Clears route calculation log information.

Usage guidelines

If you do not specify a log type, this command clears all log information.

Examples

Clear OSPF route calculation log information for all OSPF processes.

```
<Sysname> reset ospf event-log spf
```

Related commands

display ospf event-log

reset ospf event-log hello

Use **reset ospf event-log hello** to clear OSPF log information about received or sent hello packets.

NOTE:

This command is supported only in Release 6342 and later.

Syntax

reset ospf [*process-id*] **event-log hello** { **received** [**abnormal** | **dropped**] | **sent** [**abnormal** | **failed**] }

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears OSPF log information for all processes.

received: Specifies log information for received hello packets.

sent: Specifies log information for sent hello packets.

abnormal: Specifies log information for abnormal hello packets received or sent at intervals greater than or equal to 1.5 times the hello interval.

dropped: Specifies log information for received hello packets that were dropped.

failed: Specifies log information for hello packets that failed to be sent.

Examples

Clear sent hello packet log information for all OSPF processes.

```
<Sysname> reset ospf event-log hello sent
```

Related commands

display ospf event-log hello

reset ospf process

Use **reset ospf process** to restart all OSPF processes or a specified process.

Syntax

reset ospf [*process-id*] **process** [**graceful-restart**]

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPF process by its ID in the range of 1 to 65535. If you do not specify a process, this command restarts all OSPF processes.

graceful-restart: Resets the OSPF process by using GR.

Usage guidelines

The **reset ospf process** command performs the following actions:

- Clears all invalid LSAs without waiting for their timeouts.
- Makes a newly configured router ID take effect.
- Starts a new DR/BDR election.
- Keeps previous OSPF configurations.

The system prompts you to select whether to restart OSPF process upon execution of this command.

Examples

Restart all OSPF processes.

```
<Sysname> reset ospf process
Reset OSPF process? [Y/N]:y
```

reset ospf redistribution

Use **reset ospf redistribution** to restart route redistribution.

Syntax

reset ospf [*process-id*] **redistribution**

Views

User view

Predefined user roles

rfc1583 compatible

Use **rfc1583 compatible** to enable compatibility with RFC 1583.

Use **undo rfc1583 compatible** to disable compatibility with RFC 1583.

Syntax

rfc1583 compatible

undo rfc1583 compatible

Default

Compatibility with RFC 1583 is enabled.

Views

OSPF view

Predefined user roles

network-admin

Usage guidelines

RFC 1583 specifies a different method than RFC 2328 for selecting the optimal route to a destination in another AS. When multiple routes are available to the ASBR, OSPF selects the optimal route by using the following procedure:

1. Selects the route with the highest preference.
   - If RFC 2328 is compatible with RFC 1583, all these routes have equal preference.
   - If RFC 2328 is not compatible with RFC 1583, the intra-area route in a non-backbone area is preferred to reduce the burden of the backbone area. The inter-area route and intra-area route in the backbone area have equal preference.
2. Selects the route with lower cost if two routes have equal preference.
3. Selects the route with larger originating area ID if two routes have equal cost.

To avoid routing loops, set identical RFC 1583-compatibility on all routers in a routing domain.

Examples

Disable compatibility with RFC 1583.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] undo rfc1583 compatible
```

router id

Use **router id** to configure a global router ID.

Use **undo router id** to restore the default.

Syntax

router id *router-id*

undo router id

Default

No global router ID is configured.

Views

System view

Predefined user roles

network-admin

Parameters

router-id: Specifies the router ID, in the format of an IPv4 address.

Usage guidelines

OSPF uses a router ID to identify a device. If no router ID is specified, the global router ID is used.

If no global router ID is configured, the highest loopback interface IP address is used as the router ID. If no loopback interface IP address is available, the highest physical interface IP address is used, regardless of the interface status (up or down).

During an active/standby process switchover, the new active process checks whether the previously backed up router ID is valid. If not, the process selects a new router ID.

A new router ID is selected only when the interface IP address used as the router ID is removed or changed. Other events will not trigger a router ID re-selection. For example, router ID re-selection is not triggered in the following situations:

- The interface goes down.
- You change the router ID to the address of a loopback interface after a physical interface address is selected as the router ID.
- A higher interface IP address is configured as the router ID.

After a router ID is changed, you must use the **reset** command to enable it.

Examples

Configure a global router ID as 1.1.1.1.

```
<Sysname> system-view
[Sysname] router id 1.1.1.1
```

silent-interface (OSPF view)

Use **silent-interface** to disable an interface or all interfaces from receiving and sending OSPF packets.

Use **undo silent-interface** to remove the configuration.

Syntax

silent-interface { *interface-type interface-number* | **all** }

undo silent-interface { *interface-type interface-number* | **all** }

Default

An interface can receive and send OSPF packets.

Predefined user roles

network-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

all: Specifies all interfaces.

Usage guidelines

To disable a network from receiving and sending OSPF routes, use the command on the interface connected to the network.

Examples

Disable VLAN-interface 10 from receiving and sending OSPF packets.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] silent-interface vlan-interface 10
```

snmp trap rate-limit

Use **snmp trap rate-limit** to set the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

Use **undo snmp trap rate-limit** to restore the default.

Syntax

snmp trap rate-limit interval *trap-interval* **count** *trap-number*

undo snmp trap rate-limit

Default

OSPF outputs a maximum of seven SNMP notifications within 10 seconds.

Views

OSPF view

Predefined user roles

network-admin

Parameters

interval *trap-interval*: Specifies the SNMP notification output interval in the range of 2 to 60 seconds.

count *trap-number*: Specifies the number of SNMP notifications output by OSPF at each interval, in the range of 0 to 300. The value of 0 indicates that OSPF does not output SNMP notifications.

Examples

Configure OSPF to output a maximum of 10 SNMP notifications within 5 seconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] snmp trap rate-limit interval 5 count 10
```

snmp-agent trap enable ospf

Use **snmp-agent trap enable ospf** to enable SNMP notifications for OSPF.

Use **undo snmp-agent trap enable ospf** to disable SNMP notifications for OSPF.

Syntax

snmp-agent trap enable ospf [**authentication-failure** | **bad-packet** | **config-error** | **grhelper-status-change** | **grrestarter-status-change** | **if-state-change** | **lsa-maxage** | **lsa-originate** | **lsdb-approaching-overflow** | **lsdb-overflow** | **neighbor-state-change** | **nssatranslator-status-change** | **retransmit** | **virt-authentication-failure** | **virt-bad-packet** | **virt-config-error** | **virt-retransmit** | **virtgrhelper-status-change** | **virtif-state-change** | **virtneighbor-state-change**] *

undo snmp-agent trap enable ospf [**authentication-failure** | **bad-packet** | **config-error** | **grhelper-status-change** | **grrestarter-status-change** | **if-state-change** | **lsa-maxage** | **lsa-originate** | **lsdb-approaching-overflow** | **lsdb-overflow** | **neighbor-state-change** | **nssatranslator-status-change** | **retransmit** | **virt-authentication-failure** | **virt-bad-packet** | **virt-config-error** | **virt-retransmit** | **virtgrhelper-status-change** | **virtif-state-change** | **virtneighbor-state-change**] *

Default

SNMP notifications for OSPF are enabled.

Views

System view

Predefined user roles

network-admin

Parameters

authentication-failure: Specifies notifications about authentication failures on an interface.

bad-packet: Specifies notifications about error messages received on an interface.

config-error: Specifies notifications about error configuration of an interface.

grhelper-status-change: Specifies notifications about GR helper state change.

grrestarter-status-change: Specifies notifications about GR restarter state change.

if-state-change: Specifies notifications about interface state change.

lsa-maxage: Specifies LSA max age notifications.

lsa-originate: Specifies notifications about locally generated LSAs.

lsdb-approaching-overflow: Specifies notifications about approaching LSDB overflows.

lsdb-overflow: Specifies LSDB overflow notifications.

neighbor-state-change: Specifies notifications about neighbor state change.

nssatranslator-status-change: Specifies notifications about NSSA translator state change.

retransmit: Specifies notifications about packets that are received and forwarded on an interface.

virt-authentication-failure: Specifies notifications about authentication failures on a virtual interface.

virt-bad-packet: Specifies notifications about error messages received on a virtual interface.

virt-config-error: Specifies notifications about error configuration of a virtual interface.

virt-retransmit: Specifies notifications about packets that are received and forwarded on a virtual interface.

virtgrhelper-status-change: Specifies notifications about neighbor GR helper state changes of a virtual interface.

virtif-state-change: Specifies notifications about virtual interface state change.

virtneighbor-state-change: Specifies notifications about the neighbor state change of a virtual interface.

Examples

Disable SNMP notifications for OSPF.

```
<Sysname> system-view
[Sysname] undo snmp-agent trap enable ospf
```

spf-schedule-interval (OSPF view)

Use **spf-schedule-interval** to set the OSPF SPF calculation interval.

Use **undo spf-schedule-interval** to restore the default.

Syntax

spf-schedule-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo spf-schedule-interval

Default

The maximum calculation interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

Parameters

maximum-interval: Specifies the maximum OSPF SPF calculation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum OSPF SPF calculation interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the incremental OSPF SPF calculation interval in the range of 10 to 60000 milliseconds.

Usage guidelines

Based on the LSDB, an OSPF router uses SPF to calculate a shortest path tree with itself as the root. OSPF uses the shortest path tree to determine the next hop to a destination. By adjusting the SPF calculation interval, you can prevent overconsumption of bandwidth and router resources due to frequent topology changes.

For a stable network, the minimum interval is used. If network changes become frequent, the SPF calculation interval is incremented by the incremental interval × 2^{n-2} for each calculation until the maximum interval is reached. The value *n* is the number of calculation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum SPF calculation interval to 10 seconds, minimum interval to 500 milliseconds, and incremental interval to 300 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] spf-schedule-interval 10 500 300
```

stub (OSPF area view)

Use **stub** to configure an area as a stub area.

Use **undo stub** to restore the default.

Syntax

stub [**default-route-advertise-always** | **no-summary**] *

undo stub

Default

No area is a stub area.

Views

OSPF area view

Predefined user roles

network-admin

Parameters

default-route-advertise-always: Enables the ABR to advertise a default route in a Type-3 LSA into the stub area regardless of whether **FULL**-state neighbors exist in the backbone area. If you do not specify this keyword, the ABR advertises a default route in a Type-3 LSA into the stub area only when a minimum of one **FULL**-state neighbor exists in the backbone area.

no-summary: Enables the ABR to advertise only a default route in a Type-3 LSA into the stub area without advertising any other Type-3 LSAs. The area is a totally stub area.

Usage guidelines

To configure an area as a stub area, use the **stub** command on all routers attached to the area.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure Area 1 as a stub area.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] stub
```

Related commands

default-cost (OSPF area view)

stub-router (OSPF view)

Use **stub-router** to configure a router as a stub router.

Use **undo stub-router** to restore the default.

Syntax

stub-router [**external-lsa** [*max-metric-value*] | **include-stub** | **on-startup** *seconds* | **summary-lsa** [*max-metric-value*]] *

undo stub-router

Default

The router is not configured as a stub router.

Views

OSPF view

Predefined user roles

network-admin

Parameters

external-lsa *max-metric-value*: Specifies a cost for the external LSAs, in the range of 1 to 16777215. The default is 16711680.

include-stub: Specifies the cost of the stub links (link type 3) in Router LSAs to the maximum value 65535.

on-startup *seconds*: Specifies the router as a stub router during reboot, and specifies the timeout time in the range of 5 to 86400 seconds.

summary-lsa *max-metric-value*: Specifies a cost for the Type-3 LSAs, in the range of 1 to 16777215. The default cost value is 16711680.

Usage guidelines

The router LSAs sent by the stub router over different links contain different link type values. A value of 3 represents a link to a stub network, and the cost of the link is not changed. A value of 1, 2, or 4 represents a point-to-point link, a link to a transit network, or a virtual link. The cost of these links is set to 65535. Neighbors on such links will not send packets to the stub router as long as they have a route with a smaller cost.

Examples

Configure a stub router.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] stub-router
```

transmit-pacing

Use **transmit-pacing** to set the LSU transmission interval and the maximum number of LSU packets that can be sent at each interval.

Use **undo transmit-pacing** to restore the default.

Syntax

transmit-pacing interval *interval* **count** *count*

undo transmit-pacing

Default

An OSPF interface sends a maximum of three LSU packets every 20 milliseconds.

Views

OSPF view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies an interval at which an interface sends LSU packets, in the range of 10 to 1000 milliseconds. If the router has multiple OSPF interfaces, increase this interval to reduce the total number of LSU packets sent by the router every second.

count *count*: Specifies the maximum number of LSU packets sent by an interface at each interval, in the range of 1 to 200. If the router has multiple OSPF interfaces, decrease the maximum number to reduce the total number of LSU packets sent by the router every second.

Examples

Configure all the interfaces running OSPF process 1 to send a maximum of 10 LSU packets every 30 milliseconds.

```
<Sysname> system-view
[Sysname] ospf 1
[Sysname-ospf-1] transmit-pacing interval 30 count 10
```

ttl-security

Use **ttl-security** to enable OSPF GTSM for an area.

Use **undo ttl-security** to disable OSPF GTSM for an area.

Syntax

ttl-security [**hops** *hop-count*]

undo ttl-security

Default

OSPF GTSM is disabled for an OSPF area.

Views

OSPF area view

Predefined user roles

network-admin

Parameters

hops *hop-count*: Specifies the hop limit for checking OSPF packets, in the range of 1 to 254. The default hop limit is 1 for packets from common neighbors, and is 255 for packets from virtual link neighbors.

Usage guidelines

The GTSM configuration in OSPF area view applies to all OSPF interfaces in the area. GTSM checks OSPF packets from common neighbors and virtual link neighbors. It does not check OSPF packets from sham link neighbors.

GTSM protects the device by comparing the TTL value in the IP header of incoming OSPF packets against a valid TTL range. If the TTL value is within the valid TTL range, the packet is accepted. If not, the packet is discarded.

The valid TTL range is from 255 – the configured hop count + 1 to 255.

When GTSM is configured, the OSPF packets sent by the device have a TTL of 255. To use GTSM, you must configure GTSM on both the local and peer devices. You can specify different *hop-count* values for them.

The **hops** keyword configured in interface view takes precedence over the **hops** keyword configured in OSPF area view.

As a best practice, set the hop limit if a virtual link exists in an area. You can enable GTSM for the interfaces on the virtual link. If you do not know the interfaces on the virtual link, enable GTSM in area view to prevent packet loss.

Examples

Enable OSPF GTSM for OSPF area 1.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 1
[Sysname-ospf-100-area-0.0.0.1] ttl-security
```

Related commands

ospf ttl-security

vlink-peer (OSPF area view)

Use **vlink-peer** to configure a virtual link.

Use **undo vlink-peer** to remove a virtual link.

Syntax

vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | { { **hmac-md5** | **md5** } *key-id* { **cipher** | **plain** } *string* | **simple** { **cipher** | **plain** } *string* } | **retransmit** *seconds* | **trans-delay** *seconds*] *

undo vlink-peer *router-id* [**dead** | **hello** | { **hmac-md5** | **md5** } *key-id* | **retransmit** | **simple** | **trans-delay**] *

Default

No virtual links exist.

Views

OSPF area view

Predefined user roles

network-admin

Parameters

router-id: Specifies the router ID of the neighbor on the virtual link.

dead *seconds*: Specifies the dead interval in the range of 1 to 32768 seconds. The default is 40. The dead interval must be identical with that on the virtual link neighbor, and a minimum of four times the hello interval.

hello *seconds*: Specifies the hello interval in the range of 1 to 8192 seconds. The default is 10. It must be identical with the hello interval on the virtual link neighbor.

hmac-md5: Specifies the HMAC-MD5 authentication mode.

md5: Specifies the MD5 authentication mode.

simple: Specifies the simple authentication mode.

key-id: Specifies the key ID for MD5 or HMAC-MD5 authentication, in the range of 1 to 255.

cipher: Specifies a key in encrypted form.

plain: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive.

- In simple authentication mode, the plaintext form of the key is a string of 1 to 8 characters. The encrypted form of the key is a string of 33 to 41 characters.
- In MD5/HMAC-MD5 authentication mode, the plaintext form of the key is a string of 1 to 16 characters. The encrypted form of the key is a string of 33 to 53 characters.

retransmit *seconds*: Specifies the retransmission interval in the range of 1 to 3600 seconds. The default is 5.

trans-delay *seconds*: Specifies the transmission delay interval in the range of 1 to 3600 seconds. The default is 1.

Usage guidelines

As defined in RFC 2328, all non-backbone areas must maintain connectivity to the backbone. You can use the **vlink-peer** command to configure a virtual link to connect an area to the backbone.

When you configure this command, follow these guidelines:

- The smaller the hello interval is, the faster the network converges, and the more network resources are consumed.
- A retransmission interval that is too small can cause unnecessary retransmissions. A large value is appropriate for a low speed link.
- Specify an appropriate transmission delay with the **trans-delay** keyword.

You can specify either MD5/HMAC-MD5 authentication or simple authentication for a virtual link. For MD5/HMAC-MD5 authentication, you can configure multiple keys by executing this command multiple times, and each command must have a unique key ID and key string.

To modify the key of a virtual link, perform the following key rollover configurations:

1. Configure a new MD5/HMAC-MD5 authentication key for the virtual link on the local device. If the new key is not configured on the neighbor device, MD5/HMAC-MD5 authentication key rollover is triggered. During key rollover, OSPF sends multiple packets that contain both the new and old MD5/HMAC-MD5 authentication keys to ensure that the neighbor device can pass the authentication.
2. Configure the new MD5/HMAC-MD5 authentication key on the neighbor device. When the local device receives packets with the new key from the neighbor device, it exits MD5 key rollover.
3. Delete the old MD5/HMAC-MD5 authentication key from the local device and the neighbor. This step helps prevent attacks from devices that use the old key for communication and reduces system resources and bandwidth consumption caused by key rollover.

Examples

Configure a virtual link to the neighbor with router ID 1.1.1.1.

```
<Sysname> system-view
[Sysname] ospf 100
[Sysname-ospf-100] area 2
[Sysname-ospf-100-area-0.0.0.2] vlink-peer 1.1.1.1
```

Related commands

Policy-based routing commands

apply next-hop

Use **apply next-hop** to set next hops.

Use **undo apply next-hop** to remove next hops.

Syntax

apply next-hop { *ip-address* [**direct**] [**track** *track-entry-number*] }&<1-2>

undo apply next-hop [*ip-address*&<1-2>]

Default

No next hops are set.

Views

Policy node view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the IP address of the next hop.

direct: Specifies that the next hop must be directly connected to take effect.

track *track-entry-number*: Specifies a track entry by its number in the range of 1 to 1024.

&<1-2>: Indicates that the argument before it can be entered up to two times.

Usage guidelines

You can specify multiple next hops for backup in one command line or by executing this command multiple times.

With a next hop specified, the **undo apply next-hop** command removes the next hop.

Without any next hop specified, the **undo apply next-hop** command removes all next hops.

Examples

Set a directly-connected next hop of 1.1.1.1.

```
<Sysname> system-view
[Sysname] policy-based-route aa permit node 11
[Sysname-pbr-aa-11] apply next-hop 1.1.1.1 direct
```

description

Use **description** to configure a description for a policy node.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for a policy node.

Views

Policy node view

Predefined user roles

network-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Examples

Configure the description as **Officeuse** for policy node 1.

```
<Sysname> system-view
[Sysname] policy-based-route 1 permit node 1
[Sysname-pbr-1-1] description Officeuse
```

display ip policy-based-route

Use **display ip policy-based-route** to display PBR policy information.

Syntax

display ip policy-based-route [**policy** *policy-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

policy *policy-name*: Specifies a policy by its name, a case-sensitive string of 1 to 19 characters. If you do not specify a policy, this command displays information for all PBR policies.

Examples

Display all policy information.

```
<Sysname> display ip policy-based-route
Policy name: aaa
  node 1 permit:
    if-match acl 2000
    apply next-hop 1.1.1.1
```

Table 1 Command output

Field	Description
node 1 permit	The match mode of Node 1 is **permit**.
if-match acl	Compares packets with the ACL.
apply next-hop	Specifies a next hop for permitted packets.

Related commands

policy-based-route

display ip policy-based-route interface

Use **display ip policy-based-route interface** to display interface PBR configuration and statistics.

Syntax

display ip policy-based-route interface *interface-type interface-number* [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information on the master device.

Examples

Display PBR configuration and statistics on VLAN-interface 2.

```
<Sysname> display ip policy-based-route interface vlan-interface 2
Policy based routing information for interface Vlan-interface2:
Policy name: aaa
  node 0 deny:
  Matched: 0
  node 1 permit:
    if-match acl 3999
  Matched: 0
  node 2 permit:
    if-match acl 2000
    apply next-hop 2.2.2.2
  Matched: 0
  node 5 permit:
    if-match acl 3101
    apply next-hop 1.1.1.1
  Matched: 0
Total matched: 0
<Sysname> display ip policy-based-route interface vlan-interface 2
Policy based routing information for interface Vlan-interface2:
Policy name: aaa
  node 0 deny:
  Matched: 0
  node 1 permit:
    if-match acl 3999
```

```
  Matched: 0
  node 2 permit:
    if-match acl 2000
    apply next-hop 2.2.2.2
  Matched: 0
  node 5 permit:
    if-match acl 3101
    apply next-hop 1.1.1.1
  Matched: 0
Total matched: 0
```

Table 2 Command output

Field	Description
Policy based routing information for interface *XXXX*(failed)	PBR configuration and statistics on the interface. This field displays **failed** in brackets if none of the nodes in the policy has been successfully issued to the driver. The **failed** status will persist even after the policy is successfully issued. To clear the **failed** status, you must remove the policy from the interface and then apply it on the interface again. **NOTE:** The **failed** status is available on a per-slot basis. To obtain this information, you must specify a slot number when you execute the command. • For a global interface (for example, a VLAN interface), which might have member physical interfaces on multiple slots, specify a slot that contains its member interfaces. • For a physical interface, specify its slot number.
node 0 deny(not support) node 2 permit(no resource)	Match mode of the node, **permit** or **deny**. If a node fails to be issued to the driver, the command displays the cause in brackets, which include: • **not support**—The device does not support the match criteria configured on the node. • **no resource**—No sufficient resources (for example, ACLs) are available for the node. **NOTE:** The cause is available only on a per-slot basis. To obtain this information, you must specify a slot number when you execute the command. • For a global interface (for example, a VLAN interface), which might have member physical interfaces on multiple slots, specify a slot that contains its member interfaces. • For a physical interface, specify its slot number.
if-match acl	Compares packets with the ACL.
apply next-hop	Specifies a next hop for permitted packets.
Matched: 0 (no statistics resource)	Number of successful matches on the node. If the device does not have sufficient resources to count matches, this field displays **no statistics resource** in brackets. **NOTE:** The statistics collection failure cause is available only on a per-slot basis. To obtain this information, you must specify a slot number when you execute the command. • For a global interface (for example, a VLAN interface), which

Field	Description
	might have member physical interfaces on multiple slots, specify a slot that contains its member interfaces. • For a physical interface, specify its slot number.
Total matched	Total number of successful matches on all nodes.

network-operator

Examples

Display PBR configuration.

```
<Sysname> display ip policy-based-route setup
Policy name             Type     Interface
pr01                    Forward  Vlan-interface2
aaa                     Local    N/A
aaa                     Global   N/A
```

Table 4 Command output

Field	Description
Type	Type of the PBR: • **Forward**—Interface PBR. • **Local**—Local PBR. • **Global**—Global PBR.
Interface	Interface where the policy is applied. This field displays **N/A** for local PBR and global PBR.

Related commands

`ip policy-based-route`

if-match acl

Use **if-match acl** to set an ACL match criterion.

Use **undo if-match acl** to restore the default.

Syntax

if-match acl { *acl-number* | **name** *acl-name* }

undo if-match acl

Default

No ACL match criterion is set.

Views

Policy node view

Predefined user roles

network-admin

Parameters

acl-number: Specifies an ACL by its number in the range of 2000 to 2999 for a basic ACL, and in the range of 3000 to 3999 for an advanced ACL.

name *acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters starting with letter *a* to *z* or *A* to *Z*. The ACL name cannot be **all**. For the command to take effect, make sure the specified ACL is a basic or advanced ACL.

Examples

Configure Node 11 of policy **aa** to permit the packets matching ACL 2011.

```
<Sysname> system-view
[Sysname] policy-based-route aa permit node 11
[Sysname-pbr-aa-11] if-match acl 2011
```

Configure Node 11 of policy **aa** to permit the packets matching ACL **aaa**.

```
<Sysname> system-view
[Sysname] policy-based-route aa permit node 11
[Sysname-pbr-aa-11] if-match acl name aaa
```

ip local policy-based-route

Use **ip local policy-based-route** to specify a policy for local PBR.

Use **undo ip local policy-based-route** to restore the default.

Syntax

ip local policy-based-route *policy-name*

undo ip local policy-based-route

Default

No policy is specified for local PBR.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a policy by its name, a case-sensitive string of 1 to 19 characters. The specified policy must already exist.

Usage guidelines

Local PBR guides the forwarding of locally generated packets, such as ICMP packets generated by using the **ping** command.

Local PBR might affect local services, such as ping and Telnet. When you use local PBR, make sure you fully understand its impact on local services of the device.

You can specify only one policy for local PBR and must make sure the specified policy already exists.

Before you apply a new policy, you must first remove the current policy.

Examples

Configure local PBR based on policy **aaa**.

```
<Sysname> system-view
[Sysname] ip local policy-based-route aaa
```

Related commands

Use **undo policy-based-route** to delete a policy or policy node.

Syntax

policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

undo policy-based-route *policy-name* [**deny** | **node** *node-number* | **permit**]

Default

No policy nodes exist.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a policy by its name, a case-sensitive string of 1 to 19 characters.

deny: Specifies the match mode for the policy node as **deny**.

permit: Specifies the match mode for the policy node as **permit** (default mode).

node *node-number*: Specifies a policy node by its number. A smaller number has a higher priority. The value range for the *node-number* argument is 0 to 255.

Usage guidelines

A policy that has been applied to an interface or locally cannot be deleted. To delete it, you must first cancel the application.

- If a policy node is specified, the **undo policy-based-route** command deletes the specified policy node.
- If a match mode is specified, the command deletes all nodes configured with the match mode.
- If no policy node or match mode is specified, the command deletes the whole policy.

Examples

Create permit-mode of Node 10 for policy **policy1** and enter its view.

```
<Sysname> system-view
[Sysname] policy-based-route policy1 permit node 10
[Sysname-pbr-policy1-10]
```

Related commands

display ip policy-based-route

ip global policy-based-route

ip local policy-based-route

ip policy-based-route apply

reset ip policy-based-route statistics

Use **reset ip policy-based-route statistics** to clear PBR statistics.

Syntax

reset ip policy-based-route statistics [**policy** *policy-name*]

Views

User view

Predefined user roles

network-admin

Parameters

policy *policy-name*: Specifies a policy by its name, a case-sensitive string of 1 to 19 characters. If you do not specify a policy, this command clears PBR statistics for all policies.

Examples

Clear all PBR statistics.

```
<Sysname> reset ip policy-based-route statistics
```

Contents

IPv6 static routing commands

delete ipv6 static-routes all

Use **delete ipv6 static-routes all** to delete all IPv6 static routes.

Syntax

delete ipv6 static-routes all

Views

System view

Predefined user roles

network-admin

Usage guidelines

CAUTION:

This command might interrupt network communication and cause packet forwarding failure. Before executing the command, make sure you fully understand the potential impact on the network.

When you use this command, the system will prompt you to confirm the operation before deleting all the IPv6 static routes.

Examples

Delete all IPv6 static routes.

```
<Sysname> system-view
[Sysname] delete ipv6 static-routes all
This will erase all IPv6 static routes and their configurations, you must reconfigure all static routes.
Are you sure?[Y/N]:y
```

Related commands

display ipv6 route-static nib

Use **display ipv6 route-static nib** to display IPv6 static route next hop information.

Syntax

display ipv6 route-static nib [*nib-id*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

nib-id: Specifies a NIB by its ID, a hexadecimal string in the range of 1 to ffffffff.

verbose: Displays detailed IPv6 static route next hop information. If you do not specify this keyword, the command displays brief IPv6 static route next hop information.

Examples

Display brief IPv6 static route next hop information.

```
<Sysname> display ipv6 route-static nib
Total number of nexthop(s): 35

      NibID: 0x21000000        Sequence: 0
       Type: 0x41               Flushed: Yes
   UserKey0: 0x0                VrfNthp: 0
   UserKey1: 0x0                Nexthop: 2::3
    IFIndex: 0x0              LocalAddr: ::
   TopoNthp: Invalid            ExtType: 0x0

      NibID: 0x21000001        Sequence: 1

   UserKey0: 0x0                VrfNthp: 0
   UserKey1: 0x0                Nexthop: 3::4
    IFIndex: 0x0              LocalAddr: ::
   TopoNthp: Invalid            ExtType: 0x0

...
```

Table 1 Command output

Field	Description
NibID	ID of the NIB.
Sequence	Sequence number of the NIB.
Type	Type of the NIB.
Flushed	Indicates whether the route with the NIB has been flushed to the FIB.
UserKey0	Reserved data 1.
UserKey1	Reserved data 2.
VrfNthp	This field is not supported in the current software version. Index of the VPN instance to which the next hop belongs. This field displays **0** if the next hop is on the public network.
Nexthop	Next hop address.
IFIndex	Interface index
LocalAddr	Local interface address.
TopoNthp	This field is not supported in the current software version. Index of the topology that contains the next hop. This field displays **Invalid** if the next hop is on an IPv6 network, because the router does not support multiple topologies.
ExtType	NIB extension type.

Display detailed IPv6 static route next hop information.

```
<Sysname> display ipv6 route-static nib verbose
```

```
Total number of nexthop(s): 35

      NibID: 0x21000000        Sequence: 0

   TunnelID: N/A               Topology:
     Weight: 0

...
```

Table 2 Command output

Field	Description
x nexthop(s)	Number of next hops.
PrefixIndex	Prefix index of the next hop for an ECMP route.
Vrf	This field is not supported in the current software version. VPN instance name. For the public network, this field displays **default-vrf**.
OrigNexthop	Original next hop.
RealNexthop	Real next hop.
Interface	Output interface.

Field	Description
localAddr	Local interface address.
RelyDepth	Recursion depth.
TunnelCnt	This field is not supported in the current software version. Number of tunnels after route recursion.
TunnelID	This field is not supported in the current software version. ID of the tunnel after route recursion.
Topology	This field is not supported in the current software version. Topology name. This field is blank for IPv6, because IPv6 does not support multiple topologies.
Weight	ECMP routes are not supported in the current software version. ECMP route weight. This field displays 0 for non-ECMP routes.
RefCnt	Reference count of the next hop.
FlushRefCnt	Reference count of the next hop that is flushed to the FIB.
Flag	Flag of the next hop.
Version	Version of the next hop.
ExtType	NIB extension type.

display ipv6 route-static routing-table

Use **display ipv6 route-static routing-table** to display IPv6 static routing table information.

Syntax

display ipv6 route-static routing-table [*ipv6-address prefix-length*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipv6-address: Specifies the destination IPv6 address.

prefix-length: Specifies the prefix length in the range of 0 to 128.

Examples

Display IPv6 static routing table information.

```
<Sysname> display ipv6 route-static routing-table
Total number of routes: 5

Status: * - valid

*Destination: 1::1/128
       NibID: 0x21000000        NextHop: 2::2
```

```
   MainNibID: N/A             BkNextHop: N/A
     BkNibID: N/A             Interface: Vlan-interface11
     TableID: 0xa           BkInterface: N/A
        Flag: 0x80d0a          BfdSrcIp: N/A
     DbIndex: 0x3            BfdIfIndex: 0x0
        Type: Normal        BfdVrfIndex: 0
  TrackIndex: 0xffffffff          Label: NULL
  Preference: 60            vrfIndexDst: 0
     BfdMode: N/A            vrfIndexNH: 0
   Permanent: 0                     Tag: 0

*Destination: 1::1234/128
      NibID: 0x21000000        NextHop: 2::2
   MainNibID: N/A             BkNextHop: N/A
     BkNibID: N/A             Interface: NULL0
     TableID: 0xa           BkInterface: N/A
        Flag: 0x80d0a          BfdSrcIp: N/A
     DbIndex: 0x1            BfdIfIndex: 0x0
        Type: Normal        BfdVrfIndex: 0
  TrackIndex: 0xffffffff          Label: NULL
  Preference: 60            vrfIndexDst: 0
     BfdMode: N/A            vrfIndexNH: 0
   Permanent: 0                     Tag: 0

...
```

Table 3 Command output

Field	Description
Destination	Destination address/prefix.
NibID	ID of the NIB.
MainNibID	ID of the primary next hop for static route FRR.
BkNibID	ID of the backup next hop for static route FRR.
NextHop	Next hop address.
BkNextHop	Backup next hop address.
Interface	Output interface of the route.
BkInterface	Backup output interface.
TableID	ID of the table to which the route belongs.
DbIndex	Index of the database to which the route belongs.
Type	Route type: • Normal. • DHCP. • NAT.
BfdSrcIp	Source IPv6 address of the indirect BFD session.
BfdIfIndex	Index of the interface where BFD is enabled.

Field	Description
BfdVrfIndex	This field is not supported in the current software version. Index of the VPN instance where BFD is enabled. This field displays **0** if BFD is enabled for the public network.
BfdMode	BFD session mode: • **N/A**—No BFD session is configured. • **Ctrl**—Control packet mode. • **Echo**—Echo packet mode.
TrackIndex	NQA Track index.
vrfIndexDst	This field is not supported in the current software version. Index of the VPN instance to which the destination belongs. For the public network, this field displays **0**.
vrfIndexNH	This field is not supported in the current software version. Index of the VPN instance to which the next hop belongs. For the public network, this field displays **0**.
Permanent	Permanent static route flag. 1 indicates a permanent static route.

ipv6 route-static

Use **ipv6 route-static** to configure an IPv6 static route.

Use **undo ipv6 route-static** to remove an IPv6 static route.

Syntax

ipv6 route-static *ipv6-address prefix-length* { *interface-type interface-number* [*next-hop-address*] [**bfd** { **control-packet** | **echo-packet** } [**bfd-source** *ipv6-address*] | **permanent**] } [**preference** *preference*] [**tag** *tag-value*] [**description** *text*]

undo ipv6 route-static *ipv6-address prefix-length* [*interface-type interface-number* [*next-hop-address*] | *next-hop-address*] [**preference** *preference*]

Default

No IPv6 static route is configured.

Views

System view

Predefined user roles

network-admin

Parameters

ipv6-address prefix-length: Specifies the IPv6 address and prefix length.

interface-type interface-number: Specifies an output interface by its type and number. If the output interface is an NBMA interface or broadcast interface and not a point-to-point (P2P) interface, the next hop address must be specified.

next-hop-address: Specifies the next hop IPv6 address.

bfd: Enables BFD to detect reachability of the static route's next hop.

control-packet: Specifies the BFD control packet mode.

bfd-source *ipv6-address*: Specifies the source IPv6 address of BFD packets.

echo-packet: Specifies the BFD echo packet mode.

permanent: Specifies the IPv6 route as a permanent IPv6 static route. If the output interface is down, the permanent IPv6 static route is still active.

preference *preference*: Specifies a preference for IPv6 static routes, in the range of 1 to 255. The default is 60.

tag *tag-value*: Sets a tag for marking the static route, in the range of 1 to 4294967295. The default is 0. Tags of routes are used for route control in routing policies. For more information about routing policies, see *Layer 3—IP Routing Configuration Guide*.

description *text*: Configures a description for the IPv6 static route, which consists of 1 to 60 characters, including special characters such as the space, but excluding the question mark (?).

Usage guidelines

An IPv6 static route that has the destination address configured as **::/0** (a prefix length of 0) is the default IPv6 route. If the destination address of an IPv6 packet does not match any entry in the routing table, this default route is used to forward the packet.

Follow these guidelines to configure the output interface, next hop address, or both for a static route:

- If the output interface is a broadcast interface or an NBMA interface, the next hop address must be specified.
- If the output interface is a P2P interface, you can specify only the output interface. You do not need to change the configuration of the route even if the peer address is changed.

Follow these guidelines when you configure BFD for IPv6 static routes:

- If you specify the source IPv6 address of BFD packets, you must specify the IPv6 address as the next hop IPv6 address on the peer device.
- If you specify a non-P2P output interface and a direct next hop, specify the **bfd-source** *ipv6-address* option as a best practice. Make sure the source IPv6 address of BFD packets meets the following requirements:
  - The address is the same as the IPv6 address of the output interface.
  - The address is on the same network segment as the next hop IPv6 address of the same type.

    For example, if the next hop IPv6 address is a link-local address, the source IPv6 address of BFD packets must also be a link-local address.

Follow these guidelines when you configure a static route:

- Enabling BFD for a flapping route could worsen the route flapping situation. Therefore, use it with caution. For more information about BFD, see *High Availability Configuration Guide*.
- The next hop IPv6 address of echo packets must be a global unicast address.
- Do not specify the **permanent** keyword together with the **bfd** keyword.

Examples

Configure an IPv6 static route, with the destination address 1:1:2::/64 and next hop 1:1:3::1.

```
<Sysname> system-view
[Sysname] ipv6 route-static 1:1:2:: 64 1:1:3::1
```

Related commands

display ipv6 routing-table protocol

ipv6 route-static default-preference

Use **ipv6 route-static default-preference** to set a default preference for IPv6 static routes.

Use **undo ipv6 route-static default-preference** to restore the default.

Syntax

ipv6 route-static default-preference *default-preference*

undo ipv6 route-static default-preference

Default

The default preference of IPv6 static routes is 60.

Views

System view

Predefined user roles

network-admin

Parameters

default-preference: Specifies a default preference for IPv6 static routes, in the range of 1 to 255.

Usage guidelines

If no preference is specified for an IPv6 static route, the default preference applies.

When the default preference is reconfigured, it applies only to newly added IPv6 static routes.

Examples

Set a default preference of 120 for IPv6 static routes.

```
<Sysname> system-view
[Sysname] ipv6 route-static default-preference 120
```

Related commands

display ipv6 routing-table protocol

Contents

RIPng commands

The S5000V3-EI, S5000V5-EI, S5000E-X, S5000X-EI, and WAS6000 switch series do not support RIPng.

checkzero

Use **checkzero** to enable zero field check on RIPng packets.

Use **undo checkzero** to disable zero field check.

Syntax

checkzero

undo checkzero

Default

Zero field check is enabled.

Views

RIPng view

Predefined user roles

network-admin

Usage guidelines

Some fields in RIPng packet headers must be zero. These fields are called zero fields. You can enable zero field check on incoming RIPng packets. If a zero field of a packet contains a non-zero value, RIPng discards the packet.

Examples

Disable zero field check on RIPng packets for RIPng 100.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] undo checkzero
```

default cost

Use **default cost** to configure a default metric for redistributed routes.

Use **undo default cost** to restore the default.

Syntax

default cost *cost-value*

undo default cost

Default

The default metric of redistributed routes is 0.

Views

RIPng view

Predefined user roles

network-admin

Parameters

cost-value: Specifies a default metric for redistributed routes, in the range of 0 to 16.

Usage guidelines

When you use the **import-route** command to redistribute routes from another routing protocol without specifying a metric, the metric specified by the **default cost** command applies.

Examples

Configure a default metric of 2 for redistributed routes.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] default cost 2
```

Related commands

import-route

display ripng

Use **display ripng** to display state and configuration information for a RIPng process.

Syntax

display ripng [*process-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about all RIPng processes.

Examples

Display state and configuration information for all configured RIPng processes.

```
<Sysname> display ripng
  Public VPN-instance name:

RIPng process: 1
       Preference: 100
           Routing policy: abc
       Checkzero: Enabled
       Default cost: 0
       Maximum number of load balanced routes: 1
       Update time   :   30 secs  Timeout time         :  180 secs
       Suppress time :  120 secs  Garbage-collect time :  120 secs
       Update output delay:   20(ms)  Output count:    3
       Graceful-restart interval:   60 secs
       Triggered Interval : 5 50 200
       Number of periodic updates sent: 256
       Number of triggered updates sent: 0
```

Table 1 Command output

Field	Description
Public VPN-instance name	Public network where the RIPng process runs.
RIPng process	RIPng process ID.
Preference	RIPng preference.
Checkzero	Indicates whether zero field check for RIPng packet headers is enabled: **Enabled** or **Disabled**.
Default Cost	Default metric of redistributed routes.
Maximum number of load balanced routes	ECMP routes are not supported in the current software version. Maximum number of load-balanced routes.
Update time	RIPng update interval, in seconds.
Timeout time	RIPng timeout interval, in seconds.
Suppress time	RIPng suppress interval, in seconds.
Garbage-Collect time	RIPng garbage collection interval, in seconds.
Update output delay	RIPng packet sending interval, in milliseconds.
Output count	Maximum number of RIPng packets that can be sent at each interval.
Graceful-restart interval	GR interval in seconds.
Triggered Interval	Triggered update sending interval.

display ripng database

Use **display ripng database** to display all active routes in the advertising database for a RIPng process.

Syntax

display ripng *process-id* **database** [*ipv6-address prefix-length*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 address. The *prefix-length* argument specifies a prefix length in the range of 0 to 128.

Examples

Display active routes for RIPng process 1.

```
<Sysname> display ripng 1 database
   1::/64,
```

```
     cost 0, RIPng-interface
  10::/32,
     cost 0, imported
  2::2/128,
    via FE80::20C:29FF:FE7A:E3E4, cost 1
```

Table 2 Command output

Field	Description
cost	Route metric value.
imported	Indicates the route is redistributed from another routing protocol.
RIPng-interface	Route learned from the interface.
via	Next hop IPv6 address.

display ripng graceful-restart

Use **display ripng graceful-restart** to display GR information.

Syntax

display ripng [*process-id*] **graceful-restart**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Display GR information for RIPng process 1.

```
<Sysname> display ripng 1 graceful-restart
RIPng process: 1
 Graceful Restart capability    : Enabled
 Current GR state               : Normal
 Graceful Restart period        : 60  seconds
 Graceful Restart remaining time: 0   seconds
```

Table 3 Command output

Field	Description
Graceful Restart capability	Indicates whether GR is enabled: **Enabled** or **Disabled**.
Current GR state	GR state: • **Under GR**—GR is in process. • **Normal**—GR is not in progress or has completed.

display ripng interface

Use **display ripng interface** to display interface information for a RIPng process.

Syntax

display ripng *process-id* **interface** [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays information about all interfaces for the RIPng process.

Examples

Display interface information for RIPng process 1.

```
<Sysname> display ripng 1 interface
Total: 1

 Interface: Vlan-interface100
        Link-local address: FE80::20C:29FF:FEC8:B4DD
        Split-horizon: On               Poison-reverse: Off
        MetricIn: 0                     MetricOut: 1
        Default route: Off
        Update output delay: 20 (ms)    Output count: 3
        Summary address:
               1::/16
```

Table 4 Command output

Field	Description
Total	Number of interfaces running RIPng.
Interface	Name of an interface running RIPng.
Link Local Address	Link-local address of an interface running RIPng.
Split-horizon	Indicates whether split horizon is enabled: • **On**—Enabled. • **Off**—Disabled.
Poison-reverse	Indicates whether poison reverse is enabled: • **On**—Enabled. • **Off**—Disabled.
MetricIn/MetricOut	Additional metric to incoming and outgoing routes.

Field	Description
Default route	• **Only**—The interface advertises only a default route. • **Originate**—The interface advertises a default route and other RIPng routes. • **Off**—In this state, the interface does not advertise a default route. • **In garbage-collection status**—In this state, the interface advertises a default route with a metric of 16.
Update output delay	RIPng packet sending interval, in milliseconds.
Output count	Maximum number of RIPng packets that an interface can send at each interval.
Default route cost	Cost of the default route.

display ripng neighbor

Use **display ripng neighbor** to display neighbor information for a RIPng process.

Syntax

display ripng *process-id* **neighbor** [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays information about all neighbors for the RIPng process.

Examples

Display neighbor information for RIPng process 1.

```
<Sysname> display ripng 1 neighbor
Neighbor Address: FE80::230:FF:FE00:0
     Interface  : Vlan-interface1
     Version    : RIPng version 1     Last update: 00h00m27s
     Bad packets: 0                   Bad routes : 0
```

Table 5 Command output

Field	Description
Neighbor Address	Link-local address of a neighbor interface.
Interface	Name of a neighbor interface.
Version	Version of RIPng that a neighbor runs.
Last update	Time elapsed since the most recent update.

display ripng non-stop-routing

Use **display ripng non-stop-routing** to display RIPng NSR information.

Syntax

display ripng [*process-id*] **non-stop-routing**

Views

Any view

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Display NSR information for RIPng process 1.

```
<Sysname> display ripng 1 non-stop-routing
RIPng process: 1
 Nonstop Routing capability: Enabled
 Current NSR state         : Finish
```

Table 6 Command output

Field	Description
Nonstop Routing capability	Indicates whether NSR is enabled: **Enabled** or **Disabled**.
Current NSR state	NSR state: • **Initialization**—Initialization state. • **Smooth**—Upgrading data. • **Advertising**—Advertising routes. • **Redistribution**—Redistributing routes. • **Finish**—Finished.

display ripng route

Use **display ripng route** to display all RIPng routes for a RIPng process.

Syntax

display ripng *process-id* **route** [*ipv6-address prefix-length* [**verbose**] | **peer** *ipv6-address* | **statistics**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 address. The *prefix-length* argument specifies a prefix length in the range of 0 to 128.

verbose: Displays all routing information for the specified destination IPv6 address. If you do not specify this keyword, the command displays only optimal RIPng routes with the specified destination IPv6 address.

peer *ipv6-address*: Specifies a neighbor by its IPv6 address.

statistics: Displays routing information statistics, including total number of routes and the number of routes learned from each neighbor.

Examples

Display routing information for RIPng process 1.

```
<Sysname> display ripng 1 route
   Route Flags: A - Aging, S - Suppressed, G - Garbage-collect, D – Direct
                O - Optimal, F - Flush to RIB
 ------------------------------------------------------------

 Peer FE80::20C:29FF:FED4:7171 on Vlan-interface100
 Destination 4::4/128,
     via FE80::20C:29FF:FED4:7171, cost 1, tag 0, AOF, 5 secs
 Local route
 Destination 3::3/128,
     via ::, cost 0, tag 0, DOF
 Destination 6::/64,
     via ::, cost 0, tag 0, DOF
```

Display information about routes with the specified prefix for RIPng process 1.

```
<Sysname> display ripng 1 route 3::3 128 verbose
   Route Flags: A - Aging, S - Suppressed, G - Garbage-collect, D – Direct
                O - Optimal, F - Flush to RIB
 ------------------------------------------------------------
 Peer FE80::4283:59FF:FE97:205 on Vlan-interface100
 Destination 3::3/128,
     via FE80::4283:59FF:FE97:205, cost 1, tag 0, AOF, 28 secs
```

Table 7 Command output

Field	Description
A–Aging	The route is in aging state.
S–Suppressed	The route is in suppressed state.
G–Garbage-collect	The route is in Garbage-collect state.
D–Direct	The route is a direct route.
Local route	The route is a locally generated direct route.
O - Optimal	The route is an optimal route.
F - Flush to RIB	The route has been flushed to the RIB.
Peer	Neighbor connected to the interface.

Field	Description
Destination	IPv6 destination address.
via	Next hop IPv6 address.
cost	Routing metric value.
tag	Route tag.
secs	Time a route entry has stayed in the current state.

Display routing information statistics for RIPng process 1.

```
<Sysname> display ripng 1 route statistics
Peer                                          Optimal/Aging    Garbage
 FE80::20C:29FF:FED4:7171                      1/2              0
 Local                                         2/0              0
 total                                         3/2              0
```

Table 8 Command output

Field	Description
Peer	IPv6 address of the neighbor.
Optimal	Number of optimal routes.
Aging	Number of routes in aging state.
Garbage	Number of routes in Garbage-collection state.
Local	Total number of locally generated direct route.
total	Total number of routes learned from RIPng neighbors.

enable ipsec-profile

Use **enable ipsec-profile** to apply an IPsec profile to a RIPng process.

Use **undo enable ipsec-profile** to remove the IPsec profile from the RIPng process.

Syntax

enable ipsec-profile *profile-name*

undo enable ipsec-profile

Default

No IPsec profile is applied to a RIPng process.

Views

RIPng view

Predefined user roles

network-admin

Parameters

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To configure an IPsec profile, see IPsec in *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] enable ipsec-profile profile001
```

fast-reroute

Use **fast-reroute** to configure RIPng FRR.

Use **undo fast-reroute** to disable RIPng FRR.

Syntax

fast-reroute route-policy *route-policy-name*

undo fast-reroute

Default

RIPng FRR is disabled.

Views

RIPng view

Predefined user roles

network-admin

Parameters

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

RIPng FRR is available only when the state of primary link (with Layer 3 interfaces in up state) changes from bidirectional to unidirectional or down.

RIPng FRR is effective only for RIPng routes that are learned from directly connected neighbors.

Examples

Enable RIPng FRR and use routing policy **frr** to specify a backup next hop.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc index 10 permit 100:: 64
[Sysname] route-policy frr permit node 10
[Sysname-route-policy-frr-10] if-match ipv6 address prefix-list abc
[Sysname-route-policy-frr-10] apply ipv6 fast-reroute backup-interface vlan-interface 1
backup-nexthop FE80::8
[Sysname-route-policy-frr-10] quit
[Sysname] ripng 100
[Sysname-ripng-100] fast-reroute route-policy frr
```

filter-policy export

Use **filter-policy export** to configure RIPng to filter redistributed routes.

Use **undo filter-policy export** to remove the filtering.

Syntax

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **export** [*protocol* [*process-id*]]

undo filter-policy export [*protocol* [*process-id*]]

Default

RIPng does not filter redistributed routes.

Views

RIPng view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter redistributed routes.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a string of 1 to 63 characters, to filter redistributed routes.

protocol: Filters routes redistributed from a routing protocol.

process-id: Specifies the process ID of the specified routing protocol, in the range of 1 to 65535. This argument is available only when the routing protocol is **ripng** or **ospfv3**. The default is 1.

Usage guidelines

If the *protocol* argument is specified, RIPng filters only routes redistributed from the specified routing protocol. Otherwise, RIPng filters all redistributed routes.

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* command.
- To deny/permit a route with the specified destination and prefix, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the prefix of the route. For the prefix configuration to take effect, specify a contiguous prefix.

Examples

Use IPv6 prefix list to filter redistributed RIPng updates.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc index 10 permit 100:1:: 32
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy prefix-list abc export
```

Configure advanced IPv6 ACL 3000 to permit only route 2001::1/128 to pass. Use advanced IPv6 ACL 3000 to filter redistributed routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
[Sysname-acl-ipv6-adv-3000] quit
```

```
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy 3000 export
```

filter-policy import

Use **filter-policy import** to configure RIPng to filter received routes.

Use **undo filter-policy import** to restore the default.

Syntax

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **import**

undo filter-policy import

Default

RIPng does not filter received routes.

Views

RIPng view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter received routes.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a string of 1 to 63 characters, to filter received routes.

Usage guidelines

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* command.
- To deny/permit a route with the specified destination and prefix, use the **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix* command.

The **source** keyword specifies the destination address of a route and the **destination** keyword specifies the prefix of the route. For the configuration to take effect, specify a contiguous prefix.

Examples

Use the IPv6 prefix list **abc** to filter received RIPng updates.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc index 10 permit 100:1:: 32
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy prefix-list abc import
```

Configure advanced IPv6 ACL 3000 to permit only route 2001::1/128 to pass. Use advanced IPv6 ACL 3000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
```

```
[Sysname-acl-ipv6-adv-3000] quit
[Sysname] ripng 100
[Sysname-ripng-100] filter-policy 3000 import
```

graceful-restart

Use **graceful-restart** to enable Graceful Restart (GR) for RIPng.

Use **undo graceful-restart** to disable RIPng GR.

Syntax

graceful-restart

undo graceful-restart

Default

RIPng GR is disabled.

Views

RIPng view

Predefined user roles

network-admin

Usage guidelines

RIPng GR and RIPng NSR are mutually exclusive. Do not configure the **graceful-restart** command and the **non-stop-routing** command at the same time.

Examples

Enable GR for RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] graceful-restart
```

graceful-restart interval

Use **graceful-restart interval** to set the GR interval.

Use **undo graceful-restart interval** to restore the default.

Syntax

graceful-restart interval *interval*

undo graceful-restart interval

Default

The GR interval is 60 seconds.

Views

RIPng view

Predefined user roles

network-admin

Parameters

interval: Specifies the GR interval in the range of 5 to 360 seconds.

Examples

Set the GR interval to 200 seconds for RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] graceful-restart interval 200
```

import-route

Use **import-route** to redistribute routes from another routing protocol.

Use **undo import-route** to remove routes redistributed from another routing protocol.

Syntax

import-route { **direct** | **static** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

undo import-route { **direct** | **static** }

import-route { **ospfv3** | **ripng** } [*process-id*] [**allow-direct** | **cost** *cost-value* | **route-policy** *route-policy-name*] *

undo import-route { **ospfv3** | **ripng** } [*process-id*]

Default

RIPng does not redistribute routes from another routing protocol.

Views

RIPng view

Predefined user roles

network-admin

Parameters

direct: Redistributes direct routes.

ospfv3: Redistributes OSPFv3 routes.

ripng: Redistributes RIPng routes.

static: Redistributes static routes.

process-id: Specifies an OSPFv3 or RIPng process by its ID in the range of 1 to 65535. The default is 1.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. If you do not specify this keyword, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a metric for redistributed routes, in the range of 0 to 16. The default metric is 0.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

This command redistributes only active routes. To view route state information, use the **display ipv6 routing-table protocol** command.

Examples

Redistribute routes from OSPFv3process 7 into RIPng and set the metric for redistributed routes to 7.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] import-route ospfv37 cost 7
```

non-stop-routing

Use **non-stop-routing** to enable RIPng NSR.

Use **undo non-stop-routing** to disable RIPng NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

RIPng NSR is disabled.

Views

RIPng view

Predefined user roles

network-admin

Usage guidelines

RIPng NSR enabled for a RIPng process takes effect only on that process. If multiple RIPng processes exist, enable RIPng NSR for each process as a best practice.

RIPng NSR and RIPng GR are mutually exclusive. Do not configure the **non-stop-routing** command and the **graceful-restart** command at the same time.

Examples

Enable NSR for RIPng process 1.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] non-stop-routing
```

output-delay

Use **output-delay** to set the RIPng packet sending interval and the maximum number of RIPng packets that can be sent at each interval.

Use **undo output-delay** to restore the default.

Syntax

output-delay *time* **count** *count*

undo output-delay

Default

A RIPng process sends a maximum of three RIPng packets every 20 milliseconds.

Views

RIPng view

Predefined user roles

network-admin

Parameters

time: Specifies the RIPng packet sending interval in the range of 10 to 100 milliseconds.

count: Specifies the maximum number of RIPng packets sent by a RIPng process at each interval, in the range of 1 to 30.

Usage guidelines

If you configure the RIPng packet sending rate for both a RIPng process and an interface running the RIPng process, the configuration on the interface takes effect.

Examples

Configure RIPng process 1 to send a maximum of 10 RIPng packets every 60 milliseconds.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] output-delay 60 count 10
```

Related commands

ripng output-delay

preference

Use **preference** to set the preference for RIPng routes.

Use **undo preference** to restore the default.

Syntax

preference { *preference* | **route-policy** *route-policy-name* } *

undo preference

Default

The preference of RIPng routes is 100.

Views

RIPng view

Predefined user roles

network-admin

Parameters

preference: Specifies the preference for RIPng routes, in the range of 1 to 255. The smaller the value, the higher the preference.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

You can specify a routing policy to set a preference for the matching RIPng routes.

- The preference set by the routing policy applies to all matching RIPng routes. The preference of other routes is set by the **preference** command.
- If no preference is set by the routing policy, the preference of all RIPng routes is set by the **preference** command.

Examples

Set the preference for RIPng routes to 120.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] preference 120
```

reset ripng process

Use **reset ripng process** to restart a RIPng process.

Syntax

reset ripng *process-id* **process**

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Usage guidelines

After executing the command, you are prompted to confirm the operation.

Examples

Restart RIPng process 100.

```
<Sysname> reset ripng 100 process
Reset RIPng process? [Y/N]:y
```

reset ripng statistics

Use **reset ripng statistics** to clear statistics for a RIPng process.

Syntax

reset ripng *process-id* **statistics**

Views

User view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Clear statistics for RIPng process 100.

```
<Sysname> reset ripng 100 statistics
```

ripng

Use **ripng** to enable RIPng and enter RIPng view.

Use **undo ripng** to disable RIPng.

Syntax

ripng [*process-id*]

undo ripng [*process-id*]

Default

RIPng is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535. The default value is 1.

Usage guidelines

Before you configure global RIPng parameters, you must create a RIPng process. This restriction does not apply to configuring interface RIPng parameters.

If you disable a RIPng process, the configured RIPng parameters become invalid.

Examples

Create RIPng process 100 and enter its view.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100]
```

ripng default-route

Use **ripng default-route** to configure a RIPng interface to advertise a default route with a specified metric.

Use **undo ripng default-route** to disable a RIPng interface from sending a default route.

Syntax

ripng default-route { **only** | **originate** } [**cost** *cost-value* | **route-policy** *route-policy-name*] *

undo ripng default-route

Default

A RIPng process does not advertise a default route.

Views

Interface view

Predefined user roles

network-admin

Parameters

only: Advertises only an IPv6 default route (::/0).

originate: Advertises an IPv6 default route (::/0) and other routes.

cost-value: Specifies a cost for the default route, in the range of 1 to 15. The default is 1.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. The command advertises a default route only when a route in the routing table matches the routing policy.

Usage guidelines

This command enables the interface to advertise a RIPng default route in a route update regardless of whether the default route exists in the local IPv6 routing table.

A RIPng interface configured to advertise a default route does not receive any default routes from its neighbors.

Examples

Configure RIPng on VLAN-interface 100 to advertise only a default route.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng default-route only
```

Configure RIPng on VLAN-interface 101 to advertise a default route and other routes.

```
<Sysname> system-view
[Sysname] interface vlan-interface 101
[Sysname-Vlan-interface101] ripng default-route originate
```

ripng enable

Use **ripng enable** to enable RIPng on an interface.

Use **undo ripng enable** to disable RIPng on an interface.

Syntax

ripng *process-id* **enable**

undo ripng enable

Default

RIPng is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

process-id: Specifies a RIPng process by its ID in the range of 1 to 65535.

Examples

Enable RIPng 100 on VLAN-interface 100.

```
<Sysname> system-view
```

```
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng 100 enable
```

ripng ipsec-profile

Use **ripng ipsec-profile** to apply an IPsec profile to a RIPng interface.

Use **undo ripng ipsec-profile** to remove the IPsec profile from the RIPng interface.

Syntax

ripng ipsec-profile *profile-name*

undo ripng ipsec-profile

Default

No IPsec profile is applied to a RIPng interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To configure an IPsec profile, see IPsec in *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng ipsec-profile profile001
```

ripng metricin

Use **ripng metricin** to configure an interface to add a metric to inbound RIPng routes.

Use **undo ripng metricin** to restore the default.

Syntax

ripng metricin *value*

undo ripng metricin

Default

The additional metric of an inbound route is 0.

Views

Interface view

Predefined user roles

network-admin

Parameters

value: Adds an additional metric to inbound routes, in the range of 0 to 16.

Examples

Configure VLAN-interface 100 to add a metric of 12 to inbound RIPng routes.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng metricin 12
```

ripng metricout

Use **ripng metricout** to configure an interface to add a metric to outbound RIPng routes.

Use **undo ripng metricout** to restore the default.

Syntax

ripng metricout *value*

undo ripng metricout

Default

The additional metric of outbound routes is 1.

Views

Interface view

Predefined user roles

network-admin

Parameters

value: Adds an additional metric to outbound routes, in the range of 1 to 16.

Examples

Configure RIPng on VLAN-interface 100 to add a metric of 12 to outbound routes.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng metricout 12
```

ripng output-delay

Use **ripng output-delay** to set the RIPng packet sending interval and the maximum number of RIPng packets that can be sent by an interface at each interval.

Use **undo ripng output-delay** to restore the default.

Syntax

ripng output-delay *time* **count** *count*

undo ripng output-delay

Default

An interface uses the RIPng packet sending rate set for the RIPng process that the interface runs.

Views

Interface view

Predefined user roles

network-admin

Parameters

time: Specifies the RIPng packet sending interval in the range of 10 to 100 milliseconds.

count: Specifies the maximum number of RIPng packets sent at each interval, in the range of 1 to 30.

Usage guidelines

If you set the RIPng packet sending rate for both a RIPng process and an interface running the RIPng process, the configuration on the interface takes effect.

Examples

Configure VLAN-interface 100 to send a maximum of six RIPng packets every 30 milliseconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng output-delay 30 count 6
```

Related commands

output-delay

ripng poison-reverse

Use **ripng poison-reverse** to enable poison reverse.

Use **undo ripng poison-reverse** to disable poison reverse.

Syntax

ripng poison-reverse

undo ripng poison-reverse

Default

Poison reverse is disabled.

Views

Interface view

Predefined user roles

network-admin

Examples

Enable poison reverse for RIPng update messages on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng poison-reverse
```

ripng primary-path-detect bfd echo

Use **ripng primary-path-detect bfd echo** to enable BFD single-hop echo detection for RIPng FRR.

Use **undo ripng primary-path-detect bfd** to disable BFD single-hop echo detection for RIPng FRR.

Syntax

ripng primary-path-detect bfd echo

undo ripng primary-path-detect bfd

Default

BFD single-hop echo detection is disabled for RIPng FRR.

Views

Interface view

Predefined user roles

network-admin

Usage guidelines

For quicker RIPng FRR, use BFD single-hop echo detection on the primary link of redundant links to detect link failure.

Examples

Enable BFD single-hop echo detection for RIPng FRR on VLAN-interface 10.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] fast-reroute route-policy frr
[Sysname-ripng-1] quit
[Sysname] bfd echo-source-ipv6 1::1
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ripng primary-path-detect bfd echo
```

ripng split-horizon

Use **ripng split-horizon** to enable split horizon.

Use **undo ripng split-horizon** to disable split horizon.

Syntax

ripng split-horizon

undo ripng split-horizon

Default

Split horizon is enabled.

Views

Interface view

Predefined user roles

network-admin

Usage guidelines

Split horizon prevents routing loops. If you want to disable this feature, make sure the operation is indispensable.

If both poison reverse and split horizon are enabled, only poison reverse takes effect.

Examples

Enable split horizon on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ripng split-horizon
```

ripng summary-address

Use **ripng summary-address** to configure a summary network to be advertised through an interface.

Use **undo ripng summary-address** to remove a summary network.

Syntax

ripng summary-address *ipv6-address prefix-length*

undo ripng summary-address *ipv6-address prefix-length*

Default

No summary network is configured to be advertised through an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the destination IPv6 address of the summary route.

prefix-length: Specifies the prefix length of the destination IPv6 address of the summary route, in the range of 0 to 128. It indicates the number of consecutive 1s of the prefix, which defines the network ID.

Usage guidelines

Networks on the summary network will not be advertised. The cost of the summary route is the lowest cost among summarized routes.

Examples

Assign an IPv6 address with the 64-bit prefix to VLAN-interface 100 and configure a summary with the 35-bit prefix.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname-Vlan-interface100] ipv6 address 2001:200::3EFF:FE11:6770/64
[Sysname-Vlan-interface100] ripng summary-address 2001:200:: 35
```

timer triggered

Use **timer triggered** to set the interval for sending triggered updates.

Use **undo timer triggered** to restore the default.

Syntax

timer triggered *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo timer triggered

Default

The maximum, minimum, and incremental intervals for sending triggered updates are 5 seconds, 50 milliseconds, and 200 milliseconds, respectively.

Views

RIPng view

Predefines user roles

network-admin

Parameters

maximum-interval: Specifies the maximum interval for sending triggered updates, in the range of 1 to 5 seconds.

minimum-interval: Specifies the minimum interval for sending triggered updates, in the range of 10 to 5000 milliseconds.

incremental-interval: Specifies the incremental interval for sending triggered updates, in the range of 100 to 1000 milliseconds.

Usage guidelines

The minimum interval and the incremental interval cannot be greater than the maximum interval.

For a stable network, the minimum interval is used. If network changes become frequent, the incremental interval *incremental-interval* is used to increase the triggered update sending interval until the *maximum-interval* is reached.

Examples

Set the maximum, minimum, and incremental intervals for sending triggered updates to 2 seconds, 100 milliseconds, and 100 milliseconds, respectively.

```
<Sysname> system-view
[Sysname] ripng 100
[Sysname-ripng-100] timer triggered 2 100 100
```

timers

Use **timers** to set RIPng timers.

Use **undo timers** to restore the default.

Syntax

timers { **garbage-collect** *garbage-collect-value* | **suppress** *suppress-value* | **timeout** *timeout-value* | **update** *update-value* } *

undo timers { **garbage-collect** | **suppress** | **timeout** | **update** } *

Default

The garbage-collect timer is 120 seconds, the suppress timer is 120 seconds, the timeout timer is 180 seconds, and the update timer is 30 seconds.

Views

RIPng view

Predefines user roles

network-admin

Parameters

garbage-collect-value: Sets the garbage-collect timer in the range of 1 to 86400 seconds.

suppress-value: Sets the suppress timer in the range of 0 to 86400 seconds.

timeout-value: Sets the timeout timer in the range of 1 to 86400 seconds.

update-value: Sets the update timer in the range of 1 to 86400 seconds.

Usage guidelines

RIPng has the following timers:

- **Update timer**—Interval between update messages.
- **Timeout timer**—Route aging time. If no update for a route is received before the timer expires, RIPng sets the metric of the route to 16.
- **Suppress timer**—How long a RIPng route stays in suppressed state. When the metric of a route becomes 16, the route enters the suppressed state. If RIPng receives an update for the route from the same neighbor and the route in the update has a metric less than 16, RIPng uses the route to replace the suppressed route.
- **Garbage-collect timer**—Interval from when the metric of a route becomes 16 to when it is deleted from the routing table. During the garbage-collect timer length, RIPng advertises the route with a metric of 16. If no update is announced for that route before the garbage-collect timer expires, RIPng deletes the route from the routing table.

As a best practice, do not change the default values of these timers.

The timer lengths must be kept consistent on all routers in the network.

Examples

Set the update, timeout, suppress, and garbage-collect timers to 5 seconds, 15 seconds, 15 seconds, and 30 seconds.

```
<Sysname> system-view
[Sysname] ripng 1
[Sysname-ripng-1] timers update 5 timeout 15 suppress 15 garbage-collect 30
```

Contents

OSPFv3 commands

The S5110V2-SI, S5000V3-EI, S5000V5-EI, S5000E-X, S5000X-EI, and WAS6000 switch series do not support OSPFv3.

abr-summary (OSPFv3 area view)

Use **abr-summary** to configure route summarization on an ABR.

Use **undo abr-summary** to remove the configuration.

Syntax

abr-summary *ipv6-address prefix-length* [**not-advertise**] [**cost** *cost-value*]

undo abr-summary *ipv6-address prefix-length*

Default

Route summarization is not configured on an ABR.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the destination IPv6 address of the summary route.

prefix-length: Specifies the prefix length of the destination IPv6 address, in the range of 0 to 128. This argument specifies the number of consecutive 1s of the prefix, which defines the network ID.

not-advertise: Specifies not to advertise the summary IPv6 route. If you do not specify this keyword, the command advertises the IPv6 summary route.

cost *cost-value*: Specifies the cost of the summary route, in the range of 1 to 16777215. The default cost is the largest cost value among routes that are summarized.

Usage guidelines

This command applies only to an ABR to summarize multiple contiguous networks into one network.

To enable ABR to advertise specific routes that have been summarized, use the **undo abr-summary** command.

Examples

Summarize networks 2000:1:1:1::/64 and 2000:1:1:2::/64 in Area 1 into 2000:1:1::/48.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] abr-summary 2000:1:1:: 48
```

area

Use **area** to create an OSPFv3 area and enter OSPFv3 area view.

Use **undo area** to remove an OSPFv3 area.

Syntax

area *area-id*

undo area *area-id*

Default

No OSPFv3 areas exist.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

area-id: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format.

Examples

Create OSPFv3 Area 0 and enter its view.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 0
[Sysname-ospfv3-1-area-0.0.0.0]
```

asbr-summary (OSPFv3 view)

Use **asbr-summary** to configure route summarization on an ASBR.

Use **undo asbr-summary** to remove the configuration.

Syntax

asbr-summary *ipv6-address prefix-length* [**cost** *cost-value* | **not-advertise** | **nssa-only** | **tag** *tag*] *

undo asbr-summary *ipv6-address prefix-length*

Default

Route summarization is not configured on an ASBR.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the destination IPv6 address of the summary route.

prefix-length: Specifies the prefix length in the range of 0 to 128.

cost *cost-value*: Specifies the cost of the summary route, in the range of 1 to 16777214. If you do not specify this option, the largest cost among the summarized routes applies. If the routes in Type-5 LSAs translated from Type-7 LSAs are Type-2 external routes, the largest cost among the summarized routes plus 1 applies.

not-advertise: Disables advertising the summary route. If you do not specify this keyword, the command advertises the route.

nssa-only: Limits the route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. By default, the P-bit of Type-7 LSAs is set to 1. If the ASBR is also an ABR and **FULL** state neighbors exist in the backbone area, the P-bit of Type-7 LSAs originated by the ASBR is set to 0. This keyword applies to the NSSA ASBR.

tag *tag*: Specifies a tag for the summary route, in the range of 0 to 4294967295.

Usage guidelines

An ASBR can summarize routes in the following LSAs:

- Type-5 LSAs.
- Type-7 LSAs in an NSSA area.
- Type-5 LSAs translated by the ASBR (also an ABR) from Type-7 LSAs in an NSSA area.

  If the ASBR (ABR) is not a translator, it cannot summarize routes in Type-5 LSAs translated from Type-7 LSAs.

To enable ASBR to advertise specific routes that have been summarized, use the **undo asbr-summary** command.

Examples

Configure a summary route 2000::/16, and specify a cost of 100 and a tag value of 2 for the summary route.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] asbr-summary 2000:: 16 cost 100 tag 2
```

authentication-mode

Use **authentication-mode** to specify an authentication mode for an OSPFv3 area.

Use **undo authentication-mode** to restore the default.

Syntax

authentication-mode keychain *keychain-name*

undo authentication-mode

Default

No authentication is performed for an area.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

The authentication mode specified for an OSPFv3 interface has a higher priority than the mode specified for an OSPFv3 area.

When keychain authentication is configured for an OSPFv3 area, OSPFv3 performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPFv3 does not send the packet if it fails to obtain a valid send key.
2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 65535, OSPFv3 does not send the packet.

When keychain authentication is configured for an OSPFv3 area, OSPFv3 performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPFv3 discards the packet if it fails to obtain a valid accept key.
2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPFv3 discards the packet.

OSPFv3 supports only the HMAC-SHA-256 authentication algorithms.

The ID of keys used for authentication can only be in the range of 0 to 65535.

Examples

Configure OSPFv3 Area 1 to use keychain **test** for packet authentication.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] authentication-mode keychain test
```

bandwidth-reference (OSPFv3 view)

Use **bandwidth-reference** to set a reference bandwidth value for link cost calculation.

Use **undo bandwidth-reference** to restore the default.

Syntax

bandwidth-reference *value*

undo bandwidth-reference

Default

The reference bandwidth value is 100 Mbps for link cost calculation.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

value: Specifies the reference bandwidth value for link cost calculation, in the range of 1 to 4294967 Mbps.

Usage guidelines

You can configure an OSPFv3 cost for an interface with one of the following methods:

- Configure the cost value in interface view.

- Configure a bandwidth reference value. OSPFv3 computes the cost automatically based on the bandwidth reference value by using the following formula: Interface OSPFv3 cost = Bandwidth reference value / Interface bandwidth.
  - If the calculated cost is greater than 65535, the value of 65535 is used.
  - If the calculated cost is smaller than 1, the value of 1 is used.

If no cost value is configured for an interface, OSPFv3 computes the interface cost value automatically.

Examples

Set the reference bandwidth value to 1000 Mbps.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] bandwidth-reference 1000
```

default tag

Use **default tag** to set a tag for redistributed routes.

Use **undo default tag** to restore the default.

Syntax

default tag *tag*

undo default tag

Default

The tag of redistributed routes is 1.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

tag: Specifies a tag for redistributed routes, in the range of 0 to 4294967295.

Usage guidelines

If you do not set a tag for redistributed routes by using the **default-route-advertise** or **import-route** command, the tag specified by the **default tag** command applies.

Examples

Set the tag for redistributed routes to 2.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] default tag 2
```

Related commands

default-route-advertise (OSPFv3 view)

import-route

default-cost (OSPFv3 area view)

Use **default-cost** to set a cost for the default route advertised to the stub area or NSSA area.

Use **undo default-cost** to restore the default.

Syntax

default-cost *cost*

undo default-cost

Default

The cost is 1.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

value: Specifies a cost for the default route advertised to the stub area or NSSA area, in the range of 0 to 16777214.

Usage guidelines

This command takes effect only on the ABR of a stub area or the ABR or ASBR of an NSSA area.

Examples

Configure Area 1 as a stub area, and set the cost of the default route advertised to the stub area to 60.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] stub
[Sysname-ospfv3-1-area-0.0.0.1] default-cost 60
```

Related commands

nssa (OSPFv3 area view)

stub (OSPFv3 area view)

default-route-advertise (OSPFv3 view)

Use **default-route-advertise** to redistribute a default route into the OSPFv3 routing domain.

Use **undo default-route-advertise** to restore the default.

Syntax

default-route-advertise [[**always** | **permit-calculate-other**] | **cost** *cost-value* | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo default-route-advertise

Default

No default route is redistributed into the OSPFv3 routing domain.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

always: Redistributes a default route in an AS-external-LSA into the OSPFv3 routing domain regardless of whether a default route exists in the routing table. If you do not specify this keyword, the router redistributes a default route in an AS-external-LSA into the OSPFv3 routing domain only when the default route exists in the routing table.

permit-calculate-other: Enables OSPFv3 to calculate default routes received from other routers. If you do not specify this keyword, OSPFv3 does not calculate default routes from other routers. If the router does not redistribute any default route in an AS-external-LSA into the OSPFv3 routing domain, the router calculates default routes from other routers. It calculates these routes regardless of whether this keyword is specified.

cost *cost-value*: Specifies a cost for the default route, in the range of 0 to 16777214. The default is 1.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. When the routing policy is matched and one of the following conditions is met, the command redistributes a default route in an AS-external-LSA into the OSPFv3 routing domain:

- A default route exists in the routing table.
- The **always** keyword is specified.

The routing policy modifies values in the AS-external-LSA.

tag *tag*: Specifies a tag for the default route, in the range of 0 to 4294967295. If you do not specify this option, the tag specified by the **default tag** command applies.

type *type*: Specifies a type for the AS-external-LSA, 1 or 2. The default is 2.

Usage guidelines

This command redistributes a default route in an AS-external-LSA, which cannot be redistributed with the **import-route** command. If the local routing table has no default route, you must provide the **always** keyword for the command.

Examples

Redistribute a default route into the OSPFv3 routing domain. (The default route does not exist in the local router.)

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] default-route-advertise always
```

Related commands

import-route (OSPFv3 view)

display ospfv3

Use **display ospfv3** to display OSPFv3 process information.

Syntax

display ospfv3 [*process-id*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about all OSPFv3 processes.

verbose: Displays detailed OSPFv3 process information. If you do not specify this keyword, the command displays brief OSPFv3 process information.

Examples

Display detailed information about all OSPFv3 processes.

```
<Sysname> display ospfv3 verbose

Table 1 Command output

Field	Description
OSPFv3 Process 1 with Router ID 1.1.1.1	OSPFv3 process is 1, and router ID is 1.1.1.1.
Router type	Router type: • ABR. • ASBR. • NSSA. • Null.
Route tag	Tag of the routes redistributed into the OSPFv3 process.
Route tag check	Whether the check is enabled for the route tag in OSPFv3 LSAs of the OSPFv3 process.
Multi-VPN-Instance	Whether the OSPFv3 process supports multiple VPN instances: • **Multi-VPN-Instance: Disabled**—The process does not support multiple VPN instances. • **Multi-VPN-Instance: Enabled**—The process supports multiple VPN instances.
DN-bit check	Whether the check is enabled for the DN bit in OSPFv3 LSAs of the OSPFv3 process.
DN-bit set	Whether the DN bit is set for OSPFv3 LSAs in the OSPFv3 process.
Condition	Time when the router acts as a stub router: • Always. • On startup for *xxx* seconds, where *xxx* is specified by the user.

Field	Description
State	State of the stub router: • Active. • Inactive.
SPF-schedule-interval	Interval for SPF calculations.
Transmit pacing	LSU advertisement rate: • **Interval**—Specifies the interval for sending LSUs. • **Count**—Specifies the maximum number of LSUs sent at each interval.
Default ASE parameters	Default parameters of redistributed routes. **Tag** represents the route tag of the redistributed routes.
Route preference	Internal route preference.
ASE route preference	AS-external route preference.
FRR backup mode	FRR backup mode: • **LFA**—Uses the LFA algorithm to calculate a backup next hop for all routes. **LFA ABR-only** indicates that only the next hop of the route to the ABR can be used as the backup next hop. • **route-policy** *route-policy-name*—Specifies a backup next hop by using a routing policy.
LSA originated count	Number of originated LSAs.
LSA received count	Number of received LSAs.
SNMP trap rate limit interval: 10 Count: 7	The OSPFv3 process can output a maximum of seven notifications within 10 seconds.
Area count	Total number of areas.
Stub area count	Number of stub areas.
NSSA area count	Number of NSSA areas.
ExChange/Loading neighbors	Neighbors in ExChange/Loading state.
Calculation trigger type	Route calculation trigger type: • **Full**—Calculation of all routes is triggered. • **Area topology change**—Topology change in an area. • **Intra router change**—Incremental intra-area route change. • **ASBR change**—Incremental ASBR route change. • **Full IP prefix**—Calculation of all IP prefixes is triggered. • **Full intra AS**—Calculation of all intra-AS prefixes is triggered. • **Inc intra AS**—Calculation of incremental intra-AS prefixes is triggered. • **Full inter AS**—Calculation of all AS-external prefixes is triggered. • **Inc inter AS**—Calculation of incremental AS-external prefixes is triggered. • **Nexthop calculation**—Calculation of next hops is triggered. • **N/A**—Route calculation is not triggered.

Field	Description
Current calculation type	Current route calculation type: • SPF calculation. • **Intra router calculation**—Intra-area route calculation. • **ASBR calculation**—Inter-area ASBR route calculation. • **Inc intra router**—Incremental intra-area route calculation. • **Inc ASBR calculation**—Incremental inter-area ASBR route calculation. • **Full intra AS**—Calculation of all intra-AS prefixes. • **Inc intra AS**—Calculation of incremental intra-AS prefixes. • **Full inter AS**—Calculation of all AS-external prefixes. • **Inc inter AS**—Calculation of incremental AS-external prefixes. • **N/A**—Route calculation is not triggered.
Current calculation phase	Current route calculation phase: • **Calculation area topology**—Calculating area topology. • **Calculation router**—Calculating routes on routers. • **Calculation intra AS**—Calculating intra-AS routes. • **Calculation ASBR**—Calculating routes on ASBRs. • **Calculation inter AS**—Calculating AS-external routes. • **Calculation end**—Ending phase of calculation. • **N/A**—Route calculation is not triggered.
Redistribute timer	Route redistribution timer status: on or off.
Redistribute schedule type	Route redistribution scheduling type: • **RIB**—Redistribute routes through the RIB table. • **Self**—Redistribute routes through the routing table. • **N/A**—Route redistribution is not triggered.
Redistribute route count	Number of redistributed routes.
Process reset state	Process reset state: • **N/A**—The process is not reset. • **Under reset**—The process is in the reset progress. • **Under RIB smooth**—The process is synchronizing RIB routes.
Current reset type	Current process reset type: • **N/A**—The process is not reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPFv3 process. • **Undo router-id**—Delete router ID. • **Set router-id**—Set router ID.
Next reset type	Next process reset type: • **N/A**—The process is not reset. • **GR quit**—Normal reset when GR quits abnormally. • **Delete**—Delete OSPFv3 process. • **Undo router-id**—Delete router ID. • **Set router-id**—Set router ID.

Field	Description
Reset prepare message replied	Modules that reply reset prepare messages: • **P**—Neighbor maintenance module. • **S**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.
Reset process message replied	Modules that reply reset process messages: • **P**—Neighbor maintenance module. • **S**—LSDB synchronization module. • **C**—Route calculation module. • **R**—Route redistribution module.

Reset phase of module	Reset phase of each module:
	• LSDB synchronization (S) module:
	  ○ **N/A**—Not reset.
	  ○ **Delete ASE**—Delete all ASE LSAs.
	  ○ **Delete area LSA**—Delete LSAs from an area.
	  ○ **Delete area IF**—Delete interfaces from an area.
	• Route calculation (C) module:
	  ○ **N/A**—Not reset.
	  ○ **Delete topology**—Delete area topology.
	  ○ **Delete router**—Delete routes of routers.
	  ○ **Delete intra AS**—Delete intra-AS routes
	  ○ **Delete inter AS**—Delete AS-external routes.
	  ○ **Delete ASBR**—Delete ASBR routes.
	• Route redistribution (R) module:
	  ○ **N/A**—Not reset.
	  ○ **Delete import**—Delete redistributed routes.

IPsec profile name	IPsec profile applied to the interface.
Keychain authentication: Enabled (test)	Keychain authentication is enabled for the area, and the keychain **test** is used.
Created by Vlink	The area is created through virtual link.
7/5 translator state	State of the translator that translates Type-7 LSAs to Type-5 LSAs: • **Enabled**—The translator is specified through commands. • **Elected**—The translator is designated through election. • **Disabled**—The device is not a translator.
7/5 translate stability timer interval	Stability interval (in seconds) for Type-7 LSA-to-Type-5 LSA translation.

display ospfv3 abr-asbr

Use **`display ospfv3 abr-asbr`** to display information about the routes to OSPFv3 ABR and ASBR.

Syntax

`display ospfv3` [*`process-id`*] **`abr-asbr`**

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about all the routes to the OSPFv3 ABR and ASBR.

Examples

Display information about all the routes to the OSPFv3 ABR and ASBR.

```
<Sysname> display ospfv3 abr-asbr

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Destination : 1.1.1.2                                 Rtr Type : ABR
 Area        : 0.0.0.0                                 Path Type: Intra
 Interface   : Vlan102                               BkInterface: Vlan101
 NextHop     : FE80:1:1::1
 BkNexthop   : FE80:1:2::2
 Cost        : 1

 Destination : 1.1.1.3                                 Rtr Type : ASBR
 Area        : 0.0.0.0                                 Path Type: Intra
 Interface   : Vlan103                               BkInterface: Vlan104
 NextHop     : FE80:2:1::1
 BkNexthop   : FE80:1:2::4
 Cost        : 1
```

Table 2 Command output

Field	Description
OSPFv3 Process 1 with Router ID 1.1.1.1	OSPFv3 process is 1, and router ID is 1.1.1.1.
Destination	Router ID of an ABR or ASBR.
Rtr Type	Router type: ABR or ASBR.
Area	Area ID of the next hop.
Path Type	Type of the route to the ABR or ASBR: • **Intra**—Intra-area route. • **Inter**—Inter-area route.
Interface	Output interface.
NextHop	Next hop address.
BkInterface	Backup output interface.
BkNexthop	Backup next hop address.
Cost	Cost from the router to the ABR or ASBR.

display ospfv3 abr-summary

Use **display ospfv3 abr-summary** to display ABR summary route information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **abr-summary** [*ipv6-address prefix-length*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about ABR summary routes for all OSPFv3 processes.

area *area-id*: Specifies an OSPFv3 area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify this option, the command displays information about ABR summary routes for all OSPFv3 areas.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 prefix. The *prefix-length* argument specifies a prefix length in the range of 0 to 128. If you do not specify this argument, the command displays information about all summary routes on the ABR.

verbose: Displays detailed ABR summary route information. If you do not specify this keyword, the command displays brief ABR summary route information.

Examples

Display brief ABR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 abr-summary

            OSPFv3 Process 1 with Router ID 2.2.2.2

                    Area: 1.1.1.1
 Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise
 NULL0       : Active
 Cost        : 1 (Configured)
 Routes count: 2
```

Table 3 Command output

Field	Description
Area	Area to which the summary routes belong.
Total summary addresses	Total number of summary routes.
Prefix	Prefix of the summary route.

Field	Description
Status	Advertisement status of the summary route.
NULL0	Null 0 route.
Cost	Cost of the summary route.
Routes count	Number of summarized routes.

Display detailed ABR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 abr-summary verbose

            OSPFv3 Process 1 with Router ID 2.2.2.2

                       Area: 1.1.1.1
Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise
 NULL0       : Active
 Cost        : 1 (Configured)
 Routes count: 2
   Destination                                    Metric
   1000:4:10:3::/96                               1
   1000:4:11:3::/96                               1
```

Table 4 Command output

Field	Description
Destination	Destination address of a summarized route.
Metric	Metric of a summarized route.

display ospfv3 asbr-summary

Use **display ospfv3 asbr-summary** to display ASBR summary route information.

Syntax

display ospfv3 [*process-id*] **asbr-summary** [*ipv6-address prefix-length*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays information about ASBR summary routes for all OSPFv3 processes.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 prefix. The *prefix-length* argument specifies a prefix length in the range of 0 to 128. If you do not specify this argument, the command displays information about all ASBR summary routes.

verbose: Displays detailed ASBR summary route information. If you do not specify this keyword, the command displays brief ASBR summary route information.

Examples

Display brief ASBR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 asbr-summary

              OSPFv3 Process 1 with Router ID 2.2.2.2

 Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise
 NULL0       : Active
 Cost        : 1 (Configured)
 Tag         : (Not configured)
 Nssa-only   : (Not configured)
 Routes count: 2
```

Table 5 Command output

Field	Description
Total summary addresses	Total number of summary routes.
Prefix	Prefix and prefix length of the summary route.
Status	Advertisement status of the summary route: • **Advertise**—The summary route has been advertised. • **Not-advertise**—The summary route has not been advertised.
NULL0	Status of the Null 0 route: • Active. • Inactive.
Cost	Cost of the summary route: • Configured. • Not configured.
Tag	Tag of the summary route: • Configured. • Not configured.
Nssa-only	Whether the **nssa-only** attribute is configured: • Configured. • Not configured.
Routes count	Number of summarized routes.

Display detailed ASBR summary route information in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 asbr-summary verbose
```

```
              OSPFv3 Process 1 with Router ID 2.2.2.2

 Total summary addresses: 1

 Prefix      : 1000:4::/32
 Status      : Advertise
 NULL0       : Active
 Cost        : 1 (Configured)
 Tag         : (Not configured)
 Nssa-only   : (Not configured)
 Routes count: 2
  Destination                                Protocol Process Type Metric
  1000:4:10:3::/96                           Static   0       2    1
  1000:4:11:3::/96                           Static   0       2    1
```

Table 6 Command output

Field	Description
Destination	Prefix and prefix length of the summarized route.
Protocol	Routing protocol from which the route was redistributed.
Process	Process of the routing protocol from which the route was redistributed.
Type	Type of the summarized route.
Metric	Metric of the summarized route.

display ospfv3 event-log

Use **display ospfv3 event-log** to display OSPFv3 log information.

Syntax

display ospfv3 [*process-id*] **event-log** { **lsa-flush** | **peer** | **spf** }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPFv3 log information for all processes.

lsa-flush: Specifies LSA aging log information.

peer: Specifies neighbor log information.

spf: Specifies route calculation log information.

Usage guidelines

Route calculation logs show the number of routes newly installed in the IPv6 routing table.

Neighbor logs include information about the following events:

- The OSPFv3 neighbor state goes down.
- The OSPFv3 neighbor state goes backward because the local end receives BadLSReq, SeqNumberMismatch, and 1-Way events.

Examples

Display OSPFv3 LSA aging log information for OSPFv3 process 1.

```
<Sysname>display ospfv3 1 event-log lsa-flush

              OSPFv3 Process 1 with Router ID 1.3.3.3

 2014-09-02 07:55:25 Received MaxAge LSA from 1.1.1.1
 Type: 3   LS ID: 0.0.0.2         AdvRtr: 1.1.1.1           Seq#: 80000001

 2014-09-02 07:55:22 Flushed MaxAge LSA by itself
 Type: 3   LS ID: 0.0.0.2         AdvRtr: 1.3.3.3           Seq#: 80000001

 2014-09-02 07:55:07 Flushed MaxAge LSA by itself
 Type: 3   LS ID: 0.0.0.40        AdvRtr: 1.3.3.3           Seq#: 80000001

 2014-09-02 07:55:07 Flushed MaxAge LSA by itself
 Type: 3   LS ID: 0.0.0.39        AdvRtr: 1.3.3.3           Seq#: 80000001
```

Table 7 Command output

Field	Description
Received MaxAge LSA from X.X.X.X	The device received an LSA that has reached the maximum age from X.X.X.X.
Flushed MaxAge LSA by itself	The device flushed the LSA that has reached the maximum age.
Type	LSA type.
LS ID	LSA link state ID.
AdvRtr	Advertising router.
Seq#	LSA sequence number.

Display OSPFv3 route calculation log information for OSPFv3 process 1.

```
<Sysname>display ospfv3 1 event-log spf

              OSPFv3 Process 1 with Router ID 1.3.3.3

 Date       Time     Duration   Intra   Inter   External Reason
 2014-09-02 07:55:30 0.258827   0       0       0        Intra-area LSA
 2014-09-02 07:55:30 0.679      0       0       0        Intra-area LSA
 2014-09-02 07:55:30 0.51576    0       0       0        Intra-area LSA
 2014-09-02 07:55:30 0.372      0       0       0        Intra-area LSA
 2014-09-02 07:55:25 4.948353   0       0       0        Intra-area LSA
 2014-09-02 07:55:25 0.5288     0       0       0        Area 0 full neighbor
 2014-09-02 07:55:21 1.66013    0       0       0        Intra-area LSA
 2014-09-02 07:55:20 0.450905   0       0       0        Intra-area LSA
```

```
2014-09-02 07:55:15 0.253688   0       0       0       Interface state change
2014-09-02 07:55:15 0.5693     0       0       0       Intra-area LSA
```

Table 8 Command output

Field	Description
Date	Date when the route calculation starts, in YYYY-MM-DD format. YYYY represents the year, MM represents the month, and DD represents the day.
Time	Time when the route calculation starts, in hh:mm:ss format. hh represents the hour, mm represents the minutes, and ss represents the seconds.
Duration	Duration of the route calculation, in seconds.
Intra	Number of intra-area routes newly installed in the IPv6 routing table.
Inter	Number of inter-area routes newly installed in the IPv6 routing table.
External	Number of external routes newly installed in the IPv6 routing table.
Reason	Reasons why the route calculation is performed: • **Intra-area LSA**—Intra-area LSA changes. • **Inter-area LSA**—Inter-area LSA changes. • **External LSA**—External LSA changes. • **Configuration**—Configuration changes. • **Area 0 full neighbor**—Number of **FULL**-state neighbors in Area 0 changes. • **Area 0 up interface**—Number of interfaces in up state in Area 0 changes. • **AS number**—AS number changes. • **ABR summarization**—ABR summarization changes. • **GR end**—GR ends. • **Routing policy**—Routing policy changes. • **Others**—Other reasons.

Display OSPFv3 neighbor log information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 event-log peer

              OSPFv3 Process 1 with Router ID 1.1.1.1

Date       Time     Router ID       Reason       InstID  Interface
2014-09-02 16:39:13 1.3.3.3         IntPhyChange 0       Vlan101
2014-09-02 16:36:46 1.3.3.3         IntPhyChange 0       Vlan101
2014-09-02 16:34:49 1.3.3.3         BFDDown      0       Vlan101
2014-09-02 10:08:45 1.3.3.3         DeadExpired  0       Vlan102
2014-09-02 10:08:39 1.3.3.3         DeadExpired  0       VLINK1
2014-09-02 10:08:08 1.3.3.3         BFDDown      0       Vlan101
```

Table 9 Command output

Field	Description
Date	Date when the neighbor state changes, in YYYY-MM-DD format. YYYY represents the year, MM represents the month, and DD represents the day.

Field	Description
Time	Time when the neighbor state changes, in hh:mm:ss format. hh represents the hour, mm represents the minutes, and ss represents the seconds.
Router ID	Neighbor router ID.
Reason	Reasons for neighbor state changes: • **ResetConnect**—The connection is lost due to insufficient memory. • **IntChange**—The interface parameter has changed. • **ResetOspfv3**—The OSPFv3 process is reset. • **UndoOspfv3**—The OSPFv3 process is deleted. • **UndoArea**—The OSPFv3 area is deleted. • **UndoInt**—The interface is disabled. • **IntLogChange**—The logical attribute of the interface has changed. • **IntPhyChange**—The physical attribute of the interface has changed. • **DeadExpired**—The dead timer expires. • **Retrans**—Excessive retransmissions. • **BFDDown**—The interface is shut down by BFD. • **SilentInt**—The interface is configured as a silent interface. • **ConfStubArea**—The interface is configured with stub area parameters. • **ConfNssaArea**—The interface is configured with NSSA area parameters. • **VlinkDown**—The virtual link goes down. • **BadLSReq**—The interface receives BadLSReq events. • **SeqMismatch**—The interface receives SeqNumberMismatch events. • **Way**—The interface receives 1-Way events.
InstID	Instance ID for an interface.
Interface	Interface name.

display ospfv3 graceful-restart

Use **`display ospfv3 graceful-restart`** to display GR information.

Syntax

`display ospfv3` [*`process-id`*] **`graceful-restart`** [**`verbose`**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`process-id`: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays GR information for all processes.

verbose: Displays detailed GR information. If you do not specify this keyword, the command displays brief GR information.

Examples

Display brief GR information for all OSPFv3 processes (GR restarter).

```
<Sysname> display ospfv3 graceful-restart

              OSPFv3 Process 1 with Router ID 3.3.3.3

 Graceful-restart capability     : Enable
 Graceful-restart support        : Planned and unplanned, Partial
 Helper capability               : Enable
 Helper support                  : Planned and unplanned
 Current GR state                : Normal
 Graceful-restart period         : 120 seconds
 Number of neighbors under helper: 0
 Number of restarting neighbors  : 0
 Last exit reason:
   Restarter: None
   Helper   : None
```

Table 10 Command output

Field	Description
OSPFv3 Process 1 with Router ID 3.3.3.3	The GR status of OSPFv3 process 1 with router ID 3.3.3.3 is displayed.
Graceful-restart capability	Whether OSPFv3 GR is enabled: • Enabled. • Disabled.
Graceful-restart support	GR modes that the process supports (displayed only when GR is enabled): • **Planned and unplanned**—Supports both planned and unplanned GR. • **Planned only**—Supports only planned GR. • **Partial**—Supports partial GR. • **Global**—Supports global GR.
Helper capability	Whether OSPFv3 GR helper is enabled: • Enabled. • Disabled.
Helper support	Policies and GR modes that the GR helper supports (displayed only when GR helper is enabled): • **Strict LSA check**—The GR helper supports strict LSA checking. • **Planned and unplanned**—The GR helper supports both planned and unplanned GR. • **Planned only**—The GR helper supports only planned GR.

Field	Description
Current GR state	GR status: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in progress. • **Under Helper**—The process is acting as GR helper.
Graceful-restart period	GR restart interval.
Number of neighbors under helper	Number of neighbors in GR helper status.
Number of restarting neighbors	Number of neighbors in GR restarter status.

Last exit reason	Last exit reason:
	• **Restarter**—Reason that the restarter exited most recently:
	  ○ None.
	  ○ **Completed**—GR is completed.
	  ○ **Interval timer is fired**—The GR timer expires.
	  ○ **Interface state change**—An interface state change occurs.
	  ○ **Received 1-way hello**—The device receives 1-way hello packets from the neighbor.
	  ○ **Reset neighbor**—The neighbor is reset.
	  ○ **DR or BDR change**—The DR or BDR changes.
	• **Helper**—Reason that the helper exited most recently:
	  ○ None.
	  ○ **Completed**—GR is completed.
	  ○ **Received 1-way hello**—The device receives 1-way hello packets from the neighbor.
	  ○ **Grace Period timer is fired**—The GR timer expires.
	  ○ **Lsa check failed**—An LSA change on the GR helper is detected.
	  ○ **Reset neighbor**—The neighbor is reset.
	  ○ **Received MAXAGE gracelsa but neighbor is not full**—The device receives Grace-LSAs that reached the maximum age, but the neighbor is not in Full state.

Display detailed GR information for all OSPFv3 processes (GR restarter).

```
<Sysname> display ospfv3 graceful-restart verbose

               OSPFv3 Process 1 with Router ID 3.3.3.3

 Graceful-restart capability     : Enable
 Graceful-restart support        : Planned and unplanned, Partial
 Helper capability               : Enable
 Helper support                  : Planned and unplanned
 Current GR state                : Normal
 Graceful-restart period         : 120 seconds

Area: 0.0.0.5
Area flag: NSSANoSummaryNoImportRoute
7/5 translator state: Disabled
7/5 translate stability timer interval: 0
Area up interface count: 0
```

Table 11 Command output

Field	Description
Area	Area ID.
Area flag	Type of the area: • Normal. • Transit. • Stub. • **StubNoSummary**—Totally stub area. • NSSA. • **NSSANoSummary**—Totally NSSA area. • **NSSANoSummaryNoImportRoute**—Totally NSSA area with the **no-import-route** keyword configured.
7/5 translator state	State of the translator that translates Type-7 LSAs to Type-5 LSAs: • **Enabled**—The translator is specified through commands. • **Elected**—The translator is designated through election. • **Disabled**—The device is not a translator.
7/5 translate stability timer interval	Stability interval (in seconds) for Type-7 LSA-to-Type-5 LSA translation.
Area up interface count	Number of up interfaces in the area.
Interface	Interface in the area, or the output interface of the virtual link.
Restarter state	Restarter state on the interface.
State	Interface state.
Type	Interface network type.
Neighbor count of this interface	Number of neighbors on the interface.
Neighbor	Neighbor router ID.
GR state	Neighbor GR state: • **Normal**—GR is not in progress or has completed. • **Under GR**—GR is in process. • **Under Helper**—The process is acting as GR helper.
Last helper exit reason	Reason that the helper exited most recently.
Virtual-link Neighbor-ID	Router ID of the virtual link's neighbor.
Neighbor-State	Neighbor or virtual link state: Down, Init, 2-Way, ExStart, Exchange, Loading, and Full.
Local IPv6 address	Local IPv6 address of the neighbor relationship.
Remote IPv6 address	Peer IPv6 address of the neighbor relationship.
Transit area	Transit area ID.

display ospfv3 interface

Use **display ospfv3 interface** to display OSPFv3 interface information.

Syntax

display ospfv3 [*process-id*] **interface** [*interface-type interface-number* | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535.

interface-type interface-number: Specifies an interface by its type and number.

verbose: Displays detailed information about all OSPFv3 interfaces.

Usage guidelines

If you do not specify a process, this command displays brief OSPFv3 interface information for all processes.

If you do not specify the *interface-type interface-number* argument or the **verbose** keyword, this command displays brief information about all OSPFv3 interfaces.

Examples

Display OSPFv3 information about VLAN-interface 1.

```
<Sysname> display ospfv3 interface vlan-interface 1

               OSPFv3 Process 1 with Router ID 1.1.1.1

 Area: 0.0.0.0
----------------------------------------------------------------------------
 Vlan-interface1 is up, line protocol is up
  Interface ID 65697        Instance ID 0
  IPv6 prefixes
    FE80::200:12FF:FE34:1  (Link-Local address)
    2001::1
  Cost: 1       State: BDR       Type: Broadcast    MTU: 1500
  Priority: 1
  Designated router: 2.2.2.2
  Backup designated router: 1.1.1.1
  Timers: Hello 10, Dead 40, Poll 40, Retransmit 5, Transmit delay 1
  FRR backup: Enabled
  Neighbor count is 1, Adjacent neighbor count is 1
  Primary path detection mode: BFD echo
  IPsec profile name: profile001
  Keychain authentication: Enabled (test), inherited
  Exchanging/Loading neighbors: 0
```

```
Wait timer: Off,  LsAck timer: Off
Prefix-suppression is enabled
```

Table 12 Command output

Field	Description
Area	Area ID that the interface belongs to.
Interface ID	Interface ID.
Instance ID	Instance ID.
IPv6 prefixes	IPv6 prefix.
Cost	Cost value of the interface.
State	Interface state: • **DOWN**—No protocol traffic can be sent or received on the interface. • **Waiting**—The interface starts sending and receiving Hello packets. The router is trying to determine the identity of the (Backup) designated router for the network. • **P-2-P**—The interface will send Hello packets at the hello interval, and try to establish an adjacency with the neighbor. • **DR**—The router is the designated router on the network. • **BDR**—The router is the backup designated router on the network. • **DROther**—The router is a DR Other router on the attached network.
Type	Network type of the interface: PTP (P2P), PTMP (P2MP), Broadcast, or NBMA.
MTU	MTU value of the interface.
Priority	DR priority of the interface.
Designated router	DR on this link.
Backup designated router	BDR on this link.
Timers	Time intervals in seconds configured on the interface: • **Hello**—Hello interval. • **Dead**—Dead interval. • **Poll**—Polling interval on an NBMA network. • **Retransmit**—LSA retransmission interval.
Transmit Delay	LSA transmission delay on the interface, in seconds.
FRR backup	Whether LFA calculation is enabled on an interface: • **Enabled**. • **Disabled**.
Neighbor count	Number of neighbors on the interface.
Primary path detection mode	Primary link detection mode: • **BFD ctrl**—BFD control packet mode. • **BFD echo**—BFD echo packet mode.
Adjacent neighbor count	Number of adjacencies on the interface.
IPsec profile name	IPsec profile applied to the interface.

Field	Description
Keychain authentication: Enabled (test), inherited	Keychain authentication is enabled for the interface, and the keychain **test** is used. The **inherited** attribute indicates that the interface is using the authentication mode specified for the area to which the interface belongs.

display ospfv3 lsdb

Use **display ospfv3 lsdb** to display OSPFv3 LSDB information.

Syntax

display ospfv3 [*process-id*] **lsdb** [{ **external** | **grace** | **inter-prefix** | **inter-router** | **intra-prefix** | **link** | **network** | **nssa** | **router** | **unknown** [*type*] } [*link-state-id*] [**originate-router** *router-id* | **self-originate**] | **statistics** | **total** | **verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays LSDB information for all processes.

external: Displays AS external LSAs (Type-5 LSAs).

grace: Displays Grace-LSAs (Type-11 LSAs).

inter-prefix: Displays Inter-area-prefix LSAs (Type-3 LSAs).

inter-router: Displays Inter-area-router LSAs (Type-4 LSAs).

intra-prefix: Displays Intra-area-prefix LSAs (Type-9 LSAs).

link: Displays Link-LSAs (Type-8 LSAs).

network: Displays Network-LSAs (Type-2 LSAs).

nssa: Displays NSSA LSAs (Type-7 LSAs).

router: Displays Router-LSAs (Type-1 LSAs).

unknown: Displays unknown LSAs.

type: Specifies an LSA type, a hexadecimal string of 0 to ffff. If you do not specify this argument, the command displays all unknown LSAs.

link-state-id: Specifies a link state ID in IPv4 address format.

originate-router *router-id*: Specifies an advertising router by its ID.

self-originate: Displays locally originated LSAs.

statistics: Displays LSA statistics.

total: Displays the total number of LSAs in the LSDB.

verbose: Displays detailed information. If you do not specify this keyword, the command displays brief information.

Examples

Display OSPFv3 LSDB information.

```
<Sysname> display ospfv3 lsdb

               OSPFv3 Process 1 with Router ID 1.1.1.1

                SendCnt: 0       RxmtCnt: 0       Status: Stale
```

Table 16 Command output

Field	Description
SendCnt	Number of interfaces to send the LSA.
RxmtCnt	Number of LSAs in the link state retransmission list.
Status	LSA status: • Normal. • Delayed. • **Maxage routed**—The LSA has reached its maximum age. • Self originated. • **Stale**—A self-originated LSA is received during the GR process.

display ospfv3 nexthop

Use **`display ospfv3 nexthop`** to display OSPFv3 next hop information.

Syntax

`display ospfv3` [*`process-id`*] **`nexthop`**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`process-id`: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays next hop information for all OSPFv3 processes.

Examples

Display next hop information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 nexthop

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Nexthop : FE80::20C:29FF:FED7:F308              Interface: Vlan102
 RefCount: 4                                     Status   : Valid
 NbrID   : 1.1.1.1                               NbrIntID : 21

 Nexthop : FE80::20C:29FF:FED7:F312              Interface: Vlan103
 RefCount: 3                                     Status   : Valid
 NbrID   : 1.1.1.1                               NbrIntID : 38
```

Table 17 Command output

Field	Description
Nexthop	Next hop address.
Interface	Output interface.
RefCount	Reference count (routes that use the next hop).
Status	Next hop status: valid or invalid.
NbrId	Neighbor router ID.
NbrIntID	Neighbor interface ID.

display ospfv3 non-stop-routing

Use **display ospfv3 non-stop-routing** to display OSPFv3 NSR information.

Syntax

display ospfv3 [*process-id*] **non-stop-routing**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPFv3 NSR information for all OSPFv3 processes.

Examples

Display OSPFv3 NSR information.

```
<Sysname> display ospfv3 non-stop-routing

              OSPFv3 Process 1 with Router ID 3.3.3.3

 Nonstop Routing capability: Enabled
 Upgrade phase             : Normal
```

Table 18 Command output

Field	Description
Nonstop Routing capability	NSR status: enabled or disabled.
Upgrade phase	NSR phase: • **Normal**—Normal status. • **Preparation**—Upgrade preparation phase. • **Smooth**—Upgrade phase. • **Precalculation**—Route pre-calculation phase. • **Calculation**—Route calculation phase. • **Redistribution**—Route redistribution phase.

display ospfv3 peer

Use **display ospfv3 peer** to display information about OSPFv3 neighbors.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **peer** [[*interface-type interface-number*] [**verbose**] | *peer-router-id* | **statistics**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify a process, this command displays neighbor information for all processes.

area *area-id*: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format. If you do not specify an area, this command displays neighbor information for all areas.

interface-type interface-number: Specifies an interface by its type and number.

verbose: Displays detailed neighbor information.

peer-router-id: Specifies a neighbor.

statistics: Displays OSPFv3 neighbor statistics.

Usage guidelines

If you do not specify an interface and a neighbor, this command displays neighbor information for all interfaces.

Examples

Display neighbor information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 peer vlan-interface 1

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Area: 0.0.0.1
----------------------------------------------------------------------------
 Router ID       Pri State            Dead-Time InstID Interface
 2.2.2.2         1   Init/ -          00:00:36  0      Vlan1
```

Table 19 Command output

Field	Description
Router ID	Neighbor router ID.
Pri	Neighboring router priority.
State	Neighbor state.
Dead-Time	Dead time remained.
InstID	Instance ID.

Field	Description
Interface	Interface connected to the neighbor.

Display detailed neighbor information for OSPFv3 process 1.

```
<Sysname> display ospfv3 1 peer vlan-interface 1 verbose

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Area 0.0.0.1 interface Vlan1's neighbors
 Router ID: 2.2.2.2          Address: FE80::200:5EFF:FE00:100
   State: ExStart  Mode: None  Priority: 1
   DR: 2.2.2.2  BDR: None   MTU: 1500
   Options is 0x000413 (AT|-|-|-|-|-|R|-|x|E|V6)
   Dead timer due in 00:00:33
   Neighbor is up for 00:24:19
   Authentication sequence: (high) 0, (low) 59755
   Neighbor state change count: 205
   Database Summary List 0
   Link State Request List 0
   Link State Retransmission List 0
   Neighbor interface ID: 8037
   GR state: Normal
   Grace period: 0           Grace period timer: Off
   DD Rxmt Timer: Off        LS Rxmt Timer: On
```

Table 20 Command output

Field	Description
Router ID	Neighbor router ID.
Address	Link-local address of the interface.
State	Neighbor state.
Mode	Neighbor mode for LSDB synchronization.
Priority	Neighboring router priority.
DR	DR on the interface's network segment.
BDR	BDR on the interface's network segment.
MTU	Interface MTU.

Field	Description
Options	LSA options: • **AT**—Whether the Authentication Trailer option is carried in packets. • **DC**—The originating router supports OSPFv3 over on-demand circuits. • **R**—Whether the originating router is an active router. • **N**—Whether the originating router supports NSSA LSAs. • **x**—Reserved. • **E**—Whether the originating router can receive AS External LSAs. • **V6**—Whether the originating router takes part in IPv6 route calculation.
Dead timer due in hh:mm:ss	Remaining time for the dead timer, in hh:mm:ss format. hh represents the hours, mm represents the minutes, and ss represents the seconds.
Neighbor is up for hh:mm:ss	Uptime for the neighbor, in hh:mm:ss format. hh represents the hours, mm represents the minutes, and ss represents the seconds.
Authentication sequence: (high) 0, (low) 59755	Authentication sequence number carried in the received packets. The high 32-bit value is 0, and the low 32-bit value is 59755.
Neighbor state change count	Count of neighbor state changes.
Database Summary List	Number of LSAs sent in DD packet.
Link State Request List	Number of LSAs in the link state request list.
Link State Retransmission List	Number of LSAs in the link state retransmission list.
Neighbor interface ID	Interface ID of the neighbor.
GR state	GR state: • **Normal**—GR is not in progress. • **Doing GR**—Acting as the GR restarter. • Complete GR. • **Helper**—Acting as the GR helper.
Grace period	Grace-LSA sending interval.
Grace period timer	Grace-LSA sending interval timer.
DD Rxmt Timer	DD packet retransmission timer.
LS Rxmt Timer	LSU retransmission timer.

Display OSPFv3 neighbor statistics.

```
<Sysname> display ospfv3 peer statistics

              OSPFv3 Process 1 with Router ID 1.1.1.1
----------------------------------------------------------------------------
 Area ID         Down Attempt Init 2-Way ExStart Exchange Loading Full Total
 0.0.0.0         0    0       0    0     0       0        0       1    1
 Total           0    0       0    0     0       0        0       1    1
```

Table 21 Command output

Field	Description
Area ID	Area ID.
Down	In this state, neighbor initial state, the router has not received any information from a neighboring router for a period of time.
Attempt	This state is available only in an NBMA network. In this state, the OSPFv3 router has not received any information from a neighbor for a period. The router can send Hello packets at a longer interval to keep the neighbor relationship.
Init	In this state, the device received a Hello packet from the neighbor but the packet contains no router ID of the neighbor. Mutual communication is not setup.
2-Way	Mutual communication between the router and its neighbor is available. DR/BDR election is finished under this state (or higher).
ExStart	In this state, the router decides on the initial DD sequence number and active/standby relationship of the two parties.
Exchange	In this state, the router exchanges DD packets with the neighbor.
Loading	In this state, the router sends LSRs to request the neighbor for needed LSAs.
Full	LSDB synchronization has been accomplished between neighbors.
Total	Total number of neighbors under the same state.

display ospfv3 request-queue

Use **display ospfv3 request-queue** to display OSPFv3 request list information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **request-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify an OSPFv3 process, this command displays OSPFv3 request list information for all OSPFv3 processes.

area *area-id*: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format. If you do not specify an OSPFv3 area, this command displays OSPFv3 request list information for all areas.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays OSPFv3 request list information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify a neighbor, this command displays OSPFv3 request list information for all OSPFv3 neighbors.

Examples

Display OSPFv3 request list information.

```
<Sysname> display ospfv3 request-queue

               OSPFv3 Process 1 with Router ID 1.1.1.1

                   Area: 0.0.0.0
                   Interface Vlan-interface100
----------------------------------------------------------------------------
                   Nbr-ID 1.3.3.3 Request List
 Type    LinkState ID    AdvRouter       SeqNum       Age   CkSum
 0x4005  0.0.34.127      1.3.3.3         0x80000001   0027  0x274d
 0x4005  0.0.34.128      1.3.3.3         0x80000001   0027  0x2d45
 0x4005  0.0.34.129      1.3.3.3         0x80000001   0027  0x333d
 0x4005  0.0.34.130      1.3.3.3         0x80000001   0027  0x3935
```

Table 22 Command output

Field	Description
Area	Area ID.
Interface	Interface type and sequence number.
Nbr-ID	Neighbor ID.
Request list	Request list information.
Type	LSA type.
LinkState ID	Link state ID.
AdvRouter	Advertising router.
SeqNum	LSA sequence number.
Age	LSA age.
CkSum	Checksum.

display ospfv3 retrans-queue

Use **display ospfv3 retrans-queue** to display retransmission list information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **retrans-queue** [*interface-type interface-number*] [*neighbor-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify an OSPFv3 process, this command displays retransmission list information for all OSPFv3 processes.

area *area-id*: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format. If you do not specify an OSPFv3 area, this command displays retransmission list information for all OSPFv3 areas.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays retransmission list information for all interfaces.

neighbor-id: Specifies a neighbor's router ID. If you do not specify a neighbor, this command displays retransmission list information for all neighbors.

Examples

Display OSPFv3 retransmission list information.

```
<Sysname> display ospfv3 retrans-queue

```

Table 23 Command output

Field	Description
Area	Area ID.
Interface	Interface type and sequence number.
Nbr-ID	Neighbor ID.
Retransmit List	Retransmission list information.
Type	LSA type.
LinkState ID	Link state ID.
AdvRouter	Advertising router.
SeqNum	LSA sequence number.
Age	LSA age.
CkSum	Checksum.

display ospfv3 routing

Use **display ospfv3 routing** to display OSPFv3 route information.

Syntax

display ospfv3 [*process-id*] **routing** [*ipv6-address prefix-length*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPFv3 route information for all processes.

ipv6-address prefix-length: Specifies an IPv6 address. The *ipv6-address* argument specifies an IPv6 prefix. The *prefix-length* argument specifies a prefix length in the range of 0 to 128.

Examples

Display OSPFv3 routing information.

```
<Sysname> display ospfv3 routing

              OSPFv3 Process 1 with Router ID 9.9.9.9
------------------------------------------------------------------------
 I  - Intra area route,  E1 - Type 1 external route,  N1 - Type 1 NSSA route
 IA - Inter area route,  E2 - Type 2 external route,  N2 - Type 2 NSSA route
 *  - Selected route

*Destination: 1::/64
  Type       : IA                        Area       : 0.0.0.1

```

Table 24 Command output

Field	Description
Destination	Destination network segment.

Type	Route type.
Area	Area ID.
AdvRouter	Advertising router.
Preference	OSPFv3 route preference.
NibID	Next hop ID.
Cost	Route cost value.
Interface	Output interface.
BkInterface	Backup output interface.
Nexthop	Primary next hop IP address.
BkNexthop	Backup next hop IP address.
Interface	Output interface.
AdvRouter	Advertising router.
Area	Area ID.
Tag	Tag of external routes.
Preference	Route preference.
Total	Total number of routes.
Intra area	Number of intra-area routes.
Inter area	Number of inter-area routes.
ASE	Number of Type-5 external routes.
NSSA	Number of Type-7 external routes.

display ospfv3 spf-tree

Use **display ospfv3 spf-tree** to display OSPFv3 SPF tree information.

Syntax

display ospfv3 [*process-id*] [**area** *area-id*] **spf-tree** [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify a process, this command displays SPF tree information for all OSPFv3 processes.

area *area-id*: Specifies an OSPFv3 area by its ID. The area ID is an IP address or a decimal integer in the range of 0 to 4294967295 that is translated into the IP address format. If you do not specify an area, this command displays SPF tree information for all OSPFv3 areas.

verbose: Displays detailed OSPFv3 SPF tree information. If you do not specify this keyword, the command displays brief OSPFv3 SPF tree information.

Examples

Display brief SPF tree information for Area 0 in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 area 0 spf-tree

               OSPFv3 Process 1 with Router ID 1.1.1.1

 Flags: S-Node is on SPF tree       R-Node is directly reachable
        I-Node or Link is init      D-Node or Link is to be deleted
        P-Neighbor is parent        A-Node is in candidate list
        C-Neighbor is child         H-Nexthop changed
        N-Link is a new path        V-Link is involved

                 Area: 0.0.0.0  Shortest Path Tree

 SPFNode         Type   Flag         SPFLink         Type   Cost  Flag
>1.1.1.1         Router S R
                                 -->2.2.2.2         RT2RT  1     C
                                 -->2.2.2.2         RT2RT  1     P
```

Table 25 Command output

Field	Description
SPFNode	SPF node, represented by the advertising router ID. Node type: • **Network**—Network node. • **Router**—Router node. Node flag: • **I**—The node is in initialization state. • **A**—The node is on the candidate list. • **S**—The node is on the SPF tree. • **R**—The node is directly connected to the root node. • **D**—The node is to be deleted.
SPFLink	SPF link, representing the advertising router ID. Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network. Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **L**—The link is on the area change list.

Display detailed topology information for Area 0 in OSPFv3 process 1.

```
<Sysname> display ospfv3 1 area 0 spf-tree verbose

               OSPFv3 Process 1 with Router ID 1.1.1.1

Table 26 Command output

Field	Description
SPFNode	SPF node.
AdvID	ID of the advertising router.
LsID	Link state ID.
NodeType	Node type.
Distance	Cost to the root node.
NodeFlag	Node flag.
Nexthop count	Number of next hops.
NbrID	Neighbor router ID.
NbrIntID	Neighbor interface ID.

Field	Description
Interface	Output interface.
NhFlag	Next hop flag: valid or invalid.
BkInterface	Backup output interface.
RefCount	Reference count (routes that use the backup next hop).
Nexthop	Next hop.
BkNexthop	Backup next hop.
SPFLink count	Number of SPF links.
IntID	Interface ID.
LinkType	Link type: • **RT2RT**—Router to router. • **NET2RT**—Network to router. • **RT2NET**—Router to network.
LinkCost	Link cost.
LinkNewCost	New link cost.
LinkFlag	Link flag: • **I**—The link is in initialization state. • **P**—The peer is the parent node. • **C**—The peer is the child node. • **D**—The link is to be deleted. • **H**—The next hop is changed. • **V**—When the peer node is deleted or added, the peer node is not on the SPF tree or is deleted. • **N**—The link is newly added, and both end nodes are on the SPF tree. • **L**—The link is on the area change list.
NexthopCnt	Number of next hops.
ParentLinkCnt	Number of parent links.

display ospfv3 statistics

Use **display ospfv3 statistics** to display OSPFv3 statistics.

Syntax

display ospfv3 [*process-id*] **statistics** [**error** | **packet** [*interface-type interface-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays OSPFv3 statistics for all processes.

error: Displays error statistics. If you do not specify this keyword, the command displays OSPFv3 packet, LSA, and route statistics.

packet: Displays packet statistics.

interface-type interface-number: Specifies an interface by its type and number. If you do not specify this argument, the command displays statistics for all interfaces.

Examples

Display OSPFv3 statistics.

```
<Sysname> display ospfv3 statistics

              OSPFv3 Process 1 with Router ID 1.1.1.1
                  Packet Statistics
------------------------------------------------------------
 Type                         Recv               Send
 Hello                        1746               1284

Table 28 Command output

Field	Description
Transmit error	Packets with error when being transmitted.
Neighbor state low	Packets received in low neighbor state.
Packet too small	Packets too small in length.
Bad version	Packets with wrong version.
Bad checksum	Packets with wrong checksum.
Unknown neighbor	Packets received from unknown neighbors.
Bad area ID	Packets with invalid area ID.
Bad packet	Packets illegal.
Packet dest error	Packets with wrong destination addresses.
Inactive area packet	Packets received in inactive areas.
Router ID confusion	Packets with duplicate router ID.
Bad virtual link	Packets on wrong virtual links.
HELLO: Hello-time mismatch	Hello packets with mismatched hello timer.
HELLO: Dead-time mismatch	Hello packets with mismatched dead timer.
HELLO: Ebit option mismatch	Hello packets with mismatched E-bit in the option field.
DD: Ebit option mismatch	DD packets with mismatched E-bit in the option field.
DD: Unknown LSA type	DD packets with unknown LSA type.
DD: MTU option mismatch	DD packets with mismatched MTU.
REQ: Empty request	LSR packets with no request information.
REQ: Bad request	Bad LSR packets.
UPD: LSA checksum bad	LSU packets with wrong LSA checksum.
UPD: Unknown LSA type	LSU packets with unknown LSA type.
UPD: Less recent LSA	LSU packets without the most recent LSA.
UPD: LSA length bad	LSU packets with wrong LSA length.
UPD: LSA AdvRtr id bad	LSU packets with wrong LSA advertising router.
ACK: Bad ack packet	Bad LSAck packets for LSU packets.
ACK: Invalid ack	Invalid LSAck packets.
Interface down	Shutdown times of the interface.
Multicast incapable	Failures to join the multicast group.
Authentication failure	Failures to authenticate the received packets.

Field	Description
AuthSeqNumber error	Authentication sequence number errors in the received packets.

Display OSPFv3 packet statistics for all processes and interfaces.

```
<Sysname>display ospfv3 statistics packet

Input	Number of received packets.
Output	Number of sent packets.
Area	Area ID.
Interface	Interface name.

display ospfv3 vlink

Use **display ospfv3 vlink** to display OSPFv3 virtual link information.

Syntax

display ospfv3 [*process-id*] **vlink**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command displays the OSPFv3 virtual link information for all OSPFv3 processes.

Examples

Display OSPFv3 virtual link information.

```
<Sysname> display ospfv3 vlink

              OSPFv3 Process 1 with Router ID 1.1.1.1

 Virtual-link Neighbor-ID: 12.2.2.2, Neighbor-state: Full
 Interface: 2348 (Vlan-interface12), Instance-ID: 0
 Local  IPv6 address: 3:3333::12
 Remote IPv6 address: 2:2222::12
 Cost: 1  State: P-2-P  Type: Virtual
 Transit area: 0.0.0.1
 Timers: Hello 10, Dead 40, Retransmit 5, Transmit delay 1
 IPsec profile name: profile001
 Keychain authentication: Enabled (test), inherited
```

Table 30 Command output

Field	Description
Virtual-link Neighbor-ID	ID of the neighbor on the virtual link.
Neighbor-State	Neighbor state: Down, Init, 2-Way, ExStart, Exchange, Loading, or Full.
Interface	Number and name of the local interface on the virtual link.
Cost	Interface route cost.
State	Interface state.
Type	Virtual link.
Transit Area	Transit area ID. This field is displayed when a virtual link is present on the interface.
Timers	Values of OSPFv3 timers (in seconds): **Hello**, **Dead**, and **Retransmit**.
Transmit delay	LSA transmission delay on the interface, in seconds.
IPsec profile name	IPsec profile applied to the virtual link.
Keychain authentication: Enabled (test), inherited	Keychain authentication is enabled for the virtual link, and the keychain **test** is used. The **inherited** attribute indicates that the virtual link is using the authentication mode specified for the backbone area.

enable ipsec-profile

Use **enable ipsec-profile** to apply an IPsec profile to an OSPFv3 area.

Use **undo enable ipsec-profile** to remove the IPsec profile from the OSPFv3 area.

Syntax

enable ipsec-profile *profile-name*

undo enable ipsec-profile

Default

No IPsec profile is applied to an area.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To protect routing information and prevent attacks, OSPFv3 can authenticate protocol packets by using an IPsec profile. For more information about IPsec profiles, see *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to Area 0 in OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 0
[Sysname-ospfv3-1-area-0.0.0.0] enable ipsec-profile profile001
```

event-log

Use **event-log** to set the maximum number of OSPFv3 logs.

Use **undo event-log** to remove the configuration.

Syntax

event-log { **lsa-flush** | **peer** | **spf** } **size** *count*

undo event-log { **lsa-flush** | **peer** | **spf** } **size**

Default

The maximum number of LSA aging logs, neighbor logs, or route calculation logs is 10.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

lsa-flush: Specifies the maximum number of LSA aging logs.

peer: Specifies the maximum number of neighbor logs.

spf: Specifies the maximum number of route calculation logs.

size *count*: Specifies the maximum number of OSPFv3 logs, in the range of 0 to 65535.

Examples

Set the maximum number of route calculation logs to 50 in OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
```

```
[Sysname-ospfv3-100] event-log spf size 50
```

fast-reroute (OSPFv3 view)

Use **fast-reroute** to configure OSPFv3 FRR.

Use **undo fast-reroute** to restore the default.

Syntax

fast-reroute { **lfa** [**abr-only**] | **route-policy** *route-policy-name* }

undo fast-reroute

Default

OSPFv3 FRR is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

lfa: Uses the LFA algorithm to calculate a backup next hop for all routes.

abr-only: Uses the next hop of the route to the ABR as the backup next hop.

route-policy *route-policy-name*: Uses a routing policy to designate a backup next hop. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

Usage guidelines

Do not use the **fast-reroute lfa** command together with the **vlink-peer** command.

Examples

Enable FRR to calculate a backup next hop for all routes by using LFA algorithm in OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] fast-reroute lfa
```

filter (OSPFv3 area view)

Use **filter** to configure inbound/outbound Inter-Area-Prefix-LSA filtering on an ABR.

Use **undo filter** to remove the configuration.

Syntax

filter { *ipv6-acl-number* | **prefix-list** *prefix-list-name* | **route-policy** *route-policy-name* } { **export** | **import** }

undo filter { **export** | **import** }

Default

Inter-Area-Prefix-LSAs are not filtered.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter inbound/outbound Inter-Area-Prefix-LSAs.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Inter-Area-Prefix-LSAs.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter inbound/outbound Inter-Area-Prefix-LSAs.

export: Filters Inter-Area-Prefix-LSAs advertised to other areas.

import: Filters Inter-Area-Prefix-LSAs advertised into the local area.

Usage guidelines

This command applies only to an ABR.

Examples

Use IPv6 prefix list **my-prefix-list** to filter inbound Inter-Area-Prefix-LSAs. Use IPv6 basic ACL 2000 to filter outbound Inter-Area-Prefix-LSAs in OSPFv3 Area 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] filter prefix-list my-prefix-list import
[Sysname-ospfv3-1-area-0.0.0.1] filter 2000 export
```

filter-policy export (OSPFv3 view)

Use **filter-policy export** to configure OSPFv3 to filter redistributed routes.

Use **undo filter-policy export** to remove the configuration.

Syntax

filter-policy { *ipv6-acl-number* | **prefix-list** *prefix-list-name* } **export** [**direct** | { **ospfv3** | **ripng** } [*process-id*] | **static**]

undo filter-policy export [**direct** | { **ospfv3** | **ripng** } [*process-id*] | **static**]

Default

Redistributed routes are not filtered.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter redistributed routes by destination address.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter redistributed routes by destination address.

direct: Filters redistributed direct routes.

ospfv3: Filters redistributed OSPFv3 routes.

ripng: Filters redistributed RIPng routes.

process-id: Specifies a process by its ID in the range of 1 to 65535. The default value is 1.

static: Filters redistributed static routes.

Usage guidelines

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix*.
- To deny/permit a route with the specified destination and prefix, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix*.

The **source** keyword specifies the destination address of a route, and the **destination** keyword specifies the prefix of the route. For the configuration to take effect, specify a contiguous prefix.

Using the **filter-policy export** command filters only routes redistributed by the **import-route** command. If the **import-route** command is not configured to redistribute routes from other protocols and other OSPFv3 processes, the **filter-policy export** command does not take effect.

If you do not specify a routing protocol, the command filters all redistributed routes.

Examples

Use IPv6 prefix list **abc** to filter redistributed routes.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc permit 2002:1:: 64
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy prefix-list abc export
```

Configure IPv6 advanced ACL 3000 to permit only route 2001::1/128. Use ACL 3000 to filter redistributed routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
[Sysname-acl-ipv6-adv-3000] quit
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy 3000 export
```

filter-policy import (OSPFv3 view)

Use **filter-policy import** to configure OSPFv3 to filter routes calculated using received LSAs.

Use **undo filter-policy import** to remove the configuration.

Syntax

filter-policy { *ipv6-acl-number* [**gateway** *prefix-list-name*] | **prefix-list** *prefix-list-name* [**gateway** *prefix-list-name*] | **gateway** *prefix-list-name* | **route-policy** *route-policy-name* } **import**

undo filter-policy import

Default

Routes calculated using received LSAs are not filtered.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999 to filter routes by destination.

gateway *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes by next hop. If you do not specify this option, the command does not filter routes by next hop.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters, to filter routes by destination.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to filter received routes.

Usage guidelines

To use an advanced ACL (with a number from 3000 to 3999) in the command, configure the ACL in one of the following ways:

- To deny/permit a route with the specified destination, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix*.
- To deny/permit a route with the specified destination and prefix, use **rule** [*rule-id*] { **deny** | **permit** } **ipv6 source** *sour sour-prefix* **destination** *dest dest-prefix*.

The **source** keyword specifies the destination address of a route, and the **destination** keyword specifies the prefix of the route. For the configuration to take effect, specify a contiguous prefix.

Using the **filter-policy import** command filters only routes computed by OSPFv3. Routes that fail to pass the filter are not added to the routing table.

Examples

Use IPv6 prefix list **abc** to filter received routes.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc permit 2002:1:: 64
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy prefix-list abc import
```

Configure IPv6 advanced ACL 3000 to permit only route 2001::1/128 to pass. Use ACL 3000 to filter received routes.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule 10 permit ipv6 source 2001::1 128 destination
ffff:ffff:ffff:ffff:ffff:ffff:ffff:ffff 128
```

```
[Sysname-acl-ipv6-adv-3000] rule 100 deny ipv6
[Sysname-acl-ipv6-adv-3000] quit
[Sysname] ospfv3
[Sysname-ospfv3-1] filter-policy 3000 import
```

graceful-restart enable

Use **graceful-restart enable** to enable the GR capability for OSPFv3.

Use **undo graceful-restart enable** to disable the GR capability for OSPFv3.

Syntax

graceful-restart enable [**global** | **planned-only**] *

undo graceful-restart enable

Default

The GR capability for OSPFv3 is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

global: Enables global GR. In global GR mode, a GR process can be completed only when all GR helpers exist. A GR process fails if a GR helper fails (for example, the interface connected to the GR helper goes down). If you do not specify this keyword, the command enables partial GR. In partial GR mode, a GR process can be completed as long as one GR helper exists.

planned-only: Enables planned GR only. If you do not specify this keyword, the command enables both planned GR and unplanned GR.

Usage guidelines

GR includes planned GR and unplanned GR.

- **Planned GR**—Manually restarts OSPFv3 or performs an active/standby switchover. Before OSPFv3 restart or active/standby switchover, the GR restarter sends Grace-LSAs to GR helpers.
- **Unplanned GR**—OSPFv3 restarts or an active/standby switchover occurs because of device failure. Before OSPFv3 restart or active/standby switchover, the GR restarter does not send Grace-LSAs to GR helpers.

OSPFv3 GR and OSPFv3 NSR are mutually exclusive. Do not configure the **graceful-restart enable** command and the **non-stop-routing** command at the same time.

To prevent service interruption after a master/backup switchover, a GR restarter running OSPFv3 must perform the following tasks:

- Keep the GR restarter forwarding entries stable during reboot.
- Establish all adjacencies and obtain complete topology information after reboot.

Examples

Enable the GR capability for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart enable
```

Related commands

graceful-restart helper enable

graceful-restart helper enable

Use **graceful-restart helper enable** to enable the GR helper capability for OSPFv3.

Use **undo graceful-restart helper enable** to disable the GR helper capability for OSPFv3.

Syntax

graceful-restart helper enable [**planned-only**]

undo graceful-restart helper enable

Default

The GR helper capability for OSPFv3 is enabled.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

planned-only: Enables only planned GR for the GR helper. If you do not specify this keyword, the command enables both planned GR and unplanned GR for the GR helper.

Usage guidelines

Upon receiving the Grace-LSA, the neighbors with the GR helper capability enter the helper mode (and are called GR helpers). Then, the GR restarter retrieves its adjacencies and LSDB with the help of the GR helpers.

Examples

Enable the GR helper capability for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart helper enable
```

Related commands

graceful-restart enable

graceful-restart helper strict-lsa-checking

Use **graceful-restart helper strict-lsa-checking** to enable strict LSA checking for the GR helper.

Use **undo graceful-restart helper strict-lsa-checking** to disable strict LSA checking for the GR helper.

Syntax

graceful-restart helper strict-lsa-checking

undo graceful-restart helper strict-lsa-checking

Default

Strict LSA checking for the GR helper is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

Usage guidelines

With GR helper enabled, when an LSA change on the GR helper is detected, the GR helper device exits the GR helper mode.

Examples

Enable strict LSA checking for the GR helper in OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart helper strict-lsa-checking
```

Related commands

graceful-restart helper enable

graceful-restart interval

Use **graceful-restart interval** to set the GR restart interval.

Use **undo graceful-restart interval** to restore the default.

Syntax

graceful-restart interval *interval*

undo graceful-restart interval

Default

The GR restart interval is 120 seconds.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

interval: Specifies GR restart interval in the range of 40 to 1800 seconds.

Usage guidelines

For GR restart to succeed, the value of the GR restart interval cannot be smaller than the maximum OSPFv3 neighbor dead time of all the OSPFv3 interfaces.

Examples

Set the GR restart interval for OSPFv3 process 1 to 100 seconds.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] graceful-restart interval 100
```

Related commands

ospfv3 timer dead

import-route (OSPFv3 view)

Use **import-route** to redistribute routes.

Use **undo import-route** to disable route redistribution.

Syntax

import-route { **direct** | **static** } [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

import-route { **ospfv3** | **ripng** } [*process-id* | **all-processes**] [**allow-direct** | **cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] *

undo import-route { | **direct** | { **ospfv3** | **ripng** } [*process-id* | **all-processes**] | **static** }

Default

OSPFv3 route redistribution is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

direct: Redistributes direct routes.

static: Redistributes static routes.

ospfv3: Redistributes OSPFv3 routes.

ripng: Redistributes RIPng routes.

process-id: Specifies the process ID of a routing protocol, in the range of 1 to 65536. The default is 1.

all-processes: Redistributes routes from all the processes of the specified routing protocol.

allow-direct: Redistributes the networks of the local interfaces enabled with the specified routing protocol. If you do not specify this keyword, the networks of the local interfaces are not redistributed. If you specify both the **allow-direct** keyword and the **route-policy** *route-policy-name* option, make sure the **if-match** rule defined in the routing policy does not conflict with the **allow-direct** keyword. For example, if you specify the **allow-direct** keyword, do not configure the **if-match route-type** rule for the routing policy. Otherwise, the **allow-direct** keyword does not take effect.

cost *cost-value*: Specifies a cost for redistributed routes, in the range of 1 to 16777214. If you do not specify a cost, the cost for redistributed routes is 1.

nssa-only: Limits the route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. If you do not specify this keyword, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit of Type-7 LSAs originated by the router is set to 0. This keyword applies to NSSA routers.

route-policy *route-policy-name*: Specifies a routing policy to filter redistributed routes. The *route-policy-name* argument is a case-sensitive string of 1 to 63 characters.

tag *tag*: Specifies a tag for external LSAs, in the range of 0 to 4294967295. If you do not specify this option, the tag specified by the **default tag** command applies.

type *type*: Specifies the type for redistributed routes, 1 or 2. The default is 2.

Usage guidelines

An external route is a route to a destination outside the OSPFv3 AS. External routes include the following types:

- **Type-1 external routes**—Have high credibility. The cost of Type-1 external routes is comparable with the cost of OSPFv3 internal routes. The cost of a Type-1 external route equals the cost from the router to the ASBR plus the cost from the ASBR to the external route's destination.
- **Type-2 external routes**—Have low credibility. OSPFv3 considers the cost from the ASBR to a Type-2 external route is much bigger than the cost from the ASBR to an OSPFv3 internal router. The cost of a Type-2 external route equals the cost from the ASBR to the Type-2 external route's destination.

The **import-route** command cannot redistribute default routes.

The **import-route nssa-only** command redistributes AS-external routes in Type-7 LSAs only into the NSSA area.

Examples

Configure OSPFv3 process 1 to redistribute routes from RIPng and specify the type as type 2 and cost as 50.

```
<Sysname> system-view
[Sysname] ospfv3
[Sysname-ospfv3-1] import-route ripng 10 type 2 cost 50
```

Configure OSPFv3 process 100 to redistribute the routes discovered by OSPFv3 process 160.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] import-route ospfv3 160
```

Related commands

default-route-advertise (OSPFv3 view)

log-peer-change

Use **log-peer-change** to enable logging for neighbor state changes.

Use **undo log-peer-change** to disable logging for neighbor state changes.

Syntax

log-peer-change

undo log-peer-change

Default

Logging for neighbor state changes is enabled.

Views

OSPFv3 view

Predefined user roles

network-admin

Usage guidelines

This feature enables the device to deliver logs about neighbor state changes to its information center. The information center processes logs according to user-defined output rules (whether and where to output logs). For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Disable logging for neighbor state changes for OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] undo log-peer-change
```

lsa-generation-interval

Use **lsa-generation-interval** to set the OSPFv3 LSA generation interval.

Use **undo lsa-generation-interval** to restore the default.

Syntax

lsa-generation-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo lsa-generation-interval

Default

The maximum interval is 5 seconds, the minimum interval is 0 milliseconds, and the incremental interval is 0 milliseconds.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

maximum-interval: Specifies the maximum OSPFv3 LSA generation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum OSPFv3 LSA generation interval in the range of 10 to 60000 milliseconds. The default is 0, which indicates that the minimum interval can be any value.

incremental-interval: Specifies the OSPFv3 LSA generation incremental interval in the range of 10 to 60000 milliseconds.

Usage guidelines

When network changes are infrequent, LSAs are generated at the minimum interval. If network changes become frequent, the LSA generation interval is incremented by the incremental interval × 2^{n-2} for each generation until the maximum interval is reached. The value *n* is the number of generation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum LSA generation interval to 2 seconds, minimum interval to 100 milliseconds, and incremental interval to 100 milliseconds.

```
<Sysname> system-view
[Sysname] ospfv3 100
```

```
[Sysname-ospfv3-100] lsa-generation-interval 2 100 100
```

Related commands

lsa-arrival-interval

non-stop-routing

Use **non-stop-routing** to enable OSPFv3 NSR.

Use **undo non-stop-routing** to disable OSPFv3 NSR.

Syntax

non-stop-routing

undo non-stop-routing

Default

OSPFv3 NSR is disabled.

Views

OSPFv3 view

Predefined user roles

network-admin

Usage guidelines

This command takes effect only for the current process. As a best practice, enable OSPFv3 NSR for each process if multiple OSPFv3 processes exist.

OSPFv3 NSR and OSPFv3 GR are mutually exclusive. Do not configure the **non-stop-routing** command and the **graceful-restart enable** command at the same time.

Examples

Enable NSR for OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] non-stop-routing
```

nssa (OSPFv3 area view)

Use **nssa** to configure an area as an NSSA area.

Use **undo nssa** to restore the default.

Syntax

nssa [**default-route-advertise** [**cost** *cost-value* | **nssa-only** | **route-policy** *route-policy-name* | **tag** *tag* | **type** *type*] * | **no-import-route** | **no-summary** | [**translate-always** | **translate-never**] | **suppress-fa** | **translator-stability-interval** *value*] *

undo nssa

Default

No area is configured as an NSSA area.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

default-route-advertise: Used on an NSSA ABR or an ASBR only. If it is configured on an NSSA ABR, the ABR redistributes a default route in a Type-7 LSA into the NSSA area. It redistributes a default route regardless of whether a default route exists in the routing table. If it is configured on an ASBR, the ASBR redistributes a default route in a Type-7 LSA only when the default route exists in the routing table.

cost *cost-value*: Specifies a cost for the default route, in the range of 0 to 16777214. If you do not specify this option, the default cost specified by the **default-cost** command applies.

nssa-only: Limits the default route advertisement to the NSSA area by setting the P-bit of Type-7 LSAs to 0. If you do not specify this keyword, the P-bit of Type-7 LSAs is set to 1. If the router acts as both an ASBR and an ABR and **FULL** state neighbors exist in the backbone area, the P-bit is set to 0.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. When the specified routing policy is matched, the command redistributes a default route in a Type-7 LSA into the OSPFv3 routing domain. The routing policy modifies values in the Type-7 LSA.

tag *tag*: Specifies a tag for the default route, in the range of 0 to 4294967295.

type *type*: Specifies a type for the Type-7 LSA, 1 or 2. The default is 2.

no-import-route: Used on an NSSA ABR to control the **import-route** command to not redistribute routes into the NSSA area.

no-summary: Used only on an ABR to advertise a default route in a Type-3 summary LSA into the NSSA area and to not advertise other summary LSAs into the area. The area is a totally NSSA area.

translate-always: Always translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

translate-never: Never translates Type-7 LSAs to Type-5 LSAs. This keyword takes effect only on an NSSA ABR.

suppress-fa: Suppresses the forwarding address in the Type-7 LSAs from being placed in the Type-5 LSAs.

translator-stability-interval *value*: Specifies the stability interval of the translator. During the interval, the translator can maintain its translating capability after another device becomes the new translator. The *value* argument is the stability interval in the range of 0 to 900 seconds. The default interval is 0. A value of 0 means the translator does not maintain its translating capability when a new translator arises.

Usage guidelines

All routers attached to an NSSA area must be configured with the **nssa** command in area view.

Examples

Configure Area 1 as an NSSA area.

```
<Sysname> system-view
[Sysname] ospfv3 120
[Sysname-ospfv3-120] area 1
[Sysname-ospfv3-120-area-0.0.0.1] nssa
```

Related commands

default-cost (OSPFv3 area view)

ospfv3

Use **ospfv3** to enable an OSPFv3 process and enter OSPFv3 view.

Use **undo ospfv3** to disable an OSPFv3 process.

Syntax

ospfv3 [*process-id*]

undo ospfv3 [*process-id*]

Default

No OSPFv3 process is enabled.

Views

System view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. The default process ID is 1.

Usage guidelines

Specify a router ID for the OSPFv3 process. Otherwise, the OSPFv3 process cannot generate LSAs.

Examples

Enable OSPFv3 process 120 and set the router ID to 1.1.1.1.

```
<Sysname> system-view
[Sysname] ospfv3 120
[Sysname-ospfv3-120] router-id 1.1.1.1
```

ospfv3 area

Use **ospfv3 area** to enable an OSPFv3 process on an interface and specify an area for the interface.

Use **undo ospfv3 area** to disable an OSPFv3 process on an interface.

Syntax

ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]

undo ospfv3 *process-id* **area** *area-id* [**instance** *instance-id*]

Default

No OSPFv3 processes are enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535.

area-id: Specifies an area by its ID, an IPv4 address or a decimal integer in the range of 0 to 4294967295 that is translated into the IPv4 address format.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Examples

Configure VLAN-interface 10 to run instance 1 of OSPFv3 process 1 in Area 1.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 1 area 1 instance 1
```

ospfv3 authentication-mode

Use **ospfv3 authentication-mode** to specify an authentication mode for an OSPFv3 interface.

Use **undo ospfv3 authentication-mode** to remove the configuration.

Syntax

ospfv3 authentication-mode keychain *keychain-name* [**instance** *instance-id*]

undo ospfv3 authentication-mode [**instance** *instance-id*]

Default

No authentication is performed for an OSPFv3 interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

keychain: Specifies keychain authentication.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

When keychain authentication is configured for an OSPFv3 interface, OSPFv3 performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPFv3 does not send the packet if it fails to obtain a valid send key.
2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 65535, OSPFv3 does not send the packet.

When keychain authentication is configured for an OSPFv3 interface, OSPFv3 performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPFv3 discards the packet if it fails to obtain a valid accept key.
2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPFv3 discards the packet.

OSPFv3 supports only the HMAC-SHA-256 authentication algorithm.

The ID of keys used for authentication can only be in the range of 0 to 65535.

Examples

Configure GigabitEthernet 1/0/1 to use the keychain **test** for OSPFv3 packet authentication.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ospfv3 authentication-mode keychain test
```

ospfv3 bfd enable

Use **ospfv3 bfd enable** to enable BFD on an OSPFv3 interface.

Use **undo ospfv3 bfd enable** to disable BFD on an OSPFv3 interface.

Syntax

ospfv3 bfd enable [**instance** *instance-id*]

undo ospfv3 bfd enable [**instance** *instance-id*]

Default

BFD is disabled on an OSPFv3 interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

BFD provides a mechanism to quickly detect the connectivity of links between OSPFv3 neighbors, improving the convergence speed of OSPFv3.

OSPFv3 uses BFD to implement bidirectional control detection.

Examples

Enable BFD on VLAN-interface 11 in instance 1.

```
<Sysname> system-view
[Sysname] interface vlan-interface 11
[Sysname-Vlan-interface11] ospfv3 bfd enable instance 1
```

ospfv3 cost

Use **ospfv3 cost** to set an OSPFv3 cost for an interface in an instance.

Use **undo ospfv3 cost** to remove the configuration.

Syntax

ospfv3 cost *cost-value* [**instance** *instance-id*]

undo ospfv3 cost [**instance** *instance-id*]

Default

The cost is 1 for a VLAN interface, is 0 for a loopback interface, and is computed according to the interface bandwidth for other interfaces.

Views

Interface view

Predefined user roles

network-admin

Parameters

cost-value: Specifies an OSPFv3 cost in the range of 0 to 65535 for a loopback interface, and in the range of 1 to 65535 for other interfaces.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Examples

Set the OSPFv3 cost to 33 for VLAN-interface 10 in instance 1.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 cost 33 instance 1
```

ospfv3 dr-priority

Use **ospfv3 dr-priority** to set the router priority for an interface in an instance.

Use **undo ospfv3 dr-priority** to remove the configuration.

Syntax

ospfv3 dr-priority *priority* [**instance** *instance-id*]

undo ospfv3 dr-priority [**instance** *instance-id*]

Default

An interface has a router ID of 1.

Views

Interface view

Predefined user roles

network-admin

Parameters

priority: Specifies a router priority in the range of 0 to 255.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

An interface's router priority determines its privilege in DR/BDR selection.

Examples

Set the router priority for VLAN-interface 10 in instance 1 to 8.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 dr-priority 8 instance 1
```

ospfv3 fast-reroute lfa-backup exclude

Use **ospfv3 fast-reroute lfa-backup exclude** to disable LFA on an interface.

Use **undo ospfv3 fast-reroute lfa-backup exclude** to remove the configuration.

Syntax

ospfv3 fast-reroute lfa-backup exclude [**instance** *instance-id*]

undo ospfv3 fast-reroute lfa-backup exclude [**instance** *instance-id*]

Default

LFA is enabled on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

An interface enabled with LFA can be selected as a backup interface. After you disable LFA on the interface, it cannot be selected as a backup interface.

Examples

Disable VLAN-interface 11 from calculating a backup next hop by using the LFA algorithm.

```
<Sysname> system-view
[Sysname] interface vlan-interface 11
[Sysname-Vlan-interface11] ospfv3 fast-reroute lfa-backup exclude
```

ospfv3 ipsec-profile

Use **ospfv3 ipsec-profile** to apply an IPsec profile to an OSPFv3 interface.

Use **undo ospfv3 ipsec-profile** to remove the IPsec profile from the OSPFv3 interface.

Syntax

ospfv3 ipsec-profile *profile-name* [**instance** *instance-id*]

undo ospfv3 ipsec-profile [**instance** *instance-id*]

Default

No IPsec profile is applied to an OSPFv3 interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

An IPsec profile must be specified in this command. For more information about IPsec profiles, see *Security Configuration Guide*.

Examples

Apply IPsec profile **profile001** to VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 ipsec-profile profile001
```

ospfv3 mib-binding

Use **ospfv3 mib-binding** to bind an OSPFv3 process to MIB.

Use **undo ospfv3 mib-binding** to restore the default.

Syntax

ospfv3 mib-binding *process-id*

undo ospfv3 mib-binding

Default

MIB is bound to the OSPFv3 process with the smallest process ID.

Views

System view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535.

Usage guidelines

If the specified process ID does not exist, the MIB binding configuration fails.

Deleting an OSPFv3 process that has been bound to MIB unbinds the OSPFv3 process from MIB, and re-binds MIB to the OSPFv3 process with the smallest process ID.

Examples

Bind OSPFv3 process 100 to MIB.

```
<Sysname> system-view
[Sysname] ospfv3 mib-binding 100
```

ospfv3 mtu-ignore

Use **ospfv3 mtu-ignore** to configure an interface to ignore MTU check during DD packet exchange.

Use **undo ospfv3 mtu-ignore** to remove the configuration.

Syntax

ospfv3 mtu-ignore [**instance** *instance-id*]

undo ospfv3 mtu-ignore [**instance** *instance-id*]

Default

An interface performs MTU check during DD packet exchange.

Views

Interface view

Predefined user roles

network-admin

Parameters

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

A neighbor relationship can be established only if the interface's MTU is the same as that of the peer.

Examples

Configure VLAN-interface 10 that belongs to instance 1 to ignore MTU check during DD packet exchange.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 mtu-ignore instance 1
```

ospfv3 network-type

Use **ospfv3 network-type** to specify the network type for an OSPFv3 interface.

Use **undo ospfv3 network-type** to remove the configuration.

Syntax

ospfv3 network-type { **broadcast** | **nbma** | **p2mp** [**unicast**] | **p2p** } [**instance** *instance-id*]

undo ospfv3 network-type [**instance** *instance-id*]

Default

The network type of an OSPFv3 interface is broadcast.

Views

Interface view

Predefined user roles

network-admin

Parameters

broadcast: Specifies the network type as broadcast.

nbma: Specifies the network type as NBMA.

p2mp: Specifies the network type as P2MP.

unicast: Specifies the P2MP interface to unicast OSPFv3 packets. By default, a P2MP interface multicasts OSPFv3 packets.

p2p: Specifies the network type as P2P.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

If a router on a broadcast network does not support multicast, configure the network type for the connected interfaces as NBMA.

When the network type of an interface is NBMA or P2MP unicast, you must use the **peer** command to specify the neighbor.

When the network type of an interface is P2MP unicast, all OSPFv3 packets are unicast by the interface.

Examples

Specify the OSPFv3 network type for VLAN-interface 20 as NBMA.

```
<Sysname> system-view
[Sysname] interface vlan-interface 20
[Sysname-Vlan-interface20] ospfv3 network-type nbma
```

Related commands

ospfv3 dr-priority

ospfv3 peer

Use **ospfv3 peer** to specify a neighbor and the DR priority of the neighbor.

Use **undo ospfv3 peer** to remove the configuration.

Syntax

ospfv3 peer *ipv6-address* [**cost** *cost-value* | **dr-priority** *priority*] [**instance** *instance-id*]

undo ospfv3 peer *ipv6-address* [**instance** *instance-id*]

Default

No link-local address is specified for the neighbor interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the link-local IPv6 address of the neighbor.

cost *cost-value*: Specifies the cost of the neighbor, in the range of 1 to 65535.

dr-priority *priority*: Specifies the DR priority of the neighbor, in the range of 0 to 255. The default is 1.

instance *instance-id:* Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

For NBMA and P2MP interfaces (only when in unicast mode), you must specify the link-local IPv6 addresses of their neighbors because these interfaces cannot find neighbors through broadcasting hello packets. For NBMA interfaces, you can also specify DR priorities for their neighbors.

Examples

On VLAN-interface 10, specify the link-local address of its neighbor as FE80::1111.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 peer fe80::1111
```

ospfv3 prefix-suppression

Use **ospfv3 prefix-suppression** to disable an OSPFv3 interface from advertising all its prefixes.

Use **undo ospfv3 prefix-suppression** to remove the configuration.

Syntax

ospfv3 prefix-suppression [**disable**] [**instance** *instance-id*]

undo ospfv3 prefix-suppression [**instance** *instance-id*]

Default

Prefix suppression is disabled on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

disable: Disables prefix suppression for an interface.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

To disable prefix suppression for an interface associated with an OSPFv3 process that has been enabled with prefix suppression, use the **ospfv3 prefix-suppression disable** command on that interface.

Examples

Enable prefix suppression for VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 prefix-suppression
```

Related commands

prefix-suppression

ospfv3 primary-path-detect bfd

Use **ospfv3 primary-path-detect bfd** to enable BFD for OSPFv3 FRR.

Use **undo ospfv3 primary-path-detect bfd** to disable BFD for OSPFv3 FRR.

Syntax

ospfv3 primary-path-detect bfd { **ctrl** | **echo** } [**instance** *instance-id*]

undo ospfv3 primary-path-detect bfd [**instance** *instance-id*]

Default

BFD is disabled for OSPFv3 FRR.

Views

Interface view

Predefined user roles

network-admin

Parameters

ctrl: Enables BFD control packet mode.

echo: Enables BFD echo packet mode.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

This command enables OSPFv3 FRR to use BFD to detect primary link failures.

Examples

On VLAN-interface 10, enable BFD echo packet mode for OSPFv3 FRR.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] fast-reroute lfa
[Sysname-ospfv3-1] quit
[Sysname] bfd echo-source-ipv6 1::1
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 primary-path-detect bfd echo
```

ospfv3 timer dead

Use **ospfv3 timer dead** to set the OSPFv3 neighbor dead time.

Use **undo ospfv3 timer dead** to remove the configuration.

Syntax

ospfv3 timer dead *seconds* [**instance** *instance-id*]

undo ospfv3 timer dead [**instance** *instance-id*]

Default

The OSPFv3 neighbor dead time is 40 seconds for P2P and broadcast interfaces, and is 120 seconds for P2MP and NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the dead time in the range of 1 to 65535 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

If an interface receives no hello packet from a neighbor within the dead time, the interface determines that the neighbor is down.

The dead time must be a minimum of four times the hello time and must be identical on interfaces attached to the same network segment.

Examples

Set the OSPFv3 neighbor dead time to 60 seconds for VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 timer dead 60
```

Related commands

ospfv3 timer hello

ospfv3 timer hello

Use **ospfv3 timer hello** to set the hello interval for an interface.

Use **undo ospfv3 timer hello** to remove the configuration.

Syntax

ospfv3 timer hello *seconds* [**instance** *instance-id*]

undo ospfv3 timer hello [**instance** *instance-id*]

Default

The hello interval is 10 seconds for P2P and broadcast interfaces, and is 30 seconds for P2MP or NBMA interfaces.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the hello interval in the range of 1 to 65535 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

The shorter the hello interval is, the faster the topology converges and the more resources are consumed. Make sure the hello interval on two neighboring interfaces is the same.

Examples

Set the hello interval to 20 seconds for VLAN-interface 10.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 timer hello 20
```

Related commands

ospfv3 timer dead

ospfv3 timer poll

Use **ospfv3 timer poll** to set the poll interval on an NBMA interface.

Use **undo ospfv3 timer poll** to remove the configuration.

Syntax

ospfv3 timer poll *seconds* [**instance** *instance-id*]

undo ospfv3 timer poll [**instance** *instance-id*]

Default

The poll interval is 120 seconds on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the poll interval in the range of 1 to 65535 seconds.

instance *instance-id*: Specifies an interface instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

When an NBMA interface finds its neighbor is down, it sends hello packets at the poll interval.

The poll interval must be a minimum of four times the hello interval.

Examples

Set the poll interval on VLAN-interface 10 to 120 seconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 timer poll 120
```

Related commands

ospfv3 timer hello

ospfv3 timer retransmit

Use **ospfv3 timer retransmit** to set the LSA retransmission interval for an interface.

Use **undo ospfv3 timer retransmit** to remove the configuration.

Syntax

ospfv3 timer retransmit *seconds* [**instance** *instance-id*]

undo ospfv3 timer retransmit [**instance** *instance-id*]

Default

The interval is 5 seconds.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the LSA retransmission interval in the range of 1 to 3600 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

After the device sends an LSA to its neighbor, it waits for an acknowledgment. If the device receives no acknowledgment after the LSA retransmission interval elapses, it will retransmit the LSA.

To avoid unnecessary retransmissions, set an appropriate retransmission interval. For example, you can set a large retransmission interval value on a low-speed link.

Examples

Set the LSA retransmission interval to 12 seconds on VLAN-interface10 in instance 1.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 timer retransmit 12 instance 1
```

ospfv3 trans-delay

Use **ospfv3 trans-delay** to set the transmission delay for an interface.

Use **undo ospfv3 trans-delay** to remove the configuration.

Syntax

ospfv3 trans-delay *seconds* [**instance** *instance-id*]

undo ospfv3 trans-delay [**instance** *instance-id*]

Default

The transmission delay is 1 second.

Views

Interface view

Predefined user roles

network-admin

Parameters

seconds: Specifies the transmission delay in the range of 1 to 3600 seconds.

instance *instance-id*: Specifies an instance by its ID in the range of 0 to 255. The default is 0.

Usage guidelines

Each LSA in the LSDB has an age that is incremented by 1 every second, but the age does not change during transmission. Adding a transmission delay into the age time is important in low speed networks.

Examples

Set the transmission delay to 3 seconds for VLAN-interface 10 in instance 1.

```
<Sysname> system-view
[Sysname] interface vlan-interface 10
[Sysname-Vlan-interface10] ospfv3 trans-delay 3 instance 1
```

preference

Use **preference** to set a preference for OSPFv3 routes.

Use **undo preference** to remove the configuration.

Syntax

preference [**ase**] { *preference* | **route-policy** *route-policy-name* } *

undo preference [**ase**]

Default

The preference is 10 for OSPFv3 internal routes and 150 for OSPFv3 external routes.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

ase: Specifies a preference for OSPFv3 external routes. If you do not specify this keyword, the command sets a preference for OSPFv3 internal routes.

preference: Specifies the preference value in the range of 1 to 255. A smaller value represents a higher preference.

route-policy *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters, to set a preference for matching routes.

Usage guidelines

If multiple routing protocols find multiple routes to the same destination, the router uses the route found by the protocol with the highest preference.

Examples

Set a preference of 150 for OSPFv3 routes.

```
<Sysname> system-view
[Sysname] OSPFv3
[Sysname-OSPFv3-1] preference 150
```

prefix-suppression

Use **prefix-suppression** to disable an OSPFv3 process from advertising all prefixes except for the prefixes of loopback interfaces and passive interfaces.

Use **undo prefix-suppression** to restore the default.

Syntax

prefix-suppression

undo prefix-suppression

Default

An OSPFv3 process advertises all prefixes.

Views

OSPFv3 view

Predefined user roles

network-admin

Usage guidelines

By default, an OSPFv3 interface advertises all of its prefixes in LSAs. To speed up OSPFv3 convergence, you can suppress interfaces from advertising all of their prefixes. This feature helps improve network security by preventing IP routing to the suppressed networks.

To disable an OSPFv3 process from advertising the prefixes of loopback and passive interfaces, configure prefix suppression on the interfaces by using the **ospfv3 prefix-suppression** command.

When prefix suppression is enabled:

- OSPFv3 does not advertise the prefixes of suppressed interfaces in Type-8 LSAs.
- On broadcast and NBMA networks, the DR does not advertise the prefixes of suppressed interfaces in Type-9 LSAs that reference Type-2 LSAs.
- On P2P and P2MP networks, OSPFv3 does not advertise the prefixes of suppressed interfaces in Type-9 LSAs that reference Type-1 LSAs.

Examples

Enable prefix suppression for OSPFv3 process 100.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] prefix-suppression
```

Related commands

ospfv3 prefix-suppression

reset ospfv3 event-log

Use **reset ospfv3 event-log** to clear OSPFv3 log information.

Syntax

reset ospfv3 [*process-id*] **event-log** [**lsa-flush** | **peer** | **spf**]

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears OSPFv3 log information for all OSPFv3 processes.

lsa-flush: Clears LSA aging log information.

peer: Clears neighbor log information.

spf: Clears route calculation log information.

Usage guidelines

If you do not specify a log type, this command clears all log information.

Examples

Clear OSPFv3 route calculation log information for all OSPFv3 processes.

```
<Sysname> reset ospfv3 event-log spf
```

Related commands

display ospfv3 event-log

reset ospfv3 process

Use **reset ospfv3 process** to restart OSPFv3 processes.

Syntax

reset ospfv3 [*process-id*] **process** [**graceful-restart**]

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command restarts all OSPFv3 processes.

graceful-restart: Restarts the OSPFv3 process by using GR.

Usage guidelines

The **reset ospfv3 process** command performs the following actions:

- Clears all invalid LSAs without waiting for their timeouts.
- Starts a new DR/BDR election.
- Keeps previous OSPFv3 configurations.

The system prompts you to select whether to restart OSPFv3 process upon execution of this command.

Examples

Restart all OSPFv3 processes.

```
<Sysname> reset ospfv3 process
Reset OSPFv3 process? [Y/N]:y
```

reset ospfv3 redistribution

Use **reset ospfv3 redistribution** to restart route redistribution.

Syntax

reset ospfv3 [*process-id*] **redistribution**

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command restarts route redistribution for all OSPFv3 processes.

Examples

Restart route redistribution.

```
<Sysname> reset ospfv3 redistribution
```

reset ospfv3 statistics

Use **reset ospfv3 statistics** to clear OSPFv3 statistics.

Syntax

reset ospfv3 [*process-id*] **statistics**

Views

User view

Predefined user roles

network-admin

Parameters

process-id: Specifies an OSPFv3 process by its ID in the range of 1 to 65535. If you do not specify this argument, the command clears statistics for all OSPFv3 processes.

Examples

Clear statistics for all OSPFv3 processes.

```
<Sysname> reset ospfv3 statistics
```

router-id

Use **router-id** to configure a router ID.

Use **undo router-id** to restore the default.

Syntax

router-id *router-id*

undo router-id

Default

No router ID is configured.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

router-id: Specifies a router ID in IPv4 address format.

Usage guidelines

The router ID is the unique identifier for the device to run OSPFv3 in the AS. An OSPFv3 process cannot run without a router ID.

You must specify a unique router ID for each OSPFv3 process in an AS and on a router.

Examples

Configure the router ID 10.1.1.3 for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] router-id 10.1.1.3
```

Related commands

ospfv3

silent-interface(OSPFv3 view)

Use **silent-interface** to disable the specified interface from receiving and sending OSPFv3 packets.

Use **undo silent-interface** to remove the configuration.

Syntax

silent-interface { *interface-type interface-number* | **all** }

undo silent-interface { *interface-type interface-number* | **all** }

Default

An interface can receive and send OSPFv3 packets.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

all: Specifies all interfaces.

Usage guidelines

Multiple processes can disable the same interface from receiving and sending OSPFv3 packets. However, the **silent-interface** command takes effect only on interfaces enabled with the current process.

Examples

Disable VLAN-interface 10 from receiving and sending OSPFv3 packets in OSPFv3 processes 100 and 200.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] router-id 10.100.1.9
[Sysname-ospfv3-100] silent-interface vlan-interface 10
[Sysname-ospfv3-100] quit
[Sysname] ospfv3 200
[Sysname-ospfv3-200] router-id 20.100.1.9
[Sysname-ospfv3-200] silent-interface vlan-interface 10
```

snmp context-name

Use **snmp context-name** to configure an SNMP context for OSPFv3.

Use **undo snmp context-name** to restore the default.

Syntax

snmp context-name *context-name*

undo snmp context-name

Default

No SNMP contexts exist for OSPFv3.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

context-name: Specifies a context name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

The standard OSPFv3 MIB provides only single-instance MIB objects. For SNMP to correctly identify OSPFv3 management information in the standard OSPFv3 MIB, you must configure a unique context name for OSPFv3. If multiple OSPFv3 processes exist, you must assign a unique context to each process.

Context is a method introduced to SNMPv3 for multiple-instance management. For SNMPv1/v2c, you must specify a community name as a context name for protocol identification.

Examples

Configure the SNMP context name as **mib** for OSPFv3 process 1.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] snmp context-name mib
```

snmp trap rate-limit

Use **snmp trap rate-limit** to set the SNMP notification output interval and the maximum number of SNMP notifications that can be output at each interval.

Use **undo snmp trap rate-limit** to restore the default.

Syntax

snmp trap rate-limit interval *trap-interval* **count** *trap-number*

undo snmp trap rate-limit

Default

OSPFv3 outputs a maximum of seven SNMP notifications within 10 seconds.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

interval *trap-interval*: Specifies the SNMP notification output interval in the range of 2 to 60 seconds.

count *trap-number*: Specifies the number of SNMP notifications output by OSPFv3 at each interval, in the range of 0 to 300. The value of 0 indicates that OSPFv3 does not output SNMP notifications.

Examples

Configure OSPFv3 to output a maximum of 10 SNMP notifications within 5 seconds.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] snmp trap rate-limit interval 5 count 10
```

snmp-agent trap enable ospfv3

Use **snmp-agent trap enable ospfv3** to enable SNMP notifications for OSPFv3.

Use **undo snmp-agent trap enable ospfv3** to disable SNMP notifications for OSPFv3.

Syntax

snmp-agent trap enable ospfv3 [**grrestarter-status-change** | **grhelper-status-change** | **if-state-change** | **if-cfg-error** | **if-bad-pkt** | **neighbor-state-change** | **nssatranslator-status-change** | **virtif-bad-pkt** | **virtif-cfg-error** | **virtif-state-change** | **virtgrhelper-status-change** | **virtneighbor-state-change**] *

undo snmp-agent trap enable ospfv3 [**grrestarter-status-change** | **grhelper-status-change** | **if-state-change** | **if-cfg-error** | **if-bad-pkt** | **neighbor-state-change** | **nssatranslator-status-change** | **virtif-bad-pkt** | **virtif-cfg-error** | **virtif-state-change** | **virtgrhelper-status-change** | **virtneighbor-state-change**] *

Default

SNMP notifications for OSPFv3 are enabled.

Views

System view

Predefined user roles

network-admin

Parameters

grrestarter-status-change: Specifies notifications about GR restarter state changes.

grhelper-status-change: Specifies notifications about GR helper state changes.

if-state-change: Specifies notifications about interface state changes.

if-cfg-error: Specifies notifications about error configuration of an interface.

if-bad-pkt: Specifies notifications about error messages received on an interface.

neighbor-state-change: Specifies notifications about neighbor state changes.

nssatranslator-status-change: Specifies notifications about NSSA translator state changes.

virtif-bad-pkt: Specifies notifications about error messages received on a virtual interface.

virtif-cfg-error: Specifies notifications about error configuration of a virtual interface.

virtif-state-change: Specifies notifications about virtual interface state changes.

virtgrhelper-status-change: Specifies notifications about neighbor GR helper state changes of a virtual interface.

virtneighbor-state-change: Specifies notifications about the neighbor state changes of a virtual interface.

Examples

Disable SNMP notifications for OSPFv3.

```
<Sysname> system-view
[Sysname] undo snmp-agent trap enable ospfv3
```

spf-schedule-interval

Use **spf-schedule-interval** to set the OSPFv3 SPF calculation interval.

Use **undo spf-schedule-interval** to restore the default.

Syntax

spf-schedule-interval *maximum-interval* [*minimum-interval* [*incremental-interval*]]

undo spf-schedule-interval

Default

The maximum SPF calculation interval is 5 seconds, the minimum interval is 50 milliseconds, and the incremental interval is 200 milliseconds.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

maximum-interval: Specifies the maximum OSPFv3 route calculation interval in the range of 1 to 60 seconds.

minimum-interval: Specifies the minimum OSPFv3 route calculation interval in the range of 10 to 60000 milliseconds.

incremental-interval: Specifies the incremental OSPFv3 route calculation interval in the range of 10 to 60000 milliseconds.

Usage guidelines

Based on the LSDB, an OSPFv3 router uses SPF to calculate a shortest path tree with itself being the root. OSPFv3 uses the shortest path tree to determine the next hop to a destination. By adjusting the SPF calculation interval, you can prevent overconsumption of bandwidth and router resources due to frequent topology changes.

For a stable network, the minimum interval is used. If network changes become frequent, the SPF calculation interval is incremented by the incremental interval × 2^{n-2} for each calculation until the maximum interval is reached. The value *n* is the number of calculation times.

The minimum interval and the incremental interval cannot be greater than the maximum interval.

Examples

Set the maximum SPF calculation interval to 10 seconds, minimum interval to 500 milliseconds, and incremental interval to 300 milliseconds.

```
<Sysname> system-view
```

```
[Sysname] ospfv3 100
[Sysname-ospfv3-100] spf-schedule-interval 10 500 300
```

stub (OSPFv3 area view)

Use **stub** to configure an area as a stub area.

Use **undo stub** to restore the default.

Syntax

stub [**default-route-advertise-always** | **no-summary**] *

undo stub

Default

No area is configured as a stub area.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

default-route-advertise-always: Enables the ABR to always advertise a default route into the stub area.

no-summary: Enables the ABR to advertise only a default route in an Inter-Area-Prefix-LSA into the stub area. No AS-external-LSA, Inter-Area-Prefix-LSA, or other Inter-Area-Router-LSA is advertised in the area. The area is a totally stub area.

Usage guidelines

To remove the **no-summary** configuration on an ABR, execute the **stub** command again to overwrite it.

To configure an area as a stub area, execute the **stub** command on all routers attached to the area.

Examples

Configure OSPFv3 area 1 as a stub area.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] stub
```

Related commands

default-cost (OSPFv3 area view)

stub-router

Use **stub-router** to configure a router as a stub router.

Use **undo stub-router** to restore the default.

Syntax

stub-router r-bit [**include-stub** | **on-startup** *seconds*] *

stub-router max-metric [**external-lsa** [*max-metric-value*] | **summary-lsa** [*max-metric-value*] | **include-stub** | **on-startup** *seconds*] *

undo stub-router

Default

The router is not configured as a stub router.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

r-bit: Clears the R-bit of the Option field in Type-1 LSAs.

max-metric: Advertises the locally generated Type-1 LSAs with the maximum cost of 65535.

external-lsa *max-metric-value*: Specifies a cost for external LSAs, in the range of 1 to 16777215. The default is 16711680.

summary-lsa *max-metric-value*: Specifies a cost for Type-3 and Type-4 LSAs, in the range of 1 to 16777215. The default is 16711680.

include-stub: Specifies the cost for Type-9 LSAs that reference Type-1 LSAs to the maximum value 65535.

on-startup *seconds*: Specifies the router as a stub router during reboot, and specifies the timeout time in the range of 5 to 86400 seconds.

Usage guidelines

You can use the **stub-router r-bit** command or **stub-router max-metric** command to configure a router as a stub router.

- The **stub-router r-bit** command clears the R-bit of the Option field in Type-1 LSAs. When the R-bit is clear, the OSPFv3 router can participate in OSPFv3 topology distribution without forwarding traffic.
- The **stub-router max-metric** command specifies the OSPFv3 max-metric router LSA feature. This feature enables OSPFv3 to advertise its locally generated Type-1 LSAs with a maximum cost of 65535. Neighbors do not send packets to the stub router as long as they have a route with a smaller cost.

Examples

Configure a stub router.

```
<Sysname> system-view
[Sysname] ospfv3 100
[Sysname-ospfv3-100] stub-router r-bit
```

transmit-pacing

Use **transmit-pacing** to set the LSU transmission interval and the maximum number of LSU packets that can be sent at each interval.

Use **undo transmit-pacing** to restore the default.

Syntax

transmit-pacing interval *interval* **count** *count*

undo transmit-pacing

Default

An OSPFv3 interface sends a maximum of three LSU packets every 20 milliseconds.

Views

OSPFv3 view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies an interval at which an interface sends LSU packets, in the range of 10 to 1000 milliseconds. If the router has multiple OSPFv3 interfaces, increase the interval to reduce the total number of LSU packets sent by the router every second.

count *count*: Specifies the maximum number of LSU packets sent by an interface at each interval, in the range of 1 to 200. If the router has multiple OSPFv3 interfaces, decrease the maximum number to reduce the total number of LSU packets sent by the router every second.

Examples

Configure all the interfaces running OSPFv3 process 1 to send a maximum of 10 LSU packets every 30 milliseconds.

```
<Sysname> system-view
[Sysname] ospfv3 1
[Sysname-ospfv3-1] transmit-pacing interval 30 count 10
```

vlink-peer (OSPFv3 area view)

Use **vlink-peer** to configure a virtual link.

Use **undo vlink-peer** to remove a virtual link.

Syntax

vlink-peer *router-id* [**dead** *seconds* | **hello** *seconds* | **instance** *instance-id* | **ipsec-profile** *profile-name* | **keychain** *keychain-name* | **retransmit** *seconds* | **trans-delay** *seconds*] *

undo vlink-peer *router-id* [**dead** | **hello** | **ipsec-profile** | **retransmit** | **trans-delay**] *

Default

No virtual links exist.

Views

OSPFv3 area view

Predefined user roles

network-admin

Parameters

router-id: Specifies the router ID of the neighbor on the virtual link.

dead *seconds*: Specifies the dead interval in the range of 1 to 32768 seconds. The default is 40. The dead interval must be identical with that on the virtual link neighbor, and must be a minimum of four times the hello interval.

hello *seconds*: Specifies the hello interval in the range of 1 to 8192 seconds. The default is 10. It must be identical with the hello interval on the virtual link neighbor.

instance *instance-id*: Specifies the instance ID of a virtual link, in the range of 0 to 255. The default is 0.

ipsec-profile *profile-name:* Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters. For more information about IPsec profiles, see *Security Configuration Guide*.

keychain: Specifies the keychain authentication mode.

keychain-name: Specifies a keychain by its name, a case-sensitive string of 1 to 63 characters.

retransmit *seconds*: Specifies the retransmission interval in the range of 1 to 3600 seconds. The default is 5.

trans-delay *seconds*: Specifies the transmission delay interval in the range of 1 to 3600 seconds. The default is 1.

Usage guidelines

You can configure a virtual link to maintain connectivity between a non-backbone area and the backbone, or maintain connectivity within the backbone. A virtual link is similar to an interface with OSPFv3 enabled. You can configure parameters such as **hello**, **dead**, **retransmit** and **trans-delay** for the virtual link.

Both ends of a virtual link must be ABRs that are configured with the **vlink-peer** command.

The following guidelines apply to parameters:

- The smaller the hello interval is, the faster the network converges, and the more network resources are consumed.
- For a low speed link, set a large retransmission interval to avoid unnecessary retransmissions.
- Specify a transmission delay with the **trans-delay** keyword depending on the interface delay.

The authentication mode specified for an OSPFv3 virtual link has a higher priority than the mode specified for the backbone area. If no authentication mode is specified for the virtual link, the mode specified for the backbone area applies.

When keychain authentication is configured for an OSPFv3 virtual link, OSPFv3 performs the following operations before sending a packet:

1. Obtains a valid send key from the keychain.

   OSPFv3 does not send the packet if it fails to obtain a valid send key.
2. Uses the key ID, authentication algorithm, and key string to authenticate the packet.

   If the key ID is greater than 65535, OSPFv3 does not send the packet.

When keychain authentication is configured for an OSPFv3 virtual link, OSPFv3 performs the following operations after receiving a packet:

1. Uses the key ID carried in the packet to obtain a valid accept key from the keychain.

   OSPFv3 discards the packet if it fails to obtain a valid accept key.
2. Uses the authentication algorithm and key string for the valid accept key to authenticate the packet.

   If the authentication fails, OSPFv3 discards the packet.

OSPFv3 supports only the HMAC-SHA-256 authentication algorithm.

The ID of keys used for authentication can only be in the range of 0 to 65535.

Examples

Configure a virtual link to 10.10.0.3.

```
<Sysname> system-view
[Sysname] ospfv3 1
```

```
[Sysname-ospfv3-1] area 1
[Sysname-ospfv3-1-area-0.0.0.1] vlink-peer 10.10.0.3
```

IPv6 policy-based routing commands

apply next-hop

Use **apply next-hop** to set next hops.

Use **undo apply next-hop** to remove next hops.

Syntax

apply next-hop { *ipv6-address* [**direct**] [**track** *track-entry-number*] } &<1-2>

undo apply next-hop [*ipv6-address*&<1-2>]

Default

No next hops are set.

Views

IPv6 policy node view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the IPv6 address of the next hop.

direct: Specifies that the next hop must be directly connected to take effect.

track *track-entry-number*: Specifies a track entry by its number in the range of 1 to 1024.

&<1-2>: Indicates that the argument before it can be entered up to two times.

Usage guidelines

You can specify multiple next hops for backup in one command line or by executing this command multiple times.

With a next hop specified, the **undo apply next-hop** command removes the next hop.

Without any next hop specified, the **undo apply next-hop** command removes all next hops.

Examples

Set a directly-connected next hop of 1::1.

```
<Sysname> system-view
[Sysname] ipv6 policy-based-route aa permit node 11
[Sysname-pbr6-aa-11] apply next-hop 1::1
```

description

Use **description** to configure a description for an IPv6 policy node.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for an IPv6 policy node.

Views

IPv6 policy node view

Predefined user roles

network-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Examples

Configure the description as **Officeuse** for IPv6 policy node 1.

```
<Sysname> system-view
[Sysname] ipv6 policy-based-route 1 permit node 1
[Sysname-pbr6-1-1] description Officeuse
```

display ipv6 policy-based-route

Use **display ipv6 policy-based-route** to display IPv6 PBR policy information.

Syntax

display ipv6 policy-based-route [**policy** *policy-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

policy *policy-name*: Specifies a policy by its name, a case-sensitive string of 1 to 19 characters. If you do not specify a policy, this command displays information for all IPv6 PBR policies.

Examples

Display all IPv6 policy information.

```
<Sysname> display ipv6 policy-based-route
Policy name: aaa
  node 1 permit:
    if-match acl 2000
    apply next-hop 1000::1
```

Table 1 Command output

Field	Description
node 1 permit	The match mode of Node 1 is **permit**.
if-match acl	Compares IPv6 packets with IPv6 ACL.
apply next-hop	Specifies a next hop for permitted IPv6 packets.

Related commands

ipv6 policy-based-route (system view)

display ipv6 policy-based-route interface

Use **display ipv6 policy-based-route interface** to display IPv6 interface PBR configuration and statistics.

Syntax

display ipv6 policy-based-route interface *interface-type interface-number* [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 interface PBR configuration and statistics for the master device.

Examples

Display IPv6 PBR configuration and statistics on VLAN-interface 2.

```
<Sysname> display ipv6 policy-based-route interface vlan-interface 2
Policy based routing information for interface Vlan-inerface2(failed):
Policy name: aaa
  node 0 deny:
  Matched: 0
  node 1 permit:
    if-match acl 3999
  Matched: 0
  node 2 permit:
    if-match acl 2000
    apply next-hop 1000::1
  Matched: 0
  node 5 permit:
    if-match acl 3101
    apply next-hop 1000::1
  Matched: 0
Total matched: 0
<Sysname> display ipv6 policy-based-route interface Vlan-inerface2
Policy based routing information for interface Vlan-inerface2:
Policy name: aaa
  node 0 deny(not support):
  Matched: 0
  node 1 permit:
```

```
    if-match acl 3999
  Matched: 0
  node 2 permit(no resource):
    if-match acl 2000
    apply next-hop 1000::1
  Matched: 0
  node 5 permit:
    if-match acl 3101
    apply next-hop 1000::1
  Matched: 0 (no statistics resource)
Total matched: 0
```

Table 2 Command output

Field	Description
Policy based routing information for interface *XXXX* (failed)	IPv6 PBR configuration and statistics on the interface. This field displays **failed** in brackets if none of the nodes in the policy has been successfully issued to the driver. The **failed** status will persist even after the policy is successfully issued. To clear the **failed** status, you must remove the policy from the interface and then apply it on the interface again. **NOTE:** The **failed** status is available on a per-slot basis. To obtain this information, you must specify a slot number when you execute the command. • For a global interface (for example, a VLAN interface), which might have member physical interfaces on multiple slots, specify a slot that contains its member interfaces. • For a physical interface, specify its slot number.
node 0 deny(not support) node 2 permit(no resource)	Match mode of the node, **permit** or **deny**. If a node fails to be issued to the driver, the command displays the cause in brackets, which include: • **not support**—The device does not support the match criteria configured on the node. • **no resource**—No sufficient resources (for example, ACLs) are available for the node. **NOTE:** The cause is available only on a per-slot basis. To obtain this information, you must specify a slot number when you execute the command. • For a global interface (for example, a VLAN interface), which might have member physical interfaces on multiple slots, specify a slot that contains its member interfaces. • For a physical interface, specify its slot number.
if-match acl	Compares IPv6 packets with the IPv6 ACL.
apply next-hop	Specifies a next hop for permitted IPv6 packets.
Matched: 0 (no statistics resource)	Number of successful matches on the node. If the device does not have sufficient resources to count matches, this field displays **no statistics resource** in brackets. **NOTE:** The statistics collection failure cause is available only on a per-slot basis. To obtain this information, you must specify a slot number when you execute the command.

Field	Description
	• For a global interface (for example, a VLAN interface), which might have member physical interfaces on multiple slots, specify a slot that contains its member interfaces. • For a physical interface, specify its slot number.
Total matched	Total number of successful matches on all nodes.

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 local PBR configuration and statistics for the master device.

Examples

Display IPv6 local PBR configuration and statistics.

```
<Sysname> display ipv6 policy-based-route local
Policy based routing information for local:
Policy name: aaa
  node 0 deny:
  Matched: 0
  node 1 permit:
    if-match acl 3999
  Matched: 0
  node 2 permit:
    if-match acl 2000
    apply next-hop 1::1
  Matched: 0
  node 5 permit:
    if-match acl 3101
    apply next-hop 2::2
  Matched: 0
Total matched: 0
```

Table 3 Command output

Field	Description
Policy based routing information for local	IPv6 local PBR configuration and statistics.
node 0 deny/node 2 permit	Match mode of the node, **permit** or **deny**.
if-match acl	Compares packets with the ACL.
apply next-hop	Specifies a next hop for permitted packets.
Matched: 0	Number of successful matches on the node.
Total matched	Total number of successful matches on all nodes.

Related commands

Syntax

`display ipv6 policy-based-route setup`

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display IPv6 PBR configuration.

```
<Sysname> display ipv6 policy-based-route setup
Policy name             Type               Interface
pr01                    Forward            Vlan-interface 2
pr02                    Local              N/A
pr03                    Global             N/A
```

Table 4 Command output

Field	Description
Policy name	Policy name.
Type	Type of the PBR: • **Forward**—Interface PBR. • **Local**—Local PBR. • **Global**—Global PBR.
Interface	Interface where the policy is applied. This field displays **N/A** for IPv6 local PBR and IPv6 global PBR.

Related commands

ipv6 policy-based-route (interface view)

if-match acl

Use **if-match acl** to set an ACL match criterion.

Use **undo if-match acl** to restore the default.

Syntax

if-match acl { *ipv6-acl-number* | **name** *ipv6-acl-name* }

undo if-match acl

Default

No ACL match criterion is set.

Views

IPv6 policy node view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 ACL by its number in the range of 2000 to 3999. The value range of a basic ACL is 2000 to 2999 and that of an advanced ACL is 3000 to 3999.

name *ipv6-acl-name*: Specifies an IPv6 ACL by its name, a case-insensitive string of 1 to 63 characters starting with a letter. The ACL name cannot be **all**. For the command to take effect, make sure the specified IPv6 ACL is a basic or advanced ACL.

Examples

Configure Node 10 of policy **aa** to permit the packets matching ACL 2000.

```
<Sysname> system-view
[Sysname] ipv6 policy-based-route aa permit node 10
[Sysname-pbr6-aa-10] if-match acl 2000
```

Configure Node 10 of policy **aa** to permit the packets matching ACL **aaa**.

```
<Sysname> system-view
[Sysname] ipv6 policy-based-route aa permit node 10
[Sysname-pbr6-aa-10] if-match acl name aaa
```

ipv6 local policy-based-route

Use **ipv6 local policy-based-route** to configure IPv6 local PBR based on a specified policy.

Use **undo ipv6 local policy-based-route** to restore the default.

Syntax

ipv6 local policy-based-route *policy-name*

undo ipv6 local policy-based-route

Default

No policy is referenced for IPv6 local PBR.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a policy by its name, a case-sensitive string of 1 to 19 characters. The specified IPv6 policy must already exist.

Usage guidelines

You can apply only one policy locally. Before you apply a new policy, you must first remove the current policy.

IPv6 local PBR is used to route locally generated packets except the packets destined for the sender. This feature might affect local services. Do not configure IPv6 local PBR unless doing so is required.

Examples

Configure IPv6 local PBR based on policy **aaa**.

```
<Sysname> system-view
[Sysname] ipv6 local policy-based-route aaa
```

Related commands

display ipv6 policy-based-route setup

ipv6 policy-based-route (system view)

ipv6 policy-based-route (interface view)

Use **ipv6 policy-based-route** to configure IPv6 interface PBR by applying an IPv6 policy to an interface.

Use **undo ipv6 policy-based-route** to restore the default.

Syntax

ipv6 policy-based-route *policy-name*

undo ipv6 policy-based-route

Default

No IPv6 policy is applied to an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a policy by its name, a case-sensitive string of 1 to 19 characters. The specified policy must already exist.

Examples

Apply policy **aaa** to VLAN-interface 2.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname-Vlan-interface2] ipv6 policy-based-route aaa
```

Related commands

display ipv6 policy-based-route setup

ipv6 policy-based-route (system view)

ipv6 policy-based-route (system view)

Use **ipv6 policy-based-route** to create an IPv6 policy node and enter its view, or enter the view of an existing IPv6 policy node.

Use **undo ipv6 policy-based-route** to delete an IPv6 policy or IPv6 policy node.

Syntax

ipv6 policy-based-route *policy-name* [**deny** | **permit**] **node** *node-number*

undo ipv6 policy-based-route *policy-name* [**deny** | **node** *node-number* | **permit**]

Default

No IPv6 policy nodes exist.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a policy name, a case-sensitive string of 1 to 19 characters.

deny: Specifies the match mode for the policy node as **deny**.

permit: Specifies the match mode for the policy node as **permit** (default mode).

node *node-number*: Specifies the number of the IPv6 policy node. A smaller number has a higher priority. The value range for the *node-number* argument is 0 to 255.

Usage guidelines

To delete an IPv6 policy that has already applied to an interface, you must delete the policy from the interface first.

If a policy node is specified, the **undo ipv6 policy-based-route** command deletes the specified policy node. If a match mode is specified, the command deletes all nodes configured with the match mode. If no node is specified, the command deletes the whole policy.

Examples

Create permit-mode Node 10 for IPv6 policy **aaa** and enter its view.

```
<Sysname> system-view
[Sysname] ipv6 policy-based-route aaa permit node 10
[Sysname-pbr6-aaa-10]
```

apply cost

Use **apply cost** to set a cost for routes.

Use **undo apply cost** to restore the default.

Syntax

apply cost [**+** | **-**] *cost-value*

undo apply cost

Default

No cost is set for routes.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

+: Increases a cost value.

-: Decreases a cost value.

cost-value: Specifies a cost in the range of 0 to 4294967295.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set a cost of 120 for OSPF external routes.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match route-type external-type1or2
[Sysname-route-policy-policy1-10] apply cost 120
```

apply cost-type

Use **apply cost-type** to set a cost type for routes.

Use **undo apply cost-type** to restore the default.

Syntax

apply cost-type { **type-1** | **type-2** }

undo apply cost-type

Default

No cost type is set for routes.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

type-1: Sets the cost type to OSPF Type-1 external route.

type-2: Sets the cost type to OSPF Type-2 external route.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set the cost type for routes that have a tag of 8 to OSPF Type-1 external routes.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match tag 8
[Sysname-route-policy-policy1-10] apply cost-type type-1
```

apply ip-precedence

Use **apply ip-precedence** to set an IP precedence for matching routes.

Use **undo apply ip-precedence** to restore the default.

Syntax

apply ip-precedence { *value* | **clear** }

undo apply ip-precedence

Default

No IP precedence is set.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

value: Specifies an IP precedence in the range of 0 to 7.

clear: Clears the IP precedence of matching routes.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set an IP precedence of 3 for routes matching prefix list 100.

```
<Sysname> system-view
[Sysname] ip prefix-list 100 permit 192.168.10.1 24
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ip address prefix-list 100
[Sysname-route-policy-policy1-10] apply ip-precedence 3
```

apply preference

Use **apply preference** to set a preference for a routing protocol.

Use **undo apply preference** to restore the default.

Syntax

apply preference *preference*

undo apply preference

Default

No preference is set for a routing protocol.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

preference: Specifies a preference in the range of 1 to 255.

Usage guidelines

If you have set preferences for routing protocols by using the **preference** command, the **apply preference** command sets a new preference for the matching routing protocol. Unmatched routing protocols still use the preferences set by using the **preference** command.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set the preference for OSPF external routes to 90.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match route-type external-type1or2
[Sysname-route-policy-policy1-10] apply preference 90
```

apply prefix-priority

Use **apply prefix-priority** to set a prefix priority for routes.

Use **undo apply prefix-priority** to restore the default.

Syntax

apply prefix-priority { **critical** | **high** | **medium** }

undo apply prefix-priority

Default

No prefix priority is set, which means the prefix priority is low.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

critical: Sets the critical prefix priority for routes.

high: Sets the high prefix priority for routes.

medium: Sets the medium prefix priority for routes.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set prefix priority **critical** for routes matching prefix list **abc**.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ip address prefix-list abc
[Sysname-route-policy-policy1-10] apply prefix-priority critical
```

apply tag

Use **apply tag** to set a tag for IGP routes.

Use **undo apply tag** to restore the default.

Syntax

apply tag *tag-value*

undo apply tag

Default

No routing tag is set for IGP routes.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

tag-value: Specifies the tag value in the range of 0 to 4294967295.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set a tag of 100 for IGP routes.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] apply tag 100
```

continue

Use **continue** to specify the next node to be matched.

Use **undo continue** to restore the default.

Syntax

continue [*node-number*]

undo continue

Default

No next node is specified.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

node-number: Specifies the routing policy node number in the range of 0 to 65535.

Usage guidelines

The specified next node must have a larger number than the current node.

Example

Specify the next node 20 for node 10 of the routing policy **policy1**.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] continue 20
```

display route-policy

Use **display route-policy** to display routing policy information.

Syntax

display route-policy [**name** *route-policy-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *route-policy-name*: Specifies a routing policy by its name, a case-sensitive string of 1 to 63 characters. If you do not specify this option, the command displays information about all routing policies.

Examples

Display information about routing policy **policy1**.

```
<Sysname> display route-policy name policy1
Route-policy: policy1
  Permit : 1
          if-match cost 10
          continue: next node 11
          apply preference 10
```

Table 1 Command output

Field	Description
Route-policy	Routing policy name.

permit	Match mode: • **Permit**. • **Deny**.
if-match	Match criterion.
continue	Specify the next node to be matched.
apply	Action.

if-match cost

Use **if-match cost** to match routes that have the specified cost.

Use **undo if-match cost** to restore the default.

Syntax

if-match cost *cost-value*

undo if-match cost

Default

No cost match criterion is configured.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

cost-value: Specifies a cost in the range of 0 to 4294967295.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to permit routes with a cost of 8.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match cost 8
```

if-match interface

Use **if-match interface** to match routes that have the specified output interfaces.

Use **undo if-match interface** to remove the specified output interface match criterion.

Syntax

if-match interface { *interface-type interface-number* }&<1-16>

undo if-match interface [*interface-type interface-number*]&<1-16>

Default

No output interface match criterion is configured.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

interface-type interface-number: Specifies an interface by its type and number.

&<1-16>: Indicates that you can specify a maximum of 16 interfaces.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to permit routes with the output interface VLAN-interface 1.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match interface vlan-interface 1
```

if-match route-type

Use **if-match route-type** to set a route-type match criterion.

Use **undo if-match route-type** to remove the specified route-type match criterion.

Syntax

if-match route-type { **external-type1** | **external-type1or2** | **external-type2** | **internal** | **nssa-external-type1** | **nssa-external-type1or2** | **nssa-external-type2** } *

undo if-match route-type [**external-type1** | **external-type1or2** | **external-type2** | **internal** | **nssa-external-type1** | **nssa-external-type1or2** | **nssa-external-type2**] *

Default

No route-type match criterion is set.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

external-type1: Matches OSPF Type 1 external routes.

external-type1or2: Matches OSPF Type 1 and Type 2 external routes.

external-type2: Matches OSPF Type 2 external routes.

internal: Matches OSPF internal routes (including OSPF intra-area and inter-area routes).

nssa-external-type1: Matches OSPF NSSA Type 1 external routes.

nssa-external-type1or2: Matches OSPF NSSA Type 1 and 2 external routes.

nssa-external-type2: Matches OSPF NSSA Type 2 external routes.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to match OSPF internal routes.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
```

```
[Sysname-route-policy-policy1-10] if-match route-type internal
```

if-match tag

Use **if-match tag** to match IGP routes that have the specified tag.

Use **undo if-match tag** to restore the default.

Syntax

if-match tag *tag-value*

undo if-match tag

Default

No tag match criterion is configured.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

tag-value: Specifies a tag in the range of 0 to 4294967295.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to match IGP routes that have a tag of 8.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match tag 8
```

route-policy

Use **route-policy** to create a routing policy and a node and enter routing policy node view, or enter the view of an existing routing policy node.

Use **undo route-policy** to remove a routing policy or a node of it.

Syntax

route-policy *route-policy-name* { **deny** | **permit** } **node** *node-number*

undo route-policy *route-policy-name* [**deny** | **permit**] [**node** *node-number*]

Default

No routing policies exist.

Views

System view

Predefined user roles

network-admin

Parameters

route-policy-name: Specifies a routing policy name, a case-sensitive string of 1 to 63 characters.

deny: Specifies the deny match mode for the routing policy node. If a route matches all the **if-match** clauses of the node, it is denied without being compared with the next node. If a route does not match any **if-match** clauses of the node, the route is compared with the next node.

permit: Specifies the permit match mode for the routing policy node. If a route matches all the **if-match** clauses of the node, it is handled by the **apply** clauses of the node. If a route does not match any **if-match** clauses of the node, the route is compared with the next node.

node *node-number*: Specifies a node number in the range of 0 to 65535. A node with a smaller number is matched first.

Usage guidelines

Use a routing policy to filter routing information. A routing policy can contain several nodes and each node contains a set of **if-match** and **apply** clauses. The **if-match** clauses define the match criteria of the node and the **apply** clauses define the actions to be taken on packets matching the criteria. The relation between the **if-match** clauses of a node is logical AND. All the **if-match** clauses must be met. The relation between nodes is logical OR. A packet passing a node passes the routing policy. If a packet does not pass any nodes, the packet does not pass the routing policy.

Examples

Create node 10 in **permit** mode for routing policy **policy1** and enter routing policy node view.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10]
```

Related commands

display route-policy

route-policy-change delay-time

Use **route-policy-change delay-time** to set the routing policy change delay timer.

Use **undo route-policy-change delay-time** to restore the default.

Syntax

route-policy-change delay-time { *time-value* | **unlimited** }

undo route-policy-change delay-time

Default

Routing policy changes immediately take effect, but the routing protocol waits five seconds before processing routes from the new routing policy.

Views

System view

Predefined user roles

network-admin

Parameters

time-value: Specifies the routing policy change delay timer in the range of 60 to 3600 seconds. When this delay timer expires, the routing protocol waits five seconds before processing routes from the new routing policy.

unlimited: Sets an infinite delay timer.

Usage guidelines

This command makes a routing policy take effect after a delayed time interval, which prevents incomplete routing policy configuration from being issued to cause incorrect route advertisement. The system automatically starts the timer when a routing policy changes. The changes will not take effect on the routing policy until the change delay timer expires.

A routing policy changes when one of the following events occurs:

- A routing policy is created.
- A routing policy node, **if-match** clause, or **apply** clause is added, modified, or deleted for a routing policy.
- An IPv4 prefix list, IPv6 prefix list, AS path list, community list, extended community list, or MAC list is added, modified, or deleted.
- The ACL used by an **if-match** clause changes.

To have enough time to complete routing policy configuration, you can specify the **unlimited** keyword for the command. Then, execute the **undo** form of the command after you complete the configuration.

If you modify the routing policy change delay timer before it expires, the timer will be reset.

Examples

Set the routing policy change delay timer to 60 seconds.

```
<Sysname> system-view
[Sysname] route-policy-change delay-time 6
```

IPv4 routing policy commands

apply fast-reroute

Use **apply fast-reroute** to set a backup link for fast reroute (FRR).

Use **undo apply fast-reroute** to restore the default.

Syntax

apply fast-reroute { **backup-interface** *interface-type interface-number* [**backup-nexthop** *ip-address*] | **backup-nexthop** *ip-address* }

undo apply fast-reroute

Default

No backup link for FRR is configured.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

backup-interface *interface-type interface-number*: Specifies a backup output interface by its type and number. If the specified interface is a non-P2P interface, you must also specify a backup next hop. Non-P2P interfaces include NBMA and broadcast interfaces.

backup-nexthop *ip-address*: Specifies a backup next hop.

Examples

Configure node 10 of routing policy **policy1** to set the backup output interface VLAN-interface 1 and backup next hop 193.1.1.8 for the route destined for 100.1.1.0/24.

```
<Sysname> system-view
[Sysname] ip prefix-list abc index 10 permit 100.1.1.0 24
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ip address prefix-list abc
[Sysname-route-policy-policy1-10] apply fast-reroute backup-interface vlan-interface 1
backup-nexthop 193.1.1.8
```

apply ip-address next-hop

Use **apply ip-address next-hop** to set a next hop for IPv4 routes.

Use **undo apply ip-address next-hop** to restore the default.

Syntax

apply ip-address next-hop *ip-address* [**public**]

undo apply ip-address next-hop

Default

No next hop is set for IPv4 routes.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the next hop IP address.

public: Specifies the public network.

Usage guidelines

If you use this command to set a next hop for redistributed routes, the configuration does not take effect.

If you do not specify the **public** keyword, the next hop belongs to the public network.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set next hop 193.1.1.8 for routes matching prefix list 100.

```
<Sysname> system-view
[Sysname] ip prefix-list 100 permit 192.168.10.1 24
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ip address prefix-list 100
[Sysname-route-policy-policy1-10] apply ip-address next-hop 193.1.1.8
```

display ip prefix-list

Use **display ip prefix-list** to display IPv4 prefix list statistics.

Syntax

display ip prefix-list [**name** *prefix-list-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters. If you do not specify this option, the command displays statistics for all IPv4 prefix lists.

Examples

Display the statistics for IPv4 prefix list **abc**.

```
<Sysname> display ip prefix-list name abc
Prefix-list: abc
 Permitted 0
 Denied 0
        index: 10        Deny   6.6.6.0/24              ge  26  le  28
```

Table 2 Command output

Field	Description
Prefix-list	Name of the IPv4 prefix list.
Permitted	Number of routes matching the criterion.
Denied	Number of routes not matching the criterion.
index	Index of an item.
deny	Match mode of the item: • **Permit**. • **Deny**.
6.6.6.0/24	IP address and mask.
ge	Greater-equal, the lower mask length limit.
le	Less-equal, the upper mask length limit.

Related commands

ip prefix-list

reset ip prefix-list

if-match ip

Use **if-match ip** to match IPv4 routes whose destination, next hop, or source address matches an ACL or IPv4 prefix list.

Use **undo if-match ip** to remove the specified ACL or IPv4 prefix list match criterion.

Syntax

if-match ip { **address** | **next-hop** } { **acl** *ipv4-acl-number* | **prefix-list** *prefix-list-name* }

undo if-match ip { **address** | **next-hop** | **route-source** } [**acl** | **prefix-list**]

Default

No ACL or IPv4 prefix list match criterion is configured.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

address: Matches the destination address of IPv4 routes.

next-hop: Matches the next hop of IPv4 routes.

acl *ipv4-acl-number*: Specifies an ACL by its number. The value range for the *ipv4-acl-number* argument is 2000 to 3999 for the **address** keyword, and 2000 to 2999 for the **next-hop** keyword and **route-source** keyword.

prefix-list *prefix-list-name*: Specifies an IP prefix list by its name, a case-sensitive string of 1 to 63 characters.

Examples

Configure node 10 of routing policy **policy1** to match IPv4 routes whose next hop matches IP prefix list **p1**.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ip next-hop prefix-list p1
```

ip prefix-list

Use **ip prefix-list** to configure an IPv4 prefix list or an item for the list.

Use **undo ip prefix-list** to remove an IPv4 prefix list or an item of it.

Syntax

ip prefix-list *prefix-list-name* [**index** *index-number*] { **deny** | **permit** } *ip-address mask-length* [**greater-equal** *min-mask-length*] [**less-equal** *max-mask-length*]

undo ip prefix-list *prefix-list-name* [**index** *index-number*]

Default

No IPv4 prefix lists exist.

Views

System view

Predefined user roles

network-admin

Parameters

prefix-list-name: Specifies an IPv4 prefix list name, a case-sensitive string of 1 to 63 characters.

index *index-number*: Specifies an index number for an IPv4 prefix list item, in the range of 1 to 65535. An item with a smaller index number is matched first. If you do not specify this option, the index number starts from 10 and increments by 10 for each of the consecutive prefix list items.

deny: Specifies the deny mode. If a route matches the item, the route is denied without being compared with the next item. If a route does not match the item, the route is compared with the next item.

permit: Specifies the permit mode. If a route matches the item, it passes the IPv4 prefix list. If a route does not match the item, the route is compared with the next item.

ip-address mask-length: Specifies an IPv4 prefix and mask length. The value range for the *mask-length* argument is 0 to 32.

greater-equal *min-mask-length*, **less-equal** *max-mask-length*: Specifies a prefix length range. The **greater-equal** keyword means "greater than or equal to" and the **less-equal** keyword means "less than or equal to." The prefix length range relation is *mask-length* <= *min-mask-length* <= *max-mask-length* <= 32.

- If only the *min-mask-length* argument is specified, the prefix length range is [*min-mask-length*, 32].
- If only the *max-mask-length* argument is specified, the prefix length range is [*mask-length*, *max-mask-length*].
- If both the *min-mask-length* and *max-mask-length* arguments are specified, the prefix length range is [*min-mask-length*, *max-mask-length*].

Usage guidelines

An IPv4 prefix list is used to filter IPv4 addresses. It can contain multiple items, each of which specifies a range of IPv4 prefixes. The relation between the items is logical OR. If an item is passed, the IPv4 prefix list is passed. If no item is passed, the IP prefix list cannot be passed.

If both the *ip-address* and *mask-length* arguments are specified as 0.0.0.0 0, only the default route will be matched.

To match all routes, use 0.0.0.0 0 **less-equal** 32.

Examples

Configure IP prefix list **p1** to permit routes destined for network 10.0.0.0/8 and with mask length 17 or 18.

```
<Sysname> system-view
[Sysname] ip prefix-list p1 permit 10.0.0.0 8 greater-equal 17 less-equal 18
```

IPv6 routing policy commands

apply ipv6 fast-reroute

Use **apply ipv6 fast-reroute** to set a backup link for fast reroute (FRR).

Use **undo apply ipv6 fast-reroute** to restore the default.

Syntax

apply ipv6 fast-reroute { **backup-interface** *interface-type interface-number* [**backup-nexthop** *ipv6-address*] | **backup-nexthop** *ipv6-address* }

undo apply ipv6 fast-reroute

Default

No backup link for FRR is configured.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

backup-interface *interface-type interface-number*: Specifies a backup output interface by its type and number. If the specified interface is a non-P2P interface, you must also specify a backup next hop. Non-P2P interfaces include NBMA and broadcast interfaces.

backup-nexthop *ipv6-address*: Specifies an IPv6 backup next hop.

Examples

Configure node 10 of routing policy **policy1** to set the backup next hop 1::1/64 for the route destined for 100::1/64.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc index 10 permit 100::1 64
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ipv6 address prefix-list abc
[Sysname-route-policy-policy1-10] apply ipv6 fast-reroute backup-nexthop 1::1
```

apply ipv6 next-hop

Use **apply ipv6 next-hop** to set a next hop for IPv6 routes.

Use **undo apply ipv6 next-hop** to restore the default.

Syntax

apply ipv6 next-hop *ipv6-address*

undo apply ipv6 next-hop

Default

No next hop is set for IPv6 routes.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the next hop IPv6 address.

Usage guidelines

If you use this command to set a next hop for redistributed routes, the configuration does not take effect.

Examples

Configure node 10 in **permit** mode for routing policy **policy1** to set next hop 3ffe:506::1 for IPv6 routes matching prefix list 100.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list 100 permit 2::2 64
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ipv6 address prefix-list 100
[Sysname-route-policy-policy1-10] apply ipv6 next-hop 3ffe:506::1
```

display ipv6 prefix-list

Use **display ipv6 prefix-list** to display IPv6 prefix list statistics.

Syntax

display ipv6 prefix-list [**name** *prefix-list-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters. If you do not specify this option, the command displays statistics for all IPv6 prefix lists.

Examples

Display the statistics for all IPv6 prefix lists.

```
<Sysname> display ipv6 prefix-list
Prefix-list6: 666
 Permitted 0
 Denied 0
        index: 10        Permit 6::/64                 ge  66  le  88
```

Table 3 Command output

Field	Description
Prefix-list6	Name of the IPv6 prefix list.
Permitted	Number of routes matching the criterion.
Denied	Number of routes not matching the criterion.
index	Index number of an item.
permit	Match mode of the item: • **Permit**. • **Deny**.
6::/64	IPv6 address and prefix length for matching.
ge	Greater-equal, the lower prefix length limit.
le	Less-equal, the upper prefix length limit.

Related commands

reset ipv6 prefix-list

if-match ipv6

Use **if-match ipv6** to match IPv6 routes whose destination, next hop, or source address matches an ACL or IPv6 prefix list.

Use **undo if-match ipv6** to remove the specified ACL or IPv6 prefix list match criterion.

Syntax

if-match ipv6 { **address** | **next-hop** | **route-source** } { **acl** *ipv6-acl-number* | **prefix-list** *prefix-list-name*

undo if-match ipv6 { **address** | **next-hop** | **route-source** } [**acl** | **prefix-list**]

Default

No ACL or IPv6 prefix list match criterion is configured.

Views

Routing policy node view

Predefined user roles

network-admin

Parameters

address: Matches the destination address of IPv6 routes.

next-hop: Matches the next hop of IPv6 routes.

route-source: Matches the source address of IPv6 routes.

acl *ipv6-acl-number*: Specifies an IPv6 ACL by its number. The value range for the *ipv6-acl-number* argument is 2000 to 3999 for the **address** keyword, and 2000 to 2999 for the **next-hop** and **route-source** keywords.

prefix-list *prefix-list-name*: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters.

Examples

Configure node 10 of routing policy **policy1** to permit routes whose next hop matches IPv6 prefix list **p1**.

```
<Sysname> system-view
[Sysname] route-policy policy1 permit node 10
[Sysname-route-policy-policy1-10] if-match ipv6 next-hop prefix-list p1
```

ipv6 prefix-list

Use **ipv6 prefix-list** to configure an IPv6 prefix list or an item for it.

Use **undo ipv6 prefix-list** to remove an IPv6 prefix list or an item.

Syntax

ipv6 prefix-list *prefix-list-name* [**index** *index-number*] { **deny** | **permit** } *ipv6-address* { *prefix-length* [**greater-equal** *min-prefix-length*] [**less-equal** *max-prefix-length*] | **inverse** *inverse-prefix-length* }

undo ipv6 prefix-list *prefix-list-name* [**index** *index-number*]

Default

No IPv6 prefix lists exist.

Views

System view

Predefined user roles

network-admin

Parameters

prefix-list-name: Specifies an IPv6 prefix list name, a case-sensitive string of 1 to 63 characters.

index *index-number*: Specifies an index number for an IPv6 prefix list item, in the range of 1 to 65535. An item with a smaller index number is matched first. If you do not specify this option, the index number starts from 10 and increments by 10 for each of the consecutive IPv6 prefix list items.

deny: Specifies the deny mode. If a route matches the item, the route is denied without being compared with the next item. If a route does not match the item, the route is compared with the next item.

permit: Specifies the permit mode. If a route matches the item, it passes the IPv6 prefix list. If a route does not match the item, the route is compared with the next item.

ipv6-address: Specifies an IPv6 address.

prefix-length: Specifies the IPv6 prefix length. The value range for the *prefix-length* argument is 0 to 128.

greater-equal *min-mask-length*, **less-equal** *max-mask-length*: Specifies a prefix length range. The **greater-equal** keyword means "greater than or equal to" and the **less-equal** keyword means "less than or equal to."

The prefix length range relation is *mask-length* <= *min-mask-length* <= *max-mask-length* <= 128.

- If only the *min-prefix-length* argument is specified, the prefix length range is [*min-prefix-length*, 128].
- If only the *max-prefix-length* argument is specified, the prefix length range is [*prefix-length*, *max-prefix-length*].
- If both the *min-prefix-length* and *max-prefix-length* arguments are specified, the prefix length range is [*min-prefix-length*, *max-prefix-length*].

inverse *inverse-prefix-length*: Matches IPv6 addresses from the least significant bit to the specified length. The value range for the *inverse-prefix-length* argument is 1 to 128.

Usage guidelines

An IPv6 prefix list is used to filter IPv6 addresses. An IPv6 prefix list can have multiple items, and each of them specifies a range of IPv6 prefixes. The relation between the items is logical OR. A route passing an item passes the IPv6 prefix list. A route passing no item does not pass the IPv6 prefix list.

If the *ipv6-address prefix-length* argument is specified as :: 0, only the default route matches.

To match all routes, configure :: 0 **less-equal** 128.

Examples

Permit IPv6 addresses with a mask length between 32 bits and 64 bits.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc permit :: 0 greater-equal 32 less-equal 64
```

Deny IPv6 addresses with a prefix 3FFE:D00::/32 and a prefix length greater than or equal to 32 bits.

```
<Sysname> system-view
[Sysname] ipv6 prefix-list abc deny 3FFE:D00:: 32 less-equal 128
```

Related commands

display ipv6 prefix-list

reset ipv6 prefix-list

reset ipv6 prefix-list

Use **reset ipv6 prefix-list** to clear IPv6 prefix list statistics.

Syntax

reset ipv6 prefix-list [*prefix-list-name*]

Views

User view

Predefined user roles

network-admin

Parameters

prefix-list-name: Specifies an IPv6 prefix list by its name, a case-sensitive string of 1 to 63 characters. If you do not specify this argument, the command clears statistics for all IPv6 prefix lists.

Examples

Clear the statistics for IPv6 prefix list **abc**.

```
<Sysname> reset ipv6 prefix-list abc
```

Related commands

display ipv6 prefix-list

ipv6 prefix-list

IP Multicast Command Reference

This command reference is applicable to the following switches and software versions:

H3C S5120V2-LI switch series (Release 6308P01 and later)
H3C S3100V3-SI switch series (Release 6309P01 and later)
H3C S5110V2 switch series (Release 6310 and later)
H3C S5110V2-SI switch series (Release 6310 and later)
H3C S5000V3-EI switch series (Release 6310 and later)
H3C S5000V5-EI switch series (Release 6319P01 and later)
H3C S5000E-X switch series (Release 6310 and later)
H3C S5130S-LI switch series (Release 6310 and later)

Preface

This command reference describes IP multicast configuration commands. It covers the commands for configuring IPv4 multicast and IPv6 multicast. With these multicast configuration commands, you can implement efficient point-to-multipoint data transmission in your network.

This preface includes the following topics about the documentation:

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** >

Convention	Description
	Folder.

Symbols

Convention	Description
⚠ **WARNING!**	An alert that calls attention to important information that if not understood or followed can result in personal injury.
△ **CAUTION:**	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
ⓘ **IMPORTANT:**	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

IGMP snooping commands

display igmp-snooping

Use **display igmp-snooping** to display IGMP snooping status.

Syntax

display igmp-snooping [**global** | **vlan** *vlan-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

global: Displays the global IGMP snooping status.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

Usage guidelines

If you do not specify any parameters, this command displays the global IGMP snooping status and the IGMP snooping status in all VLANs.

Examples

Display the global IGMP snooping status and the IGMP snooping status for all VLANs.

```
<Sysname> display igmp-snooping
IGMP snooping information: Global
 Global-enable: Enabled
 Host-aging-time: 260s
 Router-aging-time: 260s
 Max-response-time: 10s
 Last-member-query-interval: 1s
 Report-aggregation: Enabled
 Host-tracking: Disabled
 Dot1p-priority: --

IGMP snooping information: VLAN 1
 IGMP snooping: Enabled
 Drop-unknown: Disabled
 Version: 2
 Host-aging-time: 260s
 Router-aging-time: 260s
 Max-response-time: 10s
 Last-member-query-interval: 1s
 Querier: Enabled (IP: 1.1.1.1, Expires: 00:02:05)
 Querier-election: Enabled
 Query-interval: 125s
 General-query source IP: 1.1.1.1
```

```
 Special-query source IP: 2.2.2.2
 Report source IP: 3.0.0.3
 Leave source IP: 1.0.0.1
 Host-tracking: Disabled
 Dot1p-priority: 2
 Proxy: Disabled

IGMP snooping information: VLAN 10
 IGMP snooping: Enabled
 Drop-unknown: Enabled
 Version: 3
 Host-aging-time: 260s
 Router-aging-time: 260s
 Max-response-time: 10s
 Last-member-query-interval: 1s
 Querier: Enabled (IP: 1.1.1.1, Expires: 00:02:05)
 Querier-election: Enabled
 Query-interval: 125s
 General-query source IP: 1.1.1.1
 Special-query source IP: 2.2.2.2
 Report source IP: 3.0.0.3
 Leave source IP: 1.0.0.1
 Host-tracking: Disabled
 Dot1p-priority: --
 Proxy: Disabled
```

Table 1 Command output

Field	Description
Global-enable	Global IGMP snooping status: • Enabled. • Disabled.
IGMP snooping	IGMP snooping status in a VLAN: • **Enabled**. • **Disabled**. • **Globally enabled**. • **Inactive**—IGMP snooping configuration does not take effect.
Drop-unknown	Status of dropping unknown multicast data: • Enabled. • Disabled.
Version	IGMP snooping version.
Host-aging-time	Aging timer for the dynamic member port.
Router-aging-time	Aging timer for the dynamic router port.
Max-response-time	Maximum response time for IGMP general queries.
Last-member-query-interval	Interval for sending IGMP group-specific queries.
Report-aggregation	Status of IGMP report suppression: • Enabled.

Field	Description
	• Disabled.
Dot1p-priority	802.1p priority for IGMP messages. If the priority is not configured, this field displays two hyphens (--).
Querier	Status of IGMP snooping querier: • Enabled. • Disabled.
(IP: 1.1.1.1, Expires: 00:02:05)	IGMP snooping querier information: • **IP**—IP address of the IGMP snooping querier. • **Expire**—Remaining aging time for the IGMP snooping querier. This field is not displayed if IGMP snooping querier election is disabled.
Querier-election	Status of IGMP snooping querier election: • Enabled. • Disabled.
Query-interval	Interval for sending IGMP general queries.
General-query source IP	Source IP address of IGMP general queries.
Special-query source IP	Source IP address of IGMP group-specific queries.
Report source IP	Source IP address of IGMP reports.
Leave source IP	Source IP address of IGMP leave messages.
Host-tracking	Status of host tracking: • Enabled • Disabled. • Globally enabled.
Proxy	Status of IGMP snooping proxying: • Enabled. • Disabled.

display igmp-snooping group

Use **display igmp-snooping group** to display information about dynamic IGMP snooping group entries.

Syntax

display igmp-snooping group [*group-address* | *source-address*] * [**vlan** *vlan-id*] [**interface** *interface-type interface-number* | [**verbose**] [**slot** *slot-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

group-address: Specifies a multicast group by its IP address in the range of 224.0.1.0 to 239.255.255.255. If you do not specify a multicast group, this command displays information about dynamic IGMP snooping group entries for all multicast groups.

source-address: Specifies a multicast source by its IP address. If you do not specify a multicast source, this command displays information about dynamic IGMP snooping group entries for all multicast sources.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about dynamic IGMP snooping group entries for all VLANs.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays brief information about dynamic IGMP snooping group entries for all interfaces.

verbose: Displays detailed information about dynamic IGMP snooping group entries. If you do not specify this keyword, the command displays brief information about dynamic IGMP snooping group entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about dynamic IGMP snooping group entries for the master device.

Examples

Display brief information about dynamic IGMP snooping group entries for GigabitEthernet 1/0/1.

```
<Sysname> display igmp-snooping group interface gigabitethernet 1/0/1
Total 1 entries.

GE1/0/1:
  VLAN 2: Total 1 entries.
   (0.0.0.0, 224.1.1.1)                    (00:03:23)
```

Display detailed information about dynamic IGMP snooping group entries for VLAN 2.

```
<Sysname> display igmp-snooping group vlan 2 verbose
Total 2 entries.

VLAN 2: Total 2 entries.
  (0.0.0.0, 224.1.1.1)
    Attribute: local port
    FSM information: dummy
    Host slots (0 in total):
    Host ports (1 in total):
      GE1/0/2                               (00:03:23)
  (1.1.1.1, 224.1.1.1)
    Attribute: local port
    FSM information: dummy
    Host ports (1 in total):
      GE1/0/2                               (00:04:04)
```

Table 2 Command output

Field	Description
Total 1 entries	Total number of dynamic IGMP snooping group entries.

Field	Description
VLAN 2: Total 1 entries	Total number of dynamic IGMP snooping group entries in VLAN 2.
(0.0.0.0, 224.1.1.1)	(S, G) entry, where **0.0.0.0** in the S position means all multicast sources.
Attribute	Entry attribute: • **global port**—The entry has a global port. • **local port**—The entry has a port that resides on the member device for which the information is displayed. • **slot**—The entry has ports that reside on other member devices except the member device for which the information is displayed.
FSM information	Finite state machine information of the entry: • **delete**—The entry attributes have been deleted. • **dummy**—The entry is a new temporary entry. • **no info**—No entry exists. • **normal**—The entry is a correct entry.
Host slots (0 in total)	Member IDs and total number of the member devices that have member ports, except for the specified member device or the master device when no member device is specified.
Host ports (1 in total)	Member ports, and the total number of member ports.
(00:03:23)	Remaining aging time for the dynamic member port. For a global port (such as Layer 2 aggregate interfaces), this field is always displayed. For a non-global port, this field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.

Related commands

`reset igmp-snooping group`

display igmp-snooping host-tracking

Use **`display igmp-snooping host-tracking`** to display host tracking information.

Syntax

`display igmp-snooping host-tracking vlan` *`vlan-id`* **`group`** *`group-address`* [**`source`** *`source-address`*] [**`slot`** *`slot-number`*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`vlan` *`vlan-id`*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

`group` *`group-address`*: Specifies a multicast group by its IP address in the range of 224.0.1.0 to 239.255.255.255.

source *source-address*: Specifies a multicast source by its IP address. If you do not specify a multicast source, this command displays host tracking information for all multicast sources.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays host tracking information for the master device.

Examples

Display tracking information for hosts that have joined multicast group 224.1.1.1 in VLAN 2.

```
<Sysname> display igmp-snooping host-tracking vlan 2 group 224.1.1.1
VLAN 2
  (0.0.0.0, 224.1.1.1)
    Port: GE1/0/1
      Host                                    Uptime          Expires
      1.1.1.1                                 00:02:20        00:00:40
      2.2.2.2                                 00:02:21        00:00:39
```

Table 3 Command output

Field	Description
VLAN	VLAN ID.
(0.0.0.0, 224.1.1.1)	(S, G) entry, where 0.0.0.0 in the S position means any multicast sources.
Port	Member port.
Host	IP address of the host.
Uptime	Length of time elapsed since the host joined the multicast group.
Expires	Remaining timeout time for the host. The host timeout time is the same as the aging timer for the port. The timer is reset when the port receives an IGMP report from the host. This field displays **timeout** if the host times out.

Related commands

host-tracking (IGMP-snooping view)

igmp-snooping enable

igmp-snooping host-tracking

display igmp-snooping router-port

Use **display igmp-snooping router-port** to display dynamic router port information.

Syntax

display igmp-snooping router-port [**vlan** *vlan-id*] [**verbose**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

verbose: Displays detailed information. If you do not specify the keyword, this command displays brief information.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays dynamic router port information for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays dynamic router port information for the master device.

Examples

Display brief information about dynamic router ports for VLAN 2.

```
<Sysname> display igmp-snooping router-port vlan 2
VLAN 2:
  Router ports (2 in total):
    GE1/0/1                                (00:01:30)
    GE1/0/2                                (00:00:23)
```

Display detailed information about dynamic router ports for VLAN 2.

```
<Sysname> display igmp-snooping router-port vlan 2 verbose
VLAN 2:
  Router slots (0 in total):
  Router ports (2 in total):
    GE1/0/1                              (00:01:30)
    GE1/0/2                              (00:00:23)
```

Table 4 Command output

Field	Description
VLAN 2	VLAN ID.
Router slots (0 in total)	Member IDs and total number of the member devices that have dynamic router ports, except for the specified member device or the master device when no member device is specified.
Router ports (2 in total)	Dynamic router ports and total number of dynamic router ports.
(00:01:30)	Remaining aging time for the dynamic router port. For a global port, this field is always displayed. For a global port, this field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.

Related commands

reset igmp-snooping router-port

display igmp-snooping static-group

Use **display igmp-snooping static-group** to display information about static IGMP snooping group entries.

Syntax

display igmp-snooping static-group [*group-address* | *source-address*] * [**vlan** *vlan-id*] [**verbose**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

group-address: Specifies a multicast group by its IP address in the range of 224.0.1.0 to 239.255.255.255. If you do not specify a multicast group, this command displays information about static IGMP snooping group entries for all multicast groups.

source-address: Specifies a multicast source by its IP address. If you do not specify a multicast source, this command displays information about static IGMP snooping group entries for all multicast sources.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about static IGMP snooping group entries for all VLANs.

verbose: Displays detailed information about static IGMP snooping group entries. If you do not specify the keyword, this command displays brief information about static IGMP snooping group entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about static IGMP snooping group entries for the master device.

Examples

Display detailed information about static IGMP snooping group entries for VLAN 2.

```
<Sysname> display igmp-snooping static-group vlan 2 verbose
Total 1 entries.

VLAN 2: Total 1 entries.
  (0.0.0.0, 224.1.1.1)
    Attribute: local port
    FSM information: dummy
    Host slots (0 in total):
    Host ports (1 in total):
      GE1/0/2
```

Table 5 Command output

Field	Description
Total 1 entries	Total number of static IGMP snooping group entries.
VLAN 2: Total 1 entries	Total number of static IGMP snooping group entries in VLAN 2.
(0.0.0.0, 224.1.1.1)	(S, G) entry, where **0.0.0.0** in the S position means all multicast sources.
Attribute	Entry attribute: • **global port**—The entry has a global port. • **local port**—The entry has a port that resides on the member device for which the information is displayed. • **slot**—The entry has ports that reside on other member devices except the member device for which the information is displayed.
FSM information	Finite state machine information of the entry: • **delete**—The entry attributes have been deleted.

Field	Description
	• **dummy**—The entry is a new temporary entry. • **no info**—No entry exists. • **normal**—The entry is a correct entry.
Host slots (0 in total)	Member IDs and total number of the member devices that have member ports, except for the specified member device or the master device when no member device is specified.
Host ports (1 in total)	Member ports and total number of member ports.

display igmp-snooping static-router-port

Use **display igmp-snooping static-router-port** to display static router port information.

Syntax

display igmp-snooping static-router-port [**vlan** *vlan-id*] [**verbose**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

verbose: Displays detailed information about static router ports. If you do not specify this keyword, the command displays brief information about static router ports.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays static router port information for the master device.

Examples

Display brief information about static router ports for VLAN 2.

```
<Sysname> display igmp-snooping static-router-port vlan 2
VLAN 2:
  Router ports (2 in total):
    GE1/0/1
    GE1/0/2
```

Display detailed information about static router ports for VLAN 2.

```
<Sysname> display igmp-snooping static-router-port vlan 2 verbose
VLAN 2:
  Router slots (0 in total):
  Router ports (2 in total):
    GE1/0/1
    GE1/0/2
```

Table 6 Command output

Field	Description
VLAN 2	VLAN ID.
Router slots (0 in total)	Member IDs and total number of the member devices that have static router ports, except for the specified member device or the master device when no member device is specified.
Router ports (2 in total)	Static router ports and total number of static router ports.

display igmp-snooping statistics

Use **display igmp-snooping statistics** to display statistics for the IGMP messages and PIMv2 hello messages learned through IGMP snooping.

Syntax

display igmp-snooping statistics

Examples

Display statistics for the IGMP messages and PIMv2 hello messages learned through IGMP snooping.

```
<Sysname> display igmp-snooping statistics
Received IGMP general queries:  0
Received IGMPv1 reports:  0
Received IGMPv2 reports:  19
Received IGMP leaves:  0
Received IGMPv2 specific queries:  0
Sent     IGMPv2 specific queries:  0
Received IGMPv3 reports:  1
Received IGMPv3 reports with right and wrong records:  0
Received IGMPv3 specific queries:  0
Received IGMPv3 specific sg queries:  0
Sent     IGMPv3 specific queries:  0
Sent     IGMPv3 specific sg queries:  0
Received PIMv2 hello:  0
Received error IGMP messages:  19
```

Table 7 Command output

Field	Description
general queries	Number of IGMP general queries.
specific queries	Number of IGMP group-specific queries.
reports	Number of IGMP reports.

Field	Description
leaves	Number of IGMP leave messages.
reports with right and wrong records	Number of IGMP reports with correct and incorrect records.
specific sg queries	Number of IGMP group-and-source-specific queries.
PIMv2 hello	Number of PIMv2 hello messages.
error IGMP messages	Number of IGMP messages with errors.

reset igmp-snooping statistics

display l2-multicast fast-forwarding cache

Use **display l2-multicast fast-forwarding cache** to display Layer 2 multicast fast forwarding entries.

Syntax

display l2-multicast fast-forwarding cache [**vlan** *vlan-id*] [*source-address* | *group-address*] * [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

source-address: Specifies a multicast source address. If you do not specify a multicast source, this command displays Layer 2 multicast fast forwarding entries for all multicast sources.

group-address: Specifies a multicast group address in the range of 224.0.1.0 to 239.255.255.255. If you do not specify a multicast group, this command displays Layer 2 multicast fast forwarding entries for all multicast groups.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays Layer 2 multicast fast forwarding entries for the master device.

Examples

Display Layer 2 multicast fast forwarding entries.

```
<Sysname> display l2-multicast fast-forwarding cache
Total 1 entries, 1 matched

(10.1.1.2,225.1.1.1)
     Status      : Enable                VLAN            : 1
     Source port : 9876                  Destination port: 5432
     Protocol    : 17                    Flag            : 0x2
     Ingress port: GigabitEthernet1/0/2
     List of 1 egress ports:
```

```
        GigabitEthernet1/0/3
        Status: Enable                Flag: 0x10
```

Table 8 Command output

Field	Description
Total 1 entries, 1 matched	Total number of (S, G) entries in the Layer 2 multicast fast forwarding table, and the total number of matching entries.
(10.1.1.2, 225.1.1.1)	(S, G) entry in the Layer 2 multicast fast forwarding table.
Protocol	Protocol number.
VLAN	VLAN ID.
Flag	Flag for the (S, G) entry or the outgoing port. This field displays one flag or the sum of multiple flags. In this example, the value 0x2 means that the entry has only one flag 0x2. The following flags are available for an entry: • **0x1**—The entry is created because of packets passed through between cards. • **0x2**—The entry is added by multicast forwarding. The following flags are available for an outgoing interface: • **0x1**—The port is added to the entry because of packets passed through between cards. • **0x2**—The port is added to an existing entry. • **0x10**—The port is associated with the entry. • **0x20**—The port is to be deleted.
Status	Status of the (S, G) entry or the outgoing port: • **Enabled**—Available. • **Disabled**—Unavailable.
Ingress port	Incoming port of the (S, G) entry.
List of 1 egress ports	Outgoing port list of the (S, G) entry.

Parameters

group *group-address*: Specifies a multicast group by its IP address. If you do not specify a multicast group, this command displays information about all Layer 2 IP multicast groups.

source *source-address*: Specifies a multicast source by its IP address. If you do not specify a multicast source, this command displays information about Layer 2 IP multicast groups for all multicast sources.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about Layer 2 IP multicast groups for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about Layer 2 IP multicast groups for the master device.

Examples

Display information about Layer 2 IP multicast groups for VLAN 2.

```
<Sysname> display l2-multicast ip vlan 2
Total 1 entries.

VLAN 2: Total 1 entries.
  (0.0.0.0, 224.1.1.1)
    Attribute: static, success
    Host ports (1 in total):
      GE1/0/1                                (S, SUC)
```

Table 9 Command output

Field	Description
Total 1 entries	Total number of Layer 2 IP multicast groups.
VLAN 2: Total 1 entries	Total number of Layer 2 IP multicast groups in VLAN 2.
(0.0.0.0, 224.1.1.1)	(S, G) entry, where **0.0.0.0** in the S position means all multicast sources.
Attribute	Entry attribute: • **dynamic**—The entry is created by a dynamic protocol. • **static**—The entry is created by a static protocol. • **pim**—The entry is created by PIM. • **kernel**—The entry is obtained from the kernel. • **success**—Processing has succeeded. • **fail**—Processing has failed.
Host ports (1 in total)	Member ports and total number of member ports.
(S, SUC)	Port attribute: • **D**—Dynamic port. • **S**—Static port. • **P**—PIM port. • **K**—Port obtained from the kernel. • **R**—Port learned from (*, *) entries. • **W**—Port learned from (*, G) entries. • **SUC**—Processing has succeeded. • **F**—Processing has failed.

display l2-multicast ip forwarding

Use **display l2-multicast ip forwarding** to display Layer 2 multicast IP forwarding entries.

Syntax

display l2-multicast ip forwarding [**group** *group-address* | **source** *source-address*] * [**vlan** *vlan-id*] [**slot** *slot-number*]

Views

Predefined user roles

network-admin

network-operator

Parameters

mac-address: Specifies a MAC multicast group by its multicast MAC address. If you do not specify a MAC multicast group, this command displays information about all Layer 2 MAC multicast groups.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about Layer 2 MAC multicast groups for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about Layer 2 MAC multicast groups for the master device.

Examples

Display information about Layer 2 MAC multicast groups for VLAN 2.

```
<Sysname> display l2-multicast mac vlan 2
Total 1 entries.

VLAN 2: Total 1 entries.
  MAC group address: 0100-5e01-0101
    Attribute: success
    Host ports (1 in total):
      GE1/0/1
```

Table 11 Command output

Field	Description
Total 1 entries	Total number of Layer 2 MAC multicast groups.
VLAN 2: Total 1 entries	Total number of Layer 2 MAC multicast groups in VLAN 2.
MAC group address	Address of the MAC multicast group.
Attribute	Entry attribute: • **success**—Processing has succeeded. • **fail**—Processing has failed.
Host ports (1 in total)	Member ports and total number of member ports.

display l2-multicast mac forwarding

Use **display l2-multicast mac forwarding** to display Layer 2 multicast MAC forwarding entries.

Syntax

display l2-multicast mac forwarding [*mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]

Views

network-admin

network-operator

Parameters

mac-address: Specifies a MAC multicast group by its MAC address. If you do not specify a MAC multicast group, this command displays Layer 2 multicast MAC forwarding entries for all MAC multicast groups.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays Layer 2 multicast MAC forwarding entries for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays Layer 2 multicast MAC group entries for the master device.

Examples

Display Layer 2 multicast MAC forwarding entries for VLAN 2.

```
<Sysname> display l2-multicast mac forwarding vlan 2
Total 1 entries.

VLAN 2: Total 1 entries.
  MAC group address: 0100-5e01-0101
    Host ports (3 in total):
      GigabitEthernet1/0/1
      GigabitEthernet1/0/2
      GigabitEthernet1/0/3
```

Table 12 Command output

Field	Description
Total 1 entries	Total number of Layer 2 multicast MAC forwarding entries.
VLAN 2: Total 1 entries	Total number of Layer 2 multicast MAC forwarding entries in VLAN 2.
MAC group address	Address of the MAC multicast group.
Host ports (3 in total)	Member ports and total number of member ports.

display mac-address [multicast]

Use **display mac-address** [**multicast**] to display static multicast MAC address entries.

Syntax

display mac-address [*mac-address* [**vlan** *vlan-id*] | [**multicast**] [**vlan** *vlan-id*] [**count**]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

mac-address: Specifies a multicast MAC address. The MAC address can be any legal multicast MAC address except 0100-5Exx-xxxx and 3333-xxxx-xxxx, where "x" represents a hexadecimal number in the range of 0 to F.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays MAC address entries for all VLANs.

multicast: Specifies static multicast MAC address entries.

count: Specifies the number of MAC address entries. If you specify this keyword, the command displays the number of matching MAC address entries. If you do not specify this keyword, the command displays the contents of the matching entries rather than the entry count.

Usage guidelines

If you do not specify any parameters, this command displays all MAC address table entries, including unicast MAC address entries and static multicast MAC address entries.

Examples

Display static multicast MAC address entries for VLAN 2.

```
<Sysname> display mac-address multicast vlan 2
MAC Address      VLAN ID    State            Port/NickName            Aging
0100-0001-0001   2          Multicast        GE1/0/1                  N
```

Display the number of static multicast MAC address entries.

```
<Sysname> display mac-address multicast count
1 mac address(es) found.
```

Table 13 Command output

Field	Description
MAC address	MAC address of a multicast group.
VLAN ID	ID of the VLAN to which the network device identified by the MAC address belongs.
State	Status of the MAC address. If the multicast MAC address entry is static, this field displays **Multicast**.
Port/NickName	Outgoing ports or nickname of the Egress RB in a TRILL network for the packet that is sent to the MAC address in this MAC address entry. TRILL is not supported in the current software version.
Aging	Aging timer state. If this entry never expires, this field displays **N**.
1 mac address(es) found	One static multicast MAC address entry is found.

mac-address multicast

dot1p-priority (IGMP-snooping view)

Use **dot1p-priority** to set the 802.1p priority for IGMP messages globally.

Use **undo dot1p-priority** to restore the default.

Syntax

dot1p-priority *priority*

undo dot1p-priority

Default

The global 802.1p priority is 6 for IGMP messages.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

priority: Specifies an 802.1p priority for IGMP messages, in the range of 0 to 7. The greater the value, the higher the priority.

Usage guidelines

You can set the 802.1p priority globally for all VLANs in IGMP-snooping view or for a VLAN in VLAN view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

Examples

Set the 802.1p priority for IGMP messages to 3 globally.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] dot1p-priority 3
```

Related commands

igmp-snooping dot1p-priority

dscp

Use **dscp** to set the DSCP value for outgoing IGMP protocol packets.

Use **undo dscp** to restore the default.

Syntax

dscp *dscp-value*

undo dscp

Default

The DSCP value is 48 for outgoing IGMP protocol packets.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

dscp-value: Specifies a DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value is carried in the ToS field of an IP packet to determine the transmission priority of the packet. A greater DSCP value represents a higher priority.

Examples

Set the DSCP value to 63 for outgoing IGMP protocol packets.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] dscp 63
```

enable (IGMP-snooping view)

Use **enable** to enable IGMP snooping for VLANs.

Use **undo enable** to disable IGMP snooping for VLANs.

Syntax

enable vlan *vlan-list*

undo enable vlan *vlan-list*

Default

IGMP snooping status in a VLAN is consistent with the global IGMP snooping status.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094.

Usage guidelines

You must enable the IGMP snooping feature by using the **igmp-snooping** command before you enable IGMP snooping for VLANs.

You can enable IGMP snooping for multiple VLANs by using this command in IGMP-snooping view or for a VLAN by using the **igmp-snooping enable** command in VLAN view. The configuration in IGMP-snooping view has the same priority as the configuration in VLAN view, and the most recent configuration takes effect.

Examples

Enable the IGMP snooping feature, and then enable IGMP snooping for VLAN 2 through VLAN 10.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] enable vlan 2 to 10
```

Related commands

igmp-snooping

igmp-snooping enable

entry-limit (IGMP-snooping view)

Use **entry-limit** to globally set the maximum number of IGMP snooping forwarding entries, including dynamic entries and static entries.

Use **undo entry-limit** to restore the default.

Syntax

entry-limit *limit*

undo entry-limit

Default

The maximum number of IGMP snooping forwarding entries is 4294967295.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

limit: Specifies the maximum number of IGMP snooping forwarding entries, in the range of 0 to 4294967295.

Examples

Set the global maximum number of IGMP snooping forwarding entries to 512.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] entry-limit 512
```

fast-leave (IGMP-snooping view)

Use **fast-leave** to enable fast-leave processing globally.

Use **undo fast-leave** to disable fast-leave processing globally.

Syntax

fast-leave [**vlan** *vlan-list*]

undo fast-leave [**vlan** *vlan-list*]

Default

Fast-leave processing is disabled.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

The fast-leave processing feature enables the device to immediately remove a port from the forwarding entry for a multicast group when the port receives a leave message.

You can enable fast-leave processing globally for all ports in IGMP-snooping view or for a port in interface view. For a port, the port-specific configuration takes priority over the global configuration.

Examples

Globally enable fast-leave processing for VLAN 2.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] fast-leave vlan 2
```

Related commands

igmp-snooping fast-leave

global-enable (IGMP-snooping view)

Use **global-enable** to enable IGMP snooping globally.

Use **undo global-enable** to disable IGMP snooping globally.

Syntax

global-enable

undo global-enable

Default

IGMP snooping is disabled globally.

Views

IGMP-snooping view

Predefined user roles

network-admin

Usage guidelines

To configure other IGMP snooping features for VLANs, you must enable IGMP snooping for the specific VLANs even though IGMP snooping is enabled globally.

Examples

Enable IGMP snooping globally.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] global-enable
```

Related commands

enable (IGMP-snooping view)

igmp-snooping

igmp-snooping disable

igmp-snooping enable

group-policy (IGMP-snooping view)

Use **group-policy** to globally configure a multicast group policy to control the multicast groups that hosts can join.

Use **undo group-policy** to globally delete multicast group policies.

Syntax

group-policy *ipv4-acl-number* [**vlan** *vlan-list*]

undo group-policy [**vlan** *vlan-list*]

Default

No multicast group policies exist. Hosts can join any multicast groups.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

ipv4-acl-number: Specifies an IPv4 basic or advanced ACL by its number in the range of 2000 to 3999. Hosts can join only the multicast groups that the ACL permits. If the ACL does not exist or does not have valid rules, hosts cannot join multicast groups.

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

A multicast group policy filters IGMP reports to control the multicast groups that hosts can join.

This command does not take effect on static member ports, because static member ports do not send IGMP reports.

You can configure a multicast group policy globally for all ports in IGMP-snooping view or for a port in interface view. For a port, the port-specific configuration takes priority over the global configuration.

When you configure a rule in the IPv4 ACL, follow these restrictions and guidelines:

- In a basic ACL, the **source** *source-address source-wildcard* option specifies a multicast group address.
- In an advanced ACL, the **source** *source-address source-wildcard* option specifies a multicast source address. The **destination** *dest-address dest-wildcard* option specifies a multicast group address.

  To match the following IGMP reports, set the **source** *source-address source-wildcard* option to 0.0.0.0:

  - IGMPv1 and IGMPv2 reports.
  - IGMPv3 IS_EX and IGMPv3 TO_EX reports that do not carry multicast source addresses.
- Among the other optional parameters, only the **fragment** keyword and the **time-range** *time-range-name* option take effect.

You can configure different ACLs for all ports in different VLANs. If you configure multiple ACLs for all ports in the same VLAN, the most recent configuration takes effect.

Examples

Configure a multicast group policy for VLAN 2 so that hosts in VLAN 2 can join only multicast group 225.1.1.1.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule permit source 225.1.1.1 0
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] igmp-snooping
[Sysname-igmp-snooping] group-policy 2000 vlan 2
```

Related commands

igmp-snooping group-policy

host-aging-time (IGMP-snooping view)

Use **host-aging-time** to set the aging timer for dynamic member ports globally.

Use **undo host-aging-time** to restore the default.

Syntax

host-aging-time *seconds*

undo host-aging-time

Default

The aging timer for dynamic member ports is 260 seconds.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging timer for dynamic member ports, in the range of 1 to 8097894 seconds.

Usage guidelines

You can set the timer globally for all VLANs in IGMP-snooping view or for a VLAN in VLAN view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

To avoid mistakenly deleting multicast group members, set the aging timer for dynamic member ports to be greater than the value calculated by using the following formula:

[IGMP general query interval] + [maximum response time for IGMP general queries]

As a best practice, set the aging timer of dynamic member ports to the value calculated by using the following formula:

[IGMP general query interval] × 2 + [maximum response time for IGMP general queries]

Examples

Set the global aging timer for dynamic member ports to 300 seconds.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] host-aging-time 300
```

Related commands

enable (IGMP-snooping view)

igmp-snooping enable

igmp-snooping disable

igmp-snooping access-policy

Use **igmp-snooping access-policy** to configure an IGMP snooping access control policy.

Use **undo igmp-snooping access-policy** to delete an IGMP snooping access control policy.

Syntax

igmp-snooping access-policy *ipv4-acl-number*

undo igmp-snooping access-policy { *ipv4-acl-number* | **all** }

Default

No IGMP snooping access control policies exist. Multicast users can join or leave any multicast groups.

Views

User profile view

Predefined user roles

network-admin

Parameters

ipv4-acl-number: Specifies an IPv4 basic or advanced ACL by its number, in the range of 2000 to 3999. Multicast users can join or leave only the multicast groups that the ACL permits. If the ACL does not exist or does not have valid rules, multicast users cannot join or leave any multicast groups.

all: Specifies all IGMP snooping access control policies.

Usage guidelines

You can repeat this command to configure multiple IGMP snooping access control policies. A multicast user can join or leave a multicast group if its IGMP report or leave message is permitted by one of the IGMP snooping access control policies.

When you configure a rule in the IPv4 ACL, follow these restrictions and guidelines:

- In a basic ACL, the **source** *source-address source-wildcard* option specifies a multicast group address.
- In an advanced ACL, the **source** *source-address source-wildcard* option specifies a multicast source address. The **destination** *dest-address dest-wildcard* option specifies a multicast group address.

  To match the following IGMP messages, set the **source** *source-address source-wildcard* option to 0.0.0.0:

    - IGMPv1 report and leave messages.
    - IGMPv2 report and leave messages.
    - IGMPv3 IS_EX and IGMPv3 TO_EX reports that do not carry multicast source addresses.
- Among the other optional parameters, only the **fragment** keyword and the **time-range** *time-range-name* option take effect.

Examples

In user profile **abc**, configure an IGMP snooping access control policy to allow multicast users to join or leave only multicast group 225.1.1.1.

```
<Sysname> system-view
[Sysname] acl basic 2001
[Sysname-acl-ipv4-basic-2001] rule permit source 225.1.1.1 0
[Sysname-acl-ipv4-basic-2001] quit
[Sysname] user-profile abc
[Sysname-user-profile-abc] igmp-snooping access-policy 2001
```

igmp-snooping dot1p-priority

Use **igmp-snooping dot1p-priority** to set the 802.1p priority for IGMP messages in a VLAN.

Use **undo igmp-snooping dot1p-priority** to restore the default.

Syntax

igmp-snooping dot1p-priority *priority*

undo igmp-snooping dot1p-priority

Default

The 802.1p priority is 6 for IGMP messages in a VLAN.

Views

VLAN view

Predefined user roles

network-admin

Parameters

priority: Specifies an 802.1p priority for IGMP messages, in the range of 0 to 7. The greater the value, the higher the priority.

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command.

You can set the 802.1p priority for a VLAN in VLAN view or globally for all VLANs in IGMP-snooping view. The VLAN-specific configuration takes priority over the global configuration.

Examples

In VLAN 2, enable IGMP snooping, and set the 802.1p priority for IGMP messages to 3.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping dot1p-priority 3
```

Related commands

igmp-snooping enable

igmp-snooping drop-unknown

Use **igmp-snooping drop-unknown** to enable dropping unknown multicast data packets for a VLAN.

Use **undo igmp-snooping drop-unknown** to disable dropping unknown multicast data packets for a VLAN.

Syntax

igmp-snooping drop-unknown

undo igmp-snooping drop-unknown

Default

Dropping unknown multicast data packets is disabled. Unknown multicast data packets are flooded.

Views

VLAN view

Predefined user roles

network-admin

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command.

Examples

In VLAN 2, enable IGMP snooping, and enable dropping unknown multicast data packets.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping drop-unknown
```

Related commands

igmp-snooping enable

igmp-snooping { disable | enable }

Use **igmp-snooping enable** to enable IGMP snooping for a VLAN.

Use **igmp-snooping disable** to disable IGMP snooping for a VLAN.

Use **undo igmp-snooping** to restore the IGMP snooping status in a VLAN to the global IGMP snooping status.

Syntax

igmp-snooping { **disable** | **enable** }

undo igmp-snooping

Default

The IGMP snooping status in a VLAN is consistent with the global IGMP snooping status.

Views

VLAN view

Predefined user roles

network-admin

Usage guidelines

You must enable the IGMP snooping feature by using the **igmp-snooping** command before you enable IGMP snooping for a VLAN.

You can enable IGMP snooping for a VLAN by using this command in VLAN view or for multiple VLANs by using the **enable** command in IGMP-snooping view. The configuration in VLAN view has the same priority as the configuration in IGMP-snooping view, and the most recent configuration takes effect.

Examples

Enable the IGMP snooping feature, and then enable IGMP snooping for VLAN 2.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
```

Disable IGMP snooping for VLAN 2.

```
<Sysname> system-view
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping disable
```

Related commands

enable (IGMP-snooping view)

igmp-snooping fast-leave

Use **igmp-snooping fast-leave** to enable fast-leave processing on a port.

Use **undo igmp-snooping fast-leave** to disable fast-leave processing on a port.

Syntax

igmp-snooping fast-leave [**vlan** *vlan-list*]

undo igmp-snooping fast-leave [**vlan** *vlan-list*]

Default

Fast-leave processing is disabled on a port.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

The fast-leave processing feature enables the device to immediately remove a port from the forwarding entry for a multicast group when the port receives a leave message.

You can enable fast-leave processing for a port in interface view or globally for all ports in IGMP-snooping view. For a port, the port-specific configuration takes priority over the global configuration.

Examples

Enable fast-leave processing for VLAN 2 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping fast-leave vlan 2
```

Related commands

igmp-snooping general-query source-ip

Use **igmp-snooping general-query source-ip** to configure the source IP address for IGMP general queries.

Use **undo igmp-snooping general-query source-ip** to restore the default.

Syntax

igmp-snooping general-query source-ip *ip-address*

undo igmp-snooping general-query source-ip

Default

In a VLAN, the source IP address of IGMP general queries is the IP address of the current VLAN interface. If the current VLAN interface does not have an IP address, the source IP address is 0.0.0.0.

Views

VLAN view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the source IP address for IGMP general queries.

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command.

Examples

In VLAN 2, enable IGMP snooping, and specify 10.1.1.1 as the source IP address of IGMP general queries.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping general-query source-ip 10.1.1.1
```

igmp-snooping group-limit

Use **igmp-snooping group-limit** to set the maximum number of multicast groups that a port can join.

Use **undo igmp-snooping group-limit** to remove the limit on the maximum number of multicast groups that a port can join.

Syntax

igmp-snooping group-limit *limit* [**vlan** *vlan-list*]

undo igmp-snooping group-limit [**vlan** *vlan-list*]

Default

No limit is placed on the maximum number of multicast groups that a port can join.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

limit: Specifies the maximum number of multicast groups that a port can join, in the range of 0 to 4294967295.

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

This command takes effect only on the multicast groups that a port joins dynamically.

Examples

On GigabitEthernet 1/0/1, set the maximum number of multicast groups the port can join in VLAN 2 to 10.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping group-limit 10 vlan 2
```

igmp-snooping group-policy

Use **igmp-snooping group-policy** to configure a multicast group policy on a port to control the multicast groups that hosts attached to the port can join.

Use **undo igmp-snooping group-policy** to delete multicast group policies on a port.

Syntax

igmp-snooping group-policy *ipv4-acl-number* [**vlan** *vlan-list*]

undo igmp-snooping group-policy [**vlan** *vlan-list*]

Default

No multicast group polices exist on a port. Hosts attached to the port can join any multicast groups.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

ipv4-acl-number: Specifies an IPv4 basic or advanced ACL by its number in the range of 2000 to 3999. Hosts can join only the multicast groups that the ACL permits. If the ACL does not exist or does not have valid rules, hosts cannot join multicast groups.

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

A multicast group policy filters IGMP reports to control the multicast groups that hosts can join.

This command does not take effect on static member ports, because static member ports do not send IGMP reports.

You can configure a multicast group policy for a port in interface view or globally for all ports in IGMP-snooping view. For a port, the port-specific configuration takes priority over the global configuration.

When you configure a rule in the IPv4 ACL, follow these restrictions and guidelines:

- In a basic ACL, the **source** *source-address source-wildcard* option specifies a multicast group address.
- In an advanced ACL, the **source** *source-address source-wildcard* option specifies a multicast source address. The **destination** *dest-address dest-wildcard* option specifies a multicast group address.

  To match the following IGMP reports, set the **source** *source-address source-wildcard* option to 0.0.0.0:

  - IGMPv1 and IGMPv2 reports.
  - IGMPv3 IS_EX and IGMPv3 TO_EX reports that do not carry multicast source addresses.
- Among the other optional parameters, only the **fragment** keyword and the **time-range** *time-range-name* option take effect.

You can configure different ACLs on a port for different VLANs. If you configure multiple ACLs on a port for the same VLAN, the most recent configuration takes effect.

Examples

On GigabitEthernet 1/0/1, configure a multicast group policy for VLAN 2 so that hosts in VLAN 2 can join only multicast group 225.1.1.1.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule permit source 225.1.1.1 0
[Sysname-acl-ipv4-basic-2000] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping group-policy 2000 vlan 2
```

Related commands

group-policy (IGMP-snooping view)

igmp-snooping host-aging-time

Use **igmp-snooping host-aging-time** to set the aging timer for dynamic member ports in a VLAN.

Use **undo igmp-snooping host-aging-time** to restore the default.

Syntax

igmp-snooping host-aging-time *seconds*

undo igmp-snooping host-aging-time

Default

The aging timer for dynamic member ports is 260 seconds.

Views

VLAN view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging timer for dynamic member ports, in the range of 1 to 8097894 seconds.

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command.

You can set the timer for a VLAN in VLAN view or globally for all VLANs in IGMP-snooping view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

To avoid mistakenly deleting multicast group members, set the aging timer for dynamic member ports to be greater than the value calculated by using the following formula:

[IGMP general query interval] + [maximum response time for IGMP general queries]

As a best practice, set the aging timer of dynamic member ports to the value calculated by using the following formula:

[IGMP general query interval] × 2 + [maximum response time for IGMP general queries]

Examples

In VLAN 2, enable IGMP snooping, and set the aging timer for dynamic member ports to 300 seconds.

```
<Sysname> system-view
```

```
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping host-aging-time 300
```

Related commands

enable (IGMP-snooping view)

igmp-snooping enable

igmp-snooping host-join

Use **igmp-snooping host-join** to configure a port as a simulated member host for a multicast group.

Use **undo igmp-snooping host-join** to remove the configuration of a simulated member host for a multicast group.

Syntax

igmp-snooping host-join *group-address* [**source-ip** *source-address*] **vlan** *vlan-id*

undo igmp-snooping host-join { *group-address* [**source-ip** *source-address*] **vlan** *vlan-id* | **all** }

Default

A port is not configured as a simulated member host for multicast groups.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

group-address: Specifies a multicast group in the range of 224.0.1.0 to 239.255.255.255.

source-ip *source-address*: Specifies a multicast source by its IP address. If you specify a multicast source, this command configures the port as a simulated member host for a multicast source and group. If you do not specify a multicast source, this command configures the port as a simulated member host for a multicast group. This option takes effect on IGMPv3 snooping devices.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

all: Specifies all multicast groups.

Usage guidelines

The version of IGMP running on a simulated member host is the same as the version of IGMP snooping running on the port. The port ages out in the same way as a dynamic member port.

Examples

Configure GigabitEthernet 1/0/1 as a simulated member host of the multicast source and group (1.1.1.1, 232.1.1.1) in VLAN 2.

```
<Sysname> system-view
```

```
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping version 3
[Sysname-vlan2] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping host-join 232.1.1.1 source-ip 1.1.1.1 vlan
2
```

igmp-snooping host-tracking

Use **igmp-snooping host-tracking** to enable host tracking for a VLAN.

Use **undo igmp-snooping host-tracking** to disable host tracking for a VLAN.

Syntax

igmp-snooping host-tracking

undo igmp-snooping host-tracking

Default

Host tracking is disabled.

Views

VLAN view

Predefined user roles

network-admin

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command for the VLAN.

You can enable host tracking for a VLAN in VLAN view or globally for all VLANs in IGMP-snooping view. For a VLAN, the VLAN-specific configuration has the same priority as the global configuration.

Examples

In VLAN 2, enable IGMP snooping, and then enable host tracking.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable

```

Related commands

enable (IGMP-snooping view)

igmp-snooping enable

igmp-snooping router-aging-time

Use **igmp-snooping router-aging-time** to set the aging timer for dynamic router ports in a VLAN.

Use **undo igmp-snooping router-aging-time** to restore the default.

Syntax

igmp-snooping router-aging-time *seconds*

undo igmp-snooping router-aging-time

Default

The aging timer for dynamic router ports is 260 seconds.

Views

VLAN view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging timer for dynamic router ports, in the range of 1 to 8097894 seconds.

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command.

You can set the timer for a VLAN in VLAN view or globally for all VLANs in IGMP-snooping view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

Examples

In VLAN 2, enable IGMP snooping, and set the aging timer for dynamic router ports to 100 seconds.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping router-aging-time 100
```

igmp-snooping router-port-deny

Use **igmp-snooping router-port-deny** to disable a port from becoming a dynamic router port.

Use **undo igmp-snooping router-port-deny** to allow a port to become a dynamic router port.

Syntax

igmp-snooping router-port-deny [**vlan** *vlan-list*]

undo igmp-snooping router-port-deny [**vlan** *vlan-list*]

Default

A port is allowed to become a dynamic router port.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you specify VLANs, this command takes effect only when the port belongs to the specified VLANs. If you do not specify a VLAN, this command takes effect on all VLANs to which the port belongs.

Examples

Disable GigabitEthernet 1/0/1 from becoming a dynamic router port in VLAN 2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping router-port-deny vlan 2
```

igmp-snooping source-deny

Use **igmp-snooping source-deny** to enable multicast source port filtering on a port to discard all multicast data packets.

Use **undo igmp-snooping source-deny** to disable multicast source port filtering on a port.

Syntax

igmp-snooping source-deny

undo igmp-snooping source-deny

Default

Multicast source port filtering is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

You can enable this feature for a port in interface view or for the specified ports in IGMP-snooping view. For a port, the configuration in interface view has the same priority as the configuration in IGMP-snooping view, and the most recent configuration takes effect.

Examples

Enable source port filtering for multicast data on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping source-deny
```

Related commands

source-deny (IGMP-snooping view)

igmp-snooping special-query source-ip

Use **igmp-snooping special-query source-ip** to configure the source IP address for IGMP group-specific queries.

Use **undo igmp-snooping special-query source-ip** to restore the default.

Syntax

igmp-snooping special-query source-ip *ip-address*

undo igmp-snooping special-query source-ip

Default

In a VLAN, the source IP address of IGMP group-specific queries is one of the following:

- The source address of IGMP group-specific queries if the IGMP snooping querier of the VLAN has received IGMP general queries.
- The IP address of the current VLAN interface if the IGMP snooping querier does not receive an IGMP general query.
- 0.0.0.0 if the IGMP snooping querier does not receive an IGMP general query and the current VLAN interface does not have an IP address.

Views

VLAN view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the source IP address for IGMP group-specific queries.

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command.

Examples

In VLAN 2, enable IGMP snooping, and specify 10.1.1.1 as the source IP address of IGMP group-specific queries.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping special-query source-ip 10.1.1.1
```

Related commands

enable (IGMP-snooping view)

igmp-snooping enable

igmp-snooping static-group

Use **igmp-snooping static-group** to configure a port as a static member port of a multicast group.

Use **undo igmp-snooping static-group** to remove the configuration of static member ports.

Syntax

igmp-snooping static-group *group-address* [**source-ip** *source-address*] **vlan** *vlan-id*

undo igmp-snooping static-group { *group-address* [**source-ip** *source-address*] **vlan** *vlan-id* | **all** }

Default

A port is not a static member port of a multicast group.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

group-address: Specifies a multicast group address in the range of 224.0.1.0 to 239.255.255.255.

source-ip *source-address*: Specifies a multicast source by its IP address. If you specify a multicast source, this command configures the port as a static member port for a multicast source and group. If you do not specify a multicast source, this command configures the port as a static member port for a multicast group. This option takes effect on IGMPv3 snooping devices.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

all: Specifies all multicast groups.

Examples

Configure GigabitEthernet 1/0/1 as a static member port of the multicast source and group (1.1.1.1, 225.0.0.1) in VLAN 2.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping version 3
[Sysname-vlan2] quit
[Sysname] interface GigabitEthernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping static-group 225.0.0.1 source-ip 1.1.1.1
vlan 2
```

igmp-snooping static-router-port

Use **igmp-snooping static-router-port** to configure a port as a static router port.

Use **undo igmp-snooping static-router-port** to remove the configuration of static router ports.

Syntax

igmp-snooping static-router-port vlan *vlan-id*

undo igmp-snooping static-router-port { **all** | **vlan** *vlan-id* }

Default

A port is not a static router port.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

all: Specifies all VLANs.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

Examples

Configure GigabitEthernet 1/0/1 as a static router port in VLAN 2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] igmp-snooping static-router-port vlan 2
```

igmp-snooping version

Use **igmp-snooping version** to specify an IGMP snooping version for a VLAN.

Use **undo igmp-snooping version** to restore the default.

Syntax

igmp-snooping version *version-number*

undo igmp-snooping version

Default

The IGMP snooping version in a VLAN is 2.

Views

VLAN view

Predefined user roles

network-admin

Parameters

version-number: Specifies an IGMP snooping version, 2 or 3.

Usage guidelines

You must enable IGMP snooping for a VLAN before you execute this command.

You can specify the version for a VLAN in VLAN view or for the specified VLANs in IGMP-snooping view. The VLAN-specific configuration has the same priority as the configuration in IGMP-snooping view, and the most recent configuration takes effect.

Examples

In VLAN 2, enable IGMP snooping, and specify IGMP snooping version 3.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] igmp-snooping version 3
```

Related commands

last-member-query-interval (IGMP-snooping view)

Use **last-member-query-interval** to set the IGMP last member query interval globally.

Use **undo last-member-query-interval** to restore the default.

Syntax

last-member-query-interval *interval*

undo last-member-query-interval

Default

The IGMP last member query interval is 1 second.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

interval: Specifies an IGMP last member query interval in the range of 1 to 25 seconds.

Usage guidelines

You can set the interval for a VLAN in VLAN view or globally for all VLANs in IGMP-snooping view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

Examples

Set the global IGMP last member query interval to 3 seconds.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] last-member-query-interval 3
```

Related commands

igmp-snooping last-member-query-interval

mac-address multicast

Use **mac-address multicast** to configure a static multicast MAC address entry.

Use **undo mac-address multicast** to delete a static multicast MAC address entry.

Syntax

In system view:

mac-address multicast *mac-address* **interface** *interface-list* **vlan** *vlan-id*

undo mac-address [**multicast**] [[*mac-address* [**interface** *interface-list*]] **vlan** *vlan-id*]

In Layer 2 aggregate interface view or Layer 2 Ethernet interface view:

mac-address multicast *mac-address* **vlan** *vlan-id*

undo mac-address [**multicast**] *mac-address* **vlan** *vlan-id*

Default

No static multicast MAC address entries exist.

Views

System view

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

mac-address: Specifies a static multicast MAC address, in the format of H-H-H. You must specify an unused multicast MAC address. A multicast MAC address is a MAC address in which the least significant bit of the most significant octet is 1.

interface *interface-list*: Specifies a space-separated list of up to four interface items. Each item specifies an interface or an interface list in the format of *start-interface-type interface-number* **to** *end-interface-type interface-number*. The *interface-type interface-number* argument specifies an interface by its type and number. The available interface types include Layer 2 Ethernet interfaces and Layer 2 aggregate interfaces.

vlan *vlan-id*: Specifies an existing VLAN by its VLAN ID in the range of 1 to 4094. The system gives a prompt if the specified interface does not belong to the VLAN.

Usage guidelines

You do not need to enable IP multicast routing before you execute this command.

You can configure static multicast MAC address entries for the specified interfaces in system view or for the current interface in interface view.

If you do not specify the **multicast** keyword in the **undo mac-address** command, all static unicast MAC address entries and static multicast MAC entries are deleted.

Examples

Configure a static multicast MAC address entry. In the entry, the multicast MAC address is 0100-5E00-0003 and the outgoing ports are GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 in VLAN 2.

```
<Sysname> system-view
[Sysname] mac-address multicast 0100-5e00-0003 interface gigabitethernet 1/0/1 to
gigabitethernet 1/0/5 vlan 2
```

Configure a static multicast MAC address entry on GigabitEthernet 1/0/1. In the entry, the multicast MAC address is 0100-5E00-0003 and the outgoing port is GigabitEthernet 1/0/1, which belongs to VLAN 2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-address multicast 0100-5e00-0003 vlan 2
```

Related commands

display mac-address multicast

max-response-time (IGMP-snooping view)

Use **max-response-time** to set the maximum response time for IGMP general queries globally.

Use **undo max-response-time** to restore the default.

Syntax

max-response-time *seconds*

undo max-response-time

Default

The maximum response time for IGMP general queries is 10 seconds.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

seconds: Specifies the maximum response time for IGMP general queries, in the range of 1 to 3174 seconds.

Usage guidelines

You can set the time for a VLAN in VLAN view or globally for all VLANs in IGMP-snooping view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

To avoid mistakenly deleting multicast group members, set the maximum response time for IGMP general queries to be less than the IGMP general query interval.

Examples

Set the global maximum response time for IGMP general queries to 5 seconds.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] max-response-time 5
```

Related commands

igmp-snooping max-response-time

igmp-snooping query-interval

overflow-replace (IGMP-snooping view)

Use **overflow-replace** to enable the multicast group replacement feature globally.

Use **undo overflow-replace** to disable the multicast group replacement feature globally.

Syntax

overflow-replace [**vlan** *vlan-list*]

undo overflow-replace [**vlan** *vlan-list*]

Default

The multicast group replacement feature is disabled.

Views

IGMP-snooping view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

This command takes effect only on the multicast groups that a port joins dynamically.

You can enable the multicast group replacement feature globally for all ports in IGMP-snooping view or for a port in interface view. For a port, the port-specific configuration takes priority over the global configuration.

Examples

Globally enable the multicast group replacement feature for VLAN 2.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] overflow-replace vlan 2
```

Related commands

display pim-snooping neighbor

Use **display pim-snooping neighbor** to display PIM snooping neighbor information.

Syntax

display pim-snooping neighbor [**vlan** *vlan-id*] [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays PIM snooping neighbor information for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays PIM snooping neighbor information for the master device.

verbose: Displays detailed information about PIM snooping neighbors. If you do not specify this keyword, the command displays brief information about PIM snooping neighbors.

Examples

Display detailed information about PIM snooping neighbors for VLAN 2.

```
<Sysname> display pim-snooping neighbor vlan 2 verbose
Total 2 neighbors.

VLAN 2: Total 2 neighbors.
  10.1.1.2
    Slots (0 in total):
    Ports (1 in total):
      GE1/0/1                          (02:02:23)    LAN Prune Delay(T)
  10.1.1.3
    Slots (0 in total):
    Ports (1 in total):
      GE1/0/2                          (02:02:25)
```

Table 1 Command output

Field	Description
Total 2 neighbors	Total number of PIM snooping neighbors.
VLAN 2: Total 2 neighbors	Total number of PIM snooping neighbors in VLAN 2.
10.1.1.2	IP address of the PIM snooping neighbor.
Slots (0 in total)	Member IDs and total number of the member devices that have the neighbor, except for the specified member device or the master device

Field	Description
	when no member device is specified.
Ports (1 in total)	Ports where the PIM snooping neighbors reside, and the total number of the ports.
(02:02:23)	Remaining aging timer for a PIM snooping neighbor on the port. This field is always displayed for global ports (such as Layer 2 aggregate interfaces). For a non-global port, this field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.
LAN Prune Delay	The PIM hello message sent by the PIM snooping neighbor has the LAN_Prune_Delay option.
(T)	The join message suppression feature has been disabled for the PIM snooping neighbor.

Field	Description
VLAN 2	VLAN ID.
Router slots (0 in total)	Member IDs and total number of the member devices that have router ports, except for the specified member device or the master device when no member device is specified.
Router ports (2 in total)	Router ports and total number of router ports.
(00:01:30)	Remaining aging time for the router port. For a global port, this field is always displayed. For a non-global port, this field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.

display pim-snooping routing-table

Use **display pim-snooping routing-table** to display PIM snooping routing entries.

Syntax

display pim-snooping routing-table [**vlan** *vlan-id*] [**slot** *slot-number*] [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays PIM snooping routing entries for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays PIM snooping routing entries for the master device.

verbose: Displays detailed information about PIM snooping routing entries. If you do not specify the keyword, this command displays brief information about PIM snooping routing entries.

Examples

Display detailed information about PIM snooping routing entries for VLAN 2.

```
<Sysname> display pim-snooping routing-table vlan 2 verbose
Total 1 entries.
FSM Flag: NI-no info, J-join, PP-prune pending

VLAN 2: Total 1 entries.
```

```
(172.10.10.1, 225.1.1.1)
  FSM information: dummy
  Upstream neighbor: 20.1.1.1
    Upstream Slots (0 in total):
    Upstream Ports (1 in total):
      GE1/0/1
    Downstream Slots (0 in total):
    Downstream Ports (2 in total):
      GE1/0/2
        Expires: 00:03:01, FSM: J
        Downstream Neighbors (2 in total):
          7.1.1.1
            Expires: 00:59:19, FSM: J
          7.1.1.11
            Expires: 00:59:20, FSM: J
      GE1/0/3
        Expires: 00:02:21, FSM: PP
```

Table 3 Command output

Field	Description
Total 1 entries	Total number of (S, G) entries and (*, G) entries.
FSM Flag: NI-no info, J-join, PP-prune pending	State machine flag of the downstream port: • **NI**—Initial state. • **J**—Join. • **PP**—Prune pending.
VLAN 2: Total 1 entries	Total number of (S, G) entries and (*, G) entries in VLAN 2.
(172.10.10.1, 225.1.1.1)	(S, G) entry.
FSM information	Finite state machine information of the entry: • **delete**—The entry attributes have been deleted. • **dummy**—The entry is a new temporary entry. • **no info**—The entry does not exist. • **normal**—The entry is a correct entry.
Upstream neighbor	Upstream neighbor of the (S, G) or (*, G) entry.
Upstream Slots (0 in total)	Member IDs and total number of the member devices that have the upstream neighbor, except for the specified member device or the master device when no member device is specified.
Upstream Ports (1 in total)	Upstream ports, and the total number of upstream ports. This field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.
Downstream Slots (0 in total)	Member IDs and total number of the member devices that have downstream ports, except for the specified member device or the master device when no member device is specified.
Downstream Ports (2 in total)	Downstream ports of the upstream neighbor, and the total number of the downstream ports.
Downstream Neighbors (2 in total)	Downstream neighbors of the downstream port, and the total number of the downstream neighbors.

Field	Description
Expires: 00:03:01, FSM: J	Remaining aging time for the downstream port or downstream neighbor, and the finite state machine information. For a global port, this field is always displayed. For a non-global port, this field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.

display pim-snooping statistics

Use **display pim-snooping statistics** to display statistics for the PIM messages learned through PIM snooping.

Syntax

display pim-snooping statistics

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display statistics for the PIM messages learned through PIM snooping.

```
<Sysname> display pim-snooping statistics
Received PIMv2 hello:  100
Received PIMv2 join/prune:  100
Received PIMv2 error:  0
Received PIMv2 messages in total:  200
Received PIMv1 messages in total:  0
```

Table 4 Command output

Field	Description
Received PIMv2 hello	Number of received PIMv2 hello messages.
Received PIMv2 join/prune	Number of received PIMv2 join/prune messages.
Received PIMv2 error	Number of received PIMv2 messages with errors.
Received PIMv2 messages in total	Total number of received PIMv2 messages.
Received PIMv1 messages in total	Total number of received PIMv1 messages.

Related commands

reset pim-snooping statistics

pim-snooping enable

Use **pim-snooping enable** to enable PIM snooping for a VLAN.

Use **undo pim-snooping enable** to disable PIM snooping for a VLAN.

Syntax

pim-snooping enable

undo pim-snooping enable

Default

PIM snooping is disabled for a VLAN.

Views

VLAN view

Predefined user roles

network-admin

Usage guidelines

You must enable the IGMP snooping feature and enable IGMP snooping for a VLAN before you enable PIM snooping for the VLAN.

PIM snooping does not take effect on sub-VLANs of a multicast VLAN.

Examples

Enable the IGMP snooping feature, and then enable IGMP snooping and PIM snooping for VLAN 2.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] pim-snooping enable
```

Related commands

igmp-snooping

igmp-snooping enable

pim-snooping graceful-restart join-aging-time

Use **pim-snooping graceful-restart join-aging-time** to set the aging time for global downstream ports and global router ports on the new master device after a master/subordinate switchover.

Use **undo pim-snooping graceful-restart join-aging-time** to restore the default.

Syntax

pim-snooping graceful-restart join-aging-time *seconds*

undo pim-snooping graceful-restart join-aging-time

Default

The aging time is 210 seconds for global downstream ports and global router ports on the new master device after a master/subordinate switchover.

Views

VLAN view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging time in the range of 210 to 18000 seconds.

Usage guidelines

You must enable PIM snooping for a VLAN before you execute this command.

Global ports include Layer 2 aggregate interfaces. A global downstream port or a global router port is a global port that acts as a downstream port or router port, respectively.

Examples

In VLAN 2, set the aging time to 600 seconds for global downstream ports and global router ports on the new master device after a master/subordinate switchover.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] pim-snooping enable
[Sysname-vlan2] pim-snooping graceful-restart join-aging-time 600
```

Related commands

pim-snooping enable

pim-snooping graceful-restart neighbor-aging-time

Use **pim-snooping graceful-restart neighbor-aging-time** to set the aging time for global neighbor ports on the new master device after a master/subordinate switchover.

Use **undo pim-snooping graceful-restart neighbor-aging-time** to restore the default.

Syntax

pim-snooping graceful-restart neighbor-aging-time *seconds*

undo pim-snooping graceful-restart neighbor-aging-time

Default

The aging time is 105 seconds for global neighbor ports on the new master device after a master/subordinate switchover.

Views

VLAN view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging time in the range of 105 to 18000 seconds.

Usage guidelines

You must enable PIM snooping in a VLAN before you execute this command.

Global ports include Layer 2 aggregate interfaces. A global neighbor port is a global port that acts as a neighbor port.

Examples

In VLAN 2, set the aging time to 300 seconds for global neighbor ports on the new master device after a master/subordinate switchover.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] igmp-snooping enable
[Sysname-vlan2] pim-snooping enable
[Sysname-vlan2] pim-snooping graceful-restart neighbor-aging-time 300
```

Multicast VLAN commands

display multicast-vlan

Use **display multicast-vlan** to display information about multicast VLANs.

Syntax

display multicast-vlan [*vlan-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan-id: Specifies a multicast VLAN ID in the range of 1 to 4094. If you do not specify a multicast VLAN ID, this command displays information about all multicast VLANs.

Examples

Display information about all multicast VLANs.

```
<Sysname> display multicast-vlan
Total 2 multicast VLANs.

Multicast VLAN 100:
  Sub-VLAN list(3 in total):
    2-3, 6
  Port list(3 in total):
    GE1/0/1
    GE1/0/2
    GE1/0/3

Multicast VLAN 200:
  Sub-VLAN list(0 in total):
  Port list(0 in total):
```

Table 1 Command output

Field	Description
Total 2 multicast VLANs	Total number of multicast VLANs.
Sub-VLAN list(3 in total)	Sub-VLAN list of the multicast VLAN, and the total number of the sub-VLANs.
Port list(3 in total)	Port list of the multicast VLAN, and the total number of the ports.

display multicast-vlan forwarding-table

Use **display multicast-vlan forwarding-table** to display multicast VLAN forwarding entries.

Syntax

display multicast-vlan forwarding-table [*group-address* [**mask** { *mask-length* | *mask* }] | *source-address* [**mask** { *mask-length* | *mask* }] | **slot** *slot-number* | **subvlan** *vlan-id* | **vlan** *vlan-id*] *

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

group-address: Specifies a multicast group by its IP address in the range of 224.0.0.0 to 239.255.255.255. If you do not specify a multicast group, this command displays multicast VLAN forwarding entries for all multicast groups.

mask { *mask-length* | *mask* }: Specifies a mask length or subnet mask for the multicast group address. The value range for the *mask-length* argument is 4 to 32 (default), and the default value for the *mask* argument is 255.255.255.255.

source-address: Specifies a multicast source by its IP address. If you do not specify a multicast source, this command displays multicast VLAN forwarding entries for all multicast sources.

mask { *mask-length* | *mask* }: Specifies a mask length or subnet mask for the multicast source address. The value range for the *mask-length* argument is 0 to 32 (default), and the default value for the *mask* argument is 255.255.255.255.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays multicast VLAN forwarding entries for the master device.

subvlan *vlan-id*: Specifies a sub-VLAN by its VLAN ID. If you do not specify a sub-VLAN, this command displays multicast VLAN forwarding entries for all sub-VLANs.

vlan *vlan-id*: Specifies a multicast VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a multicast VLAN, this command displays multicast VLAN forwarding entries for all multicast VLANs.

Examples

Display all multicast VLAN forwarding entries.

```
<Sysname> display multicast-vlan forwarding-table
Multicast VLAN 100 Forwarding Table
Total 1 entries, 1 matched

00001. (1.1.1.1, 225.0.0.1)
     Flags: 0x10000
     Multicast VLAN: 100
     List of sub-VLANs (3 in total):
       1: VLAN 10
       2: VLAN 20
       3: VLAN 30
```

Table 2 Command output

Field	Description
Multicast VLAN 100 Forwarding Table	Forwarding entries for multicast VLAN 100.
Total 1 entries, 1 matched	Total number of (S, G) entries, and the number of matching entries.
00001	Sequence number of the (S, G) entry.
(1.1.1.1, 255.0.0.1)	(S, G) entry, where **0.0.0.0** in the S position means all multicast sources.
Flags	Entry flag. This field displays one flag or the sum of multiple flags. In this example, the value 0x10000 means that the entry has only one flag 0x10000. The following flags are available for an entry: • **0x1**—The entry is in inactive state. • **0x4**—The entry fails to update. • **0x8**—The sub-VLAN information fails to update for the entry. • **0x200**—The entry is in GR state. • **0x10000**—The entry is a multicast VLAN forwarding entry.
List of sub-VLANs (3 in total)	Sub-VLAN list of the multicast VLAN, and the total number of the sub-VLANs.

display multicast-vlan group

Use **display multicast-vlan group** to display information about multicast groups in multicast VLANs.

Syntax

display multicast-vlan group [*source-address* | *group-address* | **slot** *slot-number* | **verbose** | **vlan** *vlan-id*] *

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

source-address: Specifies a multicast source by its IP address. If you do not specify a multicast source, this command displays information about multicast groups for all multicast sources in multicast VLANs.

group-address: Specifies a multicast group by its IP address in the range of 224.0.1.0 to 239.255.255.255. If you do not specify a multicast group, this command displays information for all multicast groups in multicast VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about multicast groups in multicast VLANs for the master device.

verbose: Displays detailed information.

vlan *vlan-id*: Specifies a multicast VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a multicast VLAN, this command displays information about multicast groups for all multicast VLANs.

Examples

Display detailed information about all multicast groups in multicast VLANs.

```
<Sysname> display multicast-vlan group verbose
Total 6 entries.

Multicast VLAN 10: Total 3 entries.
  (2.2.2.2, 225.1.1.2)
    Flags: 0x70000020
    Sub-VLANs (1 in total):
      VLAN 40
  (111.112.113.115, 225.1.1.4)
    Flags: 0x70000030
    Sub-VLANs (1 in total):
      VLAN 40
  (0.0.0.0, 226.1.1.6)
    Flags: 0x60000020
    Sub-VLANs (1 in total):
      VLAN 40

Multicast VLAN 20: Total 3 entries.
  (2.2.2.2, 225.1.1.2)
    Flags: 0x70000010
    Sub-VLANs (0 in total):
  (111.112.113.115, 225.1.1.4)
    Flags: 0x70000010
    Sub-VLANs (0 in total):
  (0.0.0.0, 226.1.1.6)
    Flags: 0x50000010
    Sub-VLANs (0 in total):
```

Table 3 Command output

Field	Description
Total 6 entries	Total number of (S, G) entries.
Multicast VLAN 10: Total 3 entries	Total number of (S, G) entries in multicast VLAN 10.
(0.0.0.0, 226.1.1.6)	(S, G) entry, where **0.0.0.0** in the S position means all multicast sources.
Flags	Entry flag. This field displays one flag or the sum of multiple flags. For example, the value 0x70000020 means that the entry has flags 0x20, 0x10000000, 0x20000000, and 0x40000000. The following flags are available for an entry: • **0x10**—The entry is created by the multicast VLAN. • **0x20**—The entry is created by the sub-VLAN of the multicast VLAN. • **0x40**—The entry is to be deleted.

Field	Description

	• **0x10000000**—This value represents one of the following situations:
	  ◦ The entry is newly created.
	  ◦ The device receives an IGMP query that matches the (S, G) entry but does not receive any matching IGMPv1 reports within an IGMP general query interval.
	• **0x20000000**—The device does not receive IGMPv2 or IGMPv3 reports that match the (S, G) entry within an IGMP general query interval.
	• **0x40000000**—The device does not receive IGMPv3 IS_EX (NULL) reports that match the (S, G) entry within an IGMP general query interval.

Sub-VLANs (1 in total)	Sub-VLAN list of the multicast VLAN, and the total number of the sub-VLANs.

Related commands

reset multicast-vlan group

multicast-vlan

Use **multicast-vlan** to configure a multicast VLAN and enter its view, or enter the view of an existing multicast VLAN.

Use **undo multicast-vlan** to remove the configuration of multicast VLANs.

Syntax

multicast-vlan *vlan-id*

undo multicast-vlan { **all** | *vlan-id* }

Default

No multicast VLANs exist.

Views

System view

Predefined user roles

network-admin

Parameters

vlan-id: Specifies an existing VLAN by its ID in the range of 1 to 4094.

all: Specifies all multicast VLANs.

Usage guidelines

You can configure a maximum of five multicast VLANs.

You must enable IGMP snooping for the VLAN to be configured as a multicast VLAN.

Examples

Enable IGMP snooping for VLAN 100. Configure VLAN 100 as a multicast VLAN and enter its view.

```
<Sysname> system-view
[Sysname] igmp-snooping
[Sysname-igmp-snooping] quit
[Sysname] vlan 100
```

```
[Sysname-vlan100] igmp-snooping enable
[Sysname-vlan100] quit
[Sysname] multicast-vlan 100
[Sysname-mvlan-100]
```

Related commands

`igmp-snooping enable`

multicast-vlan entry-limit

Use **`multicast-vlan entry-limit`** to set the maximum number of multicast VLAN forwarding entries.

Use **`undo multicast-vlan entry-limit`** to restore the default.

Syntax

`multicast-vlan entry-limit` *`limit`*

`undo multicast-vlan entry-limit`

Default

The following matrix shows the default values for the maximum number of multicast VLAN forwarding entries:

Hardware	Maximum number of multicast VLAN forwarding entries
S5110V2-SI switch series S5000V3-EI switch series S5000V5-EI switch series S5000E-X switch series S5000X-EI switch series S5110V2 switch series WS5810-WiNet switch series	240
S5120V2-LI switch series S5130S-LI switch series S5120V3-SI switch series MS4320V2 switch series MS4320 switch series	500
WAS6000 switch series	• WAS6124 and WAS6148: 500 • Other switches: 240

Views

System view

Predefined user roles

network-admin

Parameters

limit: Specifies the maximum number of multicast VLAN forwarding entries. The following matrix shows the value range for this argument:

Hardware	Value range
S5110V2-SI switch series S5000V3-EI switch series S5000V5-EI switch series S5000E-X switch series S5000X-EI switch series WAS6000 switch series S5110V2 switch series WS5810-WiNet switch series	0 to 240
S5120V2-LI switch series S5130S-LI switch series S5120V3-SI switch series MS4320V2 switch series MS4320 switch series	0 to 500
S3100V3-SI switch series	• Switches with product code LS-3100V3-18TP-SI-H1, LS-3100V3-28TP-SI-H1, LS-3100V3-52TP-SI-H1, or LS-3100V3-20TP-PWR-SI-H1: 0 to 240 • Other switches: 0 to 500
MS4200 switch series	• Switches with product code LS-MS4200-28TP-H1, LS-MS4200-18TP-H1, or LS-MS4200-20TP-PWR-H1: 0 to 240 • Other switches: 0 to 500
WS5820-WiNet switch series	• Switches with product code WS5820-28P-POE-WiNet: 0 to 240 • Other switches: 0 to 500

MS4300V2 switch series	• MS4300V2-28P, MS4300V2-52P: 0 to 240 • MS4300V2-10P: 0 to 500
MS4320V3 switch series	• MS4320V3-28P, MS4320V3-52P: 0 to 240 • Other switches: 0 to 500
S5120V3-LI switch series	• S5120V2-20P-LI, S5120V2-28P-LI, S5120V2-52P-LI, S5120V2-28P-PWR-LI, S5120V2-52P-PWR-LI: 0 to 240 • Other switches: 0 to 500

Usage guidelines

If the configured value is smaller than the current number of multicast VLAN forwarding entries, the device cannot create new entries until some entries age out or are manually removed. To allow new entries to be created immediately, use the **reset multicast-vlan group** command to remove multicast VLAN forwarding entries.

Examples

Set the maximum number of multicast VLAN forwarding entries to 128.

```
<Sysname> system-view
[Sysname] multicast-vlan entry-limit 128
```

Related commands

entry-limit (IGMP-snooping view)

port (multicast-VLAN view)

Use **port** to assign user ports to a multicast VLAN.

Use **undo port** to delete user ports from a multicast VLAN.

Syntax

port *interface-list*

undo port { **all** | *interface-list* }

Default

A multicast VLAN does not have user ports.

Views

Multicast VLAN view

Predefined user roles

network-admin

Parameters

interface-list: Specifies a port in the form of *interface-type interface-number*, or a port range in the form of *interface-type interface-number* to *interface-type interface-number*.

all: Specifies all user ports in the current multicast VLAN.

Usage guidelines

You can assign only Layer 2 Ethernet ports or Layer 2 aggregate interfaces to multicast VLANs. Additionally, you can assign a port to only one multicast VLAN.

For ports to be assigned to a multicast VLAN, you must enable IGMP snooping for the VLANs to which the ports belong.

Examples

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/3 as user ports to multicast VLAN 100.

```
<Sysname> system-view
[Sysname] multicast-vlan 100
[Sysname-mvlan-100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/3
```

port multicast-vlan

Use **port multicast-vlan** to assign a user port to a multicast VLAN.

Use **undo port multicast-vlan** to restore the default.

Syntax

port multicast-vlan *vlan-id*

undo port multicast-vlan

Default

A port does not belong to a multicast VLAN.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

vlan-id: Specifies a multicast VLAN by its VLAN ID in the range of 1 to 4094.

Usage guidelines

You can assign a port to only one multicast VLAN.

For a port to be assigned to a multicast VLAN, you must enable IGMP snooping for the VLAN to which the port belongs.

Examples

Assign GigabitEthernet 1/0/1 as a user port to multicast VLAN 100.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port multicast-vlan 100
```

reset multicast-vlan group

Use **reset multicast-vlan group** to clear multicast groups in multicast VLANs.

Syntax

reset multicast-vlan group [*source-address* [**mask** { *mask-length* | *mask* }] | *group-address* [**mask** { *mask-length* | *mask* }] | **vlan** *vlan-id*] *

Views

User view

Predefined user roles

network-admin

Parameters

source-address: Specifies a multicast source by its IP address. If you do not specify a multicast source, this command clears multicast groups for all multicast sources in multicast VLANs.

mask { *mask-length* | *mask* }: Specifies a mask length or subnet mask for the multicast source address. The value range for the *mask-length* argument is 0 to 32 (default), and the default value for the *mask* argument is 255.255.255.255.

group-address: Specifies a multicast group by its IP address in the range of 224.0.1.0 to 239.255.255.255. If you do not specify a multicast group, this command clears all multicast groups in multicast VLANs.

mask { *mask-length* | *mask* }: Specifies a mask length or subnet mask for the multicast group address. The value range for the *mask-length* argument is 4 to 32 (default), and the default value for the *mask* argument is 255.255.255.255.

vlan *vlan-id*: Specifies a multicast VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a multicast VLAN, this command clears multicast groups for all multicast VLANs.

Examples

Clear multicast groups for all multicast VLANs.

```
<Sysname> reset multicast-vlan group
```

Related commands

display multicast-vlan group

subvlan (multicast-VLAN view)

Use **subvlan** to assign VLANs as sub-VLANs to a multicast VLAN.

Use **undo subvlan** to delete sub-VLANs from a multicast VLAN.

Syntax

subvlan *vlan-list*

undo subvlan { **all** | *vlan-list* }

Default

A multicast VLAN does not have sub-VLANs.

Views

Multicast VLAN view

Predefined user roles

network-admin

Parameters

vlan-list: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The value range for the VLAN ID is 1 to 4094. The specified VLANs must exist and cannot be multicast VLANs or sub-VLANs of other multicast VLANs.

all: Specifies all sub-VLANs of the current multicast VLAN.

Usage guidelines

You must enable IGMP snooping for VLANs to be configured as sub-VLANs.

Examples

Assign VLAN 10 through VLAN 15 as sub-VLANs to multicast VLAN 100.

```
<Sysname> system-view
[Sysname] multicast-vlan 100
[Sysname-mvlan-100] subvlan 10 to 15
```

Contents

MLD snooping commands

display ipv6 l2-multicast fast-forwarding cache

Use **display ipv6 l2-multicast fast-forwarding cache** to display Layer 2 IPv6 multicast fast forwarding entries.

Syntax

display ipv6 l2-multicast fast-forwarding cache [**vlan** *vlan-id*] [*ipv6-source-address* | *ipv6-group-address*] * [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

ipv6-source-address: Specifies an IPv6 multicast source address. If you do not specify an IPv6 multicast source, this command displays Layer 2 IPv6 multicast forwarding entries for all IPv6 multicast sources.

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F. If you do not specify an IPv6 multicast group, this command displays Layer 2 IPv6 multicast forwarding entries for all IPv6 multicast groups.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays Layer 2 IPv6 multicast fast forwarding entries for the master device.

Examples

Display Layer 2 IPv6 multicast fast forwarding entries.

```
<Sysname> display ipv6 l2-multicast fast-forwarding cache
Total 1 entries, 1 matched

(1::6, FF1E::2)
      Status      : Enable                VLAN            : 1
      Source port : 9876                  Destination port: 5432
      Protocol    : 17                    Flag            : 0x2
      Ingress port: GigabitEthernet1/0/2
      List of 1 egress ports:
           GigabitEthernet1/0/3
           Status: Enable                Flag: 0x10
```

Table 1 Command output

Field	Description
Total 1 entries, 1 matched	Total number of (S, G) entries in the Layer 2 IPv6 multicast fast forwarding table, and the total number of matching entries.

Field	Description
(1::6, FF1E::2)	(S, G) entry in the Layer 2 IPv6 multicast fast forwarding table.
Protocol	Protocol number.
VLAN	VLAN ID.
Flag	Flag for the (S, G) entry or the outgoing port. This field displays one flag or the sum of multiple flags. In this example, the value 0x2 means that the entry has only one flag 0x2. The following flags are available for an entry: • **0x1**—The entry is created because of packets passed through between cards. • **0x2**—The entry is added by multicast forwarding. The following flags are available for an outgoing interface: • **0x1**—The port is added to the entry because of packets passed through between cards. • **0x2**—The port is added to an existing entry. • **0x10**—The port is associated with the entry. • **0x20**—The port is to be deleted.
Status	Status of the (S, G) entry or the outgoing port: • **Enabled**—Available. • **Disabled**—Unavailable.
Ingress port	Incoming port of the (S, G) entry.
List of 1 egress ports	List of outgoing ports of the (S, G) entry.

Predefined user roles

network-admin

network-operator

Parameters

`group` *`ipv6-group-address`*: Specifies an IPv6 multicast group by its IPv6 address. If you do not specify an IPv6 multicast group, this command displays information about all Layer 2 IPv6 multicast groups.

`source` *`ipv6-source-address`*: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this command displays information about Layer 2 IPv6 multicast groups for all IPv6 multicast sources.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about Layer 2 IPv6 multicast groups for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about Layer 2 IP multicast groups for the master device.

Examples

Display information about Layer 2 IPv6 multicast groups for VLAN 2.

```
<Sysname> display ipv6 l2-multicast ip vlan 2
Total 1 entries.

VLAN 2: Total 1 entries.
   (::, FF1E::101)
    Attribute: static, success
    Host ports (1 in total):
      GE1/0/1                                (S, SUC)
```

Table 2 Command output

Field	Description
Total 1 entries	Total number of Layer 2 IPv6 multicast groups.
VLAN 2: Total 1 entries	Total number of Layer 2 IPv6 multicast groups in VLAN 2.
(::, FF1E::101)	(S, G) entry, where a double colon (::) in the S position means all IPv6 multicast sources.
Attribute	Entry attribute: • **dynamic**—The entry is created by a dynamic protocol. • **static**—The entry is created by a static protocol. • **pim**—The entry is created by IPv6 PIM. • **kernel**—The entry is obtained from the kernel. • **success**—Processing has succeeded. • **fail**—Processing has failed.
Host ports (1 in total)	Member ports and total number of member ports.
(S, SUC)	Port attribute: • **D**—Dynamic port. • **S**—Static port. • **P**—IPv6 PIM port. • **K**—Port obtained from the kernel. • **R**—Port learned from (*, *) entries. • **W**—Port learned from (*, G) entries. • **SUC**—Processing has succeeded. • **F**—Processing has failed.

display ipv6 l2-multicast ip forwarding

Use **display ipv6 l2-multicast ip forwarding** to display Layer 2 IPv6 multicast IP forwarding entries.

Syntax

display ipv6 l2-multicast ip forwarding [**group** *ipv6-group-address* | **source** *ipv6-source-address*] * [**vlan** *vlan-id*] [**slot** *slot-number*]

Parameters

group *ipv6-group-address*: Specifies an IPv6 multicast group by its IPv6 address. If you do not specify an IPv6 multicast group, this command displays Layer 2 IPv6 multicast IP forwarding entries for all IPv6 multicast groups.

source *ipv6-source-address*: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this command displays Layer 2 IPv6 multicast IP forwarding entries for all IPv6 multicast sources.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays Layer 2 IPv6 multicast IP forwarding entries for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays Layer 2 IPv6 multicast IP forwarding entries for the master device.

Examples

Display Layer 2 IPv6 multicast IP forwarding entries for VLAN 2.

```
<Sysname> display ipv6 l2-multicast ip forwarding vlan 2
Total 1 entries.

VLAN 2: Total 1 entries.
   (::, FF1E::101)
    Host ports (3 in total):
      GigabitEthernet1/0/1
      GigabitEthernet1/0/2
      GigabitEthernet1/0/3
```

Table 3 Command output

Field	Description
Total 1 entries	Total number of Layer 2 IPv6 multicast IP forwarding entries.
VLAN 2: Total 1 entries	Total number of Layer 2 IPv6 multicast IP forwarding entries in VLAN 2.
(::, FF1E::101)	(S, G) entry, where a double colon (::) in the S position means all IPv6 multicast sources.
Host ports (3 in total)	Member ports and total number of member ports.

display ipv6 l2-multicast mac

Use **display ipv6 l2-multicast mac** to display information about Layer 2 IPv6 multicast MAC multicast groups.

Syntax

display ipv6 l2-multicast mac [*mac-address*] [**vlan** *vlan-id*] [**slot** *slot-number*]

Views

Predefined user roles

network-admin

network-operator

Parameters

mac-address: Specifies an IPv6 multicast MAC address. If you do not specify an IPv6 multicast MAC address, this command displays information about all Layer 2 IPv6 multicast MAC multicast groups.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about Layer 2 IPv6 multicast MAC multicast groups for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about Layer 2 IPv6 multicast MAC multicast groups for the master device.

Examples

Display information about Layer 2 IPv6 multicast MAC multicast groups for VLAN 2.

```
<Sysname> display ipv6 l2-multicast mac vlan 2
Total 1 entries.

VLAN 2: Total 1 entries.
  MAC group address: 3333-0000-0101
    Attribute: success
    Host ports (1 in total):
      GE1/0/1
```

Table 4 Command output

Field	Description
Total 1 entries	Total number of Layer 2 IPv6 MAC multicast groups.
VLAN 2: Total 1 entries	Total number of Layer 2 IPv6 MAC multicast groups in VLAN 2.
MAC group address	IPv6 address of the Layer 2 IPv6 MAC multicast group.
Attribute	Entry attribute: • **success**—Processing has succeeded. • **fail**—Processing has failed.
Host ports (1 in total)	Member ports and total number of member ports.

display ipv6 l2-multicast mac forwarding

Use **display ipv6 l2-multicast mac forwarding** to display Layer 2 IPv6 multicast MAC forwarding entries.

Predefined user roles

network-admin

network-operator

Parameters

mac-address: Specifies an IPv6 MAC multicast group by its IPv6 MAC address. If you do not specify an IPv6 MAC multicast group, this command displays Layer 2 IPv6 multicast MAC forwarding entries for all IPv6 MAC multicast groups.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays Layer 2 IPv6 multicast MAC forwarding entries for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays Layer 2 IPv6 multicast MAC forwarding entries for the master device.

Examples

Display Layer 2 IPv6 multicast MAC forwarding entries for VLAN 2.

```
<Sysname> display ipv6 l2-multicast mac forwarding vlan 2
Total 1 entries.

VLAN 2: Total 1 entries.
  MAC group address: 3333-0000-0101
    Host ports (3 in total):
      GigabitEthernet1/0/1
      GigabitEthernet1/0/2
      GigabitEthernet1/0/3
```

Table 5 Command output

Field	Description
Total 1 MAC entries	Total number of Layer 2 IPv6 multicast MAC forwarding entries.
VLAN 2: Total 1 entries	Total number of Layer 2 IPv6 multicast MAC forwarding entries in VLAN 2.
MAC group address	Address of the IPv6 MAC multicast group.
Host ports (3 in total)	Member ports, and the total number of member ports.

display mld-snooping

Use **display mld-snooping** to display MLD snooping status.

Syntax

display mld-snooping [**global** | **vlan** *vlan-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`global`: Displays the global MLD snooping status.

`vlan` *`vlan-id`*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

Usage guidelines

If you do not specify any parameters, this command displays the global MLD snooping status and the MLD snooping status in all VLANs.

Examples

Display the global MLD snooping status and the MLD snooping status for all VLANs.

```
<Sysname> display mld-snooping
MLD snooping information: Global
  Global-enable: Enabled
 Host-aging-time: 260s
 Router-aging-time: 260s
 Max-response-time: 10s
 Last-listener-query-interval: 1s
 Report-aggregation: Enabled
 Host-tracking: Disabled
 Dot1p-priority: --

MLD snooping information: VLAN 1
 MLD snooping: Enabled
 Drop-unknown: Disabled
 Version: 1
 Host-aging-time: 260s
 Router-aging-time: 260s

Proxy: Disabled
```

Table 6 Command output

Field	Description
Global-enable	Global MLD snooping status: • Enabled. • Disabled.
MLD snooping	MLD snooping status in a VLAN: • **Enabled**. • **Disabled**. • **Globally enabled**. • **Inactive**—MLD snooping configuration does not take effect.
Drop-unknown	Status of dropping unknown IPv6 multicast data: • Enabled. • Disabled.
Version	MLD snooping version.
Host-aging-time	Aging timer for the dynamic member port.
Router-aging-time	Aging timer for the dynamic router port.
Max-response-time	Maximum time for responding to MLD general queries.
Last-listener-query-interval	Interval for sending MLD multicast-address-specific queries.
Report-aggregation	Status of MLD report suppression: • Enabled. • Disabled.
Dot1p-priority	802.1p priority for MLD messages. This field displays two hyphens (--) if the 802.1p priority is not configured.
Querier	Status of MLD snooping querier: • Enabled. • Disabled.
(IP: FE80::2FF:FFFF:FE00:1, Expires: 00:02:05)	MLD snooping querier information: • **IP**—IP address of the MLD snooping querier. • **Expire**—Remaining aging time for the MLD snooping querier. This field is not displayed if MLD snooping querier election is disabled.
Querier-election	Status of MLD snooping querier election: • Enabled. • Disabled.
Query-interval	Interval for sending MLD general queries.

Field	Description
General-query source IP	Source IPv6 address of MLD general queries.
Special-query source IP	Source IPv6 address of MLD multicast-address-specific queries.
Report source IP	Source IPv6 address of MLD reports.
Done source IP	Source IPv6 address of MLD done messages.
Host-tracking	Status of host tracking: • Enabled. • Disabled. • Globally enabled.
Proxy	Status of MLD snooping proxying: • Enabled. • Disabled.

display mld-snooping group

Use **display mld-snooping group** to display information about dynamic MLD snooping group entries.

Syntax

display mld-snooping group [*ipv6-group-address* | *ipv6-source-address*] * [**vlan** *vlan-id*] [**interface** *interface-type interface-number* | [**verbose**] [**slot** *slot-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F. If you do not specify an IPv6 multicast group, this command displays information about all dynamic MLD snooping group entries.

ipv6-source-address: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this command displays information about dynamic MLD snooping group entries for all IPv6 multicast sources.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about dynamic MLD snooping group entries for all VLANs.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays brief information about dynamic MLD snooping group entries for all interfaces.

verbose: Displays detailed information about dynamic MLD snooping group entries. If you do not specify this keyword, the command displays brief information about dynamic MLD snooping group entries.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about dynamic MLD snooping group entries for the master device.

Examples

Display brief information about dynamic MLD snooping group entries for GigabitEthernet 1/0/1.

```
<Sysname> display mld-snooping group interface
Total 1 entries.

GE1/0/1:
  VLAN 2: Total 1 entries.
   (::,FF1E::101)                    (00:03:23)
```

Display detailed information about dynamic MLD snooping group entries for VLAN 2.

```
<Sysname> display mld-snooping group vlan 2 verbose
Total 2 entries.

VLAN 2: Total 2 entries.
  (::,FF1E::101)
    Attribute: local port
    FSM information: dummy
    Host slots (0 in total):
    Host ports (1 in total):
      GE1/0/2                              (00:03:23)
  (12::, FF1E::101)
    Attribute: local port
    FSM information: dummy
    Host ports (1 in total):
      GE1/0/2                             (00:04:02)
```

Table 7 Command output

Field	Description
Total 1 entries	Total number of dynamic MLD snooping group entries.
VLAN 2: Total 1 entries	Total number of dynamic MLD snooping group entries in VLAN 2.
(::, FF1E::101)	(S, G) entry, where a double colon (::) in the S position means all IPv6 multicast sources.
Attribute	Entry attribute: • **global port**—The entry has a global port. • **local port**—The entry has a port that resides on the member device for which the information is displayed. • **slot**—The entry has ports that reside on other member devices, but not on the member device for which the information is displayed.
FSM information	Finite state machine information of the entry: • **delete**—The entry attributes have been deleted. • **dummy**—The entry is a new temporary entry. • **no info**—The entry does not exist. • **normal**—The entry is a correct entry.
Host slots (0 in total)	Member IDs and total number of the member devices that have member ports, except for the specified member device or the master device when no member device is specified.

Field	Description
Host ports (1 in total)	Member ports and total number of member ports.
(00:03:23)	Remaining aging time for the dynamic member port. This field is always displayed for a global port (such as Layer 2 aggregate interfaces). For a non-global port, this field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.

Related commands

reset mld-snooping group

display mld-snooping host-tracking

Use **display mld-snooping host-tracking** to display host tracking information.

Syntax

display mld-snooping host-tracking vlan *vlan-id* **group** *ipv6-group-address* [**source** *ipv6-source-address*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

group *ipv6-group-address*: Specifies an IPv6 multicast group by its IPv6 address. The value range for the *ipv6-group-address* argument is FFxy::/16, where "x" and "y" represent any hexadecimal numbers in the range of 0 to F.

source *ipv6-source-address*: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this commands displays host tracking information for all IPv6 multicast sources.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays host tracking information for the master device.

Examples

Display tracking information for hosts that have joined IPv6 multicast group FF1E::2 in VLAN 2.

```
<Sysname> display mld-snooping host-tracking vlan 2 group FF1E::2
VLAN 2
 (1::6, FF1E::2)
    Port: GE1/0/1
      Host                                    Uptime          Expires
      1::2                                    00:02:20        00:00:40
      1::3                                    00:02:21        00:00:39
```

Table 8 Command output

Field	Description
VLAN	VLAN ID.
(1::6, FF1E::2)	(S, G) entry, where 0::0 in the S position means any IPv6 multicast sources.
Port	Member port.
Host	IPv6 address of the host.
Uptime	Length of time elapsed since the host joined the IPv6 multicast group.
Expires	Remaining timeout time for the host. The host timeout time is the same as the aging timer of the port. The timer is reset when the port receives an MLD report from the host. This field displays **timeout** if the host times out.

display mld-snooping router-port

Use **display mld-snooping router-port** to display dynamic router port information.

Syntax

display mld-snooping router-port [**vlan** *vlan-id*] [**verbose**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

verbose: Displays detailed information about dynamic router ports. If you do not specify this keyword, the command displays brief information about dynamic router ports.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays dynamic router port information for all VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays dynamic router port information for the master device.

Examples

Display brief information about dynamic router ports for VLAN 2.

```
<Sysname> display mld-snooping router-port vlan 2
VLAN 2:
  Router ports (2 in total):
    GE1/0/1                          (00:01:30)
    GE1/0/2                          (00:00:23)
```

Display detailed information about dynamic router ports for VLAN 2.

```
<Sysname> display mld-snooping router-port vlan 2 verbose
VLAN 2:
  Router slots (0 in total):
  Router ports (2 in total):
    GE1/0/1                          (00:01:30)
    GE1/0/2                          (00:00:23)
```

Table 9 Command output

Field	Description
VLAN 2	VLAN ID.
Router slots (0 in total)	Member IDs and total number of the member devices that have dynamic router ports, except for the specified member device or the master device when no member device is specified.
Router ports (2 in total)	Dynamic router ports and total number of dynamic router ports.
(00:01:30)	Remaining aging time for the dynamic router port. This field is always displayed for a global port (including Layer 2 aggregate interfaces). For a non-global port, this field is displayed when one of the following conditions exists: • The port is on the specified member device. • The port is on the master device and no member device is specified.

Parameters

ipv6-group-address: Specifies an IPv6 multicast group by its IPv6 address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F. If you do not specify an IPv6 multicast group, this command displays information about static MLD snooping group entries for all IPv6 multicast groups.

ipv6-source-address: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this command displays information about static MLD snooping group entries for all IPv6 multicast sources.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify a VLAN, this command displays information about static MLD snooping group entries for all VLANs.

verbose: Displays detailed information. If you do not specify this keyword, the command displays brief information.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about static MLD snooping group entries for the master device.

Examples

Display detailed information about static MLD snooping group entries for VLAN 2.

```
<Sysname> display mld-snooping static-group vlan 2 verbose
Total 1 entries.

VLAN 2: Total 1 entries.
  (::,FF1E::101)
    Attribute: local port
    FSM information: dummy
    Host slots (0 in total):
    Host ports (1 in total):
      GE1/0/2
```

Table 10 Command output

Field	Description
Total 1 entries	Total number of static MLD snooping group entries.
VLAN 2: Total 1 entries	Total number of static MLD snooping group entries in VLAN 2.
(::, FF1E::101)	(S, G) entry, where a double colon (::) in the S position means all IPv6 multicast sources.
Attribute	Entry attribute: • **global port**—The entry has a global port. • **local port**—The entry has a port that resides on the member device for which the information is displayed. • **slot**—The entry has ports that reside on other member devices, but not on the member device for which the information is displayed.
FSM information	Finite state machine information of the entry: • **delete**—The entry attributes have been deleted. • **dummy**—The entry is a new temporary entry. • **no info**—The entry does not exist. • **normal**—The entry is a correct entry.
Host slots (0 in total)	Member IDs and total number of the member devices that have member ports, except for the specified member device or the master device when no member device is specified.
Host ports (1 in total)	Member ports and total number of member ports.

display mld-snooping static-router-port

Use **display mld-snooping static-router-port** to display static router port information.

Syntax

display mld-snooping static-router-port [**vlan** *vlan-id*] [**verbose**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

verbose: Displays detailed information about static router ports. If you do not specify this keyword, the command displays brief information about static router ports.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays static router port information for the master device.

Examples

Display brief information about static router ports for VLAN 2.

```
<Sysname> display mld-snooping static-router-port vlan 2
VLAN 2:
  Router ports (2 in total):
    GE1/0/1
    GE1/0/2
```

Display detailed information about static router ports for VLAN 2.

```
<Sysname> display mld-snooping static-router-port vlan 2 verbose
VLAN 2:
  Router slots (0 in total):
  Router ports (2 in total):
    GE1/0/1
    GE1/0/2
```

Table 11 Command output

Field	Description
VLAN 2	VLAN ID.
Router slots (0 in total)	Member IDs and total number of the member devices that have static router ports, except for the specified member device or the master device when no member device is specified.
Router ports (2 in total)	Static router ports and total number of static router ports.

display mld-snooping statistics

Use **display mld-snooping statistics** to display statistics for the MLD messages and IPv6 PIM hello messages learned through MLD snooping.

Syntax

display mld-snooping statistics

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display statistics for the MLD messages and IPv6 PIM hello messages learned through MLD snooping.

```
<Sysname> display mld-snooping statistics
Received MLD general queries:  0
Received MLDv1 specific queries:  0
Received MLDv1 reports:  0
Received MLD dones:  0
Sent     MLDv1 specific queries:  0
Received MLDv2 reports:  0
Received MLDv2 reports with right and wrong records:  0
Received MLDv2 specific queries:  0
Received MLDv2 specific sg queries:  0
Sent     MLDv2 specific queries:  0
Sent     MLDv2 specific sg queries:  0
Received IPv6 PIM hello:  0
Received error MLD messages:  0
```

Table 12 Command output

Field	Description
general queries	Number of MLD general queries.
specific queries	Number of MLD multicast-address-specific queries.
reports	Number of MLD reports.
dones	Number of MLD done messages.
reports with right and wrong records	Number of MLD reports with correct and incorrect records.
specific sg queries	Number of MLD multicast-address-and-source-specific queries.
IPv6 PIM hello	Number of IPv6 PIM hello messages.
error MLD messages	Number of MLD messages with errors.

Related commands

`reset mld-snooping statistics`

dot1p-priority (MLD-snooping view)

Use **`dot1p-priority`** to set the 802.1p priority for MLD messages globally.

Use **`undo dot1p-priority`** to restore the default.

Syntax

`dot1p-priority` *`priority`*

undo dot1p-priority

Default

The global 802.1p priority for MLD messages is 6.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

priority: Specifies an 802.1p priority for MLD messages, in the range of 0 to 7. The greater the value, the higher the priority.

Usage guidelines

You can set the 802.1p priority globally for all VLANs in MLD-snooping view or for a VLAN in VLAN view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

Examples

Set the 802.1p priority for MLD messages to 3 globally.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] dot1p-priority 3
```

Related commands

mld-snooping dot1p-priority

dscp

Use **dscp** to set the DSCP value for outgoing MLD protocol packets.

Use **undo dscp** to restore the default.

Syntax

dscp *dscp-value*

undo dscp

Default

The DSCP value is 48 for outgoing MLD protocol packets.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

dscp-value: Specifies a DSCP value in the range of 0 to 63.

Usage guidelines

The DSCP value is carried in the Traffic Class field of an IPv6 packet to determine the transmission priority of the packet. A greater DSCP value represents a higher priority.

Examples

Set the DSCP value to 63 for outgoing MLD protocol packets.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] dscp 63
```

enable (MLD-snooping view)

Use **enable** to enable MLD snooping for VLANs.

Use **undo enable** to disable MLD snooping for VLANs.

Syntax

enable vlan *vlan-list*

undo enable vlan *vlan-list*

Default

The MLD snooping status in a VLAN is consistent with the global MLD snooping status.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094.

Usage guidelines

You must enable the MLD snooping feature by using the **mld-snooping** command before you enable MLD snooping for VLANs.

You can enable MLD snooping for multiple VLANs by using this command in MLD-snooping view or for a VLAN by using the **mld-snooping enable** command in VLAN view. The configuration in VLAN view has the same priority as the configuration in MLD-snooping view, and the most recent configuration takes effect.

Examples

Enable the MLD snooping feature, and then enable MLD snooping for VLAN 2 through VLAN 10.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] enable vlan 2 to 10
```

Related commands

mld-snooping

mld-snooping enable

entry-limit (MLD-snooping view)

Use **entry-limit** to globally set the maximum number of MLD snooping forwarding entries, including dynamic entries and static entries.

Use **undo entry-limit** to restore the default.

Syntax

entry-limit *limit*

undo entry-limit

Default

The maximum number of MLD snooping forwarding entries is 4294967295.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

limit: Specifies the maximum number of MLD snooping forwarding entries, in the range of 0 to 4294967295.

Examples

Set the global maximum number of MLD snooping forwarding entries to 512.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] entry-limit 512
```

fast-leave (MLD-snooping view)

Use **fast-leave** to enable fast-leave processing globally.

Use **undo fast-leave** to disable fast-leave processing globally.

Syntax

fast-leave [**vlan** *vlan-list*]

undo fast-leave [**vlan** *vlan-list*]

Default

Fast-leave processing is disabled.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect for all VLANs.

Usage guidelines

The fast-leave processing feature enables the device to immediately remove a port from the forwarding entry for an IPv6 multicast group when the port receives a done message.

You can enable fast-leave processing globally for all ports in MLD-snooping view or for a port in interface view. For a port, the port-specific configuration takes priority over the global configuration.

Examples

Globally enable MLD snooping fast-leave processing for VLAN 2.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] fast-leave vlan 2
```

Related commands

mld-snooping fast-leave

global-enable (MLD-snooping view)

Use **global-enable** to enable MLD snooping globally.

Use **undo global-enable** to disable MLD snooping globally.

Syntax

global-enable

undo global-enable

Default

MLD snooping is disabled globally.

Views

MLD-snooping view

Predefined user roles

network-admin

Usage guidelines

To configure other MLD snooping features for VLANs, you must enable MLD snooping for the specific VLANs even though MLD snooping is enabled globally.

Examples

Enable MLD snooping globally.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] global-enable
```

Related commands

enable (MLD-snooping view)

mld-snooping disable

mld-snooping enable

group-policy (MLD-snooping view)

Use **group-policy** to globally configure an IPv6 multicast group policy to control the IPv6 multicast groups that hosts can join.

Use **undo group-policy** to globally delete IPv6 multicast group policies.

Syntax

group-policy *ipv6-acl-number* [**vlan** *vlan-list*]

undo group-policy [**vlan** *vlan-list*]

Default

No IPv6 multicast group policies exist. Hosts can join any IPv6 multicast groups.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 basic or advanced ACL by its number in the range of 2000 to 3999. Hosts can join only IPv6 multicast groups that the ACL permits. If the ACL does not exist or does not have valid rules, hosts cannot join IPv6 multicast groups.

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect for all VLANs.

Usage guidelines

An IPv6 multicast group policy filters MLD reports to control the IPv6 multicast groups that hosts can join.

This command does not take effect on static member ports, because static member ports do not send MLD reports.

You can configure an IPv6 multicast group policy globally for all ports in MLD-snooping view or for a port in interface view. For a port, the port-specific configuration takes priority over the global configuration.

When you configure a rule in the IPv6 ACL, follow these restrictions and guidelines:

- In a basic ACL, the **source** *source-address source-prefix* option specifies an IPv6 multicast group address.
- In an advanced ACL, the **source** *source-address source-prefix* option specifies an IPv6 multicast source address. The **destination** *dest-address dest-prefix* option specifies an IPv6 multicast group address.

  To match MLDv1 reports, set the **source** *source-address source-prefix* option to 0::0.
- Among the other optional parameters, only the **fragment** keyword and the **time-range** *time-range-name* option take effect.

You can configure different ACLs for all ports in different VLANs. If you configure multiple ACLs for all ports in the same VLAN, the most recent configuration takes effect.

Examples

Configure an IPv6 multicast group policy for VLAN 2 so that hosts in VLAN 2 can join only IPv6 multicast group FF03::101.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2000
[Sysname-acl-ipv6-basic-2000] rule permit source ff03::101 128
[Sysname-acl-ipv6-basic-2000] quit
[Sysname] mld-snooping
[Sysname-mld-snooping] group-policy 2000 vlan 2
```

Related commands

mld-snooping group-policy

host-aging-time (MLD-snooping view)

Use **host-aging-time** to set the aging timer for dynamic member ports globally.

Use **undo host-aging-time** to restore the default.

Syntax

host-aging-time *seconds*

undo host-aging-time

Default

The aging timer for dynamic member ports is 260 seconds.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging timer for dynamic member ports, in the range of 1 to 8097894 seconds.

Usage guidelines

You can set the timer globally for all VLANs in MLD-snooping view or for a VLAN in VLAN view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

To avoid mistakenly deleting IPv6 multicast group members, set the aging timer for dynamic member ports to be greater than the value calculated by using the following formula:

[MLD general query interval] + [maximum response time for MLD general queries]

As a best practice, set the aging timer of dynamic member ports to the value calculated by using the following formula:

[MLD general query interval] × 2 + [maximum response time for MLD general queries]

Examples

Set the global aging timer for dynamic member ports to 300 seconds.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] host-aging-time 300
```

Related commands

mld-snooping host-aging-time

host-tracking (MLD-snooping view)

Use **host-tracking** to enable host tracking globally.

Use **undo host-tracking** to disable host tracking globally.

Syntax

host-tracking

undo host-tracking

Default

Host tracking is disabled.

Views

MLD-snooping view

Predefined user roles

network-admin

Usage guidelines

You can enable host tracking globally for all VLANs in MLD-snooping view or for a VLAN in VLAN view. For a VLAN, the global configuration has the same priority as the VLAN-specific configuration.

Examples

Enable host tracking globally.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] host-tracking
```

last-listener-query-interval (MLD-snooping view)

Use **last-listener-query-interval** to set the MLD last listener query interval globally.

Use **undo last-listener-query-interval** to restore the default.

Syntax

last-listener-query-interval *interval*

undo last-listener-query-interval

Default

The MLD last listener query interval is 1 second.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

interval: Specifies an MLD last listener query interval in the range of 1 to 25 seconds.

Usage guidelines

You can set the interval for a VLAN in VLAN view or globally for all VLANs in MLD-snooping view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

Examples

Set the global MLD last listener query interval to 3 seconds.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] last-listener-query-interval 3
```

Related commands

mld-snooping last-listener-query-interval

max-response-time (MLD-snooping view)

Use **max-response-time** to set the maximum response time for MLD general queries globally.

Use **undo max-response-time** to restore the default.

Syntax

max-response-time *seconds*

undo max-response-time

Default

The maximum response time for MLD general queries is 10 seconds.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

seconds: Specifies the maximum response time for MLD general queries, in the range of 1 to 3174 seconds.

Usage guidelines

You can set the time globally for all VLANs in MLD-snooping view or for a VLAN in VLAN view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

To avoid mistakenly deleting IPv6 multicast group members, set the maximum response time for MLD general queries to be less than the MLD general query interval.

Examples

Set the global maximum response time for MLD general queries to 5 seconds.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] max-response-time 5
```

mld-snooping access-policy

Use **mld-snooping access-policy** to configure an MLD snooping access control policy.

Use **undo mld-snooping access-policy** to delete an MLD snooping access control policy.

Syntax

mld-snooping access-policy *ipv6-acl-number*

undo mld-snooping access-policy { *ipv6-acl-number* | **all** }

Default

No MLD snooping access control policies exist. IPv6 multicast users can join or leave any IPv6 multicast groups.

Views

User profile view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 basic or advanced ACL by its number, in the range of 2000 to 3999. IPv6 multicast users can join only the IPv6 multicast groups that the ACL permits. If the ACL does not exist or does not have valid rules, IPv6 multicast users cannot join or leave any IPv6 multicast groups.

all: Specifies all MLD snooping access control policies.

Usage guidelines

You can repeat this command to configure multiple MLD snooping access control policies. An IPv6 multicast user can join or leave an IPv6 multicast group if its MLD report or done message is permitted by one of the MLD snooping access control policies.

When you configure a rule in the IPv6 ACL, follow these restrictions and guidelines:

- In a basic ACL, the **source** *source-address source-prefix* option specifies an IPv6 multicast group address.
- In an advanced ACL, the **source** *source-address source-prefix* option specifies an IPv6 multicast source address. The **destination** *dest-address dest-prefix* option specifies an IPv6 multicast group address.

  To match the following MLD messages, set the **source** *source-address source-prefix* option to 0::0:

  - MLDv1 report and done messages.
  - MLDv2 IS_EX and MLDv2 TO_EX reports that do not carry IPv6 multicast source addresses.
- Among the other optional parameters, only the **fragment** keyword and the **time-range** *time-range-name* option take effect.

Examples

In user profile **abc**, configure an MLD snooping access control policy to allow IPv6 multicast users to join or leave only IPv6 multicast group FF03::101.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2001
[Sysname-acl6-basic-2001] rule permit source ff03::101 16
[Sysname-acl6-basic-2001] quit
[Sysname] user-profile abc
[Sysname-user-profile-abc] mld-snooping access-policy 2001
```

mld-snooping done source-ip

Use **mld-snooping done source-ip** to configure the source IPv6 address for MLD done messages.

Use **undo mld-snooping done source-ip** to restore the default.

Syntax

mld-snooping done source-ip *ipv6-address*

undo mld-snooping done source-ip

Default

In a VLAN, the source IPv6 address of MLD done messages is the IPv6 link-local address of the current VLAN interface. If the current VLAN interface does not have an IPv6 link-local address, the source IPv6 address is FE80::02FF:FFFF:FE00:0001.

Views

VLAN view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the source IPv6 address for MLD done messages.

Usage guidelines

You must enable MLD snooping for a VLAN before you execute this command.

Examples

In VLAN 2, enable MLD snooping, and specify FE80:0:0:1::1 as the source IPv6 address of MLD done messages.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable

undo mld-snooping fast-leave [**vlan** *vlan-list*]

Default

Fast-leave processing is disabled on a port.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

The fast-leave processing feature enables the device to immediately remove a port from the forwarding entry for an IPv6 multicast group when the port receives a done message.

You can enable fast-leave processing for a port in interface view or globally for all ports in MLD-snooping view. For a port, the port-specific configuration takes priority over the global configuration.

Examples

Enable fast-leave processing for VLAN 2 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mld-snooping fast-leave vlan 2
```

Related commands

mld-snooping general-query source-ip

Use **mld-snooping general-query source-ip** to configure the source IPv6 address for MLD general queries.

Use **undo mld-snooping general-query source-ip** to restore the default.

Syntax

mld-snooping general-query source-ip *ipv6-address*

undo mld-snooping general-query source-ip

Default

In a VLAN, the source IPv6 address for MLD general queries is the IPv6 link-local address of the current VLAN interface. If the current VLAN interface does not have an IPv6 link-local address, the source IPv6 address is FE80::02FF:FFFF:FE00:0001.

Views

VLAN view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the source IPv6 address for MLD general queries.

Usage guidelines

You must enable MLD snooping for a VLAN before you execute this command.

Examples

In VLAN 2, enable MLD snooping, and specify FE80:0:0:1::1 as the source IPv6 address for MLD general queries.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable
[Sysname-vlan2] mld-snooping general-query source-ip fe80:0:0:1::1
```

Related commands

mld-snooping group-limit

Use **mld-snooping group-limit** to set the maximum number of IPv6 multicast groups that a port can join.

Use **undo mld-snooping group-limit** to remove the limit on the maximum number of IPv6 multicast groups that a port can join.

Syntax

mld-snooping group-limit *limit* [**vlan** *vlan-list*]

undo mld-snooping group-limit [**vlan** *vlan-list*]

Default

No limit is placed on the maximum number of IPv6 multicast groups that a port can join.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

limit: Specifies the maximum number of multicast groups that a port can join, in the range of 0 to 4294967295.

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect for all VLANs.

Usage guidelines

This command takes effect only on the IPv6 multicast groups that a port joins dynamically.

Examples

On GigabitEthernet 1/0/1, set the maximum number to 10 for IPv6 multicast groups that the port can join in VLAN 2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mld-snooping group-limit 10 vlan 2
```

mld-snooping group-policy

Use **mld-snooping group-policy** to configure an IPv6 multicast group policy on a port to control the IPv6 multicast groups that hosts attached to the port can join.

Use **undo mld-snooping group-policy** to delete IPv6 multicast group policies on a port.

Syntax

mld-snooping group-policy *ipv6-acl-number* [**vlan** *vlan-list*]

undo mld-snooping group-policy [**vlan** *vlan-list*]

Default

No IPv6 multicast group policies exist. Hosts attached to the port can join any IPv6 multicast groups.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

ipv6-acl-number: Specifies an IPv6 basic or advanced ACL number in the range of 2000 to 3999. Hosts can join only the IPv6 multicast groups that the ACL permits. If the ACL does not exist or does not have valid rules, hosts cannot join IPv6 multicast groups.

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

An IPv6 multicast group policy filters MLD reports to control the IPv6 multicast groups that hosts can join.

This command does not take effect on static member ports, because static member ports do not send MLD reports.

You can configure an IPv6 multicast group policy for a port in interface view or globally for all ports in MLD-snooping view. For a port, the port-specific configuration takes priority over the global configuration.

When you configure a rule in the IPv6 ACL, follow these restrictions and guidelines:

- In a basic ACL, the **source** *source-address source-prefix* option specifies an IPv6 multicast group address.
- In an advanced ACL, the **source** *source-address source-prefix* option specifies an IPv6 multicast source address. The **destination** *dest-address dest-prefix* option specifies an IPv6 multicast group address.

  To match MLDv1 reports and MLD IS_EX and MLDv2 TO_EX reports that do not carry IPv6 multicast source addresses, set the **source** *source-address source-prefix* option to 0::0.
- Among the other optional parameters, only the **fragment** keyword and the **time-range** *time-range-name* option take effect.

You can configure different ACLs for different VLANs on a port. If you configure multiple ACLs for the same VLANs on a port, the most recent configuration takes effect.

Examples

On GigabitEthernet 1/0/1, configure an IPv6 multicast group policy for VLAN 2 so that hosts attached to the port in VLAN 2 can join only the group FF03::101.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2000
[Sysname-acl-ipv6-basic-2000] rule permit source ff03::101 128
[Sysname-acl-ipv6-basic-2000] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mld-snooping group-policy 2000 vlan 2
```

mld-snooping host-aging-time

Use **mld-snooping host-aging-time** to set the aging timer for dynamic member ports in a VLAN.

Use **undo mld-snooping host-aging-time** to restore the default.

Syntax

mld-snooping host-aging-time *seconds*

undo mld-snooping host-aging-time

Default

The aging timer for dynamic member ports is 260 seconds.

Views

VLAN view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging timer for dynamic member ports, in the range of 1 to 8097894 seconds.

Usage guidelines

You must enable MLD snooping for a VLAN before you execute this command.

You can set the timer for a VLAN in VLAN view or globally for all VLANs in MLD-snooping view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

To avoid mistakenly deleting IPv6 multicast group members, set the aging timer for dynamic member ports to be greater than the value calculated by using the following formula:

[MLD general query interval] + [maximum response time for MLD general queries]

As a best practice, set the aging timer of dynamic member ports to the value calculated by using the following formula:

[MLD general query interval] × 2 + [maximum response time for MLD general queries]

Examples

In VLAN 2, enable MLD snooping, and set the aging timer for dynamic member ports in the VLAN to 300 seconds.

```
<Sysname> system-view
```

```
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable
[Sysname-vlan2] mld-snooping host-aging-time 300
```

Related commands

enable (MLD-snooping view)

host-aging-time (MLD-snooping view)

mld-snooping enable

mld-snooping host-join

Use **mld-snooping host-join** to configure a port as a simulated member host for an IPv6 multicast group or an IPv6 multicast source and group.

Use **undo mld-snooping host-join** to remove the configuration of a simulated member host for an IPv6 multicast group.

Syntax

mld-snooping host-join *ipv6-group-address* [**source-ip** *ipv6-source-address*] **vlan** *vlan-id*

undo mld-snooping host-join { *ipv6-group-address* [**source-ip** *ipv6-source-address*] **vlan** *vlan-id* | **all** }

Default

A port is not a simulated member host of any IPv6 multicast groups or any IPv6 multicast sources and groups.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F.

source-ip *ipv6-source-address*: Specifies an IPv6 multicast source by its IPv6 address. If you specify an IPv6 multicast source, this command configures the port as a simulated member host for an IPv6 multicast source and group. If you do not specify an IPv6 multicast source, this command configures the port as a simulated member host for an IPv6 multicast group. This option takes effect on MLDv2 snooping devices.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

all: Specifies all IPv6 multicast groups and all IPv6 multicast sources and groups.

Usage guidelines

The version of MLD running on a simulated member host is the same as the version of MLD snooping running on the port. The port ages out in the same way as a dynamic member port.

Examples

Configure GigabitEthernet 1/0/1 as a simulated member host for the IPv6 multicast group (*, FF3E::101) in VLAN 2.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable
[Sysname-vlan2] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mld-snooping host-join ff3e::101 vlan 2
```

mld-snooping host-tracking

Use **mld-snooping host-tracking** to enable host tracking for a VLAN.

Use **undo mld-snooping host-tracking** to disable host tracking for a VLAN.

Syntax

mld-snooping host-tracking

undo mld-snooping host-tracking

Default

Host tracking is disabled.

Views

VLAN view

Predefined user roles

network-admin

Usage guidelines

You must enable MLD snooping for a VLAN before you execute this command for the VLAN.

You can enable host tracking for a VLAN in VLAN view or globally for all VLANs in MLD-snooping view. For a VLAN, the VLAN-specific configuration has the same priority as the global configuration.

Examples

In VLAN 2, enable MLD snooping, and then enable host tracking.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable
[Sysname-vlan2] mld-snooping host-tracking
```

Use **mld-snooping static-group** to configure a port as a static member port of an IPv6 multicast group or an IPv6 multicast source and group.

Use **undo mld-snooping static-group** to delete the configuration of static member ports.

Syntax

mld-snooping static-group *ipv6-group-address* [**source-ip** *ipv6-source-address*] **vlan** *vlan-id*

undo mld-snooping static-group { *ipv6-group-address* [**source-ip** *ipv6-source-address*] **vlan** *vlan-id* | **all** }

Default

A port is not a static member port of IPv6 multicast groups.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F.

source-ip *ipv6-source-address*: Specifies an IPv6 multicast source by its IPv6 address. If you specify an IPv6 multicast source, this command configures the port as a static member port of an IPv6 multicast source and group. If you do not specify an IPv6 multicast source, this command configures the port as a static member port of an IPv6 multicast group. This option takes effect on MLDv2 snooping devices.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

all: Specifies all IPv6 multicast groups and all IPv6 multicast sources and groups.

Examples

Configure GigabitEthernet 1/0/1 as a static member port for the IPv6 multicast group (*, FF3E::101) in VLAN 2.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable
[Sysname-vlan2] quit
```

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mld-snooping static-group ff3e::101 vlan 2
```

mld-snooping static-router-port

Use **mld-snooping static-router-port** to configure a port as a static router port.

Use **undo mld-snooping static-router-port** to remove the configuration of static router ports.

Syntax

mld-snooping static-router-port vlan *vlan-id*

undo mld-snooping static-router-port { **all** | **vlan** *vlan-id* }

Default

A port is not a static router port.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

all: Specifies all VLANs.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

Examples

Configure GigabitEthernet 1/0/1 as a static router port in VLAN 2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mld-snooping static-router-port vlan 2
```

mld-snooping version

Use **mld-snooping version** to specify an MLD snooping version for a VLAN.

Use **undo mld-snooping version** to restore the default.

Syntax

mld-snooping version *version-number*

undo mld-snooping version

Default

The MLD snooping version in a VLAN is 1.

Views

VLAN view

Predefined user roles

network-admin

Parameters

version-number: Specifies an MLD snooping version, 1 or 2.

Usage guidelines

You must enable MLD snooping for a VLAN before you configure this command.

You can specify the version for a VLAN in VLAN view or for the specified VLANs in MLD-snooping view. The VLAN-specific configuration has the same priority as the configuration in MLD-snooping view, and the most recent configuration takes effect.

Examples

In VLAN 2, enable MLD snooping, and specify MLD snooping version 2.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable
[Sysname-vlan2] mld-snooping version 2
```

Related commands

enable (MLD-snooping view)

mld-snooping enable

version (MLD-snooping view)

overflow-replace (MLD-snooping view)

Use **overflow-replace** to enable the IPv6 multicast group replacement feature globally.

Use **undo overflow-replace** to disable the IPv6 multicast group replacement feature globally.

Syntax

overflow-replace [**vlan** *vlan-list*]

undo overflow-replace [**vlan** *vlan-list*]

Default

The IPv6 multicast group replacement feature is disabled.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094. If you do not specify a VLAN, this command takes effect on all VLANs.

Usage guidelines

This command takes effect only on the IPv6 multicast groups that a port joins dynamically.

You can enable IPv6 multicast group replacement globally for all ports in MLD-snooping view or for a port in interface view. For a port, the port-specific configuration takes priority over the global configuration.

Examples

Globally enable the IPv6 multicast group replacement feature for VLAN 2.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] overflow-replace vlan 2
```

Related commands

Examples

Disable MLD report suppression.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] undo report-aggregation
```

reset ipv6 l2-multicast fast-forwarding cache

Use **reset ipv6 l2-multicast fast-forwarding cache** to clear Layer 2 IPv6 multicast fast forwarding entries.

Syntax

reset ipv6 l2-multicast fast-forwarding cache [**vlan** *vlan-id*] { { *ipv6-source-address* | *ipv6-group-address* } * | **all** } [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

Parameters

vlan *vlan-id*: Specifies a VLAN by its VLAN ID in the range of 1 to 4094.

ipv6-source-address: Specifies an IPv6 multicast source address.

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command clears Layer 2 IPv6 multicast fast forwarding entries for the master device.

all: Specifies all Layer 2 IPv6 multicast fast forwarding entries.

Examples

Clear all Layer 2 IPv6 multicast fast forwarding entries.

```
<Sysname> reset ipv6 l2-multicast fast-forwarding cache all
```

Clear the Layer 2 IPv6 multicast fast forwarding entry for the IPv6 group (*, FF1E::2).

```
<Sysname> reset ipv6 l2-multicast fast-forwarding cache FF1E::2
```

Related commands

display mld-snooping statistics

router-aging-time (MLD-snooping view)

Use **router-aging-time** to set the aging timer for dynamic router ports globally.

Use **undo router-aging-time** to restore the default.

Syntax

router-aging-time *seconds*

undo router-aging-time

Default

The aging timer for dynamic router ports is 260 seconds.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

seconds: Specifies an aging timer for dynamic router ports, in the range of 1 to 8097894 seconds.

Usage guidelines

You can set the timer globally for all VLANs in MLD-snooping view or for a VLAN in VLAN view. For a VLAN, the VLAN-specific configuration takes priority over the global configuration.

Examples

Set the global aging timer for dynamic router ports to 100 seconds.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] router-aging-time 100
```

Related commands

mld-snooping router-aging-time

source-deny (MLD-snooping view)

Use **source-deny** to enable IPv6 multicast source port filtering on ports to discard all IPv6 multicast data packets.

Use **undo source-deny** to disable IPv6 multicast source port filtering on ports.

Syntax

source-deny port *interface-list*

undo source-deny port *interface-list*

Default

IPv6 multicast source port filtering is disabled.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

port *interface-list*: Specifies a space-separated list of port items. Each item specifies a port by its port type and number or a range of ports in the form of *start-interface-type interface-number* **to** *end-interface-type interface-number*.

Usage guidelines

You can enable this feature for the specified ports in MLD-snooping view or for a port in interface view. For a port, the configuration in MLD-snooping view has the same priority as the configuration in interface view, and the most recent configuration takes effect.

Examples

Enable source port filtering for IPv6 multicast data on ports GigabitEthernet 1/0/1 through GigabitEthernet 1/0/4.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] source-deny port gigabitethernet 1/0/1 to gigabitethernet 1/0/4
```

Related commands

mld-snooping source-deny

version (MLD-snooping view)

Use **version** to specify an MLD snooping version for VLANs.

Use **undo version** to restore the default.

Syntax

version *version-number* **vlan** *vlan-list*

undo version vlan *vlan-list*

Default

The MLD snooping version in a VLAN is 1.

Views

MLD-snooping view

Predefined user roles

network-admin

Parameters

version-number: Specifies an MLD snooping version, 1 or 2.

vlan *vlan-list*: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The VLAN ID is in the range of 1 to 4094.

Usage guidelines

You must enable MLD snooping for the specified VLANs before you execute this command.

You can specify the version for the specified VLANs in MLD-snooping view or for a VLAN in VLAN view. The VLAN-specific configuration has the same priority as the configuration in MLD-snooping view, and the most recent configuration takes effect.

Examples

Enable MLD snooping for VLAN 2 through VLAN 10, and specify MLD snooping version 2 for these VLANs.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] enable vlan 2 to 10
[Sysname-mld-snooping] version 2 vlan 2 to 10
```

ipv6 pim-snooping enable

Use **ipv6 pim-snooping enable** to enable IPv6 PIM snooping for a VLAN.

Use **undo ipv6 pim-snooping enable** to disable IPv6 PIM snooping for a VLAN.

Syntax

ipv6 pim-snooping enable

undo ipv6 pim-snooping enable

Default

IPv6 PIM snooping is disabled for a VLAN.

Views

VLAN view

Predefined user roles

network-admin

Usage guidelines

IPv6 PIM snooping does not take effect on sub-VLANs of IPv6 multicast VLANs.

You must enable the MLD snooping feature and enable MLD snooping for a VLAN before you execute this command.

Examples

Enable the MLD snooping feature, and then enable MLD snooping and IPv6 PIM snooping for VLAN 2.

```
<Sysname> system-view
[Sysname] mld-snooping
[Sysname-mld-snooping] quit
[Sysname] vlan 2
[Sysname-vlan2] mld-snooping enable

IPv6 multicast VLAN commands

display ipv6 multicast-vlan

Use **display ipv6 multicast-vlan** to display information about IPv6 multicast VLANs.

Syntax

display ipv6 multicast-vlan [*vlan-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

vlan-id: Specifies an IPv6 multicast VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify an IPv6 multicast VLAN, this command displays information about all IPv6 multicast VLANs.

Examples

Display information about all IPv6 multicast VLANs.

```
<Sysname> display ipv6 multicast-vlan
Total 2 IPv6 multicast VLANs.

IPv6 multicast VLAN 100:
  Sub-VLAN list(3 in total):
    2-3, 6
  Port list(3 in total):
    GE1/0/1
    GE1/0/2
    GE1/0/3

IPv6 multicast VLAN 200:
  Sub-VLAN list(0 in total):
  Port list(0 in total):
```

Table 1 Command output

Field	Description
Total 2 IPv6 multicast VLANs	Total number of IPv6 multicast VLANs.
Sub-VLAN list(3 in total)	Sub-VLAN list of the IPv6 multicast VLAN, and the total number of the sub-VLANs.
Port list(3 in total)	Port list of the IPv6 multicast VLAN, and the total number of the ports.

display ipv6 multicast-vlan forwarding-table

Use **display ipv6 multicast-vlan forwarding-table** to display IPv6 multicast VLAN forwarding entries.

Syntax

display ipv6 multicast-vlan forwarding-table [*ipv6-source-address* [*prefix-length*] | *ipv6-group-address* [*prefix-length*] | **slot** *slot-number* | **subvlan** *vlan-id* | **vlan** *vlan-id*] *

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipv6-source-address: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this command displays IPv6 multicast VLAN forwarding entries for all IPv6 multicast sources.

prefix-length: Specifies a prefix length of the IPv6 multicast source address. The value range is 0 to 128 and the default value is 128.

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16, where "x" and "y" represent any hexadecimal numbers in the range of 0 to F. If you do not specify an IPv6 multicast group, this command displays IPv6 multicast VLAN forwarding entries for all IPv6 multicast groups.

prefix-length: Specifies a prefix length of the IPv6 multicast group address. The value range is 8 to 128 and the default value is 128.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays IPv6 multicast VLAN forwarding entries for the master device.

subvlan *vlan-id*: Specifies a sub-VLAN by its VLAN ID. If you do not specify a sub-VLAN, this command displays IPv6 multicast VLAN forwarding entries for all sub-VLANs.

vlan *vlan-id*: Specifies an IPv6 multicast VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify an IPv6 multicast VLAN, this command displays IPv6 multicast VLAN forwarding entries for all VLANs.

Examples

Display all IPv6 multicast VLAN forwarding entries.

```
<Sysname> display ipv6 multicast-vlan forwarding-table
IPv6 multicast VLAN 100 Forwarding Table
Total 1 entries, 1 matched

00001. (1::1, FF0E::1)
     Flags: 0x10000
     IPv6 multicast VLAN: 100
     List of sub-VLANs (3 in total):
       1: VLAN 10
       2: VLAN 20
       3: VLAN 30
```

Table 2 Command output

Field	Description
IPv6 multicast VLAN 100 Forwarding Table	The multicast forwarding table for IPv6 multicast VLAN 100.
Total 1 entries, 1 matched	Total number of (S, G) entries, and the number of matching entries.
00001	Sequence number of the (S, G) entry.
(1::1, FF0E::1)	(S, G) entry, where a double colon (::) in the S position means all IPv6 multicast sources.
Flags	Entry flag. This field displays one flag or the sum of multiple flags. In this example, the value 0x10000 means that the entry has only one flag 0x10000. The following flags are available for an entry: • **0x1**—The entry is in inactive state. • **0x4**—The entry fails to update. • **0x8**—The sub-VLAN information fails to update for the entry. • **0x200**—The entry is in GR state. • **0x10000**—The entry is an IPv6 multicast VLAN forwarding entry.
List of sub-VLANs (3 in total)	Sub-VLAN list of the IPv6 multicast VLAN, and the total number of the sub-VLANs.

display ipv6 multicast-vlan group

Use **display ipv6 multicast-vlan group** to display information about IPv6 multicast groups in IPv6 multicast VLANs.

Syntax

display ipv6 multicast-vlan group [*ipv6-source-address* | *ipv6-group-address* | **slot** *slot-number* | **verbose** | **vlan** *vlan-id*] *

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipv6-source-address: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this command displays information about IPv6 multicast groups for all IPv6 multicast sources in IPv6 multicast VLANs.

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F. If you do not specify an IPv6 multicast group, this command displays information about all IPv6 multicast groups in IPv6 multicast VLANs.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about IPv6 multicast groups in IPv6 multicast VLANs for the master device.

verbose: Displays detailed information. If you do not specify the keyword, this command displays brief information.

vlan *vlan-id*: Specifies an IPv6 multicast VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify an IPv6 multicast VLAN, this command displays information about IPv6 multicast groups for all IPv6 multicast VLANs.

Examples

Display detailed information about all IPv6 multicast groups in IPv6 multicast VLANs.

```
<Sysname> display ipv6 multicast-vlan group verbose
Total 6 entries.

IPv6 multicast VLAN 10: Total 3 entries.
  (2::2, FF0E::2)
    Flags: 0x70000020
    Sub-VLANs (1 in total):
      VLAN 40
  (22::22, FF0E::4)
    Flags: 0x70000030
    Sub-VLANs (1 in total):
      VLAN 40
  (::, FF0E::10)
    Flags: 0x10000030
    Sub-VLANs (1 in total):
      VLAN 40

IPv6 multicast VLAN 20: Total 3 entries.
  (2::2, FF0E::2)
    Flags: 0x70000010
    Sub-VLANs (0 in total):
  (22::22, FF0E::4)
    Flags: 0x70000010
    Sub-VLANs (0 in total):
  (::, FF0E::10)
    Flags: 0x50000010
    Sub-VLANs (0 in total):
```

Table 3 Command output

Field	Description
Total 6 entries	Total number of (S, G) entries.
IPv6 multicast VLAN 10: Total 3 entries	Total number of (S, G) entries in IPv6 multicast VLAN 10.
(::, FF0E::10)	(S, G) entry, where a double colon (::) in the S position means all IPv6 multicast sources.
Flags	Entry flag. This field displays one flag or the sum of multiple flags. For example, the value 0x70000020 means that the entry has flags 0x20, 0x10000000, 0x20000000, and 0x40000000. The following flags are available for an entry: • **0x10**—The entry is created by the IPv6 multicast VLAN. • **0x20**—The entry is created by the sub-VLAN of the IPv6

Field	Description

	multicast VLAN.
	• **0x40**—The entry is to be deleted.
	• **0x10000000**—This value represents one of the following situations:
	  ○ The entry is newly created.
	  ○ The device receives an MLD query within an MLD general query interval.
	• **0x20000000**—The device does not receive MLDv1 or MLDv2 reports that match the entry within an MLD general query interval.
	• **0x40000000**—The device does not receive MLDv2 IS_EX (NULL) reports that match the entry within an MLD general query interval.

Sub-VLANs (1 in total)	Sub-VLAN list of the IPv6 multicast VLAN, and the total number of the sub-VLANs.

Related commands

reset ipv6 multicast-vlan group

ipv6 multicast-vlan

Use **ipv6 multicast-vlan** to configure an IPv6 multicast VLAN and enter its view, or enter the view of an existing IPv6 multicast VLAN.

Use **undo ipv6 multicast-vlan** to remove the configuration of IPv6 multicast VLANs.

Syntax

ipv6 multicast-vlan *vlan-id*

undo ipv6 multicast-vlan { **all** | *vlan-id* }

Default

No IPv6 multicast VLANs exist.

Views

System view

Predefined user roles

network-admin

Parameters

vlan-id: Specifies an existing VLAN ID in the range of 1 to 4094.

all: Specifies all IPv6 multicast VLANs.

Usage guidelines

The total number of IPv6 multicast VLANs on the device cannot exceed 5.

You must enable MLD snooping for the VLAN to be configured as an IPv6 multicast VLAN.

Examples

Enable MLD snooping for VLAN 100. Configure VLAN 100 as an IPv6 multicast VLAN and enter its view.

```
<Sysname> system-view
[Sysname] mld-snooping
```

```
[Sysname-mld-snooping] quit
[Sysname] vlan 100
[Sysname-vlan100] mld-snooping enable
[Sysname-vlan100] quit
[Sysname] ipv6 multicast-vlan 100
[Sysname-ipv6-mvlan-100]
```

Related commands

mld-snooping enable

ipv6 multicast-vlan entry-limit

Use **ipv6 multicast-vlan entry-limit** to set the maximum number of IPv6 multicast VLAN forwarding entries.

Use **undo ipv6 multicast-vlan entry-limit** to restore the default.

Syntax

ipv6 multicast-vlan entry-limit *limit*

undo ipv6 multicast-vlan entry-limit

Default

The following matrix shows the default values for the maximum number of IPv6 multicast VLAN forwarding entries:

Hardware	Maximum number of multicast VLAN forwarding entries
S5110V2-SI switch series S5000V3-EI switch series S5000V5-EI switch series S5000E-X switch series S5000X-EI switch series S5110V2 switch series WS5810-WiNet switch series	60
S5120V2-LI switch series S5130S-LI switch series S5120V3-SI switch series MS4320V2 switch series MS4320 switch series	120
WAS6000 switch series	• WAS6124 and WAS6148: 500 • Other switches: 240
S3100V3-SI switch series	• Switches with product code LS-3100V3-18TP-SI-H1, LS-3100V3-28TP-SI-H1, LS-3100V3-52TP-SI-H1, or LS-3100V3-20TP-PWR-SI-H1: 60 • Other switches: 120
MS4200 switch series	• Switches with product code LS-MS4200-28TP-H1, LS-MS4200-18TP-H1, or LS-MS4200-20TP-PWR-H1: 60 • Other switches: 120

WS5820-WiNet switch series	• Switches with product code WS5820-28P-POE-WiNet: 60 • Other switches: 120
MS4300V2 switch series	• MS4300V2-28P, MS4300V2-52P: 60 • MS4300V2-10P: 120
MS4320V3 switch series	• MS4320V3-28P, MS4320V3-52P: 60 • Other switches: 120
S5120V3-LI switch series	• S5120V2-20P-LI, S5120V2-28P-LI, S5120V2-52P-LI, S5120V2-28P-PWR-LI, S5120V2-52P-PWR-LI: 60 • Other switches: 120

Views

System view

Predefined user roles

network-admin

Parameters

limit: Specifies the maximum number of IPv6 multicast VLAN forwarding entries. The following matrix shows the value range for this argument:

Hardware	Value range
S5110V2-SI switch series S5000V3-EI switch series S5000V5-EI switch series S5000E-X switch series S5000X-EI switch series WAS6000 switch series S5110V2 switch series WS5810-WiNet switch series	0 to 60
S5120V2-LI switch series S5130S-LI switch series S5120V3-SI switch series MS4320V2 switch series MS4320 switch series	0 to 120
S3100V3-SI switch series	• Switches with product code LS-3100V3-18TP-SI-H1, LS-3100V3-28TP-SI-H1, LS-3100V3-52TP-SI-H1, or LS-3100V3-20TP-PWR-SI-H1: 0 to 60 • Other switches: 0 to 120
MS4200 switch series	• Switches with product code LS-MS4200-28TP-H1, LS-MS4200-18TP-H1, or LS-MS4200-20TP-PWR-H1: 0 to 60 • Other switches: 0 to 120
WS5820-WiNet switch series	• Switches with product code WS5820-28P-POE-WiNet: 0 to 60 • Other switches: 0 to 120

MS4300V2 switch series	• MS4300V2-28P, MS4300V2-52P: 0 to 60 • MS4300V2-10P: 0 to 120
MS4320V3 switch series	• MS4320V3-28P, MS4320V3-52P: 0 to 60 • Other switches: 0 to 120
S5120V3-LI switch series	• S5120V2-20P-LI, S5120V2-28P-LI, S5120V2-52P-LI, S5120V2-28P-PWR-LI, S5120V2-52P-PWR-LI: 0 to 60 • Other switches: 0 to 120

Usage guidelines

If the configured value is smaller than the current number of IPv6 multicast VLAN forwarding entries, the device cannot create new entries until some entries age out or are manually removed. To allow new entries to be created immediately, use the **reset ipv6 multicast-vlan group** command to remove IPv6 multicast VLAN forwarding entries.

Examples

Set the maximum number of IPv6 multicast VLAN forwarding entries to 120.

```
<Sysname> system-view
[Sysname] ipv6 multicast-vlan entry-limit 120
```

Related commands

entry-limit (MLD-snooping view)

ipv6 port multicast-vlan

Use **ipv6 port multicast-vlan** to assign a user port to an IPv6 multicast VLAN.

Use **undo ipv6 port multicast-vlan** to restore the default.

Syntax

ipv6 port multicast-vlan *vlan-id*

undo ipv6 port multicast-vlan

Default

A port does not belong to an IPv6 multicast VLAN.

Views

Layer 2 Ethernet interface view

Layer 2 aggregate interface view

Predefined user roles

network-admin

Parameters

vlan-id: Specifies an IPv6 multicast VLAN by its VLAN ID in the range of 1 to 4094.

Usage guidelines

You can assign a port to only one IPv6 multicast VLAN.

For the port to be assigned to an IPv6 multicast VLAN, you must enable MLD snooping for the VLAN to which the port belongs.

Examples

Assign GigabitEthernet 1/0/1 to IPv6 multicast VLAN 100.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] ipv6 port multicast-vlan 100
```

port (IPv6 multicast VLAN view)

Use **port** to assign user ports to an IPv6 multicast VLAN.

Use **undo port** to delete user ports from an IPv6 multicast VLAN.

Syntax

port *interface-list*

undo port { **all** | *interface-list* }

Default

An IPv6 multicast VLAN does not have user ports.

Views

IPv6 multicast VLAN view

Predefined user roles

network-admin

Parameters

interface-list: Specifies a port in the form of *interface-type interface-number*, or a port range in the form of *interface-type interface-number* to *interface-type interface-number*.

all: Specifies all user ports in the current IPv6 multicast VLAN.

Usage guidelines

You can assign only Layer 2 Ethernet interfaces or Layer 2 aggregate interfaces as user ports to an IPv6 multicast VLAN. Additionally, you can assign a port to only one IPv6 multicast VLAN.

For ports to be assigned to an IPv6 multicast VLAN, you must enable MLD snooping for the VLANs to which the ports belong.

Examples

Assign GigabitEthernet 1/0/1 through GigabitEthernet 1/0/5 as user ports to IPv6 multicast VLAN 100.

```
<Sysname> system-view
[Sysname] ipv6 multicast-vlan 100
[Sysname-ipv6-mvlan-100] port gigabitethernet 1/0/1 to gigabitethernet 1/0/5
```

reset ipv6 multicast-vlan group

Use **reset ipv6 multicast-vlan group** to clear IPv6 multicast group entries in IPv6 multicast VLANs.

Syntax

reset ipv6 multicast-vlan group [*ipv6-group-address* [*prefix-length*] | *ipv6-source-address* [*prefix-length*] | **vlan** *vlan-id*] *

Views

User view

Predefined user roles

network-admin

Parameters

ipv6-group-address: Specifies an IPv6 multicast group address. The value range for this argument is FFxy::/16 (excluding FFx1::/16 and FFx2::/16), where "x" and "y" represent any hexadecimal numbers in the range of 0 to F. If you do not specify an IPv6 multicast group, this command clears all IPv6 multicast group entries in IPv6 multicast VLANs.

prefix-length: Specifies a prefix length of the IPv6 multicast group address. The value range is 8 to 128 and the default value is 128.

ipv6-source-address: Specifies an IPv6 multicast source by its IPv6 address. If you do not specify an IPv6 multicast source, this command clears IPv6 multicast group entries for all IPv6 multicast sources in IPv6 multicast VLANs.

prefix-length: Specifies a prefix length of the IPv6 multicast source address. The value range is 0 to 128 and the default value is 128.

vlan *vlan-id*: Specifies an IPv6 multicast VLAN by its VLAN ID in the range of 1 to 4094. If you do not specify an IPv6 multicast VLAN, this command clears IPv6 multicast group entries for all IPv6 multicast VLANs.

Examples

Clear all IPv6 multicast group entries for all IPv6 multicast VLANs.

```
<Sysname> reset ipv6 multicast-vlan group
```

Related commands

display ipv6 multicast-vlan group

subvlan (IPv6 multicast VLAN view)

Use **subvlan** to assign VLANs as sub-VLANs to an IPv6 multicast VLAN.

Use **undo subvlan** to delete sub-VLANs from an IPv6 multicast VLAN.

Syntax

subvlan *vlan-list*

undo subvlan { **all** | *vlan-list* }

Default

An IPv6 multicast VLAN does not have sub-VLANs.

Views

IPv6 multicast VLAN view

Predefined user roles

network-admin

Parameters

vlan-list: Specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN by its ID or a range of VLANs in the form of *start-vlan-id* **to** *end-vlan-id*. The value range for the VLAN ID is 1 to 4094. The specified VLANs must exist and cannot be multicast VLANs or sub-VLANs of other IPv6 multicast VLANs.

all: Specifies all sub-VLANs of the current IPv6 multicast VLAN.

Usage guidelines

You must enable MLD snooping for VLANs to be configured as sub-VLANs of an IPv6 multicast VLAN.

Examples

Assign VLAN 10 through VLAN 15 as sub-VLANs to multicast VLAN 100.

```
<Sysname> system-view
[Sysname] ipv6 multicast-vlan 100
[Sysname-ipv6-mvlan-100] subvlan 10 to 15
```

ACL and QoS Command Reference

This command reference is applicable to the following switches and software versions:

H3C S5120V2-LI switch series (Release 6308P01 and later)
H3C S3100V3-SI switch series (Release 6309P01 and later)
H3C S5110V2 switch series (Release 6310 and later)
H3C S5110V2-SI switch series (Release 6310 and later)
H3C S5000V3-EI switch series (Release 6310 and later)
H3C S5000V5-EI switch series (Release 6319P01 and later)
H3C S5000E-X switch series (Release 6310 and later)
H3C S5130S-LI switch series (Release 6310 and later)
H3C MS4320V2 switch series (Release 6308P01 and later)
H3C MS4320 switch series (Release 6308P01 and later)
H3C MS4300V2 switch series (Release 6308P01 and later)
H3C MS4200 switch series (Release 6310 and later)
H3C WS5810-WiNet switch series (Release 6308P01 and later)
H3C WS5820-WiNet switch series (Release 6308P01 and later)
H3C WAS6000 switch series (Release 6308P01 and later)
H3C S5000X-EI switch series (Release 6329 and later)
H3C MS4320V3 switch series (Release 6329 and later)
H3C S5120V3-SI switch series (Release 6329 and later)
H3C S5120V3-LI switch series (Release 6329 and later)

Software version: Release 63xx
Document version: 6W105-20230524

Preface

This command reference describes the ACL and QoS configuration commands.

This preface includes the following topics about the documentation:

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Contents

ACL commands

acl

Use **acl** to create an ACL and enter its view, or enter the view of an existing ACL.

Use **undo acl** to delete the specified or all ACLs.

Syntax

Command set 1:

acl [**ipv6**] { **name** *acl-name* | **number** *acl-number* [**name** *acl-name*] [**match-order** { **auto** | **config** }] }

undo acl [**ipv6**] { **all** | **name** *acl-name* | **number** *acl-number* }

Command set 2:

acl [**ipv6**] { **advanced** | **basic** } { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

acl mac { *acl-number* | **name** *acl-name* } [**match-order** { **auto** | **config** }]

undo acl [**ipv6**] { **all** | { **advanced** | **basic** } { *acl-number* | **name** *acl-name* } }

undo acl mac { **all** | *acl-number* | **name** *acl-name* }

Default

No ACLs exist.

Views

System view

Predefined user roles

network-admin

Parameters

ipv6: Specifies the IPv6 ACL type. To specify the IPv4 ACL type, do not use this keyword.

basic: Specifies the basic ACL type.

advanced: Specifies the advanced ACL type.

mac: Specifies the Layer 2 ACL type.

number *acl-number*: Assigns a number to the ACL.

acl-number: Assigns a number to the ACL. The following are available value ranges:

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *acl-name*: Assigns a name to the ACL. The *acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**.

match-order: Specifies the order in which ACL rules are compared against packets.

- **auto**: Compares ACL rules in depth-first order.

- **config**: Compares ACL rules in ascending order of rule ID. The rule with a smaller ID has a higher priority. If you do not specify a match order, the **config** order applies by default.

all: Specifies all ACLs of the specified type.

Usage guidelines

If you create a numbered ACL, you can enter the view of the ACL by using either of the following commands:

- The **acl** [**ipv6**] **number** *acl-number* command.
- The **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** } *acl-number* command.

If you create a ACL by using the **acl** [**ipv6**] **number** *acl-number* **name** *acl-name* command, you can enter the view of the ACL by using either of the following commands:

- **acl** [**ipv6**] **name** *acl-name* (for only basic ACLs and advanced ACLs).
- **acl** [**ipv6**] **number** *acl-number* [**name** *acl-name*].
- **acl** { [**ipv6**] { **advanced** | **basic** } | **mac**] } **name** *acl-name*.

If you create a named ACL by using the **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** } **name** *acl-name* command, you can enter the view of the ACL by using either of the following commands:

- **acl** [**ipv6**] **name** *acl-name* (for only basic ACLs and advanced ACLs).
- **acl** { [**ipv6**] { **advanced** | **basic** } | **mac** } **name** *acl-name*.

You can change the match order only for ACLs that do not contain any rules.

Matching packets are forwarded through slow forwarding if an ACL rule contains match criteria or has functions enabled in addition to the following match criteria and functions:

- Source and destination IP addresses.
- Source and destination ports.
- Transport layer protocol.
- ICMP or ICMPv6 message type, message code, and message name.
- Logging.
- Time range.

Slow forwarding requires packets to be sent to the control plane for forwarding entry calculation, which affects the device forwarding performance.

Examples

Create IPv4 basic ACL 2000 and enter its view.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000]
```

Create IPv4 basic ACL **flow** and enter its view.

```
<Sysname> system-view
[Sysname] acl basic name flow
[Sysname-acl-ipv4-basic-flow]
```

Create IPv4 advanced ACL 3000 and enter its view.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000]
```

Create IPv6 basic ACL 2000 and enter its view.

```
<Sysname> system-view
```

```
[Sysname] acl ipv6 basic 2000
[Sysname-acl-ipv6-basic-2000]
```

Create IPv6 basic ACL **flow** and enter its view.

```
<Sysname> system-view
[Sysname] acl ipv6 basic name flow
[Sysname-acl-ipv6-basic-flow]
```

Create IPv6 advanced ACL **abc** and enter its view.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced name abc
[Sysname-acl-ipv6-adv-abc]
```

Create Layer 2 ACL 4000 and enter its view.

```
<Sysname> system-view
[Sysname] acl mac 4000
[Sysname-acl-mac-4000]
```

Create Layer 2 ACL **flow** and enter its view.

```
<Sysname> system-view
[Sysname] acl mac name flow
[Sysname-acl-mac-flow]
```

Related commands

display acl

acl copy

Use **acl copy** to create an ACL by copying an ACL that already exists.

Syntax

acl [**ipv6** | **mac**] **copy** { *source-acl-number* | **name** *source-acl-name* } **to** { *dest-acl-number* | **name** *dest-acl-name* }

Views

System view

Predefined user roles

network-admin

Parameters

ipv6: Specifies the IPv6 ACL type.

mac: Specifies the Layer 2 ACL type.

source-acl-number: Specifies an existing source ACL by its number. The following are available value ranges:

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *source-acl-name*: Specifies an existing source ACL by its name. The *source-acl-name* argument is a case-insensitive string of 1 to 63 characters.

dest-acl-number: Assigns a unique number to the new ACL. The following are available value ranges:

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *dest-acl-name*: Assigns a unique name to the new ACL. The *dest-acl-name* argument is a case-insensitive string of 1 to 63 characters. It must start with an English letter and to avoid confusion, it cannot be **all**.

Usage guidelines

The new ACL and the source ACL must be the same type.

When specifying an ACL by its number, follow these rules:

- To specify an IPv6 ACL, you must specify both its ACL number and the **ipv6** keyword.
- To specify a Layer 2 ACL, you can specify its ACL number without the **mac** keyword.

To specify an IPv6 ACL or Layer 2 ACL by a name, you must specify both the ACL name and the **ipv6** or **mac** keyword.

The new ACL has the same properties and content as the source ACL, but uses a different number or name from the source ACL.

Examples

Create IPv4 basic ACL 2002 by copying IPv4 basic ACL 2001.

```
<Sysname> system-view
[Sysname] acl copy 2001 to 2002
```

Create IPv4 basic ACL **paste** by copying IPv4 basic ACL **test**.

```
<Sysname> system-view
[Sysname] acl copy name test to name paste
```

acl logging interval

Use **acl logging interval** to enable logging for packet filtering and set the interval.

Use **undo acl logging interval** to restore the default.

Syntax

acl logging interval *interval*

undo acl logging interval

Default

The interval is 0. The device does not generate log entries for packet filtering.

Views

System view

Predefined user roles

network-admin

Parameters

interval: Specifies the interval at which log entries are generated and output. It must be a multiple of 5, in the range of 0 to 1440 minutes. To disable the logging, set the value to 0.

Usage guidelines

The logging feature is available for IPv4 or IPv6 ACL rules that have the **logging** keyword.

You can configure the ACL module to generate log entries for packet filtering and output them to the information center at the output interval. The log entry records the number of matching packets and the matched ACL rules. When the first packet of a flow matches an ACL rule, the output interval starts, and the device immediately outputs a log entry for this packet. When the output interval ends, the device outputs a log entry for subsequent matching packets of the flow. For more information about the information center, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure the device to generate and output packet filtering log entries every 10 minutes.

```
<Sysname> system-view
[Sysname] acl logging interval 10
```

acl trap interval

Use **acl trap interval** to enable SNMP notifications for packet filtering and set the interval.

Use **undo acl interval** to restore the default.

Syntax

acl trap interval *interval*

undo acl trap interval

Default

The interval is 0. The device does not generate SNMP notifications for packet filtering.

Views

System view

Predefined user roles

network-admin

Parameters

interval: Specifies the interval at which SNMP notifications are generated and output. It must be a multiple of 5, in the range of 0 to 1440 minutes. To disable SNMP notifications, set the value to 0.

Usage guidelines

The SNMP notifications feature is available for IPv4 or IPv6 ACL rules that have the **logging** keyword.

You can configure the ACL module to generate SNMP notifications for packet filtering and output them to the SNMP module at the output interval. The notification records the number of matching packets and the matched ACL rules. When the first packet of a flow matches an ACL rule, the output interval starts, and the device immediately outputs a notification for this packet. When the output interval ends, the device outputs a notification for subsequent matching packets of the flow. For more information about SNMP, see *Network Management and Monitoring Configuration Guide*.

Examples

Configure the device to generate and output packet filtering SNMP notifications every 10 minutes.

```
<Sysname> system-view
```

```
[Sysname] acl trap interval 10
```

rule (IPv4 basic ACL view)

rule (IPv6 advanced ACL view)

rule (IPv6 basic ACL view)

description

Use **description** to configure a description for an ACL.

Use **undo description** to delete an ACL description.

Syntax

description *text*

undo description

Default

An ACL does not have a description.

Views

IPv4 basic/advanced ACL view

IPv6 basic/advanced ACL view

Layer 2 ACL view

Predefined user roles

network-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Examples

Configure a description for IPv4 basic ACL 2000.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] description This is an IPv4 basic ACL.
```

Related commands

display acl

display acl

Use **display acl** to display ACL configuration and match statistics.

Syntax

display acl [**ipv6** | **mac**] { *acl-number* | **all** | **name** *acl-name* }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipv6: Specifies the IPv6 ACL type.

mac: Specifies the Layer 2 ACL type.

acl-number: Specifies an ACL by its number. The following are available value ranges:

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

all: Specifies all ACLs of the specified type.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

This command displays ACL rules in **config** or **auto** order, whichever is configured.

To specify the IPv4 ACL type, do not specify the **ipv6** or **mac** keyword.

Examples

Display configuration and match statistics for IPv4 basic ACL 2001.

```
<Sysname> display acl 2001
Basic IPv4 ACL 2001, 1 rule, match-order is auto,
This is an IPv4 basic ACL.
ACL's step is 5, start ID is 0
 rule 5 permit source 1.1.1.1 0
 rule 5 comment This rule is used on GigabitEthernet1/0/1.
```

Display configuration and match statistics for IPv4 advanced ACL **acl1_L4_IN**.

```
<Sysname> display acl name acl1_L4_IN
Advanced IPv4 ACL named acl1_L4_IN, 1 rule,
This is a dynamic advanced IPv4 ACL.
ACL's step is 5, start ID is 0
 rule 0 permit source 1.1.1.1 0
```

Table 1 Command output

Field	Description
Basic IPv4 ACL 2001	Type and number of the ACL. The following field information is about IPv4 basic ACL 2001.
1 rule	The ACL contains one rule.
match-order is auto	The match order for the ACL is **auto**, which sorts ACL rules in depth-first order. This field is not displayed when the match order is **config**.
This is an IPv4 basic ACL.	Description of the ACL.
ACL's step is 5	The rule numbering step is 5.
start ID is 0	The start rule ID is 0.
rule 5 permit source 1.1.1.1 0	Content of rule 5. The rule permits packets sourced from the IP address 1.1.1.1.

rule 5 comment This rule is used on GigabitEthernet1/0/1.	Comment of rule 5.
This is a dynamic advanced IPv4 ACL.	The ACL is added dynamically by an application module. This type of ACL can only be added, modified, or deleted by an application module and cannot be configured through CLI commands. This type of ACL is supported only in Release 6309P01 and later.

display packet-filter

Use **display packet-filter** to display ACL application information for packet filtering.

Syntax

display packet-filter interface [*interface-type interface-number*] [**inbound** | **outbound**] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface [*interface-type interface-number*]: Specifies an interface by its type and number. If you do not specify an interface, this command displays ACL application information for packet filtering on all interfaces. If you specify an Ethernet interface, you do not need to specify the **slot** *slot-number* option.

inbound: Specifies the inbound direction.

outbound: Specifies the outbound direction.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays ACL application information for packet filtering for the master device.

Usage guidelines

If neither the **inbound** keyword nor the **outbound** keyword is specified, this command displays ACL application information for packet filtering in both directions.

Examples

Display ACL application information for inbound packet filtering on interface GigabitEthernet 1/0/1.

```
<Sysname> display packet-filter interface gigabitethernet 1/0/1 inbound
Interface: GigabitEthernet1/0/1
 Inbound policy:
  IPv4 ACL 2001r
  IPv6 ACL 2002 (Failed)
  MAC ACL 4003
```

Table 1 Command output

Field	Description
Interface	Interface to which the ACL applies.

Inbound policy	ACL used for filtering incoming traffic.
Outbound policy	ACL used for filtering outgoing traffic.
IPv4 ACL 2001	IPv4 basic ACL 2001 has been successfully applied.
IPv6 ACL 2002 (Failed)	The device has failed to apply IPv6 basic ACL 2002.
Hardware-count	ACL rule match counting in hardware has been successfully enabled.
Hardware-count (Failed)	The device has failed to enable counting ACL rule matches in hardware.
IPv4 default action	Packet filter default action for packets that do not match any IPv4 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.
IPv6 default action	Packet filter default action for packets that do not match any IPv6 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.
MAC default action	Packet filter default action for packets that do not match any Layer 2 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.

display packet-filter statistics

Use **display packet-filter statistics** to display packet filtering statistics.

Syntax

display packet-filter statistics interface *interface-type interface-number* { **inbound** | **outbound** } [[**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }] [**brief**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number.

inbound: Specifies the inbound direction.

outbound: Specifies the outbound direction.

ipv6: Specifies the IPv6 ACL type.

mac: Specifies the Layer 2 ACL type.

acl-number: Specifies an ACL by its number. The following are available value ranges:

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters.

brief: Displays brief statistics.

Usage guidelines

If *acl-number*, **name** *acl-name*, **ipv6**, or **mac** is not specified, this command displays packet filtering statistics for all ACLs.

To specify the IPv4 ACL type, do not specify the **ipv6** or **mac** keyword.

Examples

Display packet filtering statistics for all ACLs on incoming packets of GigabitEthernet 1/0/1.

```
<Sysname> display packet-filter statistics interface gigabitethernet 1/0/1 inbound
Interface: GigabitEthernet1/0/1
 Inbound policy:
  IPv4 ACL 2001, Hardware-count
   From 2011-06-04 10:25:21 to 2011-06-04 10:35:57
   rule 0 permit source 2.2.2.2 0 (2 packets)
   rule 5 permit source 1.1.1.1 0 (Failed)
   Totally 2 packets permitted, 0 packets denied
   Totally 100% permitted, 0% denied

  IPv6 ACL 2000

  MAC ACL 4000
   rule 0 permit
```

Table 2 Command output

Field	Description
Interface	Interface to which the ACL applies.
Inbound policy	ACL used for filtering incoming traffic.
Outbound policy	ACL used for filtering outgoing traffic.
IPv4 ACL 2001	IPv4 basic ACL 2001 has been successfully applied.
IPv4 ACL 2002 (Failed)	The device has failed to apply IPv4 basic ACL 2002.

Hardware-count	ACL rule match counting in hardware has been successfully enabled.
Hardware-count (Failed)	The device has failed to enable counting ACL rule matches in hardware.
From 2011-06-04 10:25:21 to 2011-06-04 10:35:57	Start time and end time of the statistics. The start time is the time when the packet filter was deployed to the member device.
2 packets	Two packets matched the rule. This field is not displayed when no packets matched the rule.
No resource	Resources are not enough for counting matches for the rule. In packet filtering statistics, this field is displayed for a rule when resources are not sufficient for rule match counting.
rule 5 permit source 1.1.1.1 0 (Failed)	The device has failed to apply rule 5.
Totally 2 packets permitted, 0 packets denied	Number of packets permitted and denied by the ACL.
Totally 100% permitted, 0% denied	Ratios of permitted and denied packets to all packets.
IPv4 default action	Packet filter default action for packets that do not match any IPv4 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.
IPv6 default action	Packet filter default action for packets that do not match any IPv6 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.
MAC default action	Packet filter default action for packets that do not match any Layer 2 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.

Related commands

`reset packet-filter statistics`

display packet-filter statistics sum

Use **`display packet-filter statistics sum`** to display accumulated packet filtering statistics for an ACL.

Syntax

display packet-filter statistics sum { **inbound** | **outbound** } [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* } [**brief**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

inbound: Specifies the inbound direction.

outbound: Specifies the outbound direction.

ipv6: Specifies the IPv6 ACL type.

mac: Specifies the Layer 2 ACL type.

acl-number: Specifies an ACL by its number.

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters.

brief: Displays brief statistics.

Usage guidelines

To specify the IPv4 ACL type, do not specify the **ipv6** or **mac** keyword.

Examples

Display accumulated packet filtering statistics for IPv4 basic ACL 2001 on incoming packets.

```
<Sysname> display packet-filter statistics sum inbound 2001
Sum:
 Inbound policy:
  IPv4 ACL 2001
   rule 0 permit source 2.2.2.2 0 (2 packets)
   rule 5 permit source 1.1.1.1 0
   Totally 2 packets permitted, 0 packets denied
   Totally 100% permitted, 0% denied
```

Display brief accumulated packet filtering statistics for IPv4 basic ACL 2000 on incoming packets.

```
<Sysname> display packet-filter statistics sum inbound 2000 brief
Sum:
 Inbound policy:
  IPv4 ACL 2000
   Totally 2 packets permitted, 0 packets denied
   Totally 100% permitted, 0% denied
```

Table 3 Command output

Field	Description
Sum	Accumulated packet filtering statistics.
Inbound policy	Accumulated packet filtering statistics in the inbound direction.
Outbound policy	Accumulated packet filtering statistics in the outbound direction.
IPv4 ACL 2001	Accumulated packet filtering statistics of IPv4 basic ACL 2001.
2 packets	Two packets matched the rule. This field is not displayed when no packets matched the rule.
Totally 2 packets permitted, 0 packets denied	Number of packets permitted and denied by the ACL.
Totally 100% permitted, 0% denied	Ratios of permitted and denied packets to all packets.

Related commands

reset packet-filter statistics

display packet-filter verbose

Use **display packet-filter verbose** to display ACL application details for packet filtering.

Syntax

display packet-filter verbose interface *interface-type interface-number* { **inbound** | **outbound** } [[**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. The **slot** *slot-number* option is not available for an Ethernet interface.

inbound: Specifies the inbound direction.

outbound: Specifies the outbound direction.

ipv6: Specifies the IPv6 ACL type.

mac: Specifies the Layer 2 ACL type.

acl-number: Specifies an ACL by its number.

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays ACL application details for packet filtering for the master device.

Usage guidelines

If *acl-number*, **name** *acl-name*, **ipv6**, or **mac** is not specified, this command displays application details of all ACLs for packet filtering.

To specify the IPv4 ACL type, do not specify the **ipv6** or **mac** keyword.

Examples

Display application details of all ACLs for inbound packet filtering on GigabitEthernet 1/0/1.

```
<Sysname> display packet-filter verbose interface gigabitethernet 1/0/1 inbound
Interface: GigabitEthernet1/0/1
 Inbound policy:
  IPv4 ACL 2001
   rule 0 permit
   rule 5 permit source 1.1.1.1 0 (Failed)

  IPv6 ACL 2000
   rule 0 permit

  MAC ACL 4000

  IPv4 default action: Deny

  IPv6 default action: Deny, Hardware-count (Failed)

  MAC default action: Deny
```

Table 4 Command output

Field	Description
Interface	Interface to which the ACL applies.
Inbound policy	ACL used for filtering incoming traffic.
Outbound policy	ACL used for filtering outgoing traffic.
IPv4 ACL 2001	IPv4 basic ACL 2001 has been successfully applied.
IPv4 ACL 2002 (Failed)	The device has failed to apply IPv4 basic ACL 2002.
Hardware-count	ACL rule match counting in hardware has been successfully enabled.
Hardware-count (Failed)	The device has failed to enable counting ACL rule matches in hardware.
rule 5 permit source 1.1.1.1 0 (Failed)	The device has failed to apply rule 5.
IPv4 default action	Packet filter default action for packets that do not match any IPv4 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been

	successfully applied for packet filtering.
IPv6 default action	Packet filter default action for packets that do not match any IPv6 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.
MAC default action	Packet filter default action for packets that do not match any Layer 2 ACLs: • **Deny**—The default action **deny** has been successfully applied for packet filtering. • **Deny (Failed)**—The device has failed to apply the default action **deny** for packet filtering. The action **permit** still functions. • **Permit**—The default action **permit** has been successfully applied for packet filtering.

display qos-acl resource

Use **display qos-acl resource** to display QoS and ACL resource usage.

Syntax

display qos-acl resource [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays QoS and ACL resource usage for all member devices.

Usage guidelines

This command does not display any usage data if the specified device does not support counting QoS and ACL resources.

The following features cannot work correctly when QoS and ACL resources are insufficient:

- Packet filtering.
- Device login.
- 802.1X.
- MAC authentication.

For these features to work correctly, reserve enough QoS and ACL resources.

Examples

Display QoS and ACL resource usage.

```
<Sysname> display qos-acl resource
Interfaces: GE1/0/1 to GE1/0/24, XGE1/0/51 to XGE1/0/52 (slot 1)
```

```
-------------------------------------------------------------------------
 Type             Total      Reserved   Configured Remaining  Usage
-------------------------------------------------------------------------
 TTI ACL          256        0          0          256        0%
 PCL ACL          512        16         0          496        3%
 PCL Counter      656        14         0          642        2%
 IPCL Meter       768        0          0          768        0%
 EPCL Meter       128        0          0          128        0%

Interfaces: GE1/0/25 to GE1/0/48, XGE1/0/49 to XGE1/0/50 (slot 1)
-------------------------------------------------------------------------
 Type             Total      Reserved   Configured Remaining  Usage
-------------------------------------------------------------------------
 TTI ACL          256        0          0          256        0%
 PCL ACL          512        16         0          496        3%
 PCL Counter      656        14         0          642        2%
 IPCL Meter       768        0          0          768        0%
 EPCL Meter       128        0          0          128        0%
```

Table 5 Command output

Field	Description
Interfaces	Interface range for the resources.
Type	Resource type: • **TTI ACL**—ACL resources used for interfaces. These resources are used only for QinQ and VLAN mapping in the current software version. • **PCL ACL**—ACL resources used for policies, including resources used by protocol packets and used by the application modules that reference ACLs. • **PCL Counter**—Accounting resources used for policies. • **IPCL Meter**—Traffic policing resources used in inbound QoS policies. • **EPCL Meter**—Traffic policing resources used in outbound QoS policies.
Total	Total number of resources.
Reserved	Number of reserved resources.
Configured	Number of resources that has been applied.
Remaining	Number of resources that you can apply.
Usage	Configured and reserved resources as a percentage of total resources. If the percentage is not an integer, this field displays the integer part. For example, if the actual usage is 50.8%, this field displays 50%.

packet-filter

Use **packet-filter** to apply an ACL to an interface to filter packets.

Use **undo packet-filter** to remove an ACL from an interface.

Syntax

packet-filter [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* } { **inbound** | **outbound** } [**hardware-count**]

undo packet-filter [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* } { **inbound** | **outbound** }

Default

No ACL is applied to an interface to filter packets.

Views

Layer 2 Ethernet interface view

VLAN interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies the IPv6 ACL type.

mac: Specifies the Layer 2 ACL type.

acl-number: Specifies an ACL by its number.

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters.

inbound: Filters incoming packets.

outbound: Filters outgoing packets.

hardware-count: Enables counting ACL rule matches performed in hardware. If you do not specify this keyword, rule matches for the ACL are not counted in hardware.

Usage guidelines

If you use the *acl-number* argument to specify an ACL, follow these guidelines:

- To specify an IPv4 ACL, use the *acl-number* argument directly.
- To specify an IPv6 ACL, specify the **ipv6** keyword, and then the *acl-number* argument.
- To specify a Layer 2 ACL, the **mac** keyword is not a must. You can either specify the **mac** keyword and then the *acl-number* argument or specify only the *acl-number* argument.

If you use the **name** *acl-name* option to specify an ACL, follow these guidelines:

- To specify an IPv4 ACL, use the **name** *acl-name* option.
- To specify an IPv6 or Layer 2 ACL, specify the related keyword and then the **name** *acl-name* option.

The **hardware-count** keyword in this command enables match counting in hardware for all rules in an ACL, and the **counting** keyword in the **rule** command enables match counting specific to rules.

To disable ACL rule match counting in hardware when resources are insufficient, you must execute the **undo packet-filter** command and then reconfigure the **packet-filter** command without specifying the **hardware-count** keyword.

To disable ACL rule match counting in hardware when resources are sufficient, you can directly reconfigure the **packet-filter** command without specifying the **hardware-count** keyword.

To the same direction of an interface, you can apply a maximum of three ACLs: one IPv4 ACL, one IPv6 ACL, and one Layer 2 ACL.

The inbound packet filtering configured on a VLAN interface filters all packets, including packets forwarded at Layer 3 by the VLAN interface and packets forwarded at Layer 2 by the physical ports associated with the VLAN interface.

The outbound packet filtering configured on a VLAN interface filters only packets forwarded at Layer 3.

Examples

Apply IPv4 basic ACL 2001 to filter incoming traffic on GigabitEthernet 1/0/1, and enable counting ACL rule matches performed in hardware.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] packet-filter 2001 inbound hardware-count
```

Related commands

display packet-filter

display packet-filter statistics

display packet-filter verbose

packet-filter default deny

Use **packet-filter default deny** to set the packet filtering default action to **deny**. The packet filter denies packets that do not match any ACL rule.

Use **undo packet-filter default deny** to restore the default.

Syntax

packet-filter default deny

undo packet-filter default deny

Default

The packet filtering default action is **permit**. The packet filter permits packets that do not match any ACL rule.

Views

System view

Predefined user roles

network-admin

Usage guidelines

The packet filter applies the default action to all ACL applications for packet filtering. The default action appears in the **display** command output for packet filtering.

Examples

Set the packet filter default action to **deny**.

```
<Sysname> system-view
[Sysname] packet-filter default deny
```

Related commands

display packet-filter

display packet-filter statistics

display packet-filter verbose

reset packet-filter statistics

Use **reset packet-filter statistics** to clear the packet filtering statistics.

Syntax

reset packet-filter statistics interface [*interface-type interface-number*] { **inbound** | **outbound** } [[**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }]

Views

User view

Predefined user roles

network-admin

Parameters

interface [*interface-type interface-number*]: Specifies an interface by its type and number. If you do not specify an interface, this command clears packet filtering statistics for all interfaces.

inbound: Specifies the inbound direction.

outbound: Specifies the outbound direction.

ipv6: Specifies the IPv6 ACL type.

mac: Specifies the Layer 2 ACL type.

acl-number: Specifies an ACL by its number.

- 2000 to 2999 for basic ACLs.
- 3000 to 3999 for advanced ACLs.
- 4000 to 4999 for Layer 2 ACLs.

name *acl-name*: Specifies an ACL by its name. The *acl-name* argument is a case-insensitive string of 1 to 63 characters.

Usage guidelines

If *acl-number*, **name** *acl-name*, **ipv6**, or **mac** is not specified, this command clears the packet filtering statistics for all ACLs.

To specify the IPv4 ACL type, do not specify the **ipv6** or **mac** keyword.

Examples

Clear IPv4 basic ACL 2001 statistics for inbound packet filtering on GigabitEthernet 1/0/1.

```
<Sysname> reset packet-filter statistics interface gigabitethernet 1/0/1 inbound 2001
```

Related commands

rule (IPv4 advanced ACL view)

Use **rule** to create or edit an IPv4 advanced ACL rule.

Use **undo rule** to delete an entire IPv4 advanced ACL rule or some attributes in the rule.

Syntax

rule [*rule-id*] { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port* | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * } | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port* | **time-range** *time-range-name*] *

undo rule *rule-id* [{ { **ack** | **fin** | **psh** | **rst** | **syn** | **urg** } * | **established** } | **counting** | **destination** | **destination-port** | { **dscp** | { **precedence** | **tos** } * | **fragment** | **icmp-type** | **logging** | **source** | **source-port** | **time-range**] *

undo rule { **deny** | **permit** } *protocol* [{ { **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } * | **established** } | **counting** | **destination** { *dest-address dest-wildcard* | **any** } | **destination-port** *operator port* | { **dscp** *dscp* | { **precedence** *precedence* | **tos** *tos* } * | **fragment** | **icmp-type** { *icmp-type* [*icmp-code*] | *icmp-message* } | **logging** | **source** { *source-address source-wildcard* | **any** } | **source-port** *operator port* | **time-range** *time-range-name*] *

Default

No IPv4 advanced ACL rules exist.

Views

IPv4 advanced ACL view

Predefined user roles

network-admin

Parameters

rule-id: Specifies a rule ID in the range of 0 to 65534. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 28, the rule is numbered 30.

deny: Denies matching packets.

permit: Allows matching packets to pass.

protocol: Specifies a protocol carried over IPv4 by its number in the range of 0 to 255 or by its keyword, as shown in Table 6.

Table 6 Protocols carried over IPv4

Number	Keyword	Description
N/A	**ip**	Matches IPv4 packets.
1	**icmp**	Matches ICMP packets.
2	**igmp**	Matches IGMP packets.
4	**ipinip**	Matches IP-in-IP packets.
6	**tcp**	Matches TCP packets.
17	**udp**	Matches UDP packets.
89	**ospf**	Matches OSPF packets.

Table 7 describes the parameters that you can specify, regardless of the value for the *protocol* argument.

Table 7 Match criteria and other rule information for IPv4 advanced ACL rules

Parameters	Function	Description
source { *source-address source-wildcard* | **any** }	Specifies a source address.	The *source-address source-wildcard* arguments specify a source IP address and a wildcard mask in dotted decimal notation. An all-zero wildcard represents a host address. The **any** keyword specifies any source IP address.
destination { *dest-address dest-wildcard* | **any** }	Specifies a destination address.	The *dest-address dest-wildcard* arguments specify a destination IP address and a wildcard mask in dotted decimal notation. An all-zero wildcard mask represents a host address. The **any** keyword represents any destination IP address.
counting	Enables rule match counting in software.	The **counting** keyword enables match counting specific to rules, and the **hardware-count** keyword in the **packet-filter** command enables match counting in hardware for all rules in an ACL. If the **counting** keyword is not specified, matches for the rule are not counted in software.
precedence *precedence*	Specifies an IP precedence value.	The *precedence* argument can be a number in the range of 0 to 7, or in words: **routine** (0), **priority** (1), **immediate** (2), **flash** (3), **flash-override** (4), **critical** (5), **internet** (6), or **network** (7).
tos *tos*	Specifies a ToS preference.	The *tos* argument can be a number in the range of 0 to 15, or in words: **max-reliability** (2), **max-throughput** (4), **min-delay** (8), **min-monetary-cost** (1), or **normal** (0).
dscp *dscp*	Specifies a DSCP priority.	The *dscp* argument can be a number in the range of 0 to 63, or in words: **af11** (10), **af12** (12), **af13** (14), **af21** (18), **af22** (20), **af23** (22), **af31** (26), **af32** (28), **af33** (30), **af41** (34), **af42** (36), **af43** (38), **cs1** (8), **cs2** (16), **cs3** (24), **cs4** (32), **cs5** (40), **cs6** (48), **cs7** (56), **default** (0), or **ef** (46).
fragment	Applies the rule only to fragments.	If you do not specify this keyword, the rule applies to all fragments and non-fragments.
logging	Logs the number of matching packets.	This feature requires that the module (for example, packet filtering) that uses the ACL supports logging.
time-range *time-range-name*	Specifies a time range for the rule.	The *time-range-name* argument is a case-insensitive string of 1 to 32

		characters. It must start with an English letter. If the time range is not configured, the system creates the rule. However, the rule using the time range can take effect only after you configure the time range. For more information about time range, see *ACL and QoS Configuration Guide*.

If the *protocol* argument is **tcp** (6) or **udp** (17), set the parameters shown in Table 8.

Table 8 TCP/UDP-specific parameters for IPv4 advanced ACL rules

Parameters	Function	Description
source-port *operator port*	Specifies a UDP or TCP source port.	The *operator* argument can be **lt** (lower than), **gt** (greater than), **eq** (equal to), or **range** (inclusive range). The *port1* and *port2* arguments are TCP or UDP port numbers in the range of 0 to 65535. The *port2* argument is needed only when the *operator* argument is **range**. The **lt**, **gt**, and **range** values are supported only in Release 6320 and later.
destination-port *operator port*	Specifies a UDP or TCP destination port.	TCP port numbers can be represented as: **chargen** (19), **bgp** (179), **cmd** (514), **daytime** (13), **discard** (9), **dns** (53), **domain** (53), **echo** (7), **exec** (512), **finger** (79), **ftp** (21), **ftp-data** (20), **gopher** (70), **hostname** (101), **irc** (194), **klogin** (543), **kshell** (544), **login** (513), **lpd** (515), **nntp** (119), **pop2** (109), **pop3** (110), **smtp** (25), **sunrpc** (111), **tacacs** (49), **talk** (517), **telnet** (23), **time** (37), **uucp** (540), **whois** (43), and **www** (80). UDP port numbers can be represented as: **biff** (512), **bootpc** (68), **bootps** (67), **discard** (9), **dns** (53), **dnsix** (90), **echo** (7), **mobilip-ag** (434), **mobilip-mn** (435), **nameserver** (42), **netbios-dgm** (138), **netbios-ns** (137), **netbios-ssn** (139), **ntp** (123), **rip** (520), **snmp** (161), **snmptrap** (162), **sunrpc** (111), **syslog** (514), **tacacs-ds** (65), **talk** (517), **tftp** (69), **time** (37), **who** (513), and **xdmcp** (177).
{ **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* } *	Specifies one or more TCP flags including ACK, FIN, PSH, RST, SYN, and URG.	Parameters specific to TCP. The value for each argument can be 0 (flag bit not set) or 1 (flag bit set). The TCP flags in a rule are ANDed. For example, a rule configured with **ack** 0 **psh** 1 matches packets that have the ACK flag bit not set and the PSH flag bit set.
established	Specifies the flags for indicating the established status of a TCP connection.	Parameter specific to TCP. The rule matches TCP connection packets with the ACK or RST flag bit set.

If the *protocol* argument is **icmp** (1), set the parameters shown in Table 9.

Table 9 ICMP-specific parameters for IPv4 advanced ACL rules

Parameters	Function	Description
icmp-type { *icmp-type* *icmp-code* | *icmp-message* }	Specifies the ICMP message type and code.	The *icmp-type* argument is in the range of 0 to 255. The *icmp-code* argument is in the range of 0 to 255. The *icmp-message* argument specifies a message name. Supported ICMP message names and their corresponding type and code values are listed in Table 10.

Table 10 ICMP message names supported in IPv4 advanced ACL rules

ICMP message name	ICMP message type	ICMP message code
echo	8	0
echo-reply	0	0
fragmentneed-DFset	3	4
host-redirect	5	1
host-tos-redirect	5	3
host-unreachable	3	1
information-reply	16	0
information-request	15	0
net-redirect	5	0
net-tos-redirect	5	2
net-unreachable	3	0
parameter-problem	12	0
port-unreachable	3	3
protocol-unreachable	3	2
reassembly-timeout	11	1
source-quench	4	0
source-route-failed	3	5
timestamp-reply	14	0
timestamp-request	13	0
ttl-exceeded	11	0

Usage guidelines

Within an ACL, the permit or deny statement of each rule must be unique. If the rule you are creating or editing has the same deny or permit statement as another rule in the ACL, the rule will not be created or changed.

You can edit ACL rules only when the match order is **config**.

To view the existing IPv4 basic and advanced ACL rules, use the **display acl all** command.

The **undo rule** *rule-id* command without any optional parameters deletes an entire rule. If you specify optional parameters, the **undo rule** *rule-id* command deletes the specified attributes for the rule.

The **undo rule** { **deny** | **permit** } command can only be used to delete an entire rule. You must specify all the attributes of the rule for the command.

Examples

Create an IPv4 advanced ACL rule to permit TCP packets with the destination port 80 from 129.9.0.0/16 to 202.38.160.0/24.

```
<Sysname> system-view
[Sysname] acl advanced 3000
[Sysname-acl-ipv4-adv-3000] rule permit tcp source 129.9.0.0 0.0.255.255 destination
202.38.160.0 0.0.0.255 destination-port eq 80
```

Create IPv4 advanced ACL rules to permit all IP packets but the ICMP packets destined for 192.168.1.0/24.

```
<Sysname> system-view
[Sysname] acl advanced 3001
[Sysname-acl-ipv4-adv-3001] rule deny icmp destination 192.168.1.0 0.0.0.255
[Sysname-acl-ipv4-adv-3001] rule permit ip
```

Create IPv4 advanced ACL rules to permit inbound and outbound FTP packets.

```
<Sysname> system-view
[Sysname] acl advanced 3002
[Sysname-acl-ipv4-adv-3002] rule permit tcp source-port eq ftp
[Sysname-acl-ipv4-adv-3002] rule permit tcp source-port eq ftp-data
[Sysname-acl-ipv4-adv-3002] rule permit tcp destination-port eq ftp
[Sysname-acl-ipv4-adv-3002] rule permit tcp destination-port eq ftp-data
```

Create IPv4 advanced ACL rules to permit inbound and outbound SNMP and SNMP trap packets.

```
<Sysname> system-view
[Sysname] acl advanced 3003
[Sysname-acl-ipv4-adv-3003] rule permit udp source-port eq snmp
[Sysname-acl-ipv4-adv-3003] rule permit udp source-port eq snmptrap
[Sysname-acl-ipv4-adv-3003] rule permit udp destination-port eq snmp
[Sysname-acl-ipv4-adv-3003] rule permit udp destination-port eq snmptrap
```

rule (IPv4 basic ACL view)

Use **rule** to create or edit an IPv4 basic ACL rule.

Use **undo rule** to delete an entire IPv4 basic ACL rule or some attributes in the rule.

Syntax

rule [*rule-id*] { **deny** | **permit** } [**counting** | **fragment** | **logging** | **source** { *source-address source-wildcard* | **any** } | **time-range** *time-range-name*] *

undo rule *rule-id* [**counting** | **fragment** | **logging** | **source** | **time-range**] *

undo rule { **deny** | **permit** } [**counting** | **fragment** | **logging** | **source** { *source-address source-wildcard* | **any** } | **time-range** *time-range-name*] *

Default

No IPv4 basic ACL rules exist.

Views

IPv4 basic ACL view

Predefined user roles

network-admin

Parameters

rule-id: Specifies a rule ID in the range of 0 to 65534. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 28, the rule is numbered 30.

deny: Denies matching packets.

permit: Allows matching packets to pass.

counting: Enables rule match counting in software. If you do not specify this keyword, matches for the rule are not counted in software.

fragment: Applies the rule only to fragments. If you do not specify this keyword, the rule applies to both fragments and non-fragments.

logging: Logs the number of matching packets. This feature is available only when the application module (for example, packet filtering) that uses the ACL supports the logging feature.

source { *source-address source-wildcard* | **any** }: Matches a source address. The *source-address* and *source-wildcard* arguments specify a source IP address and a wildcard mask in dotted decimal notation. A wildcard mask of zeros represents a host address. The **any** keyword represents any source IP address.

time-range *time-range-name*: Specifies a time range for the rule. The *time-range-name* argument is a case-insensitive string of 1 to 32 characters. It must start with an English letter. If the time range is not configured, the system creates the rule. However, the rule using the time range can take effect only after you configure the time range. For more information about time range, see *ACL and QoS Configuration Guide*.

Usage guidelines

Within an ACL, the permit or deny statement of each rule must be unique. If the rule you are creating or editing has the same deny or permit statement as another rule in the ACL, the rule will not be created or changed.

You can edit ACL rules only when the match order is **config**.

The **counting** keyword in this command enables match counting specific to rules, and the **hardware-count** keyword in the **packet-filter** command enables match counting in hardware for all rules in an ACL.

To view the existing IPv4 basic and advanced ACL rules, use the **display acl all** command.

The **undo rule** *rule-id* command without any optional parameters deletes an entire rule. If you specify optional parameters, the **undo rule** *rule-id* command deletes the specified attributes for the rule.

The **undo rule** { **deny** | **permit** } command can only be used to delete an entire rule. You must specify all the attributes of the rule for the command.

Examples

Create a rule in IPv4 basic ACL 2000 to deny the packets from any source IP subnet but 10.0.0.0/8, 172.17.0.0/16, or 192.168.1.0/24.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule permit source 10.0.0.0 0.255.255.255
[Sysname-acl-ipv4-basic-2000] rule permit source 172.17.0.0 0.0.255.255
[Sysname-acl-ipv4-basic-2000] rule permit source 192.168.1.0 0.0.0.255
[Sysname-acl-ipv4-basic-2000] rule deny source any
```

Parameters

rule-id: Specifies a rule ID in the range of 0 to 65534. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 28, the rule is numbered 30.

deny: Denies matching packets.

permit: Allows matching packets to pass.

protocol: Specifies a protocol carried over IPv6 by its number in the range of 0 to 255 or by its keyword, as shown in Table 11.

Table 11 Protocols carried over IPv6

Number	Keyword	Description
N/A	**ipv6**	Matches IPv6 packets.
1	**icmpv6**	Matches ICMPv6 packets.
6	**tcp**	Matches TCP packets.
17	**udp**	Matches UDP packets.
50	**ipv6-esp**	Matches IPv6-ESP packets.
51	**ipv6-ah**	Matches IPv6-AH packets.
89	**ospf**	Matches OSPF packets.

Table 12 describes the parameters that you can specify, regardless of the value for the *protocol* argument.

Table 12 Match criteria and other rule information for IPv6 advanced ACL rules

Parameters	Function	Description
source { *source-address source-prefix* | *source-address/source-prefix* | **any** }	Specifies a source IPv6 address.	The *source-address* argument specifies an IPv6 source address. The *source-prefix* argument specifies a prefix length in the range of 1 to 128. The **any** keyword represents any IPv6 source address.
destination { *dest-address dest-prefix* | *dest-address/dest-prefix* | **any** }	Specifies a destination IPv6 address.	The *dest-address* argument specifies a destination IPv6 address. The *dest-prefix* argument specifies a prefix length in the range of 1 to 128. The **any** keyword represents any IPv6 destination address.
counting	Enables rule match counting in software.	The **counting** keyword enables match counting specific to rules, and the **hardware-count** keyword in the **packet-filter ipv6** command enables match counting in hardware for all rules in an ACL. If the **counting** keyword is not specified,

		matches for the rule are not counted in software.
dscp *dscp*	Specifies a DSCP preference.	The *dscp* argument can be a number in the range of 0 to 63, or in words, **af11** (10), **af12** (12), **af13** (14), **af21** (18), **af22** (20), **af23** (22), **af31** (26), **af32** (28), **af33** (30), **af41** (34), **af42** (36), **af43** (38), **cs1** (8), **cs2** (16), **cs3** (24), **cs4** (32), **cs5** (40), **cs6** (48), **cs7** (56), **default** (0), or **ef** (46).
flow-label *flow-label-value*	Specifies a flow label value in an IPv6 packet header.	The *flow-label-value* argument is in the range of 0 to 1048575.
fragment	Applies the rule only to fragments.	If you do not specify this keyword, the rule applies to all fragments and non-fragments.
logging	Logs the number of matching packets.	This feature requires that the module (for example, packet filtering) that uses the ACL supports logging.
routing [**type** *routing-type*]	Specifies an IPv6 routing header type.	*routing-type*: Value of the IPv6 routing header type, in the range of 0 to 255. If you specify the **type** *routing-type* option, the rule applies to the specified type of IPv6 routing header. If you do not specify the **type** *routing-type* option, the rule applies to all types of IPv6 routing headers.
hop-by-hop [**type** *hop-type*]	Specifies an IPv6 Hop-by-Hop Options header type.	*hop-type*: Value of the IPv6 Hop-by-Hop Options header type, in the range of 0 to 255. If you specify the **type** *hop-type* option, the rule applies to the specified type of IPv6 Hop-by-Hop Options header. If you do not specify the **type** *hop-type* option, the rule applies to all types of IPv6 Hop-by-Hop Options header.
time-range *time-range-name*	Specifies a time range for the rule.	The *time-range-name* argument is a case-insensitive string of 1 to 32 characters. It must start with an English letter. If the time range is not configured, the system creates the rule. However, the rule using the time range can take effect only after you configure the time range. For more information about time range, see *ACL and QoS Configuration Guide*.

If the *protocol* argument is **tcp** (6) or **udp** (17), set the parameters shown in Table 13.

Table 13 TCP/UDP-specific parameters for IPv6 advanced ACL rules

Parameters	Function	Description
source-port *operator port*	Specifies a UDP or TCP source port.	The *operator* argument can be **lt** (lower than), **gt** (greater than), **eq** (equal to), or **range** (inclusive range). The *port1* and *port2* arguments are TCP or UDP port numbers in the range of 0 to 65535. The *port2* argument is needed only when the *operator* argument is **range**. The **lt**, **gt**, and **range** values are supported only in Release 6320 and later.
destination-port *operator port*	Specifies a UDP or TCP destination port.	

		TCP port numbers can be represented as: **chargen** (19), **bgp** (179), **cmd** (514), **daytime** (13), **discard** (9), **dns** (53), **domain** (53), **echo** (7), **exec** (512), **finger** (79), **ftp** (21), **ftp-data** (20), **gopher** (70), **hostname** (101), **irc** (194), **klogin** (543), **kshell** (544), **login** (513), **lpd** (515), **nntp** (119), **pop2** (109), **pop3** (110), **smtp** (25), **sunrpc** (111), **tacacs** (49), **talk** (517), **telnet** (23), **time** (37), **uucp** (540), **whois** (43), and **www** (80). UDP port numbers can be represented as: **biff** (512), **bootpc** (68), **bootps** (67), **discard** (9), **dns** (53), **dnsix** (90), **echo** (7), **mobilip-ag** (434), **mobilip-mn** (435), **nameserver** (42), **netbios-dgm** (138), **netbios-ns** (137), **netbios-ssn** (139), **ntp** (123), **rip** (520), **snmp** (161), **snmptrap** (162), **sunrpc** (111), **syslog** (514), **tacacs-ds** (65), **talk** (517), **tftp** (69), **time** (37), **who** (513), and **xdmcp** (177).
{ **ack** *ack-value* | **fin** *fin-value* | **psh** *psh-value* | **rst** *rst-value* | **syn** *syn-value* | **urg** *urg-value* }*	Specifies one or more TCP flags, including ACK, FIN, PSH, RST, SYN, and URG.	Parameters specific to TCP. The value for each argument can be 0 (flag bit not set) or 1 (flag bit set). The TCP flags in a rule are ANDed. For example, a rule configured with **ack** 0 **psh** 1 matches packets that have the ACK flag bit not set and the PSH flag bit set.
established	Specifies the flags for indicating the established status of a TCP connection.	Parameter specific to TCP. The rule matches TCP packets with the ACK or RST flag bit set.

If the *protocol* argument is **icmpv6** (58), set the parameters shown in Table 14.

Table 14 ICMPv6-specific parameters for IPv6 advanced ACL rules

Parameters	Function	Description
icmp6-type { *icmp6-type icmp6-code* | *icmp6-message* }	Specifies the ICMPv6 message type and code.	The *icmp6-type* argument is in the range of 0 to 255. The *icmp6-code* argument is in the range of 0 to 255. The *icmp6-message* argument specifies a message name. Supported ICMP message names and their corresponding type and code values are listed in Table 15.

Table 15 ICMPv6 message names supported in IPv6 advanced ACL rules

ICMPv6 message name	ICMPv6 message type	ICMPv6 message code
echo-reply	129	0
echo-request	128	0
err-Header-field	4	0
frag-time-exceeded	3	1
hop-limit-exceeded	3	0
host-admin-prohib	1	1
host-unreachable	1	3
neighbor-advertisement	136	0
neighbor-solicitation	135	0

network-unreachable	1	0
packet-too-big	2	0
port-unreachable	1	4
redirect	137	0
router-advertisement	134	0
router-solicitation	133	0
unknown-ipv6-opt	4	2
unknown-next-hdr	4	1

Usage guidelines

If an IPv6 advanced ACL is for QoS traffic classification or packet filtering:

- Do not specify the **fragment** keyword.
- Do not specify the **routing**, **hop-by-hop**, or **flow-label** keyword if the ACL is for outbound application.

Within an ACL, the permit or deny statement of each rule must be unique. If the rule you are creating or editing has the same deny or permit statement as another rule in the ACL, the rule will not be created or changed.

You can edit ACL rules only when the match order is **config**.

To view the existing IPv6 basic and advanced ACL rules, use the **display acl ipv6 all** command.

The **undo rule** *rule-id* command without any optional parameters deletes an entire rule. If you specify optional parameters, the **undo rule** *rule-id* command deletes the specified attributes for a rule.

The **undo rule** { **deny** | **permit** } command can only be used to delete an entire rule. You must specify all the attributes of the rule for the command.

Examples

Create an IPv6 advanced ACL rule to permit TCP packets with the destination port 80 from 2030:5060::/64 to FE80:5060::/96.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3000
[Sysname-acl-ipv6-adv-3000] rule permit tcp source 2030:5060::/64 destination
fe80:5060::/96 destination-port eq 80
```

Create IPv6 advanced ACL rules to permit all IPv6 packets but the ICMPv6 packets destined for FE80:5060:1001::/48.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3001
[Sysname-acl-ipv6-adv-3001] rule deny icmpv6 destination fe80:5060:1001:: 48
[Sysname-acl-ipv6-adv-3001] rule permit ipv6
```

Create IPv6 advanced ACL rules to permit inbound and outbound FTP packets.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3002
[Sysname-acl-ipv6-adv-3002] rule permit tcp source-port eq ftp
[Sysname-acl-ipv6-adv-3002] rule permit tcp source-port eq ftp-data
[Sysname-acl-ipv6-adv-3002] rule permit tcp destination-port eq ftp
[Sysname-acl-ipv6-adv-3002] rule permit tcp destination-port eq ftp-data
```

Create IPv6 advanced ACL rules to permit inbound and outbound SNMP and SNMP trap packets.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3003
[Sysname-acl-ipv6-adv-3003] rule permit udp source-port eq snmp
[Sysname-acl-ipv6-adv-3003] rule permit udp source-port eq snmptrap
[Sysname-acl-ipv6-adv-3003] rule permit udp destination-port eq snmp
[Sysname-acl-ipv6-adv-3003] rule permit udp destination-port eq snmptrap
```

Create IPv6 advanced ACL 3004, and configure two rules: one permits packets with the Hop-by-Hop Options header type as 5, and the other one denies packets with other Hop-by-Hop Options header types.

```
<Sysname> system-view
[Sysname] acl ipv6 advanced 3004
[Sysname-acl-ipv6-adv-3004] rule permit ipv6 hop-by-hop type 5
[Sysname-acl-ipv6-adv-3004] rule deny ipv6 hop-by-hop
```

rule (IPv6 basic ACL view)

Use **rule** to create or edit an IPv6 basic ACL rule.

Use **undo rule** to delete an entire IPv6 basic ACL rule or some attributes in the rule.

Syntax

rule [*rule-id*] { **deny** | **permit** } [**counting** | **fragment** | **logging** | **routing** [**type** *routing-type*] | **source** { *source-address source-prefix* | *source-address*/*source-prefix* | **any** } | **time-range** *time-range-name*] *

undo rule *rule-id* [**counting** | **fragment** | **logging** | **routing** | **source** | **time-range**] *

undo rule { **deny** | **permit** } [**counting** | **fragment** | **logging** | **routing** [**type** *routing-type*] | **source** { *source-address source-prefix* | *source-address*/*source-prefix* | **any** } | **time-range** *time-range-name*] *

Default

No IPv6 basic ACL rules exist.

Views

IPv6 basic ACL view

Predefined user roles

network-admin

Parameters

rule-id: Specifies a rule ID in the range of 0 to 65534. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple

of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 28, the rule is numbered 30.

deny: Denies matching packets.

permit: Allows matching packets to pass.

counting: Enables rule match counting in software. If you do not specify this keyword, matches for the rule are not counted in software.

fragment: Applies the rule only to fragments. If you do not specify this keyword, the rule applies to both fragments and non-fragments.

logging: Logs the number of matching packets. This feature is available only when the application module (for example, packet filtering) that uses the ACL supports the logging feature.

routing [**type** *routing-type*]: Applies the rule to the specified type of IPv6 routing header or all types of IPv6 routing headers. The *routing-type* argument specifies the value of the IPv6 routing header type, in the range of 0 to 255. If you do not specify the **type** *routing-type* option, the rule applies to all types of IPv6 routing headers.

source { *source-address source-prefix* | *source-address*/*source-prefix* | **any** }: Matches a source IPv6 address. The *source-address* argument specifies a source IPv6 address. The *source-prefix* argument specifies an address prefix length in the range of 1 to 128. The **any** keyword represents any IPv6 source address.

time-range *time-range-name*: Specifies a time range for the rule. The *time-range-name* argument is a case-insensitive string of 1 to 32 characters. It must start with an English letter. If the time range is not configured, the system creates the rule. However, the rule using the time range can take effect only after you configure the time range. For more information about time range, see *ACL and QoS Configuration Guide*.

Usage guidelines

The **fragment** keyword is not supported for a QoS policy or a packet filter.

The **routing** keyword is not supported for an outbound QoS policy or packet filter.

Within an ACL, the permit or deny statement of each rule must be unique. If the rule you are creating or editing has the same deny or permit statement as another rule in the ACL, the rule will not be created or changed.

You can edit ACL rules only when the match order is **config**.

The **counting** keyword in this command enables match counting specific to rules, and the **hardware-count** keyword in the **packet-filter ipv6** command enables match counting in hardware for all rules in an ACL.

To view the existing IPv6 basic and advanced ACL rules, use the **display acl ipv6 all** command.

The **undo rule** *rule-id* command without any optional parameters deletes an entire rule. If you specify optional parameters, the **undo rule** *rule-id* command deletes the specified attributes for a rule.

The **undo rule** { **deny** | **permit** } command can only be used to delete an entire rule. You must specify all the attributes of the rule for the command.

Examples

Create an IPv6 basic ACL rule to deny the packets from any source IP subnet but 1001::/16, 3124:1123::/32, or FE80:5060:1001::/48.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2000
[Sysname-acl-ipv6-basic-2000] rule permit source 1001:: 16
```

```
[Sysname-acl-ipv6-basic-2000] rule permit source 3124:1123:: 32
[Sysname-acl-ipv6-basic-2000] rule permit source fe80:5060:1001:: 48
[Sysname-acl-ipv6-basic-2000] rule deny source any
```

Default

No Layer 2 ACL rules exist.

Views

Layer 2 ACL view

Predefined user roles

network-admin

Parameters

rule-id: Specifies a rule ID in the range of 0 to 65534. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 28, the rule is numbered 30.

deny: Denies matching packets.

permit: Allows matching packets to pass.

cos *dot1p:* Matches an 802.1p priority. The 802.1p priority can be specified by one of the following values:

- A priority number in the range of 0 to 7.
- A priority name: **best-effort** (0), **background** (1), **spare** (2), **excellent-effort** (3), **controlled-load** (4), **video** (5), **voice** (6), or **network-management** (7).

counting: Enables rule match counting in software. If you do not specify this keyword, matches for the rule are not counted in software.

dest-mac *dest-address dest-mask:* Matches a destination MAC address range. The *dest-address* and *dest-mask* arguments represent a destination MAC address and mask in the H-H-H format.

lsap *lsap-type lsap-type-mask:* Matches the DSAP and SSAP fields in LLC encapsulation. The *lsap-type* argument is a hexadecimal number that represents the encapsulation format. The value range for the *lsap-type* argument is 0 to ffff. The *lsap-type-mask* argument is a hexadecimal number that represents the LSAP mask. The value range for the *lsap-type-mask* argument is 0 to ffff.

type *protocol-type protocol-type-mask*: Matches one or more protocols in the Layer 2. The *protocol-type* argument is a hexadecimal number that represents a protocol type in Ethernet_II and Ethernet_SNAP frames. The value range for the *protocol-type* argument is 0 to ffff. The *protocol-type-mask* argument is a hexadecimal number that represents a protocol type mask. The value range for the *protocol-type-mask* argument is 0 to ffff.

source-mac *source-address source-mask:* Matches a source MAC address range. The *source-address* argument represents a source MAC address, and the *sour-mask* argument represents a mask in the H-H-H format.

time-range *time-range-name*: Specifies a time range for the rule. The *time-range-name* argument is a case-insensitive string of 1 to 32 characters. It must start with an English letter. If the time range is not configured, the system creates the rule. However, the rule using the time range can take effect only after you configure the time range. For more information about time range, see *ACL and QoS Configuration Guide*.

Usage guidelines

Within an ACL, the permit or deny statement of each rule must be unique. If the rule you are creating or editing has the same deny or permit statement as another rule in the ACL, the rule will not be created or changed.

You can edit ACL rules only when the match order is **config**.

The **counting** keyword in this command enables match counting specific to rules, and the **hardware-count** keyword in the **packet-filter** command enables match counting in hardware for all rules in an ACL.

To view the existing Layer 2 ACL rules, use the **display acl mac all** command.

The **undo rule** *rule-id* command without any optional parameters deletes an entire rule. If you specify optional parameters, the **undo rule** *rule-id* command deletes the specified attributes for the rule.

The **undo rule** { **deny** | **permit** } command can only be used to delete an entire rule. You must specify all the attributes of the rule for the command.

Examples

Create a rule in Layer 2 ACL 4000 to permit ARP packets and deny RARP packets.

```
<Sysname> system-view
[Sysname] acl mac 4000
[Sysname-acl-mac-4000] rule permit type 0806 ffff
[Sysname-acl-mac-4000] rule deny type 8035 ffff
```

rule comment

Use **rule comment** to configure a comment for an ACL rule.

Use **undo rule comment** to delete an ACL rule comment.

Syntax

rule *rule-id* **comment** *text*

undo rule *rule-id* **comment**

Default

A rule does not have a comment.

Views

IPv4 basic/advanced ACL view

IPv6 basic/advanced ACL view

Layer 2 ACL view

Predefined user roles

network-admin

Parameters

rule-id: Specifies an ACL rule ID in the range of 0 to 65534. The ACL rule must already exist.

text: Specifies a comment about the ACL rule, a case-sensitive string of 1 to 127 characters.

Usage guidelines

This command adds a comment to a rule if the rule does not have a comment. It modifies the comment for a rule if the rule already has a comment.

Examples

Create a rule for IPv4 basic ACL 2000, and add a comment about the rule.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] rule 0 deny source 1.1.1.1 0
[Sysname-acl-ipv4-basic-2000] rule 0 comment This rule is used on gigabitethernet 1/0/1.
```

display acl

step

Use **step** to set a rule numbering step for an ACL.

Use **undo step** to restore the default.

Syntax

step *step-value* [**start** *start-value*]

undo step

Default

The rule numbering step is 5, and the start rule ID is 0.

Views

IPv4 basic/advanced ACL view

IPv6 basic/advanced ACL view

Layer 2 ACL view

Predefined user roles

network-admin

Parameters

step-value: Specifies the ACL rule numbering step in the range of 1 to 20.

start *start-value*: Specifies the start rule ID in the range of 0 to 20.

Usage guidelines

The rule numbering step sets the increment by which the system numbers rules automatically. If you do not specify a rule ID when creating an ACL rule, the system automatically assigns it a rule ID. This rule ID is the nearest higher multiple of the numbering step to the current highest rule ID, starting from the start rule ID. For example, if the rule numbering step is 5 and the current highest rule ID is 12, the rule is numbered 15.

The wider the numbering step, the more rules you can insert between two rules. Whenever the step or start rule ID changes, the rules are renumbered, starting from the start rule ID. For example, if there are five rules numbered 0, 5, 9, 10, and 15, changing the step from 5 to 2 causes the rules to be renumbered 0, 2, 4, 6, and 8.

Examples

Set the rule numbering step to 2 for IPv4 basic ACL 2000.

```
<Sysname> system-view
[Sysname] acl basic 2000
[Sysname-acl-ipv4-basic-2000] step 2
```

Traffic class commands

description

Use **description** to configure a description for a traffic class.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for a traffic class.

Views

Traffic class view

Predefined user roles

network-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 127 characters.

Usage guidelines

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure the description as **classifier** for traffic class **class1**.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] description classifier
```

display traffic classifier

Use **display traffic classifier** to display traffic classes.

Syntax

display traffic classifier user-defined [*classifier-name*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

user-defined: Specifies user-defined traffic classes.

classifier-name: Specifies a traffic class by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a traffic class, this command displays all traffic classes.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the traffic classes for the master device.

Examples

Display all user-defined traffic classes.

```
<Sysname> display traffic classifier user-defined

  User-defined classifier information:

   Classifier: 1 (ID 100)
     Operator: AND
     Rule(s) :
      If-match acl 2000

   Classifier: 2 (ID 101)
     Operator: AND
     Rule(s) :
      If-match protocol ipv6

   Classifier: 3 (ID 102)
     Operator: AND
     Rule(s) :
      -none-
```

Table 1 Command output

Field	Description
Classifier	Traffic class name and its match criteria.
Operator	Match operator you set for the traffic class. If the operator is AND, the traffic class matches the packets that match all its match criteria. If the operator is OR, the traffic class matches the packets that match any of its match criteria.
Rule(s)	Match criteria.

if-match

Use **if-match** to define a match criterion.

Use **undo if-match** to delete a match criterion.

Syntax

if-match *match-criteria*

undo if-match *match-criteria*

Default

No match criterion is configured.

Views

Traffic class view

Predefined user roles

network-admin

Parameters

match-criteria: Specifies a match criterion. Table 2 shows the available match criteria.

Table 2 Available match criteria

Option	Description
acl [**ipv6** | **mac**] { *acl-number* | **name** *acl-name* }	Matches an ACL. The value range for the *acl-number* argument is as follows: • 2000 to 3999 for IPv4 ACLs. • 2000 to 3999 for IPv6 ACLs. • 4000 to 4999 for Layer 2 MAC ACLs. The *acl-name* argument is a case-insensitive string of 1 to 63 characters, which must start with an English letter. To avoid confusion, make sure the argument is not **all**.
any	Matches all packets.
customer-vlan-id *vlan-id-list*	Matches VLAN IDs in inner VLAN tags of double-tagged packets. The *vlan-id-list* argument specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN or a range of VLANs in the form of *vlan-id1* **to** *vlan-id2*. The value for *vlan-id2* must be greater than or equal to the value for *vlan-id1*. The value range for the *vlan-id* argument is 1 to 4094. The **if-match customer-vlan-id** *vlan-id-list* command can only be used to match single-tagged packets for the nesting (outer VLAN tag adding) action,
destination-mac *mac-address* [*mac-address-mask*]	Matches a destination MAC address. This option takes effect only on Ethernet interfaces.
dscp *dscp-value*&<1-8>	Matches DSCP values. The *dscp-value*&<1-8> argument specifies a space-separated list of up to eight DSCP values. The value range for the *dscp-value* argument is 0 to 63 or keywords shown in Table 4.
ip-precedence *ip-precedence-value*&<1-8>	Matches IP precedence values. The *ip-precedence-value*&<1-8> argument specifies a space-separated list of up to eight IP precedence values. The value range for the *ip-precedence-value* argument is 0 to 7.
protocol *protocol-name*	Matches a protocol. The *protocol-name* argument can be **ip** or **ipv6**.

Option	Description
service-dot1p *dot1p-value*&<1-8>	Matches 802.1p priority values in outer VLAN tags. The *dot1p-value*&<1-8> argument specifies a space-separated list of up to eight 802.1p priority values. The value range for the *dot1p-value* argument is 0 to 7.
service-vlan-id *vlan-id-list*	Matches VLAN IDs in outer VLAN tags. The *vlan-id-list* argument specifies a space-separated list of up to 10 VLAN items. Each item specifies a VLAN or a range of VLANs in the form of *vlan-id1* **to** *vlan-id2*. The value for *vlan-id2* must be greater than or equal to the value for *vlan-id1*. The value range for the *vlan-id* argument is 1 to 4094. You can use this option to match single-tagged packets typically except for the nesting (outer VLAN tag adding) action.
source-mac *mac-address* [*mac-address-mask*]	Matches a source MAC address. This option takes effect only on Ethernet interfaces.

Usage guidelines

In a traffic class with the logical OR operator, you can configure multiple **if-match** commands for any of the available match criteria.

When you configure a match criterion that can have multiple values in one **if-match** command, follow these restrictions and guidelines:

- You can specify up to eight values for any of the following match criteria in one **if-match** command:
  - 802.1p priority.
  - DSCP.
  - VLAN ID.
- If a packet matches one of the specified values, it matches the **if-match** command.
- To delete a criterion that has multiple values, the specified values in the **undo if-match** command must be the same as those specified in the **if-match** command. The order of the values can be different.

When you configure ACL-based match criteria, follow these restrictions and guidelines:

- The ACL must already exist.
- The ACL is used for classification only and the permit/deny actions in ACL rules are ignored. Actions taken on matching packets are defined in traffic behaviors.

You can use both AND and OR operators to define the match relationships between the criteria for a class. For example, you can define relationships among three match criteria in traffic class **classA** as follows:

```
traffic classifier classB operator and
if-match criterion 1
if-match criterion 2
traffic classifier classA operator or
if-match criterion 3
```

Examples

Define a match criterion for traffic class **class1** to match the packets with a destination MAC address of 0050-ba27-bed3.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match destination-mac 0050-ba27-bed3
```

Define a match criterion for traffic class **class2** to match the packets with a source MAC address of 0050-ba27-bed2.

```
<Sysname> system-view
[Sysname] traffic classifier class2
[Sysname-classifier-class2] if-match source-mac 0050-ba27-bed2
```

Define a match criterion for traffic class **class1** to match the packets with a source MAC address of 0050-ba27-bed3 and a MAC address mask of ffff-ffff-0000.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match destination-mac 0050-ba27-bed3 ffff-ffff-0000
```

Define a match criterion for traffic class **class2** to match the packets with a source MAC address of 0050-ba27-bed2 and a MAC address mask of ffff-ffff-0000.

```
<Sysname> system-view
[Sysname] traffic classifier class2
[Sysname-classifier-class2] if-match source-mac 0050-ba27-bed2 ffff-ffff-0000
```

Define a match criterion for traffic class **class1** to match the packets with 802.1p priority 5 in the outer VLAN tag.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match service-dot1p 5
```

Define a match criterion for traffic class **class1** to match advanced ACL 3101.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match acl 3101
```

Define a match criterion for traffic class **class1** to match the ACL named **flow**.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match acl name flow
```

Define a match criterion for traffic class **class1** to match advanced IPv6 ACL 3101.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match acl ipv6 3101
```

Define a match criterion for traffic class **class1** to match the IPv6 ACL named **flow**.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match acl ipv6 name flow
```

Define a match criterion for traffic class **class1** to match all packets.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match any
```

Define a match criterion for traffic class **class1** to match the packets with a DSCP value of 1, 6, or 9.

```
<Sysname> system-view
[Sysname] traffic classifier class1 operator or
```

```
[Sysname-classifier-class1] if-match dscp 1 6 9
```

Define a match criterion for traffic class **class1** to match IP packets.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1] if-match protocol ip
```

Define a match criterion for traffic class **class1** to match the packets with VLAN ID 2, 7, or 10 in the outer VLAN tag.

```
<Sysname> system-view
[Sysname] traffic classifier class1 operator or
[Sysname-classifier-class1] if-match service-vlan-id 2 7 10
```

traffic classifier

Use **traffic classifier** to create a traffic class and enter its view, or enter the view of an existing traffic class.

Use **undo traffic classifier** to delete a traffic class.

Syntax

traffic classifier *classifier-name* [**operator** { **and** | **or** }]

undo traffic classifier *classifier-name*

Default

No traffic classes exist.

Views

System view

Predefined user roles

network-admin

Parameters

classifier-name: Specifies a name for the traffic class, a case-sensitive string of 1 to 31 characters.

operator: Sets the operator to logic AND (the default) or OR for the traffic class.

and: Specifies the logic AND operator. The traffic class matches the packets that match all its criteria.

or: Specifies the logic OR operator. The traffic class matches the packets that match any of its criteria.

Examples

Create a traffic class named **class1**.

```
<Sysname> system-view
[Sysname] traffic classifier class1
[Sysname-classifier-class1]
```

Related commands

display traffic classifier

Traffic behavior commands

accounting

Use **accounting** to configure a traffic accounting action in a traffic behavior.

Use **undo accounting** to restore the default.

Syntax

accounting { **byte** | **packet** }

undo accounting

Default

No traffic accounting action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

byte: Counts traffic in bytes.

packet: Counts traffic in packets.

Examples

Configure a traffic accounting action in traffic behavior **database** to count traffic in bytes.

```
<Sysname> system-view
[Sysname] traffic behavior database
[Sysname-behavior-database] accounting byte
```

car

Use **car** to configure a CAR action in absolute value in a traffic behavior.

Use **undo car** to restore the default.

Syntax

car cir *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**green** *action* | **red** *action* | **yellow** *action*] *

car cir *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *

undo car

Default

No CAR action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

cir *committed-information-rate*: Specifies the committed information rate (CIR) in the range of 8 to 160000000 kbps, in increments of 8.

cbs *committed-burst-size*: Specifies the committed burst size (CBS) in bytes. The value range for *committed-burst-size* is 512 to 256000000, in increments of 512. The default value for this argument is the product of 62.5 and the CIR and must be an integral multiple of 512. When the product is not an integral multiple of 512, it is rounded up to the nearest integral multiple of 512 that is greater than the product. A default value greater than 256000000 is converted to 256000000.

ebs *excess-burst-size*: Specifies the excess burst size (EBS) in bytes. The value range for *excess-burst-size* is 0 to 256000000, in increments of 512. If the PIR is configured, the default EBS is the product of 62.5 and the PIR and must be an integral multiple of 512. When the product is not an integral multiple of 512, it is rounded up to the nearest integral multiple of 512. A default value greater than 256000000 is converted to 256000000.

pir *peak-information-rate*: Specifies the peak information rate (PIR) in the range of 8 to 160000000 kbps, in increments of 8.

green *action*: Specifies the action to take on packets that conform to the CIR. The default setting is **pass**.

red *action*: Specifies the action to take on packets that conform to neither CIR nor PIR. The default setting is **discard**.

yellow *action*: Specifies the action to take on packets that conform to the PIR but not to the CIR. The default setting is **pass**.

action: Sets the action to take on the packet:

- **discard**: Drops the packet.
- **pass**: Permits the packet to pass through.
- **remark-dot1p-pass** *new-cos*: Sets the 802.1p priority value of the 802.1p packet to *new-cos* and permits the packet to pass through. The *new-cos* argument is in the range of 0 to 7.
- **remark-dscp-pass** *new-dscp*: Sets the DSCP value of the packet to *new-dscp* and permits the packet to pass through. The *new-dscp* argument is in the range of 0 to 63.
- **remark-lp-pass** *new-local-precedence*: Sets the local precedence value of the packet to *new-local-precedence* and permits the packet to pass through. The *new-local-precedence* argument is in the range of 0 to 7.

Usage guidelines

To use two rates for traffic policing, configure the **car** command with the **pir** *peak-information-rate* option. To use one rate for traffic policing, configure the **car** command without the **pir** *peak-information-rate* option.

If you execute the **car** command multiple times in the same traffic behavior, the most recent configuration takes effect.

Examples

Configure a CAR action in traffic behavior **database**:

- Set the CIR to 200 kbps, CBS to 51200 bytes, and EBS to 0.
- Transmit the conforming packets, and mark the excess packets with DSCP value 0 and transmit them.

```
<Sysname> system-view
```

```
[Sysname] traffic behavior database
[Sysname-behavior-database] car cir 200 cbs 51200 ebs 0 green pass red remark-dscp-pass
0
```

display traffic behavior

Use **display traffic behavior** to display traffic behaviors.

Syntax

display traffic behavior user-defined [*behavior-name*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

user-defined: Specifies user-defined traffic behaviors.

behavior-name: Specifies a behavior by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a traffic behavior, this command displays all traffic behaviors.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the traffic behaviors for the master device.

Examples

Display all user-defined traffic behaviors.

```
<Sysname> display traffic behavior user-defined

  User-defined behavior information:

    Behavior: 1 (ID 100)
      Marking:
        Remark dscp 3
      Committed Access Rate:
        CIR 112 (kbps), CBS 5120 (Bytes), EBS 512 (Bytes)
        Green action  : pass
        Yellow action : pass
        Red action    : discard

    Behavior: 2 (ID 101)
      Accounting enable: Packet
      Filter enable: Permit
      Redirecting:
        Redirect to the CPU

    Behavior: 3 (ID 102)
      -none-
```

Table 3 Command output

Field	Description
Behavior	Name and contents of a traffic behavior.
Marking	Information about priority marking.
Remark dscp	Action of setting the DSCP value for packets.
Committed Access Rate	Information about the CAR action.
Green action	Action to take on green packets.
Yellow action	Action to take on yellow packets.
Red action	Action to take on red packets.
Accounting enable	Class-based accounting action.
Filter enable	Traffic filtering action.
Redirecting	Information about traffic redirecting.
Mirroring	Information about traffic mirroring.
none	No other traffic behavior is configured.

filter

Use **filter** to configure a traffic filtering action in a traffic behavior.

Use **undo filter** to restore the default.

Syntax

filter { **deny** | **permit** }

undo filter

Default

No traffic filtering action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

deny: Drops packets.

permit: Transmits packets. The permitted packets can be processed by other class-behavior associations in the same QoS policy.

Examples

Configure a traffic filtering action as **deny** in traffic behavior **database**.

```
<Sysname> system-view
[Sysname] traffic behavior database
[Sysname-behavior-database] filter deny
```

nest top-most

Use **nest top-most** to configure an outer VLAN tag adding action in a traffic behavior.

Use **undo nest top-most** to restore the default.

Syntax

nest top-most vlan *vlan-id*

undo nest top-most

Default

No outer VLAN tag adding action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

vlan-id *vlan-id*: Specifies the VLAN ID to be added in the outer VLAN tag, in the range of 1 to 4094.

Usage guidelines

If a QoS policy contains an outer VLAN tag adding action, apply it only to the incoming traffic of an interface.

If you execute the **nest top-most** command multiple times in the same traffic behavior, the most recent configuration takes effect.

Examples

Configure traffic behavior **b1** to add an outer VLAN tag with VLAN ID 123.

```
<Sysname> system-view
[Sysname] traffic behavior b1
[Sysname-behavior-b1] nest top-most vlan 123
```

redirect

Use **redirect** to configure a traffic redirecting action in a traffic behavior.

Use **undo redirect** to restore the default.

Syntax

redirect { **cpu** | **interface** *interface-type interface-number* }

undo redirect { **cpu** | **interface** *interface-type interface-number* }

Default

No traffic redirecting action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

cpu: Redirects traffic to the CPU.

interface *interface-type interface-number*: Redirects traffic to an interface specified by its type and number.

Usage guidelines

If you execute the **redirect** command multiple times in the same traffic behavior, the most recent configuration takes effect.

A traffic redirecting action takes effect only when the QoS policy is applied to the inbound direction.

For traffic redirecting to an access port, make sure the PVID of the interfaces to which the QoS policy is applied is the same as the PVID of the access port. Otherwise, the access port drops redirected packets.

For traffic redirecting to a trunk port, make sure the PVID of the interfaces to which the QoS policy is applied is in the allowed VLAN list of the trunk port. Otherwise, the trunk port drops redirected packets.

If a QoS policy applied to a user profile contains the **redirect interface** action, make sure the redirected-to interface and the incoming interface of packets are in the same VLAN.

Examples

Configure redirecting traffic to GigabitEthernet 1/0/1 in traffic behavior **database**.

```
<Sysname> system-view
[Sysname] traffic behavior database
[Sysname-behavior-database] redirect interface gigabitethernet 1/0/1
```

Related commands

classifier behavior

qos policy

traffic behavior

remark dot1p

Use **remark dot1p** to configure an 802.1p priority marking action in a traffic behavior.

Use **undo remark dot1p** to restore the default.

Syntax

remark [**green** | **red** | **yellow**] **dot1p** *dot1p-value*

undo remark [**green** | **red** | **yellow**] **dot1p**

Default

No 802.1p priority marking action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

green: Specifies green packets.

red: Specifies red packets.

yellow: Specifies yellow packets.

dot1p-value: Specifies the 802.1p priority to be marked for packets, in the range of 0 to 7.

Usage guidelines

If you execute the **remark dot1p** command multiple times for the same color, the most recent configuration takes effect.

Examples

Configure traffic behavior **database** to mark matching traffic with 802.1p 2.

```
<Sysname> system-view
[Sysname] traffic behavior database
[Sysname-behavior-database] remark dot1p 2
```

remark dscp

Use **remark dscp** to configure a DSCP marking action in a traffic behavior.

Use **undo remark dscp** to restore the default.

Syntax

remark [**green** | **red** | **yellow**] **dscp** *dscp-value*

undo remark [**green** | **red** | **yellow**] **dscp**

Default

No DSCP marking action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

green: Specifies green packets.

red: Specifies red packets.

yellow: Specifies yellow packets.

dscp-value: Specifies a DSCP value, which can be a number from 0 to 63 or a keyword in Table 4.

Table 4 DSCP keywords and values

Keyword	DSCP value (binary)	DSCP value (decimal)
af11	001010	10
af12	001100	12
af13	001110	14
af21	010010	18
af22	010100	20
af23	010110	22
af31	011010	26
af32	011100	28

Keyword	DSCP value (binary)	DSCP value (decimal)
af33	011110	30
af41	100010	34
af42	100100	36
af43	100110	38
cs1	001000	8
cs2	010000	16
cs3	011000	24
cs4	100000	32
cs5	101000	40
cs6	110000	48
cs7	111000	56
default	000000	0
ef	101110	46

Examples

Configure traffic behavior **database** to mark matching traffic with DSCP 6.

```
<Sysname> system-view
[Sysname] traffic behavior database
[Sysname-behavior-database] remark dscp 6
```

remark local-precedence

Use **remark local-precedence** to configure a local precedence marking action in a traffic behavior.

Use **undo remark local-precedence** to restore the default.

Syntax

remark local-precedence *local-precedence-value*

undo remark local-precedence

Default

No local precedence marking action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

local-precedence-value: Specifies the local precedence to be marked for packets, in the range of 0 to 7.

Usage guidelines

A local precedence marking action takes effect only when the QoS policy is applied to the inbound direction.

Examples

Configure traffic behavior **database** to mark matching traffic with local precedence 2.

```
<Sysname> system-view
[Sysname] traffic behavior database
[Sysname-behavior-database] remark local-precedence 2
```

remark service-vlan-id

Use **remark service-vlan-id** to configure an SVLAN marking action in a traffic behavior.

Use **undo remark service-vlan-id** to restore the default.

Syntax

remark service-vlan-id *vlan-id*

undo remark service-vlan-id

Default

No SVLAN marking action is configured.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

vlan-id: Specifies an SVLAN ID in the range of 1 to 4094.

Usage guidelines

An SVLAN marking action can be applied only to an interface.

Examples

Configure traffic behavior **b1** to mark matching packets with SVLAN 222.

```
<Sysname> system-view
[Sysname] traffic behavior b1
[Sysname-behavior-b1] remark service-vlan-id 222
```

traffic behavior

Use **traffic behavior** to create a traffic behavior and enter its view, or enter the view of an existing traffic behavior.

Use **undo traffic behavior** to delete a traffic behavior.

Syntax

traffic behavior *behavior-name*

undo traffic behavior *behavior-name*

Default

No traffic behaviors exist.

Views

System view

Predefined user roles

network-admin

Parameters

behavior-name: Specifies a name for the traffic behavior, a case-sensitive string of 1 to 31 characters.

Examples

Create a traffic behavior named **behavior1**.

```
<Sysname> system-view
[Sysname] traffic behavior behavior1
[Sysname-behavior-behavior1]
```

Related commands

display traffic behavior

QoS policy commands

classifier behavior

Use **classifier behavior** to associate a traffic behavior with a traffic class in a QoS policy.

Use **undo classifier** to delete a class-behavior association from a QoS policy.

Syntax

classifier *classifier-name* **behavior** *behavior-name* [**insert-before** *before-classifier-name*]

undo classifier *classifier-name*

Default

No traffic behavior is associated with a traffic class.

Views

QoS policy view

Predefined user roles

network-admin

Parameters

classifier-name: Specifies a traffic class by its name, a case-sensitive string of 1 to 31 characters.

behavior-name: Specifies a traffic behavior by its name, a case-sensitive string of 1 to 31 characters.

insert-before *before-classifier-name*: Inserts the new traffic class before an existing traffic class in the QoS policy. The *before-classifier-name* argument specifies an existing traffic class by its name, a case-sensitive string of 1 to 31 characters. If you do not specify the **insert-before** *before-classifier-name* option, the new traffic class is placed at the end of the QoS policy.

Usage guidelines

A traffic class can be associated only with one traffic behavior in a QoS policy.

If the specified traffic class or traffic behavior does not exist, the system defines a null traffic class or traffic behavior.

Examples

Associate traffic class **database** with traffic behavior **test** in QoS policy **user1**.

```
<Sysname> system-view
[Sysname] qos policy user1
[Sysname-qospolicy-user1] classifier database behavior test
```

Associate traffic class **database** with traffic behavior **test** in QoS policy **user1**, and insert traffic class **database** before an existing traffic class named **class-a**.

```
<Sysname> system-view
[Sysname] qos policy user1
[Sysname-qospolicy-user1] classifier database behavior test insert-before class-a
```

Related commands

qos policy

display qos policy

Use **display qos policy** to display QoS policies.

Syntax

display qos policy user-defined [*policy-name* [**classifier** *classifier-name*]] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

user-defined: Specifies user-defined QoS policies.

policy-name: Specifies a QoS policy by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a QoS policy, this command displays all user-defined QoS policies.

classifier *classifier-name*: Specifies a traffic class by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a traffic class, this command displays all traffic classes.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the QoS policies for the master device.

Examples

Display all user-defined QoS policies.

```
<Sysname> display qos policy user-defined

  User-defined QoS policy information:

  Policy: 1 (ID 100)
   Classifier: 1 (ID 100)
     Behavior: 1
      Marking:
```

```
      Remark dscp 3
    Committed Access Rate:
      CIR 112 (kbps), CBS 51200 (Bytes), EBS 512 (Bytes)
      Green action  : pass
      Yellow action : pass
      Red action    : discard
  Classifier: 2 (ID 101)
    Behavior: 2
     Accounting enable: Packet
     Filter enable: Permit
     Marking:
      Remark dot1p 4
  Classifier: 3 (ID 102)
    Behavior: 3
     -none-
```

Table 5 Command output

Field	Description
User-defined QoS policy information	Information about a user-defined QoS policy.
System-defined QoS policy information	Information about a system-defined QoS policy.

For the description of other fields, see Table 1 and Table 3.

display qos policy global

Use **display qos policy global** to display QoS policies applied globally.

Syntax

display qos policy global [**slot** *slot-number*] [**inbound** | **outbound**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

inbound: Specifies the QoS policy applied in the inbound direction.

outbound: Specifies the QoS policy applied in the outbound direction.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays global QoS policies for the master device.

Usage guidelines

If you do not specify a direction, this command displays both inbound and outbound global QoS policies.

Examples

Display QoS policies applied globally.

```
<Sysname> display qos policy global
  Direction: Inbound
  Policy: 1
   Classifier: 1
     Operator: AND
     Rule(s) :
      If-match acl 2000
     Behavior: 1
      Marking:
        Remark dscp 3
      Committed Access Rate:
        CIR 112 (kbps), CBS 51200 (Bytes), EBS 512 (Bytes)
        Green action  : pass
        Yellow action : pass
        Red action    : discard
        Green packets : 0 (Packets) 0 (Bytes)
        Yellow packets: 0 (Packets) 0 (Bytes)
        Red packets   : 0 (Packets) 0 (Bytes)
   Classifier: 2
     Operator: AND
     Rule(s) :
      If-match protocol ipv6
     Behavior: 2
      Accounting enable:
        0 (Packets)
      Filter enable: Permit
      Marking:
        Remark dscp 3
   Classifier: 3
     Operator: AND
     Rule(s) :
      -none-
     Behavior: 3
      -none-
```

Table 6 Command output

Field	Description
Direction	Direction in which the QoS policy is applied.
Green packets	Statistics about green packets.
Yellow packets	Statistics about yellow packets.
Red packets	Statistics about red packets.

For the description of other fields, see Table 1 and Table 3.

display qos policy interface

Use **display qos policy interface** to display the QoS policies applied to interfaces.

Syntax

display qos policy interface [*interface-type interface-number*] [**inbound** | **outbound**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number.

inbound: Specifies the QoS policy applied to incoming traffic.

outbound: Specifies the QoS policy applied to outgoing traffic.

Usage guidelines

If you do not specify a direction, this command displays the QoS policy applied to incoming traffic and the QoS policy applied to outgoing traffic.

Examples

Display the QoS policy applied to the incoming traffic of GigabitEthernet 1/0/1.

```
<Sysname> display qos policy interface gigabitethernet 1/0/1 inbound
Interface: GigabitEthernet1/0/1
  Direction: Inbound
  Policy: 1
   Classifier: 1
     Matched : 0 (Packets) 0 (Bytes)
     5-minute statistics:
      Forwarded: 0/0 (pps/bps)
      Dropped  : 0/0 (pps/bps)
     Operator: AND
     Rule(s) :
      If-match acl 2000
     Behavior: 1
      Marking:
        Remark dscp 3
      Committed Access Rate:
        CIR 112 (kbps), CBS 51200 (Bytes), EBS 512 (Bytes)
        Green action  : pass
        Yellow action : pass
        Red action    : discard
        Green packets : 0 (Packets) 0 (Bytes)
        Yellow packets: 0 (Packets) 0 (Bytes)
        Red packets   : 0 (Packets) 0 (Bytes)
   Classifier: 2
```

```
    Matched : 0 (Packets) 0 (Bytes)
    5-minute statistics:
     Forwarded: 0/0 (pps/bps)
     Dropped  : 0/0 (pps/bps)
    Operator: AND
    Rule(s) :

Table 7 Command output

Field	Description
Direction	Direction in which the QoS policy is applied.
Matched	Number of matching packets.
Forwarded	Average rate of successfully forwarded matching packets in a statistics collection period.
Dropped	Average rate of dropped matching packets in a statistics collection period.
Green packets	Traffic statistics for green packets.
Yellow packets	Traffic statistics for yellow packets.
Red packets	Traffic statistics for red packets.

For the description of other fields, see Table 1 and Table 3.

display qos policy user-profile

Use **`display qos policy user-profile`** to display QoS policies applied to user profiles.

Syntax

display qos policy user-profile [**name** *profile-name*] [**user-id** *user-id*] [**slot** *slot-number*] [**inbound** | **outbound**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *profile-name*: Specifies a user profile by its name, a case-sensitive string of 1 to 31 characters. Valid characters include English letters, digits, and underscores (_). The name must start with an English letter and must be unique. If you do not specify a user profile, this command displays QoS policies applied to all user profiles.

user-id *user-id*: Specifies an online user by a system-assigned, hexadecimal ID in the range of 0 to fffffffe. If you do not specify an online user, this command displays QoS policies applied to user profiles for all online users.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays QoS policies applied to user profiles for all member devices.

inbound: Specifies QoS policies applied to incoming traffic.

outbound: Specifies QoS policies applied to outgoing traffic.

Usage guidelines

If you do not specify a direction, this command displays QoS policies applied in the inbound direction and QoS policies applied in the outbound direction.

Examples

Display the QoS policy applied to user profile **abc** for a global user.

```
<Sysname> display qos policy user-profile name abc user-id 30000000 inbound
User-Profile: abc
  User ID: 0x30000000(global)
    Direction: Inbound
    Policy: p1
     Classifier: default-class
       Matched : 0 (Packets) 0 (Bytes)
       Operator: AND
       Rule(s) :
        If-match any
       Behavior: be
         -none-
```

Display the QoS policy applied to user profile **abc** for a local user.

```
<Sysname> display qos policy user-profile name abc user-id 30000001 inbound
User-Profile: abc
  slot 2:
    User ID: 0x30000001(local)
      Direction: Inbound
      Policy: p1
       Classifier: default-class
```

```
Matched : 0 (Packets) 0 (Bytes)
Operator: AND
Rule(s) :
 If-match any
Behavior: be
 -none-
```

Table 8 Command output

Field	Description
global	Indicates a global user, who comes online from a global interface such as an aggregate interface.
local	Indicates a local user, who comes online from a physical interface.
Matched	Number of packets that meet match criteria.
Direction	Direction in which the QoS policy is applied.
Green packets	Statistics about green packets.
Yellow packets	Statistics about yellow packets.
Red packets	Statistics about red packets.

For the description of other fields, see Table 1 and Table 3.

display qos vlan-policy

Use **display qos vlan-policy** to display QoS policies applied to VLANs.

Syntax

display qos vlan-policy { **name** *policy-name* | **vlan** [*vlan-id*] } [**slot** *slot-number*] [**inbound** | **outbound**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name *policy-name*: Specifies a QoS policy by its name, a case-sensitive string of 1 to 31 characters.

vlan *vlan-id*: Specifies a VLAN by its ID in the range of 1 to 4094.

inbound: Displays QoS policies applied to incoming traffic.

outbound: Displays QoS policies applied to outgoing traffic.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays QoS policies applied to VLANs for the master device.

Usage guidelines

If you do not specify a direction, this command displays QoS policies applied to VLANs in both the inbound and outbound directions.

Examples

Display QoS policies applied to VLAN 2.

```
<Sysname> display qos vlan-policy vlan 2
Vlan 2
  Direction: Inbound
  Policy: 1
   Classifier: 1
     Operator: AND
     Rule(s) :
      If-match acl 2000
     Behavior: 1
      Marking:
        Remark dscp 3
      Committed Access Rate:
        CIR 112 (kbps), CBS 5120 (Bytes), EBS 512 (Bytes)
        Green action  : pass
        Yellow action : pass
        Red action    : discard
        Green packets : 0(Packets) 0(Bytes)
        Yellow packets: 0(Packets) 0(Bytes)
        Red packets   : 0(Packets) 0(Bytes)
   Classifier: 2
     Operator: AND
     Rule(s) :
      If-match protocol ipv6
     Behavior: 2
      Accounting enable:
        0 (Packets)
      Filter enable: Permit
      Marking:
        Remark dscp 3
   Classifier: 3
     Operator: AND
     Rule(s) :
      -none-
     Behavior: 3
      -none-
```

Table 9 Command output

Field	Description
Direction	Direction in which the QoS policy is applied.
Green packets	Statistics about green packets.
Yellow packets	Statistics about yellow packets.
Red packets	Statistics about red packets.

For the description of other fields, see Table 1 and Table 3.

qos apply policy (interface view)

Use **qos apply policy** to apply a QoS policy to an interface.

Use **undo qos apply policy** to remove an applied QoS policy.

Syntax

qos apply policy *policy-name* { **inbound** | **outbound** }

undo qos apply policy *policy-name* { **inbound** | **outbound** }

Default

No QoS policy is applied.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a QoS policy by its name, a case-sensitive string of 1 to 31 characters.

inbound: Applies the QoS policy to incoming traffic.

outbound: Applies the QoS policy to outgoing traffic.

Examples

Apply QoS policy **TEST1** to the outgoing traffic of GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos apply policy TEST1 outbound
```

qos apply policy (user profile view)

Use **qos apply policy** to apply a QoS policy to a user profile.

Use **undo qos apply policy** to remove a QoS policy applied to a user profile.

Syntax

qos apply policy *policy-name* { **inbound** | **outbound** }

undo qos apply policy *policy-name* { **inbound** | **outbound** }

Default

No QoS policy is applied to a user profile.

Views

User profile view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a QoS policy by its name, a case-sensitive string of 1 to 31 characters.

inbound: Applies the QoS policy to the incoming traffic of the device (traffic sent by online users).

outbound: Applies the QoS policy to the outgoing traffic of the device (traffic received by online users).

Usage guidelines

Deleting a user profile also removes the QoS policies applied to the user profile.

For a user profile to be active, the QoS policy applied in user profile view cannot be empty. A user profile supports only the **car** and **accounting** actions in a QoS policy.

Examples

Apply QoS policy **test** to incoming traffic of user profile **user**.

```
<Sysname> system-view
[Sysname] user-profile user
[Sysname-user-profile-user] qos apply policy test outbound
```

qos apply policy global

Use **qos apply policy global** to apply a QoS policy globally.

Use **undo qos apply policy global** to remove a globally applied QoS policy.

Syntax

qos apply policy *policy-name* **global** { **inbound** | **outbound** }

undo qos apply policy *policy-name* **global** { **inbound** | **outbound** }

Default

No QoS policy is applied globally.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a QoS policy by its name, a case-sensitive string of 1 to 31 characters.

inbound: Applies the QoS policy to the incoming packets on all interfaces.

outbound: Applies the QoS policy to the outgoing packets on all interfaces.

Usage guidelines

A global QoS policy takes effect on all incoming or outgoing traffic depending on the direction in which the QoS policy is applied.

Examples

Globally apply QoS policy **user1** to the incoming traffic.

```
<Sysname> system-view
[Sysname] qos apply policy user1 global inbound
```

qos policy

Use **qos policy** to create a QoS policy and enter its view, or enter the view of an existing QoS policy.

Use **undo qos policy** to delete a QoS policy.

Syntax

qos policy *policy-name*

undo qos policy *policy-name*

Default

No QoS policies exist.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a name for the QoS policy, a case-sensitive string of 1 to 31 characters.

Usage guidelines

To delete a QoS policy that has been applied to an object, you must first remove the QoS policy from the object.

Examples

Create a QoS policy named **user1**.

```
<Sysname> system-view
[Sysname] qos policy user1
[Sysname-qospolicy-user1]
```

Related commands

classifier behavior

qos apply policy

qos apply policy global

qos vlan-policy

qos vlan-policy

Use **qos vlan-policy** to apply a QoS policy to the specified VLANs.

Use **undo qos vlan-policy** to remove a QoS policy from the specified VLANs.

Syntax

qos vlan-policy *policy-name* **vlan** *vlan-id-list* { **inbound** | **outbound** }

undo qos vlan-policy *policy-name* **vlan** *vlan-id-list* { **inbound** | **outbound** }

Default

No QoS policy is applied to a VLAN.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a QoS policy by its name, a case-sensitive string of 1 to 31 characters.

vlan *vlan-id-list*: Specifies a space-separated list of up to eight VLAN IDs or a VLAN ID range in the form of *vlan-id1* **to** *vlan-id2*. The value for *vlan-id2* must be greater than or equal to the value for *vlan-id1*. The value range for the *vlan-id* argument is 1 to 4094.

inbound: Applies the QoS policy to incoming packets.

outbound: Applies the QoS policy to outgoing packets.

Examples

Apply QoS policy **test** to the incoming traffic of VLAN 200, VLAN 300, VLAN 400, and VLAN 500.

```
<Sysname> system-view
[Sysname] qos vlan-policy test vlan 200 300 400 500 inbound
```

reset qos policy global

Use **reset qos policy global** to clear statistics for QoS policies applied globally.

Syntax

reset qos policy global [**inbound** | **outbound**]

Views

User view

Predefined user roles

network-admin

Parameters

inbound: Specifies the QoS policy applied to the inbound direction globally.

outbound: Specifies the QoS policy applied to the outbound direction globally.

Usage guidelines

If you do not specify a direction, this command clears statistics for the global QoS policies in both directions.

Examples

Clear statistics for the QoS policy applied to the inbound direction globally.

```
<Sysname> reset qos policy global inbound
```

reset qos vlan-policy

Use **reset qos vlan-policy** to clear the statistics for QoS policies applied to VLANs.

Syntax

reset qos vlan-policy [**vlan** *vlan-id*] [**inbound** | **outbound**]

Views

User view

Predefined user roles

network-admin

Parameters

vlan *vlan-id*: Specifies a VLAN ID in the range of 1 to 4094.

inbound: Specifies the QoS policy applied to incoming traffic.

outbound: Specifies the QoS policy applied to outgoing traffic.

Usage guidelines

If you do not specify a direction, this command clears the statistics of the QoS policies in both directions of the VLAN.

Examples

Clear the statistics of QoS policies applied to VLAN 2.

```
<Sysname> reset qos vlan-policy vlan 2
```

Priority mapping commands

Priority map commands

display qos map-table

Use **display qos map-table** to display the configuration of priority maps.

Syntax

display qos map-table [**dot1p-lp** | **dscp-dot1p** | **dscp-dscp**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

The device provides the following types of priority map.

Table 10 Priority maps

Priority mapping	Description
dot1p-lp	802.1p-local priority map.
dscp-dot1p	DSCP-802.1p priority map.
dscp-dscp	DSCP-DSCP priority map.

Usage guidelines

If you do not specify a priority map, this command displays the configuration of all priority maps.

Examples

Display the configuration of the 802.1p-local priority map.

```
<Sysname> display qos map-table dot1p-lp
MAP-TABLE NAME: dot1p-lp   TYPE: pre-define
IMPORT  :  EXPORT
   0    :    2
   1    :    0
   2    :    1
   3    :    3
   4    :    4
   5    :    5
   6    :    6
   7    :    7
```

Table 11 Command output

Field	Description
MAP-TABLE NAME	Name of the priority map.
TYPE	Type of the priority map.
IMPORT	Input values of the priority map.
EXPORT	Output values of the priority map.

import

Use **import** to configure mappings for a priority map.

Use **undo import** to restore the specified or all mappings to the default for a priority map.

Syntax

import *import-value-list* **export** *export-value*

undo import { *import-value-list* | **all** }

Default

The default priority maps are used. For more information, see *ACL and QoS Configuration Guide*.

Views

Priority map view

Predefined user roles

network-admin

Parameters

import-value-list: Specifies a list of input values.

export-value: Specifies the output value.

all: Restores all mappings in the priority map to the default.

Examples

Configure the 802.1p-local priority map to map 802.1p priority values 4 and 5 to local priority 1.

```
<Sysname> system-view
[Sysname] qos map-table dot1p-lp
[Sysname-maptbl-dot1p-lp] import 4 5 export 1
```

Related commands

display qos map-table

qos map-table

Use **qos map-table** to enter the specified priority map view.

Syntax

qos map-table { **dot1p-lp** | **dscp-dot1p** | **dscp-dscp** }

Views

System view

Predefined user roles

network-admin

Parameters

For the description of the keywords, see Table 10.

Examples

Enter 802.1p-local priority map view.

```
<Sysname> system-view
[Sysname] qos map-table dot1p-lp
[Sysname-maptbl-dot1p-lp]
```

Related commands

display qos map-table

import

Priority trust mode commands

display qos trust interface

Use **display qos trust interface** to display the priority trust mode and port priorities of an interface.

Syntax

display qos trust interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the priority trust mode and port priorities of all interfaces.

Examples

Display the priority trust mode and port priority of GigabitEthernet 1/0/1.

```
<Sysname> display qos trust interface gigabitethernet 1/0/1
Interface: GigabitEthernet1/0/1
 Port priority information
  Port priority: 0
  Port dscp priority: -
  Port priority trust type: none
```

Table 12 Command output

Field	Description
Interface	Interface type and interface number.

Field	Description
Port priority	Port priority set for the interface.
Port dscp priority	DSCP value rewritten for packets. If you have not rewritten the DSCP value of packets, this field displays a hyphen (-).
Port priority trust type	Priority trust mode on the interface: • **dot1p**—Uses the 802.1p priority of received packets for mapping. • **dscp**—Uses the DSCP precedence of received IP packets for mapping. • **none**—Trusts no packet priority.

qos trust

Use **qos trust** to configure the priority trust mode for an interface.

Use **undo qos trust** to restore the default.

Syntax

qos trust { **dot1p** | **dscp** }

undo qos trust

Default

An interface does not trust any packet priority and uses the port priority as the 802.1p priority for mapping.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

dot1p: Uses the 802.1p priority in incoming packets for priority mapping.

dscp: Uses the DSCP value in incoming packets for priority mapping.

Examples

Set the priority trust mode to 802.1p priority on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos trust dot1p
```

Related commands

display qos trust interface

Port priority commands

qos priority

Use **qos priority** to change the port priority of an interface.

Use **undo qos priority** to restore the default.

Syntax

qos priority [**dscp**] *priority-value*

undo qos priority [**dscp**]

Default

The port priority is 0.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

priority-value: Specifies a priority value. If the **dscp** keyword is not specified, this argument specifies the port priority in the range of 0 to 7. If the **dscp** keyword is specified, this argument specifies the DSCP value to be set for packets, in the range of 0 to 63.

Examples

Set the port priority of GigabitEthernet 1/0/1 to 2.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos priority 2
```

Related commands

display qos trust interface

GTS and rate limit commands

GTS commands

display qos gts interface

Use **display qos gts interface** to display the GTS configuration for interfaces.

Syntax

display qos gts interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the GTS configuration for all interfaces.

Examples

Display the GTS configuration for all interfaces.

```
<Sysname> display qos gts interface
Interface: GigabitEthernet1/0/1
 Rule: If-match queue 1
  CIR 512 (kbps), CBS 51200 (Bytes)
```

Table 13 Command output

Field	Description
Interface	Interface name, including the interface type and interface number.
Rule	Match criteria.
CIR	CIR in kbps.
CBS	CBS in bytes.

qos gts

Use **qos gts** to set GTS parameters on an interface.

Use **undo qos gts** to delete the GTS configuration on an interface.

Syntax

qos gts queue *queue-id* **cir** *committed-information-rate* [**cbs** *committed-burst-size*]

undo qos gts queue *queue-id*

Default

No GTS parameters are configured.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

queue *queue-id*: Shapes the packets in a queue specified by its ID. The value range for *queue-id* is 0 to 7.

cir *committed-information-rate*: Specifies the CIR in kbps. The value range for *committed-information-rate* is 8 to 102400 for 100-Mbps interfaces, 8 to 1048576 for GE interfaces, and 8 to 10485760 for 10-GE interfaces. The specified value must be an integral multiple of 8.

cbs *committed-burst-size*: Specifies the CBS in bytes. The value range for *committed-burst-size* is 512 to 16777216, in increments of 512. The default value for this argument is the product of 62.5 and the CIR and must be a multiple of 512. When the product is not a multiple of 512, it is rounded up to the nearest integral multiple of 512 that is greater than the product. A default value greater than 16777216 is converted to 16777216.

Examples

Shape the packets of queue 1 on GigabitEthernet 1/0/1. The GTS parameters are as follows:

- The CIR is 6400 kbps.
- The CBS is 51200 bytes.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos gts queue 1 cir 6400 cbs 51200
```

Rate limit commands

display qos lr interface

Use **display qos lr interface** to display the rate limit configuration for interfaces.

Syntax

display qos lr interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the rate limit configuration for all interfaces.

Examples

Display the rate limit configuration for all interfaces.

```
<Sysname> display qos lr interface
Interface: GigabitEthernet1/0/1
 Direction: Outbound
  CIR 2000 (kbps), CBS 20480 (Bytes)
```

Table 14 Command output

Field	Description
Interface	Interface name, including the interface type and interface number.
Direction	Direction in which the rate limit configuration is applied.
CIR	CIR in kbps.
CBS	CBS in bytes.

qos lr

Use **qos lr** to configure rate limiting on an interface.

Use **undo qos lr** to delete the rate limit configuration on an interface.

Syntax

qos lr { **inbound** | **outbound** } **cir** *committed-information-rate* [**cbs** *committed-burst-size*]

undo qos lr { **inbound** | **outbound** }

Default

No rate limit is configured.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

inbound: Limits the rate of incoming packets.

outbound: Limits the rate of outgoing packets.

cir *committed-information-rate*: Specifies the CIR in kbps. The value range for *committed-information-rate* is 8 to 102400 for 100-Mbps interfaces, 8 to 1048576 for GE interfaces, and 8 to 10485760 for 10-GE interfaces. The specified value must be a multiple of 8.

cbs *committed-burst-size*: Specifies the CBS in bytes. The value range for *committed-burst-size* is 512 to 134217728, in increments of 512. The default value for this argument is the product of 62.5 and the CIR and must be a multiple of 512. When the product is not a multiple of 512, it is rounded up to the nearest integral multiple of 512 that is greater than the product. A default value greater than 134217728 is converted to 134217728.

Examples

Limit the rate of outgoing packets on GigabitEthernet 1/0/1, with CIR 256 kbps and CBS 51200 bytes.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos lr outbound cir 256 cbs 51200
```

Congestion management commands

Common commands

display qos queue interface

Use **display qos queue interface** to display the queuing information for interfaces.

Syntax

display qos queue interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the queuing information for all interfaces.

Examples

Display the queuing information for all interfaces.

```
<Sysname> display qos queue interface
Interface: GigabitEthernet1/0/1
Output queue: Weighted Round Robin queuing
 Queue ID     Queue name     Group     Byte count
 -------------------------------------------------
 0            be             1         1
 1            af1            1         2
 2            af2            1         3
 3            af3            1         4
 4            af4            1         5
 5            ef             1         9
 6            cs6            1         13

Table 15 Command output

Field	Description
Interface	Interface name, including the interface type and interface number.
Output queue	Type of the current output queue.
Group	Number of the group that holds the queue.
Weight	Packet-count scheduling weight of the queue. N/A is displayed for a queue that uses the SP scheduling algorithm.

SP commands

display qos queue sp interface

Use **display qos queue sp interface** to display the SP queuing configuration of an interface.

Syntax

display qos queue sp interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the SP queuing configuration of all interfaces.

Examples

Display the SP queuing configuration of GigabitEthernet 1/0/1.

```
<Sysname> display qos queue sp interface gigabitethernet 1/0/1
Interface: GigabitEthernet1/0/1
 Output queue: Strict Priority queuing
```

Table 16 Command output

Field	Description
Interface	Interface type and interface number.
Output queue	Type of the current output queue.

qos sp

Use **qos sp** to enable SP queuing on an interface.

Use **undo qos sp** to restore the default.

Syntax

qos sp

undo qos sp

Default

An interface uses packet-count WRR queuing.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Examples

Enable SP queuing on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos sp
```

Related commands

display qos queue sp interface

WRR commands

display qos queue wrr interface

Use **display qos queue wrr interface** to display the WRR queuing configuration of an interface.

Syntax

display qos queue wrr interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the WRR queuing configuration of all interfaces.

Examples

Display the WRR queuing configuration of GigabitEthernet 1/0/1.

```
<Sysname> display qos queue wrr interface gigabitethernet 1/0/1
Interface: GigabitEthernet1/0/1
 Output queue: Weighted Round Robin queuing
 Queue ID        Queue name      Group           Weight
 ------------------------------------------------------
 0               be              1               1
 1               af1             1               1
```

```
2               af2             1               1

4               af4             1               1
5               ef              1               1
6               cs6             1               1
7               cs7             sp              N/A
```

Table 17 Command output

Field	Description
Interface	Interface type and interface number.
Output queue	Type of the current output queue.
Group	ID of the group a queue is assigned to.
Weight	Packet-count queue scheduling weight of a queue. N/A is displayed for a queue that uses the SP scheduling algorithm.

qos wrr

Use **qos wrr** to enable WRR queuing on an interface.

Use **undo qos wrr** to restore the default.

Syntax

qos wrr weight

undo qos wrr weight

Default

An interface uses packet-count WRR queuing.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

weight: Allocates bandwidth to queues in packets.

Usage guidelines

You must use the **qos wrr** command to enable WRR queuing before you can configure WRR queuing parameters for a queue on an interface.

Examples

Enable packet-count WRR queuing on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wrr weight
```

Related commands

display qos queue wrr interface

qos wrr weight

Use **qos wrr weight** to configure the WRR queuing parameters for a queue on an interface.

Use **undo qos wrr** to restore the default.

Syntax

qos wrr *queue-id* **group 1 weight** *schedule-value*

undo qos wrr *queue-id*

Default

All queues on a WRR-enabled interface are in WRR group 1, and queues 0 through 7 have a weight of 1, 2, 3, 4, 5, 9, 13, and 15, respectively.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

queue-id: Specifies a queue by its ID. The value range for this argument is 0 to 7 or keywords in Table 18.

Table 18 The number-keyword map for the *queue-id* argument

Number	Keyword
0	be
1	af1
2	af2
3	af3
4	af4
5	ef
6	cs6
7	cs7

group 1: Specifies WRR group 1. Only WRR group 1 is supported in the current software version.

weight: Allocates bandwidth to queues in packets.

schedule-value: Specifies a scheduling weight. The value range for this argument is 1 to 15.

Usage guidelines

You must use the **qos wrr** command to enable WRR queuing before you can configure WRR queuing parameters for a queue on an interface.

Examples

Enable packet-based WRR queuing on GigabitEthernet 1/0/1, assign queue 0 to WRR group 1, and specify scheduling weight 10 for queue 0.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wrr weight
```

```
[Sysname-GigabitEthernet1/0/1] qos wrr 0 group 1 weight 10
```

Related commands

display qos queue wrr interface

qos wrr

qos wrr group sp

Use **qos wrr group sp** to assign a queue to the SP group.

Use **undo qos wrr group sp** to remove a queue from the SP group.

Syntax

qos wrr *queue-id* **group sp**

undo qos wrr *queue-id*

Default

All queues on a WRR-enabled interface are in WRR group 1.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

queue-id: Specifies a queue by its ID. The value range for this argument is 0 to 7 or keywords in Table 18.

Usage guidelines

This command is available only on a WRR-enabled interface. Queues in the SP group are scheduled with SP. The SP group has higher scheduling priority than the WRR groups.

You must use the **qos wrr** command to enable WRR queuing before you can configure this command on an interface.

A queue in the SP group is not scheduled if the queue has the lowest priority among all queues with traffic load on the interface.

Examples

Enable WRR queuing on GigabitEthernet 1/0/1, and assign queue 0 to the SP group.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos wrr weight
[Sysname-GigabitEthernet1/0/1] qos wrr 0 group sp
```

Queue scheduling profile commands

display qos qmprofile configuration

Use **display qos qmprofile configuration** to display the queue scheduling profile configuration.

Syntax

display qos qmprofile configuration [*profile-name*] [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

profile-name: Specifies a queue scheduling profile by its name, a case-sensitive string of 1 to 31 characters. If you do not specify a queue scheduling profile, this command displays the configuration of all queue scheduling profiles.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays the queue scheduling profile configuration for the master device.

Examples

Display the configuration of queue scheduling profile **myprofile**.

```
<Sysname> display qos qmprofile configuration myprofile
Queue management profile: myprofile (ID 1)
Queue ID  Type  Group   Schedule   Schedule  Min         Max
                        unit       value     bandwidth   bandwidth
------------------------------------------------------------------------
be        SP    N/A     N/A        N/A       N/A         N/A
af1       SP    N/A     N/A        N/A       N/A         N/A

cs7       SP    N/A     N/A        N/A       N/A         N/A
```

Table 19 Command output

Field	Description
Queue management profile	Queue scheduling profile name.
Type	Queue scheduling type: • SP. • WRR.
Group	Priority group to which the queue belongs. The value can only be 1. **N/A** indicates this field is ignored.

Field	Description
Schedule unit	Scheduling unit, which can only be **weight**. **N/A** indicates that this field is ignored.
Schedule value	This field indicates the number of packets scheduled each time. **N/A** indicates that this field is ignored.
Min bandwidth	Minimum guaranteed bandwidth for the queue. **N/A** indicates that this field is ignored.
Max bandwidth	This field is not supported in the current software version. Maximum allowed bandwidth for the queue. **N/A** indicates that this field is ignored.

display qos qmprofile interface

Use **display qos qmprofile interface** to display the queue scheduling profile applied to an interface.

Syntax

display qos qmprofile interface [*interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the queue scheduling profiles applied to all interfaces.

Examples

Display the queue scheduling profile applied to GigabitEthernet 1/0/1.

```
<Sysname> display qos qmprofile interface gigabitethernet 1/0/1
Interface: GigabitEthernet1/0/1
Direction: Outbound
 Queue management profile: myprofile
```

Table 20 Command output

Field	Description
Direction	Direction in which the queue scheduling profile is applied.
Queue management profile	Name of the queue scheduling profile applied to the interface.

qos apply qmprofile

Use **qos apply qmprofile** to apply a queue scheduling profile to the outbound direction of an interface.

Use **undo qos apply qmprofile** to restore the default.

Syntax

qos apply qmprofile *profile-name*

undo qos apply qmprofile

Default

No queue scheduling profile is applied to an interface.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

profile-name: Specifies a queue scheduling profile by its name, a case-sensitive string of 1 to 31 characters.

Usage guidelines

You can apply only one queue scheduling profile to an interface.

Examples

Apply queue scheduling profile **myprofile** to the outbound direction of GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] qos apply qmprofile myprofile
```

Related commands

display qos qmprofile interface

qos qmprofile

Use **qos qmprofile** to create a queue scheduling profile and enter its view, or enter the view of an existing queue scheduling profile.

Use **undo qos qmprofile** to delete a queue scheduling profile.

Syntax

qos qmprofile *profile-name*

undo qos qmprofile *profile-name*

Default

No user-created queue scheduling profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

profile-name: Specifies a name for the queue scheduling profile, a case-sensitive string of 1 to 31 characters.

Usage guidelines

To delete a queue scheduling profile already applied to an object, first remove it from the object.

Examples

Create a queue scheduling profile named **myprofile** and enter queue scheduling profile view.

```
<Sysname> system-view
[Sysname] qos qmprofile myprofile
[Sysname-qmprofile-myprofile]
```

Related commands

display qos qmprofile interface

queue

queue

Use **queue** to configure queue scheduling parameters.

Use **undo queue** to delete queue scheduling parameter settings.

Syntax

queue *queue-id* { **sp** | **wrr group** *group-id* **weight** *schedule-value* }

undo queue *queue-id*

Default

All queues in a queue scheduling profile are SP queues.

Views

Queue scheduling profile view

Predefined user roles

network-admin

Parameters

queue-id: Specifies a queue by its ID. The value range for this argument is 0 to 7 or keywords in Table 18.

sp: Enables SP for the queue.

wrr: Enables WRR for the queue.

group *group-id*: Specifies a WRR group by its ID. The group ID can only be 1.

weight: Allocates bandwidth to queues in packets.

schedule-value: Specifies the scheduling weight. The value range for this argument is 1 to 15.

Examples

Create a queue scheduling profile named **myprofile**, and configure queue 0 to use SP.

```
<Sysname> system-view
[Sysname] qos qmprofile myprofile
[Sysname-qmprofile-myprofile] queue 0 sp
```

Create a queue scheduling profile named **myprofile**. Configure queue 1 to meet the following requirements:

- The WRR queuing is used.
- The WRR group is group 1.
- The scheduling weight is 10.

```
<Sysname> system-view
```

```
[Sysname] qos qmprofile myprofile
[Sysname-qmprofile-myprofile] queue 1 wrr group 1 weight 10
```

Queue-based accounting commands

display qos queue-statistics interface outbound

Use **display qos queue-statistics interface outbound** to display queue-based outgoing traffic statistics for interfaces.

Syntax

display qos queue-statistics interface [*interface-type interface-number*] **outbound**

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface-type interface-number: Specifies an interface by its type and number. If you do not specify an interface, this command displays the queue-based outgoing traffic statistics for all interfaces.

Examples

Display queue-based outgoing traffic statistics for GigabitEthernet 1/0/1.

```
<Sysname> display qos queue-statistics interface gigabitethernet 1/0/1 outbound
Interface: GigabitEthernet1/0/1
 Direction: outbound
 Forwarded: 0 packets, 0 bytes
 Dropped: 0 packets, 0 bytes
 Queue 0
  Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
  Dropped: 0 packets, 0 bytes
  Current queue length: 0 packets
 Queue 1
  Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
  Dropped: 0 packets, 0 bytes
  Current queue length: 0 packets
 Queue 2
  Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
  Dropped: 0 packets, 0 bytes
  Current queue length: 0 packets
 Queue 3
  Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
```

```
 Dropped: 0 packets, 0 bytes
 Current queue length: 0 packets
Queue 4
 Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
 Dropped: 0 packets, 0 bytes
 Current queue length: 0 packets
Queue 5
 Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
 Dropped: 0 packets, 0 bytes
 Current queue length: 0 packets
Queue 6
 Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
 Dropped: 0 packets, 0 bytes
 Current queue length: 0 packets
Queue 7
 Forwarded: 0 packets, 0 bytes, 0 pps, 0 bps
 Dropped: 0 packets, 0 bytes
 Current queue length: 0 packets
```

Table 21 Command output

Field	Description
Interface	Interface for which queue-based traffic statistics are displayed.
Direction	Direction of traffic for which statistics are collected.
Forwarded	Counts forwarded traffic both in packets and in bytes.
Dropped	Counts dropped traffic both in packets and in bytes.
Current queue length	Number of packets in the queue.

Aggregate CAR commands

car name

Use **car name** to use an aggregate CAR action in a traffic behavior.

Use **undo car** to restore the default.

Syntax

car name *car-name*

undo car

Default

No aggregate CAR action is configured in a traffic behavior.

Views

Traffic behavior view

Predefined user roles

network-admin

Parameters

car-name: Specifies the name of an aggregate CAR action. This argument must start with a letter, and is a case-sensitive string of 1 to 31 characters.

Examples

Use aggregate CAR action **aggcar-1** in traffic behavior **be1**.

```
<Sysname> system-view
[Sysname] traffic behavior be1
[Sysname-behavior-be1] car name aggcar-1
```

Related commands

display qos car name

display traffic behavior user-defined

display qos car name

Use **display qos car name** to display information about aggregate CAR actions.

Syntax

display qos car name [*car-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

car-name: Specifies an aggregate CAR action by its name. This argument must start with a letter, and is a case-sensitive string of 1 to 31 characters. If you do not specify an aggregate CAR action, this command displays information about all aggregate CAR actions.

Examples

Display information about all aggregate CAR actions.

```
<Sysname> display qos car name
 Name: a
  Mode: aggregative
   CIR 32 (kbps) CBS: 2048 (Bytes) PIR: 888 (kbps) EBS: 0 (Bytes)
   Green action  : pass
   Yellow action : pass
   Red action    : discard
  Slot 0:
   Green packets : 0 (Packets), 0 (Bytes)
   Yellow packets: 0 (Packets), 0 (Bytes)
   Red packets   : 0 (Packets), 0 (Bytes)
  Slot 1:
   Green packets : 0 (Packets), 0 (Bytes)
   Yellow packets: 0 (Packets), 0 (Bytes)
   Red packets   : 0 (Packets), 0 (Bytes)
  Slot 2:
   Apply failed
```

Table 22 Command output

Field	Description
Name	Name of the aggregate CAR action.
Mode	Type of the CAR action, which can be **aggregative**.
CIR CBS PIR EBS	Parameters for the CAR action.
Green action	Action to take on green packets: • **discard**—Drops the packets. • **pass**—Permits the packets to pass through.
Yellow action	Action to take on yellow packets: • **discard**—Drops the packets. • **pass**—Permits the packets to pass through.
Red action	Action to take on red packets: • **discard**—Drops the packets. • **pass**—Permits the packets to pass through.
Green packets	Statistics about green packets.
Yellow packets	Statistics about yellow packets.
Red packets	Statistics about red packets.

qos car

Use **qos car aggregative** to configure an aggregate CAR action.

Use **undo qos car** to delete an aggregate CAR action.

Syntax

qos car *car-name* **aggregative cir** *committed-information-rate* [**cbs** *committed-burst-size* [**ebs** *excess-burst-size*]] [**green** *action* | **red** *action* | **yellow** *action*] *

qos car *car-name* **aggregative cir** *committed-information-rate* [**cbs** *committed-burst-size*] **pir** *peak-information-rate* [**ebs** *excess-burst-size*] [**green** *action* | **red** *action* | **yellow** *action*] *

undo qos car *car-name*

Default

No aggregate CAR action is configured.

Views

System view

Predefined user roles

network-admin

Parameters

car-name: Specifies the name of the aggregate CAR action. This argument must start with a letter, and is a case-sensitive string of 1 to 31 characters.

cir *committed-information-rate*: Specifies the CIR in kbps, which is an average traffic rate. The value range for *committed-information-rate* is 8 to 160000000.

cbs *committed-burst-size*: Specifies the CBS in bytes. The value range for *committed-burst-size* is 512 to 256000000, in increments of 512. The default value for this argument is the product of 62.5 and the CIR and must be an integral multiple of 512. When the product is not an integral multiple of 512, it is rounded up to the nearest integral multiple of 512 that is greater than the product. A default value greater than 256000000 is converted to 256000000.

ebs *excess-burst-size*: Specifies the EBS in bytes. The value range for *excess-burst-size* is 0 to 256000000, in increments of 512. If the PIR is configured, the default EBS is the product of 62.5 and the PIR and must be an integral multiple of 512. When the product is not an integral multiple of 512, it is rounded up to the nearest integral multiple of 512. A default value greater than 256000000 is converted to 256000000.

pir *peak-information-rate*: Specifies the PIR in kbps. The value range for *peak-information-rate* is 8 to 160000000.

green *action*: Specifies the action to take on packets that conform to CIR. The default setting is **pass**.

red *action*: Specifies the action to take on the packet that conforms to neither CIR nor PIR. The default setting is **discard**.

yellow *action*: Specifies the action to take on packets that conform to PIR but not to CIR. The default setting is **pass**.

action: Specifies the action to take on packets:

- **discard**: Drops the packet.
- **pass**: Permits the packet to pass through.
- **remark-dot1p-pass** *new-cos*: Sets the 802.1p priority value of the 802.1p packet to *new-cos* and permits the packet to pass through. The *new-cos* argument is in the range of 0 to 7.

- **remark-dscp-pass** *new-dscp*: Remarks the packet with a new DSCP value and permits the packet to pass through. The *new-dscp* argument is in the range of 0 to 63. Alternatively, you can specify the *new-dscp* argument with **af11**, **af12**, **af13**, **af21**, **af22**, **af23**, **af31**, **af32**, **af33**, **af41**, **af42**, **af43**, **cs1**, **cs2**, **cs3**, **cs4**, **cs5**, **cs6**, **cs7**, **default**, or **ef**.

Usage guidelines

To use two rates for aggregate CAR, configure the **qos car** command with the **pir** *peak-information-rate* option. To use one rate for aggregate CAR, configure the **qos car** command without the **pir** *peak-information-rate* option.

An aggregate CAR action takes effect only after it is used in a QoS policy.

Examples

Configure aggregate CAR action **aggcar-1**, where CIR is 25600, CBS is 512000, and red packets are dropped.

```
<Sysname> system-view
[Sysname] qos car aggcar-1 aggregative cir 25600 cbs 512000 red discard
```

Related commands

display qos car name

reset qos car name

Use **reset qos car name** to clear the statistics about aggregate CAR actions.

Syntax

reset qos car name [*car-name*]

Views

User view

Predefined user roles

network-admin

Parameters

car-name: Specifies an aggregate CAR action by its name. This argument must start with a letter, and is a case-sensitive string of 1 to 31 characters. If you do not specify an aggregate CAR action, this command clears statistics for all aggregate CAR actions.

Examples

Clear the statistics about aggregate CAR action **aggcar-1**.

```
<Sysname> reset qos car name aggcar-1
```

Contents

Data buffer commands

Inappropriate data buffer changes can cause system problems. Before manually changing data buffer settings, make sure you understand its impact on your device. As a best practice, use the **burst-mode enable** command if the system requires large buffer spaces. The **burst-mode enable** command and the **buffer apply** command are mutually exclusive. If you have configured the data buffer by using one command, you must execute the **undo** form of the command before using the other command.

buffer apply

Use **buffer apply** to apply manually configured data buffer settings.

Use **undo buffer apply** to restore the default.

Syntax

buffer apply

undo buffer apply

Views

System view

Predefined user roles

network-admin

Usage guidelines

For data buffer settings to take effect, you must execute this command after configuring data buffer settings.

After applying manually configured data buffer settings, you cannot directly modify the applied settings. To modify them, you must cancel the application, reconfigure data buffer settings, and reapply the new settings.

Examples

Apply manually configured data buffer settings.

```
<Sysname> system-view
[Sysname] buffer apply
```

buffer queue guaranteed

Use **buffer queue guaranteed** to set the fixed-area space for a queue.

Use **undo buffer queue guaranteed** to delete the fixed-area space setting of a queue.

Syntax

buffer egress [**slot** *slot-number*] { **cell** | **packet** } **queue** *queue-id* **guaranteed ratio** *ratio*

undo buffer egress [**slot** *slot-number*] { **cell** | **packet** } **queue** *queue-id* **guaranteed**

Default

The cell resource ratio for a queue is 12% of the total cell resources. The packet resource ratio for a queue is 12% of the total packet resources.

Views

System view

Predefined user roles

network-admin

Parameters

egress: Specifies the egress buffer.

slot *slot-number*: Specifies an IRF member device by its member ID (slot number). If you do not specify an IRF member device, this command applies to all IRF member devices.

cell: Specifies cell resources.

packet: Specifies packet resources.

queue-id: Specifies a queue by its ID in the range of 0 to 7.

ratio *ratio*: Specifies the fixed-area space ratio, in percentage. The value range for *ratio* is 1 to 100.

Usage guidelines

By default, all queues have an equal share of the fixed area. You can set the fixed-area ratio for a queue. The other queues equally share the remaining part.

The fixed-area space for a queue cannot be used by other queues. Therefore, it is also called the minimum guaranteed buffer for the queue. The sum of fixed-area space configured for all queues cannot exceed the total fixed-area space. Otherwise, the configuration fails.

Examples

Configure queue 0 to use 20% fixed-area space of cell resources in the egress buffer.

```
<Sysname> system-view
[Sysname] buffer egress cell queue 0 guaranteed ratio 20
```

buffer shared

Use **buffer shared** to set the maximum shared-area ratio for each port or a queue.

Use **undo buffer shared** to delete the maximum shared-area ratio setting of each port or a queue.

Syntax

buffer egress [**slot** *slot-number*] { **cell** | **packet** } [**queue** *queue-id*] **shared ratio** *ratio*

undo buffer egress [**slot** *slot-number*] { **cell** | **packet** } [**queue** *queue-id*] **shared**

Default

The maximum packet resource ratio for a port is 10% of the total packet resources.

The maximum cell resource ratio for a port is 10% of the total cell resources.

Views

System view

Predefined user roles

network-admin

Parameters

egress: Specifies the egress buffer.

slot *slot-number*: Specifies an IRF member device by its member ID (slot number). If you do not specify an IRF member device, this command applies to all IRF member devices.

cell: Specifies cell resources.

packet: Specifies packet resources.

queue-id: Specifies a queue by its ID in the range of 0 to 7. If you do not specify a queue, this command sets the maximum shared-area space for each port.

ratio *ratio*: Specifies the maximum shared-area space ratio, in percentage. The value range for *ratio* is 0 to 100.

Usage guidelines

By default, all ports or queueshave an equal share of the shared area. You can set the shared-area ratio for each port or a queue. The unconfigured queues use the default setting. The shared-area space for each port or queue is finally determined by the chip based on your configuration and the number of packets to be received and sent.

Examples

Configure queue 0 to use up to 10% shared-area space of cell resources in the egress buffer.

```
<Sysname> system-view
[Sysname] buffer egress cell queue 0 shared ratio 10
```

buffer total-shared

Use **buffer total-shared** to set the total shared-area ratio.

Use **undo buffer total-shared** to delete the total shared-area ratio setting.

Syntax

buffer egress [**slot** *slot-number*] { **cell** | **packet** } **total-shared ratio** *ratio*

undo buffer egress [**slot** *slot-number*] { **cell** | **packet** } **total-shared**

Default

The default for this command can be displayed by using the **display buffer** command.

Views

System view

Predefined user roles

network-admin

Parameters

egress: Specifies the egress buffer.

slot *slot-number*: Specifies an IRF member device by its member ID (slot number). If you do not specify an IRF member device, this command applies to all IRF member devices.

cell: Specifies cell resources.

packet: Specifies packet resources.

ratio *ratio*: Specifies the ratio of the shared area, in percentage. The value range for *ratio* is 0 to 100.

Usage guidelines

After you set the shared-area ratio, the remaining buffer space is automatically assigned to the fixed area.

Examples

Configure the shared area to use 50% space of cell resources in the egress buffer.

```
<Sysname> system-view
[Sysname] buffer egress cell total-shared ratio 50
```

burst-mode enable

Use **burst-mode enable** to enable the Burst feature.

Use **undo burst-mode enable** to disable the Burst feature.

Syntax

burst-mode enable

undo burst-mode enable

Default

The Burst feature is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

The Burst feature is especially useful for reducing packet losses under the following circumstances:

- Broadcast or multicast traffic is intensive, resulting in bursts of traffic.
- Traffic enters a device from a high-speed interface and goes out of a low-speed interface.
- Traffic enters a device from multiple same-rate interfaces and goes out of an interface with the same rate.

The default data buffer settings will be changed after the Burst feature is enabled. You can display the data buffer settings by using the **display buffer** command.

Examples

Enable the Burst feature.

```
<Sysname> system-view
[Sysname] burst-mode enable
```

display buffer

Use **display buffer** to display buffer size settings.

Syntax

display buffer [**slot** *slot-number*][**queue** [*queue-id*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID (slot number). If you do not specify an IRF member device, this command displays buffer size settings for all IRF member devices.

queue *queue-id*: Specifies a queue by its number in the range of 0 to 7. If you specify a queue, this command displays the fixed-area ratio and shared-area ratio for the specified queue. If you specify the **queue** keyword without the *queue-id* argument, this command displays the fixed-area ratio and shared-area ratio for each queue. If you do not specify the **queue** keyword, this command displays the total shared-area ratio.

Examples

Display buffer size settings.

```
<Sysname> display buffer
Slot  Type    Eg(Total-shared , Shared)
1     packet  0 , 20
1     cell    0 , 20

          Eg: Size of the sending buffer
Total-shared: Size of the shared buffer for all ports
      Shared: Size of the maximum shared buffer per port
        Unit: Ratio
```

Display the fixed-area ratio and shared-area ratio for the queues.

```
<Sysname> display buffer queue
Slot  Queue        Type    Eg(Guaranteed , Shared)
1     0-7          packet  12 , --
1     0-7          cell    12 , --

          Eg: Size of the sending buffer
  Guaranteed: Size of the minimum guaranteed buffer per queue
      Shared: Size of the maximum shared buffer per queue
        Unit: Ratio
```

Table 1 Command output

Field	Description
Type	Resource type: packet or cell.
Queue	Queue ID in the range of 0 to 7.
Eg	Egress buffer.
(Total-shared , Shared)	Total-shared indicates the total shared-area ratio. Shared indicates the shared-area ratio of a port.

Field	Description
(Guaranteed , Shared)	• **Guaranteed** indicates the fixed-area ratio of a queue. • **Shared** indicates the shared-area ratio of a queue. If the device does not support a resource type, this field displays two hyphens (--).

display buffer usage

Use **display buffer usage** to display buffer usage.

Syntax

display buffer usage [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

slot *slot-number*: Specifies an IRF member device by its member ID (slot number). If you do not specify an IRF member device, this command displays buffer usage for all IRF member devices.

Examples

Display buffer usage.

```
<Sysname> display buffer usage
Egress total-shared cell buffer usage on slot 1 :
Total:    2980 KB
Used:       0 KB
Free:    2980 KB
                              5sec    1min    5min
-------------------------------------------------------------------
Block 1                        0%      0%      0%
GigabitEthernet1/0/1           0%      0%      0%
GigabitEthernet1/0/2           0%      0%      0%
GigabitEthernet1/0/3           0%      0%      0%
GigabitEthernet1/0/4           0%      0%      0%
GigabitEthernet1/0/5           0%      0%      0%
```

Table 2 Command output

Field	Description
Egress total-shared cell buffer usage on slot	Usage of cell resources in the shared area on an IRF member device.
Block	Block where the port resides. The block where the ports on the front panel of the device reside is fixed to Block 1.
Total	Total size of the data buffer.

Field	Description
Used	Size of used data buffer.
Free	Size of free data buffer.
5sec	Percentage of the buffer that the port uses for the last 5 seconds.
1min	Percentage of the buffer that the port uses for the last 1 minute.
5min	Percentage of the buffer that the port uses for the last 5 minutes.

Contents

Time range commands

display time-range

Use **display time-range** to display time range configuration and status.

Syntax

display time-range { *time-range-name* | **all** }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

time-range-name: Specifies a time range name, a case-insensitive string of 1 to 32 characters. It must start with an English letter.

all: Displays the configuration and status of all existing time ranges.

Examples

Display the configuration and status of time range **t4**.

```
<Sysname> display time-range t4
Current time is 17:12:34 11/23/2010 Tuesday

Time-range : t4 (Inactive)
 10:00 to 12:00 Mon
 14:00 to 16:00 Wed
 from 00:00 1/1/2011 to 00:00 1/1/2012
 from 00:00 6/1/2011 to 00:00 7/1/2011
```

Table 1 Command output

Field	Description
Current time	Current system time.
Time-range	Configuration and status of the time range, including its name, status (active or inactive), and start time and end time.

time-range

Use **time-range** to create or edit a time range.

Use **undo time-range** to delete a time range or a statement in the time range.

Syntax

time-range *time-range-name* { *start-time* **to** *end-time days* [**from** *time1 date1*] [**to** *time2 date2*] | **from** *time1 date1* [**to** *time2 date2*] | **to** *time2 date2* }

undo time-range *time-range-name* [*start-time* **to** *end-time days* [**from** *time1 date1*] [**to** *time2 date2*] | **from** *time1 date1* [**to** *time2 date2*] | **to** *time2 date2*]

Default

No time ranges exist.

Views

System view

Predefined user roles

network-admin

Parameters

time-range-name: Specifies a time range name. The name is a case-insensitive string of 1 to 32 characters. It must start with an English letter. To avoid confusion, it cannot be **all**.

start-time **to** *end-time*: Specifies a periodic statement. Both *start-time* and *end-time* are in hh:mm format (24-hour clock). The value is in the range of 00:00 to 23:59 for the start time, and 00:00 to 24:00 for the end time. The end time must be later than the start time.

days: Specifies the day or days of the week (in words or digits) on which the periodic statement is valid. If you specify multiple values, separate each value with a space, and make sure they do not overlap. These values can take one of the following forms:

- A digit in the range of 0 to 6, for Sunday, Monday, Tuesday, Wednesday, Thursday, Friday, and Saturday.
- A day of a week in abbreviated words: **Sun**, **Mon**, **Tue**, **Wed**, **Thu**, **Fri**, and **Sat**.
- **working-day** for Monday through Friday.
- **off-day** for Saturday and Sunday.
- **daily** for the whole week.

from *time1 date1*: Specifies the start time and date of an absolute statement. The *time1* argument specifies the time of the day in hh:mm format (24-hour clock). Its value is in the range of 00:00 to 23:59. The *date1* argument specifies a date in MM/DD/YYYY or YYYY/MM/DD format, where MM is the month of the year in the range of 1 to 12, DD is the day of the month with the range varying by MM, and YYYY is the year in the calendar in the range of 1970 to 2100. If you do not specify this option, the start time is 01/01/1970 00:00 AM, the earliest time available in the system.

to *time2 date2*: Specifies the end time and date of the absolute time statement. The *time2* argument has the same format as the *time1* argument, but its value is in the range of 00:00 to 24:00. The *date2* argument has the same format and value range as the *date1* argument. The end time must be later than the start time. If you do not specify this option, the end time is 12/31/2100 24:00 PM, the maximum time available in the system.

Usage guidelines

If an existing time range name is provided, this command adds a statement to the time range.

You can create multiple statements in a time range. Each time statement can take one of the following forms:

- Periodic statement in the *start-time* **to** *end-time days* format. A periodic statement recurs periodically on a day or days of the week.
- Absolute statement in the **from** *time1 date1* **to** *time2 date2* format. An absolute statement does not recur.
- Compound statement in the *start-time* **to** *end-time days* **from** *time1 date1* **to** *time2 date2* format. A compound statement recurs on a day or days of the week only within the specified period. For example, to create a time range that is active from 08:00 to 12:00 on

Monday between January 1, 2015, 00:00 and December 31, 2015, 23:59, use the **time-range test 08:00 to 12:00 Mon from 00:00 01/01/2015 to 23:59 12/31/2015** command.

You can create a maximum of 1024 time ranges, each with a maximum of 32 periodic statements and 12 absolute statements. The active period of a time range is calculated as follows:

1. Combining all periodic statements.
2. Combining all absolute statements.
3. Taking the intersection of the two statement sets as the active period of the time range.

Examples

Create a periodic time range **t1**, setting it to be active between 8:00 to 18:00 during working days.

```
<Sysname> system-view
[Sysname] time-range t1 08:00 to 18:00 working-day
```

Create an absolute time range **t2**, setting it to be active in the whole year of 2011.

```
<Sysname> system-view
[Sysname] time-range t2 from 00:00 1/1/2011 to 24:00 12/31/2011
```

Create a compound time range **t3**, setting it to be active from 08:00 to 12:00 on Saturdays and Sundays of the year 2011.

```
<Sysname> system-view
[Sysname] time-range t3 08:00 to 12:00 off-day from 00:00 1/1/2011 to 24:00 12/31/2011
```

Create a compound time range **t4**, setting it to be active from 10:00 to 12:00 on Mondays and from 14:00 to 16:00 on Wednesdays in January and June of the year 2011.

```
<Sysname> system-view
[Sysname] time-range t4 10:00 to 12:00 1 from 00:00 1/1/2011 to 24:00 1/31/2011
[Sysname] time-range t4 14:00 to 16:00 3 from 00:00 6/1/2011 to 24:00 6/30/2011
```

Software version: Release 63xx
Document version: 6W105-20230524

Preface

This command reference describes the security configuration commands. It includes the commands for configuring the following features:

This preface includes the following topics about the documentation:

Audience

This documentation is intended for:

- Network planners.
- Field technical support and servicing engineers.
- Network administrators.

Conventions

The following information describes the conventions used in the documentation.

Command conventions

Convention	Description
Boldface	**Bold** text represents commands and keywords that you enter literally as shown.
Italic	*Italic* text represents arguments that you replace with actual values.
[ ]	Square brackets enclose syntax choices (keywords or arguments) that are optional.
{ x | y | ... }	Braces enclose a set of required syntax choices separated by vertical bars, from which you select one.
[x | y | ...]	Square brackets enclose a set of optional syntax choices separated by vertical bars, from which you select one or none.
{ x | y | ... } *	Asterisk marked braces enclose a set of required syntax choices separated by vertical bars, from which you select a minimum of one.
[x | y | ...] *	Asterisk marked square brackets enclose optional syntax choices separated by vertical bars, from which you select one choice, multiple choices, or none.
&<1-n>	The argument or keyword and argument combination before the ampersand (&) sign can be entered 1 to n times.
#	A line that starts with a pound (#) sign is comments.

GUI conventions

Convention	Description
Boldface	Window names, button names, field names, and menu items are in Boldface. For example, the **New User** window opens; click **OK**.
>	Multi-level menus are separated by angle brackets. For example, **File** > **Create** > **Folder**.

Symbols

Convention	Description
WARNING!	An alert that calls attention to important information that if not understood or followed can result in personal injury.
CAUTION:	An alert that calls attention to important information that if not understood or followed can result in data loss, data corruption, or damage to hardware or software.
IMPORTANT:	An alert that calls attention to essential information.
NOTE:	An alert that contains additional or supplementary information.
TIP:	An alert that provides helpful information.

Network topology icons

Convention	Description
	Represents a generic network device, such as a router, switch, or firewall.
	Represents a routing-capable device, such as a router or Layer 3 switch.
	Represents a generic switch, such as a Layer 2 or Layer 3 switch, or a router that supports Layer 2 forwarding and other Layer 2 features.
	Represents an access controller, a unified wired-WLAN module, or the access controller engine on a unified wired-WLAN switch.
	Represents an access point.
	Represents a wireless terminator unit.
	Represents a wireless terminator.
	Represents a mesh access point.
	Represents omnidirectional signals.
	Represents directional signals.
	Represents a security product, such as a firewall, UTM, multiservice security gateway, or load balancing device.
	Represents a security module, such as a firewall, load balancing, NetStream, SSL VPN, IPS, or ACG module.

Examples provided in this document

Examples in this document might use devices that differ from your device in hardware model, configuration, or software version. It is normal that the port numbers, sample output, screenshots, and other information in the examples differ from what you have on your device.

Documentation feedback

You can e-mail your comments about product documentation to info@h3c.com.

We appreciate your comments.

Contents

AAA commands

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

General AAA commands

aaa nas-id profile

Use **aaa nas-id profile** to create a NAS-ID profile and enter its view, or enter the view of an existing NAS-ID profile.

Use **undo aaa nas-id profile** to delete a NAS-ID profile.

Syntax

aaa nas-id profile *profile-name*

undo aaa nas-id profile *profile-name*

Default

No NAS-ID profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

profile-name: Specifies the NAS-ID profile name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

Configure a NAS-ID profile to maintain NAS-ID and VLAN bindings on the device.

During RADIUS authentication, the device uses a NAS-ID to set the NAS-Identifier attribute of RADIUS packets so that the RADIUS server can identify the access location of users.

By default, the device uses the device name as the NAS-ID.

Examples

Create a NAS-ID profile named **aaa** and enter its view.

```
<Sysname> system-view
[Sysname] aaa nas-id profile aaa
[Sysname-nas-id-prof-aaa]
```

Related commands

nas-id bind vlan

port-security nas-id-profile

portal nas-id-profile

aaa session-limit

Use **aaa session-limit** to set the maximum number of concurrent users that can log on to the device through the specified method.

Use **undo aaa session-limit** to restore the default maximum number of concurrent users for the specified login method.

Syntax

In non-FIPS mode:

aaa session-limit { **ftp** | **http** | **https** | **ssh** | **telnet** } *max-sessions*

undo aaa session-limit { **ftp** | **http** | **https** | **ssh** | **telnet** }

In FIPS mode:

aaa session-limit { **https** | **ssh** } *max-sessions*

undo aaa session-limit { **https** | **ssh** }

Default

The maximum number of concurrent users is 32 for each user type.

Views

System view

Predefined user roles

network-admin

Parameters

ftp: FTP users.

http: HTTP users.

https: HTTPS users.

ssh: SSH users.

telnet: Telnet users.

max-sessions: Specifies the maximum number of concurrent login users. The value range is 1 to 32 for FTP, SSH, and Telnet services, and is 1 to 64 for HTTP and HTTPS services.

Usage guidelines

After the maximum number of concurrent login users for a user type exceeds the upper limit, the system denies the subsequent users of this type.

Examples

Set the maximum number of concurrent FTP users to 4.

```
<Sysname> system-view
[Sysname] aaa session-limit ftp 4
```

accounting command

Use **accounting command** to specify the command line accounting method.

Use **undo accounting command** to restore the default.

Syntax

accounting command hwtacacs-scheme *hwtacacs-scheme-name*

undo accounting command

Default

The default accounting methods of the ISP domain are used for command line accounting.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The command line accounting feature works with the accounting server to record valid commands that have been successfully executed on the device.

- When the command line authorization feature is disabled, the accounting server records all valid commands that have been successfully executed.
- When the command line authorization feature is enabled, the accounting server records only authorized commands that have been successfully executed.

Command line accounting can use only a remote HWTACACS server.

Examples

In ISP domain **test**, perform command line accounting based on HWTACACS scheme **hwtac**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting command hwtacacs-scheme hwtac
```

Related commands

accounting default

command accounting (*Fundamentals Command Reference*)

hwtacacs scheme

accounting default

Use **accounting default** to specify default accounting methods for an ISP domain.

Use **undo accounting default** to restore the default.

Syntax

In non-FIPS mode:

accounting default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

undo accounting default

In FIPS mode:

accounting default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] | **local** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] }

undo accounting default

Default

The default accounting method of an ISP domain is local.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The default accounting method is used for all users that support this method and do not have an accounting method configured.

Local accounting is only used for monitoring and controlling the number of local user connections. It does not provide the statistics function that the accounting feature generally provides.

You can specify one primary default accounting method and multiple backup default accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting default radius-scheme** *radius-scheme-name* **local none** command specifies the primary default RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

Examples

In ISP domain **test**, use RADIUS scheme **rd** as the primary default accounting method and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting default radius-scheme rd local
```

Related commands

hwtacacs scheme

local-user

radius scheme

accounting lan-access

Use **accounting lan-access** to specify accounting methods for LAN users.

Use **undo accounting lan-access** to restore the default.

Syntax

In non-FIPS mode:

accounting lan-access { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] [**none**] | **local** [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

undo accounting lan-access

In FIPS mode:

accounting lan-access { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] | **local** | **radius-scheme** *radius-scheme-name* [**local**] }

undo accounting lan-access

Default

The default accounting methods of the ISP domain are used for LAN users.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

broadcast: Broadcasts accounting requests to servers in RADIUS schemes.

radius-scheme *radius-scheme-name1*: Specifies the primary broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-scheme *radius-scheme-name2*: Specifies the backup broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting lan-access radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The following guidelines apply to broadcast accounting:

- The device sends accounting requests to the primary accounting servers in the specified broadcast RADIUS schemes at the real-time accounting interval set in the primary broadcast RADIUS scheme. If the primary server is unavailable in a scheme, the device sends accounting requests to the secondary servers of the scheme in the order the servers are configured.
- The accounting result is determined by the primary broadcast RADIUS scheme. The accounting result from the backup scheme is used as reference only. If the primary scheme does not return any result, the device considers the accounting as a failure.

Examples

In ISP domain **test**, perform local accounting for LAN users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting lan-access local
```

In ISP domain **test**, perform RADIUS accounting for LAN users based on scheme **rd** and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting lan-access radius-scheme rd local
```

In ISP domain **test**, broadcast accounting requests of LAN users to RADIUS servers in schemes **rd1** and **rd2**, and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting lan-access broadcast radius-scheme rd1 radius-scheme rd2
local
```

Related commands

accounting default

accounting login

Use **accounting login** to specify accounting methods for login users.

Use **undo accounting login** to restore the default.

Syntax

In non-FIPS mode:

accounting login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

undo accounting login

In FIPS mode:

accounting login { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] | **local** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] }

undo accounting login

Default

The default accounting methods of the ISP domain are used for login users.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

Accounting is not supported for FTP, SFTP, and SCP users.

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting login radius-scheme** *radius-scheme-name* **local none** command specifies a primary default RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

Examples

In ISP domain **test**, perform local accounting for login users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting login local
```

In ISP domain **test**, perform RADIUS accounting for login users based on scheme **rd** and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting login radius-scheme rd local
```

Use **undo accounting portal** to restore the default.

Syntax

In non-FIPS mode:

accounting portal { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] [**none**] | **local** [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

undo accounting portal

In FIPS mode:

accounting portal { **broadcast radius-scheme** *radius-scheme-name1* **radius-scheme** *radius-scheme-name2* [**local**] | **local** | **radius-scheme** *radius-scheme-name* [**local**] }

undo accounting portal

Default

The default accounting methods of the ISP domain are used for portal users.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

broadcast: Broadcasts accounting requests to servers in RADIUS schemes.

radius-scheme *radius-scheme-name1*: Specifies the primary broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-scheme *radius-scheme-name2*: Specifies the backup broadcast RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local accounting.

none: Does not perform accounting.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

You can specify one primary accounting method and multiple backup accounting methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **accounting portal radius-scheme** *radius-scheme-name* **local none** command specifies a primary default RADIUS accounting method and two backup methods (local accounting and no accounting). The device performs RADIUS accounting by default and performs local accounting when the RADIUS server is invalid. The device does not perform accounting when both of the previous methods are invalid.

The following guidelines apply to broadcast accounting:

- The device sends accounting requests to the primary accounting servers in the specified broadcast RADIUS schemes at the real-time accounting interval set in the primary broadcast RADIUS scheme. If the primary server is unavailable in a scheme, the device sends accounting requests to the secondary servers of the scheme in the order the servers are configured.
- The accounting result is determined by the primary broadcast RADIUS scheme. The accounting result from the backup scheme is used as reference only. If the primary scheme does not return any result, the device considers the accounting as a failure.

Examples

In ISP domain **test**, perform local accounting for portal users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting portal local
```

In ISP domain **test**, perform RADIUS accounting for portal users based on scheme **rd** and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
```

```
[Sysname-isp-test] accounting portal radius-scheme rd local
```

In ISP domain **test**, broadcast accounting requests of portal users to RADIUS servers in schemes **rd1** and **rd2**, and use local accounting as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting portal broadcast radius-scheme rd1 radius-scheme rd2 local
```

accounting quota-out

Use **accounting quota-out** to configure access control for users that have used up their data or time accounting quotas.

Use **undo accounting quota-out** to restore the default.

Syntax

accounting quota-out { **offline** | **online** }

undo accounting quota-out

Default

The device logs off users that have used up their accounting quotas.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

offline: Logs off users that have used up their accounting quotas.

online: Allows users that have used up their accounting quotas to stay online.

Usage guidelines

If the server notifies the device of portal users' remaining accounting quotas, the time that the device logs out portal users that have used up their accounting quotas might be inaccurate.

Examples

In ISP domain **test**, configure the device to allow users that have used up their accounting quotas to stay online.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting quota-out online
```

accounting start-fail

Use **accounting start-fail** to configure access control for users that encounter accounting-start failures.

Use **undo accounting start-fail** to restore the default.

Syntax

accounting start-fail { **offline** | **online** }

undo accounting start-fail

Default

The device allows users that encounter accounting-start failures to stay online.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

offline: Logs off users that encounter accounting-start failures.

online: Allows users that encounter accounting-start failures to stay online.

Examples

In ISP domain **test**, configure the device to allow users that encounter accounting-start failures to stay online.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting start-fail online
```

accounting update-fail

Use **accounting update-fail** to configure access control for users that have failed all their accounting-update attempts.

Use **undo accounting update-fail** to restore the default.

Syntax

accounting update-fail { [**max-times** *max-times*] **offline** | **online** }

undo accounting update-fail

Default

The device allows users that have failed all their accounting-update attempts to stay online.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

max-times *max-times*: Specifies the maximum number of consecutive accounting-update failures allowed by the device for each user. The value range for the *times* argument is 1 to 255, and the default value is 1.

offline: Logs off users that have failed all their accounting-update attempts.

online: Allows users that have failed all their accounting-update attempts to stay online.

Examples

In ISP domain **test**, configure the device to allow users that have failed all their accounting-update attempts to stay online.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] accounting update-fail online
```

authentication default

Use **authentication default** to specify default authentication methods for an ISP domain.

Use **undo authentication default** to restore the default.

Syntax

In non-FIPS mode:

authentication default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **ldap-scheme** *ldap-scheme-name* [**local**] [**none**] | **local** [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

undo authentication default

In FIPS mode:

authentication default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] | **ldap-scheme** *ldap-scheme-name* [**local**] | **local** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] }

undo authentication default

Default

The default authentication method of an ISP domain is local.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

ldap-scheme *ldap-scheme-name*: Specifies an LDAP scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authentication.

none: Does not perform authentication.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The default authentication method is used for all users that support this method and do not have an authentication method configured.

You can specify one primary default authentication method and multiple backup default authentication methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authentication default radius-scheme** *radius-scheme-name* **local none** command specifies a primary default RADIUS authentication method and two backup methods (local authentication and no authentication). The device performs RADIUS authentication by default and performs local authentication when the RADIUS server is invalid. The device does not perform authentication when both of the previous methods are invalid.

Examples

In ISP domain **test**, use RADIUS scheme **rd** as the primary default authentication method and use local authentication as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authentication default radius-scheme rd local
```

Related commands

authentication super

Use **authentication super** to specify a method for user role authentication.

Use **undo authentication super** to restore the default.

Syntax

authentication super { **hwtacacs-scheme** *hwtacacs-scheme-name* | **radius-scheme** *radius-scheme-name* } *

undo authentication super

Default

The default authentication methods of the ISP domain are used for user role authentication.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

To enable a user to obtain another user role without reconnecting to the device, you must configure user role authentication. The device supports local and remote methods for user role authentication. For more information about user role authentication, see RBAC configuration in *Fundamentals Configuration Guide*.

You can specify one authentication method and one backup authentication method to use in case that the previous authentication method is invalid.

Examples

In ISP domain **test**, perform user role authentication based on HWTACACS scheme **tac**.

```
<Sysname> system-view
[Sysname] super authentication-mode scheme
[Sysname] domain test
[Sysname-isp-test] authentication super hwtacacs-scheme tac
```

undo authorization command

In FIPS mode:

authorization command { **hwtacacs-scheme** *hwtacacs-scheme-name* [**local**] | **local** }

undo authorization command

Default

The default authorization methods of the ISP domain are used for command authorization.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authorization.

none: Does not perform authorization. The authorization server does not verify whether the entered commands are permitted by the user role. The commands are executed successfully if the user role has permission to the commands.

Usage guidelines

Command authorization restricts login users to execute only authorized commands by employing an authorization server to verify whether each entered command is permitted.

When local command authorization is configured, the device compares each entered command with the user's configuration on the device. The command is executed only when it is permitted by the user's authorized user roles.

The commands that can be executed are controlled by both the access permission of user roles and command authorization of the authorization server. Access permission only controls whether the authorized user roles have access to the entered commands, but it does not control whether the user roles have obtained authorization to these commands. If a command is permitted by the access permission but denied by command authorization, this command cannot be executed.

You can specify one primary command authorization method and multiple backup command authorization methods.

When the default authorization method is invalid, the device attempts to use the backup authorization methods in sequence. For example, the **authorization command hwtacacs-scheme** *hwtacacs-scheme-name* **local none** command specifies the default

HWTACACS authorization method and two backup methods (local authorization and no authorization). The device performs HWTACACS authorization by default and performs local authorization when the HWTACACS server is invalid. The device does not perform command authorization when both of the previous methods are invalid.

Examples

In ISP domain **test**, configure the device to perform local command authorization.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization command local
```

In ISP domain **test**, perform command authorization based on HWTACACS scheme **hwtac** and use local authorization as the backup.

```

Use **undo authorization default** to restore the default.

Syntax

In non-FIPS mode:

authorization default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] [**none**] | **local** [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] [**none**] }

undo authorization default

In FIPS mode:

authorization default { **hwtacacs-scheme** *hwtacacs-scheme-name* [**radius-scheme** *radius-scheme-name*] [**local**] | **local** | **radius-scheme** *radius-scheme-name* [**hwtacacs-scheme** *hwtacacs-scheme-name*] [**local**] }

undo authorization default

Default

The default authorization method of an ISP domain is local.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

local: Performs local authorization.

none: Does not perform authorization. The following default authorization information applies after users pass authentication:

- Login users obtain the level-0 user role. Login users include the Telnet, FTP, SFTP, SCP, and terminal users. Terminal users can access the device through the console port. For more information about the level-0 user role, see RBAC configuration in *Fundamentals Configuration Guide*.
- The working directory for FTP, SFTP, and SCP login users is the root directory of the NAS. However, the users do not have permission to access the root directory.
- Non-login users can access the network.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The default authorization method is used for all users that support this method and do not have an authorization method configured.

The RADIUS authorization configuration takes effect only when the authentication method and authorization method of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the default authorization method is invalid, the device attempts to use the backup authorization methods in sequence. For example, the **authorization default radius-scheme** *radius-scheme-name* **local none** command specifies the default RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

Examples

In ISP domain **test**, use RADIUS scheme **rd** as the primary default authorization method and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization default radius-scheme rd local
```

Parameters

local: Performs local authorization.

none: Does not perform authorization. An authenticated LAN user directly accesses the network.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The RADIUS authorization configuration takes effect only when authentication and authorization methods of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the primary method is invalid, the device attempts to use the backup methods in sequence. For example, the **authorization lan-access radius-scheme** *radius-scheme-name* **local none** command specifies a primary RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

Examples

In ISP domain **test**, perform local authorization for LAN users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization lan-access local
```

In ISP domain **test**, perform RADIUS authorization for LAN users based on scheme **rd** and use local authorization as the backup.

local: Performs local authorization.

none: Does not perform authorization. The following default authorization information applies after users pass authentication:

- Login users obtain the level-0 user role. Login users include the Telnet, FTP, SFTP, SCP, and terminal users. Terminal users can access the device through the console port. For more information about the level-0 user role, see RBAC configuration in *Fundamentals Configuration Guide*.
- The working directory for FTP, SFTP, and SCP login users is the root directory of the NAS. However, the users do not have permission to access the root directory.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The RADIUS authorization configuration takes effect only when the authentication method and authorization method of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the default authorization method is invalid, the device attempts to use the backup authorization methods in sequence. For example, the **authorization login radius-scheme** *radius-scheme-name* **local none** command specifies the default RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

Examples

In ISP domain **test**, perform local authorization for login users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization login local
```

In ISP domain **test**, perform RADIUS authorization for login users based on scheme **rd** and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization login radius-scheme rd local
```

Related commands

authorization default

hwtacacs scheme

local-user

radius scheme

authorization portal

Use **authorization portal** to specify authorization methods for portal users.

Use **undo authorization portal** to restore the default.

Syntax

In non-FIPS mode:

authorization portal { **local** [**none**] | **none** | **radius-scheme** *radius-scheme-name* [**local**] [**none**] }

undo authorization portal

In FIPS mode:

authorization portal { **local** | **radius-scheme** *radius-scheme-name* [**local**] }

undo authorization portal

Default

The default authorization methods of the ISP domain are used for portal users.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

local: Performs local authorization.

none: Does not perform authorization. An authenticated portal user directly accesses the network.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

The RADIUS authorization configuration takes effect only when the authentication method and authorization method of the ISP domain use the same RADIUS scheme.

You can specify one primary authorization method and multiple backup authorization methods.

When the default authorization method is invalid, the device attempts to use the backup authorization methods in sequence. For example, the **authorization portal radius-scheme** *radius-scheme-name* **local none** command specifies the default RADIUS authorization method and two backup methods (local authorization and no authorization). The device performs RADIUS authorization by default and performs local authorization when the RADIUS server is invalid. The device does not perform authorization when both of the previous methods are invalid.

Examples

In ISP domain **test**, perform local authorization for portal users.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization portal local
```

In ISP domain **test**, perform RADIUS authorization for portal users based on scheme **rd** and use local authorization as the backup.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] authorization portal radius-scheme rd local
```

Related commands

authorization default

local-user

authorization-attribute (ISP domain view)

Use **authorization-attribute** to configure authorization attributes for users in an ISP domain.

Use **undo authorization-attribute** to restore the default of an authorization attribute.

Syntax

authorization-attribute { **acl** *acl-number* | **car inbound cir** *committed-information-rate* [**pir** *peak-information-rate*] **outbound cir** *committed-information-rate* [**pir** *peak-information-rate*] | **igmp max-access-number** *max-access-number* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **mld max-access-number** *max-access-number* | **url** *url-string* | **user-group** *user-group-name* | **user-profile** *profile-name* }

undo authorization-attribute { **acl** | **car** | **igmp** | **ip-pool** | **ipv6-pool** | **mld** | **url** | **user-group** | **user-profile** }

Default

An IPv4 user can concurrently join a maximum of four IGMP multicast groups.

An IPv6 user can concurrently join a maximum of four MLD multicast groups.

No other authorization attributes exist.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

acl *acl-number*: Specifies an ACL to filter traffic for users. The value range for the *acl-number* argument is 2000 to 4999. This option is applicable only to portal and LAN users. The device processes the traffic that matches the rules in the authorization ACL based on the permit or deny statement in the rules.

car: Specifies a CAR action for users. Typically, the attribute applies to authenticated users. If you configure the attribute in a portal preauthentication domain, the CAR action applies before portal authentication. This keyword is applicable only to portal users.

inbound: Specifies the upload rate of users.

outbound: Specifies the download rate of users.

cir *committed-information-rate*: Specifies the committed information rate in kbps, in the range of 1 to 4194303.

pir *peak-information-rate*: Specifies the peak information rate in kbps, in the range of 1 to 4194303. The peak information rate cannot be smaller than the committed information rate. If you do not specify this option, the CAR action does not restrict users by peak information rate.

igmp max-access-number *max-access-number*: Specifies the maximum number of IGMP groups that an IPv4 user can join concurrently. The value range for the *max-access-number* argument is 1 to 64. This option is applicable only to portal users.

ip-pool *ipv4-pool-name*: Specifies an IPv4 address pool for users. The *ipv4-pool-name* argument is a case-insensitive string of 1 to 63 characters. This option is applicable only to portal users.

ipv6-pool *ipv6-pool-name*: Specifies an IPv6 address pool for users. The *ipv6-pool-name* argument is a case-insensitive string of 1 to 63 characters. This option is applicable only to portal users.

mld max-access-number *max-access-number*: Specifies the maximum number of MLD groups that an IPv6 user can join concurrently. The value range for the *max-access-number* argument is 1 to 64. This option is applicable only to portal users.

url *url-string*: Specifies a redirect URL for users. Users are redirected to the URL the first time they access the network after they pass authentication. The *url-string* argument is a case-sensitive string of 1 to 255 characters. This option is applicable only to LAN users.

user-group *user-group-name*: Specifies a user group for users. The *user-group-name* argument is a case-insensitive string of 1 to 32 characters. Authenticated users obtain all attributes of the user group.

user-profile *profile-name*: Specifies an authorization user profile. The *profile-name* argument is a case-sensitive string of 1 to 31 characters. Typically, the attribute applies to authenticated users. If you configure the attribute in a portal preauthentication domain, the user profile applies before portal authentication. This option is applicable only to portal and LAN users.

Usage guidelines

If the server or NAS does not authorize a type of attribute to an authenticated user, the device authorizes the attribute in the ISP domain to the user.

You can configure multiple authorization attributes for users in an ISP domain. If you execute the command multiple times with the same attribute specified, the most recent configuration takes effect.

For portal users to come online after passing authentication, make sure ACLs assigned to portal users do not have rules specified with a source IP or MAC address.

Examples

Specify user group **abc** as the authorization user group for users in ISP domain **test**.

```
<Sysname> system-view
```

```
[Sysname] domain test
[Sysname-isp-test] authorization-attribute user-group abc
```

```

Table 1 Command output

Field	Description
Domain	ISP domain name.
State	Status of the ISP domain.
Default authentication scheme	Default authentication methods.
Default authorization scheme	Default authorization methods.
Default accounting scheme	Default accounting methods.
Login authentication scheme	Authentication methods for login users.
Login authorization scheme	Authorization methods for login users.
Login accounting scheme	Accounting methods for login users.
Super authentication scheme	Authentication methods for obtaining another user role without reconnecting to the device.
Command authorization scheme	Command line authorization methods.
Command accounting scheme	Command line accounting method.
LAN access authentication scheme	Authentication methods for LAN users.
LAN access authorization scheme	Authorization methods for LAN users.
LAN access accounting scheme	Accounting methods for LAN users.
Portal authentication scheme	Authentication methods for portal users.

Field	Description
Portal authorization scheme	Authorization methods for portal users.
Portal accounting scheme	Accounting methods for portal users.
RADIUS	RADIUS scheme.
HWTACACS	HWTACACS scheme.
LDAP	LDAP scheme.
Local	Local scheme.
None	No authentication, no authorization, or no accounting.
Accounting start failure action	Access control for users that encounter accounting-start failures: • **Online**—Allows the users to stay online. • **Offline**—Logs off the users.
Accounting update failure max-times	Maximum number of consecutive accounting-update failures allowed by the device for each user in the domain.
Accounting update failure action	Access control for users that have failed all their accounting-update attempts: • **Online**—Allows the users to stay online. • **Offline**—Logs off the users.
Accounting quota out policy	Access control for users that have used up their accounting quotas: • **Online**—Allows the users to stay online. • **Offline**—Logs off the users.
Service type	This field is not supported in the current software version. Service type of the ISP domain, including HSI, STB, and VoIP.
Session time	Online duration sent to the server for users that went offline due to connection failure or malfunction: • **Include idle time**—The online duration includes the idle timeout period. • **Exclude idle time**—The online duration does not include the idle timeout period.
Dual-stack accounting method	This field is not supported in the current software version. Accounting method for dual-stack users: • **Merge**—Merges IPv4 data with IPv6 data for accounting. • **Separate**—Separates IPv4 data from IPv6 data for accounting.
Authorization attributes	Authorization attributes for users in the ISP domain.
Idle cut	This field is not supported in the current software version. Idle cut feature status: • **Enabled**—The feature is enabled. The device logs off users that do not meet the minimum traffic requirements in an idle timeout period. • **Disabled**—The feature is disabled. It is the default idle cut state.
Idle timeout	Idle timeout period, in minutes.
Flow	Minimum traffic that a login user must generate in an idle timeout period, in bytes.
Traffic direction	Traffic direction for the idle cut feature:

Field	Description
	• **Both**. • **Inbound**. • **Outbound**.
IP pool	Name of the authorization IPv4 address pool.
User profile	Name of the authorization user profile.
Inbound CAR	Authorization inbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. If no inbound CAR is authorized, this field displays **N/A**.
Outbound CAR	Authorization outbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. If no outbound CAR is authorized, this field displays **N/A**.
ACL number	Authorization ACL for users.
User group	Authorization user group for users.
IPv6 pool	Name of the authorization IPv6 address pool for users.
URL	Authorization redirect URL for users.
IGMP access limit	Maximum number of IGMP groups that an IPv4 user is authorized to join concurrently.
MLD access limit	Maximum number of MLD groups that an IPv6 user is authorized to join concurrently.

domain

Use **domain** to create an ISP domain and enter its view, or enter the view of an existing ISP domain.

Use **undo domain** to delete an ISP domain.

Syntax

domain *isp-name*

undo domain *isp-name*

Default

A system-defined ISP domain exists. The domain name is **system**.

Views

System view

Predefined user roles

network-admin

Parameters

isp-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters. The name must meet the following requirements:

- The name cannot contain a forward slash (/), backslash (\), vertical bar (|), quotation marks ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).

- The name cannot be **d**, **de**, **def**, **defa**, **defau**, **defaul**, **default**, **i**, **if**, **if-**, **if-u**, **if-un**, **if-unk**, **if-unkn**, **if-unkno**, **if-unknow**, or **if-unknown**.

Usage guidelines

All ISP domains are in active state when they are created.

You can modify settings for the system-defined ISP domain **system**, but you cannot delete this domain.

An ISP domain cannot be deleted when it is the default ISP domain. Before you use the **undo domain** command, change the domain to a non-default ISP domain by using the **undo domain default enable** command.

Use short domain names to ensure that user names containing a domain name do not exceed the maximum name length required by different types of users.

Examples

Create an ISP domain named **test** and enter ISP domain view.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test]
```

Related commands

display domain

domain default enable

domain if-unknown

state (ISP domain view)

domain default enable

Use **domain default enable** to specify the default ISP domain. Users without any domain name included in the usernames are considered in the default domain.

Use **undo domain default enable** to restore the default.

Syntax

domain default enable *isp-name*

undo domain default enable

Default

The default ISP domain is the system-defined ISP domain **system**.

Views

System view

Predefined user roles

network-admin

Parameters

isp-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters. The ISP domain must already exist.

Usage guidelines

The system has only one default ISP domain.

An ISP domain cannot be deleted when it is the default ISP domain. Before you use the **undo domain** command, change the domain to a non-default ISP domain by using the **undo domain default enable** command.

Examples

Create an ISP domain named **test**, and configure the domain as the default ISP domain.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] quit
[Sysname] domain default enable test
```

Related commands

display domain

domain

domain if-unknown

Use **domain if-unknown** to specify an ISP domain to accommodate users that are assigned to nonexistent domains.

Use **undo domain if-unknown** to restore the default.

Syntax

domain if-unknown *isp-name*

undo domain if-unknown

Default

No ISP domain is specified to accommodate users that are assigned to nonexistent domains.

Views

System view

Predefined user roles

network-admin

Parameters

isp-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters. The name must meet the following requirements:

- The name cannot contain a forward slash (/), backslash (\), vertical bar (|), quotation marks ("), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).
- The name cannot be **d**, **de**, **def**, **defa**, **defau**, **defaul**, **default**, **i**, **if**, **if-**, **if-u**, **if-un**, **if-unk**, **if-unkn**, **if-unkno**, **if-unknow**, or **if-unknown**.

Usage guidelines

The device chooses an authentication domain for each user in the following order:

1. The authentication domain specified for the access module.
2. The ISP domain in the username.
3. The default ISP domain of the device.

If the chosen domain does not exist on the device, the device searches for the ISP domain that accommodates users assigned to nonexistent domains. If no such ISP domain is configured, user authentication fails.

NOTE:

Support for the authentication domain configuration depends on the access module.

Examples

Specify ISP domain **test** to accommodate users that are assigned to nonexistent domains.

```
<Sysname> system-view
[Sysname] domain if-unknown test
```

Related commands

display domain

local-server log change-password-prompt

Use **local-server log change-password-prompt** to enable password change prompt logging.

Use **undo local-server log change-password-prompt** to disable password change prompt logging.

Syntax

local-server log change-password-prompt

undo local-server log change-password-prompt

Default

Password change prompt logging is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command is supported only in Release 6318P01 and later.

Use this feature to enhance the protection of passwords for Telnet, SSH, HTTP, HTTPS, NETCONF over SSH, and NETCONF over SOAP users and improve the system security.

This feature enables the device to generate logs to prompt users to change their weak passwords at an interval of 24 hours and at the users' login.

A password is a weak password if it does not meet the following requirements:

- Password composition restriction configured by using the **password-control composition** command.
- Minimum password length restriction set by using the **password-control length** command.
- It cannot contain the username or the reverse letters of the username.

For a NETCONF over SSH or NETCONF over SOAP user, the device also generates a password change prompt log if any of the following conditions exists:

- The current password of the user is the default password or has expired.
- The user logs in to the device for the first time or uses a new password to log in after global password control is enabled.

The device will no longer generate password change prompt logs for a user when one of the following conditions exists:

- The password change prompt logging feature is disabled.
- The user has changed the password and the new password meets the password control requirements.
- The enabling status of a related password control feature has changed so the current password of the user meets the password control requirements.
- The password composition policy or the minimum password length has changed.

You can use the **display password-control** command to display password control configuration. For more information about password control commands, see "Password control commands."

Examples

Enable password change prompt logging.

```
<Sysname> system-view
[Sysname] local-server log change-password-prompt
```

Related commands

display password-control

password-control composition

password-control length

nas-id bind vlan

Use **nas-id bind vlan** to bind a NAS-ID with a VLAN.

Use **undo nas-id bind vlan** to remove a NAS-ID and VLAN binding.

Syntax

nas-id *nas-identifier* **bind vlan** *vlan-id*

undo nas-id *nas-identifier* **bind vlan** *vlan-id*

Default

No NAS-ID and VLAN bindings exist.

Views

NAS-ID profile view

Predefined user roles

network-admin

Parameters

nas-identifier: Specifies a NAS-ID, a case-sensitive string of 1 to 31 characters.

vlan-id: Specifies a VLAN ID in the range of 1 to 4094.

Usage guidelines

You can configure multiple NAS-ID and VLAN bindings in a NAS-ID profile.

A NAS-ID can be bound with more than one VLAN, but a VLAN can be bound with only one NAS-ID. If you configure multiple bindings for the same VLAN, the most recent configuration takes effect.

Examples

Bind NAS-ID 222 with VLAN 2 in NAS-ID profile **aaa**.

```
<Sysname> system-view
[Sysname] aaa nas-id profile aaa
[Sysname-nas-id-prof-aaa] nas-id 222 bind vlan 2
```

Related commands

aaa nas-id profile

session-time include-idle-time

Use **session-time include-idle-time** to configure the device to include the idle timeout period in the user online duration sent to the server.

Use **undo session-time include-idle-time** to restore the default.

Syntax

session-time include-idle-time

undo session-time include-idle-time

Default

The device does not include the idle timeout period in the user online duration sent to the server.

Views

ISP domain view

Predefined user roles

network-admin

Usage guidelines

Whether to configure the device to include the idle timeout period in the user online duration sent to the server, depending on the accounting policy in your network. The idle timeout period is assigned to users by the authorization server after the users pass authentication. For portal users, the device includes the idle timeout period set for the online portal user detection feature in the user online duration. For more information about online detection for portal users, see portal authentication configuration in *Security Configuration Guide*.

If the user goes offline due to connection failure or malfunction, the user online duration sent to the server is not the same as the actual online duration.

- If the **session-time include-idle-time** command is used, the user's online duration sent to the server includes the idle timeout period. The online duration that is generated on the server is longer than the actual online duration of the user.
- If the **undo session-time include-idle-time** command is used, the user's online duration sent to the server excludes the idle timeout period. The online duration that is generated on the server is shorter than the actual online duration of the user.

Examples

Configure the device to include the idle timeout period in the online duration sent to the server for users in ISP domain **test**.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] session-time include-idle-time
```

Related commands

display domain

state (ISP domain view)

Use **state** to set the status of an ISP domain.

Use **undo state** to restore the default.

Syntax

state { **active** | **block** }

undo state

Default

An ISP domain is in active state.

Views

ISP domain view

Predefined user roles

network-admin

Parameters

active: Places the ISP domain in active state to allow the users in the ISP domain to request network services.

block: Places the ISP domain in blocked state to prevent users in the ISP domain from requesting network services.

Usage guidelines

By blocking an ISP domain, you disable offline users of the domain from requesting network services. However, the online users are not affected.

Examples

Place ISP domain **test** in blocked state.

```
<Sysname> system-view
[Sysname] domain test
[Sysname-isp-test] state block
```

Related commands

display domain

Local user commands

access-limit

Use **access-limit** to set the maximum number of concurrent logins using the local user name.

Use **undo access-limit** to restore the default.

Syntax

access-limit *max-user-number*

undo access-limit

Default

The number of concurrent logins using the local user name is not limited.

Views

Local user view

Predefined user roles

network-admin

Parameters

max-user-number: Specifies the maximum number of concurrent logins, in the range of 1 to 1024.

Usage guidelines

This command takes effect only when local accounting is configured for the local user. The command does not apply to FTP, SFTP, or SCP users. These users do not support accounting.

For this command to take effect on network access users, you also need to execute the **accounting start-fail offline** command in the ISP domain view.

Examples

Set the maximum number of concurrent logins to 5 for users using the local user name **abc**.

```
<Sysname> system-view
[Sysname] local-user abc
[Sysname-luser-manage-abc] access-limit 5
```

Related commands

accounting start-fail offline

display local-user

authorization-attribute (local user view/user group view)

Use **authorization-attribute** to configure authorization attributes for a local user or user group. After the local user or a local user in the user group passes authentication, the device assigns these attributes to the user.

Use **undo authorization-attribute** to restore the default of an authorization attribute.

Syntax

authorization-attribute { **acl** *acl-number* | **idle-cut** *minutes* | **ip-pool** *ipv4-pool-name* | **ipv6-pool** *ipv6-pool-name* | **session-timeout** *minutes* | **user-profile** *profile-name* | **user-role** *role-name* | **vlan** *vlan-id* | **work-directory** *directory-name* } *

undo authorization-attribute { **acl** | **idle-cut** | **ip-pool** | **ipv6-pool** | **session-timeout** | **user-profile** | **user-role** *role-name* | **vlan** | **work-directory** } *

Default

The working directory for FTP, SFTP, and SCP users is the root directory of the NAS. However, the users do not have permission to access the root directory.

The local users created by a network-admin or level-15 user are assigned the network-operator user role.

Views

Local user view

User group view

Predefined user roles

network-admin

Parameters

acl *acl-number*: Specifies an authorization ACL. The value range for the *acl-number* argument is 2000 to 4999. The device processes the traffic that matches the rules in the authorization ACL based on the permit or deny statement in the rules.

idle-cut *minutes*: Specifies an idle timeout period in minutes. The value range for the *minutes* argument is 1 to 120. An online user is logged out if its idle period exceeds the specified idle timeout period.

ip-pool *ipv4-pool-name*: Specifies an IPv4 address pool for the user. The *ipv4-pool-name* argument is a case-insensitive string of 1 to 63 characters.

ipv6-pool *ipv6-pool-name*: Specifies an IPv6 address pool for the user. The *ipv6-pool-name* argument is a case-insensitive string of 1 to 63 characters.

session-timeout *minutes*: Specifies the session timeout timer for the user, in minutes. The value range for the *minutes* argument is 1 to 1440. The device logs off the user after the timer expires.

user-profile *profile-name*: Specifies an authorization user profile by its name. The *profile-name* argument is a case-sensitive string of 1 to 31 characters. The name can contain only letters, digits, and underscores (_). The user profile restricts the behavior of authenticated users. For more information, see *Security Configuration Guide*.

user-role *role-name*: Specifies an authorized user role. The *role-name* argument is a case-sensitive string of 1 to 63 characters. A maximum of 64 user roles can be specified for a user. For user role-related commands, see *Fundamentals Command Reference* for RBAC commands. This option is available only in local user view, and is not available in user group view.

vlan *vlan-id*: Specifies an authorized VLAN. The value range for the *vlan-id* argument is 1 to 4094. After passing authentication and being authorized a VLAN, a local user can access only the resources in this VLAN.

work-directory *directory-name*: Specifies the working directory for FTP, SFTP, or SCP users. The *directory-name* argument is a case-insensitive string of 1 to 255 characters. The directory must already exist.

Usage guidelines

Configure authorization attributes according to the application environments and purposes. Support for authorization attributes depends on the service types of users.

For portal users, only the following authorization attributes take effect: **acl**, **ip-pool**, **ipv6-pool**, **user-profile**, and **session-timeout**.

For LAN users, only the following authorization attributes take effect: **acl**, **session-timeout**, **user-profile**, and **vlan**.

For SSH, Telnet, and terminal users, only the authorization attributes **idle-cut** and **user-role** take effect.

For HTTP and HTTPS users, only the authorization attribute **user-role** takes effect.

For FTP users, only the authorization attributes **user-role** and **work-directory** take effect.

For other types of local users, no authorization attribute takes effect.

Authorization attributes configured for a user group are intended for all local users in the group. You can group local users to improve configuration and management efficiency. An authorization attribute configured in local user view takes precedence over the same attribute configured in user group view.

For portal users to come online after passing authentication, make sure ACLs assigned to portal users do not have rules specified with a source IP or MAC address.

To make sure FTP, SFTP, and SCP users can access the directory after an IRF master/subordinate switchover, do not specify slot information for the working directory.

To make sure the user have only the user roles authorized by using this command, use the **undo authorization-attribute user-role** command to remove the default user role.

The security-audit user role has access to the commands for managing security log files and security log file system. To display all the accessible commands of the security-audit user role, use the **display role name security-audit** command. For more information about security log management, see *Network Management and Monitoring Configuration Guide*. For more information about file system management, see *Fundamentals Configuration Guide*.

You cannot delete a local user if the local user is the only user that has the security-audit user role.

The security-audit user role is mutually exclusive with other user roles.

- When you assign the security-audit user role to a local user, the system requests confirmation for deleting all the other user roles of the user.
- When you assign other user roles to a local user that has the security-audit user role, the system requests confirmation for deleting the security-audit user role for the local user.

Examples

Configure the authorized VLAN of network access user **abc** as VLAN 2.

```
<Sysname> system-view
[Sysname] local-user abc class network
[Sysname-luser-network-abc] authorization-attribute vlan 2
```

Configure the authorized VLAN of user group **abc** as VLAN 3.

```
<Sysname> system-view
[Sysname] user-group abc
[Sysname-ugroup-abc] authorization-attribute vlan 3
```

Assign the **security-audit** user role to device management user **xyz** as the authorized user role.

```
<Sysname> system-view
[Sysname] local-user xyz class manage
[Sysname-luser-manage-xyz] authorization-attribute user-role security-audit
This operation will delete all other roles of the user. Are you sure? [Y/N]:y
```

Related commands

display local-user

display user-group

bind-attribute

Use **bind-attribute** to configure binding attributes for a local user.

Use **undo bind-attribute** to remove binding attributes of a local user.

Syntax

bind-attribute { **ip** *ip-address* | **location interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id* } *

undo bind-attribute { **ip** | **location** | **mac** | **vlan** } *

Default

No binding attributes are configured for a local user.

Views

Local user view

Predefined user roles

network-admin

Parameters

ip *ip-address*: Specifies the IP address to which the user is bound. This option applies only to 802.1X users.

location interface *interface-type interface-number*: Specifies the interface to which the user is bound. The *interface-type* argument represents the interface type, and the *interface-number* argument represents the interface number. To pass authentication, the user must access the network through the bound interface. This option applies only to device management, LAN, and portal users.

mac *mac-address*: Specifies the MAC address of the user in the format H-H-H. This option applies only to LAN and portal users.

vlan *vlan-id*: Specifies the VLAN to which the user belongs. The *vlan-id* argument is in the range of 1 to 4094. This option applies only to LAN and portal users.

Usage guidelines

To perform local authentication of a user, the device matches the actual user attributes with the configured binding attributes. If the user has a non-matching attribute or lacks a required attribute, the user will fail authentication.

Binding attribute check takes effect on all access services. Configure the binding attributes for a user based on the access services and make sure the device can obtain all attributes to be checked from the user's packet. For example, you can configure an IP address binding for an 802.1X user, because 802.1X authentication can include the user's IP address in the packet. However, you cannot configure IP address bindings for MAC authentication users, because MAC authentication does not use IP addresses.

The binding interface type must meet the requirements of the local user. Configure the binding interface based on the service type of the user.

- If the user is an 802.1X user, specify the 802.1X-enabled Layer 2 Ethernet interface.
- If the user is a MAC authentication user, specify the MAC authentication-enabled Layer 2 Ethernet interface.
- If the user is a Web authentication user, specify the Web authentication-enabled Layer 2 Ethernet interface.
- If the user is a portal user, specify the portal-enabled interface. Specify the Layer 2 Ethernet interface if portal is enabled on a VLAN interface and the **portal roaming enable** command is not configured.

Examples

Bind MAC address 11-11-11 with network access user **abc**.

```
<Sysname> system-view
[Sysname] local-user abc class network
[Sysname-luser-network-abc] bind-attribute mac 11-11-11
```

Related commands

display local-user

description

Use **description** to configure a description for a network access user.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for a network access user.

Views

Network access user view

Predefined user roles

network-admin

Parameters

text: Configures a description, case-sensitive string of 1 to 255 characters.

Examples

Configure a description for network access user **123**.

```
<Sysname> system-view
[Sysname] local-user 123 class network
[Sysname-luser-network-123] description Manager of MSC company
```

Related commands

display local-user

display local-user

Use **display local-user** to display the local user configuration and online user statistics.

Syntax

display local-user [**class** { **manage** | **network** } | **idle-cut** { **disable** | **enable** } | **service-type** { **ftp** | **http** | **https** | **lan-access** | **portal** | **ssh** | **telnet** | **terminal** } | **state** { **active** | **block** } | **user-name** *user-name* **class** { **manage** | **network** } | **vlan** *vlan-id*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

class: Specifies the local user type.

manage: Device management user.

network: Network access user.

idle-cut { **disable** | **enable** }: Specifies local users by the status of the idle cut feature.

service-type: Specifies the local users that use a specific type of service.

ftp: FTP users.

http: HTTP users.

https: HTTPS users.

lan-access: LAN users that typically access the network through an Ethernet, such as 802.1X users.

portal: Portal users.

ssh: SSH users.

telnet: Telnet users.

terminal: Terminal users that log in through console ports.

state { **active** | **block** }: Specifies local users in active or blocked state. A local user in active state can access network services, but a local user in blocked state cannot.

user-name *user-name*: Specifies all local users using the specified username. The username must be a case-sensitive string of 1 to 55 characters. The name must meet the following requirements:

- Cannot contain the domain name.
- Cannot contain any of the following characters: forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).
- Cannot be **a**, **al**, or **all**.

vlan *vlan-id*: Specifies all local users in a VLAN. The *vlan-id* argument is in the range of 1 to 4094.

Usage guidelines

If you do not specify any parameters, this command displays information about all local users.

Examples

Display information about all local users.

```
<Sysname> display local-user
Device management user root:
  State:                     Active
  Service type:              SSH/Telnet/Terminal
  Access limit:              Enabled           Max access number: 3
  Current access number:     1
  User group:                system
  Bind attributes:
  Authorization attributes:
    Work directory:          flash:
    User role list:          network-admin
  Password control configurations:
    Password aging:          3 days
  Password history was last reset: 0 days ago

Network access user jj:
  State:                      Active
```

```
  Service type:               LAN-access
  User group:                 system
  Bind attributes:
    IP address:               2.2.2.2
    Location bound:           GigabitEthernet1/0/1
    MAC address:              0001-0001-0001
    VLAN ID:                  2
  Authorization attributes:
    Idle timeout:             33 minutes
    Work directory:           flash:
    ACL number:               2000
    User profile:               pp
    User role list:             network-operator, level-0, level-3
  Description:                A network access user from company cc
  Validity period:
    Start date and time:      2016/01/01-00:01:01
    Expiration date and time: 2017/01/01-01:01:01
  Password control configurations:
    Password length:          4 characters

Total 2 local users matched.
```

Table 2 Command output

Field	Description
State	Status of the local user: active or blocked.
Service type	Service types that the local user can use.
Access limit	Whether the concurrent login limit is enabled.
Max access number	Maximum number of concurrent logins using the local user name.
Current access number	Current number of concurrent logins using the local user name.
User group	Group to which the local user belongs.
Bind attributes	Binding attributes of the local user.
IP address	IP address of the local user.
Location bound	Binding port of the local user.
MAC address	MAC address of the local user.
VLAN ID	Binding VLAN of the local user.
Authorization attributes	Authorization attributes of the local user.
Idle timeout	Idle timeout period of the user, in minutes.
Session-timeout	Session timeout timer for the user, in minutes.
Work directory	Directory that the FTP, SFTP, or SCP user can access.
ACL number	Authorization ACL of the local user.
VLAN ID	Authorized VLAN of the local user.
User profile	Authorization user profile of the local user.
User role list	Authorized roles of the local user.

Field	Description
IP pool	IPv4 address pool authorized to the local user.
IPv6 pool	IPv6 address pool authorized to the local user.
Password control configurations	Password control attributes that are configured for the local user.
Password aging	Password expiration time.
Password length	Minimum number of characters that a password must contain.
Password composition	Password composition policy: • Minimum number of character types that a password must contain. • Minimum number of characters from each type in a password.
Password complexity	Password complexity checking policy: • Reject a password that contains the username or the reverse of the username. • Reject a password that contains any character repeated consecutively three or more times.
Maximum login attempts	Maximum number of consecutive failed login attempts.
Action for exceeding login attempts	Action to take on the user that failed to log in after using up all login attempts.
Password history was last reset	The most recent time that the history password records were cleared.
Description	Description of the network access user.
Validity period	Validity period of the network access user.
Start date and time	Date and time from which the network access user begins to take effect.
Expiration date and time	Date and time at which the network access user expires.

display user-group

Use **display user-group** to display user group configuration.

Syntax

display user-group { **all** | **name** *group-name* }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

all: Specifies all user groups.

name *group-name*: Specifies a user group by its name, a case-insensitive string of 1 to 32 characters.

Examples

Display the configuration of all user groups.

```
<Sysname> display user-group all
```

```
Total 2 user groups matched.

User group: system
  Authorization attributes:
    Work directory:          flash:
User group: jj
  Authorization attributes:
    Idle timeout:            2 minutes
    Work directory:          flash:/
    ACL number:              2000
    VLAN ID:                 2
    User profile:            pp
  Password control configurations:
    Password aging:          2 days
```

Table 3 Command output

Field	Description
User group	User group name.
Authorization attributes	Authorization attributes of the user group.
Idle timeout	Idle timeout period, in minutes.
Session-timeout	Session timeout timer, in minutes.
Work directory	Directory that FTP, SFTP, or SCP users in the group can access.
ACL number	Authorization ACL.
VLAN ID	Authorized VLAN.
User profile	Authorization user profile.
IP pool	IPv4 address pool authorized to the user group.
IPv6 pool	IPv6 address pool authorized to the user group.
Password control configurations	Password control attributes that are configured for the user group.
Password aging	Password expiration time.
Password length	Minimum number of characters that a password must contain.
Password composition	Password composition policy: • Minimum number of character types that a password must contain. • Minimum number of characters from each type in a password.
Password complexity	Password complexity checking policy: • Reject a password that contains the username or the reverse of the username. • Reject a password that contains any character repeated consecutively three or more times.
Maximum login attempts	Maximum number of consecutive failed login attempts.
Action for exceeding login attempts	Action to take on the user that failed to log in after using up all login attempts.

group

Use **group** to assign a local user to a user group.

Use **undo group** to restore the default.

Syntax

group *group-name*

undo group

Default

A local user belongs to user group **system**.

Views

Local user view

Predefined user roles

network-admin

Parameters

group-name: Specifies the user group name, a case-insensitive string of 1 to 32 characters.

Examples

Assign device management user **111** to user group **abc**.

```
<Sysname> system-view
[Sysname] local-user 111 class manage
[Sysname-luser-manage-111] group abc
```

Related commands

display local-user

local-user

Use **local-user** to add a local user and enter its view, or enter the view of an existing local user.

Use **undo local-user** to delete local users.

Syntax

local-user *user-name* [**class** { **manage** | **network** }]

undo local-user { *user-name* **class** { **manage** | **network** } | **all** [**service-type** { **ftp** | **http** | **https** | **lan-access** | **portal** | **ssh** | **telnet** | **terminal** } | **class** { **manage** | **network** }] }

Default

No local users exist.

Views

System view

Predefined user roles

network-admin

Parameters

user-name: Specifies the local user name, a case-sensitive string of 1 to 55 characters. The name must meet the following requirements:

- Cannot contain a domain name.
- Cannot contain any of the following characters: forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).
- Cannot be a substring of **all** or **auto-delete** that starts with character **a** (for example, **a**, **al**, **all**, **au**, **aut**, **auto**, or **auto-**).

class: Specifies the local user type. If you do not specify this keyword, the command adds a device management user.

manage: Device management user that can configure and monitor the device after login. Device management users can use FTP, HTTP, HTTPS, Telnet, SSH, and terminal services.

network: Network access user that accesses network resources through the device. Network access users can use LAN access and portal services.

all: Specifies all users.

service-type: Specifies the local users that use a specific type of service.

ftp: FTP users.

http: HTTP users.

https: HTTPS users.

lan-access: LAN users that typically access the network through an Ethernet, such as 802.1X users.

portal: Portal users.

ssh: SSH users.

telnet: Telnet users.

terminal: Terminal users that log in through console ports.

Usage guidelines

As from release 6348P01, the factory defaults of the device provide a default local user named **clouduser** of the HTTP type. The user password is **admin** and the user role is **network-admin**. In versions earlier than 6348P01, no default local user is provided.

Examples

Add a device management user named **user1** and enter local user view.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1]
```

Add a network access user named **user2** and enter local user view.

```
<Sysname> system-view
[Sysname] local-user user2 class network
[Sysname-luser-network-user2]
```

Related commands

display local-user

service-type

local-user auto-delete enable

Use **local-user auto-delete enable** to enable the local user auto-delete feature.

Use **undo local-user auto-delete enable** to restore the default.

Syntax

local-user auto-delete enable

undo local-user auto-delete enable

Default

The local user auto-delete feature is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This feature enables the device to examine the validity of local users at fixed time periods of 10 minutes and automatically delete expired local users.

Examples

Enable the local user auto-delete feature.

```
<Sysname> system-view
[Sysname] local-user auto-delete enable
```

Related commands

validity-datetime

password (device management user view)

Use **password** to configure a password for a device management user.

Use **undo password** to restore the default.

Syntax

In non-FIPS mode:

password [{ **hash** | **simple** } *string*]

undo password

In FIPS mode:

password

Default

In non-FIPS mode:

A device management user does not have a password and can pass authentication after entering the correct username and passing attribute checks.

In FIPS mode:

A device management user does not have a password and cannot pass authentication.

Views

Device management user view

Predefined user roles

network-admin

Parameters

hash: Specifies a password encrypted by the hash algorithm.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in hashed form.

string: Specifies the password string. This argument is case sensitive. In non-FIPS mode, the hashed form of the password is a string of 1 to 110 characters. The plaintext form of the password is a string of 1 to 63 characters. In FIPS mode, the password is in plaintext form and is a string of 15 to 63 characters. The string must contain digits, uppercase letters, lowercase letters, and special characters.

Usage guidelines

If you do not specify any parameters, you enter the interactive mode to set a plaintext password.

In non-FIPS mode, a device management user for which no password is specified can pass authentication after entering the correct username and passing attribute checks. To enhance security, configure a password for each device management user.

In FIPS mode, a password is required for a device management user to pass authentication. You must set the password in interactive mode.

When global password control is enabled, the device handles passwords of device management users as follows:

- All passwords in the history records are saved in hashed form.
- If a user changes its own password in plaintext form, the system requests the user to enter the current plaintext password. The new password must be different from all passwords in the history records and the current password. In addition, the new password must have a minimum of four characters different from the current password.
- If a user changes the password for another user in plaintext form, the new password must be different from the latter user's all passwords in the history records and current password.
- If a user deletes its own password, the system requests the user to enter the current plaintext password.
- Except the above listed situations, the system does not request a user to enter the current plaintext password or compare the new password with passwords in the history records and the current password.

Examples

Set the password to **123456TESTplat&!** in plaintext form for device management user **user1**.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1] password simple 123456TESTplat&!
```

Configure the password in interactive mode for device management user **test**.

```
<Sysname> system-view
[Sysname] local-user test class manage
[Sysname-luser-manage-test] password
Password:
confirm :
```

Related commands

display local-user

password (network access user view)

Use **password** to configure a password for a network access user.

Use **undo password** to restore the default.

Syntax

password { **cipher** | **simple** } *string*

undo password

Default

A network access user does not have a password and can pass authentication after entering the correct username and passing attribute checks.

Views

Network access user view

Predefined user roles

network-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password string. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

As a best practice to enhance security, configure a password for each network access user.

Examples

Set the password to **123456TESTuser&!** in plaintext form for network access user **user1**.

```
<Sysname> system-view
[Sysname] local-user user1 class network
[Sysname-luser-network-user1] password simple 123456TESTuser&!
```

Related commands

display local-user

service-type

Use **service-type** to specify the service types that a local user can use.

Use **undo service-type** to remove service types configured for a local user.

Syntax

In non-FIPS mode:

service-type { **ftp** | **lan-access** | { **http** | **https** | **ssh** | **telnet** | **terminal** } * | **portal** }

undo service-type { **ftp** | **lan-access** | { **http** | **https** | **ssh** | **telnet** | **terminal** } * | **portal** }

In FIPS mode:

service-type { **lan-access** | { **https** | **ssh** | **terminal** } * | **portal** }

undo service-type { **lan-access** | { **https** | **ssh** | **terminal** } * | **portal** }

Default

A local user is not authorized to use any service.

Views

Local user view

Predefined user roles

network-admin

Parameters

ftp: Authorizes the user to use the FTP service. The authorized directory can be modified by using the **authorization-attribute work-directory** command.

http: Authorizes the user to use the HTTP service.

https: Authorizes the user to use the HTTPS service.

lan-access: Authorizes the user to use the LAN access service. The users are typically Ethernet users, for example, 802.1X users.

ssh: Authorizes the user to use the SSH service.

telnet: Authorizes the user to use the Telnet service.

terminal: Authorizes the user to use the terminal service and log in from a console port.

portal: Authorizes the user to use the portal service.

Usage guidelines

You can assign multiple service types to a user.

Examples

Authorize device management user **user1** to use the Telnet and FTP services.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1] service-type telnet
[Sysname-luser-manage-user1] service-type ftp
```

Related commands

display local-user

state (local user view)

Use **state** to set the status of a local user.

Use **undo state** to restore the default.

Syntax

state { **active** | **block** }

undo state

Default

A local user is in active state.

Views

Local user view

Predefined user roles

network-admin

Parameters

active: Places the local user in active state to allow the local user to request network services.

block: Places the local user in blocked state to prevent the local user from requesting network services.

Examples

Place device management user **user1** in blocked state.

```
<Sysname> system-view
[Sysname] local-user user1 class manage
[Sysname-luser-manage-user1] state block
```

Related commands

display local-user

user-group

Use **user-group** to create a user group and enter its view, or enter the view of an existing user group.

Use **undo user-group** to delete a user group.

Syntax

user-group *group-name*

undo user-group *group-name*

Default

A system-defined user group exists. The group name is **system**.

Views

System view

Predefined user roles

network-admin

Parameters

group-name: Specifies the user group name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

A user group consists of a group of local users and has a set of local user attributes. You can configure local user attributes for a user group to implement centralized management of user attributes for the local users in the group.

A user group that has local users cannot be deleted.

You can modify settings for the system-defined user group named **system**, but you cannot delete the user group.

Examples

Create a user group named **abc** and enter user group view.

```
<Sysname> system-view
[Sysname] user-group abc
[Sysname-ugroup-abc]
```

Related commands

display user-group

validity-datetime

Use **validity-datetime** to specify the validity period for a network access user.

Use **undo validity-datetime** to restore the default.

Syntax

validity-datetime { **from** *start-date start-time* **to** *expiration-date expiration-time* | **from** *start-date start-time* | **to** *expiration-date expiration-time* }

undo validity-datetime

Default

The validity period for a local user does not expire.

Views

Network access user view

Predefined user roles

network-admin

Parameters

from: Specifies the validity start date and time for the user. If you do not specify this option, the command defines only the expiration date and time of the user.

start-date: Specifies the date on which the user becomes effective. The date is in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

start-time: Specifies the time on the day when the user becomes effective. The time is in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

to: Specifies the expiration date and time for the user. If you do not specify this option, the command defines only the validity start date and time of the user.

expiration-date: Specifies the expiration date in the format of MM/DD/YYYY or YYYY/MM/DD. The value range for the MM argument is 1 to 12. The value range for the DD argument varies with the specified month. The value range for the YYYY argument is 2000 to 2035.

expiration-time: Specifies the expiration time in the format of hh:mm:ss. The value range for the hh argument is 0 to 23. The value range for the mm and ss arguments is 0 to 59. The mm and ss arguments are optional. For example, enter 1 to indicate 1:00:00. A value of 0 indicates 00:00:00.

Usage guidelines

Expired network access user accounts cannot be used for authentication.

When both **from** and **to** options are specified, the expiration date and time must be later than the validity start date and time.

When only the **from** option is specified, the user is valid since the specified date and time. When only the **to** option is specified, the user is valid until the specified date and time.

Examples

Specify the validity period for network access user **123**.

```
<Sysname> system-view
[Sysname] local-user 123 class network
[Sysname-luser-network-123] validity-datetime from 2015/10/01 00:00:00 to 2016/10/02
12:00:00
```

Related commands

display local-user

RADIUS commands

aaa device-id

Use **aaa device-id** to configure the device ID.

Use **undo aaa device-id** to restore the default.

Syntax

aaa device-id *device-id*

undo aaa device-id

Default

The device ID is 0.

Views

System view

Predefined user roles

network-admin

Parameters

device-id: Specifies a device ID in the range of 1 to 255.

Usage guidelines

RADIUS uses the value of the Acct-Session-ID attribute as the accounting ID for a user. The device generates an Acct-Session-ID value for each online user based on the system time, random digits, and device ID.

If you modify the device ID, the new device ID does not take effect on users that have been online during the change.

Examples

Configure the device ID as 1.

```
<Sysname> system-view
[Sysname] aaa device-id 1
```

accounting-on enable

Use **accounting-on enable** to configure the accounting-on feature.

Use **undo accounting-on enable** to disable the accounting-on feature.

Syntax

accounting-on enable [**interval** *interval* | **send** *send-times*] *

undo accounting-on enable

Default

The accounting-on feature is disabled.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies the time interval for retransmitting an accounting-on packet in seconds. The value range for the *interval* argument is 1 to 15, and the default setting is 3.

send *send-times*: Specifies the maximum number of accounting-on packet transmission attempts. The value range for the *send-times* argument is 1 to 255, and the default setting is 50.

Usage guidelines

The accounting-on feature enables the device to automatically send an accounting-on packet to the RADIUS server after a device reboot. Upon receiving the accounting-on packet, the RADIUS server logs out all online users so they can log in again through the device.

Execute the **save** command to ensure that the **accounting-on enable** command takes effect at the next device reboot. For information about the **save** command, see *Fundamentals Command Reference*.

Parameters set by using the **accounting-on enable** command take effect immediately.

Examples

Enable the accounting-on feature for RADIUS scheme **radius1**, and set the retransmission interval to 5 seconds and the transmission attempts to 15.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] accounting-on enable interval 5 send 15
```

Related commands

display radius scheme

accounting-on extended

Use **accounting-on extended** to enable the extended accounting-on feature.

Use **undo accounting-on extended** to disable the extended accounting-on feature.

Syntax

accounting-on extended

undo accounting-on extended

Default

The extended accounting-on feature is disabled.

Views

RADIUS scheme view

Predefined user roles

network-admin

network-operator

Usage guidelines

The extended accounting-on feature enhances the accounting-on feature by applying to a distributed architecture. For the extended accounting-on feature to take effect, the RADIUS server must run on IMC and the accounting-on feature must be enabled.

The extended accounting-on feature is applicable to LAN users. The user data is saved to the member devices through which the users access the IRF fabric.

When this feature is enabled, the IRF fabric automatically sends an accounting-on packet to the RADIUS server after a member device reboots (IRF fabric not reboot). The packet contains the member device identifier. Upon receiving the accounting-on packet, the RADIUS server logs out all online users that access the IRF fabric through the member device. If no users have come online through the member device, the IRF fabric does not send an accounting-on packet after the member device reboots.

The IRF fabric uses the packet retransmission interval and maximum transmission attempts set by using the **accounting-on enable** command for this feature.

Execute the **save** command to ensure that the **accounting-on extended** command takes effect at the next member device reboot. For information about the **save** command, see *Fundamentals Command Reference*.

Examples

Enable the extended accounting-on feature for RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] accounting-on extended
```

Related commands

accounting-on enable

display radius scheme

attribute 5 format port

Use **attribute 5 format port** to set the NAS-Port attribute (attribute 5) format to the port format.

Use **undo attribute 5 format** to restore the default.

Syntax

attribute 5 format port

undo attribute 5 format

Default

The NAS-Port attribute uses the default format, which contains the following portions:

- 8-bit IRF member ID.
- 4-bit slot number.
- 8-bit port index.
- 12-bit VLAN ID.

Views

RADIUS scheme view

Predefined user roles

network-admin

Usage guidelines

This command is supported only in Release 6342 and later.

Perform this task to specify the format of the NAS-Port attribute (attribute 5) sent by the device to the RADIUS server. If you specify the port format, the attribute contains the value in the last segment of the user access interface. For example, if a user comes online from GigabitEthernet 1/0/2, the value for the NAS-Port attribute is 2.

To exchange RADIUS packets correctly with a RADIUS server, configure the device with the same NAS-Port attribute format as the RADIUS server.

This command takes effect on the RADIUS packets for all types of network access users.

Examples

Set the NAS-Port attribute format to the port format in RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 5 format port
```

Related commands

display radius scheme

attribute 15 check-mode

Use **attribute 15 check-mode** to configure the Login-Service attribute check method for SSH, FTP, and terminal users.

Use **undo attribute 15 check-mode** to restore the default.

Syntax

attribute 15 check-mode { **loose** | **strict** }

undo attribute 15 check-mode

Default

The strict check method applies for SSH, FTP, and terminal users.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

loose: Matches the standard Login-Service attribute value 0 for SSH, FTP, and terminal services.

strict: Matches Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal services, respectively.

Usage guidelines

Use the loose check method only when the server does not issue Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal users.

Examples

Configure the Login-Service attribute check method as **loose** for SSH, FTP, and terminal users in RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 15 check-mode loose
```

Related commands

display radius scheme

attribute 25 car

Use **attribute 25 car** to configure the device to interpret the RADIUS class attribute (attribute 25) as CAR parameters.

Use **undo attribute 25 car** to restore the default.

Syntax

attribute 25 car

undo attribute 25 car

Default

The RADIUS class attribute is not interpreted as CAR parameters.

Views

RADIUS scheme view

Predefined user roles

network-admin

Usage guidelines

Configure the device to interpret the RADIUS class attribute if the RADIUS server uses the attribute to deliver CAR parameters for user-based traffic monitoring and control.

Examples

In RADIUS scheme **radius1**, configure the device to interpret the RADIUS class attribute as CAR parameters.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 25 car
```

Related commands

attribute 31 mac-format

Use **attribute 31 mac-format** to configure the MAC address format for RADIUS attribute 31.

Use **undo attribute 31 mac-format** to restore the default.

Syntax

attribute 31 mac-format section { **one** | { **six** | **three** } **separator** *separator-character* } { **lowercase** | **uppercase** }

undo attribute 31 mac-format

Default

A MAC address is in the format of HH-HH-HH-HH-HH-HH. The MAC address is separated by hyphens (-) into six sections with letters in upper case.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

section: Specifies the number of sections that a MAC address contains.

one: Specifies the one-section format HHHHHHHHHHHH. This keyword is available only in Release 6312 and later.

six: Specifies the six-section format HH-HH-HH-HH-HH-HH.

three: Specifies the three-section format HHHH-HHHH-HHHH.

separator *separator-character*: Specifies a case-sensitive character that separates the sections.

lowercase: Specifies the letters in a MAC address to be in lower case.

uppercase: Specifies the letters in a MAC address to be in upper case.

Usage guidelines

Configure the MAC address format for RADIUS attribute 31 to meet the requirements of the RADIUS servers.

Examples

In RADIUS scheme **radius1**, specify the MAC address format as **hh:hh:hh:hh:hh:hh** for RADIUS attribute 31.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 31 mac-format section six separator : lowercase
```

Related commands

display radius scheme

attribute 87 format interface-name

Use **attribute 87 format interface-name** to set the NAS-Port-ID attribute (attribute 87) format to the interface name format.

Use **undo attribute 87 format** to restore the default.

Syntax

attribute 87 format interface-name

undo attribute 87 format

Default

The NAS-Port-Id attribute uses the default format, which differs by user access type:

- **Default format**—The default format varies by user access type.
  - For portal users, the NAS-Port-Id attribute is in the *SlotID***00***IfNOVlanID* format:
    - *SlotID*—Represents a 2-byte IRF member ID.

        - **00**—Represents a 2-byte string of 0s.
        - *IfNO*—Represents a 3-byte port index.
        - *VLANID*—Represents a 9-byte VLAN ID.
    - For 802.1X and MAC authentication users, the NAS-Port-Id attribute is in the **slot=***xx***;subslot=***xx***;port=***xx***;vlanid=***xx* format.
        - **slot**—IRF member ID.
        - **subslot**—Slot number.
        - **port**—Port index.
        - **vlanid**—VLAN ID
- For login users, the device does not include the NAS-Port-Id attribute in RADIUS packets.

Views

RADIUS scheme view

Predefined user roles

network-admin

Usage guidelines

This command is supported only in Release 6342 and later.

Perform this task to specify the format of the NAS-Port-ID attribute (attribute 87) sent by the device to the RADIUS server. If you specify the interface name format, the attribute contains the name of the user access interface. For example, if a user access the network from GigabitEthernet 1/0/1, the NAS-Port-ID attribute is set to **GigabitEthernet1/0/1**.

To exchange RADIUS packets correctly with a RADIUS server, configure the device with the same NAS-Port-ID attribute format as the RADIUS server.

This command takes effect on the RADIUS packets for all types of network access users.

Examples

Set the NAS-Port-ID attribute format to the interface name format in RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute 87 format interface-name
```

Related commands

display radius scheme

attribute convert (RADIUS DAS view)

Use **attribute convert** to configure a RADIUS attribute conversion rule.

Use **undo attribute convert** to delete RADIUS attribute conversion rules.

Syntax

attribute convert *src-attr-name* **to** *dest-attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

undo attribute convert [*src-attr-name*]

Default

No RADIUS attribute conversion rules exist. The system processes RADIUS attributes according to the principles of the standard RADIUS protocol.

Views

RADIUS DAS view

Predefined user roles

network-admin

Parameters

src-attr-name: Specifies the source RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

dest-attr-name: Specifies the destination RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

coa-ack: Specifies the CoA acknowledgment packets.

coa-request: Specifies the CoA request packets.

received: Specifies the received DAE packets.

sent: Specifies the sent DAE packets.

Usage guidelines

The device replaces the attribute in packets that match a RADIUS attribute conversion rule with the destination RADIUS attribute in the rule.

The conversion rules take effect only when the RADIUS attribute translation feature is enabled.

When you configure RADIUS attribute conversion rules, follow these restrictions and guidelines:

- The source and destination RADIUS attributes in a rule must use the same data type.
- The source and destination RADIUS attributes in a rule cannot use the same name.
- A source RADIUS attribute can be converted only by one criterion, packet type or direction.
- One source RADIUS attribute cannot be converted to multiple destination attributes.

If you do not specify a source RADIUS attribute, the **undo attribute convert** command deletes all RADIUS attribute conversion rules.

Examples

In RADIUS DAS view, configure a RADIUS attribute conversion rule to replace the Hw-Server-String attribute in the received DAE packets with the Connect-Info attribute.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] attribute convert Hw-Server-String to Connect-Info received
```

Related commands

attribute convert (RADIUS scheme view)

Use **attribute convert** to configure a RADIUS attribute conversion rule.

Use **undo attribute convert** to delete RADIUS attribute conversion rules.

Syntax

attribute convert *src-attr-name* **to** *dest-attr-name* { { **access-accept** | **access-request** | **accounting** } * | { **received** | **sent** } * }

undo attribute convert [*src-attr-name*]

Default

No RADIUS attribute conversion rules exist. The system processes RADIUS attributes according to the principles of the standard RADIUS protocol.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

src-attr-name: Specifies the source RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

dest-attr-name: Specifies the destination RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

access-accept: Specifies the RADIUS Access-Accept packets.

access-request: Specifies the RADIUS Access-Request packets.

accounting: Specifies the RADIUS accounting packets.

received: Specifies the received RADIUS packets.

sent: Specifies the sent RADIUS packets.

Usage guidelines

The device replaces the attribute in packets that match a RADIUS attribute conversion rule with the destination RADIUS attribute in the rule.

The conversion rules take effect only when the RADIUS attribute translation feature is enabled.

When you configure RADIUS attribute conversion rules, follow these restrictions and guidelines:

- The source and destination RADIUS attributes in a rule must use the same data type.
- The source and destination RADIUS attributes in a rule cannot use the same name.
- A source RADIUS attribute can be converted only by one criterion, packet type or direction.
- One source RADIUS attribute cannot be converted to multiple destination attributes.

If you do not specify a source RADIUS attribute, the **undo attribute convert** command deletes all RADIUS attribute conversion rules.

Examples

In RADIUS scheme **radius1**, configure a RADIUS attribute conversion rule to replace the Hw-Server-String attribute of received RADIUS packets with the Connect-Info attribute.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute convert Hw-Server-String to Connect-Info received
```

Related commands

attribute translate

attribute reject (RADIUS DAS view)

Use **attribute reject** to configure a RADIUS attribute rejection rule.

Use **undo attribute reject** to delete RADIUS attribute rejection rules.

Syntax

attribute reject *attr-name* { { **coa-ack** | **coa-request** } * | { **received** | **sent** } * }

undo attribute reject [*attr-name*]

Default

No RADIUS attribute rejection rules exist.

Views

RADIUS DAS view

Predefined user roles

network-admin

Parameters

attr-name: Specifies a RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The attribute must be supported by the system.

coa-ack: Specifies the CoA acknowledgment packets.

coa-request: Specifies the CoA request packets.

received: Specifies the received DAE packets.

sent: Specifies the sent DAE packets.

Usage guidelines

Configure RADIUS attribute rejection rules for the following purposes:

- Delete attributes from the RADIUS packets to be sent if the destination RADIUS server does not identify the attributes.
- Ignore unwanted attributes in the RADIUS packets received from a RADIUS server.

The RADIUS attribute rejection rules take effect only when the RADIUS attribute translation feature is enabled.

A RADIUS attribute can be rejected only by one criterion, packet type or direction.

If you do not specify a RADIUS attribute, the **undo attribute reject** command deletes all RADIUS attribute rejection rules.

Examples

In RADIUS DAS view, configure a RADIUS attribute rejection rule to delete the Connect-Info attribute from the DAE packets to be sent.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] attribute reject Connect-Info sent
```

Related commands

attribute remanent-volume

Use **attribute remanent-volume** to set the data measurement unit for the Remanent_Volume attribute.

Use **undo attribute remanent-volume** to restore the default.

Syntax

attribute remanent-volume unit { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** }

undo attribute remanent-volume unit

Default

The data measurement unit is kilobyte for the Remanent_Volume attribute.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

byte: Specifies the unit as byte.

giga-byte: Specifies the unit as gigabyte.

kilo-byte: Specifies the unit as kilobyte.

mega-byte: Specifies the unit as megabyte.

Usage guidelines

Make sure the measurement unit is the same as the user data measurement unit on the RADIUS server.

Examples

In RADIUS scheme **radius1**, set the data measurement unit to **kilobyte** for the Remanent_Volume attribute.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute remanent-volume unit kilo-byte
```

Related commands

display radius scheme

attribute translate

Use **attribute translate** to enable the RADIUS attribute translation feature.

Use **undo attribute translate** to disable the RADIUS attribute translation feature.

Syntax

attribute translate

undo attribute translate

Default

The RADIUS attribute translation feature is disabled.

Views

RADIUS DAS view

RADIUS scheme view

Predefined user roles

network-admin

Usage guidelines

To cooperate with RADIUS servers of different vendors, enable the RADIUS attribute translation feature. Configure RADIUS attribute conversion rules and rejection rules to ensure that RADIUS attributes in the packets exchanged between the device and the server are supported by both sides.

Examples

Enable the RADIUS attribute translation feature for RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] attribute translate
```

ca-file

Use **ca-file** to specify a CA certificate file for EAP authentication.

Use **undo ca-file** to restore the default.

Syntax

ca-file *file-name*

undo ca-file

Default

No CA certificate file is specified for EAP authentication. The device does not verify the RADIUS server certificate during EAP authentication.

Views

EAP profile view

Predefined user roles

network-admin

Parameters

file-name: Specifies a CA certificate file by its name, a case-sensitive string of 1 to 91 characters.

Usage guidelines

You must specify a CA certificate file to verify the RADIUS server certificate if the EAP authentication method is PEAP-GTC, PEAP-MSCHAPv2, TTLS-GTC, or TTLS-MSCHAPv2.

Before you specify a CA certificate file, you must use FTP or TFTP to transfer the CA certificate file to the root directory of the default storage medium on the device.

In an IRF fabric, make sure a CA certificate file already exists in the root directory of the default storage medium on the master device before you specify the file.

You can specify only one CA certificate file in an EAP profile. If you execute this command multiple times, the most recent configuration takes effect.

If you change the CA certificate file, the new CA certificate file takes effect at the next server status detection.

Examples

In EAP profile **eap1**, specify CA certificate file **CA.der** for EAP authentication.

```
<Sysname> system-view
[Sysname] eap-profile eap1
[Sysname-eap-profile-eap1] ca-file CA.der
```

client

Use **client** to specify a RADIUS DAC.

Use **undo client** to remove a RADIUS DAC.

Syntax

client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string*]

undo client { **ip** *ipv4-address* | **ipv6** *ipv6-address* }

Default

No RADIUS DACs are specified.

Views

RADIUS DAS view

Predefined user roles

network-admin

Parameters

ip *ipv4-address*: Specifies a DAC by its IPv4 address.

ipv6 *ipv6-address*: Specifies a DAC by its IPv6 address.

key: Specifies the shared key for secure communication between the RADIUS DAC and server. Make sure the shared key is the same as the key configured on the RADIUS DAC. If the RADIUS DAC does not have any shared key, do not specify this option.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 117 characters. The plaintext form of the key is a string of 15 to 64 characters. The plaintext string must contain characters from digits, uppercase letters, lowercase letters, and special characters.

Usage guidelines

With the RADIUS DAS feature, the device listens to the default or specified UDP port to receive DAE requests from the specified DACs. The device processes the requests and sends DAE responses to the DACs.

The device discards any DAE packets sent from DACs that are not specified for the DAS.

You can execute the **client** command multiple times to specify multiple DACs for the DAS.

Examples

Specify the DAC as 10.110.1.2. Set the shared key to **123456** in plaintext form for secure communication between the DAS and DAC.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] client ip 10.110.1.2 key simple 123456
```

Related commands

radius dynamic-author server

port

data-flow-format (RADIUS scheme view)

Use **data-flow-format** to set the data flow and packet measurement units for traffic statistics.

Use **undo data-flow-format** to restore the default.

Syntax

data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } } *

undo data-flow-format { **data** | **packet** }

Default

Traffic is counted in bytes and packets.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

data: Specifies the unit for data flows.

byte: Specifies the unit as byte.

giga-byte: Specifies the unit as gigabyte.

kilo-byte: Specifies the unit as kilobyte.

mega-byte: Specifies the unit as megabyte.

packet: Specifies the unit for data packets.

giga-packet: Specifies the unit as giga-packet.

kilo-packet: Specifies the unit as kilo-packet.

mega-packet: Specifies the unit as mega-packet.

one-packet: Specifies the unit as one-packet.

Usage guidelines

The data flow and packet measurement units for traffic statistics must be the same as configured on the RADIUS accounting servers. Otherwise, accounting results might be incorrect.

Examples

In RADIUS scheme **radius1**, set the data flow and packet measurement units for traffic statistics to kilobyte and kilo-packet, respectively.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] data-flow-format data kilo-byte packet kilo-packet
```

Table 4 Command output

Field	Description
Index	Index number of the RADIUS scheme.
Primary authentication server	Information about the primary authentication server.
Primary accounting server	Information about the primary accounting server.
Second authentication server	Information about the secondary authentication server.
Second accounting server	Information about the secondary accounting server.
Host name	Host name of the server. This field displays **Not configured** in the following situations: • The server is not configured. • The server is specified by IP address.

Field	Description
IP	IP address of the server. This field displays **Not configured** in the following situations: • The server is not configured. • The server is specified by hostname, and the hostname is not resolved.
Port	Service port number of the server. If no port number is specified, this field displays the default port number.
VPN	This field is not supported in the current software version. MPLS L3VPN instance to which the server or the RADIUS scheme belongs. If no VPN instance is specified for the server, this field displays **Not configured**.
State	Status of the server: • **Active**—The server is in active state. • **Block**—The server is changed to blocked state automatically. • **Block (Mandatory)**—The server is set to blocked state manually.
Test profile	Test profile used for RADIUS server status detection.
Probe username	Username used for RADIUS server status detection.
Probe interval	Server status detection interval, in minutes.
Probe eap-profile	EAP profile specified for RADIUS server status detection. This field is not available if no EAP profile is specified in the test profile for RADIUS server status detection.
Weight	Weight value of the RADIUS server.
Accounting-On function	Whether the accounting-on feature is enabled.
extended function	Whether the extended accounting-on feature is enabled.
retransmission times	Number of accounting-on packet transmission attempts.
retransmission interval(seconds)	Interval at which the device retransmits accounting-on packets, in seconds.
Timeout Interval(seconds)	RADIUS server response timeout period, in seconds.
Retransmission times	Maximum number of attempts for transmitting a RADIUS packet to a single RADIUS server.
Retransmission Times for Accounting Update	Maximum number of accounting attempts.
Server Quiet Period(minutes)	Quiet period for the servers, in minutes.
Realtime Accounting Interval(seconds)	Interval for sending real-time accounting updates, in seconds.
Stop-accounting packets buffering	Whether buffering of nonresponded RADIUS stop-accounting requests is enabled.
Retransmission times	Maximum number of transmission attempts for individual RADIUS stop-accounting requests.
NAS IP Address	Source interface or source IP addresses for outgoing RADIUS packets. This field displays **Not configured** if no source interface or source IP addresses are specified for outgoing RADIUS packets.
User Name Format	Format for the usernames sent to the RADIUS server: • **with-domain**—Includes the domain name.

Field	Description
	• **without-domain**—Excludes the domain name. • **keep-original**—Forwards the username as the username is entered.
Data flow unit	Measurement unit for data flow.
Packet unit	Measurement unit for packets.
Attribute 5 format	This field is supported only in Release 6342 and later. NAS-Port attribute (attribute 5) format options: • **Port**. • **Default**.
Attribute 15 check-mode	RADIUS Login-Service attribute check method for SSH, FTP, and terminal users: • **Strict**—Matches Login-Service attribute values 50, 51, and 52 for SSH, FTP, and terminal services, respectively. • **Loose**—Matches the standard Login-Service attribute value 0 for SSH, FTP, and terminal services.
Attribute 25	RADIUS attribute 25 interpretation status: • **Standard**—The attribute is not interpreted as CAR parameters. • **CAR**—The attribute is interpreted as CAR parameters.
Attribute 87 format	This field is supported only in Release 6342 and later. NAS-Port-ID attribute (attribute 87) format options: • **Interface name**. • **Default**.
Attribute Remanent-Volume unit	Data measurement unit for the RADIUS Remanent_Volume attribute.
server-load-sharing	Status of the RADIUS server load sharing feature: • **Disabled**—The feature is disabled. The device forwards traffic to the server selected based on primary and secondary server roles. • **Enabled**—The feature is enabled. The device distributes traffic among multiple servers for load sharing.
Attribute 31 MAC format	MAC address format for RADIUS attribute 31.
Stop-accounting-packet send-force	Whether the device is enabled to forcibly send stop-accounting packets when users for which no start-accounting packets are sent go offline.
Reauthentication server selection	This field is not supported in the current software version. RADIUS server selection mode in reauthentication: • **Inherit**—The device uses the RADIUS server that performed authentication for a user to reauthenticate that user. • **Reselect**—The device searches for a reachable RADIUS server to reauthenticate a user.

display radius server-load statistics

Use **display radius server-load statistics** to display authentication and accounting load statistics for all RADIUS servers.

Syntax

display radius server-load statistics

Views

Any view

Predefined user roles

network-admin

network-operator

Usage guidelines

This command displays the following statistics:

- **Last-5-second statistics**—Total number of authentication or accounting requests sent to each RADIUS server in the last 5 seconds.
- **History statistics**—Total number of authentication or accounting requests sent to each RADIUS server since the device starts up.

The device collects the statistics as follows:

- **Last-5-second statistics**—From the device sends the first authentication or accounting request to a RADIUS server, the device counts the number of authentication or accounting requests sent to the server every 5 seconds. Then, the device updates the last-5-second authentication and accounting statistics for the server.
- **History statistics**—The device increases the history statistics for a RADIUS server by 1 each time it sends an authentication or accounting request to the server. The device does not decrease the history statistics even though users go offline or the server fails to response to a request within the timeout time.

Based on the statistics, you can adjust the load on RADIUS servers by changing the sequence in which the servers are configured or the weight values of the servers.

This command displays statistics only for RADIUS servers whose IP addresses are available or can be resolved from their hostnames.

The device deletes all statistics for a RADIUS server if the server is removed from a RADIUS scheme or the server's IP address or service port number changes.

If an active/standby switchover occurs, the last-5-second statistics are deleted. However, the history statistics are not deleted. The history statistics might be inaccurate.

If the device reboots, both the last-5-seconds statistics and the history statistics are deleted.

Examples

Display authentication and accounting load statistics for all RADIUS servers.

```
<Sysname> display radius server-load statistics
Authentication servers: 2
IP                   VPN              Port    Last 5 sec   History
1.1.1.1              N/A              1812    20           100
2.2.2.2              N/A              1812    0            20
Accounting servers: 2
IP                   VPN              Port    Last 5 sec   History
1.1.1.1              N/A              1813    20           100
2.2.2.2             N/A              1813    0            20
```

Table 5 Command output

Field	Description
Authentication servers	Total number of RADIUS authentication servers.
Accounting servers	Total number of RADIUS accounting servers.

Field	Description
IP	IP address of a RADIUS server.
VPN	This field is not supported in the current software version. MPLS L3VPN instance to which the RADIUS server belongs. This field displays **N/A** if no VPN instance is specified for the server.
Port	Service port number of the RADIUS server.
Last 5 sec	Total number of RADIUS authentication or accounting requests sent to the RADIUS server within the last 5 seconds.
History	Total number of RADIUS authentication or accounting requests sent to the RADIUS server since the device starts up.

             Set Policy:      -             -             0
   Packet With Response:      0             0             0
Packet Without Response:      0             0             -
          Access Rejects:     0             -             -
          Dropped Packet:     0             0             0
          Check Failures:     0             0             0
```

Table 6 Command output

Field	Description
Auth.	Authentication packets.
Acct.	Accounting packets.
SessCtrl.	Session-control packets.
Request Packet	Number of request packets.
Retry Packet	Number of retransmitted request packets.
Timeout Packet	Number of request packets timed out.
Access Challenge	Number of access challenge packets.
Account Start	Number of start-accounting packets.
Account Update	Number of accounting update packets.
Account Stop	Number of stop-accounting packets.
Terminate Request	Number of packets for logging off users forcibly.
Set Policy	Number of packets for updating user authorization information.
Packet With Response	Number of packets for which responses were received.
Packet Without Response	Number of packets for which no responses were received.
Access Rejects	Number of Access-Reject packets.
Dropped Packet	Number of discarded packets.
Check Failures	Number of packets with checksum errors.

Related commands

`reset radius statistics`

display stop-accounting-buffer (for RADIUS)

Use **`display stop-accounting-buffer`** to display information about buffered RADIUS stop-accounting requests to which no responses have been received.

Syntax

`display stop-accounting-buffer` { **`radius-scheme`** *`radius-scheme-name`* | **`session-id`** *`session-id`* | **`time-range`** *`start-time end-time`* | **`user-name`** *`user-name`* }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`radius-scheme` *`radius-scheme-name`*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

session-id *session-id*: Specifies a session by its ID. The *session-id* argument is a string of 1 to 64 characters and cannot contain a letter. A session ID uniquely identifies an online user for a RADIUS scheme.

time-range *start-time end-time*: Specifies a time range. The start time and end time must be in the format of hh:mm:ss-mm/dd/yyyy or hh:mm:ss-yyyy/mm/dd.

user-name *user-name*: Specifies a user by its name, a case-sensitive string of 1 to 255 characters. Whether the *user-name* argument should include the domain name depends on the setting configured by using the **user-name-format** command for the RADIUS scheme.

Examples

Display information about nonresponded RADIUS stop-accounting requests buffered for user **abc**.

```
<Sysname> display stop-accounting-buffer user-name abc
Total entries: 2
Scheme     Session ID          Username    First sending time   Attempts
rad1       1000326232325010    abc         23:27:16-08/31/2015  19
aaa        1000326232326010    abc         23:33:01-08/31/2015  20
```

Table 7 Command output

Field	Description
Session ID	Session ID, which is the value of attribute Acct-Session-Id.
First sending time	Time when the stop-accounting request was first sent.
Attempts	Number of attempts that were made to send the stop-accounting request.

Related commands

retry

retry stop-accounting (RADIUS scheme view)

stop-accounting-buffer enable (RADIUS scheme view)

user-name-format (RADIUS scheme view)

eap-profile

Use **eap-profile** to create an EAP profile and enter its view, or enter the view of an existing EAP profile.

Use **undo eap-profile** to delete an EAP profile.

Syntax

eap-profile *eap-profile-name*

undo eap-profile *eap-profile-name*

Default

No EAP profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

eap-profile-name: Specifies the EAP profile name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

An EAP profile is a collection of EAP authentication settings, including the EAP authentication method and the CA certificate file to be used for some EAP authentication methods. You can use an EAP profile in a test profile for RADIUS server status detection.

You can specify an EAP profile in multiple test profiles.

You can configure a maximum of 16 EAP profiles.

Examples

Create an EAP profile named **eap1** and enter its view.

```
<Sysname> system-view
[Sysname] eap-profile eap1
[Sysname-eap-profile-eap1]
```

Related commands

exclude

Use **exclude** to exclude an attribute from RADIUS requests.

Use **undo exclude** to cancel the configuration of excluding an attribute from RADIUS requests.

Syntax

exclude { **accounting** | **authentication** } **name** *attribute-name*

undo exclude { **accounting** | **authentication** } **name** *attribute-name*

Default

No attributes are configured to be excluded from RADIUS requests.

Views

RADIUS attribute test group view

Predefined user roles

network-admin

Parameters

accounting: Specifies RADIUS accounting requests.

authentication: Specifies RADIUS authentication requests.

name *attribute-name*: Specifies a RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters. The specified attribute must be an attribute that RADIUS requests carry by default. RADIUS authentication requests carry the following attributes by default: Service-Type, Framed-Protocol, NAS-Identifier, Acct-Session-Id, and NAS-Port-Type. RADIUS accounting requests carry the following attributes by default: NAS-Identifier, Acct-Delay-Time, Acct-Session-Id, and Acct-Terminate-Cause.

Usage guidelines

Use this command to exclude an attribute from RADIUS requests sent during an AAA test to help troubleshoot authentication or accounting failures.

Before you exclude an attribute that is already configured to be included in RADIUS requests, you must cancel the inclusion configuration by using the **undo include** command.

Examples

In RADIUS attribute test group **t1**, exclude Service-Type attribute from RADIUS authentication requests.

```
<Sysname> system-view
[Sysname] radius attribute-test-group t1
[Sysname-radius-attr-test-grp-t1] exclude authentication name Service-Type
```

Related commands

include

test-aaa

include

Use **include** to include an attribute in RADIUS requests.

Use **undo include** to cancel the configuration of including an attribute in RADIUS requests.

Syntax

include { **accounting** | **authentication** } { **name** *attribute-name* | [**vendor** *vendor-id*] **code** *attribute-code* } **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** } **value** *attribute-value*

undo include { **accounting** | **authentication**} { **name** *attribute-name* | [**vendor** *vendor-id*] **code** *attribute-code* }

Default

No attributes are configured to be included in RADIUS authentication or accounting requests.

Views

RADIUS attribute test group view

Predefined user roles

network-admin

Parameters

accounting: Specifies RADIUS accounting requests.

authentication: Specifies RADIUS authentication requests.

name *attribute-name*: Specifies a standard RADIUS attribute by its name, a case-insensitive string of 1 to 63 characters.

vendor *vendor-id*: Specifies a vendor by its ID in the range of 1 to 65535. If the attribute is a standard RADIUS attribute, do not specify this option.

code *attribute-code*: Specifies a RADIUS attribute by its code in the range of 1 to 255.

type: Specifies a data type for the attribute content.

binary: Binary type.

date: Date type.

integer: Integer type.

interface-id: Interface ID type.

ip: IPv4 address type.

ipv6: IPv6 address type.

ipv6-prefix: IPv6 address prefix type.

octets: Octet type.

string: String type.

value *attribute-value*: Specifies the value for the attribute of the data type. The value range of the *attribute-value* argument varies by data type.

- For the binary type, the value is a string of 1 to 256 hexadecimal characters, which represents a binary number with a maximum of 128 bytes.
- For the date type, the value range is 0 to 4294967295.
- For the integer type, the value range is 0 to 4294967295.
- For the interface ID type, the value range is 1 to ffffffffffffffff.
- For the IPv6 address prefix type, the value is in the format of *prefix*/*prefix-length*.
- For the octet type, the value is a string of 1 to 256 hexadecimal characters, which represents an octet number with a maximum of 128 bytes.
- For the string type, the value of this argument is a string of 1 to 253 characters.

Usage guidelines

Use this command to add an attribute that RADIUS requests do not carry by default to the RADIUS requests. The **undo** form of this command removes the attribute from the RADIUS requests.

For an attribute that RADIUS requests carry by default, you can use this command to change its value. The **undo** form of this command restores the attribute value to the default.

Table 8 shows the attributes that RADIUS requests carry by default.

Table 8 Attributes that RADIUS requests carry by default

Packet type	Attributes that the type of packets carry by default
RADIUS authentication request	User-Name, CHAP-Password (or User-Password), CHAP-Challenge, NAS-IP-Address (or NAS-IPv6-Address), Service-Type,Framed-Protocol, NAS-Identifier, NAS-Port-Type, and Acct-Session-Id.
RADIUS accounting request	User-Name, Acct-Status-Type, NAS-IP-Address (or NAS-IPv6-Address), NAS-Identifier, Acct-Session-Id, Acct-Delay-Time, and Acct-Terminate-Cause.

For the accuracy of AAA tests, the value of an attribute must be of the data type specified for that attribute.

The attribute names of standard attributes saved in the configuration file will be converted to attribute codes.

Before you include an attribute that is already configured to be excluded from RADIUS requests, you must cancel the exclusion configuration by using the **undo exclude** command.

Plan the RADIUS attributes to be included in RADIUS requests. Besides the attributes carried by default, the device adds the specified attributes to RADIUS packets in the order that they are

specified by using the **include** command. Additional attributes cannot be added to a RADIUS request if the length of the RADIUS request reaches 4096 bytes.

Examples

In RADIUS attribute test group **t1**, include Calling-Station-Id attribute with value 08-00-27-00-34-D8 in RADIUS authentication requests.

```
<Sysname> system-view
[Sysname] radius attribute-test-group t1
[Sysname-radius-attr-test-grp-t1] include authentication name Calling-Station-Id type string value 08-00-27-00-34-d8
```

Related commands

exclude

test-aaa

key (RADIUS scheme view)

Use **key** to set the shared key for secure RADIUS authentication or accounting communication.

Use **undo key** to delete the shared key for secure RADIUS authentication or accounting communication.

Syntax

key { **accounting** | **authentication** } { **cipher** | **simple** } *string*

undo key { **accounting** | **authentication** }

Default

No shared key is configured for secure RADIUS authentication or accounting communication.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

accounting: Specifies the shared key for secure RADIUS accounting communication.

authentication: Specifies the shared key for secure RADIUS authentication communication.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 117 characters. The plaintext form of the key is a string of 15 to 64 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

Usage guidelines

The shared keys configured by using this command apply to all servers in the scheme. Make sure the settings match the shared keys configured on the RADIUS servers.

The shared keys specified for specific RADIUS servers take precedence over the shared key specified with this command.

Examples

In RADIUS scheme **radius1**, set the shared key to **ok** in plaintext form for secure accounting communication.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] key accounting simple ok
```

Related commands

display radius scheme

method

Use **method** to specify the EAP authentication method.

Use **undo method** to restore the default.

Syntax

method { **md5** | **peap-gtc** | **peap-mschapv2** | **ttls-gtc** | **ttls-mschapv2** }

undo method

Default

MD5-challenge authentication is used.

Views

EAP profile view

Predefined user roles

network-admin

Parameters

md5: Specifies the MD5-challenge method.

peap-gtc: Specifies the PEAP-GTC method.

peap-mschapv2: Specifies the PEAP-MSCHAPv2 method.

ttls-gtc: Specifies the TTLS-GTC method.

ttls-mschapv2: Specifies the TTLS-MSCHAPv2 method.

Usage guidelines

You must specify an EAP authentication method that is supported by the RADIUS server to be detected.

You can specify only one EAP authentication method in an EAP profile. If you execute this command multiple times, the most recent configuration takes effect.

If you change the EAP authentication method, the new method takes effect in the next server status detection.

Examples

In EAP profile **eap1**, specify PEAP-GTC as the EAP authentication method.

```
<Sysname> system-view
[Sysname] eap-profile eap1
[Sysname-eap-profile-eap1] method peap-gtc
```

nas-ip (RADIUS scheme view)

Use **nas-ip** to specify a source interface or source IP address for outgoing RADIUS packets.

Use **undo nas-ip** to delete the specified source interface or source IP address for outgoing RADIUS packets.

Syntax

nas-ip { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

undo nas-ip [**interface** | **ipv6**]

Default

The source IP address of an outgoing RADIUS packet is that specified by using the **radius nas-ip** command in system view.

If the **radius nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The device uses the primary IPv4 address or the IPv6 address of the interface as the source IP address of an outgoing RADIUS packet.

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

Usage guidelines

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS that is configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, the RADIUS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing RADIUS packets to avoid RADIUS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **radius nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in RADIUS scheme view applies only to the RADIUS scheme.
- The setting configured by using the **radius nas-ip** command in system view applies to all RADIUS schemes.
- The setting in RADIUS scheme view takes precedence over the setting in system view.

For a RADIUS scheme, the following restrictions apply:

- You can specify only one source IPv4 address and one source IPv6 address for outgoing RADIUS packets.
- You can specify only one source interface to provide the source IP address for outgoing RADIUS packets. Make sure the route between the source interface and the RADIUS server is reachable.
- The source interface configuration and the source IP address configuration overwrite each other.

If you do not specify any parameter for the **undo nas-ip** command, the command deletes the specified source IPv4 address for outgoing RADIUS packets.

Examples

In RADIUS scheme **radius1**, specify IP address 10.1.1.1 as the source IP address for outgoing RADIUS packets.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] nas-ip 10.1.1.1
```

Related commands

display radius scheme

radius nas-ip

port

Use **port** to specify the RADIUS DAS port.

Use **undo port** to restore the default.

Syntax

port *port-number*

undo port

Default

The RADIUS DAS port number is 3799.

Views

RADIUS DAS view

Predefined user roles

network-admin

Parameters

port-number: Specifies a UDP port number in the range of 1 to 65535.

Usage guidelines

The destination port in DAE packets on the DAC must be the same as the RADIUS DAS port on the DAS.

Examples

Enable the RADIUS DAS to listen to UDP port 3790 for DAE requests.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server] port 3790
```

Related commands

client

radius dynamic-author server

primary accounting (RADIUS scheme view)

Use **primary accounting** to specify the primary RADIUS accounting server.

Use **undo primary accounting** to restore the default.

Syntax

primary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **weight** *weight-value*] *

undo primary accounting

Default

The primary RADIUS accounting server is not specified.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

host-name: Specifies the host name of the primary RADIUS accounting server, a case-insensitive string of 1 to 253 characters.

ipv4-address: Specifies the IPv4 address of the primary RADIUS accounting server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the primary RADIUS accounting server.

port-number: Specifies the service port number of the primary RADIUS accounting server. The value range for the UDP port number is 1 to 65535. The default setting is 1813.

key: Specifies the shared key for secure communication with the primary RADIUS accounting server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 117 characters. The plaintext form of the key is a string of 15 to 64 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

weight *weight-value*: Specifies a weight value for the RADIUS server. The value range for the *weight-value* argument is 0 to 100, and the default value is 0. The value **0** indicates that the RADIUS server will not be used for load sharing. This option takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme. A larger weight value represents a higher capacity to process accounting requests.

Usage guidelines

Make sure the port number and shared key settings of the primary RADIUS accounting server are the same as those configured on the server.

Two accounting servers specified for a scheme, primary or secondary, cannot have identical host name, IP address, and port number settings.

The shared key configured by using this command takes precedence over the shared key configured with the **key accounting** command.

If you use the **primary accounting** command to modify or delete the primary accounting server to which the device is sending a start-accounting request, communication with the primary server times out.

- When the RADIUS server load sharing feature is disabled, the device tries to communicate with an active server that has the highest priority for accounting.
- When the RADIUS server load sharing feature is enabled, the device returns an accounting failure message rather than searching for another active accounting server.

If you remove an actively used accounting server, the device no longer sends users' real-time accounting requests and stop-accounting requests. It does not buffer the stop-accounting requests. The device can generate incorrect accounting results.

Examples

In RADIUS scheme **radius1**, specify the primary accounting server with IP address 10.110.1.2, UDP port number 1813, and plaintext shared key **123456TESTacct&!**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] primary accounting 10.110.1.2 1813 key simple 123456TESTacct&!
```

primary authentication (RADIUS scheme view)

Use **primary authentication** to specify the primary RADIUS authentication server.

Use **undo primary authentication** to restore the default.

Syntax

primary authentication { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **test-profile** *profile-name* | **weight** *weight-value*] *

undo primary authentication

Default

The primary RADIUS authentication server is not specified.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

host-name: Specifies the host name of the primary RADIUS authentication server, a case-insensitive string of 1 to 253 characters.

ipv4-address: Specifies the IPv4 address of the primary RADIUS authentication server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the primary RADIUS authentication server.

port-number: Specifies the service port number of the primary RADIUS authentication server. The value range for the UDP port number is 1 to 65535. The default setting is 1812.

key: Specifies the shared key for secure communication with the primary RADIUS authentication server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 117 characters. The plaintext form of the key is a string of 15 to 64 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

test-profile *profile-name*: Specifies a test profile for detecting the RADIUS server status. The *profile-name* argument is a case-sensitive string of 1 to 31 characters.

weight *weight-value*: Specifies a weight value for the RADIUS server. The value range for the *weight-value* argument is 0 to 100, and the default value is 0. The value **0** indicates that the RADIUS server will not be used for load sharing. This option takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme. A larger weight value represents a higher capacity to process authentication requests.

Usage guidelines

Make sure the service port and shared key settings of the primary RADIUS authentication server are the same as those configured on the server.

Two authentication servers specified for a scheme, primary or secondary, cannot have identical host name, IP address, and port number settings.

The shared key configured by this command takes precedence over the shared key configured with the **key authentication** command.

The server status detection is triggered for the server if the specified test profile exists on the device.

If you use the **primary authentication** command to modify or delete the primary authentication server during an authentication process, communication with the primary server times out.

- When the RADIUS server load sharing feature is disabled, the device tries to communicate with an active server that has the highest priority for authentication.
- When the RADIUS server load sharing feature is enabled, the device performs the following operations:
  a. Checks the weight value and number of currently served users for each active server.
  b. Determines the most appropriate server in performance to receive an AAA request.

Examples

In RADIUS scheme **radius1**, specify the primary authentication server with IP address 10.110.1.1, UDP port number 1812, and plaintext shared key **123456TESTauth&!**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] primary authentication 10.110.1.1 1812 key simple
123456TESTauth&!
```

radius attribute extended

Use **radius attribute extended** to define an extended RADIUS attribute.

Use **undo radius attribute extended** to delete user-defined extended RADIUS attributes.

Syntax

radius attribute extended *attribute-name* [**vendor** *vendor-id*] **code** *attribute-code* **type** { **binary** | **date** | **integer** | **interface-id** | **ip** | **ipv6** | **ipv6-prefix** | **octets** | **string** }

undo radius attribute extended [*attribute-name*]

Default

No user-defined extended RADIUS attributes exist.

Views

System view

Predefined user roles

network-admin

Parameters

attribute-name: Specifies the RADIUS attribute name, a case-insensitive string of 1 to 63 characters. The name must be unique among all RADIUS attributes, including the standard and extended RADIUS attributes.

vendor *vendor-id*: Specifies a vendor ID in the range of 1 to 65535. If you do not specify a vendor ID, the device processes the RADIUS attribute as a standard RADIUS attribute.

code *attribute-code*: Specifies the ID of the RADIUS attribute in the attribute set. The value range for the *attribute-code* argument is 1 to 255.

type: Specifies a data type for the attribute content.

binary: Binary type.

date: Date type.

integer: Integer type.

interface-id: Interface ID type.

ip: IPv4 address type.

ipv6: IPv6 address type.

ipv6-prefix: IPv6 address prefix type.

octets: Octet type.

string: String type.

Usage guidelines

To support the proprietary RADIUS attributes of other vendors, perform the following tasks:

1. Use this command to define the attributes as extended RADIUS attributes.
2. Use the **attribute convert** command to map the extended RADIUS attributes to attributes supported by the system.
3. Use the **attribute translate** command to enable the RADIUS attribute translation feature for the mappings to take effect.

To cooperate with RADIUS servers of a third-party vendor, map attributes that cannot be identified by the server to server-supported attributes.

Two RADIUS attributes cannot have the same combination of attribute name, vendor ID, and attribute ID.

If you do not specify a RADIUS attribute name, the **undo radius attribute extended** command deletes all user-defined extended RADIUS attributes.

Examples

Define a string-type extended RADIUS attribute with attribute name **Owner-Password**, vendor ID 122, and attribute ID 80.

```
<Sysname> system-view
[Sysname] radius attribute extended Owner-Password vendor 122 code 80 type string
```

radius attribute-test-group

Use **radius attribute-test-group** to create a RADIUS attribute test group and enter its view, or enter the view of an existing RADIUS attribute test group.

Use **undo radius attribute-test-group** to remove a RADIUS attribute test group.

Syntax

radius attribute-test-group *attr-test-group-name*

undo radius attribute-test-group *attr-test-group-name*

Default

No RADIUS attribute test groups exist.

Views

System view

Predefined user roles

network-admin

Parameters

attr-test-group-name: Specifies the name of a RADIUS attribute test group, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A RADIUS attribute test group is a collection of RADIUS attributes that will be included in or excluded from RADIUS requests.

The system can have multiple RADIUS attribute test groups.

Examples

Create a RADIUS attribute test group named **t1** and enter its view.

```
<Sysname> system-view
[Sysname] radius attribute-test-group t1
[Sysname-radius-attr-test-grp-t1]
```

radius dscp

Use **radius dscp** to change the DSCP priority of RADIUS packets.

Use **undo radius dscp** to restore the default.

Syntax

radius [**ipv6**] **dscp** *dscp-value*

undo radius [**ipv6**] **dscp**

Default

The DSCP priority of RADIUS packets is 0.

Views

System view

Predefined user roles

network-admin

Parameters

ipv6: Specifies the IPv6 RADIUS packets. If you do not specify this keyword, the command sets the DSCP priority for the IPv4 RADIUS packets.

dscp-value: Specifies the DSCP priority of RADIUS packets, in the range of 0 to 63. A larger value represents a higher priority.

Usage guidelines

Use this command to set the DSCP priority in the ToS field of RADIUS packets for changing their transmission priority.

Examples

Set the DSCP priority of IPv4 RADIUS packets to 10.

```
<Sysname> system-view
[Sysname] radius dscp 10
```

radius dynamic-author server

Use **radius dynamic-author server** to enable the RADIUS DAS feature and enter RADIUS DAS view.

Use **undo radius dynamic-author server** to disable the RADIUS DAS feature.

Syntax

radius dynamic-author server

undo radius dynamic-author server

Default

The RADIUS DAS feature is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

After you enable the RADIUS DAS feature, the device listens to the RADIUS DAS port to receive DAE packets from specified DACs. Based on the DAE packet type and contents, the device performs one of the following operations:

- Log off online users.
- Change online user authorization information.
- Shut down or reboot online users' access ports.
- Reauthenticate online users.

Examples

Enable the RADIUS DAS feature and enter RADIUS DAS view.

```
<Sysname> system-view
[Sysname] radius dynamic-author server
[Sysname-radius-da-server]
```

Use **undo radius enable** to disable the RADIUS service.

Syntax

radius enable

undo radius enable

Default

The RADIUS service is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

By default, the RADIUS service is enabled. The device can send and receive RADIUS packets. Attackers might use RADIUS session-control and DAE ports to attack the device. To protect the device when such an attack occurs, disable the RADIUS service temporarily on the device. After the network is secure, re-enable the RADIUS service.

If settings on the RADIUS servers require modification or the RADIUS servers cannot provide services temporarily, you can temporarily disable the RADIUS service on the device.

When the RADIUS service is disabled, the device stops sending and receiving RADIUS packets. If a new user comes online, the device uses the backup authentication, authorization, or accounting method to process that user. If the device has not finished requesting authentication or accounting for a user before the RADIUS service is disabled, it uses the following rules to process that user:

- If the device has sent RADIUS authentication requests for that user to a RADIUS server, the device processes that user depending on whether it receives a response from the RADIUS server.
  - If the device receives a response from the RADIUS server, it uses the response to determine whether that user has passed authentication. If that user has passed authentication, the device assigns authorization information to that user according to the response.
  - If the device does not receive any response from the RADIUS server, it attempts to use the backup authentication method to authenticate that user.
- If the device has sent RADIUS start-accounting requests for that user to a RADIUS server, the device processes that user depending on whether it receives a response from the RADIUS server.
  - If the device receives a response from the RADIUS server, it allows that user to come online. However, the device cannot send out accounting-update or stop-accounting requests to the RADIUS server. It cannot buffer the accounting requests, either. When that user goes offline, the RADIUS server cannot log off that user in time. The accounting result might be inaccurate.
  - If the device does not receive any response from the RADIUS server, it attempts to use the backup accounting method.

Disabling the RADIUS service does not affect the RADIUS server feature of the device.

The authentication, authorization, and accounting processes undertaken by other methods are not switched to RADIUS when you re-enable the RADIUS service.

Examples

Enable the RADIUS service.

```
<Sysname> system-view
[Sysname] radius enable
```

radius nas-ip

Use **radius nas-ip** to specify a source interface or source IP address for outgoing RADIUS packets.

Use **undo radius nas-ip** to delete the specified source interface or source IP address for outgoing RADIUS packets.

Syntax

radius nas-ip { **interface** *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } }

undo radius nas-ip { **interface** | { *ipv4-address* | **ipv6** *ipv6-address* } }

Default

The source IP address of an outgoing RADIUS packet is the primary IPv4 address or the IPv6 address of the outbound interface.

Views

System view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The device uses the primary IPv4 address or the IPv6 address of the interface as the source IP address of an outgoing RADIUS packet.

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

Usage guidelines

The source IP address of RADIUS packets that a NAS sends must match the IP address of the NAS that is configured on the RADIUS server. A RADIUS server identifies a NAS by its IP address. Upon receiving a RADIUS packet, the RADIUS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing RADIUS packets to avoid RADIUS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **radius nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in RADIUS scheme view applies only to the RADIUS scheme.
- The setting configured by using the **radius nas-ip** command in system view applies to all RADIUS schemes.
- The setting in RADIUS scheme view takes precedence over the setting in system view.

You can specify only one source IPv4 address and one source IPv6 address in system view.

You can specify only one source interface to provide the source IP address for outgoing RADIUS packets. Make sure the route between the source interface and the RADIUS server is reachable.

The source interface configuration and the source IP address configuration overwrite each other.

Examples

Specify IP address 129.10.10.1 as the source IP address for outgoing RADIUS packets.

```
<Sysname> system-view
[Sysname] radius nas-ip 129.10.10.1
```

Related commands

nas-ip (RADIUS scheme view)

radius scheme

Default

No RADIUS schemes exist.

Views

System view

Predefined user roles

network-admin

Parameters

radius-scheme-name: Specifies the RADIUS scheme name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

A RADIUS scheme can be used by more than one ISP domain at the same time.

The device supports a maximum of 16 RADIUS schemes.

Examples

Create a RADIUS scheme named **radius1** and enter RADIUS scheme view.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1]
```

Related commands

display radius scheme

radius session-control client

Use **radius session-control client** to specify a RADIUS session-control client.

Use **undo radius session-control client** to remove the specified RADIUS session-control clients.

Syntax

radius session-control client { **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**key** { **cipher** | **simple** } *string*]

undo radius session-control client { **all** | { **ip** *ipv4-address* | **ipv6** *ipv6-address* } }

Default

No RADIUS session-control clients are specified.

Views

System view

Predefined user roles

network-admin

Parameters

ip *ipv4-address*: Specifies a session-control client by its IPv4 address.

ipv6 *ipv6-address*: Specifies a session-control client by its IPv6 address.

key: Specifies the shared key for secure communication with the session-control client.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 117 characters. The plaintext form of the key is a string of 15 to 64 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

all: Specifies all session-control clients.

Usage guidelines

To verify the session-control packets sent from a RADIUS server running on IMC, specify the RADIUS server as a session-control client to the device. The device matches a session-control packet to a session-control client based on the IP address, and then uses the shared key of the matched client to validate the packet.

The device searches the session-control client settings prior to searching all RADIUS scheme settings for a server with matching settings. This process narrows the search scope for finding the matched RADIUS server.

The session-control client settings take effect only when the RADIUS session-control feature is enabled.

The session-control client settings must be the same as the corresponding settings of the RADIUS server.

You can specify multiple session-control clients on the device.

Examples

Specify a session-control client with IP address 10.110.1.2 and shared key **12345** in plaintext form.

```
<Sysname> system-view
[Sysname] radius session-control client ip 10.110.1.2 key simple 12345
```

Related commands

radius session-control enable

radius session-control enable

Use **radius session-control enable** to enable the RADIUS session-control feature.

Use **undo radius session-control enable** to disable the RADIUS session-control feature.

Syntax

radius session-control enable

undo radius session-control enable

Default

The RADIUS session-control feature is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

An H3C IMC RADIUS server uses session-control packets to change the user authorization information (such as the authorization ACL, VLAN, and user group) or forcibly disconnect users. The session-control feature enables the device to receive the RADIUS session-control packets on UDP port 1812.

This feature must work with H3C IMC servers.

If the device acts as the NAS and the IMC server deployed with EAD assigns authorization ACLs to the device, you must enable the session-control feature on the device. This ensures that the authorization ACLs can take effect.

Examples

Enable the RADIUS session-control feature.

```
<Sysname> system-view
[Sysname] radius session-control enable
```

radius-server test-profile

Use **radius-server test-profile** to configure a test profile for detecting the RADIUS server status.

Use **undo radius-server test-profile** to delete a RADIUS test profile.

Syntax

radius-server test-profile *profile-name* **username** *name* [**password** { **cipher** | **simple** } *string*] [**interval** *interval*] [**eap-profile** *eap-profile-name*]

undo radius-server test-profile *profile-name*

Default

No RADIUS test profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

profile-name: Specifies the name of the test profile, which is a case-sensitive string of 1 to 31 characters.

username *name*: Specifies the username in the detection packets. The *name* argument is a case-sensitive string of 1 to 253 characters.

password: Specifies the user password in the detection packets. If you do not specify a user password, the device randomly generates a user password for each detection packet. As a best practice, specify a user password. RADIUS server might mistake detection packets that contain randomly generated passwords as attack packets.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

interval *interval*: Specifies the interval for sending a detection packet, in minutes. The value range for the *interval* argument is 1 to 3600, and the default value is 60.

eap-profile *eap-profile-name*: Specifies an EAP profile by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

The device starts detecting the status of a RADIUS server only if the test profile specified for the server exists. If you specify a nonexistent test profile for a RADIUS server, the device does not detect the status of the server until you create the test profile on the device.

To perform EAP-based status detection for a RADIUS server, you must specify a test profile that contains an EAP profile for the RADIUS server.

EAP-based detection provides more reliable detection results than simple detection. As a best practice, configure EAP-based detection on a network environment where EAP authentication is configured.

If you specify a nonexistent EAP profile in a test profile, the device performs simple detection for the RADIUS servers that use the test profile. After the EAP profile is configured, the device will start EAP-based detection at the next detection interval.

When you delete a test profile, the device stops detecting the status of RADIUS servers that use the test profile.

You can execute this command multiple times to configure multiple test profiles.

Examples

Configure a test profile named **abc** for RADIUS server status detection. A detection packet that uses username **admin** and plaintext password **abc123** is sent every 10 minutes.

```
<Sysname> system-view
[Sysname] radius-server test-profile abc username admin password simple abc123 interval
10
```

reset stop-accounting-buffer (for RADIUS)

Use **reset stop-accounting-buffer** to clear buffered RADIUS stop-accounting requests to which no responses have been received.

Syntax

reset stop-accounting-buffer { **radius-scheme** *radius-scheme-name* | **session-id** *session-id* | **time-range** *start-time end-time* | **user-name** *user-name* }

Views

User view

Predefined user roles

network-admin

Parameters

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

session-id *session-id*: Specifies a session by its ID. The *session-id* argument is a string of 1 to 64 characters and cannot contain a letter. A session ID uniquely identifies an online user for a RADIUS scheme.

time-range *start-time end-time*: Specifies a time range. The start time and end time must be in the format of hh:mm:ss-mm/dd/yyyy or hh:mm:ss-yyyy/mm/dd.

user-name *user-name*: Specifies a user by its name, a case-sensitive string of 1 to 255 characters. Whether the *user-name* argument should include the domain name depends on the setting configured by using the **user-name-format** command for the RADIUS scheme.

Examples

Clear nonresponded RADIUS stop-accounting requests buffered for user **user0001@test**.

```
<Sysname> reset stop-accounting-buffer user-name user0001@test
```

Clear nonresponded RADIUS stop-accounting requests buffered from 0:0:0 to 23:59:59 on August 31, 2015.

```
<Sysname> reset stop-accounting-buffer time-range 0:0:0-08/31/2015 23:59:59-08/31/2015
```

display stop-accounting-buffer (for RADIUS)

stop-accounting-buffer enable (RADIUS scheme view)

retry

Use **retry** to set the maximum number of attempts for transmitting a RADIUS packet to a single RADIUS server.

Use **undo retry** to restore the default.

Syntax

retry *retries*

undo retry

Default

The maximum number of RADIUS packet transmission attempts is 3.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

retries: Specifies the maximum number of RADIUS packet transmission attempts, in the range of 1 to 20.

Usage guidelines

Because RADIUS uses UDP packets to transmit data, the communication is not reliable.

If the device does not receive a response to its request from the RADIUS server within the response timeout period, the device retransmits the RADIUS request. To set the response timeout period, use the **timer response-timeout** command.

If the device does not receive a response from the RADIUS server after the maximum number of transmission attempts is reached, the device considers the request a failure.

If the client times out during the authentication process, the user is immediately logged off. To avoid user logoffs, the value multiplied by the following items cannot be larger than the client timeout period defined by the access module:

- The maximum number of RADIUS packet transmission attempts.
- The RADIUS server response timeout period.
- The number of RADIUS authentication servers in the RADIUS scheme.

When the device sends a RADIUS request to a new RADIUS server, it checks the total amount of time it has taken to transmit the RADIUS packet. If the amount of time has reached 300 seconds, the device stops sending the RADIUS request to the next RADIUS server. As a best practice, consider the number of RADIUS servers when you configure the maximum number of packet transmission attempts and the RADIUS server response timeout period.

Examples

In RADIUS scheme **radius1**, set the maximum number of RADIUS packet transmission attempts to 5.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] retry 5
```

Related commands

radius scheme

timer response-timeout (RADIUS scheme view)

retry realtime-accounting

Use **retry realtime-accounting** to set the maximum number of accounting attempts.

Use **undo retry realtime-accounting** to restore the default.

Syntax

retry realtime-accounting *retries*

undo retry realtime-accounting

Default

The maximum number of accounting attempts is 5.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

retries: Specifies the maximum number of accounting attempts, in the range of 1 to 255.

Usage guidelines

Typically, a RADIUS accounting server checks whether a user is online by using a timeout timer. If the server does not receive a real-time accounting request for a user in the timeout period, it considers that a line or device failure has occurred. The server stops accounting for the user.

To work with the RADIUS server, the NAS needs to send real-time accounting requests to the server before the timer on the server expires and to keep pace with the server in disconnecting the user

when a failure occurs. The NAS disconnects from a user according to the maximum number of accounting attempts and specific parameters.

For example, the following conditions exist:

- The RADIUS server response timeout period is 3 seconds (set by using the **timer response-timeout** command).
- The maximum number of RADIUS packet transmission attempts is 3 (set by using the **retry** command).
- The real-time accounting interval is 12 minutes (set by using the **timer realtime-accounting** command).
- The maximum number of accounting attempts is 5 (set by using the **retry realtime-accounting** command).

In the above case, the device generates an accounting request every 12 minutes, and retransmits the request if it sends the request but receives no response within 3 seconds. If the device receives no response after transmitting the request three times, it considers the accounting attempt a failure, and makes another accounting attempt. If five consecutive accounting attempts fail, the device cuts the user connection.

Examples

In RADIUS scheme **radius1**, set the maximum number of accounting attempts to 10.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] retry realtime-accounting 10
```

timer response-timeout (RADIUS scheme view)

retry stop-accounting (RADIUS scheme view)

Use **retry stop-accounting** to set the maximum number of transmission attempts for individual RADIUS stop-accounting requests.

Use **undo retry stop-accounting** to restore the default.

Syntax

retry stop-accounting *retries*

undo retry stop-accounting

Default

The maximum number of transmission attempts is 500 for individual RADIUS stop-accounting requests.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

retries: Specifies the maximum number of transmission attempts. The value range is 10 to 65535.

Usage guidelines

The maximum number of stop-accounting request transmission attempts controls the transmission of stop-accounting requests together with the following parameters:

- RADIUS server response timeout timer (set by using the **timer response-timeout** command).
- Maximum number of times to transmit a RADIUS packet per round (set by using the **retry** command).

For example, the following settings exist:

- The RADIUS server response timeout timer is 3 seconds.
- The maximum number of times to transmit a RADIUS packet per round is five.
- The maximum number of stop-accounting request transmission attempts is 20.

A stop-accounting request is retransmitted if the device does not receive a response within 3 seconds. When all five transmission attempts in this round are used, the device buffers the request and starts another round of retransmission. If 20 consecutive rounds of attempts fail, the device discards the request.

Examples

Set the maximum number of stop-accounting request transmission attempts to 1000 for RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] retry stop-accounting 1000
```

Use **undo secondary accounting** to remove a secondary RADIUS accounting server.

Syntax

secondary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **weight** *weight-value*] *

undo secondary accounting [{ *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number*]]

Default

No secondary RADIUS accounting servers are specified.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

host-name: Specifies the host name of a secondary RADIUS accounting server, a case-insensitive string of 1 to 253 characters.

ipv4-address: Specifies the IPv4 address of a secondary RADIUS accounting server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary RADIUS accounting server.

port-number: Specifies the service port number of the secondary RADIUS accounting server. The value range for the UDP port number is 1 to 65535. The default setting is 1813.

key: Specifies the shared key for secure communication with the secondary RADIUS accounting server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 117 characters. The plaintext form of the key is a string of 15 to 64 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

weight *weight-value*: Specifies a weight value for the RADIUS server. The value range for the *weight-value* argument is 0 to 100, and the default value is 0. The value **0** indicates that the RADIUS server will not be used for load sharing. This option takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme. A larger weight value represents a higher capacity to process accounting requests.

Usage guidelines

Make sure the port number and shared key settings of each secondary RADIUS accounting server are the same as those configured on the corresponding server.

A RADIUS scheme supports a maximum of 16 secondary RADIUS accounting servers. If the primary server fails, the device tries to communicate with a secondary server in active state. The device connects to the secondary servers in the order they are configured.

Two accounting servers specified for a scheme, primary or secondary, cannot have identical host name, IP address, and port number settings.

The shared key configured by this command takes precedence over the shared key configured with the **key accounting** command.

If you use the **secondary accounting** command to modify or delete a secondary accounting server to which the device is sending a start-accounting request, communication with the secondary server times out.

- When the RADIUS server load sharing feature is disabled, the device tries to communicate with an active server that has the highest priority for accounting.
- When the RADIUS server load sharing feature is enabled, the device returns an accounting failure message rather than searching for another active accounting server.

If you remove an actively used accounting server, the device no longer sends users' real-time accounting requests and stop-accounting requests. The device does not buffer the stop-accounting requests, either.

Examples

In RADIUS scheme **radius1**, specify a secondary accounting server with IP address 10.110.1.1 and UDP port 1813.

```
<Sysname> system-view
[Sysname] radius scheme radius1
```

```
[Sysname-radius-radius1] secondary accounting 10.110.1.1 1813
```

In RADIUS scheme **radius2**, specify two secondary accounting servers with IP addresses 10.110.1.1 and 10.110.1.2 and UDP port 1813.

```
<Sysname> system-view
[Sysname] radius scheme radius2
[Sysname-radius-radius2] secondary accounting 10.110.1.1 1813
[Sysname-radius-radius2] secondary accounting 10.110.1.2 1813
```

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

host-name: Specifies the host name of a secondary RADIUS authentication server, a case-insensitive string of 1 to 253 characters.

ipv4-address: Specifies the IPv4 address of a secondary RADIUS authentication server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary RADIUS authentication server.

port-number: Specifies the service port number of the secondary RADIUS authentication server. The value range for the UDP port number is 1 to 65535. The default setting is 1812.

key: Specifies the shared key for secure communication with the secondary RADIUS authentication server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 117 characters. The

plaintext form of the key is a string of 15 to 64 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

test-profile *profile-name*: Specifies a test profile for detecting the RADIUS server status. The *profile-name* argument is a case-sensitive string of 1 to 31 characters.

weight *weight-value*: Specifies a weight value for the RADIUS server. The value range for the *weight-value* argument is 0 to 100, and the default value is 0. The value **0** indicates that the RADIUS server will not be used for load sharing. This option takes effect only when the RADIUS server load sharing feature is enabled for the RADIUS scheme. A larger weight value represents a higher capacity to process authentication requests.

Usage guidelines

Make sure the port number and shared key settings of each secondary RADIUS authentication server are the same as those configured on the corresponding server.

A RADIUS scheme supports a maximum of 16 secondary RADIUS authentication servers. If the primary server fails, the device tries to communicate with a secondary server in active state. The device connects to the secondary servers in the order they are configured.

The server status detection is triggered for a server if the specified test profile exists on the device.

Two authentication servers specified for a scheme, primary or secondary, cannot have identical host name, IP address, and port number settings.

The shared key configured by this command takes precedence over the shared key configured with the **key authentication** command.

If you use the **secondary authentication** command to modify or delete a secondary authentication server during an authentication process, communication with the secondary server times out.

- When the RADIUS server load sharing feature is disabled, the device tries to communicate with an active server that has the highest priority for authentication.
- When the RADIUS server load sharing feature is enabled, the device performs the following operations:
  a. Checks the weight value and number of currently served users for each active server.
  b. Determines the most appropriate server in performance to receive an AAA request.

Examples

In RADIUS scheme **radius1**, specify a secondary authentication server with IP address 10.110.1.2 and UDP port 1812.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] secondary authentication 10.110.1.2 1812
```

In RADIUS scheme **radius2**, specify two secondary authentication servers with IP addresses 10.110.1.1 and 10.110.1.2 and UDP port 1812.

```
<Sysname> system-view
[Sysname] radius scheme radius2
[Sysname-radius-radius2] secondary authentication 10.110.1.1 1812
[Sysname-radius-radius2] secondary authentication 10.110.1.2 1812
```

server-load-sharing enable

Use **server-load-sharing enable** to enable the RADIUS server load sharing feature.

Use **undo server-load-sharing enable** to disable the RADIUS server load sharing feature.

Syntax

server-load-sharing enable

undo server-load-sharing enable

Default

The RADIUS server load sharing feature is disabled.

Views

RADIUS scheme view

Predefined user roles

network-admin

Usage guidelines

Use the RADIUS server load sharing feature to dynamically distribute the workload over multiple servers regardless of their server roles. The device forwards an AAA request to the most appropriate server of all active servers in the scheme after it compares the weight values and numbers of currently served users. Specify a weight value for each RADIUS server based on the AAA capacity of the server. A larger weight value indicates a higher AAA capacity.

In RADIUS server load sharing, once the device sends a start-accounting request to a server for a user, it forwards all subsequent accounting requests of the user to the same server. If the accounting server is unreachable, the device returns an accounting failure message rather than searching for another active accounting server.

Examples

Enable the RADIUS server load sharing feature for RADIUS scheme **radius1**.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] server-load-sharing enable
```

Related commands

snmp-agent trap enable radius

Use **snmp-agent trap enable radius** to enable SNMP notifications for RADIUS.

Use **undo snmp-agent trap enable radius** to disable SNMP notifications for RADIUS.

Syntax

snmp-agent trap enable radius [**accounting-server-down** | **accounting-server-up** | **authentication-error-threshold** | **authentication-server-down** | **authentication-server-up**] *

undo snmp-agent trap enable radius [**accounting-server-down** | **accounting-server-up** | **authentication-error-threshold** | **authentication-server-down** | **authentication-server-up**] *

Default

All RADIUS SNMP notifications are disabled.

Views

System view

Predefined user roles

network-admin

Parameters

accounting-server-down: Specifies notifications to be sent when the RADIUS accounting server becomes unreachable.

accounting-server-up: Specifies notifications to be sent when the RADIUS accounting server becomes reachable.

authentication-error-threshold: Specifies notifications to be sent when the number of authentication failures exceeds the specified threshold. The threshold is represented by the ratio of the authentication failures to the total number of authentication attempts. The value range is 1 to 100, and the default value is 30. This threshold can only be configured through the MIB.

authentication-server-down: Specifies notifications to be sent when the RADIUS authentication server becomes unreachable.

authentication-server-up: Specifies notifications to be sent when the RADIUS authentication server becomes reachable.

Usage guidelines

If you do not specify any keywords, this command enables or disables all types of notifications for RADIUS.

When SNMP notifications for RADIUS are enabled, the device supports the following notifications generated by RADIUS:

- **RADIUS server unreachable notification**—The RADIUS server cannot be reached. RADIUS generates this notification if it cannot receive any response to an accounting or authentication request within the specified RADIUS request transmission attempts.
- **RADIUS server reachable notification**—The RADIUS server can be reached. RADIUS generates this notification for a previously blocked RADIUS server after the quiet timer expires.
- **Excessive authentication failures notification**—RADIUS generates this notification when the number of authentication failures to the total number of authentication attempts exceeds the specified threshold.

Examples

Enable the device to send RADIUS accounting server unreachable notifications.

```
<Sysname> system-view
[Sysname] snmp-agent trap enable radius accounting-server-down
```

state primary

Use **state primary** to set the status of a primary RADIUS server.

Syntax

state primary { **accounting** | **authentication** } { **active** | **block** }

Default

A primary RADIUS server is in active state.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

accounting: Specifies the primary RADIUS accounting server.

authentication: Specifies the primary RADIUS authentication server.

active: Specifies the active state, the normal operation state.

block: Specifies the blocked state, the out-of-service state.

Usage guidelines

When the RADIUS server load sharing feature is disabled, the device first tries to communicate with the primary server if the primary server is in active state. If the primary server is unavailable, the device performs the following operations:

- Changes the status of the primary server to blocked.
- Starts a quiet timer for the server.
- Tries to communicate with a secondary server in active state.

When the quiet timer of the primary server times out, the status of the server automatically changes to active. If you set the server status to blocked before the quiet timer times out, the server status cannot change back to active unless you manually set the status to active.

When the RADIUS server load sharing feature is enabled, the device checks the weight value and number of currently served users only for servers in active state. The most appropriate active server is selected for communication.

When the primary server and all secondary servers are in blocked state, the device tries to communicate with the primary server.

This command can affect the RADIUS server status detection feature when a valid test profile is specified for a primary RADIUS authentication server.

- If you set the status of the server to blocked, the device stops detecting the status of the server.
- If you set the status of the server to active, the device starts to detect the status of the server.

Examples

In RADIUS scheme **radius1**, set the status of the primary authentication server to blocked.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] state primary authentication block
```

Related commands

display radius scheme

server-load-sharing enable

state secondary

state secondary

Use **state secondary** to set the status of a secondary RADIUS server.

Syntax

state secondary { **accounting** | **authentication** } [{ *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number*]] { **active** | **block** }

Default

A secondary RADIUS server is in active state.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

accounting: Specifies a secondary RADIUS accounting server.

authentication: Specifies a secondary RADIUS authentication server.

host-name: Specifies the host name of the secondary RADIUS server, a case-insensitive string of 1 to 253 characters.

ipv4-address: Specifies the IPv4 address of a secondary RADIUS server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary RADIUS server.

port-number: Specifies the service port number of a secondary RADIUS server. The value range for the UDP port number is 1 to 65535. The default port numbers for authentication and accounting are 1812 and 1813, respectively.

active: Specifies the active state, the normal operation state.

block: Specifies the blocked state, the out-of-service state.

Usage guidelines

If you do not specify an IP address, this command changes the status of all configured secondary RADIUS servers.

If the device finds that a secondary server in active state is unreachable, the device performs the following operations:

- Changes the status of the secondary server to blocked.
- Starts a quiet timer for the server.
- Tries to communicate with another secondary server in active state.

When the quiet timer of a server times out, the status of the server automatically changes to active. If you set the server status to blocked before the quiet timer times out, the server status cannot change back to active unless you manually set the status to active. If all configured secondary servers are unreachable, the device considers the authentication or accounting attempt a failure.

When the RADIUS server load sharing feature is enabled, the device checks the weight value and number of currently served users only for servers in active state. The most appropriate active server is selected for communication.

This command can affect the RADIUS server status detection feature when a valid test profile is specified for a secondary RADIUS authentication server.

- If you set the status of the server to blocked, the device stops detecting the status of the server.
- If you set the status of the server to active, the device starts to detect the status of the server.

Examples

In RADIUS scheme **radius1**, set the status of all the secondary authentication servers to blocked.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] state secondary authentication block
```

stop-accounting-buffer enable (RADIUS scheme view)

Use **stop-accounting-buffer enable** to enable buffering of RADIUS stop-accounting requests to which no responses have been received.

Use **undo stop-accounting-buffer enable** to disable the buffering feature.

Syntax

stop-accounting-buffer enable

undo stop-accounting-buffer enable

Default

The device buffers the RADIUS stop-accounting requests to which no responses have been received.

Views

RADIUS scheme view

Predefined user roles

network-admin

Usage guidelines

This command enables the device to buffer a RADIUS stop-accounting request that has no response after the maximum transmission attempts (set by using the **retry** command) have been made. The device resends the buffered request until it receives a server response or when the number of stop-accounting request transmission attempts reaches the upper limit. If no more attempts are available, the device discards the request. However, if you have removed an accounting server, stop-accounting requests destined for the server are not buffered.

Examples

Enable buffering of RADIUS stop-accounting requests to which no responses have been received.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] stop-accounting-buffer enable
```

Related commands

display stop-accounting-buffer (for RADIUS)

reset stop-accounting-buffer (for RADIUS)

stop-accounting-packet send-force

Use **stop-accounting-packet send-force** to enable forcibly sending stop-accounting packets. The device will send stop-accounting packets when users for which no start-accounting packets are sent go offline.

Use **undo stop-accounting-packet send-force** to disable forcibly sending stop-accounting packets.

Syntax

stop-accounting-packet send-force

undo stop-accounting-packet send-force

Default

Forcibly sending stop-accounting packets is disabled. The device does not send stop-accounting packets when users for which no start-accounting packets are sent go offline.

Views

RADIUS scheme view

Predefined user roles

network-admin

Usage guidelines

Typically, if the device does not send a start-accounting packet to the RADIUS server for an authenticated user, it does not send a stop-accounting packet when the user goes offline. If the server has generated a user entry for the user without start-accounting packets, it does not release the user entry when the user goes offline. This feature forces the device to send stop-accounting packets to the RADIUS server when the user goes offline for timely releasing the user entry on the server.

Examples

In RADIUS scheme **radius1**, enable forcibly sending stop-accounting packets.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] stop-accounting-packet send-force
```

Related commands

display radius scheme

test-aaa

Use **test-aaa** to perform an AAA test.

Syntax

test-aaa user *user-name* **password** *password* **radius-scheme** *radius-scheme-name* [**radius-server** { *ipv4-address* | **ipv6** *ipv6-address* } *port-number*] [**chap** | **pap**] [**attribute-test-group** attr-*test-group-name*] [**trace**]

Views

User view

Predefined user roles

network-admin

Parameters

user *user-name*: Specifies the test username, a string of 1 to 80 characters. The username can be a pure username or contain a domain name. The format for a username containing a domain name is *pure-username@domain-name*. The pure username is case sensitive and the domain name is case insensitive.

password *password*: Specifies the password of the test user, a case-sensitive string of 1 to 63 characters.

radius-scheme *radius-scheme-name*: Specifies a RADIUS scheme by its name, a case-insensitive string of 1 to 32 characters.

radius-server: Specifies a RADIUS server.

ipv4-address: Specifies the IPv4 address of the RADIUS server.

ipv6 *ipv6-address*: Specifies the IPv6 address of the RADIUS server.

port-number: Specifies the UDP port number of the RADIUS server, in the range of 1 to 65535.

chap: Specifies the CHAP authentication method (the default).

pap: Specifies the PAP authentication method.

attribute-test-group *attr-test-group-name*: Specifies a RADIUS attribute test group by its name, a case-insensitive string of 1 to 31 characters. If you do not specify a RADIUS attribute test group or the specified RADIUS attribute test group does not exist, the device does not change the attributes carried in authentication or accounting requests.

trace: Displays detailed information about RADIUS packets exchanged during the AAA test. If you do not specify this keyword, the command displays brief information about the AAA test, including the sent and received packets and the test result.

Usage guidelines

Use this command to identify the reasons for the failure of interaction between the device and the AAA servers.

The device might communicate with the AAA servers incorrectly during an AAA test. Make sure no users come online or go offline during an AAA text.

If the configuration of the specified RADIUS scheme changes, the new configuration does not affect the current AAA test. The modification will take effect in the next test.

The system can have only one AAA test at a time. Another AAA test can be performed only after the current test finishes.

Examples

Perform an AAA test and display detailed information about the test. The test uses username **user1**, password **123456**, the CHAP authentication method, and RADIUS scheme **test**.

Table 9 Command output

Field	Description
Server IP	IP address of the server.
Source IP	Source IP address of the RADIUS packet.
VPN instance	This field is not supported in the current software version. MPLS L3VPN instance to which the server belongs. This field displays **N/A** if the server belongs to the public network.
Server port	UDP port number of the server.
Packet type	Type of the RADIUS packet: • Authentication request. • Access-Accept. • Access-Reject. • Start-accounting request. • Start-accounting response. • Stop-accounting request. • Stop-accounting response.

Field	Description
Packet length	Total length of the RADIUS packet, in bytes.
Packet ID	ID of the RADIUS packet. This field is used to identity a pair of request and response packets.
[*attribute-name* (*code*)] [*length*] [*value*] [*description*]	Information about a RADIUS attribute: • ***attribute-name***—Name of the attribute. • ***code***—Code of the attribute. • ***length***—Length of the attribute, in bytes. • ***value***—Value of the attribute. • ***description***—Description of the attribute.
Reply-Message:	The RADIUS server rejected the authentication request and replied a message.
Test result	Result of the AAA test: • **Successful**—The test has succeeded. • **Failed**—The test has failed. If any request is rejected, the test fails.

timer quiet (RADIUS scheme view)

Use **`timer quiet`** to set the quiet timer for the servers specified in a RADIUS scheme.

Use **`undo timer quiet`** to restore the default.

Syntax

`timer quiet` *`minutes`*

`undo timer quiet`

Default

The server quiet timer period is 5 minutes in a RADIUS scheme.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

`minutes`: Specifies the server quiet period in minutes, in the range of 0 to 255. If you set this argument to 0, the device does not change the state of the current server for a user when the server is unreachable. It sends an authentication or accounting request of the user to the next server in active state. For an authentication or accounting request of a new user, it still tries to send the request to the current server because the current server is in active state.

Usage guidelines

Make sure the server quiet timer is set correctly.

A timer that is too short might result in frequent authentication or accounting failures. This is because the device will continue to attempt to communicate with an unreachable server that is in active state.

A timer that is too long might temporarily block a reachable server that has recovered from a failure. This is because the server will remain in blocked state until the timer expires.

Examples

In RADIUS scheme **radius1**, set the quiet timer to 10 minutes for the servers.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] timer quiet 10
```

Predefined user roles

network-admin

Parameters

interval: Specifies the real-time accounting interval in the range of 0 to 71582.

second: Specifies the measurement unit as second. If you do not specify this keyword, the real-time accounting interval is measured in minutes.

Usage guidelines

When the real-time accounting interval on the device is not zero, the device sends online user accounting information to the RADIUS accounting server at the configured interval.

When the real-time accounting interval on the device is zero, the device sends online user accounting information to the RADIUS accounting server at the real-time accounting interval configured on the server. If the real-time accounting interval is not configured on the server, the device does not send online user accounting information.

A short interval helps improve accounting precision but requires many system resources.

Table 10 Recommended real-time accounting intervals

Number of users	Real-time accounting interval
1 to 99	3 minutes
100 to 499	6 minutes
500 to 999	12 minutes
1000 or more	15 minutes or longer

When you modify the real-time accounting interval, the following rules apply to users that have been online before the modification:

- If you modify the real-time accounting interval from a non-zero value to zero or from zero to a non-zero value, the modification does not take effect on these users. These users still use the old real-time accounting interval.
- If you modify the real-time accounting interval from a non-zero value to another non-zero value, the modification takes effect immediately on these users.

If a user uses RADIUS accounting but not RADIUS authentication and authorization, the device performs real-time accounting for that user only based on the real-time accounting interval set in the user's RADIUS accounting scheme. The real-time accounting interval assigned by the RADIUS accounting server does not take effect.

Examples

In RADIUS scheme **radius1**, set the real-time accounting interval to 51 minutes.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] timer realtime-accounting 51
```

Related commands

retry realtime-accounting

timer response-timeout (RADIUS scheme view)

Use **timer response-timeout** to set the RADIUS server response timeout timer.

Use **undo timer response-timeout** to restore the default.

Syntax

timer response-timeout *seconds*

undo timer response-timeout

Default

The RADIUS server response timeout period is 3 seconds.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

seconds: Specifies the RADIUS server response timeout period, in the range of 1 to 10 seconds.

Usage guidelines

If a NAS receives no response from the RADIUS server in a period of time after sending a RADIUS request, it resends the request so that the user has more opportunity to obtain the RADIUS service. The NAS uses the RADIUS server response timeout timer to control the transmission interval.

If the client times out during the authentication process, the user is immediately logged off. To avoid user logoffs, the value multiplied by the following items cannot be larger than the client timeout period defined by the access module:

- The maximum number of RADIUS packet transmission attempts.
- The RADIUS server response timeout period.
- The number of RADIUS servers in the RADIUS scheme.

When the device sends a RADIUS request to a new RADIUS server, it checks the total amount of time it has taken to transmit the RADIUS packet. If the amount of time has reached 300 seconds, the device stops sending the RADIUS request to the next RADIUS server. As a best practice, consider the number of RADIUS servers when you configure the maximum number of packet transmission attempts and the RADIUS server response timeout period.

Examples

In RADIUS scheme **radius1**, set the RADIUS server response timeout timer to 5 seconds.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] timer response-timeout 5
```

Related commands

display radius scheme

retry

user-name-format (RADIUS scheme view)

Use **user-name-format** to specify the format of the username to be sent to a RADIUS server.

Use **undo user-name-format** to restore the default.

Syntax

user-name-format { **keep-original** | **with-domain** | **without-domain** }

undo user-name-format

Default

The ISP domain name is included in the usernames sent to a RADIUS server.

Views

RADIUS scheme view

Predefined user roles

network-admin

Parameters

keep-original: Sends the username to the RADIUS server as the username is entered.

with-domain: Includes the ISP domain name in the username sent to the RADIUS server.

without-domain: Excludes the ISP domain name from the username sent to the RADIUS server.

Usage guidelines

A username is generally in the *userid@isp-name* format, of which the *isp-name* argument is used by the device to determine the ISP domain to which a user belongs. Some earlier RADIUS servers, however, cannot recognize a username containing an ISP domain name. Before sending a username including a domain name to such a RADIUS server, the device must remove the domain name. This command allows you to specify whether to include a domain name in a username sent to a RADIUS server.

If a RADIUS scheme defines that the username is sent without the ISP domain name, do not apply the scheme to more than one ISP domain. Otherwise, the RADIUS server will consider two users in different ISP domains but with the same *userid* as one user.

For 802.1X users using EAP authentication, the **user-name-format** command configured for a RADIUS scheme does not take effect. The device does not change the usernames from clients before forwarding them to the RADIUS server.

Examples

In RADIUS scheme **radius1**, configure the device to remove the domain name from the usernames sent to the RADIUS servers.

```
<Sysname> system-view
[Sysname] radius scheme radius1
[Sysname-radius-radius1] user-name-format without-domain
```

Related commands

display radius scheme

HWTACACS commands

data-flow-format (HWTACACS scheme view)

Use **data-flow-format** to set the data flow and packet measurement units for traffic statistics.

Use **undo data-flow-format** to restore the default.

Syntax

data-flow-format { **data** { **byte** | **giga-byte** | **kilo-byte** | **mega-byte** } | **packet** { **giga-packet** | **kilo-packet** | **mega-packet** | **one-packet** } } *

undo data-flow-format { **data** | **packet** }

Default

Traffic is counted in bytes and packets.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

data: Specifies the unit for data flows.

byte: Specifies the unit as byte.

giga-byte: Specifies the unit as gigabyte.

kilo-byte: Specifies the unit as kilobyte.

mega-byte: Specifies the unit as megabyte.

packet: Specifies the unit for data packets.

giga-packet: Specifies the unit as giga-packet.

kilo-packet: Specifies the unit as kilo-packet.

mega-packet: Specifies the unit as mega-packet.

one-packet: Specifies the unit as one-packet.

Usage guidelines

The data flow and packet measurement units for traffic statistics must be the same as configured on the HWTACACS accounting servers. Otherwise, accounting results might be incorrect.

Examples

In HWTACACS scheme **hwt1**, set the data flow and packet measurement units for traffic statistics to kilobyte and kilo-packet, respectively.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] data-flow-format data kilo-byte packet kilo-packet
```

Related commands

display hwtacacs scheme

display hwtacacs scheme

Use **display hwtacacs scheme** to display the configuration or statistics of HWTACACS schemes.

Syntax

display hwtacacs scheme [*hwtacacs-scheme-name* [**statistics**]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

hwtacacs-scheme-name: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters. If you do not specify an HWTACACS scheme, this command displays the configuration of all HWTACACS schemes.

statistics: Displays the HWTACACS service statistics. If you do not specify this keyword, the command displays the configuration of the specified HWTACACS scheme.

Examples

Displays the configuration of all HWTACACS schemes.

```
<Sysname> display hwtacacs scheme
Total 1 HWTACACS schemes

Table 11 Command output

Field	Description
Index	Index number of the HWTACACS scheme.
Primary Auth Server	Primary HWTACACS authentication server.
Primary Author Server	Primary HWTACACS authorization server.
Primary Acct Server	Primary HWTACACS accounting server.
Secondary Auth Server	Secondary HWTACACS authentication server.
Secondary Author Server	Secondary HWTACACS authorization server.
Secondary Acct Server	Secondary HWTACACS accounting server.
Host name	Host name of the server. This field displays **Not configured** in the following situations: • The server is not configured. • The server is specified by IP address.
IP	IP address of the server. This field displays **Not configured** in the following situations: • The server is not configured. • The server is specified by hostname, and the hostname is not resolved.
Port	Service port of the HWTACACS server. If no port configuration is performed, this field displays the default port number.
State	Status of the HWTACACS server: active or blocked.
VPN Instance	This field is not supported in the current software version. MPLS L3VPN instance to which the HWTACACS server or scheme belongs. If no VPN instance is specified for the server or scheme, this field displays **Not configured**.
Single-connection	Single connection status: • **Enabled**—Establish only one TCP connection for all users to communicate with the server. • **Disabled**—Establish a TCP connection for each user to

Field	Description
	communicate with the server.
NAS IP Address	Source interface or source IP addresses for outgoing HWTACACS packets. This field displays **Not configured** if no source interface or source IP addresses are specified for outgoing HWTACACS packets.
Server Quiet Period(minutes)	Quiet period for the primary servers, in minutes.
Realtime Accounting Interval(minutes)	Real-time accounting interval, in minutes.
Stop-accounting packets buffering	Whether buffering of nonresponded HWTACACS stop-accounting requests is enabled.
Retransmission times	Maximum number of transmission attempts for individual HWTACACS stop-accounting requests.
Response Timeout Interval(seconds)	HWTACACS server response timeout period, in seconds.
Username Format	Format for the usernames sent to the HWTACACS server: • **with-domain**—Includes the domain name. • **without-domain**—Excludes the domain name. • **keep-original**—Forwards the username as the username is entered.
Data flow unit	Measurement unit for data flows.
Packet unit	Measurement unit for packets.

Display statistics for HWTACACS scheme **tac**.

```

Table 12 Command output

Field	Description
Primary authentication server	Primary HWTACACS authentication server.
Primary authorization server	Primary HWTACACS authorization server.
Primary accounting server	Primary HWTACACS accounting server.
Secondary authentication server	Secondary HWTACACS authentication server.
Secondary authorization server	Secondary HWTACACS authorization server.
Secondary accounting server	Secondary HWTACACS accounting server.
Round trip time	The time interval during which the device processed a pair of request and response. The unit is second.
Request packets	Total number of sent request packets.
Login request packets	Number of sent login request packets.
Change-password request packets	Number of sent request packets for changing passwords.

Field	Description
Request packets including plaintext passwords	Number of request packets that include plaintext passwords.
Request packets including ciphertext passwords	Number of request packets that include ciphertext passwords.
Response packets	Total number of received response packets.
Pass response packets	Number of response packets indicating successful authentication.
Failure response packets	Number of response packets indicating authentication or authorization failure.
Get-data response packets	Number of response packets for obtaining user data.
Get-username response packets	Number of response packets for obtaining usernames.
Get-password response packets	Number of response packets for obtaining passwords.
Restart response packets	Number of response packets for reauthentication.
Error response packets	Number of error-type response packets.
Follow response packets	Number of follow-type response packets.
Malformed response packets	Number of malformed response packets.
Continue packets	Number of sent Continue packets.
Continue-abort packets	Number of sent Continue-abort packets.
Pending request packets	Number of request packets waiting for a response.
Timeout packets/Timeout response packets	Number of timeout response packets.
Unknown type response packets	Number of unknown-type response packets.
Dropped response packets	Number of dropped response packets.
PassAdd response packets	Number of received PassAdd response packets. The packets indicate that all requested authorization attributes are assigned and additional authorization attributes are added.
PassReply response packets	Number of received PassReply response packets. The device uses the specified authorization attributes in the packets to replace the requested authorization attributes.
Accounting start request packets	Number of accounting start request packets.
Accounting stop request packets	Number of accounting stop request packets.
Accounting update request packets	Number of accounting update request packets.
Success response packets	Number of accounting success response packets.

Related commands

`reset hwtacacs statistics`

display stop-accounting-buffer (for HWTACACS)

Use **`display stop-accounting-buffer`** to display information about buffered HWTACACS stop-accounting requests to which no responses have been received.

Syntax

`display stop-accounting-buffer hwtacacs-scheme` *`hwtacacs-scheme-name`*

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

hwtacacs-scheme *hwtacacs-scheme-name*: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

Examples

Display information about nonresponded stop-accounting requests buffered for HWTACACS scheme hwt1.

```
<Sysname> display stop-accounting-buffer hwtacacs-scheme hwt1
Total entries: 2
Scheme    IP address        Username      First sending time     Attempts
hwt1      192.168.100.1     abc           23:27:16-08/31/2015    19
hwt1      192.168.90.6      bob           23:33:01-08/31/2015    20
```

Table 13 Command output

Field	Description
First sending time	Time when the stop-accounting request was first sent.
Attempts	Number of attempts that were made to send the stop-accounting request.

retry stop-accounting (HWTACACS scheme view)

stop-accounting-buffer enable (HWTACACS scheme view)

user-name-format (HWTACACS scheme view)

hwtacacs nas-ip

Use **hwtacacs nas-ip** to specify a source interface or source IP address for outgoing HWTACACS packets.

Use **undo hwtacacs nas-ip** to delete the specified source interface or source IP address for outgoing HWTACACS packets.

Syntax

hwtacacs nas-ip { **interface** *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } }

undo hwtacacs nas-ip { **interface** | { *ipv4-address* | **ipv6** *ipv6-address* } }

Default

The source IP address of an HWTACACS packet sent to the server is the primary IPv4 address or the IPv6 address of the outbound interface.

Views

System view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The device uses the primary IPv4 address or the IPv6 address of the interface as the source IP address of an outgoing HWTACACS packet.

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

Usage guidelines

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS that is configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. Upon receiving an HWTACACS packet, the HWTACACS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing HWTACACS packets to avoid HWTACACS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **hwtacacs nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in HWTACACS scheme view applies only to the HWTACACS scheme.
- The setting configured by using the **hwtacacs nas-ip** command in system view applies to all HWTACACS schemes.
- The setting in HWTACACS scheme view takes precedence over the setting in system view.

You can specify only one source IPv4 address and one source IPv6 address in system view.

You can specify only one source interface to provide the source IP address for outgoing HWTACACS packets. Make sure the route between the source interface and the HWTACACS server is reachable.

The source interface configuration and the source IP address configuration overwrite each other.

Examples

Specify IP address 129.10.10.1 as the source IP address for HWTACACS packets.

```
<Sysname> system-view
[Sysname] hwtacacs nas-ip 129.10.10.1
```

Related commands

nas-ip (HWTACACS scheme view)

hwtacacs scheme

Use **hwtacacs scheme** to create an HWTACACS scheme and enter its view, or enter the view of an existing HWTACACS scheme.

Use **undo hwtacacs scheme** to delete an HWTACACS scheme.

Syntax

hwtacacs scheme *hwtacacs-scheme-name*

undo hwtacacs scheme *hwtacacs-scheme-name*

Default

No HWTACACS schemes exist.

Views

System view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme-name: Specifies the HWTACACS scheme name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

An HWTACACS scheme can be used by more than one ISP domain at the same time.

You can configure a maximum of 16 HWTACACS schemes.

Examples

Create an HWTACACS scheme named **hwt1** and enter HWTACACS scheme view.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1]
```

Related commands

display hwtacacs scheme

key (HWTACACS scheme view)

Use **key** to set the shared key for secure HWTACACS authentication, authorization, or accounting communication.

Use **undo key** to delete the shared key for secure HWTACACS authentication, authorization, or accounting communication.

Syntax

key { **accounting** | **authentication** | **authorization** } { **cipher** | **simple** } *string*

undo key { **accounting** | **authentication** | **authorization** }

Default

No shared key is configured for secure HWTACACS authentication, authorization, or accounting communication.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

accounting: Specifies the shared key for secure HWTACACS accounting communication.

authentication: Specifies the shared key for secure HWTACACS authentication communication.

authorization: Specifies the shared key for secure HWTACACS authorization communication.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 373 characters. The plaintext form of the key is a string of 1 to 255 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 373 characters. The plaintext form of the key is a string of 15 to 255 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

Usage guidelines

The shared keys configured on the device must match those configured on the HWTACACS servers.

Examples

In HWTACACS scheme **hwt1**, set the shared key to **123456TESTauth&!** in plaintext form for secure HWTACACS authentication communication.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] key authentication simple 123456TESTauth&!
```

Set the shared key to **123456TESTautr&!** in plaintext form for secure HWTACACS authorization communication.

```
[Sysname-hwtacacs-hwt1] key authorization simple 123456TESTautr&!
```

Set the shared key to **123456TESTacct&!** in plaintext form for secure HWTACACS accounting communication.

```
[Sysname-hwtacacs-hwt1] key accounting simple 123456TESTacct&!
```

Related commands

nas-ip (HWTACACS scheme view)

Use **nas-ip** to specify a source interface or source IP address for outgoing HWTACACS packets.

Use **undo nas-ip** to delete the specified source interface or source IP address for outgoing HWTACACS packets.

Syntax

nas-ip { *ipv4-address* | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

undo nas-ip [**interface** | **ipv6**]

Default

The source IP address of an outgoing HWTACACS packet is that configured by using the **hwtacacs nas-ip** command in system view.

If the **hwtacacs nas-ip** command is not used, the source IP address is the primary IP address of the outbound interface.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a source interface by its type and number. The device uses the primary IPv4 address or the IPv6 address of the interface as the source IP address of an outgoing HWTACACS packet.

ipv4-address: Specifies an IPv4 address, which must be an address of the device. The IP address cannot be 0.0.0.0, 255.255.255.255, a class D address, a class E address, or a loopback address.

ipv6 *ipv6-address*: Specifies an IPv6 address, which must be a unicast address of the device and cannot be a loopback address or a link-local address.

Usage guidelines

The source IP address of HWTACACS packets that a NAS sends must match the IP address of the NAS that is configured on the HWTACACS server. An HWTACACS server identifies a NAS by IP address. Upon receiving an HWTACACS packet, the HWTACACS server checks the source IP address of the packet.

- If the source IP address of the packet is the IP address of a managed NAS, the server processes the packet.
- If the source IP address of the packet is not the IP address of a managed NAS, the server drops the packet.

As a best practice, specify a loopback interface address as the source IP address for outgoing HWTACACS packets to avoid HWTACACS packet loss caused by physical port errors.

If you use both the **nas-ip** command and **hwtacacs nas-ip** command, the following guidelines apply:

- The setting configured by using the **nas-ip** command in HWTACACS scheme view applies only to the HWTACACS scheme.
- The setting configured by using the **hwtacacs nas-ip** command in system view applies to all HWTACACS schemes.
- The setting in HWTACACS scheme view takes precedence over the setting in system view.

For an HWTACACS scheme, the following restrictions apply:

- You can specify only one source IPv4 address and one source IPv6 address for outgoing HWTACACS packets.
- You can specify only one source interface to provide the source IP address for outgoing HWTACACS packets. Make sure the route between the source interface and the HWTACACS server is reachable.
- The source interface configuration and the source IP address configuration overwrite each other.

If you do not specify any parameter for the **undo nas-ip** command, the command deletes the configured source IPv4 address for outgoing HWTACACS packets.

Examples

In HWTACACS scheme **hwt1**, specify IP address 10.1.1.1 as the source address for outgoing HWTACACS packets.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] nas-ip 10.1.1.1
```

hwtacacs nas-ip

primary accounting (HWTACACS scheme view)

Use **primary accounting** to specify the primary HWTACACS accounting server.

Use **undo primary accounting** to restore the default.

Syntax

primary accounting { *host-name* | *ipv4-address* | **ipv6** *ipv6-address* } [*port-number* | **key** { **cipher** | **simple** } *string* | **single-connection**] *

undo primary accounting

Default

The primary HWTACACS accounting server is not specified.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

host-name: Specifies the host name of the primary HWTACACS accounting server, a case-insensitive string of 1 to 253 characters.

ipv4-address: Specifies an IPv4 address of the primary HWTACACS accounting server.

ipv6 *ipv6-address*: Specifies an IPv6 address of the primary HWTACACS accounting server.

port-number: Specifies the service port number of the primary HWTACACS accounting server. The value range for the TCP port number is 1 to 65535. The default setting is 49.

key: Specifies the shared key for secure communication with the primary HWTACACS accounting server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 373 characters. The plaintext form of the key is a string of 1 to 255 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 373 characters. The plaintext form of the key is a string of 15 to 255 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

single-connection: The device and the primary HWTACACS accounting server use the same TCP connection to exchange accounting packets for all users. If you do not specify this keyword, the

device establishes a new TCP connection each time it exchanges accounting packets with the primary accounting server for a user.

Usage guidelines

Make sure the port number and shared key settings of the primary HWTACACS accounting server are the same as those configured on the server.

Two accounting servers specified for a scheme, primary or secondary, cannot have identical host name, IP address, and port number settings.

As a best practice, specify the **single-connection** keyword to reduce TCP connections for improving system performance if the HWTACACS server supports the single-connection method.

You can remove an accounting server only when it is not used for user accounting. Removing an accounting server affects only accounting processes that occur after the remove operation.

Examples

In HWTACACS scheme **hwt1**, specify the primary accounting server with IP address 10.163.155.12, TCP port number 49, and plaintext shared key **123456TESTacct&!**.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] primary accounting 10.163.155.12 49 key simple 123456TESTacct&!
```

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

host-name: Specifies the host name of a secondary HWTACACS accounting server, a case-insensitive string of 1 to 253 characters.

ipv4-address: Specifies the IPv4 address of a secondary HWTACACS accounting server.

ipv6 *ipv6-address*: Specifies the IPv6 address of a secondary HWTACACS accounting server.

port-number: Specifies the service port number of the secondary HWTACACS accounting server. The value range for the TCP port number is 1 to 65535. The default setting is 49.

key: Specifies the shared key for secure communication with the secondary HWTACACS accounting server.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. This argument is case sensitive. In non-FIPS mode, the encrypted form of the key is a string of 1 to 373 characters. The plaintext form of the key is a string of 1 to 255 characters. In FIPS mode, the encrypted form of the key is a string of 15 to 373 characters. The plaintext form of the key is a string of 15 to 255 characters. The plaintext string must contain digits, uppercase letters, lowercase letters, and special characters.

single-connection: The device and the secondary HWTACACS accounting server use the same TCP connection to exchange all accounting packets for all users. If you do not specify this keyword, the device establishes a new TCP connection each time it exchanges accounting packets with the secondary accounting server for a user.

Usage guidelines

Make sure the port number and shared key settings of the secondary HWTACACS accounting server are the same as those configured on the server.

An HWTACACS scheme supports a maximum of 16 secondary HWTACACS accounting servers. If the primary server fails, the device tries to communicate with a secondary server in active state. The device connects to the secondary servers in the order they are configured.

If you do not specify any parameters for the **undo secondary accounting** command, the command removes all secondary accounting servers.

Two accounting servers specified for a scheme, primary or secondary, cannot have identical host name, IP address, and port number settings.

As a best practice, specify the **single-connection** keyword to reduce TCP connections for improving system performance if the HWTACACS server supports the single-connection method.

You can remove an accounting server only when it is not used for user accounting. Removing an accounting server affects only accounting processes that occur after the remove operation.

Examples

In HWTACACS scheme **hwt1**, specify a secondary accounting server with IP address 10.163.155.12, TCP port number 49, and plaintext shared key **123456TESTacct&!**.

```
<Sysname> system-view
```

```

stop-accounting-buffer enable (HWTACACS scheme view)

Use **stop-accounting-buffer enable** to enable buffering of HWTACACS stop-accounting requests to which no responses have been received.

Use **undo stop-accounting-buffer enable** to disable buffering of HWTACACS stop-accounting requests to which no responses have been received.

Syntax

stop-accounting-buffer enable

undo stop-accounting-buffer enable

Default

The device buffers HWTACACS stop-accounting requests to which no responses have been received.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Usage guidelines

This command enables the device to buffer an HWTACACS stop-accounting request to which no response has been received. The device resends the buffered request until it receives a server response or when the number of transmission attempts reaches the maximum (set by using the **retry stop-accounting** command). If no more attempts are available, the device discards the request. However, if you have removed an accounting server, stop-accounting requests destined for the server are not buffered.

Examples

Enable buffering of HWTACACS stop-accounting requests to which no responses have been received.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] stop-accounting-buffer enable
```

timer quiet (HWTACACS scheme view)

Use **timer quiet** to set the quiet timer for the servers specified in an HWTACACS scheme.

Use **undo timer quiet** to restore the default.

Syntax

timer quiet *minutes*

undo timer quiet

Default

The server quiet period is 5 minutes.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

minutes: Specifies the server quiet period in minutes, in the range of 1 to 255.

Examples

In HWTACACS scheme **hwt1**, set the server quiet timer to 10 minutes.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] timer quiet 10
```

Related commands

display hwtacacs scheme

timer realtime-accounting (HWTACACS scheme view)

Use **timer realtime-accounting** to set the real-time accounting interval.

Use **undo timer realtime-accounting** to restore the default.

Syntax

timer realtime-accounting *minutes*

undo timer realtime-accounting

Default

The real-time accounting interval is 12 minutes.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

minutes: Specifies the real-time accounting interval in minutes, in the range of 0 to 60. Setting this interval to 0 disables the device from sending online user accounting information to the HWTACACS accounting server.

Usage guidelines

For real-time accounting, a NAS must transmit the accounting information of online users to the HWTACACS accounting server periodically. This command is used to set the interval.

A short interval helps improve accounting precision but requires many system resources.

Table 14 Recommended real-time accounting intervals

Number of users	Real-time accounting interval
1 to 99	3 minutes

Number of users	Real-time accounting interval
100 to 499	6 minutes
500 to 999	12 minutes
1000 or more	15 minutes or longer

When you modify the real-time accounting interval, the following rules apply to users that have been online before the modification:

- If you modify the real-time accounting interval from a non-zero value to zero or from zero to a non-zero value, the modification does not take effect on these users. These users still use the old real-time accounting interval.
- If you modify the real-time accounting interval from a non-zero value to another non-zero value, the modification takes effect immediately on these users.

Examples

In HWTACACS scheme **hwt1**, set the real-time accounting interval to 51 minutes.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] timer realtime-accounting 51
```

Related commands

display hwtacacs scheme

timer response-timeout (HWTACACS scheme view)

Use **timer response-timeout** to set the HWTACACS server response timeout timer.

Use **undo timer response-timeout** to restore the default.

Syntax

timer response-timeout *seconds*

undo timer response-timeout

Default

The HWTACACS server response timeout time is 5 seconds.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

seconds: Specifies the HWTACACS server response timeout time, in the range of 1 to 300 seconds.

Usage guidelines

HWTACACS is based on TCP. When the server response timeout timer or the TCP timeout timer times out, the device is disconnected from the HWTACACS server.

The client timeout period of the associated access module cannot be shorter than the total response timeout timer of all HWTACACS servers in the scheme. Any violation will result in user logoffs before the authentication, authorization, or accounting process is complete.

Examples

In HWTACACS scheme **hwt1**, set the HWTACACS server response timeout timer to 30 seconds.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] timer response-timeout 30
```

user-name-format (HWTACACS scheme view)

Use **user-name-format** to specify the format of the username to be sent to an HWTACACS server.

Use **undo user-name-format** to restore the default.

Syntax

user-name-format { **keep-original** | **with-domain** | **without-domain** }

undo user-name-format

Default

The ISP domain name is included in the usernames sent to an HWTACACS server.

Views

HWTACACS scheme view

Predefined user roles

network-admin

Parameters

keep-original: Sends the username to the HWTACACS server as the username is entered.

with-domain: Includes the ISP domain name in the username sent to the HWTACACS server.

without-domain: Excludes the ISP domain name from the username sent to the HWTACACS server.

Usage guidelines

A username is generally in the *userid@isp-name* format, of which the *isp-name* argument is used by the device to determine the ISP domain to which a user belongs. However, some HWTACACS servers cannot recognize a username containing an ISP domain name. Before sending a username including a domain name to such an HWTACACS server, the device must remove the domain name. This command allows you to specify whether to include a domain name in a username to be sent to an HWTACACS server.

If an HWTACACS scheme defines that the username is sent without the ISP domain name, do not apply the scheme to more than one ISP domain. Otherwise, the HWTACACS server will consider two users in different ISP domains but with the same *userid* as one user.

Examples

In HWTACACS scheme **hwt1**, configure the device to remove the ISP domain name from the usernames sent to the HWTACACS servers.

```
<Sysname> system-view
[Sysname] hwtacacs scheme hwt1
[Sysname-hwtacacs-hwt1] user-name-format without-domain
```

Related commands

display hwtacacs scheme

LDAP commands

attribute-map

Use **attribute-map** to specify the LDAP attribute map in an LDAP scheme.

Use **undo attribute-map** to restore the default.

Syntax

attribute-map *map-name*

undo attribute-map

Default

An LDAP scheme does not use an LDAP attribute map.

Views

LDAP scheme view

Predefined user roles

network-admin

Parameters

map-name: Specifies an LDAP attribute map by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

When the LDAP scheme used for authorization contains an LDAP attribute map, the device converts server-assigned LDAP attributes to device-recognizable AAA attributes based on the mapping entries.

You can specify only one LDAP attribute map in an LDAP scheme. If you execute this command multiple times, the most recent configuration takes effect.

If you specify another attribute map or change the mapping entries, the new settings take effect only on the LDAP authorization that occurs after your operation.

Examples

Specify LDAP attribute map **map1** in LDAP scheme **test**.

```
<Sysname> system-view
[Sysname] ldap scheme test
[Sysname-ldap-test] attribute-map map1
```

Related commands

display ldap-scheme

ldap attribute-map

authentication-server

Use **authentication-server** to specify the LDAP authentication server for an LDAP scheme.

Use **undo authentication-server** to restore the default.

Syntax

authentication-server *server-name*

undo authentication-server

Default

No LDAP authentication server is specified for an LDAP scheme.

Views

LDAP scheme view

Predefined user roles

network-admin

Parameters

server-name: Specifies the name of an LDAP server, a case-insensitive string of 1 to 64 characters.

Usage guidelines

You can specify only one LDAP authentication server in an LDAP scheme. If you execute this command multiple times, the most recent configuration takes effect.

Examples

In LDAP scheme **ldap1**, specify the LDAP authentication server as **ccc**.

```
<Sysname> system-view
[Sysname] ldap scheme ldap1
[Sysname-ldap-ldap1] authentication-server ccc
```

Related commands

display ldap scheme

ldap server

authorization-server

Use **authorization-server** to specify the LDAP authorization server for an LDAP scheme.

Use **undo authorization-server** to restore the default.

Syntax

authorization-server *server-name*

undo authorization-server

Default

No LDAP authorization server is specified for an LDAP scheme.

Views

LDAP scheme view

Predefined user roles

network-admin

Parameters

server-name: Specifies the name of an LDAP server, a case-insensitive string of 1 to 64 characters.

Usage guidelines

You can specify only one LDAP authorization server in an LDAP scheme. If you execute this command multiple times, the most recent configuration takes effect.

Examples

In LDAP scheme **ldap1**, specify the LDAP authorization server as **ccc**.

```
<Sysname> system-view
[Sysname] ldap scheme ldap1
[Sysname-ldap-ldap1] authorization-server ccc
```

ldap server

display ldap scheme

Use **display ldap scheme** to display LDAP scheme configuration.

Syntax

display ldap scheme [*ldap-scheme-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ldap-scheme-name: Specifies an LDAP scheme by its name, a case-insensitive string of 1 to 32 characters. If you do not specify an LDAP scheme, this command displays the configuration of all LDAP schemes.

Examples

Display the configuration of all LDAP schemes.

```
<Sysname> display ldap scheme
Total 1 LDAP schemes

------------------------------------------------------------------
LDAP scheme name             : aaa
  Authentication server      : aaa
    IP                       : 1.1.1.1
    Port                     : 111
    VPN instance             : Not configured
    LDAP protocol version    : LDAPv3
    Server timeout interval  : 10 seconds
    Login account DN         : Not configured
    Base DN                  : Not configured
    Search scope             : all-level
    User searching parameters:
      User object class      : Not configured
```

```
    Username attribute     : cn
    Username format        : with-domain
 Authorization server      : aaa
   IP                      : 1.1.1.1
   Port                    : 111
   VPN instance            : Not configured
   LDAP protocol version   : LDAPv3
   Server timeout interval : 10 seconds
   Login account DN        : Not configured
   Base DN                 : Not configured
   Search scope            : all-level
   User searching parameters:
     User object class     : Not configured
     Username attribute    : cn
     Username format       : with-domain
 Attribute map             : map1
-------------------------------------------------------------------
```

Table 15 Command output

Field	Description
Authentication server	Name of the LDAP authentication server. If no server is configured, this field displays **Not configured**.
Authorization server	Name of the LDAP authorization server. If no server is configured, this field displays **Not configured**.
IP	IP address of the LDAP server. If no server is specified, this field displays **Not configured**.
Port	Port number of the server. If no port number is specified, this field displays the default port number.
VPN instance	This field is not supported in the current software version. MPLS L3VPN instance to which the LDAP server belongs. If no VPN instance is specified, this field displays **Not configured**.
LDAP protocol version	LDAP version, LDAPv2 or LDAPv3.
Server timeout interval	LDAP server timeout period, in seconds.
Login account DN	DN of the administrator.
Base DN	Base DN for user search.
Search scope	User DN search scope, including: • **all-level**—All subdirectories. • **single-level**—Next lower level of subdirectories under the base DN.
User searching parameters	User search parameters.
User object class	User object class for user DN search. If no user object class is configured, this field displays **Not configured**.
Username attribute	User account attribute for login.
Username format	Format for the username sent to the server.
Attribute map	LDAP attribute map used by the scheme. If no LDAP attribute map is used, this field displays **Not configured**.

ip

Use **ip** to configure the IP address of the LDAP server.

Use **undo ip** to restore the default.

Syntax

ip *ip-address* [**port** *port-number*]

undo ip

Default

An LDAP server does not have an IP address.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the IP address of the LDAP server.

port *port-number*: Specifies the TCP port number of the LDAP server. The value range for the *port-number* argument is 1 to 65535, and the default value is 389.

Usage guidelines

The LDAP service port configured on the device must be consistent with the service port of the LDAP server.

If you change the IP address and port number of the LDAP server, the change takes effect only on the LDAP authentication that occurs after the change.

Examples

Specify the IP address and port number as 192.168.0.10 and 4300 for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] ip 192.168.0.10 port 4300
```

Related commands

ldap server

ipv6

Use **ipv6** to configure the IPv6 address of the LDAP server.

Use **undo ipv6** to restore the default.

Syntax

ipv6 *ipv6-address* [**port** *port-number*]

undo ipv6

Default

An LDAP server does not have an IPv6 address.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the IPv6 address of the LDAP server.

port *port-number*: Specifies the TCP port number of the LDAP server. The value range for the *port-number* argument is 1 to 65535, and the default value is 389.

Usage guidelines

The LDAP service port configured on the device must be consistent with the service port of the LDAP server.

If you change the IP address and port number of the LDAP server, the change takes effect only on the LDAP authentication that occurs after the change.

Examples

Specify the IPv6 address and port number as 1:2::3:4 and 4300 for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] ipv6 1:2::3:4 port 4300
```

Related commands

ldap server

ldap attribute-map

Use **ldap attribute-map** to create an LDAP attribute map and enter its view, or enter the view of an existing LDAP attribute map.

Use **undo ldap attribute-map** to delete an LDAP attribute map.

Syntax

ldap attribute-map *map-name*

undo ldap attribute-map *map-name*

Default

No LDAP attribute maps exist.

Views

System view

Predefined user roles

network-admin

Parameters

map-name: Specifies the name of the LDAP attribute map, a case-insensitive string of 1 to 31 characters.

Usage guidelines

Execute this command multiple times to create multiple LDAP attribute maps. You can add multiple mapping entries to an LDAP attribute map. Each entry defines the mapping between an LDAP attribute and an AAA attribute.

Examples

Create an LDAP attribute map named **map1** and enter LDAP attribute map view.

```
<Sysname> system-view
[Sysname] ldap attribute-map map1
[Sysname-ldap-map-map1]
```

Related commands

attribute-map

ldap scheme

map

ldap scheme

Use **ldap scheme** to create an LDAP scheme and enter its view, or enter the view of an existing LDAP scheme.

Use **undo ldap scheme** to delete an LDAP scheme.

Syntax

ldap scheme *ldap-scheme-name*

undo ldap scheme *ldap-scheme-name*

Default

No LDAP schemes exist.

Views

System view

Predefined user roles

network-admin

Parameters

ldap-scheme-name: Specifies the LDAP scheme name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

An LDAP scheme can be used by more than one ISP domain at the same time.

You can configure a maximum of 16 LDAP schemes.

Examples

Create an LDAP scheme named **ldap1** and enter LDAP scheme view.

```
<Sysname> system-view
[Sysname] ldap scheme ldap1
[Sysname-ldap-ldap1]
```

Related commands

display ldap scheme

ldap server

Use **ldap server** to create an LDAP server and enter its view, or enter the view of an existing LDAP server.

Use **undo ldap server** to delete an LDAP server.

Syntax

ldap server *server-name*

undo ldap server *server-name*

Default

No LDAP servers exist.

Views

System view

Predefined user roles

network-admin

Parameters

server-name: Specifies the LDAP server name, a case-insensitive string of 1 to 64 characters.

Examples

Create an LDAP server named **ccc** and enter LDAP server view.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc]
```

Related commands

display ldap scheme

login-dn

Use **login-dn** to specify the administrator DN.

Use **undo login-dn** to restore the default.

Syntax

login-dn *dn-string*

undo login-dn

Default

No administrator DN is specified.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

dn-string: Specifies the administrator DN for binding with the server, a case-insensitive string of 1 to 255 characters.

Usage guidelines

The administrator DN specified on the device must be consistent with the administrator DN configured on the LDAP server.

If you change the administrator DN, the change takes effect only on the LDAP authentication that occurs after the change.

Examples

Specify the administrator DN as **uid=test, ou=people, o=example, c=city** for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] login-dn uid=test,ou=people,o=example,c=city
```

Related commands

display ldap scheme

login-password

Use **login-password** to configure the administrator password for binding with the LDAP server during LDAP authentication.

Use **undo login-password** to restore the default.

Syntax

login-password { **cipher** | **simple** } *string*

undo login-password

Default

No administrator password is configured.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 128 characters. Its encrypted form is a case-sensitive string of 1 to 201 characters.

Usage guidelines

This command takes effect only after the **login-dn** command is used.

Examples

Specify the administrator password as **abcdefg** in plaintext form for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] login-password simple abcdefg
```

Related commands

display ldap scheme

login-dn

map

Use **map** to configure a mapping entry in an LDAP attribute map.

Use **undo map** to delete the specified mapping entries from the LDAP attribute map.

Syntax

map ldap-attribute *ldap-attribute-name* [**prefix** *prefix-value* **delimiter** *delimiter-value*] **aaa-attribute** { **user-group** | **user-profile** }

undo map [**ldap-attribute** *ldap-attribute-name*]

Default

An LDAP attribute map does not contain mapping entries.

Views

LDAP attribute map view

Predefined user roles

network-admin

Parameters

ldap-attribute *ldap-attribute-name*: Specifies an LDAP attribute by its name. The *ldap-attribute-name* argument is a case-insensitive string of 1 to 63 characters.

prefix *prefix-value* **delimiter** *delimiter-value*: Specifies a partial value string of the LDAP attribute for attribute mapping. The *prefix-value* argument represents the position where the partial string starts. The prefix is a case-insensitive string of 1 to 7 characters, such as **cn=**. The *delimiter-value* argument represents the position where the partial string ends, such as a comma (,). If you do not specify the **prefix** *prefix-value* **delimiter** *delimiter-value* option, the mapping entry uses the entire value string of the LDAP attribute.

aaa-attribute: Specifies an AAA attribute.

user-group: Specifies the user group attribute.

user-profile: Specifies the user profile attribute.

Usage guidelines

Because the device ignores unrecognized LDAP attributes, configure the mapping entries to include important LDAP attributes that should not be ignored.

An LDAP attribute can be mapped only to one AAA attribute. Different LDAP attributes can be mapped to the same AAA attribute.

If you do not specify an LDAP attribute for the **undo map** command, the command deletes all mapping entries from the LDAP attribute map.

Examples

In LDAP attribute map **map1**, map a partial value string of the LDAP attribute named **memberof** to AAA attribute named **user-group**.

```
<Sysname> system-view
[Sysname] ldap attribute-map map1
[Sysname-ldap-map-map1] map ldap-attribute memberof prefix cn= delimiter , aaa-attribute user-group
```

Related commands

ldap attribute-map

user-group

user-profile

protocol-version

Use **protocol-version** to specify the LDAP version.

Use **undo protocol-version** to restore the default.

Syntax

protocol-version { **v2** | **v3** }

undo protocol-version

Default

The LDAP version is LDAPv3.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

v2: Specifies the LDAP version LDAPv2.

v3: Specifies the LDAP version LDAPv3.

Usage guidelines

For successful LDAP authentication, the LDAP version used by the device must be consistent with the version used by the LDAP server.

If you change the LDAP version, the change takes effect only on the LDAP authentication that occurs after the change.

A Microsoft LDAP server supports only LDAPv3.

Examples

Specify the LDAP version as LDAPv2 for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] protocol-version v2
```

Related commands

display ldap scheme

search-base-dn

Use **search-base-dn to** specify the base DN for user search.

Use **undo search-base-dn** to restore the default.

Syntax

search-base-dn *base-dn*

undo search-base-dn

Default

No base DN is specified for user search.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

base-dn: Specifies the base DN for user search, a case-insensitive string of 1 to 255 characters.

Examples

Specify the base DN for user search as **dc=ldap,dc=com** for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] search-base-dn dc=ldap,dc=com
```

Related commands

display ldap scheme

ldap server

search-scope

Use **search-scope** to specify the user search scope.

Use **undo search-scope** to restore the default.

Syntax

search-scope { **all-level** | **single-level** }

undo search-scope

Default

The user search scope is **all-level**.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

all-level: Specifies that the search goes through all subdirectories of the base DN.

single-level: Specifies that the search goes through only the next lower level of subdirectories under the base DN.

Examples

Specify the search scope for the LDAP authentication as all subdirectories of the base DN for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] search-scope all-level
```

Related commands

display ldap scheme

ldap server

server-timeout

Use **server-timeout** to set the LDAP server timeout period, the maximum time that the device waits for an LDAP response.

Use **undo server-timeout** to restore the default.

Syntax

server-timeout *time-interval*

undo server-timeout

Default

The LDAP server timeout period is 10 seconds.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

time-interval: Specifies the LDAP server timeout period in the range of 5 to 20 seconds.

Usage guidelines

If you change the LDAP server timeout period, the change takes effect only on the LDAP authentication that occurs after the change.

Examples

Set the LDAP server timeout period to 15 seconds for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] server-timeout 15
```

Related commands

display ldap scheme

user-parameters

Use **user-parameters** to configure LDAP user attributes, including the username attribute, username format, and user-defined user object class.

Use **undo user-parameters** to restore the default of an LDAP user attribute.

Syntax

user-parameters { **user-name-attribute** { *name-attribute* | **cn** | **uid** } | **user-name-format** { **with-domain** | **without-domain** } | **user-object-class** *object-class-name* }

undo user-parameters { **user-name-attribute** | **user-name-format** | **user-object-class** }

Default

The LDAP username attribute is **cn** and the username format is **without-domain**. No user object class is specified and the default user object class of the LDAP server is used.

Views

LDAP server view

Predefined user roles

network-admin

Parameters

user-name-attribute { *name-attribute* | **cn** | **uid** }: Specifies the username attribute. The *name-attribute* argument represents an attribute value, a case-insensitive string of 1 to 64 characters. The **cn** keyword represents the user account attribute of common name, and the **uid** keyword represents the user account attribute of user ID.

user-name-format { **with-domain** | **without-domain** }: Specifies the format of the username to be sent to the server. The **with-domain** keyword means that the username contains the domain name, and the **without-domain** keyword means that the username does not contain the domain name.

user-object-class *object-class-name*: Specifies the user object class for user search. The *object-class-name* argument represents a class value, a case-insensitive string of 1 to 64 characters.

Usage guidelines

If the username on the LDAP server does not contain the domain name, specify the **without-domain** keyword. If the username contains the domain name, specify the **with-domain** keyword.

Examples

Set the user object class to **person** for LDAP server **ccc**.

```
<Sysname> system-view
[Sysname] ldap server ccc
[Sysname-ldap-server-ccc] user-parameters user-object-class person
```

Client IP: 3.3.3.3
```

Related commands

radius-server client

display radius-server active-user

Use **display radius-server active-user** to display information about activated RADIUS users.

Syntax

display radius-server active-user [*user-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

user-name: Specifies a RADIUS user name, a case-sensitive string of 1 to 55 characters. The name must meet the following requirements:

- Cannot contain a domain name.
- Cannot contain any of the following characters: forward slash (/), backslash (\), vertical bar (|), colon (:), asterisk (*), question mark (?), left angle bracket (<), right angle bracket (>), or at sign (@).
- Cannot be **a**, **al**, or **all**.

If you do not specify a RADIUS user name, this command displays information about all RADIUS users.

Examples

Display information about the activated RADIUS user named **test**.

```
<Sysname> display radius-server active-user test
Total 1 RADIUS users matched.

Username: test
  Description: A network access user from company cc
  Authorization attributes:
    VLAN ID: 2
    ACL number: 2000
  Validity period:
    Expiration time: 2015/04/03-18:00:00
```

Display information about all activated RADIUS users.

```
<Sysname> display radius-server active-user
```

```
Total 2 RADIUS users matched.

Username: 123
  Description: A network access user from company cc
  Authorization attributes:
    VLAN ID: 2
    ACL number: 3000
  Validity period:
    Expiration time: 2016/04/03-18:00:00

Username: 456
  Description: A network access user from company cc
  Authorization attributes:
    VLAN ID: 2
    ACL number: 3000
  Validity period:
    Expiration time: 2016/04/03-18:00:00
```

Table 16 Command output

Field	Description
Username	RADIUS user name.
Description	Description of the RADIUS user.
Authorization attributes	Authorization attributes of the RADIUS user.
VLAN ID	Authorization VLAN.
ACL number	Authorization ACL.
Validity period	Validity time period of the RADIUS user.
Expiration time	Expiration date and time.

`local-user`

radius-server activate

Use **`radius-server activate`** to activate the RADIUS server configuration, including RADIUS clients and users.

Syntax

`radius-server activate`

Views

System view

Predefined user roles

network-admin

Usage guidelines

Use this command to immediately activate the most recent RADIUS server configuration after you have added, modified, or deleted RADIUS clients and network access users from which RADIUS user data is generated.

Executing this command restarts the RADIUS server process and an authentication service interruption will occur during the restart.

Examples

Activate the RADIUS server configuration.

```
<Sysname> system-view
[Sysname] radius-server activate
```

Related commands

display radius-server active-client

display radius-server active-user

radius-server client

Use **radius-server client** to configure a RADIUS client.

Use **undo radius-server client** to delete a RADIUS client.

Syntax

radius-server client ip *ipv4-address* **key** { **cipher** | **simple** } *string*

undo radius-server client { **all** | **ip** *ipv4-address* }

Default

No RADIUS clients are specified.

Views

System view

Predefined user roles

network-admin

Parameters

ip *ipv4-address*: Specifies the IPv4 address of the RADIUS client, which must be a Class A, B, or C address and the first octet cannot be 0 or 127.

key: Specifies the shared key to communicate with the RADIUS client.

cipher: Specifies the key in encrypted form.

simple: Specifies the key in plaintext form.

string: Specifies a case-sensitive key string. The encrypted form of the key is a string of 1 to 117 characters. The plaintext form of the key is a string of 1 to 64 characters.

all: Specifies all RADIUS clients.

Usage guidelines

The IP address of a RADIUS client must be the same as the source IP address for outgoing RADIUS packets specified on the RADIUS client.

The shared key of a RADIUS client must be the same as the setting on the RADIUS client.

Execute this command multiple times to configure multiple RADIUS clients.

Examples

Configure a RADIUS client whose IP address is 2.2.2.2 and shared key is **test** in plaintext.

```
<Sysname> system-view
[Sysname] radius-server client ip 2.2.2.2 key simple test
```

Connection recording policy commands

aaa connection-recording policy

Use **aaa connection-recording policy** to create a connection recording policy and enter its view, or enter the view of an existing connection recording policy.

Use **aaa connection-recording policy** to delete the connection recording policy.

Syntax

aaa connection-recording policy

undo aaa connection-recording policy

Default

The connection recording policy does not exist.

Views

System view

Predefined user roles

network-admin

Usage guidelines

Use this feature on scenarios where the device acts as an FTP, SSH, SFTP, or Telnet login client to establish a connection with a login server. This feature enables the device to provide an accounting server with the connection start and termination information. When the login client establishes a connection with the login server, the system sends a start-accounting request to the accounting server. When the connection is terminated, the system sends a stop-accounting request to the accounting server.

Examples

Create a connection recording policy and enter its view.

```
<Sysname> system-view
[Sysname] aaa connection-recording policy
[sysname-connection-recording-policy]
```

Related commands

accounting hwtacacs-scheme

display aaa connection-recording policy

accounting hwtacacs-scheme

Use **accounting hwtacacs-scheme** to specify the accounting method for the connection recording policy.

Use **undo accounting** to restore the default.

Syntax

accounting hwtacacs-scheme *hwtacacs-scheme-name*

undo accounting

Default

No accounting method is specified for the connection recording policy. No accounting is performed on the connections initiated by the device as a login client.

Views

Connection recording policy view

Predefined user roles

network-admin

Parameters

hwtacacs-scheme-name: Specifies an HWTACACS scheme by its name, a case-insensitive string of 1 to 32 characters.

Usage guidelines

If the accounting method is changed, the new method takes effect only on subsequent connections initiated by the device as a login client.

For a connection, once the device sends the start-accounting request to an HWTACACS server, it sends the connection's stop-accounting packet to the same server.

If you execute this command multiple times, the most recent configuration takes effect.

The device includes the username entered by a user in the accounting packets to be sent to the AAA server for connection recording. The username format configured by using the **user-name-format** command in the accounting scheme does not take effect.

Examples

Create a connection recording policy, and specify HWTACACS scheme **tac** as the accounting method.

```
<Sysname> system-view
[Sysname] aaa connection-recording policy
[sysname-connection-recording-policy] accounting hwtacacs-scheme tac
```

Use **display dot1x** to display information about 802.1X.

Syntax

display dot1x [**sessions** | **statistics**] [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

sessions: Displays 802.1X session information.

statistics: Displays 802.1X statistics.

interface *interface-type interface-number*: Specifies a port by its type and number.

Usage guidelines

If you do not specify the **sessions** keyword or the **statistics** keyword, this command displays all information about 802.1X, including session information, statistics, and settings.

If you do not specify the **interface** *interface-type interface-number* option, this command displays all global and port-specific 802.1X information.

Examples

Display all information about 802.1X.

```
<Sysname> display dot1x
Global 802.1X parameters:
   802.1X authentication               : Enabled
   EAP authentication                  : Enabled
   Max-tx period                       : 30 s
   Handshake period                    : 15 s
   Quiet timer                         : Disabled
         Quiet period                  : 60 s
   Supp timeout                        : 30 s
   Server timeout                      : 100 s
   Reauth period                       : 3600 s
   Max auth requests                   : 2
   User aging period for Auth-Fail VLAN : 1000 s
   User aging period for critical VLAN  : 1000 s
   User aging period for guest VLAN     : 1000 s
   EAD assistant function              : Disabled
       Permit authentication-escape    : Disabled
       URL                             : http://www.dwsoft.com
```

```
      Free IP                          : 6.6.6.0         255.255.255.0
      EAD timeout                      : 30 min
  Domain delimiter                     : @
  Max EAP-TLS fragment (to-server)     : 400 bytes
Online 802.1X wired users              : 1

```

Table 1 Command output

Field	Description
Global 802.1X parameters	Global 802.1X configuration.
802.1X authentication	Whether 802.1X is enabled globally.
CHAP authentication	Performs EAP termination and uses CHAP to communicate with the RADIUS server.
EAP authentication	Relays EAP packets and supports any of the EAP authentication methods to communicate with the RADIUS server.
PAP authentication	Performs EAP termination and uses PAP to communicate with the RADIUS server.
Max-tx period	Username request timeout timer in seconds.
Handshake period	Handshake timer in seconds.
Quiet timer	Status of the quiet timer, enabled or disabled.
Quiet period	Quiet timer in seconds.
Supp timeout	Client timeout timer in seconds.
Server timeout	Server timeout timer in seconds.
Reauth period	Periodic reauthentication timer in seconds.
Max auth requests	Maximum number of attempts for sending an authentication request to a client.
User aging period for Auth-Fail VLAN	Aging timer in seconds for users in Auth-Fail VLANs.
User aging period for critical VLAN	Aging timer in seconds for users in critical VLANs.
User aging period for guest VLAN	Aging timer in seconds for users in guest VLANs.
EAD assistant function	Whether EAD assistant is enabled.
Permit authentication-escape	This field is supported only in Release 6331 and later. Whether 802.1X Auth-Fail and critical VLANs and MAC authentication critical VLANs are supported when 802.1X EAD assistant is enabled.
URL	Redirect URL for unauthenticated users using a Web browser to access the network.
Free IP	Network segment accessible to unauthenticated users.
EAD timeout	EAD rule timer in minutes.
Domain delimiter	Domain delimiters supported by the device.
Max EAP-TLS fragment (to-server)	Maximum size of EAP-TLS fragments sent in authentication packets to the server. If no maximum size is set, this field displays N/A.
Online 802.1X wired users	Number of wired online 802.1X users, including users that have passed 802.1X authentication and users that are performing 802.1X authentication.
GigabitEthernet1/0/1 is link-up	Status of the port. In this example, GigabitEthernet 1/0/1 is up.
802.1X authentication	Whether 802.1X is enabled on the port.
Handshake	Whether the online user handshake feature is enabled on the port.
Handshake reply	Whether the online user handshake reply feature is enabled on the

Field	Description
	port.
Handshake security	Whether the online user handshake security feature is enabled on the port.
Unicast trigger	Whether the 802.1X unicast trigger is enabled on the port.
Periodic reauth	Whether 802.1X periodic reauthentication is enabled on the port.
Port role	Role of the port. The port functions only as an **Authenticator**.
Authorization mode	Authorization state of the port, which can be Force-Authorized, Auto, or Force-Unauthorized.
Port access control	Access control method of the port: • **MAC-based**—MAC-based access control. • **Port-based**—Port-based access control.
Multicast trigger	Whether the 802.1X multicast trigger feature is enabled.
Mandatory auth domain	Mandatory authentication domain on the port.
Guest VLAN	802.1X guest VLAN configured on the port. If no 802.1X guest VLAN is configured on the port, this field displays **Not configured**.
Auth-Fail VLAN	802.1X Auth-Fail VLAN configured on the port. If no 802.1X Auth-Fail VLAN is configured on the port, this field displays **Not configured**.
Critical VLAN	802.1X critical VLAN configured on the port. If no 802.1X critical VLAN is configured on the port, this field displays **Not configured**.
Critical voice VLAN	Whether the 802.1X critical voice VLAN feature is enabled on the port.
Add Guest VLAN delay	Status and mode of the 802.1X guest VLAN assignment delay feature on a port: • **EAPOL**—EAPOL-triggered 802.1X guest VLAN assignment delay is enabled. • **NewMac**—New MAC-triggered 802.1X guest VLAN assignment delay is enabled. • **ALL**—Both EAPOL-triggered and new MAC-triggered 802.1X guest VLAN assignment delays are enabled. • **Disabled**—802.1X guest VLAN assignment delay is disabled.
Re-auth server-unreachable	Whether to log off online 802.1X users or keep them online when no server is reachable for 802.1X reauthentication.
Max online users	Maximum number of concurrent 802.1X users on the port.
User IP freezing	Whether user IP freezing is enabled on the port.
Reauth period	Periodic reauthentication timer in seconds on the port.
Send Packets Without Tag	Whether to remove the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients.
Max Attempts Fail Number	Maximum number of 802.1X authentication attempts for MAC authenticated users.
User aging	Status of 802.1X unauthenticated user aging on a port: • Enabled. • Disabled.

Field	Description
Server-recovery online-user-sync	Status of 802.1X online user synchronization: • Enabled. • Disabled.
Auth-Fail EAPOL	This field is not supported in the current software version. This field displays whether the device sends EAP-Success packets to 802.1X clients on their assignment to the 802.1X Auth-Fail VLAN on the port.
Critical EAPOL	This field displays whether the device sends EAP-Success packets to 802.1X clients on their assignment to the 802.1X critical VLAN on the port.
Discard duplicate EAPOL-Start	Whether the device discards duplicate 802.1X EAPOL-Start packets: • **Yes**—The device discards duplicate 802.1X EAPOL-Start packets. • **No**—The device does not discard duplicate 802.1X EAPOL-Start packets.
EAPOL packets	Number of sent (Tx) and received (Rx) EAPOL packets.
Sent EAP Request/Identity packets	Number of sent EAP-Request/Identity packets.
EAP Request/Challenge packets	Number of sent EAP-Request/MD5-Challenge packets.
EAP Success packets	Number of sent EAP-Success packets.
EAP Failure packets	Number of sent EAP-Failure packets.
Received EAPOL Start packets	Number of received EAPOL-Start packets.
EAPOL LogOff packets	Number of received EAPOL-LogOff packets.
EAP Response/Identity packets	Number of received EAP-Response/Identity packets.
EAP Response/Challenge packets	Number of received EAP-Response/MD5-Challenge packets.
Error packets	Number of received error packets.
Online 802.1X users	Number of online 802.1X users on the port, including users that have passed 802.1X authentication and users that are performing 802.1X authentication.
MAC address	MAC addresses of the online 802.1X users.
Auth state	Authentication status of the online 802.1X users.

display dot1x connection

Use **display dot1x connection** to display information about online 802.1X users.

Syntax

display dot1x connection [**open**] [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-address* | **user-name** *name-string*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

open: Displays information only about 802.1X users that use nonexistent usernames or incorrect passwords for network access in open authentication mode. If you do not specify this keyword, the command displays information about all online 802.1X users.

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command displays online 802.1X user information for all ports.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays online 802.1X user information for all member devices.

user-mac *mac-address*: Specifies an 802.1X user by MAC address. The *mac-address* argument represents the MAC address of the user, in the form of H-H-H. If you do not specify an 802.1X user, this command displays all online 802.1X user information.

user-name *name-string*: Specifies an 802.1X user by its name. The *name-string* argument represents the username, a case-sensitive string of 1 to 253 characters. If you do not specify an 802.1X user, this command displays all online 802.1X user information.

Examples

Display information about all online 802.1X users.

```
<Sysname> display dot1x connection
Total connections: 1

Slot ID: 1
User MAC address: 0015-e9a6-7cfe
Access interface: GigabitEthernet1/0/1
Username: ias
User access state: Successful
Authentication domain: h3c
IPv4 address: 192.168.1.1
IPv6 address: 2000:0:0:0:1:2345:6789:abcd
Authentication method: CHAP
AAA authentication method: Local
Initial VLAN: 1
Authorization untagged VLAN: 6
Authorization tagged VLAN list: 1 to 5 7 9 11 13 15 17 19 21 23 25 27 29 31 33 29 31 33
                                35 37 40 to 100
Authorization VSI: N/A
Authorization ACL number/name: 3001
Authorization dynamic ACL name: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Default
Session timeout period: 2 s
Packet detection:
  Max attempts: 5
  Remaining attempts: 3
  Source IPv4 address: 192.168.1.3
  Source IPv4 mask: 255.255.0.0
```

```
Online from: 2013/03/02  13:14:15
Online duration: 0h 2m 15s
```

Table 2 Command output

Field	Description
Total connections	Number of online 802.1X users.
User MAC address	MAC address of the user.
Access interface	Interface through which the user access the device.
User access state	Access state of the user. • **Successful**—The user passes 802.1X authentication and comes online. • **Open**—The user uses a nonexistent username or an incorrect password to come online in open authentication mode.
Authentication domain	ISP domain used for 802.1X authentication.
IPv4 address	IPv4 address of the user. If the device does not get the IPv4 address of the user, this field is not available.
IPv6 address	IPv6 address of the user. If the device does not get the IPv6 address of the user, this field is not available.
Authentication method	EAP message handling method: • **CHAP**—Performs EAP termination and uses CHAP to communicate with the RADIUS server. • **EAP**—Relays EAP packets and supports any of the EAP authentication methods to communicate with the RADIUS server. • **PAP**—Performs EAP termination and uses PAP to communicate with the RADIUS server.
AAA authentication method	This field is supported only in Release 6340 or later. AAA authentication method for the user to come online: • **Local**—Local authentication. • **HWTACACS**—HWTACACS authentication. • **RADIUS**—RADIUS authentication. • **None**—No authentication was performed.
Initial VLAN	VLAN to which the user belongs before 802.1X authentication.
Authorization untagged VLAN	Untagged VLAN assigned to the user. The VLAN assigned by the server to a user as an authorization VLAN might have been configured on the user access port but with a different tagging mode. For example, the server assigns an authorization VLAN with a tagged attribute, but the same VLAN configured on the port has an untagged attribute. In this situation, if the link type of the port is hybrid, the VLAN settings configured on the port take effect on the user. For more information, see 802.1X in *Security Configuration Guide*.
Authorization tagged VLAN list	Tagged VLANs assigned to the user. The VLAN assigned by the server to a user as an authorization VLAN might have been configured on the user access port but with a different tagging mode. For example, the server assigns an authorization VLAN with a tagged attribute, but the same VLAN configured on the port has an untagged attribute. In this situation, if the link type of the port is hybrid, the VLAN settings configured on the port take effect on the user.

Field	Description
	For more information, see 802.1X in *Security Configuration Guide*.
Authorization VSI	This field is not supported in the current software version. VSI assigned to the user.
Authorization ACL number/name	Number or name of the static ACL assigned to the user. If no static ACL has been assigned, this field displays **N/A**. If the ACL assignment fails, this field displays **(NOT effective)** next to the ACL number or name.
Authorization dynamic ACL name	This field is supported only in Release 6331 and later. Name of the dynamic ACL assigned to the user. If no dynamic ACL is assigned to the user, this field displays **N/A**. If the ACL assignment fails, this field displays **(NOT effective)** next to the ACL name.
Authorization user profile	User profile assigned to the user.
Authorization CAR	This field is not supported in the current software version. Authorization CAR attributes assigned by the server. If no authorization CAR attributes are assigned, this field displays **N/A**.
Authorization URL	Redirect URL assigned to the user.
Termination action	Action attribute assigned by the server to terminate the user session: • **Default**—Logs off the online authenticated 802.1X user when the server-assigned session timeout timer expires. This attribute does not take effect when 802.1X periodic reauthentication is enabled and the periodic reauthentication timer is shorter than the server-assigned session timeout timer. • **Radius-request**—Reauthenticates the online user when the server-assigned session timeout timer expires, regardless of whether the 802.1X periodic reauthentication feature is enabled or not. If the device performs local authentication, this field displays **Default**.
Session timeout period	Session timeout timer assigned by the server.
Packet detection	This field is supported only in Release 6348P01 or later. Information about the packet detection feature.
Max attempts	This field is supported only in Release 6348P01 or later. Maximum number of attempts for sending a detection packet to the user.
Remaining attempts	This field is supported only in Release 6348P01 or later. Remaining number of attempts for sending a detection packet to the user. The device decreases the number by 1 each time it makes an attempt to send the detection packet to the user.
Source IPv4 address	This field is supported only in Release 6348P01 or later. IP address specified for calculating the source IP address of ARP detection packets. If no IP address is specified, this field displays 0.0.0.0.
Source IPv4 mask	This field is supported only in Release 6348P01 or later. Mask specified for calculating the source IP address of ARP detection packets. If no mask is specified, this field displays 0.0.0.0.
Online from	Time from which the 802.1X user came online.

Field	Description
Online duration	Online duration of the 802.1X user.

display dot1x mac-address

Use **display dot1x mac-address** to display the MAC addresses of 802.1X users in a type of 802.1X VLAN.

Syntax

display dot1x mac-address { **auth-fail-vlan** | **critical-vlan** | **guest-vlan** } [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

auth-fail-vlan: Specifies 802.1X Auth-Fail VLANs.

critical-vlan: Specifies 802.1X critical VLANs.

guest-vlan: Specifies 802.1X guest VLANs.

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command displays the MAC addresses of 802.1X users in the specified type of 802.1X VLAN on all ports.

Usage guidelines

The displayed MAC addresses and MAC address count might not include all MAC addresses if a large number of 802.1X users are performing authentication frequently.

Examples

Display the MAC addresses of 802.1X users in the 802.1X Auth-Fail VLANs on all ports.

```
<Sysname> display dot1x mac-address auth-fail-vlan
Total MAC addresses: 10
Interface: GigabitEthernet1/0/1        Auth-Fail VLAN: 3    Aging time: N/A
MAC addresses: 8
  0800-2700-9427    0800-2700-2341    0800-2700-2324    0800-2700-2351
  0800-2700-5627    0800-2700-2251    0800-2700-8624    0800-2700-3f51

Interface: GigabitEthernet1/0/2        Auth-Fail VLAN: 5    Aging time: 30 sec
MAC addresses: 2
  0801-2700-9427    0801-2700-2341
```

Table 3 Command output

Field	Description
Total MAC addresses	Total number of MAC addresses in the specified type of VLAN on the specified port or all ports.
Interface	Access port of 802.1X users.

Field	Description
Type VLAN	VLAN that contains the 802.1X users. The *Type* argument has the following values: • Auth-Fail VLAN. • Critical VLAN. • Guest VLAN.
Aging time	MAC address aging time in seconds. This field displays **N/A** if the MAC addresses do not age out.
MAC addresses	Number of matching MAC addresses on a port.
xxxx-xxxx-xxxx	MAC address.

Related commands

dot1x auth-fail vlan

dot1x critical vlan

dot1x guest-vlan

dot1x

Use **dot1x** to enable 802.1X globally or on a port.

Use **undo dot1x** to disable 802.1X globally or on a port.

Syntax

dot1x

undo dot1x

Default

802.1X is neither enabled globally nor enabled for any port.

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

For the 802.1X feature to take effect on a port, you must enable the feature both globally and on the port.

Examples

Enable 802.1X globally.

```
<Sysname> system-view
[Sysname] dot1x
```

Enable 802.1X on GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x
[Sysname-GigabitEthernet1/0/1] quit
```

Related commands

display dot1x

dot1x { ip-verify-source | ipv6-verify-source } enable

Use **dot1x** { **ip-verify-source** | **ipv6-verify-source** } **enable** to enable generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users.

Use **undo dot1x** { **ip-verify-source** | **ipv6-verify-source** } **enable** to disable generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users.

Syntax

dot1x { **ip-verify-source** | **ipv6-verify-source** } **enable**

undo dot1x { **ip-verify-source** | **ipv6-verify-source** } **enable**

Default

Generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users is enabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

IMPORTANT:

This feature must operate in conjunction with the IP source guard (IPSG) feature.

This command is supported only in Release 6340 or later.

This command takes effect only on 802.1X users that come online after you execute this command. For existing online 802.1X users, the device updates the dynamic IPv4SG or IPv6SG binding entries for them only when their IP addresses change.

When you execute the **undo** form of this command, the device does not delete the existing dynamic IPv4SG or IPv6SG binding entries for online 802.1X users. Instead, the device deletes the dynamic IPv4SG or IPv6SG binding entry for an online 802.1X user only when the IP address of that user changes.

Examples

Disable generation of dynamic IPv4SG or IPv6SG binding entries for 802.1X authenticated users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] undo dot1x ip-verify-source enable
```

dot1x access-user log enable

Use **dot1x access-user log enable** to enable 802.1X user logging.

Use **undo dot1x access-user log enable** to disable 802.1X user logging.

Syntax

dot1x access-user log enable [**abnormal-logoff** | **failed-login** | **normal-logoff** | **successful-login**] *

undo dot1x access-user log enable [**abnormal-logoff** | **failed-login** | **normal-logoff** | **successful-login**] *

Default

802.1X user logging is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

abnormal-logoff: Logs exceptional logoffs of 802.1X users, such as logoffs caused by real-time accounting failures or reauthentication failures.

failed-login: Logs 802.1X user login failures.

normal-logoff: Logs logoffs requested by 802.1X users.

successful-login: Logs successful 802.1X user logins.

Usage guidelines

To prevent excessive 802.1X user log entries, use this feature only if you need to analyze abnormal 802.1X user logins or logouts.

If you do not specify any parameters, this command enables all types of 802.1X user logs.

Examples

Enable logging 802.1X user login failures.

```
<Sysname> system-view
[Sysname] dot1x access-user log enable failed-login
```

Related commands

info-center source dot1x logfile deny (*Network Management and Monitoring Command Reference*)

dot1x after-mac-auth max-attempt

Use **dot1x after-mac-auth max-attempt** to set the maximum number of 802.1X authentication attempts for MAC authenticated users on a port.

Use **undo dot1x after-mac-auth max-attempt** to restore the default.

Syntax

dot1x after-mac-auth max-attempt *max-attempts*

undo dot1x after-mac-auth max-attempt

Default

The number of 802.1X authentication attempts for MAC authenticated users is not limited on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

max-attempts: Specifies a number in the range of 1 to 50.

Usage guidelines

The device denies 802.1X authentication requests of a MAC authenticated user after the maximum number of 802.1X authentication attempts has been made.

The device will recount the number of 802.1X authentication attempts made by a MAC authenticated user if a user logoff or device reboot event occurs.

Examples

Configure GigabitEthernet 1/0/1 to allow a maximum of 10 802.1X authentication attempts made by a MAC authenticated user.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x after-mac-auth max-attempt 10
```

Related commands

display dot1x

dot1x authentication-method

Use **dot1x authentication-method** to specify an EAP message handling method.

Use **undo dot1x authentication-method** to restore the default.

Syntax

dot1x authentication-method { **chap** | **eap** | **pap** }

undo dot1x authentication-method

Default

The access device performs EAP termination and uses CHAP to communicate with the RADIUS server.

network-admin

Parameters

chap: Configures the access device to perform Extensible Authentication Protocol (EAP) termination and use the Challenge Handshake Authentication Protocol (CHAP) to communicate with the RADIUS server.

eap: Configures the access device to relay EAP packets, and supports any of the EAP authentication methods to communicate with the RADIUS server.

pap: Configures the access device to perform EAP termination and use the Password Authentication Protocol (PAP) to communicate with the RADIUS server.

Usage guidelines

The access device terminates or relays EAP packets.

- **In EAP termination mode**—The access device re-encapsulates and sends the authentication data from the client in standard RADIUS packets to the RADIUS server. The device performs either CHAP or PAP authentication with the RADIUS server. In this mode, the RADIUS server

supports only MD5-Challenge EAP authentication and the username and password EAP authentication initiated by an iNode client.

- PAP transports usernames and passwords in plain text. The authentication method applies to scenarios that do not require high security. To use PAP, the client can be an iNode 802.1X client.
- CHAP transports usernames in plain text and passwords in encrypted form over the network. CHAP is more secure than PAP.

- **In EAP relay mode**—The access device relays EAP messages between the client and the RADIUS server. The EAP relay mode supports multiple EAP authentication methods, such as MD5-Challenge, EAP-TLS, and PEAP. To use this mode, make sure the RADIUS server meets the following requirements:
  - Supports the EAP-Message and Message-Authenticator attributes.
  - Uses the same EAP authentication method as the client.

  If this mode is used, the **user-name-format** command configured in RADIUS scheme view does not take effect. For more information about the **user-name-format** command, see "RADIUS commands."

If RADIUS authentication is used, you must configure the access device to use the same authentication method (PAP, CHAP, or EAP) as the RADIUS server.

Examples

Enable the access device to terminate EAP packets and perform PAP authentication with the RADIUS server.

```
<Sysname> system-view
[Sysname] dot1x authentication-method pap
```

dot1x auth-fail vlan

Use **dot1x auth-fail vlan** to configure an 802.1X Auth-Fail VLAN on a port.

Use **undo dot1x auth-fail vlan** to restore the default.

Syntax

dot1x auth-fail vlan *authfail-vlan-id*

undo dot1x auth-fail vlan

Default

No 802.1X Auth-Fail VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

authfail-vlan-id: Specifies the ID of the 802.1X Auth-Fail VLAN on the port. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created.

Usage guidelines

An 802.1X Auth-Fail VLAN accommodates users that have failed 802.1X authentication for any reason other than unreachable servers. Users in the Auth-Fail VLAN can access a limited set of network resources.

To delete a VLAN that has been configured as an 802.1X Auth-Fail VLAN, you must first use the **undo dot1x auth-fail vlan** command.

Examples

Configure VLAN 100 as the Auth-Fail VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x auth-fail vlan 100
```

dot1x critical eapol

Use **dot1x critical eapol** to enable the sending of an EAP-Success packet to a client when the 802.1X client user is assigned to the 802.1X critical VLAN on a port.

Use **undo dot1x critical eapol** to restore the default.

Syntax

dot1x critical eapol

undo dot1x critical eapol

Default

The device sends an EAP-Failure packet to a client when the 802.1X client user is assigned to the 802.1X critical VLAN on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

By default, the device sends EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X critical VLAN. Some 802.1X clients, such as Windows built-in 802.1X clients, cannot respond to the EAP-Request/Identity packets from the device for reauthentication if they have received an EAP-Failure packet. As a result, reauthentication for these clients will fail after the authentication server becomes reachable.

To avoid this situation, enable the device to send EAP-Success packets instead of EAP-Failure packets to 802.1X clients when the client users are assigned to the 802.1X critical VLAN.

Examples

Send an EAP-Success packet to a client when the 802.1X client user is assigned to the 802.1X critical VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x critical eapol
```

Use **undo dot1x critical vlan** to restore the default.

Syntax

dot1x critical vlan *critical-vlan-id*

undo dot1x critical vlan

Default

No 802.1X critical VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

critical-vlan-id: Specifies the ID of the 802.1X critical VLAN on the port. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created.

Usage guidelines

An 802.1X critical VLAN accommodates users that fail 802.1X authentication because all the RADIUS servers in their ISP domains are unreachable. Users in the critical VLAN can access a limited set of network resources depending on the configuration.

To delete a VLAN that has been configured as an 802.1X critical VLAN, you must first use the **undo dot1x critical vlan** command.

Examples

Specify VLAN 100 as the 802.1X critical VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x critical vlan 100
```

Related commands

display dot1x

dot1x critical-voice-vlan

Use **dot1x critical-voice-vlan** to enable the 802.1X critical voice VLAN feature on a port.

Use **undo dot1x critical-voice-vlan** to restore the default.

NOTE:

This command is not supported on the following switch series:

- S5000E-X.
- S5110V2-SI.

- S5000V3-EI.
- S5000V5-EI.
- S5000X-EI.
- WAS6000.

Syntax

dot1x critical-voice-vlan

undo dot1x critical-voice-vlan

Default

The 802.1X critical voice VLAN feature is disabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

The 802.1X critical voice VLAN on a port accommodates 802.1X voice users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable.

Before you enable the 802.1X critical voice VLAN feature on the port, make sure the following requirements are met:

- The port is configured with the voice VLAN.

  To configure a voice VLAN on a port, use the **voice-vlan enable** command (see *Layer 2—LAN Switching Command Reference*).
- LLDP is enabled both globally and on the port.

  The device uses LLDP to identify voice users. For information about LLDP commands, see *Layer 2—LAN Switching Command Reference*.
- An 802.1X critical VLAN is configured on the port. This setting ensures that a voice user is assigned to the critical VLAN if it has failed authentication for unreachability of RADIUS servers before the device recognizes it as a voice user. If an 802.1X critical VLAN is not available, the voice user might be logged off instead.

Examples

Enable the 802.1X critical voice VLAN feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x critical-voice-vlan
```

dot1x duplicate-eapol-start discard

Use **dot1x duplicate-eapol-start discard** to discard duplicate EAPOL-Start requests on an interface.

Use **undo dot1x duplicate-eapol-start discard** to restore the default.

Syntax

dot1x duplicate-eapol-start discard

undo dot1x duplicate-eapol-start discard

Default

The device does not discard duplicate EAPOL-Start requests on an interface if the requests are legal.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

This command is supported only in Release 6309P01 or later.

During 802.1X authentication, the device might receive duplicate EAPOL-Start requests from an 802.1X user. By default, the device delivers the duplicate EAPOL-Start requests to the authentication server as long as they are legal. However, this mechanism might result in authentication failure if the authentication server cannot respond to duplicate EAPOL-Start requests. To resolve this issue, use this command on the user access interface to discard duplicate EAPOL-Start requests.

As a best practice, use this command only if the server cannot respond to duplicate EAPOL-Start requests. Do not use this command in other situations.

Examples

Discard duplicate EAPOL-Start requests on Ten-GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface ten-gigabitethernet 1/0/1
[Sysname-Ten-GigabitEthernet1/0/1] dot1x duplicate-eapol-start discard
```

Related commands

display dot1x

dot1x domain-delimiter

Use **dot1x domain-delimiter** to specify a set of domain name delimiters supported by the device.

Use **undo dot1x domain-delimiter** to restore the default.

Syntax

dot1x domain-delimiter *string*

undo dot1x domain-delimiter

Default

The device supports only the at sign (@) delimiter for 802.1X users.

Views

System view

Predefined user roles

network-admin

Parameters

string: Specifies a set of 1 to 16 domain name delimiters for 802.1X users. No space is required between delimiters. Available delimiters include the at sign (@), backslash (\), dot (.), and forward slash (/). If you want to use backslash (\) as the domain name delimiter, you must enter the escape character (\) along with the backslash (\) sign.

Usage guidelines

Any character in the configured set can be used as the domain name delimiter for 802.1X authentication users. Usernames that include domain names can use the format of *username*@*domain-name*, *domain-name**username*, *username*.*domain-name*, or *username*/*domain-name*.

The delimiter set you configured overrides the default setting. If the at sign (@) is not included in the delimiter set, the device does not support the 802.1X users that use this sign as the domain name delimiter.

If a username string contains multiple configured delimiters, the device takes the rightmost delimiter in the username string as the domain name delimiter. For example, if you configure the forward slash (/), dot (.), and backslash (\) as delimiters, the domain name delimiter for the username string 121.123/22\@abc is the backslash (\). The username is **@abc** and the domain name is **121.123/22**.

Examples

Specify the at sign (@) and forward slash (/) as domain name delimiters.

```
<Sysname> system-view
[Sysname] dot1x domain-delimiter @/
```

Related commands

display dot1x

dot1x ead-assistant enable

Use **dot1x ead-assistant enable** to enable the EAD assistant feature.

Use **undo dot1x ead-assistant enable** to disable the EAD assistant feature.

NOTE:

The EAD assistant feature is not supported on the following switch series:

- S5000E-X.
- S5110V2-SI.
- S5000V3-EI.
- S5000V5-EI.
- S5000X-EI.
- WAS6000.

Syntax

dot1x ead-assistant enable

undo dot1x ead-assistant enable

Default

The EAD assistant feature is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

The EAD assistant feature enables the access device to redirect the HTTP or HTTPS requests of a user to a URL to download and install EAD client. This feature eliminates the tedious job of the administrator to deploy EAD clients.

For the EAD assistant feature to take effect on a port, you must set the port authorization mode to **auto**.

The feature is mutually exclusive with MAC authentication and port security. You must disable MAC authentication and port security globally before you enable the EAD assistant feature.

As from Release 6331, the **dot1x ead-assistant permit authentication-escape** command is added to remove the 802.1X Auth-Fail VLAN and critical VLAN malfunction issue when EAD assistant is enabled. This command enables the device to remove the EAD entries of users before it assigns the users to 802.1X Auth-Fail and critical VLANs.

As from Release 6328, you can use EAD assistant in conjunction with MAC authentication. When you use both EAD assistant and MAC authentication on the device, follow these restrictions and guidelines:

- If both EAD assistant and MAC authentication are configured, the device does not mark the MAC address of a user that has failed MAC authentication as a silent MAC address. If the user has never passed MAC authentication, packets from the user can trigger MAC authentication again only after the user's EAD entry ages out.
- As a best practice, do not configure MAC authentication guest VLANs or critical VLANs. The VLANs might fail to work correctly when both EAD assistant and MAC authentication are configured on the device.
- As a best practice, do not configure the Web authentication or IP source guard feature. These features might fail to work correctly when both EAD assistant and MAC authentication are configured on the device.
- If the MAC address of a user has been marked as a silent MAC address before you enable EAD assistant, packets from the user can trigger 802.1X or MAC authentication only after the quiet timer expires.
- As from Release 6331, the **dot1x ead-assistant permit authentication-escape** command is added to remove the MAC authentication critical VLAN malfunction issue when EAD assistant is enabled. This command enables the device to remove the EAD entries of users before it assigns the users to MAC authentication critical VLANs.

To redirect the HTTPS requests of 802.1X users, you must execute the **dot1x ead-assistant url** command. By default, the device listens to port 6654 for HTTPS requests to be redirected. To change the redirect listening port number, see configuring HTTP redirect in *Layer 3—IP Services Configuration Guide*.

Examples

Enable the EAD assistant feature.

```
<Sysname> system-view
[Sysname] dot1x ead-assistant enable
```

dot1x ead-assistant free-ip

Use **dot1x ead-assistant free-ip** to configure a free IP.

Use **undo dot1x ead-assistant free-ip** to remove the specified or all free IP addresses.

Syntax

dot1x ead-assistant free-ip *ip-address* { *mask-address* | *mask-length* }

undo dot1x ead-assistant free-ip { *ip-address* { *mask-address* | *mask-length* } | **all** }

Default

No free IPs exist. Users cannot access any segments before they pass 802.1X authentication.

Views

System view

Predefined user roles

network-admin

Parameters

ip-address: Specifies a freely accessible IP address segment, also called a free IP.

mask: Specifies an IP address mask.

mask-length: Specifies IP address mask length in the range of 1 to 32.

all: Removes all free IP addresses.

Usage guidelines

With EAD assistant enabled on the device, unauthenticated 802.1X users can access the network resources in the free IP segments before they pass 802.1X authentication.

Execute this command multiple times to configure multiple free IPs.

Examples

Configure 192.168.1.1/16 as a free IP.

```
<Sysname> system-view
[Sysname] dot1x ead-assistant free-ip 192.168.1.1 255.255.0.0
```

Related commands

dot1x ead-assistant enable

dot1x ead-assistant url

Use **dot1x ead-assistant url** to configure a redirect URL for EAD assistant.

Use **undo dot1x ead-assistant url** to restore the default.

Syntax

dot1x ead-assistant url *url-string*

undo dot1x ead-assistant url

Default

No redirect URL exists for EAD assistant.

Views

System view

Predefined user roles

network-admin

Parameters

url-string: Specifies the redirect URL, a case-sensitive string of 1 to 256 characters in the format http://*string* or https://*string*. If the specified URL does not start with http:// or https://, the device prefixes the specified URL with http://. Because the URL string can contain question marks (?), you cannot obtain help information by entering a question mark at the position of this argument.

Usage guidelines

When an unauthenticated user uses a Web browser to access any network other than the free IP, the device redirects the HTTP or HTTPS requests of the user to the redirect URL.

The redirect URL must be on the free IP subnet.

If you execute this command multiple times, the most recent configuration takes effect.

By default, the device listens to port 6654 for HTTPS requests to be redirected. To change the redirect listening port number, see configuring HTTP redirect in *Layer 3—IP Services Configuration Guide*.

Examples

Configure the redirect URL as http://test.com.

```
<Sysname> system-view
[Sysname] dot1x ead-assistant url http://test.com
```

dot1x eap-tls-fragment to-server

Use **dot1x eap-tls-fragment to-server** to enable 802.1X EAP-TLS fragmentation and set the maximum EAP-TLS fragment size.

Use **undo dot1x eap-tls-fragment to-server** to restore the default.

Syntax

dot1x eap-tls-fragment to-server *eap-tls-max-length*

undo dot1x eap-tls-fragment to-server

Default

EAP-TLS messages are not fragmented.

Views

System view

Predefined user roles

network-admin

Parameters

eap-tls-max-length: Sets the maximum EAP-TLS fragment size in bytes. The value range is 100 to 1500.

Usage guidelines

802.1X EAP-TLS fragmentation takes effect only when EAP relay mode is used.

When the device uses EAP-TLS authentication method in EAP relay mode, the RADIUS packets might exceed the maximum packet size supported by the RADIUS server. This situation typically occurs when long EAP-TLS messages are encapsulated in the EAP-Message attribute of the RADIUS packet sent to the RADIUS server.

To avoid authentication failures caused by oversized packets, fragment the EAP-TLS messages depending on the maximum RADIUS packet size supported by the remote RADIUS server.

For example, the maximum packet length allowed by the server is 1200 bytes and the length of a RADIUS packet (excluding the EAP-Message attribute) is 800 bytes. To make sure the maximum length of a RADIUS packet does not exceed 1200 bytes, you must set the maximum length of an EAP-TLS fragment to a value less than 400 bytes.

Examples

Set the maximum EAP-TLS fragment size to 400 bytes.

```
<Sysname> system-view
[Sysname] dot1x eap-tls-fragment to-server 400
```

dot1x eapol untag

Use **dot1x eapol untag** to enable the device to remove the VLAN tags of all 802.1X protocol packets sent out of a port to 802.1X clients.

Use **undo dot1x eapol untag** to restore the default.

Syntax

dot1x eapol untag

undo dot1x eapol untag

Default

Whether the device removes the VLAN tags of all 802.1X protocol packets sent out of a port to 802.1X clients depends on the configuration in the VLAN module.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

CAUTION:

This command removes the VLAN tags of all 802.1X protocol packets sent out of the port to 802.1X clients. Do not use this command if VLAN-aware 802.1X clients are attached to the port. As a best practice, use this command only in the scenario described in the command usage guidelines.

This command operates on a hybrid port to have it send 802.1X protocol packets with their VLAN tags removed, regardless of whether the port is a tagged or untagged member of a VLAN.

Use this command if the 802.1X-enabled hybrid port is a tagged member of its PVID and the attached 802.1X clients cannot recognize VLAN-tagged 802.1X protocol packets.

Examples

Enable the device to remove the VLAN tags of all 802.1X protocol packets sent out of GigabitEthernet 1/0/1 to 802.1X clients.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x eapol untag
```

Related commands

dot1x guest-vlan

Use **dot1x guest-vlan** to configure an 802.1X guest VLAN on a port.

Use **undo dot1x guest-vlan** to restore the default.

Syntax

dot1x guest-vlan *guest-vlan-id*

undo dot1x guest-vlan

Default

No 802.1X guest VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

guest-vlan-id: Specifies the ID of the 802.1X guest VLAN. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created.

Usage guidelines

An 802.1X guest VLAN accommodates users that have not performed 802.1X authentication. In the guest VLAN, users can access a limited set of network resources, such as a software server, to download anti-virus software and system patches.

To delete a VLAN that has been configured as a guest VLAN, you must use the **undo dot1x guest-vlan** command first.

Examples

Specify VLAN 100 as the 802.1X guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x guest-vlan 100
```

dot1x guest-vlan-delay

Use **dot1x guest-vlan-delay** to enable 802.1X guest VLAN assignment delay on a port.

Use **undo dot1x guest-vlan-delay** to disable the specified 802.1X guest VLAN assignment delay on a port.

Syntax

dot1x guest-vlan-delay { **eapol** | **new-mac** }

undo dot1x guest-vlan-delay [**eapol** | **new-mac**]

Default

802.1X guest VLAN assignment delay is disabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

eapol: Specifies EAPOL-triggered 802.1X guest VLAN assignment delay. This keyword takes effect if 802.1X authentication is triggered by EAPOL-Start packets.

new-mac: Specifies new MAC-triggered 802.1X guest VLAN assignment delay. This keyword takes effect if 802.1X authentication is triggered by packets from unknown MAC addresses.

Usage guidelines

This command enables the device to delay assigning an 802.1X-enabled port to the 802.1X guest VLAN when 802.1X authentication is triggered on the port.

To use this feature, the 802.1X-enabled port must perform MAC-based access control.

When 802.1X authentication is triggered on a port, the device performs the following operations:

1. Sends a unicast EAP-Request/Identity packet to the MAC address that triggers the authentication.
2. Retransmits the packet if no response has been received within the username request timeout interval set by using the **dot1x timer tx-period** command.
3. Assigns the port to the 802.1X guest VLAN after the maximum number of request attempts set by using the **dot1x retry** command is reached.

If you use the **undo** command without any keyword, the command disables both EAPOL-triggered and new MAC-triggered 802.1X guest VLAN assignment delay on a port.

Examples

Enable EAPOL-triggered 802.1X guest VLAN assignment delay on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x guest-vlan-delay eapol

network-admin

Parameters

mac-address: Specifies a MAC address in the format of H-H-H, excluding broadcast, multicast, and all-zero MAC addresses.

all: Specifies all MAC addresses that are bound to a port.

Usage guidelines

This command takes effect only when the 802.1X MAC address binding feature takes effect.

802.1X MAC address binding entries, both manually added and automatically generated, never age out. They can survive a user logoff or a device reboot. To delete an entry, use the **undo dot1x mac-binding** *mac-address* command. An 802.1X MAC address binding entry cannot be deleted when the user in the entry is online.

After the number of 802.1X MAC address binding entries reaches the upper limit of concurrent 802.1X users (set by using the **dot1x max-user** command), the following restrictions exist:

- Users not in the binding entries will fail authentication even after users in the binding entries go offline.
- New 802.1X MAC address binding entries are not allowed.

Examples

Add an 802.1X MAC address binding entry on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x mac-binding 000a-eb29-75f1
```

dot1x mac-binding enable

Use **dot1x mac-binding enable** to enable the 802.1X MAC address binding feature.

Use **undo dot1x mac-binding enable** to disable the 802.1X MAC address binding feature.

Syntax

dot1x mac-binding enable

undo dot1x mac-binding enable

Default

The 802.1X MAC address binding feature is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

This command takes effect only on a port that performs MAC-based access control.

The 802.1X MAC address binding feature automatically binds MAC addresses of authenticated 802.1X users to the users' access port and generates 802.1X MAC address binding entries.

802.1X MAC address binding entries, both automatically generated and manually added, never age out. They can survive a user logoff or a device reboot. To delete an entry, use the **undo dot1x mac-binding** *mac-address* command. An 802.1X MAC address binding entry cannot be deleted when the user in the entry is online.

After the number of 802.1X MAC address binding entries reaches the upper limit of concurrent 802.1X users (set by using the **dot1x max-user** command), the following restrictions exist:

- Users not in the binding entries will fail authentication even after users in the binding entries go offline.
- New 802.1X MAC address binding entries are not allowed.

Examples

Enable 802.1X MAC address binding on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x mac-binding enable
```

dot1x mandatory-domain

Use **dot1x mandatory-domain** to specify a mandatory 802.1X authentication domain on a port.

Use **undo dot1x mandatory-domain** to restore the default.

Syntax

dot1x mandatory-domain *domain-name*

undo dot1x mandatory-domain

Default

No mandatory 802.1X authentication domain is specified on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

domain-name: Specifies the ISP domain name, a case-insensitive string of 1 to 255 characters.

Usage guidelines

When the system authenticates an 802.1X user trying to access a port, it selects an authentication domain in the following order:

1. Mandatory domain.
2. ISP domain specified in the username.
3. Default ISP domain.

Examples

Specify **my-domain** as the mandatory authentication domain for 802.1X users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x mandatory-domain my-domain
```

dot1x max-user

Use **dot1x max-user** to set the maximum number of concurrent 802.1X users on a port.

Use **undo dot1x max-user** to restore the default.

Syntax

dot1x max-user *max-number*

undo dot1x max-user

Default

A port allows a maximum of 4294967295 concurrent 802.1X users.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of concurrent 802.1X users on a port. The value range is 1 to 4294967295.

Usage guidelines

Set the maximum number of concurrent 802.1X users on a port to prevent the system resources from being overused. When the maximum number is reached, the port denies subsequent 802.1X users.

Examples

Set the maximum number of concurrent 802.1X users to 32 on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x max-user 32
```

dot1x multicast-trigger

Use **dot1x multicast-trigger** to enable the 802.1X multicast trigger feature.

Use **undo dot1x multicast-trigger** to disable the 802.1X multicast trigger feature.

Syntax

dot1x multicast-trigger

undo dot1x multicast-trigger

Default

The 802.1X multicast trigger feature is enabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

The multicast trigger feature enables the device to act as the initiator. The device periodically multicasts EAP-Request/Identity packets out of a port to detect 802.1X clients and trigger authentication. You can use the **dot1x timer tx-period** command to set the interval for sending multicast EAP-Request/Identity packets.

Examples

Enable the multicast trigger feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x multicast-trigger
```

dot1x packet-detect enable

Use **dot1x packet-detect enable** to enable packet detection for 802.1X authentication.

Use **undo dot1x packet-detect enable** to restore the default.

NOTE:

This command is supported only in Release 6348P01 and later

Syntax

dot1x packet-detect enable

undo dot1x packet-detect enable

Default

Packet detection for 802.1X authentication is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

When packet detection for 802.1X authentication is enabled on a port, the device sends detection packets to 802.1X users connected to that port at offline detection intervals set by using the offline detection timer. If the device does not receive a response from a user after it has made the maximum packet transmission attempts within an offline detection interval, it logs off that user and requests the RADIUS server to stop accounting for the user.

When packet detection for 802.1X authentication and 802.1X offline detection are both enabled, the device processes an 802.1X user as follows:

- If 802.1X offline detection determines that a user is online, the device does not send detection packets to that user.
- If 802.1X offline detection determines that a user is offline, the device does not immediately logs off that user. Instead, the device sends a detection packet to that user. It will log off that user if it does not receive a response from that user after it has made the maximum packet transmission attempts within an offline detection interval.

To ensure that the device is aware of user IP address changes, enable ARP snooping and ND snooping in conjunction with packet detection for 802.1X authentication. If you do not enable ARP snooping or ND snooping, the device is unaware of user IP address changes. As a result, the device still sends detection packets to the users' original IP addresses and falsely log off these users.

Examples

Enable packet detection for 802.1X authentication.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x packet-detect enable
```

dot1x packet-detect retry

Use **dot1x packet-detect retry** to set the maximum number of attempts for sending a detection packet to an 802.1X user.

Use **undo dot1x packet-detect retry** to restore the default.

NOTE:

This command is supported only in Release 6348P01 and later

Syntax

dot1x packet-detect retry *retries*

undo dot1x packet-detect retry

Default

The device sends a detection packet to an 802.1X user for a maximum of two times.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

retries: Sets the maximum number of attempts for sending a detection packet to an 802.1X user. The value range is 1 to 10.

Usage guidelines

When packet detection for 802.1X authentication is enabled on a port, the device sends detection packets to 802.1X users connected to that port at offline detection intervals set by using the offline detection timer. If the device does not receive a response from a user after it has made the maximum packet transmission attempts within an offline detection interval, it logs off that user and requests the RADIUS server to stop accounting for the user.

If the device fails to send a detection packet to an 802.1X user because it does not obtain the IP address of that user when that user just comes online, the device still decreases the maximum packet transmission attempts by 1. To prevent an 802.1X user from being logged off because the device does not obtain the IP address of that user when that user just comes online, the device increases the maximum number of packet transmission attempts by 10 on the basis of the original configuration.

Examples

Set the maximum number of attempts to 8 for sending a detection packet to an 802.1X user.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x packet-detect retry 8
```

Related commands

dot1x packet-detect enable

dot1x port-control

Use **dot1x port-control** to set the authorization state for the port.

Use **undo dot1x port-control** to restore the default.

Syntax

dot1x port-control { **authorized-force** | **auto** | **unauthorized-force** }

undo dot1x port-control

Default

The default port authorization state is **auto**.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

authorized-force: Places the port in authorized state, enabling users on the port to access the network without authentication.

auto: Places the port initially in unauthorized state to allow only EAPOL packets to pass, and places the port in authorized state after a user passes authentication. You can use this option in most scenarios.

unauthorized-force: Places the port in unauthorized state, denying any access requests from users on the port.

Usage guidelines

You can use this command to set the port authorization state to determine whether a client is granted access to the network.

Examples

Set the authorization state of GigabitEthernet 1/0/1 to **unauthorized-force**.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x port-control unauthorized-force
```

dot1x port-method

Use **dot1x port-method** to specify an access control method for the port.

Use **undo dot1x port-method** to restore the default.

Syntax

dot1x port-method { **macbased** | **portbased** }

undo dot1x port-method

Default

MAC-based access control applies.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

macbased: Uses MAC-based access control on the port to separately authenticate each user attempting to access the network. Using this method, when an authenticated user logs off, no other online users are affected.

portbased: Uses port-based access control on the port. Using this method, once an 802.1X user passes authentication on the port, any subsequent user can access the network through the port without authentication. When the authenticated user logs off, all other users are logged off.

Usage guidelines

If online 802.1X users are present on a port, changing its access control method will cause the online users to go offline.

Examples

Configure GigabitEthernet 1/0/1 to implement port-based access control.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x port-method portbased
```

dot1x re-authenticate

Use **dot1x re-authenticate** to enable the 802.1X periodic reauthentication feature.

Use **undo dot1x re-authenticate** to disable the 802.1X periodic reauthentication feature.

Syntax

dot1x re-authenticate

undo dot1x re-authenticate

Default

The 802.1X periodic reauthentication feature is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

Periodic reauthentication enables the access device to periodically authenticate online 802.1X users on a port. This feature tracks the connection status of online users and updates the authorization attributes assigned by the server, such as the ACL and VLAN.

You can use the **dot1x timer reauth-period** command to configure the interval for reauthentication.

If periodic reauthentication is triggered for a user while that user is waiting for online synchronization, the system performs online synchronization and does not perform reauthentication for the user.

Examples

Enable the 802.1X periodic reauthentication feature on GigabitEthernet 1/0/1, and set the periodic reauthentication interval to 1800 seconds.

```
<Sysname> system-view
[Sysname] dot1x timer reauth-period 1800
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x re-authenticate
```

dot1x retry

Use **dot1x retry** to set the maximum number of attempts for sending an authentication request to a client.

Use **undo dot1x retry** to restore the default.

Syntax

dot1x retry *retries*

undo dot1x retry

Default

A maximum of two attempts are made to send an authentication request to a client.

Views

System view

Predefined user roles

network-admin

Parameters

retries: Specifies the maximum number of attempts for sending an authentication request to a client. The value range is 1 to 10.

Usage guidelines

The access device retransmits an authentication request to a client in any of the following situations:

- The device does not receive any responses from the client within the username request timeout interval. The timer is set by using the **dot1x timer tx-period** *tx-period-value* command for the EAP-Request/Identity packet.
- The device does not receive any responses from the client within the client timeout interval. The timer is set by using the **dot1x timer supp-timeout** *supp-timeout-value* command for the EAP-Request/MD5-Challenge packet.

The access device stops retransmitting the request, if it has made the maximum number of request transmission attempts but still received no response.

Examples

Set the maximum number of attempts to 9 for sending an authentication request to a client.

```
<Sysname> system-view
[Sysname] dot1x retry 9
```

Related commands

display dot1x

dot1x timer

dot1x server-recovery online-user-sync

Use **dot1x server-recovery online-user-sync** to enable 802.1X online user synchronization.

Use **undo dot1x server-recovery online-user-sync** to disable 802.1X online user synchronization.

Syntax

dot1x server-recovery online-user-sync

undo dot1x server-recovery online-user-sync

Default

802.1X online user synchronization is disabled. The device does not synchronize online 802.1X user information on a port with a RADIUS server after the RADIUS server recovers from the unreachable state.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

IMPORTANT:

This command takes effect only when the device uses an IMC RADIUS server to authenticate 802.1X users.

To ensure that the RADIUS server maintains the same online 802.1X user information as the device after the server state changes from unreachable to reachable, use this feature.

This feature synchronizes online 802.1X user information between the device and the RADIUS server when the RADIUS server state is detected having changed from unreachable to reachable.

When synchronizing online 802.1X user information on a port with the RADIUS server, the device initiates 802.1X authentication in turn for each authenticated online 802.1X user to the RADIUS server.

If synchronization fails for an online user, the device logs off that user unless the failure occurs because the server has become unreachable again.

The amount of time required to complete online user synchronization increases as the number of online users grows. This might result in an increased delay for new 802.1X users and users in the critical VLAN to authenticate or reauthenticate to the RADIUS server and come online.

To have this feature take effect, you must use it in conjunction with the RADIUS server status detection feature, which is configurable with the **radius-server test-profile** command. When you configure this feature, make sure the detection interval is shorter than the RADIUS server quiet timer configured by using the **timer quiet** command in RADIUS scheme view. The server state changes to active on expiration of the quiet timer regardless of its actual reachability. Setting a shorter detection interval than the quiet timer prevents the RADIUS server status detection feature from falsely reporting the server reachability.

For more information about the RADIUS server status detection feature, see AAA configuration in *Security Configuration Guide*.

Examples

Enable 802.1X online user synchronization on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x server-recovery online-user-sync
```

timer quiet (RADIUS scheme view)

dot1x timer

Use **dot1x timer** to set an 802.1X timer.

Use **undo dot1x timer** to restore the default of an 802.1X timer.

Syntax

dot1x timer { **ead-timeout** *ead-timeout-value* | **handshake-period** *handshake-period-value* | **quiet-period** *quiet-period-value* | **reauth-period** *reauth-period-value* | **server-timeout** *server-timeout-value* | **supp-timeout** *supp-timeout-value* | **tx-period** *tx-period-value* | **user-aging** { **auth-fail-vlan** | **critical-vlan** | **guest-vlan** } *aging-time-value* }

undo dot1x timer { **ead-timeout** | **handshake-period** | **quiet-period** | **reauth-period** | **server-timeout** | **supp-timeout** | **tx-period** | **user-aging** { **auth-fail-vlan** | **critical-vlan** | **guest-vlan** } }

Default

The following 802.1X timers apply:

- EAD rule timer: 30 minutes.
- Handshake timer: 15 seconds.
- Quiet timer: 60 seconds.
- Periodic reauthentication timer: 3600 seconds.
- Server timeout timer: 100 seconds.
- Client timeout timer: 30 seconds.
- Username request timeout timer: 30 seconds.
- User aging timers for all applicable types of 802.1X VLANs: 1000 seconds.

Views

System view

Predefined user roles

network-admin

Parameters

ead-timeout *ead-timeout-value*: Sets the EAD rule timer in minutes. The value range for the *ead-timeout-value* argument is 1 to 1440.

handshake-period *handshake-period-value*: Sets the handshake timer in seconds. The value range for the *handshake-period-value* argument is 5 to 1024.

quiet-period *quiet-period-value*: Sets the quiet timer in seconds. The value range for the *quiet-period-value* argument is 10 to 120.

reauth-period *reauth-period-value*: Sets the periodic reauthentication timer in seconds. The value range for the *reauth-period-value* argument is 60 to 7200 prior to Release 6342. As from Release 6343P08, the value range for this argument is 60 to 86400.

server-timeout *server-timeout-value*: Sets the server timeout timer in seconds. The value range for the *server-timeout-value* argument is 100 to 300.

supp-timeout *supp-timeout-value*: Sets the client timeout timer in seconds. The value range for the *supp-timeout-value* argument is 1 to 120.

tx-period *tx-period-value*: Sets the username request timeout timer in seconds. The value range for the *tx-period-value* argument is 1 to 120.

user-aging: Sets the user aging timer for a type of 802.1X VLAN.

auth-fail-vlan: Specifies 802.1X Auth-Fail VLANs.

critical-vlan: Specifies 802.1X critical VLANs.

guest-vlan: Specifies 802.1X guest VLANs.

aging-time-value: Sets the user aging timer. The value range is 60 to 2147483647 seconds.

Usage guidelines

In most cases, the default settings are sufficient. You can edit the timers, depending on the network conditions.

- In a low-speed network, increase the client timeout timer.
- In a vulnerable network, set the quiet timer to a high value.
- In a high-performance network with quick authentication response, set the quiet timer to a low value.
- In a network with authentication servers of different performance, adjust the server timeout timer.

The network device uses the following 802.1X timers:

- **EAD rule timer (ead-timeout)**—Sets the lifetime of each EAD rule. When the timer expires or the user passes authentication, the rule is removed. If users fail to download the EAD client or fail to pass authentication before the timer expires, they must reconnect to the network to access the free IP.
- **Handshake timer (handshake-period)**—Sets the interval at which the access device sends client handshake requests to check the online status of a client that has passed authentication. If the device does not receive a response after sending the maximum number of handshake requests, it considers that the client has logged off.
- **Quiet timer (quiet-period)**—Starts when a client fails authentication. The access device must wait the time period before it can process the authentication attempts from the client.
- **Periodic reauthentication timer (reauth-period)**—Sets the interval at which the network device periodically reauthenticates online 802.1X users. To enable 802.1X periodic reauthentication on a port, use the **dot1x re-authenticate** command.
- **Server timeout timer (server-timeout)**—Starts when the access device sends a RADIUS Access-Request packet to the authentication server. If no response is received when this timer expires, the 802.1X authentication fails.

  To avoid forced logoff before the server timeout timer expires, set the server timeout timer to a value that is lower than or equal to the product of the following values:

  - The maximum number of RADIUS packet transmission attempts set by using the **retry** command in RADIUS scheme view.
  - The RADIUS server response timeout timer set by using the **timer response-timeout** command in RADIUS scheme view.

  For information about setting the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer, see AAA configuration in *Security Configuration Guide*.
- **Client timeout timer (supp-timeout)**—Starts when the access device sends an EAP-Request/MD5-Challenge packet to a client. If no response is received when this timer expires, the access device retransmits the request to the client.
- **Username request timeout timer (tx-period)**—Starts when the device sends an EAP-Request/Identity packet to a client in response to an authentication request. If the device does not receive a response before this timer expires, it retransmits the request. The timer also sets the interval at which the network device sends multicast EAP-Request/Identity packets to detect clients that cannot actively request authentication.

- **User aging timer (`user-aging`)**—Sets the user aging timer for a type of 802.1X VLAN.

  If you enable 802.1X unauthenticated user aging, you can set a user aging timer for Auth-Fail, critical, or guest VLANs. The user aging timer for a type of 802.1X VLAN determines how long a user can stay in that type of VLAN.

  For more information about how user aging operates, see the usage guidelines for the **`dot1x unauthenticated-user aging enable`** command.

  Do not set a user aging timer to a multiple of the username request timeout timer (the **`dot1x timer tx-period`** command). If you do so, the aging timer will not take effect.

The change to the periodic reauthentication timer applies to the users that have been online only after the old timer expires. Other timer changes take effect immediately on the device.

Examples

Set the server timeout timer to 150 seconds.

```
<Sysname> system-view
[Sysname] dot1x timer server-timeout 150
```

Related commands

`display dot1x`

`dot1x unauthenticated-user aging enable`

`timer response-timeout` (RADIUS scheme view)

dot1x timer reauth-period

Use **`dot1x timer reauth-period`** to set the 802.1X periodic reauthentication timer on a port.

Use **`undo dot1x timer reauth-period`** to restore the default.

Syntax

`dot1x timer reauth-period` *`reauth-period-value`*

`undo dot1x timer reauth-period`

Default

No 802.1X periodic reauthentication timer is configured on a port. The port uses the global 802.1X periodic reauthentication timer.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

`reauth-period-value`: Sets the 802.1X periodic reauthentication timer in seconds. The value range for the *`reauth-period-value`* argument is 60 to 7200 prior to Release 6342. As from Release 6343P08, the value range for this argument is 60 to 86400..

Usage guidelines

The device reauthenticates online 802.1X users on a port at the specified periodic reauthentication interval when the port is enabled with periodic reauthentication. To enable periodic reauthentication on a port, use the **`dot1x re-authenticate`** command.

A change to the periodic reauthentication timer applies to online users only after the old timer expires.

The device selects a periodic reauthentication timer for 802.1X reauthentication in the following order:

1. Server-assigned reauthentication timer.
2. Port-specific reauthentication timer.
3. Global reauthentication timer.
4. Default reauthentication timer.

Examples

Set the 802.1X periodic reauthentication timer to 60 seconds on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x timer reauth-period 60
```

dot1x unauthenticated-user aging enable

Use **dot1x unauthenticated-user aging enable** to 802.1X unauthenticated user aging.

Use **undo dot1x unauthenticated-user aging enable** to disable 802.1X unauthenticated user aging.

Syntax

dot1x unauthenticated-user aging enable

undo dot1x unauthenticated-user aging enable

Default

User aging is enabled for 802.1X users that have not been authenticated or have not passed authentication.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

802.1X unauthenticated user aging applies to users added to 802.1X guest, critical, or Auth-Fail VLANs because they have not been authenticated or have failed authentication.

When a user in one of those VLANs ages out, the device removes the user from the VLAN and deletes the MAC address entry for the user from the access port.

The 802.1X user aging mechanism on a port depends on its access control mode.

- If the port uses port-based access control, a user aging timer starts when the port is assigned to the critical or Auth-Fail VLAN. When the aging timer expires, the port is removed from the VLAN and all MAC address entries for users in the VLAN are also removed.
- If the port uses MAC-based access control, a user aging timer starts for each 802.1X user when they are assigned to the Auth-Fail, critical, or guest VLAN. When the aging timer for a user expires, the device removes that user from the VLAN.

For users in one of those VLANs on one port to be authenticated successfully and come online on another port, enable this feature. In any other scenarios, disable this feature as a best practice.

The removed users will be unable to access any network resources until after another authentication is triggered.

Examples

Disable 802.1X user aging on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] undo dot1x unauthenticated-user aging enable
```

Related commands

dot1x unicast-trigger

Use **dot1x unicast-trigger** to enable the 802.1X unicast trigger feature.

Use **undo dot1x unicast-trigger** to disable the 802.1X unicast trigger feature.

Syntax

dot1x unicast-trigger

undo dot1x unicast-trigger

Default

The 802.1X unicast trigger feature is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

The unicast trigger feature enables the access device to initiate 802.1X authentication when the device receives a data frame from an unknown source MAC address. The device sends a unicast EAP-Request/Identity packet to the unknown source MAC address. It will retransmit the packet if it does not receive any responses within a period of time (set by using the **dot1x timer tx-period** command). This process continues until the maximum number of request attempts (set by using the **dot1x retry** command) is reached.

As a best practice, do not use the unicast trigger on a port that performs port-based access control. If you do so, users on the port might fail to come online correctly.

Examples

Enable the unicast trigger feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x unicast-trigger
```

dot1x user-ip freeze

Use **dot1x user-ip freeze** to enable 802.1X user IP freezing.

Use **undo dot1x user-ip freeze** to disable 802.1X user IP freezing.

Syntax

dot1x user-ip freeze

undo dot1x user-ip freeze

Default

802.1X user IP freezing is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

This command prevents 802.1X-generated IPSG bindings from being updated because of user IP changes. For information about IP source guard commands, see "IP source guard commands."

Examples

Enable 802.1X user IP freezing on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] dot1x user-ip freeze
```

reset dot1x access-user

Use **reset dot1x access-user** to log off 802.1X users.

Syntax

reset dot1x access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username* | **vlan** *vlan-id*]

Views

User view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

mac *mac-address*: Specifies an 802.1X user by its MAC address. The *mac-address* argument is in the format of H-H-H.

username *username*: Specifies an 802.1X user by its name. The *username* argument is a case-sensitive string of 1 to 253 characters.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID. The value range for the *vlan-id* argument is 1 to 4094.

Usage guidelines

This command is supported only in Release 6318P01 and later.

Use this command to log off the specified 802.1X users and clear information about these users from the device. These users must perform 802.1X authentication to come online again.

With a VLAN specified, this command logs off the following 802.1X users:

- Users that have passed 802.1X authentication and have been assigned the specified VLAN as the authorization VLAN by the server.
- Users that stay in the specified VLAN after they have passed 802.1X authentication, because they have not been assigned an authorization VLAN yet.
- Users that are performing 802.1X authentication in the specified VLAN.

To identify the VLAN in which a user is staying, use the **display mac-address** command.

If you do not specify any parameters, the **reset dot1x access-user** command logs off all 802.1X users on the device.

Examples

Log off all 802.1X users on GigabitEthernet 1/0/1.

```
<Sysname> reset dot1x access-user interface gigabitethernet 1/0/1
```

Related commands

display dot1x connection

reset dot1x guest-vlan

Use **reset dot1x guest-vlan** to remove users from the 802.1X guest VLAN on a port.

Syntax

reset dot1x guest-vlan interface *interface-type interface-number* [**mac-address** *mac-address*]

Views

User view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

mac-address *mac-address*: Specifies the MAC address of an 802.1X user in the guest VLAN. If you do not specify this option, the command removes all 802.1X users from the 802.1X guest VLAN on the port.

Examples

Remove the 802.1X user with MAC address 1-1-1 from the 802.1X guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> reset dot1x guest-vlan interface gigabitethernet 1/0/1 mac-address 1-1-1
```

Related commands

dot1x guest-vlan

reset dot1x statistics

Use **reset dot1x statistics** to clear 802.1X statistics.

Syntax

reset dot1x statistics [**interface** *interface-type interface-number*]

Views

User view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command clears 802.1X statistics on all ports.

Examples

Clear 802.1X statistics on GigabitEthernet 1/0/1.

```
<Sysname> reset dot1x statistics interface gigabitethernet 1/0/1
```

Related commands

Table 1 Command output

Field	Description
MAC authentication	Whether MAC authentication is enabled globally.
Authentication method	Authentication method for MAC authentication: CHAP or PAP.
Username format	User account type: MAC-based or shared. • If MAC-based accounts are used, this field displays the format settings for the username. For example, **MAC address in lowercase(xxxxxxxxxxxx)** indicates that the MAC address is in hexadecimal notation without hyphens, and letters are in lower case. • If a shared account is used, this field displays **Fixed account**.
Username	Username for MAC authentication. • If MAC-based accounts are used, this field displays **mac**. • If a shared account is used, this field displays the username of the shared account for MAC authentication users. By default, the username is **mac**.

Field	Description
Password	Password for MAC authentication. • If the MAC address of each user is used as the password or if a shared account is used but no password is configured, this field displays **Not configured**. • If a password is configured, this field displays a string of asterisks (******).
MAC range accounts	MAC authentication user accounts specific to MAC address ranges.
MAC address	MAC address.
Mask	MAC address mask. A MAC address and a mask together specify a MAC address range.
Username	Username for the users in the MAC address range.
Offline detect period	Offline detection timer.
Quiet period	Quiet timer.
Server timeout	Server timeout timer.
Reauth period	Periodic MAC reauthentication timer in seconds.
User aging period for critical VLAN	Aging timer in seconds for users in critical VLANs.
User aging period for guest VLAN	Aging timer in seconds for users in guest VLANs.
Authentication domain	MAC authentication domain specified in system view. If no authentication domain is specified in system view, this field displays **Not configured, use default domain**.
Online MAC-auth wired users	Number of wired online MAC authentication users, including users that have passed MAC authentication and users that are performing MAC authentication.
Silent MAC users	Information about silent MAC addresses.
MAC address	Silent MAC address.
VLAN ID	ID of the VLAN to which the silent MAC address belongs.
From port	Name of the port that marks the MAC address as a silent MAC address.
Port index	Index of the port that marks the MAC address as a silent MAC address.
GigabitEthernet1/0/1 is link-up	Status of the link on GigabitEthernet 1/0/1. In this example, the link is up.
MAC authentication	Status of MAC authentication on the port: • Enabled. • Enabled (but NOT effective). This value is displayed if MAC authentication is enabled when the device does not have available ACL resources. • Disabled.
Carry User-IP	Whether user IP addresses are included in MAC authentication requests.
Authentication domain	MAC authentication domain specified for the port.
Auth-delay timer	Whether MAC authentication delay is enabled on the port.
Auth-delay period	MAC authentication delay timer.

Field	Description
Periodic reauth	Whether periodic MAC reauthentication is enabled on the port.
Reauth period	Periodic MAC reauthentication timer on the port.
Re-auth server-unreachable	Action taken when no server is reachable for MAC reauthentication: • **Logoff**—Logs off online MAC authentication users. • **Online**—Keeps MAC authenticated users online.
Guest VLAN	MAC authentication guest VLAN configured on the port. If no MAC authentication guest VLAN is configured, this field displays **Not configured**.
Guest VLAN reauthentication	This field is not supported in the current software version. Status of guest VLAN reauthentication in MAC authentication, which is **Enabled** or **Disabled**.
Guest VLAN auth-period	Authentication interval for users in the MAC authentication guest VLAN on the port.
Critical VLAN	MAC authentication critical VLAN configured on the port. If no MAC authentication critical VLAN is configured, this field displays **Not configured**.
Critical voice VLAN	Whether the MAC authentication critical voice VLAN feature is enabled on the port.
Host mode	MAC authentication VLAN mode for users moving from one VLAN to another on the port: • **Single VLAN**—Single-VLAN mode. • **Multiple VLAN**—Multi-VLAN mode.
Offline detection	Status of MAC authentication offline detection: • Enabled. • Disabled.
Authentication order	If parallel processing of MAC authentication and 802.1X authentication is disabled, this field displays **Default**. If parallel processing of MAC authentication and 802.1X authentication is enabled, this field displays **Parallel**.
User aging	Status of the aging feature for unauthenticated MAC authentication users on a port: • Enabled. • Disabled.
Server-recovery online-user-sync	Status of online user synchronization for MAC authentication on the port: • Enabled. • Disabled.
Guest VSI reauthentication	This field is not supported in the current software version. Status of guest VSI reauthentication in MAC authentication, which is **Enabled** or **Disabled**.
Auto-tag feature	This field is not supported in the current software version. Status of the authorization VLAN auto-tag feature: • **Enabled**. • **Disabled**.
VLAN tag configuration ignoring	This field is not supported in the current software version.

Field	Description
	Status of the ignore-config mode: • **Enabled**. • **Disabled**.
Max online users	Maximum number of concurrent online users allowed on the port.
Authentication attempts: successful 1, failed 0	MAC authentication statistics, including the number of successful and unsuccessful authentication attempts.
MAC address	MAC address of the online user.
Auth state	User status: • **Authenticated**—The user has passed MAC authentication. • **Unauthenticated**—The user has not passed MAC authentication.

display mac-authentication connection

Use **display mac-authentication connection** to display information about online MAC authentication users.

Syntax

display mac-authentication connection [**open**] [**interface** *interface-type interface-number* | **slot** *slot-number* | **user-mac** *mac-address* | **user-name** *user-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

open: Displays information only about MAC authentication users that use nonexistent usernames or incorrect passwords for network access in open authentication mode. If you do not specify this keyword, the command displays information about all online MAC authentication users.

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command displays information about online MAC authentication users for all ports.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays information about online MAC authentication users for all member devices.

user-mac *mac-address*: Specifies an online MAC authentication user by its MAC address. The *mac-address* argument represents the MAC address of the user, in the form of H-H-H. If you do not specify an online MAC authentication user, this command displays all online MAC authentication user information.

user-name *user-name*: Specifies an online MAC authentication user by its username. The user name is a case-sensitive string of 1 to 55 characters, and it can include the domain name. If you do not specify an online MAC authentication user, this command displays all online MAC authentication user information.

Examples

Display information about all online MAC authentication users.

```
<Sysname> display mac-authentication connection
Total connections: 1
Slot ID: 0
User MAC address: 0015-e9a6-7cfe
Access interface: GigabitEthernet1/0/1
Username: ias
User access state: Successful
Authentication domain: macusers
IPv4 address: 192.168.1.1
IPv6 address: 2000:0:0:0:1:2345:6789:abcd
Initial VLAN: 1
Authorization untagged VLAN: 100
Authorization tagged VLAN: N/A
Authorization VSI: N/A
Authorization ACL number/name: 3001
Authorization dynamic ACL name: N/A
Authorization user profile: N/A
Authorization CAR: N/A
Authorization URL: N/A
Termination action: Radius-request
Session timeout period: 2 sec
Offline detection: 100 sec (server-assigned)
Packet detection:
  Max attempts: 5
  Remaining attempts: 3
  Source IPv4 address: 192.168.1.3
  Source IPv4 mask: 255.255.0.0
Online from: 2013/03/02  13:14:15
Online duration: 0h 2m 15s
```

Table 2 Command output

Field	Description
Total connections	Total number of online MAC authentication users.
User MAC address	MAC address of the user.
Access interface	Interface through which the user accesses the device.
User access state	Access state of the user: • **Successful**—The user passes MAC authentication and comes online. • **Open**—The user uses a nonexistent username or an incorrect password to come online in open authentication mode.
Authentication domain	MAC authentication domain to which the user belongs.
IPv4 address	IPv4 address of the user. If no user IPv4 address is available, this field is not displayed.
IPv6 address	IPv6 address of the user.

Field	Description
	If no user IPv6 address is available, this field is not displayed.
Initial VLAN	VLAN that holds the user before MAC authentication.
Authorization untagged VLAN	Untagged VLAN assigned to the user.
Authorization tagged VLAN	Tagged VLAN assigned to the user.
Authorization VSI	This field is not supported in the current software version. VSI assigned to the user.
Authorization ACL number/name	Number or name of the static ACL assigned to the user. If no static ACL is assigned to the user, this field displays **N/A**. If the ACL assignment fails, this field displays **(NOT effective)** next to the ACL number or name.
Authorization dynamic ACL name	This field is supported only in Release 6331 and later. Name of the dynamic ACL assigned to the user. If no dynamic ACL is assigned to the user, this field displays **N/A**. If the ACL assignment fails, this field displays **(NOT effective)** next to the ACL name.
Authorization user profile	User profile assigned to the user.
Authorization CAR	This field is not supported in the current software version. Authorization CAR attributes assigned by the server. If no authorization CAR attributes are assigned, this field displays **N/A**.
Authorization URL	Redirect URL assigned to the user.
Termination action	Action attribute assigned by the server to terminate the user session: • **Default**—Logs off the online authenticated user when the server-assigned session timeout timer expires. This attribute does not take effect when periodic MAC reauthentication is enabled and the periodic reauthentication timer is shorter than the server-assigned session timeout timer. • **Radius-request**—Reauthenticates the online user when the server-assigned session timeout timer expires, regardless of whether the periodic MAC reauthentication feature is enabled or not. If the device performs local authentication, this field displays **N/A**.
Session timeout period	Session timeout timer assigned by the server.
Offline detection	Offline detection setting for the user: • **Ignore (command-configured)**—The device does not perform offline detection for the user. The setting is configured from the CLI. • ***timer* (command-configured)**—Represents the offline detection timer. The timer is configured from the CLI, • **Ignore (server-assigned)**—The device does not perform offline detection for the user. The setting is assigned by a RADIUS server. • ***timer* (server-assigned)**—Represents the offline detection timer. The timer is assigned by a RADIUS server.
Packet detection	Information about the packet detection feature. This field is supported only in Release 6348P01 and later.
Max attempts	Maximum number of attempts for sending a detection packet to the user. This field is supported only in Release 6348P01 and later.
Remaining attempts	Remaining number of attempts for sending a detection packet to the user. The device decreases the number by 1 each time it makes an

Field	Description
	attempt to send the detection packet to the user. This field is supported only in Release 6348P01 and later.
Source IPv4 address	IP address specified for calculating the source IP address of ARP detection packets. If no IP address is specified, this field displays 0.0.0.0. This field is supported only in Release 6348P01 and later.
Source IPv4 mask	Mask specified for calculating the source IP address of ARP detection packets. If no mask is specified, this field displays 0.0.0.0. This field is supported only in Release 6348P01 and later.
Online from	Time from which the MAC authentication user came online.
Online duration	Online duration of the MAC authentication user.

display mac-authentication mac-address

Use **display mac-authentication mac-address** to display the MAC addresses of MAC authentication users in a type of MAC authentication VLAN.

Syntax

display mac-authentication mac-address { **critical-vlan** | **guest-vlan** } [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

critical-vlan: Specifies MAC authentication critical VLANs.

guest-vlan: Specifies MAC authentication guest VLANs.

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command displays the MAC addresses of MAC authentication users in the specified type of MAC authentication VLAN on all ports.

Usage guidelines

The displayed MAC addresses and MAC address count might not include all MAC addresses if a large number of MAC authentication users are performing authentication frequently.

Examples

Display the MAC addresses of MAC authentication users in the MAC authentication guest VLANs on all ports.

```
<Sysname> display mac-authentication mac-address guest-vlan
Total MAC addresses: 10
Interface: GigabitEthernet1/0/1        Guest VLAN: 3           Aging time: N/A
MAC addresses: 8
  0800-2700-9427    0800-2700-2341    0800-2700-2324    0800-2700-2351
  0800-2700-5627    0800-2700-2251    0800-2700-8624    0800-2700-3f51
```

```
Interface: GigabitEthernet1/0/2        Guest VLAN: 5            Aging time: 30 sec
MAC addresses: 2
  0801-2700-9427    0801-2700-2341
```

Table 3 Command output

Field	Description
Total MAC addresses	Total number of MAC addresses in the specified type of VLAN on the specified port or all ports.
Interface	Access port of MAC authentication users.
Type VLAN	VLAN that contains the MAC authentication users. The *Type* argument has the following values: • Critical VLAN. • Guest VLAN.
Aging time	MAC address aging time in seconds. This field displays **N/A** if the MAC addresses do not age out.
MAC addresses	Number of matching MAC addresses on a port.
xxxx-xxxx-xxxx	MAC address.

Related commands

`mac-authentication critical vlan`

`mac-authentication guest-vlan`

mac-authentication

Use **`mac-authentication`** to enable MAC authentication globally or on a port.

Use **`undo mac-authentication`** to disable MAC authentication globally or on a port.

Syntax

`mac-authentication`

`undo mac-authentication`

Default

MAC authentication is disabled globally or on any port.

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

To use MAC authentication on a port, you must enable the feature both globally and on the port.

Examples

Enable MAC authentication globally.

```
<Sysname> system-view
```

```
[Sysname] mac-authentication
```

Enable MAC authentication on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication
```

Related commands

display mac-authentication

mac-authentication access-user log enable

Use **mac-authentication access-user log enable** to enable MAC authentication user logging.

Use **undo mac-authentication access-user log enable** to disable MAC authentication user logging.

Syntax

mac-authentication access-user log enable [**failed-login** | **logoff** | **successful-login**] *

undo mac-authentication access-user log enable [**failed-login** | **logoff** | **successful-login**] *

Default

MAC authentication user logging is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

failed-login: Logs MAC authentication user login failures.

logoff: Logs MAC authentication user logoffs.

successful-login: Logs successful MAC authentication user logins.

Usage guidelines

To prevent excessive MAC authentication user log entries, use this feature only if you need to analyze abnormal MAC authentication user logins or logouts.

If you do not specify any parameters, this command enables all types of MAC authentication user logs.

Examples

Enable logging MAC authentication user login failures.

```
<Sysname> system-view
[Sysname] mac-authentication access-user log enable failed-login
```

Related commands

info-center source maca logfile deny (*Network Management and Monitoring Command Reference*)

mac-authentication authentication-method

Use **mac-authentication authentication-method** to specify an authentication method for MAC authentication.

Use **undo mac-authentication authentication-method** to restore the default.

Syntax

mac-authentication authentication-method { **chap** | **pap** }

undo mac-authentication authentication-method

Default

The device uses PAP for MAC authentication.

Views

System view

Predefined user roles

network-admin

Parameters

chap: Configures the access device to use the Challenge Handshake Authentication Protocol (CHAP) to communicate with the RADIUS server.

pap: Configures the access device to use the Password Authentication Protocol (PAP) to communicate with the RADIUS server.

Usage guidelines

RADIUS-based MAC authentication supports the following authentication methods:

- **PAP**—Transports usernames and passwords in plain text. The authentication method applies to scenarios that do not require high security.
- **CHAP**—Transports usernames in plain text and passwords in encrypted form over the network. CHAP is more secure than PAP.

Examples

Configure the device to use CHAP for MAC authentication.

```
<Sysname> system-view
[Sysname] mac-authentication authentication-method chap
```

Related commands

display mac-authentication

mac-authentication carry user-ip

Use **mac-authentication carry user-ip** to include user IP addresses in MAC authentication requests sent to an IMC server.

Use **undo mac-authentication carry user-ip** to restore the default.

Syntax

mac-authentication carry user-ip [**exclude-ip acl** *acl-number*]

undo mac-authentication carry user-ip

Default

A MAC authentication request does not include the user IP address.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

exclude-ip: Specifies an ACL-based filter to identify source IP addresses that can or cannot trigger MAC authentication.

acl *acl-number*: Specifies a basic ACL. The value range for the *acl-number* argument is 2000 to 2999.

Usage guidelines

IMPORTANT:

This command can only operate in conjunction with an IMC server.

To avoid IP conflicts that result from changes to static IP addresses, use this command on a port that has MAC authentication users with static IP addresses.

This command adds user IP addresses to the MAC authentication requests sent to the authentication server. When MAC authentication is triggered for a user, the device checks the user's IP address for invalidity.

- If the IP address is valid, the device sends a MAC authentication request with the IP address included.
- If the IP address is not a valid host IP address or the triggering packet does not contain an IP address, the device does not initiate MAC authentication.
- If the packet is a DHCP packet with a source IP address of 0.0.0.0, the device sends a MAC authentication request without including the IP address. In this case, the IMC server does not examine the user IP address when it performs authentication.

Upon receipt of the authentication request that includes a user's IP address, the IMC server compares the user's IP and MAC addresses with its IP-MAC mappings.

- If an exact match is found or if no match is found, the user passes MAC authentication. In the latter case, the server creates an IP-MAC mapping for the user.
- If a mapping is found for the MAC address but the IP addresses do not match, the user fails the MAC authentication.

If the user host is configured with IPv6, the device might receive packets that contain an IPv6 link-local address, which starts with fe80. MAC authentication failure or incorrect MAC-IP binding will occur if this address is used in MAC authentication. To avoid these issues, configure a basic ACL to exclude the IPv6 IP addresses that start with fe80.

When you configure the ACL, follow these guidelines:

- The specified ACL number represents an IPv4 ACL and an IPv6 ACL with the same number. For example, if the ACL number is 2000, you specify both IPv4 ACL 2000 and IPv6 ACL 2000. The IPv4 ACL and the IPv6 ACL will be used to process IPv4 packets and IPv6 packets, respectively.
- Use permit rules to identify source IP addresses that are valid for MAC authentication. Use deny rules to identify source IP addresses that cannot trigger MAC authentication.
- In the rules, only the action keyword (permit or deny) and the source IP match criterion can take effect.
- As a best practice, configure a deny rule to exclude the IPv6 IP addresses that start with fe80 from triggering MAC authentication.
- If you configure permit rules, add a **deny all** rule at the bottom of the ACL.

Do not use this command in conjunction with the **mac-authentication guest-vlan** command on a port. If both commands are used, the device cannot perform MAC authentication for a user once that user is added to the MAC authentication guest VLAN.

Examples

Include user IP addresses in MAC authentication requests on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication carry user-ip
```

Include user IP addresses in MAC authentication requests on GigabitEthernet 1/0/1 and deny users that use IPv6 link-local addresses from performing MAC authentication on the port.

```
<Sysname> system-view
[Sysname] acl ipv6 basic 2000
[Sysname-acl-ipv6-basic-2000] rule deny source fe80:0::0:0 16
[Sysname-acl-ipv6-basic-2000] quit
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication carry user-ip exclude-ip acl 2000
```

Related commands

mac-authentication

mac-authentication critical vlan

Use **mac-authentication critical vlan** to configure a MAC authentication critical VLAN on a port.

Use **undo mac-authentication critical vlan** to restore the default.

Syntax

mac-authentication critical vlan *critical-vlan-id*

undo mac-authentication critical vlan

Default

No MAC authentication critical VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

critical-vlan-id: Specifies a VLAN as the MAC authentication critical VLAN. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created.

Usage guidelines

The MAC authentication critical VLAN accommodates users that have failed MAC authentication because all the servers in their ISP domains are unreachable. Users in the critical VLAN can access network resources in the critical VLAN.

The critical VLAN feature takes effect when MAC authentication is performed only through RADIUS servers. If a MAC authentication user fails local authentication after RADIUS authentication, the user is not assigned to the critical VLAN.

Before you delete a VLAN that has been set as a MAC authentication critical VLAN, use the **undo mac-authentication critical vlan** command to remove the critical VLAN configuration.

Examples

Configure VLAN 100 as the MAC authentication critical VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication critical vlan 100
```

Related commands

display mac-authentication

reset mac-authentication critical vlan

mac-authentication critical-voice-vlan

Use **mac-authentication critical-voice-vlan** to enable the MAC authentication critical voice VLAN feature on a port.

Use **undo mac-authentication critical-voice-vlan** to restore the default.

NOTE:

This command is not supported on the following switch series:

- S5000E-X.
- S5110V2-SI.
- S5000V3-EI.
- S5000V5-EI.
- S5000X-EI.
- WAS6000.

Syntax

mac-authentication critical-voice-vlan

undo mac-authentication critical-voice-vlan

Default

The MAC authentication critical voice VLAN feature is disabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

The MAC authentication critical voice VLAN on a port accommodates MAC authentication voice users that have failed authentication because none of the RADIUS servers in their ISP domain are reachable.

Before you enable the MAC authentication critical voice VLAN feature on the port, make sure the following requirements are met:

- The port is configured with the voice VLAN.

  To configure a voice VLAN on a port, use the **voice-vlan enable** command (see *Layer 2—LAN Switching Command Reference*).

- LLDP is enabled both globally and on the port.

  The device uses LLDP to identify voice users. For information about LLDP commands, see *Layer 2—LAN Switching Command Reference*.
- A MAC authentication critical VLAN is configured on the port. This setting ensures that a voice user is assigned to the critical VLAN if it has failed authentication for unreachability of RADIUS servers before the device recognizes it as a voice user. If a MAC authentication critical VLAN is not available, the voice user might be logged off instead.

Examples

Enable the MAC authentication critical voice VLAN feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication critical-voice-vlan
```

mac-authentication domain

Use **mac-authentication domain** to specify a global or port-specific authentication domain.

Use **undo mac-authentication domain** to restore the default.

Syntax

mac-authentication domain *domain-name*

undo mac-authentication domain

Default

The system default authentication domain is used. For more information about the default authentication domain, see the **domain default enable** command in "AAA commands."

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

domain-name: Specifies the name of an ISP domain, a case-insensitive string of 1 to 255 characters.

Usage guidelines

The global authentication domain applies to all MAC authentication-enabled ports. An authentication domain specified in Layer 2 Ethernet interface view applies only to the port. You can specify different authentication domains on different ports.

A port chooses an authentication domain for MAC authentication users in the following order:

1. Authentication domain specified on the port.

2. Global authentication domain specified in system view.
3. Default authentication domain.

Examples

Specify ISP domain **domain1** as the global MAC authentication domain.

```
<Sysname> system-view
[Sysname] mac-authentication domain domain1
```

Specify ISP domain **aabbcc** as the MAC authentication domain on GigabitEthernet 1/0/1.

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication domain aabbcc
```

Related commands

domain default enable

mac-authentication guest-vlan

Use **mac-authentication guest-vlan** to configure a MAC authentication guest VLAN on a port.

Use **undo mac-authentication guest-vlan** to restore the default.

Syntax

mac-authentication guest-vlan *guest-vlan-id*

undo mac-authentication guest-vlan

Default

No MAC authentication guest VLAN exists on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

guest-vlan-id: Specifies a VLAN as the MAC authentication guest VLAN. The value range for the VLAN ID is 1 to 4094. Make sure the VLAN has been created.

Usage guidelines

The MAC authentication guest VLAN accommodates users that have failed MAC authentication for any reason other than server unreachable. For example, the VLAN accommodates users with invalid passwords entered. You can deploy a limited set of network resources in the MAC authentication guest VLAN. For example, a software server for downloading software and system patches.

Before you delete a VLAN that has been set as a MAC authentication guest VLAN, use the **undo mac-authentication guest-vlan** command to remove the guest VLAN configuration.

Examples

Configure VLAN 100 as the MAC authentication guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication guest-vlan 100
```

Related commands

display mac-authentication

reset mac-authentication guest-vlan

mac-authentication guest-vlan auth-period

Use **mac-authentication guest-vlan auth-period** to set the interval at which the device authenticates users in the MAC authentication guest VLAN.

Use **undo mac-authentication guest-vlan auth-period** to restore the default.

Syntax

mac-authentication guest-vlan auth-period *period-value*

undo mac-authentication guest-vlan auth-period

Default

The device authenticates users in the MAC authentication guest VLAN every 30 seconds.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

period-value: Sets the authentication interval for users in the MAC authentication guest VLAN. The value range is 1 to 3600, in seconds.

Examples

Set the authentication interval to 150 seconds for users in the MAC authentication guest VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication guest-vlan auth-period 150
```

Related commands

display mac-authentication

mac-authentication guest-vlan

mac-authentication host-mode multi-vlan

Use **mac-authentication host-mode multi-vlan** to enable multi-VLAN mode for MAC authentication users on a port.

Use **undo mac-authentication host-mode** to restore the default.

Syntax

mac-authentication host-mode multi-vlan

undo mac-authentication host-mode

Default

MAC authentication operates in single-VLAN mode on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

To accommodate IP phone services or any other applications that are sensitive to delay or service interruption in a multi-VLAN environment, enable MAC authentication multi-VLAN mode.

In multi-VLAN mode, the port forwards traffic from a user in different VLANs without reauthentication if the user has been authenticated and come online in any VLAN on the port. Free of reauthentication, traffic from an online user can be sent in different VLANs without delay or service interruption.

Examples

Enable MAC authentication multi-VLAN mode on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication host-mode multi-vlan
```

Related commands

display mac-authentication

port-security mac-move permit

mac-authentication mac-range-account

Use **mac-authentication mac-range-account** to configure a username and password for MAC authentication users in a MAC address range.

Use **undo mac-authentication mac-range-account** to restore the default.

Syntax

mac-authentication mac-range-account mac-address *mac-address* **mask** { *mask* | *mask-length* } **account** *name* **password** { **cipher** | **simple** } *string*

undo mac-authentication mac-range-account { **all** | **mac-address** *mac-address* }

Default

No username or password is specifically configured for MAC authentication users in a MAC address range. The global user account policy applies to the users.

Views

System view

Predefined user roles

network-admin

Parameters

mac-address *mac-address*: Specifies a MAC address in the format of H-H-H.

mask *mask*: Specifies a MAC address mask, in the format of H-H-H. Make sure the most significant bits of the MAC address mask in binary format are consecutive 1s.

mask *mask-length*: Specifies a MAC address mask length, in the range of 1 to 48.

account *name*: Specifies a username. The name is a case-sensitive string of 1 to 55 characters, and cannot include the at sign (@).

password: Specifies the user password.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

all: Specifies all MAC address ranges.

Usage guidelines

This command is supported only in Release 6310 or later.

Use this command to configure user account settings for users in a MAC address range (for example, users with a specific OUI). For users in the specified range, this command has higher priority than the **mac-authentication user-name-format** command.

You can configure a maximum of 16 MAC address ranges. However, you must make sure the MAC address ranges do not overlap.

If you configure user account settings multiple times for the same MAC address range, the most recent configuration overwrites the previous configuration.

The **mac-authentication mac-range-account** command applies only to unicast MAC addresses.

- If you specify a MAC address range that contains only multicast MAC addresses, execution of this command will fail.
- If you specify a MAC address range that contains both unicast and multicast MAC addresses, the command takes effect only on unicast MAC addresses.

The all-zero MAC address is invalid for MAC authentication. Users with the all-zero MAC address cannot pass MAC authentication.

Examples

Configure a user account for MAC addresses that start with **aaaa**. Set the MAC address mask to **ffff-0000-0000**, the username to **user1**, and the password to **1234** in plaintext form.

```
<Sysname> system-view
[Sysname] mac-authentication mac-range-account mac-address aaaa-0000-0000 mask
ffff-0000-0000 account user1 password simple 1234
```

mac-authentication user-name-format

mac-authentication max-user

Use **mac-authentication max-user** to set the maximum number of concurrent MAC authentication users on a port.

Use **undo mac-authentication max-user** to restore the default.

Syntax

mac-authentication max-user *max-number*

undo mac-authentication max-user

Default

A port allows a maximum of 4294967295 concurrent MAC authentication users.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

max-number: Sets the maximum number of concurrent MAC authentication users on the port. The value range for this argument is 1 to 4294967295.

Usage guidelines

Set the maximum number of concurrent MAC authentication users on a port to prevent the system resources from being overused. When the maximum number is reached, the port denies subsequent MAC authentication users.

Examples

Configure GigabitEthernet 1/0/1 to support a maximum of 32 concurrent MAC authentication users.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication max-user 32
```

Related commands

mac-authentication offline-detect enable

Use **mac-authentication offline-detect enable** to enable MAC authentication offline detection on a port.

Use **undo mac-authentication offline-detect enable** to disable MAC authentication offline detection.

Syntax

mac-authentication offline-detect enable

undo mac-authentication offline-detect enable

Default

MAC authentication offline detection is enabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

IMPORTANT:

When MAC authentication offline detection is used, make sure the aging timer value for dynamic MAC address entries is less than or equal to the default offline detection timer value (300 seconds) for MAC authentication users. The aging timer for dynamic MAC address entries is configurable with the **mac-address timer aging** *seconds* command.

The MAC authentication offline detection feature monitors the online status of MAC authentication users. This feature uses an offline detection timer to set the interval that the device must wait for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user.

To set the offline detection timer, use the **mac-authentication timer** command.

Examples

Disable MAC authentication offline detection on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] undo mac-authentication offline-detect enable
```

Related commands

mac-authentication timer

mac-authentication offline-detect mac-address

Use **mac-authentication offline-detect mac-address** to configure MAC authentication offline detection for a MAC authentication user.

Use **undo mac-authentication offline-detect mac-address** to restore the default.

Syntax

mac-authentication offline-detect mac-address *mac-address* { **ignore** | **timer** *offline-detect-value* [**check-arp-or-nd-snooping**] }

undo mac-authentication offline-detect mac-address *mac-address*

Default

The offline detection settings configured on access ports take effect and the offline detection timer set in system view is used.

Views

System view

Predefined user roles

network-admin

Parameters

mac-address: Specifies a MAC address in the format of H-H-H, excluding multicast, all-zero, and all-F MAC addresses.

ignore: Skips offline detection for the specified user.

timer *offline-detect-value*: Specifies the offline detection timer for the specified user. The value range is 60 to 2147483647 seconds.

check-arp-or-nd-snooping: Uses the ARP snooping or ND snooping table in offline detection to determine the offline state of the user.

Usage guidelines

Use this command to set offline detection parameters specific to a MAC authentication user. To have this command take effect, you must make sure MAC authentication offline detection is enabled on the user's access port. The user-specific offline detection settings take effect on the online users immediately after they are configured.

Use this command as follows:

- Set an offline detection timer specific to a user and control whether to use the ARP snooping or ND snooping table to determine the offline state of the user.
  - If the ARP snooping or ND snooping table is used, the device searches the ARP snooping or ND snooping table before it checks for traffic from the user within the detection interval. If a matching ARP snooping or ND snooping entry is found, the device resets the offline detection timer and the user stays online. If the offline detection timer expires because the device has not found a matching snooping entry for the user or received traffic from the user, the device disconnects the user.
  - If the ARP or ND snooping table is not used, the device disconnects the user if it has not received traffic from that user before the offline detection timer expires.

  When disconnecting the user, the device also notifies the RADIUS server (if any) to stop user accounting.
- Skip offline detection for the user. You can choose this option if the user is a dumb terminal. A dumb terminal might fail to come online again after it is logged off by the offline detection feature.

The device uses the offline detection settings for a user in the following sequence:

1. User-specific offline detection settings.
2. Offline detection settings assigned to the user by the RADIUS server. The settings include the offline detection timer, use of the ARP or ND snooping table in offline detection, and whether to ignore offline detection.
3. Port-based offline detection settings.

Examples

Disable MAC authentication offline detection for the MAC authentication user with MAC address 000a-eb29-7511.

```
<Sysname> system-view
[Sysname] mac-authentication offline-detect mac-address 000a-eb29-7511 ignore
```

Enable MAC authentication offline detection for the MAC authentication user with MAC address 000a-eb29-7511, and set the offline detection timer to 24 hours.

```
<Sysname> system-view
[Sysname] mac-authentication offline-detect mac-address 000a-eb29-7511 timer 86400
```

mac-authentication packet-detect enable

Use **mac-authentication packet-detect enable** to enable packet detection for MAC authentication.

Use **undo mac-authentication packet-detect enable** to restore the default.

Syntax

mac-authentication packet-detect enable

undo mac-authentication packet-detect enable

Default

Packet detection for MAC authentication is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

This command is supported only in Release 6348P01 and later.

When packet detection for MAC authentication is enabled on a port, the device sends detection packets to MAC authentication users connected to that port at offline detection intervals set by using the offline detection timer. If the device does not receive a response from a user after it has made the maximum packet transmission attempts within an offline detection interval, it logs off that user and requests the RADIUS server to stop accounting for the user.

When packet detection for MAC authentication and MAC authentication offline detection are both enabled, the device processes a MAC authentication user as follows:

- If MAC authentication offline detection determines that a user is online, the device does not send detection packets to that user.
- If MAC authentication offline detection determines that a user is offline, the device does not immediately logs off that user. Instead, the device sends a detection packet to that user. It will log off that user if it does not receive a response from that user after it has made the maximum packet transmission attempts within an offline detection interval.

MAC authentication uses ARP request packets to detect the online status of IPv4 users and uses NS packets to detect the online status of IPv6 users.

To ensure that the device is aware of user IP address changes, enable ARP snooping and ND snooping in conjunction with packet detection for MAC authentication. If you do not enable ARP snooping or ND snooping, the device is unaware of user IP address changes. As a result, the device still sends detection packets to the users' original IP addresses and falsely log off these users.

Examples

Enable packet detection for MAC authentication on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication packet-detect enable
```

mac-authentication packet-detect retry

Use **mac-authentication packet-detect retry** to set the maximum number of attempts for sending a detection packet to a MAC authentication user.

Use **undo mac-authentication packet-detect retry** to restore the default.

Syntax

mac-authentication packet-detect retry *retries*

undo mac-authentication packet-detect retry

Default

The device sends a detection packet to a MAC authentication user for a maximum of two times.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

retries: Sets the maximum number of attempts for sending a detection packet to a MAC authentication user. The value range is 1 to 10.

Usage guidelines

This command is supported only in Release 6348P01 and later.

When packet detection for MAC authentication is enabled on a port, the device sends detection packets to MAC authentication users connected to that port at offline detection intervals set by using the offline detection timer. If the device does not receive a response from a user after it has made the maximum packet transmission attempts within an offline detection interval, it logs off that user and requests the RADIUS server to stop accounting for the user.

To prevent a MAC authentication user from being logged off because the device does not obtain the IP address of that user when that user just comes online, the device increases the maximum number of packet transmission attempts by 10 on the basis of the original configuration.

Examples

On GigabitEthernet 1/0/1, set the maximum number of attempts to 8 for sending a detection packet to a MAC authentication user.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication packet-detect retry 8
```

mac-authentication parallel-with-dot1x

Use **mac-authentication parallel-with-dot1x** to enable parallel processing of MAC authentication and 802.1X authentication on a port.

Use **undo mac-authentication parallel-with-dot1x** to restore the default.

Syntax

mac-authentication parallel-with-dot1x

undo mac-authentication parallel-with-dot1x

Default

Parallel processing of MAC authentication and 802.1X authentication is disabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

When you configure this command on a port, follow these restrictions and guidelines:

- Make sure the port meets the following requirements:

    - The port is configured with both 802.1X authentication and MAC authentication and performs MAC-based access control for 802.1X authentication.
    - The port is enabled with the 802.1X unicast trigger.
- For the port to perform MAC authentication before it is assigned to the 802.1X guest VLAN, use the **dot1x guest-vlan-delay new-mac** command to delay assigning the port to the 802.1X guest VLAN.

  For information about the **dot1x guest-vlan-delay new-mac** command, see "802.1X commands."
- Do not enable MAC authentication delay on the port. This operation will delay MAC authentication after 802.1X authentication is triggered.
- To configure both 802.1X authentication and MAC authentication on the port, use one of the following methods:
    - Enable the 802.1X and MAC authentication features separately on the port.
    - Enable port security on the port. The port security mode must be **userlogin-secure-or-mac** or **userlogin-secure-or-mac-ext**.

      For information about port security mode configuration, see port security in *Security Configuration Guide*.

Examples

Enable parallel processing of MAC authentication and 802.1X authentication on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication parallel-with-dot1x
```

Related commands

display mac-authentication

mac-authentication re-authenticate

Use **mac-authentication re-authenticate** to enable the periodic MAC reauthentication feature on a port.

Use **undo mac-authentication re-authenticate** to disable the periodic MAC reauthentication feature on a port.

Syntax

mac-authentication re-authenticate

undo mac-authentication re-authenticate

Default

The periodic MAC reauthentication feature is disabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

Periodic MAC reauthentication enables the access device to periodically authenticate online MAC authentication users on a port. This feature tracks the connection status of online users and updates the authorization attributes assigned by the server, such as the ACL and VLAN.

To set the periodic reauthentication timer, use the **mac-authentication timer reauth-period** command in system view or in Ethernet interface view.

If periodic reauthentication is triggered for a user while that user is waiting for online synchronization, the system performs online synchronization and does not perform reauthentication for the user.

Examples

Enable the periodic MAC reauthentication feature on GigabitEthernet 1/0/1 and set the global periodic reauthentication timer to 1800 seconds.

```
<Sysname> system-view
[Sysname] mac-authentication timer reauth-period 1800
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication re-authenticate
```

network-admin

Usage guidelines

IMPORTANT:

This command takes effect only when the device uses an IMC RADIUS server to authenticate MAC authentication users.

To ensure that the RADIUS server maintains the same online MAC authentication user information as the device after the server state changes from unreachable to reachable, use this feature.

This feature synchronizes online MAC authentication user information between the device and the RADIUS server when the RADIUS server state is detected having changed from unreachable to reachable.

When synchronizing online MAC authentication user information on a port with the RADIUS server, the device initiates MAC authentication in turn for each authenticated online MAC authentication user to the RADIUS server.

If synchronization fails for an online user, the device logs off that user unless the failure occurs because the server has become unreachable again.

The amount of time required to complete online user synchronization increases as the number of online users grows. This might result in an increased delay for new MAC authentication users and users in the critical VLAN to authenticate or reauthenticate to the RADIUS server and come online.

To have this feature take effect, you must use it in conjunction with the RADIUS server status detection feature, which is configurable with the **radius-server test-profile** command. For more information about the RADIUS server status detection feature, see AAA configuration in *Security Configuration Guide*.

Examples

Enable online user synchronization for MAC authentication on GigabitEthernet 1/0/1.

```
<Sysname> system-view
```

```
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication server-recovery online-user-sync
```

Related commands

display mac-authentication

radius-server test-profile

timer quiet (RADIUS scheme view)

mac-authentication timer (interface view)

Use **mac-authentication timer** to configure a MAC authentication timer on a port.

Use **undo mac-authentication timer** to restore the default of a MAC authentication timer.

Syntax

mac-authentication timer { **auth-delay** *auth-delay-time* | **reauth-period** *reauth-period-value* }

undo mac-authentication timer { **auth-delay** | **reauth-period** }

Default

No MAC authentication delay timer is set on a port. MAC authentication delay is disabled. MAC authentication starts immediately after it is triggered by a user packet.

No periodic MAC reauthentication timer is set on a port. The port uses the global periodic MAC reauthentication timer.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

auth-delay *auth-delay-time*: Sets the delay time for MAC authentication in seconds. The value range is 1 to 180.

reauth-period *reauth-period-value*: Sets the port-specific periodic MAC reauthentication timer in seconds. The value range is 60 to 7200 prior to Release 6343P08. As from Release 6343P08, the value range for this timer is 60 to 86400.

Usage guidelines

When both 802.1X authentication and MAC authentication are enabled on a port, you can delay MAC authentication so that 802.1X authentication is preferentially triggered. If no 802.1X authentication is triggered or if 802.1X authentication fails within the delay period, the port continues to process MAC authentication.

Do not set the port security mode to **mac-else-userlogin-secure** or **mac-else-userlogin-secure-ext** when you want to use MAC authentication delay. The delay does not take effect on a port in either of the two modes. For more information about port security modes, see "Port security commands."

The device reauthenticates online MAC authentication users on a port at the specified periodic reauthentication interval if the port is enabled with periodic MAC reauthentication. To enable periodic MAC reauthentication on a port, use the **mac-authentication re-authenticate** command.

A change to the port-specific periodic reauthentication timer applies to online users only after the old timer expires.

The device selects a periodic reauthentication timer for MAC reauthentication in the following order:

1. Server-assigned reauthentication timer.
2. Port-specific reauthentication timer.
3. Global reauthentication timer.
4. Default reauthentication timer.

Examples

Enable MAC authentication delay on GigabitEthernet 1/0/1 and set the delay time to 10 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] mac-authentication timer auth-delay 10
```

Related commands

display mac-authentication

port-security port-mode

mac-authentication timer (system view)

Use **mac-authentication timer** to configure a MAC authentication timer.

Use **undo mac-authentication timer** to restore the default of a MAC authentication timer.

Syntax

mac-authentication timer { **offline-detect** *offline-detect-value* | **quiet** *quiet-value* | **reauth-period** *reauth-period-value* | **server-timeout** *server-timeout-value* | **user-aging** { **critical-vlan** | **guest-vlan** } *aging-time-value* }

undo mac-authentication timer { **offline-detect** | **quiet** | **reauth-period** | **server-timeout** | **user-aging** { **critical-vlan** | **guest-vlan** } }

Default

The following MAC authentication timers apply:

- The offline detection timer is 300 seconds.
- The quiet timer is 60 seconds.
- The global periodic MAC reauthentication timer is 3600 seconds.
- The server timeout timer is 100 seconds.
- User aging timer for a type of MAC authentication VLAN: 1000 seconds.

Views

System view

Predefined user roles

network-admin

Parameters

offline-detect *offline-detect-value*: Sets the offline detection timer. The value range is 60 to 2147483647 seconds.

quiet *quiet-value*: Sets the quiet timer. The value range is 1 to 3600 seconds.

reauth-period *reauth-period-value*: Sets the global periodic MAC reauthentication timer, in seconds. The value range is 60 to 7200 prior to Release 6343P08. As from Release 6343P08, the value range for this timer is 60 to 86400.

server-timeout *server-timeout-value*: Sets the server timeout timer. The value range is 100 to 300 seconds.

user-aging: Sets the user aging timer for a type of MAC authentication VLAN.

critical-vlan: Specifies MAC authentication critical VLANs.

guest-vlan: Specifies MAC authentication guest VLANs.

aging-time-value: Sets the user aging timer. The value range is 60 to 2147483647 seconds.

Usage guidelines

MAC authentication uses the following timers:

- **Offline detection timer**—Sets the interval that the device must wait for traffic from a user before the device determines that the user is idle. If the device has not received traffic from a user before the timer expires, the device logs off that user and requests the accounting server to stop accounting for the user. This timer takes effect only when the MAC authentication offline detection feature is enabled.

  As a best practice, set the MAC address aging timer to the same value as the offline detection timer. This operation prevents a MAC authenticated user from being logged off within the offline detect interval because of MAC address entry expiration.
- **Quiet timer**—Sets the interval that the device must wait before the device can perform MAC authentication for a user that has failed MAC authentication. All packets from the MAC address are dropped during the quiet time. This quiet mechanism prevents repeated authentication from affecting system performance.
- **Periodic MAC reauthentication timer**—Sets the interval at which the device reauthenticates online MAC authentication users on a port if the port is enabled with periodic MAC reauthentication. A change to the global periodic reauthentication timer applies to online users only after the old timer expires.
- **Server timeout timer**—Sets the interval that the device waits for a response from a RADIUS server before the device determines that the RADIUS server is unavailable. If the timer expires during MAC authentication, the user fails MAC authentication.

  To avoid forced logoff before the server timeout timer expires, set the server timeout timer to a value that is lower than or equal to the product of the following values:

  - The maximum number of RADIUS packet transmission attempts set by using the **retry** command in RADIUS scheme view.
  - The RADIUS server response timeout timer set by using the **timer response-timeout** command in RADIUS scheme view.

  For information about setting the maximum number of RADIUS packet transmission attempts and the RADIUS server response timeout timer, see AAA configuration in *Security Configuration Guide*.
- **User aging timer (user-aging)**—Sets the user aging timer for a type of MAC authentication VLAN.

  If you enable user aging for unthenticated MAC authentication user, you can set a user aging timer for MAC authentication critical or guest VLANs. The user aging timer for a type of MAC authentication VLAN determines how long a user can stay in that type of VLAN.

  For more information about how user aging operates, see the usage guidelines for the **mac-authentication unauthenticated-user aging enable** command.

  Do not set the user aging timer for users in MAC authentication guest VLANs to a multiple of the authentication interval for them. If you do so, the aging timer will not take effect. The authentication interval for MAC authentication users in a guest VLAN is configurable with the **mac-authentication guest-vlan auth-period** command.

Examples

Set the server timeout timer to 150 seconds.

```
<Sysname> system-view
[Sysname] mac-authentication timer server-timeout 150
```

mac-authentication unauthenticated-user aging enable

Use **mac-authentication unauthenticated-user aging enable** to enable unauthenticated MAC authentication user aging.

Use **undo mac-authentication unauthenticated-user aging enable** to disable unauthenticated MAC authentication user aging.

Syntax

mac-authentication unauthenticated-user aging enable

undo mac-authentication unauthenticated-user aging enable

Default

Unauthenticated MAC authentication user aging is enabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

Unauthenticated MAC authentication user aging applies to users added to a MAC authentication guest or critical VLAN because they have not been authenticated or have failed authentication.

When a user in one of those VLANs ages out, the device removes the user from the VLAN and deletes the MAC address entry for the user from the access port.

For users in one of those VLANs on one port to be authenticated successfully and come online on another port, enable this feature. In any other scenarios, disable this feature as a best practice.

Examples

Disable unauthenticated MAC authentication user aging on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] undo mac-authentication unauthenticated-user aging enable
```

Related commands

mac-authentication timer

mac-authentication user-name-format

Use **mac-authentication user-name-format** to configure the type of user accounts for MAC authentication users.

Use **undo mac-authentication user-name-format** to restore the default.

Syntax

mac-authentication user-name-format { **fixed** [**account** *name*] | **mac-address** [{ **with-hyphen** [**separator colon**] | **without-hyphen** } [**lowercase** | **uppercase**]] } [**password** { **cipher** | **simple** } *string*]

undo mac-authentication user-name-format

Default

Each user's MAC address is used as the username and password for MAC authentication. A MAC address is in hexadecimal notation without hyphens, and letters are in lower case.

Views

System view

Predefined user roles

network-admin

Parameters

fixed: Uses a shared account for all MAC authentication users.

account *name*: Specifies the username for the shared account. The name is a case-sensitive string of 1 to 55 characters, excluding the at sign (@). If you do not specify a username, the default name **mac** applies.

mac-address: Uses MAC-based user accounts for MAC authentication users.

with-hyphen: Includes hyphens in MAC addresses. The MAC addresses use the xx-xx-xx-xx-xx-xx format or the XX-XX-XX-XX-XX-XX format.

separator colon: Uses the colon (:) in place of the hyhen (-) as the separator in MAC addresses. The MAC addresses use the xx:xx:xx:xx:xx:xx format or the XX:XX:XX:XX:XX:XX format. If you do not specify the colon as the separator, the hypen is used. The colon seperator is supported only in Release 6340 and later.

without-hyphen: Excludes hyphens from a MAC address, for example, xxxxxxxxxxxx.

lowercase: Specifies letters in lower case.

uppercase: Specifies letters in upper case.

password: Specifies the user password. If you do not specify a password for MAC-based user accounts, the device uses the MAC address of each user in the specified format as the password. If you do not specify a password for the shared account, the shared account does not have a password.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 63 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

If you specify the MAC-based user account format, the device uses the MAC address of a user as the username for MAC authentication of the user. This user account type ensures high authentication security. However, you must create on the authentication server a user account for each user, using the MAC address of the user as the username.

If you specify a shared user account, the device uses the specified username and password for MAC authentication of all users. Because all MAC authentication users use a single account for

authentication, you only need to create one account on the authentication server. This user account type is suitable for trusted networks.

Examples

Configure a shared account for MAC authentication users, and set the username to **abc** and password to plaintext string of **xyz**.

```
<Sysname> system-view
[Sysname] mac-authentication user-name-format fixed account abc password simple xyz
```

Use the MAC address of each user as both the username and password for MAC authentication. The MAC addresses are in hexadecimal notation with hyphens, and letters are in upper case.

```
<Sysname> system-view
[Sysname] mac-authentication user-name-format mac-address with-hyphen uppercase
```

display mac-authentication

reset mac-authentication access-user

Use **reset mac-authentication access-user** to log off MAC authentication users.

Syntax

reset mac-authentication access-user [**interface** *interface-type interface-number* | **mac** *mac-address* | **username** *username* | **vlan** *vlan-id*]

Views

User view

Predefined user roles

network-admin

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

mac *mac-address*: Specifies a MAC authentication user by its MAC address. The *mac-address* argument is in the format of H-H-H.

username *username*: Specifies a MAC authentication user by its name. The *username* argument is a case-sensitive string of 1 to 253 characters.

vlan *vlan-id*: Specifies a VLAN by its VLAN ID. The value range for the *vlan-id* argument is 1 to 4094.

Usage guidelines

This command is supported only in Release 6318P01 and later.

Use this command to log off the specified MAC authentication users and clear information about these users from the device. These users must perform MAC authentication to come online again.

With a VLAN specified, this command logs off the following MAC authentication users:

- Users that have passed MAC authentication and have been assigned the specified VLAN as their authorization VLAN by the server.
- Users that stay in the specified VLAN after they have passed MAC authentication, because they have not been assigned an authorization VLAN yet.
- Users that are performing MAC authentication in the specified VLAN.

To identify the VLAN in which a user is staying, use the **display mac-address** command.

If you do not specify any parameters, the **reset mac-authentication access-user** command logs off all MAC authentication users on the device.

Examples

Log off all MAC authentication users on GigabitEthernet 1/0/1.

```
<Sysname> reset mac-authentication access-user interface gigabitethernet 1/0/1
```

Portal commands

captive-bypass enable

Use **captive-bypass enable** to enable the captive-bypass feature.

Use **undo captive-bypass enable** to disable the captive-bypass feature.

Syntax

captive-bypass enable

undo captive-bypass enable

Default

The captive-bypass feature is disabled. The device automatically pushes the portal authentication page to the iOS devices and some Android devices when they are connected to the network.

Views

Portal Web server view

Predefined user roles

network-admin

Usage guidelines

With this feature enabled, the device does not automatically push the portal authentication page to iOS devices and some Android devices when they are connected to the network. The device pushes the portal authentication page only when the user accesses the Internet by using a browser.

Examples

Enable the captive-bypass feature.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] captive-bypass enable
```

Related commands

display portal web-server

default-logon-page

Use **default-logon-page** to specify the default authentication page file for the local portal Web service.

Use **undo default-logon-page** to restore the default.

Syntax

default-logon-page *file-name*

undo default-logon-page

Default

The default authentication page file is **default.zip**.

Views

Local portal Web service view

Predefined user roles

network-admin

Parameters

file-name: Specifies the default authentication page file by the file name (without the file storage directory). The file name is a case-sensitive string of 1 to 91 characters. Valid characters are letters, digits, dots (.) and underscores (_).

Usage guidelines

After you use the **default-logon-page** command to specify the file, the device decompresses the file to get the authentication pages. The device then sets them as the default authentication pages for local portal authentication.

As a best practice for the correct operation of the local portal Web service, use the default authentication page file in the root directory of the device storage medium. To use custom authentication pages, you must strictly follow the related restrictions and guidelines when customizing your own authentication pages. For more information about the restrictions and guidelines, see portal authentication configuration in *Security Configuration Guide*.

Examples

Specify file **pagefile1.zip** as the default authentication page file for local portal authentication.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] default-logon-page pagefile1.zip
```

Table 1 Command output

Field	Description
Portal information of interface	Portal configuration on the interface.

NAS-ID profile	NAS-ID profile on the interface.
Authorization	Authorization information type: ACL or user profile.
Strict checking	Whether strict checking is enabled on portal authorization information.
IPv4	IPv4 portal configuration.
IPv6	IPv6 portal configuration.
Portal status	Portal authentication status on the interface: • **Disabled**—Portal authentication is disabled. • **Enabled**—Portal authentication is enabled. • **Authorized**—The portal authentication server or portal Web server is unreachable. The interface allows users to have network access without authentication.
Portal authentication method	Authentication mode enabled on the interface: • **Direct**—Direct authentication. • **Redhcp**—Re-DHCP authentication. • **Layer3**—Cross-subnet authentication.
Portal Web server	Name of the portal Web server specified on the interface.
Secondary portal Web server	Name of the secondary portal Web server specified on the interface. This field also displays **active** if the secondary Web server is being used. This field is supported only in Release 6348P01 and later.
Portal mac-trigger-server	This field is not supported in the current software version. Name of the MAC binding server specified on the interface.
Authentication domain	Mandatory authentication domain on the interface.
User-dhcp-only	Status of the user-dhcp-only feature: • **Enabled**—Only users with IP addresses obtained through DHCP can perform portal authentication. • **Disabled**—Both users with IP addresses obtained through DHCP and users with static IP addresses can pass authentication to get online.
Pre-auth ip-pool	Name of the IP address pool specified for portal users before authentication.
Max Portal users	Maximum number of portal users allowed on an interface.
Bas-ip	BAS-IP attribute of the portal packets sent to the portal authentication server.
Bas-ipv6	BAS-IPv6 attribute of the portal packets sent to the portal authentication server.
User detection	Configuration for online detection of portal users on the interface, including detection method (ARP, ICMP, ND, or ICMPv6), detection interval, maximum number of detection attempts, and user idle time.
Action for server detection	Portal server detection configuration on the interface: • **Server type**—Type of the server. **Portal server** represents the portal authentication server, and **Web server** represents the portal Web server. • **Server name**—Name of the server. • **Action**—Action triggered by the result of server detection. This field displays **fail-permit** when the portal fail-permit feature is enabled.

Layer3 source network	Information of the portal authentication source subnet.
Destination authentication subnet	Information of the portal authentication destination subnet.
IP address	IP address of the portal authentication subnet.
Mask	Subnet mask of the portal authentication subnet.
Prefix length	Prefix length of the IPv6 portal authentication subnet address.

display portal packet statistics

Use **display portal packet statistics** to display packet statistics for portal authentication servers.

Syntax

display portal packet statistics [**server** *server-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

server *server-name*: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

This command displays statistics on packets the device sent to and received from portal authentication servers.

If you do not specify the **server** *server-name* option, this command displays packet statistics for all portal authentication servers.

Examples

Display packet statistics for portal authentication server **pts**.

```
<Sysname> display portal packet statistics server pts
 Portal server :  pts
 Invalid packets: 0
 Pkt-Type                          Total    Drops    Errors
```

```
REQ_CHALLENGE                3         0         0
ACK_CHALLENGE                3         0         0
REQ_AUTH                     3         0         0
ACK_AUTH                     3         0         0
REQ_LOGOUT                   1         0         0
ACK_LOGOUT                   1         0         0

ACK_INFO                     6         0         0
NTF_USERDISCOVER             0         0         0
NTF_USERIPCHANGE             0         0         0
AFF_NTF_USERIPCHAN           0         0         0
ACK_NTF_LOGOUT               1         0         0
NTF_HEARTBEAT                0         0         0
NTF_USER_HEARTBEAT           2         0         0
ACK_NTF_USER_HEARTBEAT       0         0         0
NTF_CHALLENGE                0         0         0
NTF_USER_NOTIFY              0         0         0
AFF_NTF_USER_NOTIFY          0         0         0
```

Table 2 Command output

Field	Description
Portal server	Name of the portal authentication server.
Invalid packets	Number of invalid packets.
Pkt-Type	Packet type.
Total	Total number of packets.
Drops	Number of dropped packets.
Errors	Number of packets that carry error information.
REQ_CHALLENGE	Challenge request packet the portal authentication server sent to the access device.
ACK_CHALLENGE	Challenge acknowledgment packet the access device sent to the portal authentication server.
REQ_AUTH	Authentication request packet the portal authentication server sent to the access device.
ACK_AUTH	Authentication acknowledgment packet the access device sent to the portal authentication server.
REQ_LOGOUT	Logout request packet the portal authentication server sent to the access device.
ACK_LOGOUT	Logout acknowledgment packet the access device sent to the portal authentication server.
AFF_ACK_AUTH	Affirmation packet the portal authentication server sent to the access device after receiving an authentication acknowledgment packet.
NTF_LOGOUT	Forced logout notification packet the access device sent to the portal authentication server.

REQ_INFO	Information request packet.
ACK_INFO	Information acknowledgment packet.
NTF_USERDISCOVER	User discovery notification packet the portal authentication server sent to the access device.
NTF_USERIPCHANGE	User IP change notification packet the access device sent to the portal authentication server.
AFF_NTF_USERIPCHAN	User IP change success notification packet the portal authentication server sent to the access device.
ACK_NTF_LOGOUT	Forced logout acknowledgment packet the portal authentication server sent to the access device.
NTF_HEARTBEAT	Server heartbeat packet the portal authentication server periodically sent to the access device.
NTF_USER_HEARTBEAT	User synchronization packet the portal authentication server sent to the access device.
ACK_NTF_USER_HEARTBEAT	User synchronization acknowledgment packet the access device sent to the portal authentication server.
NTF_CHALLENGE	Challenge request packet the access device sent to the portal authentication server.
NTF_USER_NOTIFY	User information notification packet the access device sent to the portal authentication server.
AFF_NTF_USER_NOTIFY	NTF_USER_NOTIFY acknowledgment packet the portal authentication server sent to the access device.

Related commands

`reset portal packet statistics`

display portal rule

Use **`display portal rule`** to display portal filtering rules.

Syntax

`display portal rule` { **`all`** | **`dynamic`** | **`static`** } **`interface`** *`interface-type interface-number`* [**`slot`** *`slot-number`*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`all`: Displays all portal filtering rules, including dynamic and static portal filtering rules.

`dynamic`: Displays dynamic portal filtering rules, which are generated after users pass portal authentication. These rules allow packets with specific source IP addresses to pass the interface.

`static`: Displays static portal filtering rules, which are generated after portal authentication is enabled. The interface filters packets by these rules when portal authentication is enabled.

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays portal filtering rules for all member devices.

Examples

Display all portal filtering rules on VLAN-interface 100.

```
<Sysname> display portal rule all interface vlan-interface 100 slot 1
Slot 1:
IPv4 portal rules on Vlan-interface100:
Rule 1:
 Type               : Static
 Action             : Permit
 Protocol           : Any

Table 3 Command output

Field	Description
Rule	Number of the portal filtering rule. IPv4 portal filtering rules and IPv6 portal filtering rules are numbered separately.
Type	Type of the portal filtering rule: • **Static**—Static portal filtering rule. • **Dynamic**—Dynamic portal filtering rule.
Action	Action triggered by the portal filtering rule: • **Permit**—The interface allows packets to pass. • **Redirect**—The interface redirects packets. • **Deny**—The interface forbids packets to pass.
Protocol	Transport layer protocol permitted by the portal-free rule: • **Any**—Permits any transport layer protocol. • **TCP**—Permits TCP. • **UDP**—Permits UDP.
Status	Status of the portal filtering rule: • **Active**—The portal filtering rule is effective. • **Deactive**—The portal filtering rule is not activated.

Source	Source information of the portal filtering rule.
IP	Source IP address.
Mask	Subnet mask of the source IPv4 address.
Prefix length	Prefix length of the source IPv6 address.
Port	Source transport layer port number.
MAC	Source MAC address.
Interface	Layer 2 or Layer 3 interface on which the portal filtering rule is implemented.
VLAN	Source VLAN ID.
Protocol	Transport layer protocol permitted by the portal redirect rule. This field always displays **TCP**.
Destination	Destination information of the portal filtering rule.
IP	Destination IP address.
Port	Destination transport layer port number.
Mask	Subnet mask of the destination IPv4 address.
Prefix length	Prefix length of the destination IPv6 address.
Author ACL	Authorized ACL assigned to authenticated portal users. This field is displayed only for a dynamic portal filtering rule.
Number	Number of the authorized ACL. This field displays **N/A** if the AAA server does not assign an ACL.

display portal server

Use **display portal server** to display information about portal authentication servers.

Syntax

display portal server [*server-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

server-name: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

If you do not specify the *server-name* argument, this command displays information about all portal authentication servers.

Examples

Display information about the portal authentication server **pts**.

```
<Sysname> display portal server pts
Portal server: pts
```

```
Type                 : IMC
IP                   : 192.168.0.111
VPN instance         : Not configured
Port                 : 50100
Server detection     : Timeout 60s  Action: log
User synchronization : Timeout 200s
Status               : Up
```

Table 4 Command output

Field	Description
Type	Portal authentication server type: • **CMCC**—CMCC server. • **IMC**—IMC server.
Portal server	Name of the portal authentication server.
IP	IP address of the portal authentication server.
VPN instance	This field is not supported in the current software version. MPLS L3VPN instance where the portal authentication server resides.
Port	Listening port on the portal authentication server.
Server detection	Parameters for portal authentication server detection: • Detection timeout in seconds. • Action (**log**) triggered by the reachability status change of the portal authentication server.
User synchronization	User idle timeout in seconds for portal user synchronization.

Status	Reachability status of the portal authentication server:
	• **Up**—This value indicates one of the following conditions:
	  ○ Portal authentication server detection is disabled.
	  ○ Portal authentication server detection is enabled and the server is reachable.
	• **Down**—Portal authentication server detection is enabled and the server is unreachable.

Related commands

portal enable

portal server

server-detect (portal authentication server view)

user-sync

display portal user

Use **display portal user** to display information about portal users.

Syntax

display portal user { **all** | **interface** *interface-type interface-number* | **ip** *ipv4-address* | **ipv6** *ipv6-address* } [**verbose**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

all: Displays information about all portal users.

interface *interface-type interface-number*: Displays information about portal users on the specified interface.

ip *ipv4-address*: Specifies the IPv4 address of a portal user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a portal user.

verbose: Displays detailed information about portal users.

Examples

Display information about all portal users.

```
<Sysname> display portal user all
Total portal users: 2
Username: abc
  Portal server: pts
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  000d-88f8-0eab    2.2.2.2           100    Vlan-interface100
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: N/A
    Inbound CAR: N/A
    Outbound CAR: N/A

Username: def
  Portal server: pts
  State: Online
  VPN instance: N/A
  MAC               IP                VLAN   Interface
  000d-88f8-0eac    3.3.3.3           200    Vlan-interface200
  Authorization information:
    DHCP IP pool: N/A
    User profile: N/A
    Session group profile: N/A
    ACL number: 3001
    Inbound CAR: N/A
    Outbound CAR: N/A
```

Table 5 Command output

Field	Description
Total portal users	Total number of portal users.
Username	Name of the user.
Portal server	Name of the portal authentication server.
State	Current state of the portal user: • **Initialized**—The user is initialized and ready for authentication. • **Authenticating**—The user is being authenticated. • **Waiting SetRule**—The user is waiting for authorization information. • **Authorizing**—The user is being authorized. • **Online**—The user is online. • **Waiting Traffic**—The last traffic of the user is to be collected. • **Stop Accounting**—Accounting for the user is stopped. • **Done**—The user goes offline successfully.
VPN instance	This field is not supported in the current software version. MPLS L3VPN instance to which the portal user belongs. If the portal user is on a public network, this field displays **N/A**.
MAC	MAC address of the portal user.
IP	IP address of the portal user.
VLAN	VLAN where the portal user resides.
Interface	Access interface of the portal user.
Authorization information	Authorization information for the portal user.
DHCP IP pool	Name of the authorized IP address pool. If no IP address pool is authorized for the portal user, this field displays **N/A**.
User profile	Authorized user profile: • **N/A**—No user profile is authorized. • **active**—The authorized user profile is applied to the user access interface successfully. • **inactive**—The authorized user profile is not applied to the user access interface or the user profile does not exist on the device.
Session group profile	This field is not supported in the current software version. Authorized session group profile: • **N/A**—No session group profile is authorized. • **active**—The authorized session group profile is applied to the user access interface successfully. • **inactive**—The authorized session group profile is not applied to the user access interface or the session group profile does not exist on the device.
ACL number	Authorized ACL: • **N/A**—No ACL is authorized. • **active**—The authorized ACL is applied to the user access interface successfully. • **inactive**—The authorized ACL is not applied to the user access interface or the ACL does not exist on the device.

Inbound CAR	This field is not supported in the current software version. Authorized inbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **active**—The authorized inbound CAR is applied to the user access interface successfully. • **inactive**—The authorized inbound CAR is not applied to the user access interface. • **N/A**—No inbound CAR is authorized.
Outbound CAR	This field is not supported in the current software version. Authorized outbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **active**—The authorized outbound CAR is applied to the user access interface successfully. • **inactive**—The authorized outbound CAR is not applied to the user access interface. • **N/A**—No outbound CAR is authorized.

Display detailed information about the portal user with IP address 50.50.50.3.

```
<Sysname> display portal user ip 50.50.50.3 verbose
Basic:
  Current IP address: 50.50.50.3
  Original IP address: 30.30.30.2
  Username: user1@hrss
  User ID: 0x18000002
  Access interface: Vlan-interface20
  Service-VLAN/Customer-VLAN: -/-
  MAC address: 0000-0000-0001
  Domain: hrss
  VPN instance: N/A
  Status: Online
  Portal server: test
  Portal authentication method: Direct
AAA:
  Realtime accounting interval: 720s, retry times: 5
  Idle cut: N/A
  Session duration: N/A, remaining: N/A
  Remaining traffic: N/A
  Login time: 2018-01-04 16:13:35 UTC
  Accounting-start fail action: Online
  Accounting-update fail action: Online
  Accounting quota-out action: Offline
  DHCP IP pool: N/A
ACL&QoS&Multicast:
  Inbound CAR: N/A
  Outbound CAR: N/A
  ACL number: 3000 (inactive)
  User profile: N/A
  Session group profile: N/A
```

```
  Max multicast addresses: 4
  Multicast address list: 1.2.3.1, 1.34.33.1, 3.123.123.3, 4.5.6.7

```

Table 6 Command output

Field	Description
Current IP address	IP address of the portal user after passing authentication.
Original IP address	IP address of the portal user during authentication.
Username	Name of the portal user.
User ID	Portal user ID.
Access interface	Access interface of the portal user.
Service-VLAN/Customer-VLAN	Public VLAN/Private VLAN to which the portal user belongs. If no VLAN is configured for the portal user, this field displays **-/-**.
MAC address	MAC address of the portal user.
Domain	ISP domain name for portal authentication.
VPN instance	This field is not supported in the current software version. MPLS L3VPN instance to which the portal user belongs. If the portal user is on a public network, this field displays **N/A**.
Status	Status of the portal user: • **Authenticating**—The user is being authenticated. • **Authorizing**—The user is being authorized. • **Waiting SetRule**—Deploying portal rules to the user. • **Online**—The user is online. • **Waiting Traffic**—Waiting for traffic from the user. • **Stop Accounting**—Stopping accounting for the user. • **Done**—The user is offline.
Portal server	Name of the portal server.
Portal authentication method	Portal authentication method on the access interface: • **Direct**—Direct authentication.

Field	Description
	• **Re-Dhcp**—Re-DHCP authentication. • **Layer3**—Cross-subnet authentication.
AAA	AAA information about the portal user.
Realtime accounting interval	Interval for sending real-time accounting updates, and the maximum number of accounting attempts. If the real-time accounting is not authorized, this field displays **N/A**.
Idle cut	Idle timeout period and the minimum traffic threshold. If idle cut is not authorized, this field displays **N/A**.
direction	Direction of user traffic: • **Both**—Inbound and outbound traffic. • **Inbound**—Inbound traffic. • **Outbound**—Outbound traffic.
Session duration	Session duration and the remaining session time. If the session duration is not authorized, this field displays **N/A**.
Remaining traffic	Remaining traffic for the portal user. If the remaining traffic is not authorized, this field displays **N/A**.
Login time	Time when the user logged in. The field uses the device time format, for example, 2023-1-19 2:42:30 UTC.
Accounting-start fail action	Action to take on the user when the user encounters accounting-start failure: • **Online**—Allow the user to stay online. • **Offline**—Log out the user.
Accounting-update fail action	Action to take on the user when the user encounters accounting-update failure: • **Online**—Allow the user to stay online. • **Offline**—Log out the user.
Accounting quota-out action	Action to take on the user when the data quotas of the user are used up: • **Online**—Allow the user to stay online. • **Offline**—Log out the user.
DHCP IP pool	Authorized DHCP IP address pool. If no DHCP IP address pool is authorized for the portal user, this field displays **N/A**.
Inbound CAR	This field is not supported in the current software version. Authorized inbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **active**—The authorized inbound CAR is applied to the user access interface successfully. • **inactive**—The authorized inbound CAR is not applied to the user access interface. • **N/A**—No inbound CAR is authorized.
Outbound CAR	This field is not supported in the current software version. Authorized outbound CAR: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **active**—The authorized outbound CAR is applied to the user access interface successfully. • **inactive**—The authorized outbound CAR is not applied to the user access interface.

Field	Description
	• **N/A**—No outbound CAR is authorized.
ACL number	Authorized ACL: • **N/A**—No ACL is authorized. • **active**—The authorized ACL is applied to the user access interface successfully. • **inactive**—The authorized ACL is not applied to the user access interface or the ACL does not exist on the device.
User profile	Authorized user profile: • **N/A**—No user profile is authorized. • **active**—The authorized user profile is applied to the user access interface successfully. • **inactive**—The authorized user profile is not applied to the user access interface or the user profile does not exist on the device.
Session group profile	This field is not supported in the current software version. Authorized session group profile: • **N/A**—No session group profile is authorized. • **active**—The authorized session group profile is applied to the user access interface successfully. • **inactive**—The authorized session group profile is not applied to the user access interface or the session group profile does not exist on the device.
Max multicast addresses	Maximum number of multicast groups the portal user can join.
Multicast address list	Multicast group list the portal user can join. If no multicast group is authorized, this field displays **N/A**.
User group	Name of the group where the portal user belongs. This field is invalid if the ID is 0xffffffff.
Flow statistic	Flow statistics for the portal user.
Uplink packets/bytes	Packet and byte statistics of the upstream traffic.
Downlink packets/bytes	Packet and byte statistics of the downstream traffic.
ITA	This field is not supported in the current software version. ITA traffic statistics for the portal user.
Accounting merge	This field is not supported in the current software version. Status of the accounting merge feature: • **Enabled**—The accounting merge feature is enabled. The device merges the ITA traffic of all accounting rates in the ITA policy, and applies the lowest rate to the merged traffic. • **Disabled**—The accounting merge feature is disabled. The device sends separate traffic statistics for each accounting rate to the server.
Traffic separate	This field is not supported in the current software version. Whether to exclude the amount of ITA traffic from the overall traffic statistics sent to the accounting server: • **Enabled**—ITA traffic is excluded from the overall traffic statistics. • **Disabled**—ITA traffic is included in the overall traffic statistics.
Quota-out offline	This field is not supported in the current software version. Whether to prohibit the portal user from accessing the authorized IP

Field	Description
	subnets when the user has used up its ITA data quota: • **Enabled**—User cannot access the authorized IP subnets after its ITA data quota is used up. • **Disabled**—User can access the authorized IP subnets after its ITA data quota is used up.
Level-*n* session duration	This field is not supported in the current software version. Authorized level *n* session duration and the remaining session duration. Level *n* represents the accounting level of the portal user in ITA. If the session duration is not authorized, this field displays **N/A**.
Remaining traffic	This field is not supported in the current software version. Remaining ITA traffic for the portal user.
Traffic action	This field is not supported in the current software version. Action for traffic destined for the authorized IP subnets when the portal user has used up its ITA data quota: • **Permit**—Permits traffic destined for the authorized IP subnets. • **Deny**—Denies traffic destined for the authorized IP subnets.
Inbound CAR	This field is not supported in the current software version. Authorized inbound CAR for ITA traffic: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **active**—The authorized inbound CAR is applied to the user access interface successfully. • **inactive**—The authorized inbound CAR is not applied to the user access interface. • **N/A**—No inbound CAR is authorized.
Outbound CAR	This field is not supported in the current software version. Authorized outbound CAR for ITA traffic: • **CIR**—Committed information rate in bps. • **PIR**—Peak information rate in bps. • **active**—The authorized outbound CAR is applied to the user access interface successfully. • **inactive**—The authorized outbound CAR is not applied to the user access interface. • **N/A**—No outbound CAR is authorized.
Uplink packets/bytes	This field is not supported in the current software version. Packet and byte statistics of the portal user's upstream ITA traffic.
Downlink packets/bytes	This field is not supported in the current software version. Packet and byte statistics of the portal user's downstream ITA traffic.

Related commands

`portal enable`

display portal web-server

Use **`display portal web-server`** to display information about portal Web servers.

Syntax

`display portal web-server` [*`server-name`*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

server-name: Specifies a portal Web server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

If you do not specify the *server-name* argument, this command displays information about all portal Web servers.

Examples

Display information about portal Web server **wbs**.

```
<Sysname> display portal web-server wbs
Portal Web server: wbs
    Type             : IMC
    URL              : http://www.test.com/portal
    URL parameters   : userurl=http://www.test.com/welcome
                       userip=source-address
    VPN instance     : Not configured
    Server detection : Interval: 120s  Attempts: 5  Action: log
    IPv4 status      : Up
    IPv6 status      : Up

```

Table 7 Command output

Field	Description
Type	Portal Web server type: • **CMCC**—CMCC server. • **IMC**—IMC server.
Portal Web server	Name of the portal Web server.
URL	URL of the portal Web server.
URL parameters	URL parameters for the portal Web server.
VPN instance	This field is not supported in the current software version. Name of the MPLS L3VPN where the portal Web server resides.
Server detection	Parameters for portal Web server detection: • Detection interval in seconds. • Maximum number of detection attempts. • Action (**log**) triggered by the reachability status change of the portal Web server.

IPv4 status	Current state of the IPv4 portal Web server:
	• **Up**—This value indicates one of the following conditions:
	  ○ Portal Web server detection is disabled.
	  ○ Portal Web server detection is enabled and the server is reachable.
	• **Down**—Portal Web server detection is enabled and the server is unreachable.

IPv6 status	Current state of the IPv6 portal Web server:
	• **Up**—This value indicates one of the following conditions:
	  ○ Portal Web server detection is disabled.
	  ○ Portal Web server detection is enabled and the server is reachable.
	• **Down**—Portal Web server detection is enabled and the server is unreachable.

Captive-bypass	Status of the captive-bypass feature: **Enabled** or **Disabled**.
If-match	Match rules configured for URL redirection. If no match rules are configured, this field displays **Not configured**.

Related commands

server-detect (portal Web server view)

display web-redirect rule

Use **display web-redirect rule** to display information about Web redirect rules.

Syntax

display web-redirect rule interface *interface-type interface-number* [**slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays Web redirect rules for the master device.

Examples

Display all Web redirect rules on VLAN-interface 100.

```
<Sysname> display web-redirect rule interface vlan-interface 100
IPv4 web-redirect rules on vlan-interface 100:
Rule 1:
 Type               : Dynamic
 Action             : Permit
 Status             : Active
 Source:
    IP            : 192.168.2.114
```

```
    VLAN           : Any

Rule 2:
 Type               : Static
 Action             : Redirect
 Status             : Active
 Source:
    VLAN           : Any
    Protocol       : TCP
 Destination:
    Port           : 80

IPv6 web-redirect rules on vlan-interface 100:
Rule 1:
 Type               : Static
 Action             : Redirect
 Status             : Active
 Source:
    VLAN           : Any
    Protocol       : TCP
 Destination:
    Port           : 80
```

Table 8 Command output

Field	Description
Rule	Number of the Web redirect rule.
Type	Type of the Web redirect rule: • **Static**—Static Web redirect rule, generated when the Web redirect feature takes effect. • **Dynamic**—Dynamic Web redirect rule, generated when a user visits a redirect webpage.
Action	Action in the Web redirect rule: • **Permit**—Allows packets to pass. • **Redirect**—Redirects the packets.
Status	Status of the Web redirect rule: • **Active**—The Web redirect rule is effective. • **Inactive**—The Web redirect rule is not effective.
Source	Source information in the Web redirect rule.
IP	Source IP address.
Mask	Subnet mask of the source IPv4 address.
Prefix length	Prefix length of the source IPv6 address.
VLAN	Source VLAN. If not specified, this field displays **Any**.
Protocol	Transport layer protocol permitted by the Web redirect rule. This field always displays **TCP**.
Destination	Destination information in the Web redirect rule.
Port	Destination transport layer port number. The default port number is 80.

if-match

Use **if-match** to configure a match rule for URL redirection.

Use **undo if-match** to delete a URL redirection match rule.

Syntax

if-match { **original-url** *url-string* **redirect-url** *url-string* [**url-param-encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **user-agent** *string* **redirect-url** *url-string* }

undo if-match { **original-url** *url-string* | **user-agent** *user-agent* }

Default

No URL redirection match rules exist.

Views

Portal Web server view

Predefined user roles

network-admin

Parameters

original-url *url-string*: Specifies a URL string to match the URL in HTTP requests of a portal user. The specified URL must be a complete URL starting with **http://** or **https://**, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

redirect-url *url-string*: Specifies the URL to which the user is redirected. The specified URL must be a complete URL starting with **http://** or **https://**, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

url-param-encryption: Specifies an encryption algorithm to encrypt the parameters carried in the redirection URL. If you do not specify an encryption algorithm, the parameters carried in the redirection URL are not encrypted.

aes: Specifies the AES algorithm.

des: Specifies the DES algorithm.

key: Specifies a key for encryption.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the case-sensitive key string. The string length varies by the selected encryption method:

- If **des cipher** is specified, the string length is 41 characters.
- If **des simple** is specified, the string length is 8 characters.
- If **aes cipher** is specified, the string length is 1 to 73 characters.
- If **aes simple** is specified, the string length is 1 to 31 characters.

user-agent *user-agent*: Specifies a user agent string to match the User-Agent string in HTTP or HTTPS requests. The user agent string is a case-sensitive string of 1 to 255 characters. The User-Agent string in HTTP or HTTPS requests includes information about hardware manufacturer, operating system, browser, and search engine.

Usage guidelines

A URL redirection match rule matches HTTP or HTTPS requests by user-requested URL or User-Agent information, and redirects the matching requests to the specified redirection URL.

For a user to successfully access a redirection URL, configure a portal-free rule to allow HTTP or HTTPS requests destined for the redirection URL to pass. For information about configuring portal-free rules, see the **portal free-rule** command.

For a portal Web server, you can configure the **url** command and the **if-match** command for URL redirection. The **url** command redirects all HTTP or HTTPS requests from unauthenticated users to the portal Web server for authentication. The **if-match** command allows for flexible URL redirection by redirecting specific requests to specific redirection URLs. If both commands are executed, the **if-match** command takes priority to perform URL redirection.

Examples

Configure a match rule to redirect HTTP requests destined for the URL **http://www.abc.com.cn** to the URL **http://192.168.0.1** and use **DES** to encrypt the parameters carried in this redirection URL.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match original-url http://www.abc.com.cn redirect-url
http://192.168.0.1 url-param-encryption des key simple 12345678
```

Configure a match rule to redirect HTTP requests that carry the user agent string **5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36** to the URL **http://192.168.0.1.**

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] if-match user-agent
5.0(WindowsNT6.1)AppleWebKit/537.36(KHTML,likeGecko)Chrome/36.0.1985.125Safari/537.36
redirect-url http://192.168.0.1
```

Related commands

display portal web-server

portal free-rule

url

url-parameter

ip (portal authentication server view)

Use **ip** to specify the IPv4 address of a portal authentication server.

Use **undo ip** to restore the default.

Syntax

ip *ipv4-address* [**key** { **cipher** | **simple** } *string*]

undo ip

Default

The IPv4 address of the portal authentication server is not specified.

Views

Portal authentication server view

Predefined user roles

network-admin

Parameters

ipv4-address: Specifies the IPv4 address of the portal authentication server.

key: Specifies a shared key for communication with the portal authentication server. Portal packets exchanged between the access device and the portal authentication server carry an authenticator that is generated with the shared key. The receiver uses the authenticator to check the correctness of the received portal packets.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

A portal authentication server has only one IPv4 address. Therefore, in portal authentication server view, only one IPv4 address exists. If you execute this command multiple times, the most recent configuration takes effect.

Do not configure the same IPv4 address for different portal authentication servers.

Examples

Specify **192.168.0.111** as the IPv4 address of portal authentication server **pts** and plaintext key **portal** as the shared key for communication with the portal authentication server.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] ip 192.168.0.111 key simple portal
```

Related commands

display portal server

portal server

ipv6

Use **ipv6** to specify the IPv6 address of a portal authentication server.

Use **undo ipv6** to restore the default.

Syntax

ipv6 *ipv6-address* [**key** { **cipher** | **simple** } *string*]

undo ipv6

Default

The IPv6 address of the portal authentication server is not specified.

Views

Portal authentication server view

Predefined user roles

network-admin

Parameters

ipv6-address: Specifies the IPv6 address of the portal authentication server.

key: Specifies a shared key for communication with the portal authentication server. Portal packets exchanged between the access device and the portal authentication server carry an authenticator that is generated with the shared key. The receiver uses the authenticator to check the correctness of the received portal packets.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is a case-sensitive string of 1 to 64 characters. Its encrypted form is a case-sensitive string of 1 to 117 characters.

Usage guidelines

A portal authentication server has only one IPv6 address. Therefore in portal authentication server view, only one IPv6 address exists. If you execute this command multiple times, the most recent configuration takes effect.

Do not configure the same IPv6 address for different portal authentication servers.

Examples

Specify **2000::1** as the IPv6 address of portal authentication server **pts** and plaintext key **portal** as the shared key for communication with the portal authentication server.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] ipv6 2000::1 key simple portal
```

Related commands

display portal server

portal server

port (portal authentication server view)

Use **port** to set the destination UDP port number used by the device to send unsolicited portal packets to the portal authentication server.

Use **undo port** to restore the default.

Syntax

port *port-number*

undo port

Default

The device uses 50100 as the destination UDP port number for unsolicited portal packets.

Views

Portal authentication server view

Predefined user roles

network-admin

Parameters

port-number: Specifies a destination UDP port number the device uses to send unsolicited portal packets to the portal authentication server. The value range for this argument is 1 to 65534.

Usage guidelines

The specified port must be the port that listens to portal packets on the portal authentication server.

Examples

Set the destination UDP port number to **50000** for the device to send unsolicited portal packets to portal authentication server **pts**.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] port 50000
```

Related commands

portal server

portal { bas-ip | bas-ipv6 } (interface view)

Use **portal** { **bas-ip** | **bas-ipv6** } to configure the BAS-IP or BAS-IPv6 attribute carried in the portal packets sent to the portal authentication server.

Use **undo portal** { **bas-ip** | **bas-ipv6** } to restore the default.

Syntax

portal { **bas-ip** *ipv4-address* | **bas-ipv6** *ipv6-address* }

undo portal { **bas-ip** | **bas-ipv6** }

Default

The BAS-IP attribute of an IPv4 portal reply packet sent to the portal authentication server is the source IPv4 address of the packet. The BAS-IPv6 attribute of an IPv6 portal reply packet sent to the portal authentication server is the source IPv6 address of the packet.

The BAS-IP attribute of an IPv4 portal notification packet sent to the portal authentication server is the IPv4 address of the packet's output interface. The BAS-IPv6 attribute of an IPv6 portal notification packet sent to the portal authentication server is the IPv6 address of the packet's output interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv4-address: Specifies BAS-IP for portal packets sent to the portal authentication server. This attribute must be the IPv4 address of an interface on the device. It cannot be 0.0.0.0, 1.1.1.1, a class D address, a class E address, or a loopback address.

ipv6-address: Specifies BAS-IPv6 for portal packets sent to the portal authentication server. This attribute must be the IPv6 address of an interface on the device. It cannot be a multicast address, an all-0 address, or a link-local address.

Usage guidelines

If the device runs Portal 2.0, unsolicited portal packets (such as a logout notification packet) sent to the portal authentication server must carry the BAS-IP attribute. If the device runs Portal 3.0, unsolicited portal packets sent to the portal authentication server must carry the BAS-IP or BAS-IPv6 attribute.

After this command takes effect, the source IP address for unsolicited notification portal packets the device sends to the portal authentication server is the configured BAS IP address. Otherwise, the source IP address of the packets is the IP address of the packet output interface.

You must configure the BAS-IP or BAS-IPv6 attribute on a portal authentication-enabled interface if the following conditions are met:

- The portal authentication server is an H3C IMC server or the portal authentication mode on the interface is re-DHCP.
- The portal device IP address specified on the portal authentication server is not the IP address of the portal packet output interface.

Examples

On interface VLAN-interface 100, configure the BAS-IP attribute as **2.2.2.2** for portal packets sent to the portal authentication server.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal bas-ip 2.2.2.2
```

Related commands

display portal

portal { ipv4-max-user | ipv6-max-user } (interface view)

Use **portal** { **ipv4-max-user** | **ipv6-max-user** } to set the maximum number of portal users allowed on an interface.

Use **undo portal** { **ipv4-max-user** | **ipv6-max-user** } to restore the default.

Syntax

portal { **ipv4-max-user** | **ipv6-max-user** } *max-number*

undo portal { **ipv4-max-user** | **ipv6-max-user** }

Default

The maximum number of portal users allowed on an interface is not limited.

Views

Interface view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of IPv4 or IPv6 portal users allowed on an interface, in the range of 1 to 4294967295.

Usage guidelines

If the specified maximum number is smaller than the number of current online portal users on the interface, the limit can be set successfully. The limit does not impact the online portal users. However, the device does not allow new portal users to log in from the interface until the number drops down below the limit.

Examples

Set the maximum number of IPv4 portal users to 100 on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
```

```
[Sysname–Vlan-interface100] portal ipv4-max-user 100
```

Related commands

display portal user

portal max-user

portal apply web-server (interface view)

Use **portal** [**ipv6**] **apply web-server** to specify a portal Web server. The device redirects the HTTP requests sent by unauthenticated portal users to the portal Web server.

Use **undo portal** [**ipv6**] **apply web-server** to restore the default.

Syntax

portal [**ipv6**] **apply web-server** *server-name* [**fail-permit** | **secondary**]

undo portal [**ipv6**] **apply web-server** [*server-name*]

Default

No portal Web server is specified.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies an IPv6 portal Web server. If the server is an IPv4 portal Web server, do not specify this keyword.

server-name: Specifies a portal Web server by its name, a case-sensitive string of 1 to 32 characters. The name must already exist.

fail-permit: Enables the portal fail-permit feature on the interface. The portal fail-permit feature allows portal users to access the Internet without authentication when the portal Web server is unreachable.

secondary: Specifies the secondary portal Web server. If you do not specify this keyword, this command specifies the primary portal Web server. This keyword is supported only in Release 6348P01 and later.

Usage guidelines

You can enable both IPv4 and IPv6 portal authentication on an interface. Therefore, you can specify both an IPv4 portal Web server and an IPv6 portal Web server on the interface.

When portal fail-permit is enabled for a portal authentication server and a portal Web server on the interface, portal authentication is disabled for users on the interface if either server is unreachable. Portal authentication resumes after both servers become reachable.

For HA, you can specify both a primary portal Web server and a secondary portal Web server. The device preferentially uses the primary portal Web server for portal authentication. If the primary server is unreachable, the device uses the secondary server. Once the primary server becomes reachable, the device forcibly uses the primary server.

To implement automatic primary/secondary server switchover, you must configure server detection for both the primary and secondary portal Web servers.

The fail-permit feature and the secondary portal Web server feature are mutually exclusive. You cannot configure both features for the same server by using this command.

Examples

Specify portal Web server **wbs** on VLAN-interface 100 for portal authentication.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal apply web-server wbs
```

Related commands

display portal

portal fail-permit server

portal web-server

portal authorization strict-checking

Use **portal authorization strict-checking** to enable strict checking on portal authorization information.

Use **undo portal authorization strict-checking** to disable strict checking on portal authorization information.

Syntax

portal authorization { **acl** | **user-profile** } **strict-checking**

undo portal authorization { **acl** | **user-profile** } **strict-checking**

Default

Strict checking on portal authorization information is disabled. If an authorized ACL or user profile does not exist on the device or the user profile fails to be deployed, the user will not be logged out.

Views

Interface view

Predefined user roles

network-admin

Parameters

acl: Enables strict checking on authorized ACLs.

user-profile: Enables strict checking on authorized user profiles.

Usage guidelines

CAUTION:

- The strict checking feature on an interface allows a portal user to stay online only when the authorization information for the user is successfully deployed. The strict checking fails if the authorized ACL or user profile does not exist on the device or the device fails to deploy the user profile.
- You can enable strict checking on the authorized ACL, authorized user profile, or both. If you enable both strict ACL checking and user profile checking, the user will be logged out if either checking fails.

Examples

Enable strict checking on authorized ACLs on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
```

```
[Sysname-Vlan-interface100] portal authorization acl strict-checking
```

Related commands

display portal

portal delete-user

Use **portal delete-user** to log out online portal users.

Syntax

portal delete-user { *ipv4-address* | **all** | **interface** *interface-type interface-number* | **ipv6** *ipv6-address* }

Views

System view

Predefined user roles

network-admin

Parameters

ipv4-address: Specifies the IP address of an IPv4 online portal user.

all: Specifies IPv4 and IPv6 online portal users on all interfaces.

interface *interface-type interface-number*: Specifies an interface by its type and number. If you specify this option, this command logs out all IPv4 and IPv6 online portal users on the interface.

ipv6 *ipv6-address*: Specifies the IP address of an IPv6 online portal user.

Examples

Log out the online portal user whose IP address is **1.1.1.1**.

```
<Sysname> system-view
[Sysname] portal delete-user 1.1.1.1
```

Related commands

display portal user

portal device-id

Use **portal device-id** to specify the device ID.

Use **undo portal device-id** to restore the default.

Syntax

portal device-id *device-id*

undo portal device-id

Default

A device is not configured with a device ID.

Views

System view

Predefined user roles

network-admin

Parameters

device-id: Specifies a device ID for the device, a case-sensitive string of 1 to 63 characters.

Usage guidelines

The portal authentication server uses device IDs to identify the devices that send protocol packets to the portal server.

Make sure the configured device ID is different than any other access devices communicating with the same portal authentication server.

Examples

Set the device ID of the device to 0002.0010.100.00.

```
<Sysname> system-view
[Sysname] portal device-id 0002.0010.100.00
```

portal domain (interface view)

Use **portal** [**ipv6**] **domain** to specify a portal authentication domain on an interface. All portal users accessing through the interface must use the authentication domain.

Use **undo portal** [**ipv6**] **domain** to delete the configured portal authentication domain.

Syntax

portal [**ipv6**] **domain** *domain-name*

undo portal [**ipv6**] **domain**

Default

No portal authentication domain is configured on an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies an authentication domain for IPv6 portal users. Do not specify this keyword for IPv4 portal users.

domain-name: Specifies an ISP authentication domain by its name, a case-insensitive string of 1 to 255 characters.

Usage guidelines

You can specify both an IPv4 portal authentication domain and an IPv6 portal authentication domain on an interface.

Do not specify the **ipv6** keyword for IPv4 portal users.

Examples

Specify the authentication domain as **my-domain** for IPv4 portal users on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal domain my-domain
```

Related commands

display portal

portal enable (interface view)

Use **portal** [**ipv6**] **enable** to enable portal authentication.

Use **undo portal** [**ipv6**] **enable** to disable portal authentication.

Syntax

portal enable method { **direct** | **layer3** | **redhcp** }

portal ipv6 enable method { **direct** | **layer3** }

undo portal [**ipv6**] **enable**

Default

Portal authentication is disabled.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Enables IPv6 portal authentication. Do not specify this keyword for IPv4 portal authentication.

method: Specifies an authentication mode:

- **direct**—Direct authentication.
- **layer3**—Cross-subnet authentication.
- **redhcp**—Re-DHCP authentication.

Usage guidelines

To modify the portal authentication mode, first execute the **undo portal** [**ipv6**] **enable** command to disable portal authentication and then execute the **portal** [**ipv6**] **enable** command.

Make sure the device supports IPv6 ACL and IPv6 forwarding before you enable IPv6 portal authentication on the interface.

IPv6 portal authentication does not support the re-DHCP authentication mode.

You can enable both IPv4 and IPv6 portal authentication on an interface.

Examples

Enable direct IPv4 portal authentication on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal enable method direct
```

Related commands

display portal

portal fail-permit server

Use **portal** [**ipv6**] **fail-permit server** to enable the portal fail-permit feature for a portal authentication server on the interface.

Use **undo portal** [**ipv6**] **fail-permit server** to disable the portal fail-permit feature for the portal authentication server.

Syntax

portal [**ipv6**] **fail-permit server** *server-name*

undo portal [**ipv6**] **fail-permit server**

Default

Portal fail-permit is disabled for the portal authentication server.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies an IPv6 portal authentication server. Do not specify this keyword for an IPv4 portal authentication server.

server-name: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

When portal fail-permit is enabled for a portal authentication server and a portal Web server on an interface, the interface disables portal authentication for portal users if either server is unreachable. Portal authentication resumes on the interface when both servers become reachable. After portal authentication resumes, unauthenticated portal users need to pass authentication to access network resources. Portal users who has passed authentication can continue accessing network resources.

You can enable portal fail-permit for at most one portal authentication server and one portal Web server on an interface.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enable portal fail-permit for portal authentication server **pts1** on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal fail-permit server pts1
```

Use **undo portal fail-permit web-server** to disable the portal fail-permit feature for portal Web servers.

Syntax

portal [**ipv6**] **fail-permit web-server**

undo portal [**ipv6**] **fail-permit web-server**

Default

Portal fail-permit is disabled for portal Web servers.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies IPv6 portal Web servers. Do not specify this keyword for IPv4 portal Web servers.

Usage guidelines

This command is supported only in Release 6348P01 and later.

On an interface enabled with portal fail-permit for a portal authentication server and portal Web servers, portal authentication on the interface is disabled when all portal Web servers are unreachable. For an interface, the device determines that all portal Web servers are unreachable when both the primary and secondary portal Web servers are unreachable.

Portal authentication resumes on the interface when the specified portal authentication server and a minimum of one portal Web server becomes reachable. After portal authentication resumes, unauthenticated portal users need to pass authentication to access network resources. Portal users who have passed authentication can continue accessing network resources.

Examples

Enable portal fail-permit for portal Web servers on VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal fail-permit web-server
```

Related commands

network-admin

Parameters

ipv4-network-address: Specifies an IPv4 portal authentication subnet address.

mask-length: Specifies the subnet mask length for the authentication subnet address, in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal format.

Usage guidelines

Portal users on the interface are authenticated when accessing the specified authentication destination subnet (except IP addresses and subnets specified in portal-free rules). The users can access other subnets without portal authentication.

You can configure multiple authentication destination subnets.

If you do not specify the *ipv4-network-address* argument in the **undo portal free-all except destination** command, this command deletes all IPv4 portal authentication destination subnets on the interface.

Re-DHCP authentication does not support authentication destination subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

Examples

Configure an IPv4 portal authentication destination subnet of **11.11.11.0**/**24** on VLAN-interface 2. Portal users need to pass authentication to access this subnet and can access other subnets without authentication.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname–Vlan-interface2] portal free-all except destination 11.11.11.0 24
```

Related commands

display portal

portal free-rule

Use **portal free-rule** to configure an IP-based portal-free rule.

Use **undo portal free-rule** to delete portal-free rules.

Syntax

portal free-rule *rule-number* { **destination ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **source ip** { *ipv4-address* { *mask-length* | *mask* } | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

portal free-rule *rule-number* { **destination ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] | **source ipv6** { *ipv6-address prefix-length* | **any** } [**tcp** *tcp-port-number* | **udp** *udp-port-number*] } * [**interface** *interface-type interface-number*]

undo portal free-rule { *rule-number* | **all** }

Default

No IP-based portal-free rule is configured.

Views

System view

Predefined user roles

network-admin

Parameters

rule-number: Specifies a portal-free rule number. The value range for this argument is 0 to 4294967295.

destination: Specifies the destination information.

source: Specifies the source information.

ip *ipv4-address*: Specifies an IPv4 address for the portal-free rule.

{ *mask-length* | *mask* }: Specifies the subnet mask of the IPv4 address. The value range for the *mask-length* argument is 0 to 32. The *mask* argument is in dotted decimal format.

ipv6 *ipv6-address*: Specifies an IPv6 address for the portal-free rule.

prefix-length: Specifies the prefix length of the IPv6 address, in the range of 0 to 128.

ip any: Represents any IPv4 address.

ipv6 any: Represents any IPv6 address.

tcp *tcp-port-number*: Specifies a TCP port number for the portal-free rule, in the range of 0 to 65535.

udp *udp-port-number*: Specifies a UDP port number for the portal-free rule, in the range of 0 to 65535.

all: Specifies all portal-free rules.

interface *interface-type interface-number*: Specifies a Layer 3 interface on which the portal-free rule takes effect.

Usage guidelines

You can specify both the **source** and **destination** keyword for a portal-free rule. If you specify only one keyword, the other keyword does not act as a filtering criterion.

If you specify both a source port number and a destination port number for a portal-free rule, the two port numbers must belong to the same transport layer protocol.

If you do not specify a Layer 3 interface, the portal-free rule takes effect on all portal-enabled interfaces.

You cannot configure two portal-free rules with the same filtering criteria.

Examples

Configure an IPv4-based portal-free rule:

- Set the rule number to 1.
- Specify the source IP address as 10.10.10.1/24, the destination IP address as 20.20.20.1, and the destination TCP port number as 23.
- Specify the interface where the rule is applied as VLAN-interface 1.

```
<Sysname> system-view
[Sysname] portal free-rule 1 destination ip 20.20.20.1 32 tcp 23 source ip 10.10.10.1 24
interface vlan-interface 1
```

With this rule, users in subnet 10.10.10.1/24 do not need to pass portal authentication on VLAN-interface 1 when they access services provided on TCP port 23 of host 20.20.20.1.

Configure an IPv6-based portal-free rule:

- Set the rule number to 2.
- Specify the source IP address as 2000::1/64, the destination IP address as 2001::1, and the destination TCP port number as 23.
- Specify the interface as VLAN-interface 1.

```
<Sysname> system-view
[Sysname] portal free-rule 2 destination ipv6 2001::1 128 tcp 23 source ipv6 2000::1 64
interface vlan-interface 1
```

With this rule, users in subnet 2000::1/64 do not need to pass portal authentication on VLAN-interface 1 when they access services provided on TCP port 23 of host 2001::1.

Related commands

display portal rule

portal free-rule destination

Use **portal free-rule destination** to configure a destination-based portal-free rule.

Use **undo portal free-rule** to delete portal-free rules.

Syntax

portal free-rule *rule-number* **destination** *host-name*

undo portal free-rule { *rule-number* | **all** }

Default

No destination-based portal-free rule is configured.

Views

System view

Predefined user roles

network-admin

Parameters

rule-number: Specifies a portal-free rule number. The value range for this argument is 0 to 4294967295.

destination: Specifies the destination host.

host-name: Specifies the destination host by its name, a case-insensitive string of 1 to 253 characters. Valid characters are letters, digits, hyphens (-), underscores (_), dots (.), and asterisks (*). The host name string cannot be **i**, **ip**, **ipv**, or **ipv6**.

all: Specifies all portal-free rules.

Usage guidelines

Before you configure destination-based portal-free rules, make sure a DNS server is deployed on the network.

You can configure a host name in one of the following ways:

- **For exact match**—Specify a complete host name. For example, if you configure the host name as **abc.com.cn** in the portal-free rule, only packets that contain the host name **abc.com.cn** match the rule. Packets that carry any other host names (such as **dfabc.com.cn**) do not match the rule.
- **For fuzzy match**—Specify a host name by placing the asterisk (*) wildcard character at the beginning or end of the host name string. For example, if you configure the host name as

abc.com.cn, abc, or ***abc*,** packets that carry the host name ending with **abc.com.cn**, starting with **abc**, or including **abc** match the rule.

- The asterisk (*) wildcard character represents any characters. The device treats multiple consecutive asterisks as one.
- The configured host name cannot contain only asterisks (*).

The fuzzy match feature takes effect only on HTTP or HTTPS requests initiated by Web browsers.

You cannot configure two destination-based portal-free rules with the same destination information. Otherwise the system prompts you that the same rule already exists.

Examples

Configure a destination-based portal-free rule: specify the rule number as **4** and host name as **www.h3c.com**. This rule allows the portal user who sends the HTTP/HTTPS request that carries the host name **www.h3c.com** to access network resources without authentication.

```
<Sysname> system-view
[Sysname] portal free-rule 4 destination www.h3c.com
```

Related commands

display portal rule

portal free-rule source

Use **portal free-rule source** to configure a source-based portal-free rule. The filtering criteria include source MAC address, source interface, and source VLAN.

Use **undo portal free-rule** to delete a specific or all portal-free rules.

Syntax

portal free-rule *rule-number* **source** { **interface** *interface-type interface-number* | **mac** *mac-address* | **vlan** *vlan-id* } *

undo portal free-rule { *rule-number* | **all** }

Default

No source-based portal-free rules exist.

Views

System view

Predefined user roles

network-admin

Parameters

rule-number: Specifies a portal-free rule number. The value range for this argument is 0 to 4294967295.

interface *interface-type interface-number*: Specifies a source interface by its type and number for the portal-free rule.

mac *mac-address*: Specifies a source MAC address for the portal-free rule, in the form of **H-H-H**.

vlan *vlan-id*: Specifies a source VLAN ID for the portal-free rule. This option takes effect only on portal users that access the network through VLAN interfaces.

all: Specifies all portal-free rules.

Usage guidelines

If you specify both the source VLAN and the source Layer 2 interface, the interface must be in the VLAN.

Examples

Configure source-based portal-free rule: specify the rule number as **3**, source MAC address as **1-1-1**, and source VLAN ID as **10**. This rule allows the portal user whose source MAC address is 1-1-1 from VLAN 10 to access network resources without authentication.

```
<Sysname> system-view
[Sysname] portal free-rule 3 source mac 1-1-1 vlan 10
```

Related commands

display portal rule

portal ipv6 free-all except destination

Use **portal ipv6 free-all except destination** to configure an IPv6 portal authentication destination subnet on an interface.

Use **undo portal ipv6 free-all except destination** to delete IPv6 portal authentication destination subnets on the interface.

Syntax

portal ipv6 free-all except destination *ipv6-network-address prefix-length*

undo portal ipv6 free-all except destination [*ipv6-network-address*]

Default

No IPv6 portal authentication destination subnet is configured. Portal users must pass portal authentication to access any IPv6 subnet.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6-network-address: Specifies an IPv6 portal authentication destination subnet.

prefix-length: Specifies the prefix length of the IPv6 subnet, in the range of 0 to 128.

Usage guidelines

Portal users on the interface are authenticated when accessing the specified authentication destination subnet (except IP addresses and subnets specified in portal-free rules). The users can access other subnets without portal authentication.

You can configure multiple authentication destination subnets.

If you do not specify the *ipv6-network-address* argument in the **undo portal ipv6 free-all except destination** command, this command deletes all IPv6 portal authentication destination subnets on the interface.

Re-DHCP authentication does not support authentication destination subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

Examples

Configure an IPv6 portal authentication destination subnet of **1::2/16** on VLAN-interface 2.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname–Vlan-interface2] portal ipv6 free-all except destination 1::2 16
```

Related commands

portal ipv6 layer3 source

Use **portal ipv6 layer3 source** to configure an IPv6 portal authentication source subnet.

Use **undo portal ipv6 layer3 source** to delete IPv6 portal authentication source subnets.

Syntax

portal ipv6 layer3 source *ipv6-network-address prefix-length*

undo portal ipv6 layer3 source [*ipv6-network-address*]

Default

No IPv6 portal authentication source subnet is configured. Portal users from any IPv6 subnet must pass portal authentication.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6-network-address: Specifies an IPv6 portal authentication source subnet address.

prefix-length: Specifies the prefix length of the IPv6 address, in the range of 0 to 128.

Usage guidelines

With IPv6 authentication source subnets configured, only packets from IPv6 users on the authentication source subnets can trigger portal authentication. If an unauthenticated IPv6 user is not on any authentication source subnet, the access device discards all the user's packets that do not match any portal-free rule.

If you do not specify the *ipv6-network-address* argument in the **undo portal ipv6 layer3 source** command, this command deletes all IPv6 portal authentication source subnets on the interface.

Only cross-subnet authentication supports authentication source subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

Examples

Configure an IPv6 portal authentication source subnet of **1::1/16** on VLAN-interface 2. Only portal users from subnet 1::1/16 trigger portal authentication.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname–Vlan-interface2] portal ipv6 layer3 source 1::1 16
```

Related commands

display portal

portal ipv6 free-all except destination

portal ipv6 user-detect

Use **portal ipv6 user-detect** to enable online detection of IPv6 portal users.

Use **undo portal user-detect** to disable online detection of IPv6 portal users.

Syntax

portal ipv6 user-detect type { **icmpv6** | **nd** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

undo portal ipv6 user-detect

Default

Online detection of IPv6 portal users is disabled.

Views

Interface view

Predefined user roles

network-admin

Parameters

type: Specifies the detection type.

- **icmpv6**—ICMPv6 detection.
- **nd**—ND detection.

retry *retries*: Sets the maximum number of detection attempts, in the range of 1 to 10. The default value is 3.

interval *interval*: Sets a detection interval in the range of 1 to 1200 seconds. The default interval is 3 seconds.

idle *time*: Sets the user idle timeout in the range of 60 to 3600 seconds. The default idle timeout is 180 seconds. When the timeout expires, online detection of portal users is started.

Usage guidelines

If the device receives no packets from a portal user within the idle time, the device detects the user's online status as follows:

- **ICMPv6 detection**—Sends ICMPv6 requests to the user at configurable intervals to detect the user status.
  - If the device receives a reply within the maximum number of detection attempts, it considers that the user is online and stops sending detection packets. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the device receives no reply after the maximum number of detection attempts, the device logs out the user.
- **ND detection**—Sends ND requests to the user and detects the ND entry status of the user at configurable intervals.
  - If the ND entry of the user is refreshed within the maximum number of detection attempts, the device considers that the user is online and stops detecting the user's ND entry. Then the device resets the idle timer and repeats the detection process when the timer expires.

- If the ND entry of the user is not refreshed after the maximum number of detection attempts, the device logs out the user.

Direct authentication and re-DHCP authentication support both ND detection and ICMPv6 detection. Cross-subnet authentication only supports ICMPv6 detection.

If the access device filters out ICMPv6 packets, ICMPv6 detection might fail and result in the logout of portal users. Make sure the access device does not block ICMPv6 packets before you enable ICMPv6 detection on an interface.

Examples

Enable online detection of IPv6 portal users on VLAN-interface 100. Configure the detection type as **ND**, the maximum number of detection attempts as **5**, the detection interval as **10** seconds, and the user idle timeout as **300** seconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal ipv6 user-detect type nd retry 5 interval 10 idle 300
```

portal layer3 source

Use **portal layer3 source** to configure an IPv4 portal authentication source subnet.

Use **undo portal layer3 source** to delete IPv4 portal authentication source subnets.

Syntax

portal layer3 source *ipv4-network-address* { *mask-length* | *mask* }

undo portal layer3 source [*ipv4-network-address*]

Default

No IPv4 portal authentication source subnet is configured. Portal users from any IPv4 subnet must pass portal authentication.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv4-network-address: Specifies an IPv4 portal authentication source subnet address.

mask-length: Specifies the subnet mask length of the IPv4 address, in the range of 0 to 32.

mask: Specifies the subnet mask in dotted decimal format.

Usage guidelines

With IPv4 authentication source subnets configured, only packets from IPv4 users on the authentication source subnets can trigger portal authentication. If an unauthenticated IPv4 user is not on any authentication source subnet, the access device discards all the user's packets that do not match any portal-free rule.

If you do not specify the *ipv4-network-address* argument in the **undo portal layer3 source** command, this command deletes all IPv4 portal authentication source subnets on the interface.

Only cross-subnet authentication supports authentication source subnets.

If you configure both an authentication source subnet and an authentication destination subnet on an interface, only the authentication destination subnet takes effect.

Examples

Configure an IPv4 portal authentication source subnet of **10.10.10.0**/**24** on VLAN-interface 2.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname–Vlan-interface2] portal layer3 source 10.10.10.0 24
```

Related commands

portal free-all except destination

portal local-web-server

Use **portal local-web-server** to enable HTTP- or HTTPS-based local portal Web service and enter its view.

Use **undo portal local-web-server** to disable the local portal Web service.

Syntax

portal local-web-server { **http** | **https ssl-server-policy** *policy-name* [**tcp-port** *port-number*] }

undo portal local-web-server { **http** | **https** }

Default

Local portal Web service is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

http: Specifies the HTTP-based local portal Web service, which uses HTTP to exchange authentication information with clients.

https: Specifies the HTTPS-based local portal Web service, which uses HTTPS to exchange authentication information with clients.

ssl-server-policy *policy-name*: Specifies an existing SSL server policy for HTTPS. The policy name is a case-insensitive string of 1 to 31 characters.

tcp-port *port-number*: Specifies the listening TCP port number for the HTTPS-based local portal Web service. The value range for the *port-number* argument is 1 to 65535. The default port number is 443.

Usage guidelines

In the local portal Web service, the access device also acts as the portal Web server and the portal authentication server. No external portal Web server and portal authentication server are needed.

For an interface to use the local portal Web service, the URL of the portal Web server specified for the interface must meet the following requirements:

- The IP address in the URL must be a local IP address on the device.
- The URL must be ended with **/portal/**. For example: **http://1.1.1.1/portal/**.

You cannot delete an SSL server policy by using the **undo ssl server-policy** command when the policy is associated with HTTPS.

To specify a new SSL server policy for HTTPS, first execute the **undo** form of this command to disable the existing HTTPS-based local portal Web service.

When you specify the listening TCP port number for the HTTPS-based local portal Web service, follow these restrictions and guidelines:

- For the HTTPS-based local portal Web service and other services that use HTTPS:
  - If they use the same SSL server policy, they can use the same TCP port number to listen to HTTPS.
  - If they use different SSL server policies, they cannot use the same TCP port number to listen to HTTPS.
- Do not configure the HTTPS listening TCP port number as the port number used by a known protocol (except HTTPS) or other service. For example, do not specify port numbers 80 and 23, which are used by HTTP and Telnet, respectively.
- Do not configure the same TCP port number for HTTP and HTTPS local portal Web services.

Examples

Enable the HTTP-based local portal Web service and enter its view.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] quit
```

Enable the HTTPS-based local portal Web service and associate SSL server policy **policy1** with the service.

```
<Sysname> system-view
[Sysname] portal local-web-server https ssl-server-policy policy1
[Sysname-portal-local-websvr-https] quit
```

Change the SSL server policy to **policy2**.

```
[Sysname] undo portal local-web-server https
[Sysname] portal local-web-server https ssl-server-policy policy2
[Sysname-portal-local-websvr-https] quit
```

Enable the HTTPS-based local portal Web service. In the service, the associated SSL server policy is **policy1** and the listening port number is 442.

```
<Sysname> system-view
[Sysname] portal local-web-server https ssl-server-policy policy1 tcp-port 442
[Sysname-portal-local-websvr-https] quit
```

portal log enable

Use **portal log enable** to enable logging for portal user logins and logouts.

Use **undo user log enable** to disable logging for portal user logins and logouts.

Syntax

portal log enable

undo portal log enable

Default

Portal user login and logout logging is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This feature logs information about portal user login and logout events, including the username, IP address, user's MAC address, interface name, VLAN, and reason for login failure. For portal log messages to be sent correctly, you must also configure the information center on the device. For more information about information center configuration, see *Network Management and Monitoring Configuration Guide*.

Examples

Enable logging for portal user logins and logouts.

```
<Sysname> system-view
[Sysname] portal user log enable
```

portal max-user

Use **portal max-user** to set the maximum number of total portal users allowed in the system.

Use **undo portal max-user** to restore the default.

Syntax

portal max-user *max-number*

undo portal max-user

Default

The total number of portal users allowed in the system is not limited.

Views

System view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of total portal users in the system. The value range for this argument is 1 to 4294967295.

Usage guidelines

If you configure the maximum total number smaller than the number of current online portal users on the device, this command still takes effect. The online users are not affected by this command, but the system forbids new portal users to log in.

This command sets the maximum number of online IPv4 and IPv6 portal users in all.

Make sure the total number of the maximum IPv4 and IPv6 portal users allowed on all interfaces does not exceed the system-allowed maximum number. Otherwise, the exceeding portal users will not be able to log in to the device.

Examples

Set the maximum number of online portal users allowed in the system to **100**.

```
<Sysname> system-view
[Sysname] portal max-user 100
```

Related commands

display portal user

portal { **ipv4-max-user** | **ipv6-max-user** }

portal nas-id-profile

Use **portal nas-id-profile** to specify a NAS-ID profile for an interface.

Use **undo portal nas-id-profile** to restore the default.

Syntax

portal nas-id-profile *profile-name*

undo portal nas-id-profile

Default

No NAS-ID profile is specified for an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

profile-name: Specifies the name of a NAS-ID profile, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A NAS-ID profile defines the binding relationship between VLANs and NAS-IDs. To configure a NAS-ID profile, use the **aaa nas-id profile** command.

Portal access matches only the inner VLAN ID of QinQ packets. For more information about QinQ, see *Layer 2—LAN Switching Configuration Guide*.

If an interface is specified with a NAS-ID profile, the interface prefers to use the bindings defined in the profile.

If no NAS-ID profile is specified for an interface or no matching binding is found in the specified profile, the device uses the device name as the interface NAS-ID.

Examples

Specify NAS-ID profile **aaa** for VLAN-interface 2.

```
<Sysname> system-view
[Sysname] interface vlan-interface 2
[Sysname-Vlan-interface2] portal nas-id-profile aaa
```

Related commands

aaa nas-id profile

portal nas-port-id format

Use **portal nas-port-id format** to specify the NAS-Port-Id attribute format.

Use **undo portal nas-port-id format** to restore the default.

Syntax

portal nas-port-id format { **1** | **2** | **3** | **4** }

undo portal nas-port-id format

Default

The format for the NAS-Port-Id attribute is format 2.

Views

System view

Predefined user roles

network-admin

Parameters

1: Uses format 1 for the NAS-Port-Id attribute.

2: Uses format 2 for the NAS-Port-Id attribute.

3: Uses format 3 for the NAS-Port-Id attribute.

4: Uses format 4 for the NAS-Port-Id attribute.

Usage guidelines

The NAS-Port-Id format supported by RADIUS servers varies by vendor. Use this command to specify the format of the NAS-Port-Id attribute in the RADIUS packets sent for portal users to the RADIUS server. The device then automatically constructs a value for the NAS-Port-Id attribute in the specified format to meet the RADIUS server requirements.

Format 1 contains three space-separated strings: *interface-type port-location access-node-id*. Spaces are not allowed within a string.

- The *interface-type* string specifies the interface type of the NAS port. Available options include:
  - **atm**—ATM interface.
  - **eth**—Common Ethernet interface.
  - **trunk**—Ethernet trunk interface.
  - **0**—The interface type information will be reported by the access node to the BRAS.
- The *port-location* string represents the location of the access line on the BRAS. Its format is NAS_slot/NAS_subslot/NAS_port:XPI.XCI.

Field	Description
NAS_slot	Slot number of the BRAS, in the range of 0 to 31.
NAS_subslot	Subslot number of the BRAS, in the range of 0 to 31.
NAS_Port	Port number of the BRAS, in the range of 0 to 63.
XPI.XCI	For ATM interfaces: • XPI is VPI in the range of 0 to 255. • XCI is VCI in the range of 0 to 65535. For Ethernet interfaces or Ethernet trunk interfaces: • XPI is PVLAN in the range of 0 to 4095. This field is

	set to 4096 if there is no PVLAN. • XCI is CVLAN in the range of 0 to 4095. This field is set to 4096 if the user is not assigned to a VLAN as in the situation where the end user device is directly connected to a BRAS port.

For the access node to report its access line information to the BRAS, all fields will be set to 0s except for the XPI and XCI fields.

- The *access-node-id* string specifies the attributes the of BRAS. Its format is AccessNodeIdentifier/ANI_rack/ANI_frame/ANI_slot/ANI_subslot/ANI_port:ANI_XPI.ANI_XCI, in which the :ANI_XPI.ANI_XCI portion is optional.

AccessNodeIdentifier	Identifier description of the access node, a string not longer than 50 characters without spaces.
ANI_rack	Rack number of the access node, in the range of 0 to 15.
ANI_frame	Frame number of the access node, in the range of 0 to 31.
ANI_slot	Slot number of the access node, in the range of 0 to 127.
ANI_subslot	Subslot number of the access node, in the range of 0 to 31.
ANI_port	Port number of the access node, in the range of 0 to 255.
ANI_XPI.ANI_XCI	Optional. This field is mainly used to carry CPE-side service information, identifying the further service type requirement. For example, use this field to identify specific services in a multi-PVC scenario. For ATM interfaces: • ANI_XPI is VPI in the range of 0 to 255. • ANI_XCI is VCI in the range of 0 to 65535. For Ethernet interfaces or Ethernet trunk interfaces: • ANI_XPI is PVLAN in the range of 0 to 4095. This field is set to 4096 if there is no PVLAN. • ANI_XCI is CVLAN in the range of 0 to 4095. This field is set to 4096 if the user is not assigned to a VLAN as in the situation where the end user device is directly connected to a BRAS port.

If the device does not have rack, frame, or subslot information, 0 is padded in the corresponding field.

For ATM interfaces, all fields in the access-node-id string are filled with 0s except for the ANI_XPI and ANI_XCI fields.

- Examples of format 1:

NAS-Port-Id	**Description**
atm 31/31/7:255.65535 0/0/0/0/0/0	The subscriber interface is an ATM interface. The slot number is 31, the BRAS subslot number is 31, the BRAS port number is 7, the VPI is 255, and the VCI is 65535.
eth 31/31/7:1234.2345 0/0/0/0/0/0	The subscriber interface is an Ethernet interface. The slot number is 31, the subslot number is 31, the port number is 7, the PVLAN is 1234, and the CVLAN is 2345. If there is no PVLAN, 1234 will be replaced with 4096.
eth 31/31/7:4096.2345	The subscriber interface is an Ethernet interface. The slot number

guangzhou001/1/31/63/31/127	is 31, the subslot number is 31, the port number is 7, and the VLAN ID is 2345. The access node identifier of the DSLAM is guangzhou001, the rack number is 1, the frame number is 31, the slot number is 63, subslot number is 31, and the port number is 127.
0 0/0/0:4096.1234 guangzhou001/0/31/63/31/127	The 0 and 0/0/0 strings indicate that BRAS does not have access line information and will use the information received from the access node. After receiving access line information from the access node, the BRAS transparently delivers the information or complements the BRAS access link information as configured. For example, the BRAS complements the access line information as eth 31/31/7:4096.1234 guangzhou001/0/31/63/31/127.

Format 2 is SlotID00IfNOVlanID.

- **SlotID**—Slot number, a string of 2 characters.
- **IfNO**—Slot number, a string of 3 characters.
- **VlanID**—VLAN ID, a string of 9 characters.

Format 3 is SlotID00IfNOVlanIDDHCPoption.

- **SlotID**—Slot number, a string of 2 characters.
- **IfNO**—Interface number, a string of 3 characters.
- **VlanID**—VLAN ID, a string of 9 characters.
- **DHCPoption**—DHCP option 82 is appended for IPv4 users and DHCP option 1 is appended for IPv6.

Format 4 is slot=**;subslot=**;port=**;vlanid=**;vlanid2=**.

- For non-VLAN interfaces, the slot=**;subslot=**;port=**;vlanid=0 format is used.
- For interfaces that terminate only the outermost VLAN tag, the slot=**;subslot=**;port=**;vlanid=** format is used.

Examples

Set the format of the NAS-Port-Id attribute to format 1.

```
<Sysname> system-view
[Sysname] portal nas-port-id format 1
```

portal nas-port-type

Use **portal nas-port-type** to configure the NAS-Port-Type attribute carried in outgoing RADIUS requests.

Use **undo portal nas-port-type** to restore the default.

Syntax

portal nas-port-type { **802.11** | **adsl-cap** | **adsl-dmt** | **async** | **cable** | **ethernet** | **g.3-fax** | **hdlc** | **idsl** | **isdn-async-v110** | **isdn-async-v120** | **isdn-sync** | **piafs** | **sdsl** | **sync** | **virtual** | **wireless-other** | **x.25** | **x.75** | **xdsl** }

undo portal nas-port-type

Default

The NAS-Port-Type carried in outgoing RADIUS requests is Ethernet (attribute value 15).

Views

Interface view

Predefined user roles

network-admin

Parameters

802.11: Specifies the NAS port type as Wireless-IEEE 802.11 (attribute value 19).

adsl-cap: Specifies the NAS port type as ADSL-CAP (attribute value 12).

adsl-dmt: Specifies the NAS port type as ADSL-DMT (attribute value 13).

async: Specifies the NAS port type as Async (attribute value 0).

cable: Specifies the NAS port type as Cable (attribute value 17).

ethernet: Specifies the NAS port type as Ethernet (attribute value 15).

g.3-fax: Specifies the NAS port type as G.3 Fax (attribute value 10).

hdlc: Specifies the NAS port type as HDLC Clear Channel (attribute value 7).

idsl: Specifies the NAS port type as IDSL (attribute value 14).

isdn-async-v110: Specifies the NAS port type as ISDN Async V.110 (attribute value 4).

isdn-async-v120: Specifies the NAS port type as ISDN Async V.120 (attribute value 3).

isdn-sync: Specifies the NAS port type as ISDN Sync (attribute value 2).

piafs: Specifies the NAS port type as PIAFS (attribute value 6).

sdsl: Specifies the NAS port type as SDSL (attribute value 11).

sync: Specifies the NAS port type as Sync (attribute value 1).

virtual: Specifies the NAS port type as Virtual (attribute value 5).

wireless-other: Specifies the NAS port type as Wireless-Other (attribute value 18).

x.25: Specifies the NAS port type as X.25 (attribute value 8).

x.75: Specifies the NAS port type as X.75 (attribute value 9).

xdsl: Specifies the NAS port type as xDSL (attribute value 16).

Examples

Configure the NAS-Port-Type carried in outgoing RADIUS requests as SDSL on VLAN-interface 20.

```
<Sysname> system-view
[Sysname] interface vlan-interface 20
[Sysname-Vlan-interface20] portal nas-port-type sdsl
```

portal pre-auth ip-pool

Use **portal** [**ipv6**] **pre-auth ip-pool** to specify a preauthentication IP address pool for portal users.

Use **undo portal** [**ipv6**] **pre-auth ip-pool** to restore the default.

Syntax

portal [**ipv6**] **pre-auth ip-pool** *pool-name*

undo portal [**ipv6**] **pre-auth ip-pool**

Default

No preauthentication IP address pool is specified for portal users.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies IPv6 portal users. Do not specify this keyword for IPv4 portal users.

pool-name: Specifies an IP address pool by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You must use this command to specify a preauthentication IP address pool on a portal-enabled interface in the following situation:

- Portal users access the network through a subinterface of the portal-enabled interface.
- The subinterface does not have an IP address.
- Portal users need to obtain IP addresses through DHCP.

DHCP assigns an IP address from the specified IP address pool to a user. Then, the user can use this IP address to perform portal authentication.

The specified IP address pool takes effect when the following requirements are met:

- The direct portal authentication mode is used on the interface.
- The specified IP address pool must have existed and been correctly configured.

Examples

Create IPv4 address pool **abc** for VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal pre-auth ip-pool abc
```

Related commands

dhcp server ip-pool (*Layer 3—IP Services Command Reference*)

ipv6 dhcp pool (*Layer 3—IP Services Command Reference*)

portal refresh enable

Use **portal refresh** { **arp** | **nd** } **enable** to enable the Rule ARP or ND entry feature for portal clients.

Use **undo portal refresh** { **arp** | **nd** } **enable** to disable the Rule ARP or ND entry feature for portal clients.

Syntax

portal refresh { **arp** | **nd** } **enable**

undo portal refresh { **arp** | **nd** } **enable**

Default

The Rule ARP or ND entry feature is enabled for portal clients.

Views

System view

Predefined user roles

network-admin

Parameters

arp: Enables the Rule ARP entry feature.

nd: Enables the Rule ND entry feature.

Usage guidelines

When the Rule ARP or ND entry feature is enabled for portal clients, ARP or ND entries for portal clients are Rule entries after the clients come online. The Rule ARP or ND entries will not age out and will be deleted immediately after the portal clients go offline.

If portal clients go offline and then try to come online before the ARP or ND entries are relearned for them, the clients will fail the authentication. In this case, disable this feature so that ARP or ND entries are dynamic entries after the clients come online. The dynamic ARP or ND entries are deleted only when they age out.

Enabling or disabling of this feature does not affect existing Rule/dynamic ARP or ND entries for portal users.

Examples

Disable the Rule ARP entry feature for portal clients.

```
<Sysname> system-view
[Sysname] undo portal refresh arp enable
```

portal roaming enable

Use **portal roaming enable** to enable portal roaming.

Use **undo portal roaming enable** to disable portal roaming.

Syntax

portal roaming enable

undo portal roaming enable

Default

Portal roaming is disabled. An online portal user cannot roam in its VLAN.

Views

System view

Predefined user roles

network-admin

Usage guidelines

Portal roaming applies only to portal users that log in from VLAN interfaces.

This command cannot be executed when online users are present on the device.

If portal roaming is enabled, an online portal user can access network resources from any Layer 2 port in its local VLAN. If portal roaming is disabled, the portal user can access network resources only from the Layer 2 port on which it passes authentication.

For portal roaming to take effect, you must disable the Rule ARP or ND entry feature by using the **undo portal refresh** { **arp** | **nd** } **enable** command.

Examples

Enable portal roaming.

```
<Sysname> system-view
[Sysname] portal roaming enable
```

portal server

Use **portal server** to create a portal authentication server and enter its view, or enter the view of an existing portal authentication server.

Use **undo portal server** to delete the specified portal authentication server.

Syntax

portal server *server-name*

undo portal server *server-name*

Default

No portal authentication servers exist.

Views

System view

Predefined user roles

network-admin

Parameters

server-name: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

In portal authentication server view, you can configure the following parameters and features for the portal authentication server:

- IP address of the server.
- Destination UDP port number used by the device to send unsolicited portal packets to the portal authentication server.
- Pre-shared key for communication between the access device and the server.
- Server detection feature.

You can configure multiple portal authentication servers for an access device.

Examples

Create portal authentication server **pts** and enter its view.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts]
```

Related commands

display portal server

portal user-detect

Use **portal user-detect** to enable online detection of IPv4 portal users.

Use **undo portal user-detect** to disable online detection of IPv4 portal users.

Syntax

portal user-detect type { **arp** | **icmp** } [**retry** *retries*] [**interval** *interval*] [**idle** *time*]

undo portal user-detect

Default

Online detection of IPv4 portal users is disabled.

Views

Interface view

Predefined user roles

network-admin

Parameters

type: Specifies the detection type.

- **arp**—ARP detection.
- **icmp**—ICMP detection.

retry *retries*: Sets the maximum number of detection attempts, in the range of 1 to 10. The default value is 3.

interval *interval*: Sets a detection interval in the range of 1 to 1200 seconds. The default interval is 3 seconds.

idle *time*: Sets a user idle timeout in the range of 60 to 3600 seconds. The default idle timeout is 180 seconds. When the timeout expires, online detection of IPv4 portal users is started.

Usage guidelines

If the device receives no packets from a portal user within the configured idle time, the device detects the user's online status as follows:

- **ICMP detection**—Sends ICMP requests to the user at configurable intervals to detect the user status.
  - If the device receives a reply within the maximum number of detection attempts, it considers that the user is online and stops sending detection packets. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the device receives no reply after the maximum number of detection attempts, the device logs out the user.
- **ARP detection**—Sends ARP requests to the user and detects the ARP entry status of the user at configurable intervals.
  - If the ARP entry of the user is refreshed within the maximum number of detection attempts, the device considers that the user is online and stops detecting the user's ARP entry. Then the device resets the idle timer and repeats the detection process when the timer expires.
  - If the ARP entry of the user is not refreshed after the maximum number of detection attempts, the device logs out the user.

Direct authentication and re-DHCP authentication support both ARP detection and ICMP detection. Cross-subnet authentication only supports ICMP detection.

If the access device filters out ICMP packets, ICMP detection might fail and result in the logout of portal users. Make sure the access device does not block ICMP packets before you enable ICMP detection on an interface.

Examples

Enable online detection of IPv4 portal users on VLAN-interface 100. Configure the detection type as **ARP**, the maximum number of detection attempts as **5**, the detection interval as **10** seconds, and the user idle timeout as **300** seconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal user-detect type arp retry 5 interval 10 idle 300
```

Related commands

display portal

portal user-dhcp-only (interface view)

Use **portal user-dhcp-only** to allow only users with DHCP-assigned IP addresses to pass portal authentication.

Use **undo portal user-dhcp-only** to restore the default.

Syntax

portal [**ipv6**] **user-dhcp-only**

undo portal [**ipv6**] **user-dhcp-only**

Default

Both users with DHCP-assigned IP addresses and users with static IP addresses can pass portal authentication to come online.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies IPv6 portal users. Do not specify this keyword for IPv4 portal users.

Usage guidelines

CAUTION:

- With this feature enabled, users with static IP addresses cannot pass portal authentication to get online.
- To ensure that IPv6 users can pass portal authentication when this feature is enabled, disable the temporary IPv6 address feature. Otherwise, IPv6 users will use temporary IPv6 addresses to access the IPv6 network and will fail portal authentication.

Examples

Allow only users with DHCP-assigned IP addresses on VLAN-interface 100 to pass portal authentication.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] portal user-dhcp-only
```

Related commands

display portal

portal user-rule assign-check enable

Use **portal user-rule assign-check enable** to enable the device to check the issuing of category-2 portal filtering rules.

Use **undo portal user-rule assign-check enable** to disable the device from checking the issuing of category-2 portal filtering rules.

Syntax

portal user-rule assign-check enable

undo portal user-rule assign-check enable

Default

The device does not check the issuing of category-2 portal filtering rules.

Views

System view

Predefined user roles

network-admin

Usage guidelines

To display category-2 portal filtering rules, use the **display portal rule dynamic** command.

Examples

Enable the device to check the issuing of category-2 portal filtering rules.

```
<Sysname> system-view
[Sysname] portal rule assign-check enable
```

Related commands

display portal rule

portal web-proxy port

Use **portal web-proxy port** to specify the port number of a Web proxy server.

Use **undo portal web-proxy port** to delete port numbers of Web proxy servers.

Syntax

portal web-proxy port *port-number*

undo portal web-proxy port { *port-number* | **all** }

Default

No port numbers of Web proxy servers are specified. Proxied HTTP requests are dropped.

Views

System view

Predefined user roles

network-admin

Parameters

port-number: Specifies the port number of a Web proxy server. The value range for this argument is 1 to 65535.

all: Specifies all port numbers of Web proxy servers.

Usage guidelines

To allow HTTP requests proxied by a Web proxy server to trigger portal authentication, specify the port number of the Web proxy server on the device. If a Web proxy server port is not specified on the device, HTTP requests proxied by the Web proxy server are dropped, and portal authentication cannot be triggered.

You can configure this command multiple times to specify multiple port numbers of Web proxy servers.

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, you must perform the following tasks on the device:

- Specify the port numbers of the Web proxy servers on the device.
- Configure portal-free rules to allow user packets destined for the IP address of the WPAD server to pass without authentication.

If portal users enable Web proxy in their browsers, the users must add the IP address of the portal authentication server as a proxy exception in their browsers. Then, HTTP packets that the users send to the portal authentication server will not be sent to Web proxy servers.

You cannot specify Web proxy server port 443 on the device.

Examples

Specify Web proxy server port 8080.

```
<Sysname> system-view
[Sysname] portal web-proxy port 8080
```

Related commands

portal enable method

portal web-server

Use **portal web-server** to create a portal Web server and enter its view, or enter the view of an existing portal Web server.

Use **undo portal web-server** to delete a portal Web server.

Syntax

portal web-server *server-name*

undo portal web-server *server-name*

Default

No portal Web servers exist.

Views

System view

Predefined user roles

network-admin

Parameters

server-name: Specifies a portal Web server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

The portal Web server pushes portal authentication pages to portal users during authentication. The access device redirects HTTP requests of unauthenticated portal users to the portal Web server. In portal Web server view, you can configure the URL and URL parameters for the portal Web server and the portal Web server detection feature.

Examples

Create portal Web server **wbs** and enter its view.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs]
```

Related commands

display portal web-server

portal apply web-server

reset portal packet statistics

Use **reset portal packet statistics** to clear packet statistics for portal authentication servers.

Syntax

reset portal packet statistics [**server** *server-name*]

Views

User view

Predefined user roles

network-admin

Parameters

server-name: Specifies a portal authentication server by its name, a case-sensitive string of 1 to 32 characters.

Usage guidelines

If you do not specify the **server** *server-name* option, this command clears packet statistics for all portal authentication servers.

Examples

Clear packet statistics for portal authentication server **pts**.

```
<Sysname> reset portal packet statistics server pts
```

Related commands

display portal packet statistics

server-detect (portal authentication server view)

Use **server-detect** to enable portal authentication server detection. After server detection is enabled for a portal authentication server, the device periodically detects portal packets from the server to identify its reachability status.

Use **undo server-detect** to disable portal authentication server detection.

Syntax

server-detect [**timeout** *timeout*] **log**

undo server-detect

Default

Portal authentication server detection is disabled.

Views

Portal authentication server view

Predefined user roles

network-admin

Parameters

timeout *timeout*: Specifies the detection timeout in the range of 10 to 3600 seconds. The default is 60 seconds.

log: Configures the device to send a log message after detecting reachability status change of the portal authentication server. The log message contains the name, the original state, and the current state of the portal authentication server.

Usage guidelines

The portal authentication server detection feature takes effect only when the device has a portal-enabled interface.

To test server reachability by detecting heartbeat packets, you must enable the server heartbeat feature on the portal authentication server. Only the IMC portal authentication server supports sending heartbeat packets.

The detection timeout configured on the device must be greater than the server heartbeat interval configured on the portal authentication server.

If the device receives portal packets from the portal authentication server before the detection timeout expires and verifies the correctness of the packets, the device considers the portal authentication server is reachable. Otherwise, the device considers the portal authentication server is unreachable.

Examples

Enable server detection for portal authentication server **pts**:

- Set the detection timeout to 600 seconds.
- Configure the device to send a log message if the server reachability status changes.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] server-detect timeout 600 log
```

Related commands

portal server

server-detect (portal Web server view)

Use **server-detect** to enable portal Web server detection.

Use **undo server-detect** to disable portal Web server detection.

Syntax

server-detect [**interval** *interval*] [**retry** *retries*] **log**

undo server-detect

Default

Portal Web server detection is disabled.

Views

Portal Web server view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies a detection interval in the range of 10 to 1200 seconds. The default is 20 seconds.

retry *retries*: Specifies the maximum number of consecutive detection failures, in the range of 1 to 10. The default is 3. If the number of consecutive failed detections reaches this threshold, the device considers the server as unreachable.

log: Configures the device to send a log message after detecting reachability status change of the portal Web server. The log message contains the name, the original state, and the current state of the portal Web server.

Usage guidelines

The access device performs server detection independently. No configuration on the portal Web server is required for the detection.

The portal Web server detection feature takes effect only when the URL of the portal Web server is specified and the device has a portal-enabled interface.

Examples

Enable server detection for portal Web server **wbs**:

- Set the detection interval to 600 seconds.
- Set the maximum number of consecutive detection failures to 2.
- Configure the device to send a log message after server reachability status changes.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] server-detect interval 600 retry 2 log
```

Related commands

portal web-server

server-register

Use **server-register** to configure the device to periodically send register packets to the portal authentication server.

Use **undo server-register** to restore the default.

Syntax

server-register [**interval** *interval-value*]

undo server-register

Default

The device does not send register packets to a portal authentication server.

Views

Portal authentication server view

Predefined user roles

network-admin

Parameters

interval *interval-value*: Specifies the interval at which the device sends register packets to the portal authentication server, in seconds. The value range for the *interval* argument is 1 to 3600, and the default value is 600.

Usage guidelines

This feature is typically used in scenarios where a NAT device exists between a portal authentication server and a large number of access devices.

If this feature is disabled, you must configure a static NAT mapping for each access device on the NAT device. If this feature is enabled, the access device automatically sends a register packet to the portal authentication server. When the server receives the register packet, it records register information for the access device, including the device name and the IP address and port number after NAT. The register information is used for subsequent authentication information exchanges between the server and the access device. The access device updates its register information on the server by sending register packets at regular intervals.

This feature can work with only CMCC portal authentication servers.

Examples

Configure the device to send register packets to portal authentication server **pts** at intervals of 120 seconds.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] server-register interval 120
```

Related commands

server-type

server-type (portal authentication/Web server view)

Use **server-type** to specify the type of a portal authentication server or portal Web server.

Use **undo server-type** to restore the default.

Syntax

server-type { **cmcc** | **imc** }

undo server-type

Default

The type of the portal authentication server and portal Web server is IMC.

Views

Portal authentication server view

Portal Web server view

Predefined user roles

network-admin

Parameters

cmcc: Specifies the portal server type as CMCC.

imc: Specifies the portal server type as IMC.

Usage guidelines

Specify the portal server type on the device with the server type the device actually uses.

Examples

Specify the type of portal authentication server as **imc**.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] server-type imc
```

Specify the type of portal Web server as **imc**.

```
<Sysname> system-view

[Sysname-portal-websvr-pts] server-type imc
```

Related commands

display portal server

tcp-port

Use **tcp-port** to configure a listening TCP port for the local portal Web service.

Use **undo tcp-port** to restore the default.

Syntax

tcp-port *port-number*

undo tcp-port

Default

The listening TCP port number for HTTP is 80 and that for HTTPS is the TCP port number set by the **portal local-web-server** command.

Views

Local portal Web service view

Predefined user roles

network-admin

Parameters

port-number: Specifies the listening TCP port number in the range of 1 to 65535.

Usage guidelines

To use the local portal Web service, make sure the port number in the portal Web server URL and the port number configured in this command are the same.

For successful local portal authentication, follow these guidelines:

- Do not configure the listening TCP port number for a local portal Web service as the port number used by a known protocol. For example, do not specify port numbers 21 and 23, which are used by FTP and Telnet, respectively.

- Do not configure the HTTP listening port number as the default HTTPS listening port number 443.
- Do not configure the HTTPS listening port number as the default HTTP listening port number 80.
- Do not configure the same listening port number for HTTP and HTTPS.
- For the HTTPS-based local portal Web service and other services that use HTTPS:
  - If they use the same SSL server policy, they can use the same TCP port number to listen to HTTPS.
  - If they use different SSL server policies, they cannot use the same TCP port number to listen to HTTPS.

Examples

Set the listening port number to 2331 for the HTTP-based local portal Web service.

```
<Sysname> system-view
[Sysname] portal local-web-server http
[Sysname-portal-local-websvr-http] tcp-port 2331
```

Related commands

portal local-web-server

url

Use **url** to specify a URL for a portal Web server.

Use **undo url** to restore the default.

Syntax

url *url-string*

undo url

Default

No URL is specified for a portal Web server.

Views

Portal Web server view

Predefined user roles

network-admin

Parameters

url-string: Specifies a URL for the portal Web server, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

Usage guidelines

This command specifies a URL that can be accessed through standard HTTP or HTTPS. The URL should start with **http://** or **https://**. If the URL you specify does not start with **http://** or **https://,** the system considers the URL begins with **http://** by default.

Examples

Configure the URL for portal Web server **wbs** as **http://www.test.com/portal**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
```

```
[Sysname-portal-websvr-wbs] url http://www.test.com/portal
```

Related commands

display portal web-server

url-parameter

Use **url-parameter** to configure the parameters carried in the URL of a portal Web server. The access device redirects a portal user by sending the URL with the parameters to the user.

Use **undo url-parameter** to delete the parameters carried in the URL of the portal Web server.

Syntax

url-parameter *param-name* { **original-url** | **source-address** | **source-mac** [**encryption** { **aes** | **des** } **key** { **cipher** | **simple** } *string*] | **value** *expression* }

undo url-parameter *param-name*

Default

No URL parameters are configured for a portal Web server.

Views

Portal Web server view

Predefined user roles

network-admin

Parameters

param-name: Specifies a URL parameter name, a case-sensitive string of 1 to 32 characters. Content of the parameter is determined by the following keyword you specify.

original-url: Specifies the URL of the original webpage that a portal user visits.

source-address: Specifies the user IP address.

source-mac: Specifies the user MAC address.

encryption: Specifies the encryption algorithm to encrypt the MAC address of the user.

aes: Specifies the AES algorithm.

des: Specifies the DES algorithm.

key: Specifies a key for encryption.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the case-sensitive key string. The string length varies by the selected encryption method:

- If **des cipher** is specified, the string length is 41 characters.
- If **des simple** is specified, the string length is 8 characters.
- If **aes cipher** is specified, the string length is 1 to 73 characters.
- If **aes simple** is specified, the string length is 1 to 31 characters.

value *expression*: Specifies a custom case-sensitive string of 1 to 256 characters. The string can include question marks (?). If you enter a question mark (?) in the place of the *expression* argument, the CLI does not display help information for this argument.

Usage guidelines

You can configure multiple URL parameters.

If you execute this command multiple times to configure the same URL parameter, the most recent configuration takes effect.

After you configure the URL parameters, the access device sends the portal Web server URL with these parameters to portal users. For example, assume that the URL of a portal Web server is http://www.test.com/portal, and you execute the **url-parameter userip source-address** and **url-parameter userurl value http://www.abc.com/welcome** commands. Then, the access device sends to the user whose IP address is 1.1.1.1 the URL **http://www.test.com/portal?userip=1.1.1.1&userurl=http://www.abc.com/welcome**.

When you configure the *param-name* argument in this command, you must use the URL parameter name supported by the actual portal server. Different portal server types support different URL parameter names.

For example, the IMC server supports parameter names **userurl**, **userip**, and **usermac** for the keywords **original-url**, **source-address**, and **source-mac**, respectively. To carry the user IP information in the portal Web server URL, you must configure the parameter name as **userip** and specify the **source-address** keyword.

If you specify the encryption algorithm for a parameter, the redirection URL carries the encrypted value for the parameter. Execute the **url-parameter usermac source-mac encryption des key simple 12345678** command. Then the access device sends to the user with MAC address 1111-1111-1111 the URL **http://www.test.com/portal?usermac=xxxxxxxxx&userip=1.1.1.1&userurl=http://www.test.com/welcome**, where **xxxxxxxxx** represents the encrypted user MAC address.

Examples

Configure URL parameters **userip** and **userurl** for the portal Web server **wbs**. Configure the value of the **userip** parameter as **source-address** (the IP addresses of users) and that of the **userurl** parameter as **http://www.abc.com/welcome**.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] url-parameter userip source-address
[Sysname-portal-websvr-wbs] url-parameter userurl value http://www.abc.com/welcome
```

Configure URL parameter **usermac** for the portal Web server **wbs**. Configure the value of the **usermac** parameter as **source-mac** (the MAC addresses of users) and specify DES to encrypt the MAC addresses.

```
<Sysname> system-view
[Sysname] portal web-server wbs
[Sysname-portal-websvr-wbs] url-parameter usermac source-mac encryption des key simple
12345678
```

Related commands

display portal web-server

user-sync

Use **user-sync** to enable portal user synchronization for a portal authentication server.

Use **undo user-sync** to disable portal user synchronization for a portal authentication server.

Syntax

user-sync timeout *timeout*

undo user-sync

Default

Portal user synchronization is disabled for a portal authentication server.

Views

Portal authentication server view

Predefined user roles

network-admin

Parameters

timeout *timeout*: Sets a detection timeout for synchronization packets, in the range of 60 to 18000 seconds.

Usage guidelines

After this feature is enabled, the device replies to and periodically detects the synchronization packets from the portal authentication server. In this way, information about online portal users on the device and on the portal authentication server remains consistent.

Portal user synchronization requires that the portal authentication server support the portal user heartbeat feature. Now, only the IMC portal authentication server supports portal user heartbeat. To implement portal user synchronization, you need to configure the user heartbeat feature on the portal authentication server. Make sure the user heartbeat interval configured on the portal authentication server is not greater than the synchronization detection timeout configured on the access device.

Deleting a portal authentication server on the device also deletes the user synchronization configuration for the server.

If you execute this command multiple times, the most recent configuration takes effect.

For information of the users considered as nonexistent on the portal authentication server, the device deletes the information after the configured detection timeout expires.

If the user information from the portal authentication server does not exist on the device, the device encapsulates IP addresses of the users in user heartbeat reply packets to the server. The portal authentication server then deletes the users.

Examples

Enable portal user synchronization for portal authentication server **pts** and set the detection timeout to **600** seconds. If a use has not appeared in the synchronization packets sent by the portal authentication server for 600 seconds, the access device logs out the user.

```
<Sysname> system-view
[Sysname] portal server pts
[Sysname-portal-server-pts] user-sync timeout 600
```

Related commands

portal server

web-redirect url

Use **web-redirect url** to enable the Web redirect feature.

Use **undo web-redirect url** to disable the Web redirect feature.

Syntax

web-redirect [**ipv6**] **url** *url-string* [**interval** *interval*]

undo web-redirect [**ipv6**]

Default

The Web redirect feature is disabled.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6: Specifies the IPv6 Web redirect feature. Do not specify this keyword for the IPv4 Web redirect feature.

url *url-string*: Specifies the URL to which the user is redirected. The URL is required to be complete and begins with **http://** or **https://**, a string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

interval *interval*: Specifies the time interval at which the user is redirected to the specified URL. It is in the range of 60 to 86400 seconds. The default interval is 86400 seconds.

Usage guidelines

With Web redirect enabled on an interface, a user on the interface is first redirected to the specified URL before the user can access an external network through a Web browser. After the specified interval, the user is redirected to the specified URL again.

Web redirect does not work when both Web redirect and portal authentication are enabled.

The Web redirect feature takes effect only on HTTP packets that use the default port number 80.

Examples

Configure IPv4 Web redirect on VLAN-interface 100. Set the redirect URL to **http://192.0.0.1** and the interval to **3600** seconds.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] web-redirect url http://192.0.0.1 interval 3600
```

Web authentication commands

display web-auth

Use **display web-auth** to display Web authentication configuration and running status on interfaces.

Syntax

display web-auth [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays Web authentication configuration for all interfaces.

Examples

Display Web authentication configuration on GigabitEthernet 1/0/1.

```
<Sysname> display web-auth interface gigabitethernet 1/0/1
 Global Web-auth parameters:
   Temp entry aging time     : 500 s
   HTTP proxy port numbers   : Not configured
   HTTPS proxy port numbers  : Not configured
 Total online web-auth users  : 1

 GigabitEthernet1/0/1  is link-up
   Port role               : Authenticator
   Web-auth domain          : my-domain
   Auth-Fail VLAN           : Not configured
   Offline-detect           : Not configured
   Max online users         : 1024
   Web-auth enable          : Enabled

   Total online web-auth users: 1
```

Table 1 Command output

Field	Description
Global Web-auth parameters	Global Web authentication configuration.
Temp entry aging time	Aging timer for temporary MAC address entries. This field is supported only in Release 6343P08 and later.
HTTP proxy port numbers	HTTP port numbers of the Web proxy servers.
HTTPS proxy port numbers	HTTPS port numbers of the Web proxy servers.

Total online web-auth users	Total number of online Web authentication users on the device.
GigabitEthernet1/0/1 is link-up	State of the interface: • **link-up**—The interface is both administratively and physically up. • **link-down**—The interface is down.
Port role	Role of the port. The port functions only as an **Authenticator**.
Web-auth domain	ISP domain used by Web authentication.
Auth-fail VLAN	Auth-Fail VLAN for Web authentication. This field displays **Not configured** if no Auth-Fail VLAN is configured.
Offline-detect	Interval of Web authentication user detection. This field displays **Not configured** if online detection for Web authentication users is disabled.
Max online users	Maximum number of Web authentication users allowed on the interface.
Web-auth enable	State of Web authentication: • Enabled. • Disabled.
Total online web-auth users	Total number of online Web authentication users on the interface.

display web-auth free-ip

Use **display web-auth free-ip** to display Web authentication-free subnets.

Syntax

display web-auth free-ip

Views

Any view

Predefined user roles

network-admin

network-operator

Examples

Display Web authentication-free subnets.

```
<Sysname> display web-auth free-ip
      Free IP
                      : 1.1.0.0       255.255.0.0
                      : 1.2.0.0       255.255.0.0
```

Related commands

web-auth free-ip

display web-auth server

Use **display web-auth server** to display Web authentication server information.

Syntax

display web-auth server [*server-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

server-name: Specifies a Web authentication server name, a case-sensitive string of 1 to 32 characters. If you do not specify a Web authentication server, this command displays information about all Web authentication servers.

Examples

Display information about Web authentication server **aaa**.

```
<Sysname> display web-auth server aaa
Web-auth server: aaa
  IP                   : 8.8.8.8
  Port                 : 80
  URL                  : http://8.8.8.8/portal/
  Redirect-wait-time   : 5
  URL parameters       : Not configured
```

Table 2 Command output

Field	Description
Web-auth server	Name of the Web authentication server.
IP	IP address of the Web authentication server.
Port	Port number of the Web authentication server.
URL	Redirection URL of the Web authentication server.
Redirect-wait-time	Time before redirecting an authenticated user to the webpage requested by the user.
URL parameters	Parameters in the redirection URL.

display web-auth user

Use **display web-auth user** to display information about online Web authentication users on interfaces.

Syntax

display web-auth user [**interface** *interface-type interface-number* | **slot** *slot-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies an interface by its type and number. If you do not specify an interface, this command displays information about online Web authentication users on all interfaces.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays online Web authentication user information for all member devices.

Examples

Display information about online Web authentication users on GigabitEthernet 1/0/1.

```
<Sysname> display web-auth user interface gigabitethernet 1/0/1
  Total online web-auth users: 1

User name: user1
  MAC address: 0000-2700-b076
  Access interface: GigabitEthernet 1/0/1
  Initial VLAN: 1
  Authorization VLAN: N/A
  Authorization ACL ID: N/A
  Authorization user profile: N/A
```

Table 3 Command output

Field	Description
Total online web-auth users	Total number of online Web authentication users.
User Name	Name of the online Web authentication user.
MAC address	MAC address of the online Web authentication user.
Access interface	Access interface of the online Web authentication user.
Initial VLAN	Initial VLAN of the user before the user passes Web authentication.
Authorization VLAN	Authorization VLAN ID of the online Web authentication user.
Authorization ACL ID	Authorization ACL number of the online Web authentication user.
Authorization user profile	Status of user profile of the online Web authentication user: • **N/A**—No user profile is authorized. • **Active**—The authorized user profile is applied to the user access interface successfully. • **Inactive**—The authorized user profile is not applied to the user access interface or the user profile does not exist on the device.

ip

Use **ip** to specify the IP address and port number for a Web authentication server.

Use **undo ip** to restore the default.

Syntax

ip *ipv4-address* **port** *port-number*

undo ip

Default

No IP address or port number is specified for a Web authentication server.

Views

Web authentication server view

Predefined user roles

network-admin

Parameters

ipv4-address: Specifies the IPv4 address of the Web authentication server. This IP address is that of a Layer 3 interface on the access device and must be routable to and from the Web authentication user.

port *port-number*: Specifies the port number of the Web authentication server, in the range of 1 to 65535.

User guidelines

As a best practice, use the IP address of a loopback interface as the IP address of the Web authentication server. A loopback interface has the following advantages:

- The status of a loopback interface is stable. This can avoid authentication page access failures caused by interface failures.
- A loopback interface does not forward received packets. This can avoid impacting system performance when there are many network access requests.

The port number of the Web authentication server must be the same as the listening port of the local portal Web service. For more information about the local portal Web service configuration, see portal authentication in *Security Configuration Guide*.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Enter the view of Web authentication server **wbs**.

```
<Sysname> system-view
[Sysname] web-auth server wbs
```

Specify 192.168.1.1 as the IP address and 8080 as the port number for Web authentication server **wbs**.

```
[Sysname-web-auth-server-wbs] ip 192.168.1.1 port 8080
```

Related commands

url

tcp-port

redirect-wait-time

Use **redirect-wait-time** to set the redirection wait time. After a user passes Web authentication, the device waits for the specified period of time before redirecting the user to the specified webpage.

Use **undo redirect-wait-time** to restore the default.

Syntax

redirect-wait-time *period*

undo redirect-wait-time

Default

The redirection wait time is 5 seconds.

Views

Web authentication server view

Predefined user roles

network-admin

Parameters

period: Specifies the redirection wait time in the range of 1 to 90 seconds.

Usage guidelines

After a user passes Web authentication and is assigned an authorization VLAN, the user might need to change the IP address of the authentication client. To ensure that the redirection URL can be successfully opened, set the redirection wait time to be greater than the time that the user takes to update the IP address of the client.

Examples

Set the redirection wait time for authenticated users to 10 seconds.

```
<Sysname> system-view
[Sysname] web-auth server wbs
[Sysname-web-auth-server-wbs] redirect-wait-time 10
```

url

Use **url** to specify the redirection URL for a Web authentication server.

Use **undo url** to restore the default.

Syntax

url *url-string*

undo url

Default

No redirection URL is specified for a Web authentication server.

Views

Web authentication server view

Predefined user roles

network-admin

Parameters

url-string: Specifies the redirection URL for the Web authentication server, a case-sensitive string of 1 to 256 characters. The URL string can include question marks (?). If you enter a question mark (?) in the place of the *url-string* argument, the CLI does not display help information for this argument.

Usage guidelines

The redirection URL is a URL that can be accessed through standard HTTP or HTTPS. The redirection URL should start with **http://** or **https://**. If the redirection URL does not start with http:// or https://, the system determines that the URL begins with **http://**.

The IP address and port number in the URL must be the same as the IP address and port number of the Web authentication server.

Examples

Specify **http://192.168.1.1:80/portal/** as the redirection URL for Web authentication server **wbs**.

```
<Sysname> system-view
[Sysname] web-auth server wbs
[Sysname-web-auth-server-wbs] url http://192.168.1.1:80/portal/
```

Related commands

ip

tcp-port

url-parameter

Use **url-parameter** to add parameters to the redirection URL of Web authentication.

Use **undo url-parameter** to delete parameters from the redirection URL of Web authentication.

Syntax

url-parameter *parameter-name* { **original-url** | **source-address** | **source-mac** | **value** *expression* }

undo url-parameter *parameter-name*

Default

No URL parameters are added to the redirection URL of Web authentication.

Views

Web authentication server view

Predefined user roles

network-admin

Parameters

parameter-name: Specifies a URL parameter name, a case-sensitive string of 1 to 32 characters. Content of the parameter is determined by the following keyword you specify.

original-url: Specifies the URL of the original webpage that a portal user visits.

source-address: Specifies the user IP address.

source-mac: Specifies the user MAC address.

value *expression*: Specifies a custom case-sensitive string of 1 to 256 characters. The string can include question marks (?). If you enter a question mark (?) in the place of the *expression* argument, the CLI does not display help information for this argument.

Usage guidelines

You can repeat this command to add multiple URL parameters to the redirection URL of Web authentication. For example, to add the user IP address and a custom string of **http://www.abc.com/welcome** to the redirection URL, execute the following commands:

- **url-parameter userip source-address**.
- **url-parameter userurl value http://www.abc.com/welcome**.

The device will redirect Web requests from IP address 1.1.1.1 to the URL at **http://192.168.1.1/portal?userip=1.1.1.1&userurl=http://www.abc.com/welcome**.

If you execute this command multiple times to configure the same URL parameter, the most recent configuration takes effect.

When you configure the *parameter-name* argument in this command, you must use the URL parameter name supported by the Web browser. Different Web browsers support different URL parameter names.

Examples

Add parameters **userip** and **userurl** to the redirection URL of portal Web server **wbs**.

```
<Sysname> system-view
[Sysname] web-auth server wbs
[Sysname-web-auth-server-wbs] url-parameter userip source-address
[Sysname-web-auth-server-wbs] url-parameter userurl value http://www.abc.com/welcome
```

Related commands

web-auth server

web-auth auth-fail vlan

Use **web-auth auth-fail vlan** to specify an Auth-Fail VLAN for Web authentication.

Use **undo web-auth auth-fail vlan** to restore the default.

Syntax

web-auth auth-fail vlan *authfail-vlan-id*

undo web-auth auth-fail vlan

Default

No Auth-Fail VLAN is specified for Web authentication.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

authfail-vlan-id: Specifies the Auth-Fail VLAN ID in a range of 1 to 4094. The specified VLAN must already exist.

User guidelines

After you configure this command on an interface, users who failed Web authentication on the interface can access resources in the Auth-Fail VLAN. You must also configure the IP address of the server that provides the resources as an authentication-free IP address.

To make the Auth-Fail VLAN take effect, you must also enable MAC-based VLAN on the interface, and set the subnet of the Auth-Fail VLAN as the Web authentication-free subnet.

Because MAC-based VLAN takes effect only on Hybrid ports, Auth-Fail VLAN also takes effect only on Hybrid ports.

If a user fails Web authentication, the device maps the MAC address of the user to the Auth-Fail VLAN.

You cannot delete the VLAN that has been configured as an Auth-Fail VLAN. To delete this VLAN, first cancel the Auth-Fail VLAN configuration by using **undo web-auth auth-fail vlan** command.

Examples

Specify VLAN 5 as Web authentication Auth-Fail VLAN on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] port link-type hybrid
```

```
[Sysname–GigabitEthernet1/0/1] mac-vlan enable
[Sysname–GigabitEthernet1/0/1] web-auth auth-fail vlan 5
```

Related commands

display web-auth

web-auth domain

Use **web-auth domain** to specify an authentication domain for Web authentication users on an interface.

Use **undo web-auth domain** to restore the default.

Syntax

web-auth domain *domain-name*

undo web-auth domain

Default

No authentication domain is specified for Web authentication users on an interface.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

domain-name: Specifies an ISP authentication domain name, a case-insensitive string of 1 to 255 characters.

User guidelines

After you configure this command, the device uses the authentication domain for authentication, authorization and accounting (AAA) of the Web authentication users on the interface.

Examples

Specify domain **my-domain** as the authentication domain of Web authentication users on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname–GigabitEthernet1/0/1] web-auth domain my-domain
```

web-auth enable

Use **web-auth enable** to enable Web authentication.

Use **undo web-auth enable** to disable Web authentication.

Syntax

web-auth enable apply server *server-name*

undo web-auth enable

Default

Web authentication is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

server-name: Specifies the Web authentication server name, a case-sensitive string of 1 to 32 characters.

User guidelines

Use this command to enable Web authentication on an interface and specify a Web authentication server.

For Web authentication to operate correctly, do not enable port security or configure the port security mode on the Layer 2 Ethernet interface enabled with Web authentication.

Examples

Enable Web authentication and specify Web authentication server **wbs** on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] web-auth enable apply server wbs
```

Related commands

web-auth server

web-auth free-ip

Use **web-auth free-ip** to specify a Web authentication-free subnet.

Use **undo web-auth free-ip** to restore the default.

Syntax

web-auth free-ip *ip-address* { *mask-length* | *mask* }

undo web-auth free-ip { *ip-address* { *mask-length* | *mask* } | **all** }

Default

No Web-authentication-free subnets exist.

Views

System view

Predefined user roles

network-admin

Parameters

ip-address: Specifies the Web authentication-free subnet address.

mask-length: Specifies the mask length of the Web authentication-free subnet address, in the range of 1 to 32.

mask: Specifies a mask for the Web authentication-free subnet in dotted decimal notation.

all: Specifies all Web authentication-free subnets.

User guidelines

Web authentication users can access resources in Web authentication-free subnets without being authenticated.

You can repeat this command to configure multiple Web authentication-free subnets.

Examples

Configure subnet 192.168.0.0/24 as a Web authentication-free subnet.

```
<Sysname> system-view
[Sysname] web-auth free-ip 192.168.0.0 24
```

web-auth max-user

Use **web-auth max-user** to set the maximum number of Web authentication users allowed on an interface.

Use **undo web-auth max-user** to restore the default.

Syntax

web-auth max-user *max-number*

undo web-auth max number

Default

The maximum number of Web authentication users allowed on an interface is 1024.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of Web authentication users allowed on an interface. The value range for this argument is 1 to 2048.

User guidelines

If the specified maximum number is smaller than the number of current online Web authentication users on the interface, the limit can be set successfully. The limit does not impact the online Web authentication users. However, the device does not allow new Web authentication users to log in from the interface until the number drops down below the limit.

This command specifies the maximum number of only IPv4 Web authentication users.

Examples

On GigabitEthernet 1/0/1, set the maximum number of Web authentication users to 32.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] web-auth max-user 32
```

Related commands

display web-auth

web-auth offline-detect

Use **web-auth offline-detect** to enable online detection of Web authentication users.

Use **undo web-auth max-user** to disable online detection of Web authentication users.

Syntax

web-auth offline-detect interval *interval*

undo web-auth offline-detect interval

Default

Online detection of Web authentication users is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

interval: Specifies the Web authentication user detection interval, in the range of 60 to 65535 seconds.

User guidelines

This feature enables the device to detect packets of an online user at the specified detection interval. If no packet from the user is received within the interval, the device logs out the user and notifies the RADIUS server to stop accounting for the user.

To prevent the device from mistakenly logging out users, set the detection interval to be the same as the aging time of MAC address entries.

Examples

On GigabitEthernet 1/0/1, enable online detection of Web authentication users and set the detection interval to 3600 seconds.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] web-auth offline-detect interval 3600
```

web-auth proxy port

Use **web-auth proxy port** to add the port number of a Web proxy server, so that HTTP requests forwarded by the Web proxy server trigger Web authentication.

Use **undo web-auth proxy port** to delete one or all Web proxy server port numbers.

Syntax

web-auth proxy port *port number*

undo web-auth proxy port { *port-number* | **all** }

Default

No Web proxy server port numbers are configured on the device.

Views

System view

Predefined user roles

network-admin

Parameters

port number: Specifies a Web proxy server TCP port number, in the range of 1 to 65535.

all: Specifies all Web proxy server TCP port numbers.

User guidelines

By default, proxied HTTP requests cannot trigger Web authentication but are silently dropped. To allow such HTTP requests to trigger Web authentication, specify the port numbers of the Web proxy servers on the device.

You can repeat this command to add the port numbers of multiple Web proxy servers.

If a user's browser uses the Web Proxy Auto-Discovery (WPAD) protocol to discover Web proxy servers, you must perform the following tasks:

- Add the port numbers of the Web proxy servers on the device.
- Configure authentication-free rules to allow user packets destined for the IP address of the WPAD server to pass without authentication.
- For Web authentication to support Web proxy:
- You must add the port numbers of the Web proxy servers on the device.
- Users must make sure their browsers that use a Web proxy server do not use the proxy server for the listening IP address of the local portal Web service. Then, HTTP packets that the Web authentication user sends to the local portal Web service are not sent to the Web proxy server.

Examples

Add the Web proxy server TCP port number of 7777 for Web authentication.

```
<Sysname> system-view
[Sysname] web-auth proxy port 7777
```

web-auth server

Use **web-auth server** to create a Web authentication server and enter its view, or enter the view of an existing Web authentication server.

Use **undo web-auth server** to delete a Web authentication server.

Syntax

web-auth server *server-name*

undo web-auth server *server-name*

Default

No Web authentication servers exist.

Views

System view

Predefined user roles

network-admin

Parameters

server-name: Specifies a Web authentication server name, a case-sensitive string of 1 to 32 characters.

User guidelines

In Web authentication server view, you can configure the following parameters and features for the Web authentication server:

- IP address of the server.
- Redirection URL.

- Parameters to be carried in the redirection URL.

Examples

Create a Web authentication server named **wbs** and enter its view.

```
<Sysname> system-view
[Sysname] web-auth server wbs
[Sysname-web-auth-server-wbs]
```

Related commands

web-auth enable apply server

web-auth timer temp-entry-aging

Use **web-auth timer temp-entry-aging** to configure the aging timer for temporary MAC address entries.

Use **undo web-auth timer temp-entry-aging** to restore the default.

Syntax

web-auth timer temp-entry-aging *aging-time-value*

undo web-auth timer temp-entry-aging

Default

The aging timer for temporary MAC address entries is 60 seconds.

Views

System view

Default command level

network-admin

Parameters

aging-time-value: Specifies the aging timer in seconds for temporary MAC address entries, in the range of 60 to 2147483647.

Usage guidelines

This command is supported only in Release 6343P08 and later.

If Web authentication is enabled, the device generates a temporary MAC address entry when it detects traffic from a user for the first time. The entry records the MAC address, access interface, and VLAN ID of the user, as well as the aging time of the entry.

The aging timer works as follows:

- If the user does not initiate authentication when the aging timer expires, the device deletes the temporary entry.
- If the user passes authentication before the aging timer expires, the device delete the aging timer and records online information for the Web authentication user.
- If the user fails authentication before the aging timer expires and an Auth-Fail VLAN is specified for Web authentication, the device binds the MAC address of the user to the Auth-fail VLAN and reset the aging timer. If the user still fails authentication when the aging timer expires, the device deletes the temporary entry for the user.

As a best practice, change the aging timer to a bigger value in the following cases:

- Web authentication users without access rights frequently send traffic in a short time. As a result, the access device continuously initiates the web authentication process, increasing the load on the device.

- When a user fails authentication, the user does not have enough time to obtain resources from the Auth-Fail VLAN, for example, it failed to download the virus patches.

Examples

Set the aging timer for temporary MAC address entries to 500 seconds.

```
<Sysname> system-view
[Sysname] web-auth timer temp-entry-aging 500
```

Port security commands

display port-security

Use **display port-security** to display port security configuration, operation information, and statistics for ports.

Syntax

display port-security [**interface** *interface-type interface-number*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number. If you do not specify a port, this command displays port security information for all ports.

Examples

Display port security information for all ports.

```
<Sysname> display port-security
Global port security parameters:
   Port security        : Enabled
   AutoLearn aging time   : 0 min
   Disableport timeout    : 20 s
   Blockmac timeout      : 180 s
   MAC move             : Denied
   Authorization fail    : Online
   NAS-ID profile        : Not configured
   Dot1x-failure trap    : Disabled
   Dot1x-logon trap      : Disabled
   Dot1x-logoff trap     : Enabled
   Intrusion trap        : Disabled
   Address-learned trap   : Enabled
   Mac-auth-failure trap  : Disabled
   Mac-auth-logon trap    : Enabled
   Mac-auth-logoff trap   : Disabled
   Open authentication    : Disabled
   OUI value list        :
    Index :  1         Value : 123401

 GigabitEthernet1/0/1 is link-up
   Port mode                   : userLogin
   NeedToKnow mode              : Disabled
   Intrusion protection mode     : NoAction
   Security MAC address attribute
```

```
   Learning mode           : Sticky
   Aging type              : Periodical
Max secure MAC addresses      : 32
Current secure MAC addresses   : 0
Authorization               : Permitted
NAS-ID profile              : Not configured
Free VLANs                  : Not configured
Open authentication          : Disabled
MAC-move VLAN check bypass    : Disabled
```

Table 1 Command output

Field	Description
Port security	Whether the port security feature is enabled.
AutoLearn aging time	Sticky MAC address aging timer, in minutes or seconds.
Disableport timeout	Silence period (in seconds) of the port that receives illegal packets.
Blockmac timeout	This field is not supported in the current software version. Block timer (in seconds) for MAC addresses in the blocked MAC address list.
MAC move	Status of MAC move: • If the feature is enabled, this field displays **Permitted**. • If the feature is disabled, this field displays **Denied**.
Authorization fail	Action to be taken for users that fail authorization: • **Online**—Allows the users to go online. • **Offline**—Logs off the users.
NAS-ID profile	NAS-ID profile applied globally.
Dot1x-failure trap	Whether SNMP notifications for 802.1X authentication failures are enabled.
Dot1x-logon trap	Whether SNMP notifications for 802.1X authentication successes are enabled.
Dot1x-logoff trap	Whether SNMP notifications for 802.1X authenticated user logoffs are enabled.
Intrusion trap	Whether SNMP notifications for intrusion protection are enabled. If they are enabled, the device sends SNMP notifications after illegal packets are detected.
Address-learned trap	Whether SNMP notifications for MAC address learning are enabled. If they are enabled, the device sends SNMP notifications after it learns a new MAC address.
Mac-auth-failure trap	Whether SNMP notifications for MAC authentication failures are enabled.
Mac-auth-logon trap	Whether SNMP notifications for MAC authentication successes are enabled.
Mac-auth-logoff trap	Whether SNMP notifications for MAC authentication user logoffs are enabled.
Open authentication	Whether global open authentication mode is enabled.
OUI value list	List of OUI values allowed for authentication.

Field	Description
Port mode	Port security mode: • noRestrictions. • autoLearn. • macAddressWithRadius. • macAddressElseUserLoginSecure. • macAddressElseUserLoginSecureExt. • secure. • userLogin. • userLoginSecure. • userLoginSecureExt. • macAddressOrUserLoginSecure. • macAddressOrUserLoginSecureExt. • userLoginWithOUI. For more information about port security modes, see *Security Configuration Guide*.
NeedToKnow mode	Need to know (NTK) mode: • **NeedToKnowOnly**—Forwards only unicast frames with an authenticated destination MAC address. • **NeedToKnowWithBroadcast**—Forwards only broadcast and unicast frames with an authenticated destination MAC address. • **NeedToKnowWithMulticast**—Forwards only broadcast, multicast, and unicast frames with an authenticated destination MAC address. • **NeedToKnowAuto**—Forwards only broadcast, multicast, and unicast frames with an authenticated destination MAC address, and only when the port has online users. • **Disabled**—NTK is disabled.
Intrusion protection mode	Intrusion protection action: • **BlockMacAddress**—Adds the source MAC address of the illegal packet to the blocked MAC address list. • **DisablePort**—Shuts down the port that receives illegal packets permanently. • **DisablePortTemporarily**—Shuts down the port that receives illegal packets for some time. • **NoAction**—Does not perform intrusion protection.
Learning mode	Secure MAC address learning mode: • **Dynamic**. • **Sticky**.
Aging type	Secure MAC address aging type: • **Periodical**—Timer aging only. • **Inactivity**—Inactivity aging feature together with the aging timer.
Max secure MAC addresses	Maximum number of secure MAC addresses (or online users) that port security allows on the port.
Current secure MAC addresses	Number of secure MAC addresses stored.

Field	Description
Authorization	Whether the authorization information from the authentication server (RADIUS server or local device) is ignored: • **Permitted**—Authorization information from the authentication server takes effect. • **Ignored**—Authorization information from the authentication server does not take effect.
NAS-ID profile	NAS-ID profile applied to the port.
Free VLANs	This field is supported only in Release 6328 and later. VLANs in which packets will not trigger authentication. If you do not configure free VLANs, this field displays **Not configured**.
Open authentication	Whether open authentication mode is enabled on the port.
MAC-move VLAN check bypass	Whether the VLAN check bypass feature is enabled for users moving to the port from other ports.

display port-security mac-address block

Use **display port-security mac-address block** to display information about blocked MAC addresses.

Syntax

display port-security mac-address block [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

vlan *vlan-id*: Specifies a VLAN by its ID. The value range is 1 to 4094.

count: Displays only the count of the blocked MAC addresses.

Usage guidelines

If you do not specify any parameters, this command displays information about all blocked MAC addresses.

Examples

Display information about all blocked MAC addresses.

```
<Sysname> display port-security mac-address block
 MAC ADDR           Port                    VLAN ID
 000f-3d80-0d2d     GE1/0/1                 30

 --- On slot 1, 1 MAC address(es) found ---

 --- 1 mac address(es) found ---
```

Display the count of all blocked MAC addresses.

```
<Sysname> display port-security mac-address block count

--- On slot 1, 1 MAC address(es) found ---

--- 1 mac address(es) found ---
```

Table 2 Command output

Field	Description
MAC ADDR	Blocked MAC address.
Port	Port having received frames with the blocked MAC address being the source address.
VLAN ID	ID of the VLAN to which the port belongs.
number mac address(es) found	Number of blocked MAC addresses.

Related commands

port-security intrusion-mode

display port-security mac-address security

Use **display port-security mac-address security** to display information about secure MAC addresses.

Syntax

display port-security mac-address security [**interface** *interface-type interface-number*] [**vlan** *vlan-id*] [**count**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

interface *interface-type interface-number*: Specifies a port by its type and number.

vlan *vlan-id*: Specifies a VLAN by its ID. The value range is 1 to 4094.

count: Displays only the count of the secure MAC addresses.

Usage guidelines

Secure MAC addresses are those that are automatically learned by the port in autoLearn mode or configured by the **port-security mac-address security** command.

If you do not specify any parameters, this command displays information about all secure MAC addresses.

Examples

Display information about all secure MAC addresses.

```
<Sysname> display port-security mac-address security
 MAC ADDR       VLAN ID  STATE        PORT INDEX               AGING TIME
```

```
0002-0002-0002  1       Secure       GE1/0/1                    Not aged

--- Number of secure MAC addresses: 1 ---
```

Display only the count of the secure MAC addresses.

```
<Sysname> display port-security mac-address security count

--- Number of secure MAC addresses: 1 ---
```

Table 3 Command output

Field	Description
MAC ADDR	Secure MAC address.
VLAN ID	ID of the VLAN to which the port belongs.
STATE	Type of the MAC address. This field displays **Secure** for a secure MAC address.
PORT INDEX	Port to which the secure MAC address belongs.
AGING TIME	The remaining amount of time before the secure MAC address ages out. • If the secure MAC address is a static MAC address, this field displays **Not aged**. • If the secure MAC address is a sticky MAC address, this field displays the remaining lifetime. If the remaining lifetime is less than 60 seconds, the lifetime is counted in seconds. If the lifetime is not less than 60 seconds, the lifetime is counted in minutes. By default, sticky MAC addresses do not age out, and this field displays **Not aged**.
Number of secure MAC addresses	Number of secure MAC addresses stored.

Related commands

port-security mac-address security

port-security access-user log enable

Use **port-security access-user log enable** to enable port security user logging.

Use **undo port-security access-user log enable** to disable port security user logging.

Syntax

port-security access-user log enable [**failed-authorization** | **mac-learning** | **violation** | **vlan-mac-limit**] *

undo port-security access-user log enable [**failed-authorization** | **mac-learning** | **violation** | **vlan-mac-limit**] *

Default

Port security user logging is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

failed-authorization: Logs authorization failures of 802.1X or MAC authentication users.

mac-learning: Logs MAC address learning events.

violation: Logs intrusion protection events.

vlan-mac-limit: Logs the first access attempt from a new MAC access in a VLAN after port security's MAC address limit for that VLAN is reached. For each VLAN, the system does not log any access attempts from new MAC addresses except the first one after the MAC address limit is reached.

Usage guidelines

To prevent excessive port security user log entries, use this feature only if you need to analyze abnormal port security user events.

If you do not specify any parameters, this command enables all types of port security user logs.

Examples

Enable intrusion protection event logging.

```
<Sysname> system-view
[Sysname] port-security access-user log enable violation
```

Related commands

info-center source portsec logfile deny (*Network Management and Monitoring Command Reference*)

port-security authentication open

Use **port-security authentication open** to enable open authentication mode on a port.

Use **undo port-security authentication open** to disable open authentication mode on a port.

Syntax

port-security authentication open

undo port-security authentication open

Default

Open authentication mode is disabled on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

This command enables access users (802.1X or MAC authentication users) of a port to come online and access the network even if they use nonexistent usernames or incorrect passwords.

Access users that come online in open authentication mode are called open users. Authorization and accounting are not available for open users. To display open user information, use the following commands:

- **display dot1x connection open**.
- **display mac-authentication connection open**.

Open authentication mode does not affect the access of users that use correct user information on the port.

The open authentication mode setting has lower priority than the 802.1X Auth-Fail VLAN and the MAC authentication guest VLAN. Open authentication mode does not take effect on a port if the port is also configured with the 802.1X Auth-Fail VLAN or the MAC authentication guest VLAN.

For information about 802.1X authentication or MAC authentication, see *Security Configuration Guide*.

Examples

Enable open authentication mode on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security authentication open
```

Related commands

port-security authentication open global

Use **port-security authentication open global** to enable global open authentication mode.

Use **undo port-security authentication open global** to disable global open authentication mode.

Syntax

port-security authentication open global

undo port-security authentication open global

Default

Global open authentication mode is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command enables access users (802.1X or MAC authentication users) to come online and access the network even if they use nonexistent usernames or incorrect passwords.

Access users that come online in open authentication mode are called open users. Authorization and accounting are not available for open users. To display open user information, use the following commands:

- **display dot1x connection open**.
- **display mac-authentication connection open**.

Open authentication mode does not affect the access of users that use correct user information.

The open authentication mode setting has lower priority than the 802.1X Auth-Fail VLAN and the MAC authentication guest VLAN. Open authentication mode does not take effect on a port if the port is also configured with the 802.1X Auth-Fail VLAN or the MAC authentication guest VLAN.

For information about 802.1X authentication or MAC authentication, see *Security Configuration Guide*.

Examples

Enable global open authentication mode.

```
<Sysname> system-view
[Sysname] port-security authentication open global
```

Related commands

display dot1x connection

display mac-authentication connection

port-security authentication open

port-security authorization ignore

Use **port-security authorization ignore** to configure a port to ignore the authorization information received from the authentication server (a RADIUS server or the local device).

Use **undo port-security authorization ignore** to restore the default.

Syntax

port-security authorization ignore

undo port-security authorization ignore

Default

A port uses the authorization information from the server.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

After a user passes RADIUS or local authentication, the server performs authorization based on the authorization attributes configured for the user account. For example, the server can assign a VLAN. If you do not want the port to use such authorization attributes for users, use this command to ignore the authorization information from the server.

Examples

Configure GigabitEthernet 1/0/1 to ignore the authorization information from the authentication server.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security authorization ignore
```

Related commands

display port-security

port-security authorization-fail offline

Use **port-security authorization-fail offline** to enable the authorization-fail-offline feature.

Use **undo port-security authorization-fail offline** to disable the authorization-fail-offline feature.

Syntax

port-security authorization-fail offline [**quiet-period**]

undo port-security authorization-fail offline

Default

The authorization-fail-offline feature is disabled. The device does not log off users that have failed authorization.

Views

System view

Predefined user roles

network-admin

Parameters

quiet-period: Enables the quiet timer for 802.1X or MAC authentication users that are logged off by the authorization-fail-offline feature. The device adds these users to the 802.1X or MAC authentication quiet queue. Within the quiet timer, the device does not process packets from these users or authenticate them. If you do not specify this keyword, the quiet timer feature is disabled for users that are logged off by the authorization-fail-offline feature. The device immediately authenticates these users upon receiving packets from them.

Usage guidelines

The authorization-fail-offline feature logs off port security users that have failed ACL or user profile authorization.

A user fails ACL or user profile authorization in the following situations:

- The device or server fails to assign the specified ACL or user profile to the user.
- The device or server assigns an ACL or user profile that does not exist on the device to the user.

If this feature is disabled, the device does not log off users that have failed ACL or user profile authorization. However, the device outputs messages to report the failure.

For the **quiet-period** keyword to take effect, complete the following tasks:

- For 802.1X users, use the **dot1x quiet-period** command to enable the quiet timer and use the **dot1x timer quiet-period** command to set the timer.
- For MAC authentication users, use the **mac-authentication timer quiet** command to set the quiet timer for MAC authentication.

Examples

Enable the authorization-fail-offline feature.

```
<Sysname> system-view
[Sysname] port-security authorization-fail offline
```

Related commands

display port-security

dot1x quiet-period

dot1x timer quiet-period

mac-authentication timer

port-security enable

Use **port-security enable** to enable port security.

Use **undo port-security enable** to disable port security.

Syntax

port-security enable

undo port-security enable

Default

Port security is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

You must disable global 802.1X and MAC authentication before you enable port security on a port.

Enabling or disabling port security resets the following security settings to the default:

- 802.1X access control mode is MAC-based.
- Port authorization state is auto.

When online users are present on a port, disabling port security logs off the online users.

Examples

Enable port security.

```
<Sysname> system-view
[Sysname] port-security enable
```

Related commands

display port-security

dot1x

dot1x port-control

dot1x port-method

mac-authentication

port-security free-vlan

Use **port-security free-vlan** to configure free VLANs for port security.

Use **undo port-security free-vlan** to restore the default.

Syntax

port-security free-vlan *vlan-id-list*

undo port-security free-vlan *vlan-id-list*

Default

No free VLANs are configured for port security on a port. Authentication will be triggered by packets from users in any VLAN on the port that is configured with 802.1X, MAC authentication, or a port security authentication mode.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

vlan-id-list: Specifies a space-separated list of up to 10 VLAN items. Each VLAN item specifies a VLAN by VLAN ID or specifies a range of VLANs in the form of *start-vlan-id* to *end-vlan-id*. The value range for VLAN IDs is 1 to 4094. The end VLAN ID must be equal to or greater than the start VLAN ID.

Usage guidelines

This command is supported only in Release 6328 and later.

This command allows packets from the specified VLANs to not trigger 802.1X or MAC authentication on a port configured with any of the following features:

- 802.1X authentication.
- MAC authentication.
- Any of the following port security modes:
  - userLogin.
  - userLoginSecure.
  - userLoginWithOUI.
  - userLoginSecureExt.
  - macAddressWithRadius.
  - macAddressOrUserLoginSecure.
  - macAddressElseUserLoginSecure.
  - macAddressOrUserLoginSecureExt.
  - macAddressElseUserLoginSecureExt.

Execute this command multiple times to specify multiple free VLANs for port security.

Examples

Configure free VLANs for port security on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security free-vlan 2 3
```

Related commands

display port-security

port-security intrusion-mode

Use **port-security intrusion-mode** to configure the intrusion protection action to take when intrusion protection detects illegal frames on a port.

Use **undo port-security intrusion-mode** to restore the default.

Syntax

port-security intrusion-mode { blockmac | disableport | disableport-temporarily }

undo port-security intrusion-mode

Default

Intrusion protection is disabled.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

blockmac: Adds the source MAC addresses of illegal frames to the blocked MAC address list and discards frames with blocked source MAC addresses for a period set by the block timer. A blocked MAC address will be unblocked when the block timer expires. The timer is fixed at 3 minutes. To display the blocked MAC address list, use the **display port-security mac-address block** command.

disableport: Disables the port permanently when an illegal frame is received on the port.

disableport-temporarily: Disables the port for a period of time whenever it receives an illegal frame. You can use the **port-security timer disableport** command to set the period.

Usage guidelines

To bring up the port disabled by the intrusion protection feature, use the **undo shutdown** command.

Examples

Configure GigabitEthernet 1/0/1 to block the source MAC addresses of illegal frames after intrusion protection detects the illegal frames.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security intrusion-mode blockmac
```

Related commands

display port-security

display port-security mac-address block

port-security timer disableport

port-security mac-address aging-type inactivity

Use **port-security mac-address aging-type inactivity** to enable inactivity aging for secure MAC addresses.

Use **undo port-security mac-address aging-type inactivity** to disable inactivity aging for secure MAC addresses.

Syntax

port-security mac-address aging-type inactivity

undo port-security mac-address aging-type inactivity

Default

The inactivity aging feature is disabled for secure MAC addresses.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

This command enables the device to periodically detect traffic data from secure MAC addresses.

If only the aging timer is configured, the aging timer counts up regardless of whether traffic data has been sent from the secure MAC addresses. When you use the aging timer together with the inactivity aging feature, the aging timer restarts once traffic data is detected from the secure MAC addresses. The secure MAC addresses age out only when no traffic data is detected within the aging timer.

The inactivity aging feature prevents the unauthorized use of a secure MAC address when the authorized user is offline. The feature also removes outdated secure MAC addresses so that new secure MAC addresses can be learned or configured.

If the aging timer is set to a value not less than 60 seconds, the traffic data detection interval is fixed at 30 seconds.

If the aging timer is set to a value less than 60 seconds, the traffic data detection interval is the effective aging period.

To set the aging timer for secure MAC addresses, use the **port-security timer autolearn aging** command.

This command takes effect only on sticky MAC addresses and dynamic secure MAC addresses.

Examples

Enable inactivity aging for secure MAC addresses on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security mac-address aging-type inactivity
```

Related commands

display port-security

port-security mac-address dynamic

Use **port-security mac-address dynamic** to enable the dynamic secure MAC feature.

Use **undo port-security mac-address dynamic** to disable the dynamic secure MAC feature.

Syntax

port-security mac-address dynamic

undo port-security mac-address dynamic

Default

The dynamic secure MAC feature is disabled. Sticky MAC addresses can be saved to the configuration file. Once saved, they survive a device reboot.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

The dynamic secure MAC feature converts sticky MAC addresses to dynamic and disables saving them to the configuration file.

After you execute this command, you cannot manually configure sticky MAC addresses, and secure MAC addresses learned by a port in autoLearn mode are dynamic. All dynamic MAC addresses are lost at reboot. Use this command when you want to clear all sticky MAC addresses after a device reboot.

You can display dynamic secure MAC addresses by using the **display port-security mac-address security** command.

The **undo port-security mac-address dynamic** command converts all dynamic secure MAC addresses on the port to sticky MAC addresses. You can manually configure sticky MAC addresses.

Examples

Enable the dynamic secure MAC feature on GigabitEthernet 1/0/1.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security mac-address dynamic
```

display port-security

display port-security mac-address security

port-security mac-address security

Use **port-security mac-address security** to add a secure MAC address.

Use **undo port-security mac-address security** to remove a secure MAC address.

Syntax

In Layer 2 Ethernet interface view:

port-security mac-address security [**sticky**] *mac-address* **vlan** *vlan-id*

undo port-security mac-address security [**sticky**] *mac-address* **vlan** *vlan-id*

In system view:

port-security mac-address security [**sticky**] *mac-address* **interface** *interface-type interface-number* **vlan** *vlan-id*

undo port-security mac-address security [[*mac-address* [**interface** *interface-type interface-number*]] **vlan** *vlan-id*]

Default

No manually configured secure MAC address entries exist.

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

sticky: Specifies the MAC address type as sticky. If you do not specify this keyword, the command configures a static secure MAC address.

mac-address: Specifies a MAC address, in H-H-H format.

interface *interface-type interface-number*: Specifies a port by its type and number.

vlan *vlan-id*: Specifies the VLAN to which the secure MAC address belongs. The value range for the *vlan-id* argument is 1 to 4094.

Usage guidelines

Secure MAC addresses are MAC addresses configured or learned in autoLearn mode, and if saved, can survive a device reboot. You can bind a secure MAC address only to one port in a VLAN.

You can add important or frequently used MAC addresses as sticky or static secure MAC addresses to avoid the secure MAC address limit causing authentication failure. To successfully add secure MAC addresses on a port, first complete the following tasks:

- Enable port security on the port.
- Set the port security mode to autoLearn.
- Configure the port to permit packets of the specified VLAN to pass or add the port to the VLAN. Make sure the VLAN already exists.

Sticky MAC addresses can be manually configured or automatically learned in autoLearn mode. Sticky MAC addresses do not age out by default. You can use the **port-security timer autolearn aging** command to set an aging timer for the sticky MAC addresses. When the timer expires, the sticky MAC addresses are removed.

Static secure MAC addresses never age out unless you perform the following operations:

- Remove these MAC addresses by using the **undo port-security mac-address security** command.
- Change the port security mode.
- Disable the port security feature.

You cannot change the type of a secure address entry that has been added or add two entries that are identical except for their entry type. For example, you cannot add the **port-security mac-address security sticky 1-1-1 vlan 10** entry when a **port-security mac-address security 1-1-1 vlan 10** entry exists. To add the new entry, you must delete the old entry.

Examples

Enable port security, set GigabitEthernet 1/0/1 to operate in autoLearn mode, and configure the port to support a maximum number of 100 secure MAC addresses.

```
<Sysname> system-view
[Sysname] port-security enable
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security max-mac-count 100
[Sysname-GigabitEthernet1/0/1] port-security port-mode autolearn
```

Specify MAC address 0001-0002-0003 in VLAN 4 as a sticky MAC address.

```
[Sysname-GigabitEthernet1/0/1] port-security mac-address security sticky 0001-0002-0003
vlan 4
[Sysname-GigabitEthernet1/0/1] quit
```

In system view, specify MAC address 0001-0001-0002 in VLAN 10 as a secure MAC address for GigabitEthernet 1/0/1.

```
[Sysname] port-security mac-address security 0001-0001-0002 interface gigabitethernet
1/0/1 vlan 10
```

Related commands

port-security mac-limit

Use **port-security mac-limit** to set the maximum number of MAC addresses that port security allows for specific VLANs on a port.

Use **undo port-security mac-limit** to restore the default.

Syntax

port-security mac-limit *max-number* **per-vlan** *vlan-id-list*

undo port-security mac-limit *max-number* **per-vlan** *vlan-id-list*

Default

The maximum number is 2147483647.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

max-number: Specifies the maximum number of MAC addresses. The value range is 1 to 2147483647.

per-vlan *vlan-id-list*: Applies the maximum number to a VLAN list on per-VLAN basis. The *vlan-id-list* argument specifies a space-separated list of up to 10 VLAN items. Each VLAN item specifies a VLAN by VLAN ID or specifies a range of VLANs in the form of *vlan-id1* **to** *vlan-id2*. The value range for the VLAN IDs is 1 to 4094. The value for the *vlan-id2* argument must be equal to or greater than the value for the *vlan-id1* argument.

Usage guidelines

This command limits the number of MAC addresses that port security allows to access a port through specific VLANs. Use this command to prevent resource contentions among MAC addresses and ensure reliable performance for each access user on the port. When the number of MAC addresses in a VLAN on the port reaches the upper limit, the device denies any subsequent MAC addresses in the VLAN on the port.

Port security allows the access of the following types of MAC addresses on a port:

- MAC addresses that pass 802.1X or MAC authentication.
- MAC addresses in the MAC authentication guest VLAN or MAC authentication critical VLAN.
- MAC addresses in the 802.1X guest VLAN, 802.1X Auth-Fail VLAN, or 802.1X critical VLAN.

On a port, the maximum number of MAC addresses in a VLAN cannot be smaller than the number of existing MAC addresses in the VLAN. If the specified maximum number is smaller, the setting does not take effect.

Examples

On GigabitEthernet 1/0/1, configure VLAN 1, VLAN 5, and VLANs 10 through 20 each to allow a maximum of 32 MAC authentication and 802.1X users.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security mac-limit 32 per-vlan 1 5 10 to 20
```

port-security mac-move bypass-vlan-check

Use **port-security mac-move bypass-vlan-check** to enable VLAN check bypass on a port for users moving to it.

Use **undo port-security mac-move bypass-vlan-check** to disable VLAN check bypass on a port for users moving to it.

Syntax

port-security mac-move bypass-vlan-check

undo port-security mac-move bypass-vlan-check

Default

VLAN check bypass is disabled in port security for users moving to a port. When reauthenticating a user that has moved to the port, the device examines whether the VLAN to which the user belongs is permitted by the port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Usage guidelines

This command is supported only in Release 6318P01 and later.

Enable VLAN check bypass on a port to skip checking VLAN information in the packets that trigger 802.1X authentication or MAC authentication for users moving to that port.

For a user moving between ports, the port from which the user moves is called the source port and the port to which the user moves is called the destination port.

When you configure VLAN check bypass, follow these guidelines:

- To ensure a successful reauthentication, enable VLAN check bypass on a destination port if the source port is enabled with MAC-based VLAN.
- If the destination port is an 802.1X-enabled trunk port, you must configure it to send 802.1X protocol packets without VLAN tags.

Examples

Enable VLAN check bypass for users moving to GigabitEthernet 1/0/1 from other ports.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security mac-move bypass-vlan-check
```

port-security mac-move permit

port-security mac-move permit

Use **port-security mac-move permit** to enable MAC move on the device.

Use **undo port-security mac-move permit** to disable MAC move on the device.

Syntax

port-security mac-move permit

undo port-security mac-move permit

Default

MAC move is disabled on the device.

Views

System view

Predefined user roles

network-admin

Usage guidelines

Port security MAC move takes effect in the following scenarios:

- **Inter-port move on a device**—An online user authenticated through 802.1X or MAC authentication moves between ports on the device. The user VLAN or authentication method might change or stay unchanged after the move.
- **Inter-VLAN move on a port**—An online user authenticated through 802.1X or MAC authentication moves between VLANs on a trunk or hybrid port. In addition, the packets that trigger authentication have VLAN tags.

Port security MAC move allows an online user authenticated through 802.1X or MAC authentication on one port or VLAN to be reauthenticated and come online on another port or VLAN without going offline first. After the user passes authentication on the new port or VLAN, the system removes the authentication session of the user on the original port or VLAN.

NOTE:

For MAC authentication, the MAC move feature applies only when MAC authentication single-VLAN mode is used. The MAC move feature does not apply to MAC authentication users that move between VLANs on a port with MAC authentication multi-VLAN mode enabled.

If this feature is disabled, 802.1X or MAC authenticated users must go offline first before they can be reauthenticated successfully on a new port or VLAN to come online.

802.1X or MAC authenticated users cannot move between ports on a device or between VLANs on a port if the maximum number of online users on the authentication server has been reached.

Examples

Enable MAC move.

```
<Sysname> system-view
[Sysname] port-security mac-move permit
```

port-security max-mac-count

Use **port-security max-mac-count** to set the maximum number of secure MAC addresses that port security allows on a port.

Use **undo port-security max-mac-count** to restore the default.

Syntax

port-security max-mac-count *max-count* [**vlan** [*vlan-id-list*]]

undo port-security max-mac-count [**vlan** [*vlan-id-list*]]

Default

Port security does not limit the number of secure MAC addresses on a port.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

max-count: Specifies the maximum number of secure MAC addresses that port security allows on the port. The value range is 1 to 2147483647.

vlan [*vlan-id-list*]: Specifies a space-separated list of up to 10 VLAN items. Each VLAN item specifies a VLAN ID or a range of VLAN IDs in the form of *start-vlan-id* **to** *end-vlan-id*. The end VLAN ID cannot be smaller than the start VLAN ID. The value range for VLAN IDs is 1 to 4094. If you do not specify the **vlan** keyword, this command sets the maximum number of secure MAC addresses that port security allows on a port. If you do not specify the *vlan-id-list* argument, this command sets the maximum number of secure MAC addresses for each VLAN on the port. This option takes effect only on a port that operates in autoLearn mode.

Usage guidelines

For autoLearn mode, this command sets the maximum number of secure MAC addresses (both configured and automatically learned) on the port.

In any other mode that enables 802.1X, MAC authentication, or both, this command sets the maximum number of authenticated MAC addresses on the port. The actual maximum number of concurrent users that the port accepts equals the smaller of the following values:

- The value set by using this command.
- The maximum number of concurrent users allowed by the authentication mode in use.

For example, in userLoginSecureExt mode, if 802.1X allows more concurrent users than port security's limit on the number of MAC addresses, port security's limit takes effect.

When you configure this command, follow these guidelines and restrictions:

- Make sure the maximum number of secure MAC addresses for a VLAN is not less than the number of MAC addresses currently saved for the VLAN.
- If you execute this command multiple times to set the maximum number of secure MAC addresses for the same VLAN, the most recent configuration takes effect.

- You cannot change port security's limit on the number of MAC addresses when the port is operating in autoLearn mode.

Examples

Set the maximum number of secure MAC address port security allows on GigabitEthernet 1/0/1 to 100.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security max-mac-count 100
```

Related commands

display port-security

port-security nas-id-profile

Use **port-security nas-id-profile** to apply a NAS-ID profile to global or port-based port security.

Use **undo port-security nas-id-profile** to restore the default.

Syntax

port-security nas-id-profile *profile-name*

undo port-security nas-id-profile

Default

No NAS-ID profile is applied to port security globally or on any port.

Views

System view

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

profile-name: Specifies a NAS-ID profile by its name. The argument is a case-insensitive string of 1 to 31 characters.

Usage guidelines

A NAS-ID profile defines NAS-ID and VLAN bindings. You can create a NAS-ID profile by using the **aaa nas-id profile** command.

The device selects a NAS-ID profile for a port in the following order:

1. The port-specific NAS-ID profile.
2. The NAS-ID profile applied globally.

If no NAS-ID profile is applied or no matching binding is found in the selected profile, the device uses the device name as the NAS-ID.

Examples

Apply NAS-ID profile **aaa** to GigabitEthernet 1/0/1 for port security.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security nas-id-profile aaa
```

Globally apply NAS-ID profile **aaa** to port security.

```
<Sysname> system-view
[Sysname] port-security nas-id-profile aaa
```

Related commands

aaa nas-id profile

port-security ntk-mode

Use **port-security ntk-mode** to configure the NTK feature.

Use **undo port-security ntk-mode** to restore the default.

Syntax

port-security ntk-mode { **ntk-withbroadcasts** | **ntk-withmulticasts** | **ntkauto** | **ntkonly** }

undo port-security ntk-mode

Default

The NTK feature is not configured on a port and all frames are allowed to be sent.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

ntk-withbroadcasts: Forwards only broadcast and unicast frames with an authenticated destination MAC address.

ntk-withmulticasts: Forwards only broadcast, multicast, and unicast frames with an authenticated destination MAC address.

ntkauto: Forwards only broadcast, multicast, and unicast frames with an authenticated destination MAC address, and only when the port has online users.

ntkonly: Forwards only unicast frames with an authenticated destination MAC address.

Usage guidelines

The NTK feature checks the destination MAC addresses in outbound frames. This feature allows frames to be sent only to devices passing authentication, preventing illegal devices from intercepting network traffic.

Examples

Set the NTK mode of GigabitEthernet 1/0/1 to **ntkonly**, allowing the port to forward received packets only to devices passing authentication.

```
<Sysname> system-view
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security ntk-mode ntkonly
```

Related commands

display port-security

port-security oui

Use **port-security oui** to configure an OUI value for user authentication.

Use **undo port-security oui** to delete the OUI value with the specified OUI index.

Syntax

port-security oui index *index-value* **mac-address** *oui-value*

undo port-security oui index *index-value*

Default

No OUI values are configured.

Views

System view

Predefined user roles

network-admin

Parameters

index-value: Specifies the OUI index, in the range of 1 to 16.

oui-value: Specifies an OUI string, a 48-bit MAC address in the H-H-H format. The system uses only the 24 high-order bits as the OUI value.

Usage guidelines

You can configure multiple OUI values.

An OUI, the first 24 binary bits of a MAC address, is assigned by IEEE to uniquely identify a device vendor. Use this command to allow devices of specific vendors to access the network without being authenticated. For example, you can specify the OUIs of IP phones and printers.

The OUI values configured by this command apply only to the ports operating in userLoginWithOUI mode. In userLoginWithOUI mode, a port allows only one 802.1X user and one user whose MAC address matches one of the configured OUI values.

Examples

Configure an OUI value of 000d2a, and set the index to 4.

```
<Sysname> system-view
[Sysname] port-security oui index 4 mac-address 000d-2a10-0033
```

Related commands

display port-security

port-security packet-detect arp-source-ip factor

Use **port-security packet-detect arp-source-ip factor** to specify an IP address and mask for calculating the source IP of ARP detection packets.

Use **undo port-security packet-detect arp-source-ip factor** to restore the default.

NOTE:

This command is supported only in Release 6348P01 and later.

Syntax

port-security packet-detect arp-source-ip factor *ip-address* { *mask* | *mask-length* }

undo port-security packet-detect arp-source-ip factor

Default

No IP address or mask is specified for calculating the source IP of ARP detection packets. The source IP of ARP detection packets is 0.0.0.0.

Views

System view

Predefined user roles

network-admin

Parameters

ip-address { *mask* | *mask-length* }: Specifies an IP address and mask for calculating the source IP of ARP detection packets. The *mask* argument represents the IP address mask, in dotted decimal notation. The mask cannot be 255.255.255.255. The *mask-length* argument represents the IP address mask length, in the range of 0 to 31.

Usage guidelines

By default, the device uses 0.0.0.0 as the source IP address of ARP detection packets. The network might have users that cannot respond to ARP detection packets with source IP address 0.0.0.0. As a result, the device inadequately determines that these users have gone offline. To resolve the issue, use this command to specify an IP address and mask for calculating the source IP of ARP detection packets sent to a user in conjunction with the user's IP address.

The device uses the following formula to calculate the source IP address of ARP detection packets: source IP = (user IP & specified mask) | (specified IP & ~specified mask). The ~mask parameter represents the reverse of a mask. For example, the reverse mask of 255.255.255.0 is 0.0.0.255. If the IP address of a user is 192.168.8.1/24 and the IP address and mask specified by using this command is 1.1.1.11/255.255.255.0, the source IP address of ARP detection packets is 192.168.8.11/24.

To avoid the source IP address of ARP detection packets being the same as the destination IP address, follow these restrictions and guidelines:

- The mask length specified by using this command must be equal to or longer than the mask length of users' IP addresses.
- The mask cannot be 255.255.255.255.

This command takes effect only on users that come online after this command is executed.

Examples

Specify 0.0.0.11/24 for calculating the source IP of ARP detection packets.

```
<Sysname> system-view
[Sysname] port-security packet-detect arp-source-ip factor 0.0.0.11 24
```

port-security port-mode

Use **port-security port-mode** to set the port security mode of a port.

Use **undo port-security port-mode** to restore the default.

Syntax

port-security port-mode { autolearn | mac-authentication | mac-else-userlogin-secure | mac-else-userlogin-secure-ext | secure |

userlogin | userlogin-secure | userlogin-secure-ext | userlogin-secure-or-mac | userlogin-secure-or-mac-ext | userlogin-withoui }

undo port-security port-mode

Default

A port operates in noRestrictions mode, where port security does not take effect.

Views

Layer 2 Ethernet interface view

Predefined user roles

network-admin

Parameters

Keyword	Security mode	Description
autolearn	autoLearn	A port in this mode can learn MAC addresses. The automatically learned MAC addresses are not added to the MAC address table as dynamic MAC address. Instead, the MAC addresses are added to the secure MAC address table as secure MAC addresses. You can also configure secure MAC addresses by using the **port-security mac-address security** command. A port in autoLearn mode allows frames sourced from the following MAC addresses to pass: • Secure MAC addresses. • MAC addresses configured by using the **mac-address dynamic** and **mac-address static** commands. When the number of secure MAC addresses reaches the upper limit set by the **port-security max-mac-count** command, the port changes to **secure** mode.
mac-authentication	macAddressWithRadius	In this mode, a port performs MAC authentication for users and services multiple users.
mac-else-userlogin-secure	macAddressElseUserLoginSecure	This mode is the combination of the macAddressWithRadius and userLoginSecure modes, with MAC authentication having a higher priority. In this mode, the port allows one 802.1X authentication user and multiple MAC authentication users to log in. • Upon receiving a non-802.1X frame, a port in this mode performs only MAC authentication. • Upon receiving an 802.1X frame, the port performs MAC authentication and then, if MAC authentication fails, 802.1X authentication.
mac-else-userlogin-secure-ext	macAddressElseUserLoginSecureExt	Same as the macAddressElseUserLoginSecure mode except that a port in this mode supports multiple 802.1X and MAC authentication users.

Keyword	Security mode	Description
secure	secure	In this mode, MAC address learning is disabled on the port and you can configure MAC addresses by using the **mac-address static** and **mac-address dynamic** commands. The port permits only frames sourced from the following MAC addresses to pass: • Secure MAC addresses. • MAC addresses configured by using the **mac-address static** and **mac-address dynamic** commands.
userlogin	userLogin	In this mode, a port performs 802.1X authentication and implements port-based access control. If one 802.1X user passes authentication, all the other 802.1X users of the port can access the network without authentication.
userlogin-secure	userLoginSecure	In this mode, a port performs 802.1X authentication and implements MAC-based access control. The port services only one user passing 802.1X authentication.
userlogin-secure-ext	userLoginSecureExt	Same as the userLoginSecure mode, except that this mode supports multiple online 802.1X users.
userlogin-secure-or-mac	macAddressOrUserLoginSecure	This mode is the combination of the userLoginSecure and macAddressWithRadius modes. In this mode, the port allows one 802.1X authentication user and multiple MAC authentication users to log in. In this mode, the port performs 802.1X authentication first. By default, if 802.1X authentication fails, MAC authentication is performed. However, the port in this mode processes authentication differently when the following conditions exist: • The port is enabled with parallel processing of MAC authentication and 802.1X authentication. • The port is enabled with the 802.1X unicast trigger. • The port receives a packet from an unknown MAC address. Under such conditions, the port sends a unicast EAP-Request/Identity packet to the MAC address to initiate 802.1X authentication. After that, the port immediately processes MAC authentication without waiting for the 802.1X authentication result.
userlogin-secure-or-mac-ext	macAddressOrUserLoginSecureExt	Same as the macAddressOrUserLoginSecure mode, except that a port in this mode supports multiple 802.1X and MAC authentication users.
userlogin-withoui	userLoginWithOUI	Similar to the userLoginSecure mode. In addition, a port in this mode also permits frames from a user whose MAC address contains a specific OUI. In this mode, the port performs OUI check at first. If the OUI check fails, the port performs 802.1X authentication. The port permits frames that pass OUI check or 802.1X authentication.

Usage guidelines

To change the security mode for a port security enabled port, you must set the port in noRestrictions mode first. Do not change port security mode when the port has online users.

IMPORTANT:

If you are configuring the autoLearn mode, first set port security's limit on the number of secure MAC addresses by using the **port-security max-mac-count** command. You cannot change the setting when the port is operating in autoLearn mode.

When port security is enabled, you cannot enable 802.1X or MAC authentication, or change the access control mode or port authorization state. The port security automatically modifies these settings in different security modes.

As a best practice, do not enable the **mac-else-userlogin-secure** or **mac-else-userlogin-secure-ext** mode on the port where MAC authentication delay is enabled. The two modes are mutually exclusive with the MAC authentication delay feature. For more information about MAC authentication delay, see "MAC authentication commands."

Examples

Enable port security, and set GigabitEthernet 1/0/1 to operate in secure mode.

```
<Sysname> system-view
[Sysname] port-security enable
[Sysname] interface gigabitethernet 1/0/1
[Sysname-GigabitEthernet1/0/1] port-security port-mode secure
```

Change the port security mode of GigabitEthernet 1/0/1 to userLogin.

```
[Sysname-GigabitEthernet1/0/1] undo port-security port-mode
[Sysname-GigabitEthernet1/0/1] port-security port-mode userlogin
```

port-security timer autolearn aging

Use **port-security timer autolearn aging** to set the secure MAC aging timer.

Use **undo port-security timer autolearn aging** to restore the default.

Syntax

port-security timer autolearn aging [**second**] *time-value*

undo port-security timer autolearn aging

Default

Secure MAC addresses do not age out.

Views

System view

Predefined user roles

network-admin

Parameters

second: Specifies the aging timer in seconds for secure MAC addresses. If you do not specify this keyword, the command sets the aging timer in minutes for secure MAC addresses.

time-value: Specifies the aging timer. The value range is 0 to 129600 if the unit is minute. To disable the aging timer, set the timer to 0. The value range is 10 to 7776000 if the unit is second.

Usage guidelines

The timer applies to all sticky secure MAC addresses and those automatically learned by a port.

The effective aging timer varies by the aging timer setting:

- If the aging timer is set in seconds, the effective aging timer can be either of the following values:
  - The nearest multiple of 30 seconds to the configured aging timer if the configured timer is not less than 60 seconds. The effective aging timer is not less than the configured aging timer.
  - The configured aging timer if the configured timer is less than 60 seconds.
- If the aging timer is set in minutes, the effective aging timer is the configured aging timer.

A short aging time improves port access security and port resource utility but affects online user stability. Set an appropriate secure MAC address aging timer according to your device performance and the network environment.

When a short aging time (less than 60 seconds) works with inactivity aging, do not assign a large value to the maximum number of secure MAC addresses on a port. A large value in this case might affect device performance.

Examples

Set the secure MAC aging timer to 30 minutes.

```
<Sysname> system-view
[Sysname] port-security timer autolearn aging 30
```

Set the secure MAC aging timer to 50 seconds.

```
<Sysname> system-view
[Sysname] port-security timer autolearn aging second 50
```

display port-security

port-security intrusion-mode

port-security traffic-statistics enable

Use **port-security traffic-statistics enable** to enable traffic statistics for 802.1X and MAC authentication users.

Use **undo port-security traffic-statistics enable** to disable traffic statistics for 802.1X and MAC authentication users.

Syntax

port-security traffic-statistics enable

undo port-security traffic-statistics enable

Default

The device does not collect traffic statistics for 802.1X and MAC authentication users. 802.1X and MAC authentication user statistics collected and sent to the accounting server only include the online duration of the users.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command is available in Release 6312 and later.

To collect and send traffic statistics of 802.1X and MAC authentication users to the accounting server in addition to their online duration, use this command to enable the traffic statistics feature for 802.1X and MAC authentication users.

This feature takes effect only on users that come online after the feature is enabled.

This feature takes effect on 802.1X and MAC authentication users when port security is enabled, or when 802.1X and MAC authentication are separately enabled on the device.

If a port performs MAC authentication or 802.1X authentication in MAC-based access control mode, this feature collects user traffic statistics on a per-MAC basis on the port.

If a port performs 802.1X authentication in port-based access control mode, this feature collects user traffic statistics on a per-port basis on the port.

With this feature enabled, the device requires more ACL resources for new 802.1X or MAC authentication users. If the device has run out of ACL resources, the authentication will fail for new 802.1X or MAC authentication users.

Enable this feature only if traffic accounting is required and only if there are sufficient ACL resources. If the network has a large number of online 802.1X and MAC authentication users when this feature is enabled, ACL resources might become insufficient. This issue causes authentication failure of new 802.1X and MAC authentication users. For more information about 802.1X and MAC authentication, see *Security Configuration Guide*.

Examples

Enable traffic statistics for 802.1X and MAC authentication users.

```
<Sysname> system-view
[Sysname] port-security traffic-statistics enable
```

snmp-agent trap enable port-security

Use **snmp-agent trap enable port-security** to enable SNMP notifications for port security.

Use **undo snmp-agent trap enable port-security** to disable SNMP notifications for port security.

Syntax

snmp-agent trap enable port-security [**address-learned** | **dot1x-failure** | **dot1x-logoff** | **dot1x-logon** | **intrusion** | **mac-auth-failure** | **mac-auth-logoff** | **mac-auth-logon**] *

undo snmp-agent trap enable port-security [**address-learned** | **dot1x-failure** | **dot1x-logoff** | **dot1x-logon** | **intrusion** | **mac-auth-failure** | **mac-auth-logoff** | **mac-auth-logon**] *

Default

All port security SNMP notifications are disabled.

Views

System view

Predefined user roles

network-admin

Parameters

address-learned: Specifies notifications about MAC address learning.

dot1x-failure: Specifies notifications about 802.1X authentication failures.

dot1x-logoff: Specifies notifications about 802.1X user logoffs.

dot1x-logon: Specifies notifications about 802.1X authentication successes.

intrusion: Specifies notifications about illegal frame detection.

mac-auth-failure: Specifies notifications about MAC authentication failures.

mac-auth-logoff: Specifies notifications about MAC authentication user logoffs.

mac-auth-logon: Specifies notifications about MAC authentication successes.

Usage guidelines

To report critical port security events to an NMS, enable SNMP notifications for port security. For port security event notifications to be sent correctly, you must also configure SNMP on the device. For more information about SNMP configuration, see *Network Management and Monitoring Configuration Guide*.

If you do not specify a notification, this command enables all SNMP notifications for port security.

For this command to take effect, make sure the intrusion protection feature is configured.

Examples

Enable SNMP notifications about MAC address learning.

```
<Sysname> system-view
[Sysname] snmp-agent trap enable port-security address-learned
```

network-operator

Parameters

name *profile-name*: Specifies a user profile by its name, a case-sensitive string of 1 to 31 characters. Valid characters include English letters, digits, and underscores (_). The name must start with an English letter and must be unique. If you do not specify this option, the command displays configuration and online user information for all user profiles.

slot *slot-number*: Specifies an IRF member device by its member ID. If you do not specify a member device, this command displays user profile configuration and online user information for all member devices.

Examples

Display configuration and online user information for user profile **aaa**.

```
<Sysname> display user-profile name aaa
  User-Profile: aaa
    Inbound:
      Policy: p1

    User user_1:
      Authentication type: 802.1X
      Network attributes:
        Interface    : GigabitEthernet1/0/1
        MAC address  : 0000-1111-2222
      Failed action list:
        Inbound: Policy p1
```

Table 1 Command output

Field	Description
User-Profile	User profile name.
Inbound	Policy applied to incoming traffic.
Outbound	Policy applied to outgoing traffic.
Policy	Policy name.

Field	Description
User user_1	Username of a user account with which a user profile is associated.
Authentication type	Authentication type: • **802.1X**—802.1X authentication. • **Portal**—Portal authentication. • **MACA**—MAC authentication.
Network attributes	Online user information.
Failed action list	Actions that failed to be applied to the user.

user-profile

Use **user-profile** to create a user profile and enter its view, or enter the view of an existing user profile.

Use **undo user-profile** to delete a user profile.

Syntax

user-profile *profile-name*

undo user-profile *profile-name*

Default

No user profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

profile-name: Specifies a user profile by its name, a case-sensitive string of 1 to 31 characters. A user profile name can only contain English letters, digits, and underscores (_), and it must start with an English letter. The name must be unique.

Examples

Create user profile **a123** and enter the view of **a123**.

```
<Sysname> system-view
[Sysname] user-profile a123
[Sysname-user-profile-a123]
```

Contents

Password control commands

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

display password-control

Use **display password-control** to display password control configuration.

Syntax

display password-control [**super**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

super: Displays the password control information for the super passwords. If you do not specify this keyword, the command displays the global password control configuration.

Examples

Display the global password control configuration.

```
<Sysname> display password-control
 Global password control configurations:
Password control:                    Enabled (device management users)
                                     Enabled (network access users)
 Password aging:                      Enabled (90 days)
 Password length:                     Enabled (10 characters)
 Password composition:                Enabled (1 types, 1 characters per type)
 Password history:                    Enabled (max history records:4)
 Early notice on password expiration:  7 days
 Maximum login attempts:              3
 User authentication timeout:         600 seconds
 Action for exceeding login attempts:  Lock user for 1 minutes
 Password history was last reset:     0 days ago (device management users)
                                      0 days ago (network access users)
 Minimum interval between two updates: 24 hours
 User account idle time:              90 days
 Logins with aged password:           3 times in 30 days
 Password complexity:                 Disabled (username checking)
                                      Disabled (repeated characters checking)
 Password change:                     Enabled (first login)
                                      Enabled (mandatory weak password change)
```

Display the password control configuration for super passwords.

```
<Sysname> display password-control super
```

```
Super password control configurations:
Password aging:                         Enabled (90 days)
Password length:                        Enabled (10 characters)
Password composition:                   Enabled (1 types, 1 characters per type)
```

Table 1 Command output

Field	Description
Password control	Whether the password control feature is enabled for device management or network access users.
Password aging	Whether password expiration is enabled and, if enabled, the aging time.
Password length	Whether the minimum password length restriction feature is enabled and, if enabled, the setting.
Password composition	Whether the password composition restriction feature is enabled and, if enabled, the settings.
Password history	Whether the password history management feature is enabled and, if enabled, the setting.
Early notice on password expiration	Number of days during which the user is notified of the pending password expiration.
User authentication timeout	User authentication timeout time.
Maximum login attempts	Allowed maximum number of consecutive failed login attempts for FTP and VTY users.
Action for exceeding login attempts	Action to be taken after a user fails to log in after the specified number of attempts.
Password history was last reset	Last time when the password history records of the device management or network access users were deleted.
Minimum interval between two updates	Minimum password update interval.
Logins with aged password	Number of times and maximum number of days a user can log in using an expired password.
Password complexity	Whether the following password complexity checking is enabled: • **username checking**—Checks whether a password contains the username or the reverse of the username. • **repeated characters checking**—Checks whether a password contains any character that appears consecutively three or more times.
Password change	Status of the password change at first login feature: • Enabled (first login). • Disabled (first login). • Enabled (mandatory weak password change). • Disabled (mandatory weak password change).

display password-control blacklist

Use **display password-control blacklist** to display password control blacklist information.

Syntax

display password-control blacklist [**user-name** *user-name* | **ip** *ipv4-address* | **ipv6** *ipv6-address*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

user-name *user-name*: Specifies a user by its username, a case-sensitive string of 1 to 55 characters.

ip *ipv4-address*: Specifies the IPv4 address of a user.

ipv6 *ipv6-address*: Specifies the IPv6 address of a user.

Usage guidelines

If you do not specify any parameters, this command displays information about all users in the password control blacklist.

The users' IP addresses and user accounts are added to the password control blacklist when the users fail authentication. You can use this command to view information about blacklisted FTP, Web, and virtual terminal line (VTY) users.

Users accessing the system through the console interface are not blacklisted for the following reasons:

- The system is unable to obtain the IP addresses of these users.
- These users are privileged and, therefore, relatively secure to the system.

Examples

Display password control blacklist information.

```
<Sysname> display password-control blacklist
 Blacklist items matched: 2.
 Username                    IP address          Login failures   Lock flag
 abcd                        169::168:34:1       4                lock
 admin                       192.168.34.1        1                unlock
```

Table 2 Command output

Field	Description
Blacklist items matched	Number of blacklisted users.
IP address	IP address of the user.
Login failures	Number of login failures.
Lock flag	Whether the user account is locked for the user: • **unlock**—Not limited. • **lock**—Disabled temporarily or permanently, depending on the **password-control login-attempt** command.

password-control { aging | composition | history | length } enable

Use **password-control** { **aging** | **composition** | **history** | **length** } **enable** to enable a password restriction feature.

Use **undo password-control** { **aging** | **composition** | **history** | **length** } **enable** to disable a password restriction feature.

Syntax

password-control { **aging** | **composition** | **history** | **length** } **enable**

undo password-control { **aging** | **composition** | **history** | **length** } **enable**

Default

The password restriction features are all enabled.

Views

System view

Predefined user roles

network-admin

Parameters

aging: Enables the password expiration feature.

composition: Enables the password composition restriction.

history: Enables the password history management feature.

length: Enables the minimum password length restriction.

Usage guidelines

In versions earlier than Release 6318P01:

- For a specific password restriction setting to take effect, make sure you enable both the global password control and the specific password restriction. For example, if the global password control and the minimum length restriction feature are not enabled, the **password-control length** command does not take effect.
- If the global password control feature is enabled, the following rules apply:
  - In non-FIPS mode, a password must contain a minimum of 4 characters and a minimum of 4 characters must be different.
  - In FIPS mode, a password must contain a minimum of 15 characters and a minimum of 4 characters must be different.

In Release 6318P01 and later:

- The password expiration feature or the password history management feature takes effect only after the global password control is also enabled.
- In non-FIPS mode, the password composition restriction and the minimum password length restriction are enabled by default regardless of whether or not the global password control feature is enabled. The default minimum password length and default password composition restriction vary by device model.
- In FIPS mode, the password composition restriction or the minimum password length restriction takes effect only after the global password control is also enabled. When the password composition restriction takes effect, a password, by default, must contain a minimum of 4 different characters. When the minimum password length restriction takes effect, a password, by default, must contain a minimum of 15 characters.

If a password of a device management user is in hashed form, a restriction setting does not take effect for the password even when the following requirements are met:

- The global password control is enabled.
- The specific password restriction feature is enabled.

For more information about configuring a password for a device management user, see "AAA commands."

If the password history management feature is disabled, the system will not compare the new password with history passwords, but the system will not stop recording history passwords. When the number of history password records of a user reaches the maximum number set by the **password-control history** command, the newest history record overwrites the earliest one.

Examples

Enable the password control feature globally.

```
<Sysname> system-view
[Sysname] password-control enable
```

Enable the password composition restriction feature.

```
[Sysname] password-control composition enable
```

Enable the password expiration feature.

```
[Sysname] password-control aging enable
```

Enable the minimum password length restriction feature.

```
[Sysname] password-control length enable
```

Enable the password history management feature.

```
[Sysname] password-control history enable
```

Related commands

display password-control

password-control enable

password-control aging

Use **password-control aging** to set the password aging time.

Use **undo password-control aging** to restore the default.

Syntax

password-control aging *aging-time*

undo password-control aging

Default

A password expires after 90 days. The password aging time for a user group equals the global setting. The password aging time for a local user equals that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

Parameters

aging-time: Specifies the password aging time in days, in the range of 1 to 365.

Usage guidelines

The aging time depends on the view:

- The time in system view has global significance and applies to all user groups.
- The time in user group view applies to all local users in the user group.
- The time in local user view applies only to the local user.

A password aging time with a smaller application scope has higher priority. The system prefers to use the password aging time in local user view for a local user.

- If no password aging time is configured for the local user, the system uses the password aging time for the user group to which the local user belongs.
- If no password aging time is configured for the user group, the system uses the global password aging time.

Examples

Globally set the passwords to expire after 80 days.

```
<Sysname> system-view
[Sysname] password-control aging 80
```

Set the passwords for user group **test** to expire after 90 days.

```
[Sysname] user-group test
[Sysname-ugroup-test] password-control aging 90
[Sysname-ugroup-test] quit
```

Set the password for device management user **abc** to expire after 100 days.

```
[Sysname] local-user abc class manage
[Sysname-luser-manage-abc] password-control aging 100
```

Related commands

display local-user

display password-control

display user-group

password-control aging enable

password-control alert-before-expire

Use **password-control alert-before-expire** to set the number of days before a user's password expires during which the user is notified of the pending password expiration.

Use **undo password-control alert-before-expire** to restore the default.

Syntax

password-control alert-before-expire *alert-time*

undo password-control alert-before-expire

Default

The default is 7 days.

Views

System view

Predefined user roles

network-admin

Parameters

alert-time: Specifies the number of days before a user password expires during which the user is notified of the pending password expiration. The value range is 1 to 30.

Usage guidelines

This command is effective only for non-FTP users. FTP users can only have their passwords changed by the administrator.

Examples

Configure the device to notify a user about pending password expiration 10 days before the user's password expires.

```
<Sysname> system-view
[Sysname] password-control alert-before-expire 10
```

Related commands

display password-control

password-control authentication-timeout

Use **password-control authentication-timeout** to set the user authentication timeout time.

Use **undo password-control authentication-timeout** to restore the default.

Syntax

password-control authentication-timeout *timeout*

undo password-control authentication-timeout

Default

The user authentication timeout time is 600 seconds.

Views

System view

Predefined user roles

network-admin

Parameters

timeout: Specifies the user authentication timeout time in seconds, in the range of 30 to 600.

Usage guidelines

This command takes effect only on Telnet and terminal users. When the authentication for a user times out, the connection will be terminated.

Examples

Set the user authentication timeout time to 40 seconds.

```
<Sysname> system-view
[Sysname] password-control authentication-timeout 40
```

Related commands

display password-control

password-control change-password first-login enable

Use **password-control change-password first-login enable** to enable the password change at first login feature.

Use **undo password-control change-password first-login enable** to disable the password change at first login feature.

Syntax

password-control change-password first-login enable

undo password-control change-password first-login enable

Default

The password change at first login feature is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

For the password change at first login feature to take effect, make sure the global password control and password change features are both enabled.

In FIPS mode, the password change at first login feature cannot be disabled.

Examples

Enable password change at first login.

```
<Sysname> system-view
[Sysname] password-control change-password first-login enable
```

Related commands

display password-control

password-control enable

password-control change-password weak-password enable

Use **password-control change-password weak-password enable** to enable mandatory weak password change.

Use **undo password-control change-password weak-password enable** to disable mandatory weak password change.

Syntax

password-control change-password weak-password enable

undo password-control change-password weak-password enable

Default

The mandatory weak password change feature is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command is available only in Release 6318P01 and later.

The system checks for weak login passwords for Telnet, SSH, HTTP, or HTTPS device management users. A password is weak if it does not meet the following requirements:

- Password composition restriction.
- Minimum password length restriction.
- Password complexity checking policy.

By default, the system displays a message about a weak password but does not force the user to change it. To improve the device security, you can enable the mandatory weak password change feature, which forces the users to change the identified weak passwords. The users can log in to the device only after their passwords meet the password requirements.

To view the password requirements, use the **display password-control** command. To change the password composition restriction, the minimum password length, and the password complexity checking policy, use the **password-control composition**, **password-control length**, and **password-control complexity** commands, respectively.

Examples

Enable the mandatory weak password change feature.

```
<Sysname> system-view
[Sysname] password-control change-password weak-password enable
```

Related commands

display password-control

password-control { **aging** | **composition** | **history** | **length** }

password-control complexity

password-control composition

password-control length

password-control enable

password-control complexity

Use **password-control complexity** to configure the password complexity checking policy.

Use **undo password-control complexity** to remove a password complexity checking item.

Syntax

password-control complexity { **same-character** | **user-name** } **check**

undo password-control complexity { **same-character** | **user-name** } **check**

Default

In versions earlier than Release 6318P01:

The global password complexity checking policy is that both username checking and repeated character checking are disabled. The password complexity checking policy for a user group equals the global setting. The password complexity checking policy for a local user equals that of the user group to which the local user belongs.

In Release 6318P01 and later:

- In non-FIPS mode:

  The global password complexity checking policy is that username checking is enabled and repeated character checking is disabled. The password complexity checking policy for a user group equals the global setting. The password complexity checking policy for a local user equals that of the user group to which the local user belongs.

- In FIPS mode:

  The global password complexity checking policy is that both username checking and repeated character checking are disabled. The password complexity checking policy for a user group equals the global setting. The password complexity checking policy for a local user equals that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

Parameters

`same-character`: Refuses a password that contains a minimum of three consecutive identical characters. For example, the password **aaabc** is not complex enough.

`user-name`: Refuses a password that contains the username or the reverse of the username. For example, if the username is **123**, a password such as **abc123** or **321df** is not complex enough.

Usage guidelines

The password complexity checking policy depends on the view:

- The policy in system view has global significance and applies to all user groups.
- The policy in user group view applies to all local users in the user group.
- The policy in local user view applies only to the local user.

A password complexity checking policy with a smaller application scope has higher priority. The system prefers to use the password complexity checking policy in local user view for a local user.

- If no policy is configured for the local user, the system uses the policy for the user group to which the local user belongs.
- If no policy is configured for the user group, the system uses the global policy.

In versions earlier than Release 6318P01, the password complexity checking is disabled. The password complexity checking takes effect only after you enable the global password control feature and execute the **`password-control complexity`** command.

In Release 6318P01 and later:

- In non-FIPS mode, username checking is enabled regardless of whether or not the global password control feature is enabled.
- In FIPS mode, the password complexity checking is disabled. The password complexity checking takes effect only after you enable the global password control feature and execute the **`password-control complexity`** command.

You can enable both username checking and repeated character checking.

Examples

Configure the password complexity checking policy, refusing any password that contains the username or the reverse of the username.

```
<Sysname> system-view
```

```
[Sysname] password-control complexity user-name check
```

Related commands

display local-user

display password-control

display user-group

password-control composition

Use **password-control composition** to configure the password composition policy.

Use **undo password-control composition** to restore the default.

Syntax

password-control composition type-number *type-number* [**type-length** *type-length*]

undo password-control composition

Default

In non-FIPS mode:

- In versions earlier than Release 6318P01, the password using the global composition policy must contain a minimum of one character type and a minimum of one character for each type.
- In Release 6318P01 and later, the password using the global composition policy must contain a minimum of two character types and a minimum of one character for each type.

In FIPS mode:

The password using the global composition policy must contain a minimum of four character types and a minimum of one character for each type.

In both non-FIPS and FIPS modes:

The password composition policy for a user group is the same as the global policy. The password composition policy for a local user is the same as that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

Parameters

type-number *type-number*: Specifies the minimum number of character types that a password must contain. The value range for the *type-number* argument is 1 to 4 in non-FIPS mode and fixed at 4 in FIPS mode.

type-length *type-length*: Specifies the minimum number of characters that are from each type in the password. The value range for the *type-length* argument is 1 to 63 in non-FIPS mode, and 1 to 15 in FIPS mode.

Usage guidelines

The password composition policy depends on the view:

- The policy in system view has global significance and applies to all user groups.

- The policy in user group view applies to all local users in the user group.
- The policy in local user view applies only to the local user.

A password composition policy with a smaller application scope has higher priority. The system prefers to use the password composition policy in local user view for a local user.

- If no policy is configured for the local user, the system uses the policy for the user group to which the local user belongs.
- If no policy is configured for the user group, the system uses the global policy.

The product of the minimum number of character types and minimum number of characters for each type cannot be greater than the maximum length of passwords.

Examples

Specify that all passwords must each contain a minimum of four character types and a minimum of five characters for each type.

```
<Sysname> system-view
[Sysname] password-control composition type-number 4 type-length 5
```

Specify that passwords in user group **test** must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname] user-group test
[Sysname-ugroup-test] password-control composition type-number 4 type-length 5
[Sysname-ugroup-test] quit
```

Specify that the password of device management user **abc** must contain a minimum of four character types and a minimum of five characters for each type.

```
[Sysname] local-user abc class manage
[Sysname-luser-manage-abc] password-control composition type-number 4 type-length 5
```

Related commands

display local-user

display password-control

display user-group

password-control composition enable

password-control enable

Use **password-control enable** to enable the password control feature globally.

Use **undo password-control enable** to disable the password control feature globally.

Syntax

password-control enable [**network-class**]

undo password-control enable [**network-class**]

Default

In non-FIPS mode:

The password control feature is disabled globally for device management and network access users.

In FIPS mode:

The password control feature is enabled globally and cannot be disabled for device management users.

The password control feature is disabled globally for network access users.

Views

System view

Predefined user roles

network-admin

Parameters

network-class: Enables global password control for network access users. If you do not specify this keyword, the command enables global password control for device management users.

Usage guidelines

When you enable global password control, the device automatically generates a .dat file and saves the file to the storage media. The file is used to record authentication and login information of local users. Do not manually delete or modify the file.

In versions earlier than Release 6318P01:

A specific password control feature (password expiration, minimum password length, password history management, and password composition restriction) takes effect only after the global password control feature is enabled.

In Release 6318P01 and later versions:

The password expiration feature and the password history management feature take effect only after the global password control feature is also enabled.

After the global password control feature is enabled, the passwords configured for local users must contain a minimum of four different characters.

After the global password control feature is enabled for device management users, you cannot display the password and super password configuration for device management users by using the corresponding **display** commands.

After the global password control feature is enabled for network access users, you cannot display the password configuration for network access users by using the corresponding **display** commands.

You can configure all password control features for device management users.

You can configure only the following password control features for network access users:

- Password complexity checking policy.
- Password composition policy.
- Minimum password length.
- Minimum password update interval.
- Maximum number of history password records for each user.

Examples

Enable the password control feature globally for device management users.

```
<Sysname> system-view
[Sysname] password-control enable
```

Enable the password control feature globally for network access users.

```
<Sysname> system-view
[Sysname] password-control enable network-class
```

Related commands

display password-control

password-control complexity

password-control { **composition** | **history** | **length** } **enable**

password-control update-interval

password-control expired-user-login

Use **password-control expired-user-login** to set the maximum number of days and maximum number of times that a user can log in after the password expires.

Use **undo password-control expired-user-login** to restore the defaults.

Syntax

password-control expired-user-login delay *delay* **times** *times*

undo password-control expired-user-login

Default

A user can use an expired password to log in three times within 30 days after the password expires. If all three attempts fail or the user makes a login attempt after 30 days, the system prompts the user to set a new password.

Views

System view

Predefined user roles

network-admin

Parameters

delay *delay*: Specifies the maximum number of days during which a user can log in using an expired password. The value range for the *delay* argument is 1 to 90.

times *times*: Specifies the maximum number of times a user can log in after the password expires. The value range is 0 to 10. For a user to set a new password at the system prompt immediately after the password expires, set the value to 0.

Usage guidelines

This command is effective only on non-FTP login users. An FTP user cannot continue to log in after its password expires.

Examples

Allow a user to log in five times within 60 days after the password expires.

```
<Sysname> system-view
[Sysname] password-control expired-user-login delay 60 times 5
```

Related commands

display password-control

password-control history

Use **password-control history** to set the maximum number of history password records for each user.

Use **undo password-control history** to restore the default.

Syntax

password-control history *max-record-number*

undo password-control history

Default

The maximum number of history password records for each user is 4.

Views

System view

Predefined user roles

network-admin

Parameters

max-record-number: Specifies the maximum number of history password records for each user. The value range is 2 to 15.

Usage guidelines

The global password control feature enables the system to record history passwords. When the number of history password records of a user reaches the maximum number, the newest history record overwrites the earliest one.

To delete the existing records, use one of the following methods:

- Use the **undo password-control enable** command to disable the password control feature globally.
- Use the **reset password-control history-record** command to clear the passwords manually.

Examples

Set the maximum number of history password records for each user to 10.

```
<Sysname> system-view
[Sysname] password-control history 10
```

Related commands

display password-control

password-control history enable

reset password-control blacklist

password-control length

Use **password-control length** to set the minimum password length.

Use **undo password-control length** to restore the default.

Syntax

password-control length *length*

undo password-control length

Default

In non-FIPS mode:

The global minimum password length is 10 characters.

In FIPS mode:

The global minimum password length is 15 characters.

In both non-FIPS and FIPS modes:

The minimum password length for a user group equals the global setting. The minimum password length for a local user equals that of the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

Parameters

length: Specifies the minimum password length in characters. The value range for this argument is 4 to 32 in non-FIPS mode, and 15 to 32 in FIPS mode.

Usage guidelines

The minimum length setting depends on the view:

- The setting in system view has global significance and applies to all user groups.
- The setting in user group view applies to all local users in the user group.
- The setting in local user view applies only to the local user.

A minimum password length with a smaller application scope has higher priority. The system prefers to use the minimum password length in local user view for a local user.

- If no minimum password length is configured for the local user, the system uses the minimum password length for the user group to which the local user belongs.
- If no minimum password length is configured for the user group, the system uses the global minimum password length.

Examples

Set the global minimum password length to 16 characters.

```
<Sysname> system-view
[Sysname] password-control length 16
```

Set the minimum password length to 16 characters for the user group **test**.

```
[Sysname] user-group test
[Sysname-ugroup-test] password-control length 16
[Sysname-ugroup-test] quit
```

Set the minimum password length to 16 characters for the device management user **abc**.

```
[Sysname] local-user abc class manage
[Sysname-luser-manage-abc] password-control length 16
```

display user-group

password-control length enable

password-control login idle-time

Use **password-control login idle-time** to set the maximum account idle time.

Use **undo password-control login idle-time** to restore the default.

Syntax

password-control login idle-time *idle-time*

undo password-control login idle-time

Default

The maximum account idle time is 90 days.

Views

System view

Predefined user roles

network-admin

Parameters

idle-time: Specifies the maximum account idle time in days. The value range is 0 to 365. 0 means no restriction for account idle time.

Usage guidelines

If a user account is idle for this period of time, the account becomes invalid and can no longer be used to log in to the device.

The account might become invalid if the system time changes after your last successful login. You cannot use an invalid account to log in. To disable the account idle time restriction, set the idle time value to 0.

Examples

Set the maximum account idle time to 30 days.

```
<Sysname> system-view
[Sysname] password-control login idle-time 30
```

Related commands

display password-control

password-control login-attempt

Use **password-control login-attempt** to configure the login attempt limit. The settings include the maximum number of consecutive login failures and the action to be taken when the maximum number is reached.

Use **undo password-control login-attempt** to restore the default.

Syntax

password-control login-attempt *login-times* [**exceed** { **lock** | **lock-time** *time* | **unlock** }]

undo password-control login-attempt

Default

The global login-attempt settings:

- The maximum number of consecutive login failures is 3.
- The locking period is 1 minute.

The login-attempt settings for a user group equal the global settings.

The login-attempt settings for a local user equal those for the user group to which the local user belongs.

Views

System view

User group view

Local user view

Predefined user roles

network-admin

Parameters

login-times: Specifies the maximum number of consecutive login failures. The value range is 2 to 10.

exceed: Specifies an action to be taken for the user who fails to log in after making the maximum number of attempts.

- **lock**: Disables the user account permanently.
- **lock-time** *time*: Disables the user account for a period of time. The user can uses this user account when the timer expires. The value range for the *time* argument is 1 to 360 minutes.
- **unlock**: Allows the user account to continue using this account to perform login attempts.

Usage guidelines

The login-attempt policy depends on the view:

- The policy in system view has global significance and applies to all user groups.
- The policy in user group view applies to all local users in the user group.
- The policy in local user view applies only to the local user.

A login-attempt policy with a smaller application scope has higher priority. The system prefers to use the login-attempt policy in local user view for a local user.

- If no policy is configured for the local user, the system uses the policy for the user group to which the local user belongs.
- If no policy is configured for the user group, the system uses the global policy.

If an FTP or VTY user fails to log in, the system adds the user account and the user's IP address to the password control blacklist. When the maximum number of consecutive login failures is reached, the login attempt limit feature is triggered.

Whether a blacklisted user and user account are locked depends on the locking setting:

- If a user account is permanently locked for a user, the user cannot use this account unless this account is removed from the password control blacklist. To remove the user account, use the **reset password-control blacklist** command.
- To use a temporarily locked user account, the user can perform either of the following tasks:
  - Wait until the locking timer expires.
  - Remove the user account from the password control blacklist.
- If the user account and the user are blacklisted but not locked, the user can continue using this account to log in. The account and the user's IP address are removed from the password control blacklist when the user uses the account to successfully log in to the device.

NOTE:

This account is locked only for this user. Other users can still use this account, and the blacklisted user can use other user accounts.

The **password-control login-attempt** command takes effect immediately after being executed, and can affect the users already in the password control blacklist.

Examples

Allow a maximum of four consecutive login failures on a user account, and disable the user account if the limit is reached.

```
<Sysname> system-view
[Sysname] password-control login-attempt 4 exceed lock
```

Use the user account **test** to log in to the device, and enter incorrect password for four times.

Display the password control blacklist. The output shows that the user account is on the blacklist, and its status is **lock**.

```
[Sysname] display password-control blacklist

 Username: test
    IP: 192.168.44.1        Login failures: 4      Lock flag: lock

 Blacklist items matched: 1.
```

Verify that the user at 192.168.44.1 cannot use this user account to log in.

Allow a maximum of two consecutive login failures on a user account, and disable the account for 3 minutes if the limit is reached.

```
<Sysname> system-view
[Sysname] password-control login-attempt 2 exceed lock-time 3
```

Use the user account **test** to log in to the device, and enter incorrect password for two attempts.

Display the password control blacklist. The output shows that the user account is on the blacklist and its status is **lock**.

```
[Sysname] display password-control blacklist

 Username: test
    IP: 192.168.44.1        Login failures: 2      Lock flag: lock

 Blacklist items matched: 1.
```

Verify that after 3 minutes, the user account is removed from the password control blacklist and the user at 192.168.44.1 can use this account.

password-control super aging

Use **password-control super aging** to set the aging time for super passwords.

Use **undo password-control super aging** to restore the default.

Syntax

password-control super aging *aging-time*

undo password-control super aging

Default

A super password expires after 90 days.

Views

System view

Predefined user roles

network-admin

Parameters

aging-time: Specifies the super password aging time in days, in the range of 1 to 365.

Examples

Set the super passwords to expire after 10 days.

```
<Sysname> system-view
[Sysname] password-control super aging 10
```

Related commands

display password-control

password-control aging

password-control super composition

Use **password-control super composition** to configure the composition policy for super passwords.

Use **undo password-control super composition** to restore the default.

Syntax

password-control super composition type-number *type-number* [**type-length** *type-length*]

undo password-control super composition

Default

In non-FIPS mode:

- In versions earlier than Release 6318P01, a super password must contain a minimum of one character type and a minimum of one character for each type.
- In Release 6318P01 and later, a super password must contain a minimum of two character types and a minimum of one character for each type.

In FIPS mode:

A super password must contain a minimum of four character types and a minimum of one character for each type.

Views

System view

Predefined user roles

network-admin

Parameters

type-number *type-number*: Specifies the minimum number of character types that a super password must contain. The value range for the *type-number* argument is 1 to 4 in non-FIPS mode and fixed at 4 in FIPS mode.

type-length *type-length*: Specifies the minimum number of characters that are from each character type. The value range for the *type-length* argument is 1 to 63 in non-FIPS mode, and 1 to 15 in FIPS mode.

Usage guidelines

The product of the minimum number of character types and minimum number of characters for each type cannot be greater than the maximum length of the super password.

Examples

Specify that a super password must contain a minimum of four character types and a minimum of five characters for each type.

```
<Sysname> system-view
[Sysname] password-control super composition type-number 4 type-length 5
```

Related commands

display password-control

password-control composition

password-control super length

Use **password-control super length** to set the minimum length for super passwords.

Use **undo password-control super length** to restore the default.

Syntax

password-control super length *length*

undo password-control super length

Default

In non-FIPS mode:

The minimum super password length is 10 characters.

In FIPS mode:

The minimum super password length is 15 characters.

Views

System view

Predefined user roles

network-admin

Parameters

length: Specifies the minimum length of super passwords in characters. The value range for this argument is 4 to 63 in non-FIPS mode, and 15 to 63 in FIPS mode.

Examples

Set the minimum length of super passwords to 16 characters.

```
<Sysname> system-view
[Sysname] password-control super length 16
```

Related commands

password-control length

password-control update-interval

Use **password-control update-interval** to set the minimum password update interval, which is the minimum interval at which users can change their passwords.

Use **undo password-control update-interval** to restore the default.

Syntax

password-control update-interval *interval*

undo password-control update-interval

Default

The minimum password update interval is 24 hours.

Views

System view

Predefined user roles

network-admin

Parameters

interval: Specifies the minimum password update interval in hours, in the range of 0 to 168. 0 means no requirements for password update interval.

Usage guidelines

The set minimum interval is not effective on a device management user who is prompted to change the password at the first login or after the password expires.

Examples

Set the minimum password update interval to 36 hours.

```
<Sysname> system-view
[Sysname] password-control update-interval 36
```

Related commands

display password-control

reset password-control blacklist

Use **reset password-control blacklist** to remove blacklisted users.

Syntax

reset password-control blacklist [**user-name** *user-name*]

Views

User view

Predefined user roles

network-admin

Parameters

user-name *user-name*: Specifies the username of a user account to be removed from the password control blacklist. The username is a case-sensitive string of 1 to 55 characters.

Usage guidelines

You can use this command to remove a user account that is blacklisted due to excessive login failures. Then the blacklisted user can use this user account to log in.

Examples

Remove the user account named **test** from the password control blacklist.

```
<Sysname> reset password-control blacklist user-name test
Are you sure to delete the specified user in blacklist? [Y/N]:
```

Related commands

display password-control blacklist

reset password-control history-record

Use **reset password-control history-record** to delete history password records.

Syntax

reset password-control history-record [**super** [**role** *role-name*] | **user-name** *user-name* | **network-class** [**user-name** *user-name*]]

Views

User view

Predefined user roles

network-admin

Parameters

super: Deletes the history records of the specified super password or all super passwords.

role *role name*: Specifies a user role name, a case-sensitive string of 1 to 63 characters. If you do not specify this option, the command deletes the history records of all super passwords.

network-class: Deletes the history password records of network access users. If you do not specify this keyword, the command deletes the history password records of device management users.

user-name *user-name*: Specifies the username of the user whose password records are to be deleted. The *user-name* argument is a case-sensitive string of 1 to 55 characters. If you do not specify this option, the command deletes all history password records of the specified user type.

Usage guidelines

If you do not specify any parameters, this command deletes the history password records of all local users.

Examples

Delete the history password records of all device management users.

```
<Sysname> reset password-control history-record
Are you sure you want to delete all device management users' history records? [Y/N]:y
```

Delete the history password records of all network access users.

```
<Sysname> reset password-control history-record network-class
Are you sure you want to delete all network access users' history records? [Y/N]:y
```

Public key management commands

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

display public-key local public

Use **display public-key local public** to display local public keys.

Syntax

display public-key local { **dsa** | **ecdsa** | **rsa** } **public** [**name** *key-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

dsa: Specifies the DSA key pair type.

ecdsa: Specifies the ECDSA key pair type.

rsa: Specifies the RSA key pair type.

name *key-name*: Specifies a local key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command displays the public keys of all local key pairs of the specified type.

Usage guidelines

You can copy and distribute the public key of a local key pair to peer devices.

You cannot display a host public key that has the default key pair name by specifying the **name** *key-name* option. To view a host public key that has the default key pair name, display all local public keys by using this command without specifying a key pair name.

Examples

Display all local RSA public keys.

```
<Sysname> display public-key local rsa public

   4D
```

Table 1 Command output

Field	Description
Key name	Name of the local key pair. If you did not specify a name when creating the key pair, the default name is used followed by the word **default** in brackets. The following is the default key pair name for each key algorithm: • **hostkey**—Default RSA host key pair name. • **serverkey**—Default RSA server key pair name. • **dsakey**—Default DSA host key pair name. • **ecdsakey**—Default ECDSA host key pair name.
Key type	Options include: • RSA. • DSA. • ECDSA.
Time when key pair created	Date and time when the local key pair was created.
Key code	Public key string.

Related commands

`public-key local create`

display public-key peer

Use **`display public-key peer`** to display information about peer host public keys.

Syntax

display public-key peer [**brief** | **name** *publickey-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

brief: Displays brief information about all peer host public keys. The brief information includes only the key type, key modulus, and key name.

name *publickey-name*: Displays detailed information about a peer host public key, including its key code. The *publickey-name* argument specifies a peer host public by its name, a case-sensitive string of 1 to 64 characters.

Usage guidelines

If you do not specify any keywords, this command displays detailed information about all peer host public keys configured on the local device.

You can use the **public-key peer** command or the **public-key peer import sshkey** command to configure a peer host public key on the local device.

Examples

Display detailed information about the peer host public key **idrsa**.

```
<Sysname> display public-key peer name idrsa

=============================================
Key name: idrsa
Key type: RSA
Key modulus: 1024
Key code:
   30819F300D06092A864886F70D010101050003818D0030818902818100C5971581A78B5388
   B3C9063EC6B53D395A6704D9752B6F9B7B1F734EEB5DD509F0B050662C46FFB8D27F797E37
   918F6270C5793F1FC63638970A0E4D51A3CEF7CFF6E92BFAFD73F530E0BDE27056E81F2525
   6D0883836FD8E68031B2C272FE2EA75C87734A7B8F85B8EBEB3BD51CC26916AF3B3FDC32C3
   42C142D41BB4884FEB0203010001
```

Table 2 Command output

Field	Description
Key name	Name of the peer host public key.
Key type	Key type: RSA, DSA or ECDSA.
Key modulus	Key modulus length in bits.
Key code	Public key string.

Display brief information about all peer host public keys.

```
<Sysname> display public-key peer brief
Type  Modulus  Name
```

```
--------------------------
RSA   1024    idrsa
DSA   1024    10.1.1.1
```

Table 3 Command output

Field	Description
Type	Key type: RSA, DSA or ECDSA.
Modulus	Key modulus length in bits.
Name	Name of the peer host public key.

Related commands

public-key peer

public-key peer import sshkey

peer-public-key end

Use **peer-public-key end** to exit public key view to system view and save the configured peer host public key.

Syntax

peer-public-key end

Views

Public key view

Predefined user roles

network-admin

Usage guidelines

After you type the peer host public key on the local device, use this command to exit public key view and to save the peer host public key.

The system verifies the public key before saving it. If the key is not in the correct format, the system discards the key and displays an error message. If the key is valid, for example, the key was displayed by the **display public-key local public** command, the system saves the key.

Examples

Exit public key view and save the configured peer host public key.

```
<Sysname> system-view
[Sysname] public-key peer key1
Enter public key view. Return to system view with "peer-public-key end" command.
[Sysname-pkey-public-key-key1]30819F300D06092A864886F70D010101050003818D0030818902818

[Sysname-pkey-public-key-key1]0001
```

```
[Sysname-pkey-public-key-key1] peer-public-key end
[Sysname]
```

Related commands

display public-key local public

display public-key peer

public-key peer

public-key local create

Use **public-key local create** to create local key pairs.

Syntax

In non-FIPS mode:

public-key local create { **dsa** | **ecdsa** [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

In FIPS mode:

public-key local create { **dsa** | **ecdsa** [**secp256r1** | **secp384r1** | **secp521r1**] | **rsa** } [**name** *key-name*]

Default

No local key pairs exist.

Views

System view

Predefined user roles

network-admin

Parameters

dsa: Specifies the DSA key pair type.

ecdsa: Specifies the ECDSA key pair type.

- **secp192r1**: Uses the secp192r1 curve to create a 192-bit ECDSA key pair.
- **secp256r1**: Uses the secp256r1 curve to create a 256-bit ECDSA key pair.
- **secp384r1**: Uses the secp384r1 curve to create a 384-bit ECDSA key pair.
- **secp521r1**: Uses the secp521r1 curve to create a 521-bit ECDSA key pair.

By default, the secp192r1 curve is used in non-FIPS mode and the secp256r1 curve is used in FIPS mode.

rsa: Specifies the RSA key pair type.

name *key-name*: Assigns a name to the key pair. The *key-name* argument is a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not assign a name to the key pair, the key pair takes the default name.

Table 4 Default local key pair names

Type	Default name
RSA	• Host key pair: **hostkey** • Server key pair: **serverkey**
DSA	**dsakey**

Type	Default name
ECDSA	**ecdsakey**

Usage guidelines

The key algorithm must be the same as required by the security application.

When you create an RSA or DSA key pair, enter an appropriate key modulus length at the prompt. The longer the key modulus length, the higher the security, and the longer the key generation time.

When you create an ECDSA key pair, choose the appropriate elliptic curve. The elliptic curve determines the ECDSA key length. The longer the key length, the higher the security, and the longer the key generation time.

See Table 5 for more information about key modulus lengths and key lengths.

If you do not assign the key pair a name, the system assigns the default name to the key pair and marks the key pair as **`default`**. You can also assign the default name to another key pair, but the system does not mark the key pair as **default**. The name of a key pair must be unique among all manually named key pairs that use the same key algorithm. If a name conflict occurs, the system asks whether you want to overwrite the existing key pair.

The key pairs are automatically saved and can survive system reboots.

Table 5 A comparison of different types of asymmetric key algorithms

Type	Generated key pairs	Modulus/key length

RSA	• In non-FIPS mode:
	  ◦ One host key pair, if you specify a key pair name.
	  ◦ One server key pair and one host key pair, if you do not specify a key pair name.
	  Both key pairs use their default names.
	• In FIPS mode: One host key pair.
	NOTE:
	Only SSH 1.5 uses the RSA server key pair.
		RSA key modulus length:
		• In non-FIPS mode: 512 to 4096 bits, 1024 bits by default.
		To ensure security, use a minimum of 768 bits.
		• In FIPS mode: A multiple of 256 bits in the range of 2048 to 4096 bits, 2048 bits by default.

DSA	One host key pair.	DSA key modulus length: • In non-FIPS mode: 512 to 2048 bits, 1024 bits by default. To ensure security, use a minimum of 768 bits. • In FIPS mode: 2048 bits.
ECDSA	One host key pair.	ECDSA key length: • In non-FIPS mode: 192, 256, 384, or 521 bits. • In FIPS mode: 256, 384, or 521 bits.

Examples

Create local RSA key pairs with default names.

```
<Sysname> system-view
[Sysname] public-key local create rsa
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
```

```
Input the modulus length [default = 1024]:
Generating Keys...
....
Create the key pair successfully.
```

Create a local DSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local create dsa
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
....
Create the key pair successfully.
```

Create a local ECDSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local create ecdsa
Generating Keys...
Create the key pair successfully.
```

Create a local RSA key pair with the name **rsa1**.

```
<Sysname> system-view
[Sysname] public-key local create rsa name rsa1
The range of public key modulus is (512 ~ 4096).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
..
Create the key pair successfully.
```

Create a local DSA key pair with the name **dsa1**.

```
<Sysname> system-view
[Sysname] public-key local create dsa name dsa1
The range of public key modulus is (512 ~ 2048).
If the key modulus is greater than 512, it will take a few minutes.
Press CTRL+C to abort.
Input the modulus length [default = 1024]:
Generating Keys...
.....
Create the key pair successfully.
```

Create a local ECDSA key pair with the name **ecdsa1**.

```
<Sysname> system-view
[Sysname] public-key local create ecdsa name ecdsa1
Generating Keys...
Create the key pair successfully.
```

In FIPS mode, create a local RSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local create rsa
```

```
The range of public key modulus is (2048 ~ 4096), a multiple of 256.
It will take a few minutes.Press CTRL+C to abort.
Input the modulus length [default = 2048]:
Generating Keys...
....
Create the key pair successfully.
```

In FIPS mode, create a local DSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local create dsa
The range of public key modulus is (2048 ~ 2048).
It will take a few minutes.Press CTRL+C to abort.
Input the modulus length [default = 2048]:
..
Create the key pair successfully.
```

Related commands

display public-key local public

public-key local destroy

public-key local destroy

Use **public-key local destroy** to destroy local key pairs.

Syntax

public-key local destroy { **dsa** | **ecdsa** | **rsa** } [**name** *key-name*]

Views

System view

Predefined user roles

network-admin

Parameters

dsa: Specifies the DSA key pair type.

ecdsa: Specifies the ECDSA key pair type.

rsa: Specifies the RSA key pair type.

name *key-name*: Specifies a local key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command destroys all key pairs of the specified type.

Usage guidelines

To avoid key compromise, destroy the local key pair and generate a new pair after any of the following conditions occurs:

- An intrusion event has occurred.
- The storage media of the device is replaced.
- The local certificate has expired. For more information about local certificates, see *Security Configuration Guide*.

Examples

Destroy the local RSA key pairs with the default names.

```
<Sysname> system-view
[Sysname] public-key local destroy rsa
Confirm to destroy the key pair? [Y/N]:y
```

Destroy the local DSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local destroy dsa
Confirm to destroy the key pair? [Y/N] :y
```

Destroy the local ECDSA key pair with the default name.

```
<Sysname> system-view
[Sysname] public-key local destroy ecdsa
Confirm to destroy the key pair? [Y/N]:y
```

Destroy the local RSA key pair **rsa1**.

```
<Sysname> system-view
[Sysname] public-key local destroy rsa name rsa1
Confirm to destroy the key pair? [Y/N]:y
```

Destroy the local DSA key pair **dsa1**.

```
<Sysname> system-view
[Sysname] public-key local destroy dsa name dsa1
Confirm to destroy the key pair? [Y/N] :y
```

Destroy the local ECDSA key pair **ecdsa1**.

```
<Sysname> system-view
[Sysname] public-key local destroy ecdsa name ecdsa1
Confirm to destroy the key pair? [Y/N]:y
```

Related commands

public-key local create

public-key local export dsa

Use **public-key local export dsa** to export a local DSA host public key.

Syntax

public-key local export dsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Views

System view

Predefined user roles

network-admin

Parameters

name *key-name*: Specifies a local DSA key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command exports the host public key of the local DSA key pair with the default name.

openssh: Exports the host public key in OpenSSH format.

ssh2: Exports the host public key in SSH 2.0 format.

filename: Specifies the name of the file for saving the DSA host public key. The file name is a case-insensitive string of 1 to 128 characters. The name cannot be all dots (.), hostkey, serverkey, dsakey, or ecdsakey, and cannot start with a slash (/) or contain **./** and **../**. For more information about

file names, see *Fundamentals Configuration Guide*. If you do not specify a file name, this command displays the key on the monitor screen.

Usage guidelines

You can use this command to export a local DSA host public key before distributing it to a peer device.

To distribute a local DSA host public key to a peer device:

1. Save the exported local host public key to a file by using one of the following methods:
   - Use the **public-key local export dsa** [**name** *key-name*] { **openssh** | **ssh2** } command to export the local host public key, and then copy and paste the key to a file.
   - Use the **public-key local export dsa** [**name** *key-name*] { **openssh** | **ssh2** } *filename* command to export the key to a file. You cannot export the key to the folder **pkey** or its subfolders.
2. Transfer a copy of the file to the peer device, for example, by using FTP in binary mode or TFTP. For more information about FTP and TFTP, see *Fundamentals Configuration Guide*.
3. On the peer device, use the **public-key peer import sshkey** command to import the host public key from the file.

SSH 2.0 and OpenSSH are different public key formats. Choose the correct format that is supported on the device where you import the host public key.

Examples

Export the host public key of the local DSA key pair with the default name in OpenSSH format to a file named **key.pub**.

```
<Sysname> system-view
[Sysname] public-key local export dsa openssh key.pub
```

Display the host public key of the local DSA key pair with the default name in SSH 2.0 format.

```
<Sysname> system-view

Related commands

public-key local create

public-key peer import sshkey

public-key local export ecdsa

Use **public-key local export ecdsa** to export a local ECDSA host public key.

Syntax

public-key local export ecdsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Views

System view

Predefined user roles

network-admin

Parameters

name *key-name*: Specifies a local ECDSA key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command exports the host public key of the local ECDSA key pair with the default name.

openssh: Exports the host public key in OpenSSH format.

ssh2: Exports the host public key in SSH 2.0 format.

filename: Specifies the name of the file for saving the local host public key. The file name is a case-insensitive string of 1 to 128 characters. The name cannot be dots (.), hostkey, serverkey, dsakey, or ecdsakey, and cannot start with a slash (/) or contain ***./*** and ***../***. For more information about file names, see *Fundamentals Configuration Guide*. If you do not specify a file name, this command displays the key on the monitor screen.

Usage guidelines

You can use this command to export a local ECDSA host public key before distributing it to a peer device.

To distribute a local ECDSA host public key to a peer device:

1. Save the exported ECDSA host public key to a file by using one of the following methods:
   - Use the **public-key local export ecdsa** [**name** *key-name*] { **openssh** | **ssh2** } command to export the local host public key, and then copy and paste it to a file.
   - Use the **public-key local export ecdsa** [**name** *key-name*] { **openssh** | **ssh2** } *filename* command to export the host public key to a file. You cannot export the key to the folder **pkey** or its subfolders.
2. Transfer a copy of the file to the peer device, for example, by using FTP in binary mode or TFTP. For more information about FTP and TFTP, see *Fundamentals Configuration Guide*.
3. On the peer device, use the **public-key peer import sshkey** command to import the host public key from the file.

SSH 2.0 and OpenSSH are different public key formats. Choose the correct format that is supported by the device where you import the host public key.

Only the ECDSA host public key generated by using the secp256r1 curve can be exported.

Examples

Export the host public key of the local ECDSA key pair with the default name in OpenSSH format to the file named **key.pub**.

```
<Sysname> system-view
[Sysname] public-key local export ecdsa openssh key.pub
```

Display the host public key of the local ECDSA key pair with the default name in SSH 2.0 format.

```
<Sysname> system-view
[Sysname] public-key local export ecdsa ssh2
---- BEGIN SSH2 PUBLIC KEY ----
Comment: "ecdsa-sha2-nistp256-2014/07/06"
AAAAE2VjZHNhLXNoYTItbmlzdHAyNTYAAAAIbmlzdHAyNTYAAABBBBREw5tkARpbV+sYArt/xcW+UJEAevx7O
ckTtTLPBiLP5bWkSdKbvo+3oHRuIyZqmNTIcxuBjuBap+pHc919C58=
---- END SSH2 PUBLIC KEY ----
```

Display the host public key of the local ECDSA key pair with the default name in OpenSSH format.

```
<Sysname> system-view
[Sysname] public-key local export ecdsa openssh
ecdsa-sha2-nistp256
AAAAE2VjZHNhLXNoYTItbmlzdHAyNTYAAAAIbmlzdHAyNTYAAABBBBREw5tkARpbV+sYArt/xcW+UJEAevx7O
ckTtTLPBiLP5bWkSdKbvo+3oHRuIyZqmNTIcxuBjuBap+pHc919C58=
 ecdsa-key
```

Related commands

public-key local create

public-key peer import sshkey

public-key local export rsa

Use **public-key local export rsa** to export a local RSA host public key.

Syntax

In non-FIPS mode:

public-key local export rsa [**name** *key-name*] { **openssh** | **ssh1** | **ssh2** } [*filename*]

In FIPS mode:

public-key local export rsa [**name** *key-name*] { **openssh** | **ssh2** } [*filename*]

Views

System view

Predefined user roles

network-admin

Parameters

name *key-name*: Specifies a local RSA key pair by its name, a case-insensitive string of 1 to 64 characters. Valid characters are letters, digits, and hyphens (-). If you do not specify a key pair, this command exports the host public key of the local RSA key pair with the default name.

openssh: Exports the host public key in OpenSSH format.

ssh1: Exports the host public key in SSH 1.5 format.

ssh2: Exports the host public key in SSH 2.0 format.

filename: Specifies the name of the file for saving the RSA host public key. The file name is a case-insensitive string of 1 to 128 characters. The name cannot be all dots (.), hostkey, serverkey, dsakey, or ecdsakey, and cannot start with a slash (/) or contain **./** and **../**. For more information about file names, see *Fundamentals Configuration Guide*. If you do not specify a file name, this command displays the key on the monitor screen.

Usage guidelines

You can use this command to export a local RSA host public key before distributing it to a peer device.

To distribute a local RSA host public key to a peer device:

1. Save the exported local host public key to a file by using one of the following methods:
   - Use the **public-key local export rsa** [**name** *key-name*] { **openssh** | **ssh2** } command to export the key, and then copy and paste it to a file.
   - Use the **public-key local export rsa** [**name** *key-name*] { **openssh** | **ssh2** } *filename* command to export key to a file. You cannot export the key to the folder **pkey** or its subfolders.
2. Transfer a copy of the file to the peer device, for example, by using FTP in binary mode or TFTP. For more information about FTP and TFTP, see *Fundamentals Configuration Guide*.
3. On the peer device, use the **public-key peer import sshkey** command to import the host public key from the file.

Choose the correct public key format that is supported on the device where you import the host public key. In FIPS mode, the device only supports SSH 2.0 and OpenSSH.

Examples

Export the host public key of the local RSA key pair with the default name in OpenSSH format to the file **key.pub**.

```
<Sysname> system-view
[Sysname] public-key local export rsa openssh key.pub
```

Display the host public key of the local RSA key pair with the default name in SSH 2.0 format.

```
<Sysname> system-view
[Sysname] public-key local export rsa ssh2
---- BEGIN SSH2 PUBLIC KEY ----
Comment: "rsa-key-2011/05/12"

```

Related commands

`public-key local create`

`public-key peer import sshkey`

public-key peer

Use **`public-key peer`** to assign a name to a peer host public key and enter public key view, or enter the view of an existing peer host public key.

Use **`undo public-key peer`** to delete a peer host public key.

Syntax

public-key peer *keyname*

undo public-key peer *keyname*

Default

No peer host public keys exist.

Views

System view

Predefined user roles

network-admin

Parameters

keyname: Specifies a key name, a case-sensitive string of 1 to 64 characters.

Usage guidelines

After you execute this command to enter the public key view, type the public key. Spaces and carriage returns are allowed, but are not saved.

To configure a peer host public key on the local device, first obtain the peer public key in hexadecimal notation, and then perform the following tasks on the local device:

1. Execute the **public-key peer** command to enter public key view.
2. Type the public key.
3. Execute the **peer-public-key end** command to save the public key and return to system view.

The public key you type in the public key view must be in a correct format. If the peer device is an H3C device, use the **display public-key local public** command to display and record its public key.

Examples

Assign the name **key1** to the peer host public key and enter public key view.

```
<Sysname> system-view
[Sysname] public-key peer key1
Enter public key view. Return to system view with "peer-public-key end" command.
[Sysname-pkey-public-key-key1]
```

Related commands

display public-key local public

display public-key peer

peer-public-key end

public-key peer import sshkey

Use **public-key peer import sshkey** to import a peer host public key from a public key file.

Use **undo public-key peer** to remove a peer host public key.

Syntax

public-key peer *keyname* **import sshkey** *filename*

undo public-key peer *keyname*

Default

No peer host public keys exist.

Views

System view

Predefined user roles

network-admin

Parameters

keyname: Specifies a name for a peer host public key, a case-sensitive string of 1 to 64 characters.

filename: Specifies a public key file by its name, a case-insensitive string of 1 to 128 characters. The name cannot be all dots (.), hostkey, serverkey, dsakey, or ecdsakey, and cannot start with a slash (/) or contain ***./*** and ***../***. For more information about file names, see *Fundamentals Configuration Guide*.

Usage guidelines

After you configure this command, the system automatically transforms the host public key to the PKCS format, and saves the key.

Before you use this command, make sure you have got a copy of the public key file from the peer device through FTP in binary mode or through TFTP.

In non-FIPS mode, the device supports importing public keys in the format of SSH 1.5, SSH 2.0, and OpenSSH.

In FIPS mode, the device supports importing public keys in the format of SSH 2.0 and OpenSSH.

Examples

Import the peer host public key **key2** from the public key file **key.pub**.

```
<Sysname> system-view
[Sysname] public-key peer key2 import sshkey key.pub
```

Related commands

display public-key peer

public-key local export dsa

public-key local export ecdsa

Contents

PKI commands

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

attribute

Use **attribute** to configure a rule to filter certificates based on an attribute in the certificate issuer name, subject name, or alternative subject name field.

Use **undo attribute** to remove an attribute rule.

Syntax

attribute *id* { **alt-subject-name** { **fqdn** | **ip** } | { **issuer-name** | **subject-name** } { **dn** | **fqdn** | **ip** } } { **ctn** | **equ** | **nctn** | **nequ** } *attribute-value*

undo attribute *id*

Default

No attribute rules exist.

Views

Certificate attribute group view

Predefined user roles

network-admin

Parameters

id: Specifies a rule ID in the range of 1 to 16.

alt-subject-name: Specifies the alternative subject name field.

fqdn: Specifies the FQDN attribute.

ip: Specifies the IP address attribute.

dn: Specifies the DN attribute.

issuer-name: Specifies the issuer name field.

subject-name: Specifies the subject name field.

ctn: Specifies the contain operation.

equ: Specifies the equal operation.

nctn: Specifies the not-contain operation.

nequ: Specifies the not-equal operation.

attribute-value: Sets an attribute value, a case-insensitive string of 1 to 128 characters.

Usage guidelines

Different certificate fields support different attributes.

- The subject name field and the issuer name field can contain a single DN, multiple FQDNs, and multiple IP addresses.
- The alternative subject name field can contain multiple FQDNs and IP addresses but zero DNs.

An attribute rule is a combination of an attribute-value pair with an operation keyword, as listed in Table 1.

Table 1 Combinations of attribute-value pairs and operation keywords

Operation	DN	FQDN/IP
ctn	The DN contains the specified attribute value.	Any FQDN or IP address contains the specified attribute value.
nctn	The DN does not contain the specified attribute value.	None of the FQDNs or IP addresses contain the specified attribute value.
equ	The DN is the same as the specified attribute value.	Any FQDN or IP address is the same as the specified attribute value.
nequ	The DN is not the same as the specified attribute value.	None of the FQDNs or IP addresses are the same as the specified attribute value.

A certificate matches an attribute rule if it contains an attribute that matches the criterion defined in the rule. For example, a certificate matches the **attribute 1 subject-name dn ctn abc** rule if it meets the following conditions:

- The subject name field of the certificate contains the DN attribute.
- The DN attribute value contains the **abc** string.

A certificate matches an attribute group if it matches all attribute rules in the group.

Examples

Create a certificate attribute group and enter its view.

```
<Sysname> system-view
[Sysname] pki certificate attribute-group mygroup
```

Configure an attribute rule to match certificates that contain the **abc** string in the subject DN.

```
[Sysname-pki-cert-attribute-group-mygroup] attribute 1 subject-name dn ctn abc
```

Configure an attribute rule to match certificates that do not contain FQDN **abc** in the issuer name field.

```
[Sysname-pki-cert-attribute-group-mygroup] attribute 2 issuer-name fqdn nequ abc
```

Configure an attribute rule to match certificates that do not contain IP address **10.0.0.1** in the alternative subject name field.

```
[Sysname-pki-cert-attribute-group-mygroup] attribute 3 alt-subject-name ip nequ 10.0.0.1
```

Related commands

display pki certificate attribute-group

rule

ca identifier

Use **ca identifier** to specify the trusted CA.

Use **undo ca identifier** to restore the default.

Syntax

ca identifier *name*

undo ca identifier

Default

No trusted CA is specified.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

name: Specifies the trusted CA by its name, a case-sensitive string of 1 to 63 characters.

Usage guidelines

To obtain a CA certificate in a PKI domain, you must specify the trusted CA name. The trusted CA name uniquely identifies the CA to be used if multiple CAs exist on the CA server specified for the PKI domain.

Make sure the specified CA name is consistent with the name of the CA that owns the CA certificate to be obtained.

Examples

Set the name of the trusted CA to **new-ca**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] ca identifier new-ca
```

certificate request entity

Use **certificate request entity** to specify the PKI entity for certificate request.

Use **undo certificate request entity** to restore the default.

Syntax

certificate request entity *entity-name*

undo certificate request entity

Default

No PKI entity is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

entity-name: Specifies a PKI entity by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A PKI entity describes the identity attributes of an entity for certificate request, including the following information:

- Common name.
- Organization.
- Unit in the organization.
- Locality.
- State and country where the entity resides.
- FQDN.

- IP address.

You can specify only one PKI entity for a PKI domain. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify PKI entity **en1** for certificate request in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request entity en1
```

Related commands

pki entity

certificate request from

Use **certificate request from** to specify the type of certificate request reception authority.

Use **undo certificate request from** to restore the default.

Syntax

certificate request from { **ca** | **ra** }

undo certificate request from

Default

The type of certificate request reception authority is not specified.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

ca: Sends certificate requests to the CA.

ra: Sends certificate requests to the RA.

Usage guidelines

The CA server determines whether the CA or RA accepts certificate requests. This authority setting must be consistent with the setting on the CA server.

Examples

Sends certificate requests to the RA.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request from ra
```

certificate request mode

Use **certificate request mode** to set the certificate request mode.

Use **undo certificate request mode** to restore the default.

Syntax

certificate request mode { **auto** [**password** { **cipher** | **simple** } *string*] | **manual** }

undo certificate request mode

Default

The certificate request mode is manual.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

auto: Specifies the auto certificate request mode.

password: Specifies a password for certificate revocation.

cipher: Specifies a password in encrypted form.

simple: Specifies a password in plaintext form. For security purposes, the password specified in plaintext form will be stored in encrypted form.

string: Specifies the password. Its plaintext form is a case-sensitive string of 1 to 31 characters. Its encrypted form is a case-sensitive string of 1 to 73 characters.

manual: Specifies the manual certificate request mode.

Usage guidelines

A certificate request can be submitted to a CA in offline or online mode. In online mode, a certificate request can be automatically or manually submitted:

- **Auto request mode**—A PKI entity automatically obtains the CA certificate and submits a certificate request to the CA when both of the following conditions exist:
  - An associated application (IKE, for example) performs identity authentication.
  - No certificate is available for the application on the device.

  In auto request mode, specify the password for certificate revocation as required by the CA policy.
- **Manual request mode**—You must manually obtain the CA certificate and submit certificate requests.

Examples

Set the certificate request mode to **auto**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request mode auto
```

Set the certificate request mode to **auto**, and set the certificate revocation password in plain text to **123456**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request mode auto password simple 123456
```

Related commands

pki request-certificate

certificate request polling

Use **certificate request polling** to set the polling interval and the maximum number of attempts to query certificate request status.

Use **undo certificate request polling** to restore the defaults.

Syntax

certificate request polling { **count** *count* | **interval** *interval* }

undo certificate request polling { **count** | **interval** }

Default

The polling interval is 20 minutes, and the maximum number of attempts is 50.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

count *count*: Specifies the maximum number of query attempts. The value range is 1 to 100.

interval *interval*: Specifies a polling interval in minutes. The value range is 5 to 168.

Usage guidelines

After a PKI entity submits a certificate request, it might take the CA server a while to issue the certificate if the CA administrator must manually approve the certificate request. During this period, the PKI entity periodically queries the CA server for the certificate request status. The periodic query operation stops until the PKI entity obtains the certificate or the maximum number of query attempts is reached. If the maximum number of query attempts is reached, the certificate request fails.

If the CA server automatically approves certificate requests, the PKI entity can obtain the certificate immediately after it submits a certificate request. In this case, the PKI entity does not send queries to the CA server.

Examples

Set the polling interval to 15 minutes, and the maximum number of query attempts to 40.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] certificate request polling interval 15
[Sysname-pki-domain-aaa] certificate request polling count 40
```

Related commands

display pki certificate request-status

certificate request url

Use **certificate request url** to specify the URL of the certificate request reception authority (CA or RA) to which the device should send SCEP certificate requests.

Use **undo certificate request url** to restore the default.

Syntax

certificate request url *url-string*

undo certificate request url

Default

The URL of the certificate request reception authority is not specified.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

url-string: Specifies the URL of the certificate request reception authority, a case-sensitive string of 1 to 511 characters. The URL length is restricted by the CLI string limitation or the *url-string* parameter, whichever is smaller.

Usage guidelines

The certificate request URL contains the location of the certificate request reception authority server and the path of the application script on the server, in the format http://*server_location/cgi_script_location.*

Examples

Set the certificate request URL to **http://169.254.0.1/certsrv/mscep/mscep.dll**.

```
<Sysname> system-view
[Sysname] pki domain a
[Sysname-pki-domain-a] certificate request url
http://169.254.0.1/certsrv/mscep/mscep.dll
```

common-name

Use **common-name** to set the common name for a PKI entity.

Use **undo common-name** to restore the default.

Syntax

common-name *common-name-sting*

undo common-name

Default

No common name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

common-name-sting: Specifies a common name, a case-sensitive string of 1 to 63 characters. No comma can be included. You can set the username of the PKI entity as the common name.

Examples

Set the common name to **test** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] common-name test
```

country

Use **country** to set the country code of a PKI entity.

Use **undo country** to restore the default.

Syntax

country *country-code-string*

undo country

Default

No country code is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

country-code-string: Specifies a country code, a case-sensitive string of two characters. For example, CN is the country code for China.

Examples

Set the country code to **CN** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] country CN
```

crl check enable

Use **crl check enable** to enable CRL checking.

Use **undo crl check enable** to disable CRL checking.

Syntax

crl check enable

undo crl check enable

Default

CRL checking is enabled.

Views

PKI domain view

Predefined user roles

network-admin

Usage guidelines

A CRL is a list of revoked certificates signed and published by a CA. Revoked certificates should no longer be trusted.

Enable CRL checking to ensure that the device only accepts certificates that have not been revoked by the issuing CA.

Examples

Disable CRL checking.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] undo crl check enable
```

Related commands

pki import

pki retrieve-certificate

pki validate-certificate

crl url

Use **crl url** to specify the URL of the CRL repository.

Use **undo crl url** to restore the default.

Syntax

crl url *url-string*

undo crl url

Default

The URL of the CRL repository is not specified.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

url-string: Specifies the URL of the CRL repository, a case-sensitive string of 1 to 511 characters. The URL format is ldap://*server_location* or http://*server_location*. The URL length is restricted by the CLI string limitation or the *url-string* parameter, whichever is smaller.

Usage guidelines

To use CRL checking, a CRL must be obtained from a CRL repository.

The device selects a CRL repository in the following order:

1. CRL repository specified in the PKI domain by using this command.
2. CRL repository in the certificate that is being verified.
3. CRL repository in the CA certificate or CRL repository in the upper-level CA certificate if the CA certificate is the certificate being verified.

After the previous selection process, if the CRL repository is not found, the device obtains the CRL through SCEP. In this scenario, the CA certificate and the local certificates must have been obtained.

If an LDAP URL is specified, the device must connect to the LDAP server to obtain the CRL. If the LDAP URL does not contain the address of the LDAP server, use the **ldap-server** command to configure the server address in the PKI domain.

Examples

Set the URL of the CRL repository to **http://169.254.0.30**.

```
<Sysname> system-view
```

```
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] crl url http://169.254.0.30
```

Parameters

policy-name: Specifies a certificate-based access control policy by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

If you do not specify a policy name, this command displays information about all certificate-based access control policies.

Examples

Display information about certificate-based access control policy **mypolicy**.

```
<Sysname> display pki certificate access-control-policy mypolicy
 Access control policy name: mypolicy
     Rule 1  deny    mygroup1
     Rule 2  permit  mygroup2
```

Display information about all certificate-based access control policies.

```
<Sysname> display pki certificate access-control-policy
 Total PKI certificate access control policies: 2
 Access control policy name: mypolicy1
     Rule 1  deny    mygroup1
     Rule 2  permit  mygroup2
 Access control policy name: mypolicy2
     Rule 1  deny    mygroup3
     Rule 2  permit  mygroup4
```

Table 2 Command output

Field	Description
Total PKI certificate access control policies	Total number of certificate-based access control policies.

Field	Description
permit	Permit certificates that match the attribute group in the access control rule.
deny	Deny certificates that match the attribute group in the access control rule.

network-operator

Parameters

group-name: Specifies a certificate attribute group by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

If you do not specify a certificate attribute group, this command displays information about all certificate attribute groups.

Examples

Display information about certificate attribute group **mygroup**.

```
<Sysname> display pki certificate attribute-group mygroup
 Attribute group name: mygroup
      Attribute  1 subject-name     dn    ctn   abc
      Attribute  2 issuer-name      fqdn  nctn  app
```

Display information about all certificate attribute groups.

```
<Sysname> display pki certificate attribute-group
 Total PKI certificate attribute groups: 2.
 Attribute group name: mygroup1
      Attribute  1 subject-name     dn    ctn   abc
      Attribute  2 issuer-name      fqdn  nctn  app
Attribute group name: mygroup2
      Attribute  1 subject-name     dn    ctn   def
      Attribute  2 issuer-name      fqdn  nctn  fqd
```

Table 3 Command output

Field	Description
Total PKI certificate attribute groups	Total number of certificate attribute groups.
ctn	Contain operation.
nctn	Not-contain operation.
equ	Equal operation.
nequ	Not-equal operation.
Attribute 1 subject-name dn ctn abc	Attribute rule contents: • **alt-subject-name**—Alternative subject name. • **issuer-name**—Certificate issuer name. • **subject-name**—Certificate subject name. • **fqdn**—FQDN of the PKI entity. • **ip**—IP address of the PKI entity. • **dn**—DN of the PKI entity. • **ctn**—Indicates the contain operation. • **equ**—Indicates the equal operation. • **nctn**—Indicates the not-contain operation. • **nequ**—Indicates the not-equal operation.

display pki certificate domain

Use **`display pki certificate domain`** to display information about certificates.

Syntax

`display pki certificate domain` *`domain-name`* { **`ca`** | **`local`** | **`peer`** [**`serial`** *`serial-num`*] }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`domain-name`: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 4.

Table 4 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>

Character name	Symbol	Character name	Symbol
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

ca: Specifies the CA certificate.

local: Specifies the local certificates.

peer: Specifies the peer certificates.

serial *serial-num*: Specifies the serial number of a peer certificate.

Usage guidelines

If you specify the **CA** keyword, this command displays information about all CA certificates in the domain. If the domain has RA certificates, the RA certificates are also displayed.

If you specify the **local** keyword, this command displays information about all local certificates in the domain.

If you specify the **peer** keyword without a serial number, this command displays brief information about all peer certificates. If you specify a serial number, this command display detailed information about the specified peer certificate.

Examples

Display information about the CA certificate in PKI domain **aaa**.

```
<Sysname> display pki certificate domain aaa ca

Related commands

pki domain

pki retrieve-certificate

display pki certificate request-status

Use **display pki certificate request-status** to display certificate request status.

Syntax

display pki certificate request-status [**domain** *domain-name*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 5.

Table 5 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

If you do not specify a PKI domain, this command displays the certificate request status for all PKI domains.

Examples

Display certificate request status for PKI domain **aaa**.

```
<Sysname> display pki certificate request-status domain aaa
Certificate Request Transaction 1
    Domain name: aaa
    Status: Pending
    Key usage: General
    Remain polling attempts: 10
    Next polling attempt after : 1191 seconds
```

Display certificate request statuses for all PKI domains.

```
<Sysname> display pki certificate request-status
Certificate Request Transaction 1
    Domain name: domain1
    Status: Pending
    Key usage: General
    Remain polling attempts: 10
    Next polling attempt after : 1191 seconds
```

```
Certificate Request Transaction 2
    Domain name: domain2
    Status: Pending
    Key usage: Signature
    Remain polling attempts: 10
    Next polling attempt after : 188 seconds
```

Table 6 Command output

Field	Description
Certificate Request Transaction *number*	Certificate request transaction number, starting from 1.
Status	Certificate request status, including only the pending status.
Key usage	Certificate purposes: • **General**—Signature and encryption. • **Signature**—Signature only. • **Encryption**—Encryption only.
Remain polling attempts	Remaining number of attempts to query certificate request status.
Next polling attempt after	Remaining seconds before the next request status polling.

Related commands

`certificate request polling`

`pki domain`

`pki retrieve-certificate`

display pki crl domain

Use **`display pki crl domain`** to display information about the CRL saved at the local for a PKI domain.

Syntax

`display pki crl domain` *`domain-name`*

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`domain-name`: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 7.

Table 7 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.

Character name	Symbol	Character name	Symbol
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

Use this command to determine whether a certificate has been revoked.

Examples

Display information about the CRL saved at the local for PKI domain **aaa**.

```
<Sysname> display pki crl domain aaa

Table 8 Command output

Field	Description
Version	CRL version number.
Signature Algorithm	Signature algorithm used by the CA to sign the CRL.
Issuer	Name of the CA that issued the CRL.
Last Update	Most recent CRL update time.
Next Update	Next CRL update time.
X509v3 Authority Key Identifier	X509v3 ID of the CA that issues the CRL.
keyid	Key ID. This field identifies the key pair used to sign the CRL.
Signature Algorithm:	Signature algorithm and signature data.

Related commands

pki retrieve-crl

fqdn

Use **fqdn** to set the FQDN of an entity.

Use **undo fqdn** to restore the default.

Syntax

fqdn *fqdn-name-string*

undo fqdn

Default

No FQDN is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

fqdn-name-string: Specifies an FQDN, a case-sensitive string of 1 to 255 characters in the format *hostname*@*domainname*.

Usage guidelines

An FQDN uniquely identifies a PKI entity on a network.

Examples

Set the FQDN to **pki.domain-name.com** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] fqdn abc@pki.domain.com
```

ip

Use **ip** to assign an IP address to a PKI entity.

Use **undo ip** to restore the default.

Syntax

ip { *ip-address* | **interface** *interface-type interface-number* }

undo ip

Default

No IP address is assigned to the PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

ip-address: Specifies an IPv4 address.

interface *interface-type interface-number*: Specifies an interface by its type and number. The primary IPv4 address of the interface will be used as the IP address of the PKI entity.

Usage guidelines

Use this command to assign an IP address to a PKI entity or specify an interface for the entity. The interface's primary IPv4 address will be used as the IP address of the PKI entity. If you specify an interface, make sure the interface is assigned an IP address before the PKI entity requests a certificate.

Examples

Assign IP address **192.168.0.2** to PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] ip 192.168.0.2
```

ldap-server

Use **ldap-server** to specify an LDAP server for a PKI domain.

Use **undo ldap-server** to restore the default.

Syntax

ldap-server host *hostname* [**port** *port-number*]

undo ldap-server

Default

No LDAP server is specified for a PKI domain.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

host *hostname*: Specifies an LDAP server by its IPv4 address, IPv6 address, or domain name. The domain name is a case-sensitive string of 1 to 255 characters.

port *port-number*: Specifies the port number of the LDAP server. The value range is 1 to 65535, and the default is 389.

Usage guidelines

You must specify an LDAP server for a PKI domain in the following situations:

- The certificate repository uses LDAP for certificate distribution.
- The CRL repository uses LDAP for CRL distribution. However, the CRL repository URL configured for the PKI domain does not contain the IP address or host name of the LDAP server.

You can specify only one LDAP server for a PKI domain. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify LDAP server **10.0.0.1** for PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] ldap-server host 10.0.0.1
```

Related commands

pki retrieve-certificate

pki retrieve-crl

locality

Use **locality** to set the locality of a PKI entity.

Use **undo locality** to restore the default.

Syntax

locality *locality-name*

undo locality

Default

No locality is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

locality-name: Specifies a locality, a case-sensitive string of 1 to 63 characters. No comma can be included. You can set a city name as the locality.

Examples

Set the locality to **pukras** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
```

```
[Sysname-pki-entity-en] locality pukras
```

organization

Use **organization** to set an organization name for a PKI entity.

Use **undo organization** to restore the default.

Syntax

organization *org-name*

undo organization

Default

No organization name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

org-name: Specifies an organization name, a case-sensitive string of 1 to 63 characters. No comma can be included.

Examples

Set the organization name to **abc** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] organization abc
```

organization-unit

Use **organization-unit** to set an organization unit name for a PKI entity.

Use **undo organization-unit** to restore the default.

Syntax

organization-unit *org-unit-name*

undo organization-unit

Default

No organization unit name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

org-unit-name: Specifies an organization unit name, a case-sensitive string of 1 to 63 characters. No commas can be included.

Examples

Set the organization unit name to **rdtest** for PKI entity **en**.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en] organization-unit rdtest
```

pki abort-certificate-request

Use **pki abort-certificate-request** to abort the certificate request for a PKI domain.

Syntax

pki abort-certificate-request domain *domain-name*

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 9.

Table 9 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

You can abort a certificate request and change some parameters, such as common name, country code, or FQDN, in the certificate request before the CA issues the certificate. Use the **display pki certificate request-status** command to display the certificate request status.

Examples

Abort the certificate request for PKI domain **1**.

```
<Sysname> system-view
[Sysname] pki abort-certificate-request domain 1
The certificate request is in process.
Confirm to abort it? [Y/N]:y
```

Related commands

display pki certificate request-status

pki request-certificate domain

pki certificate access-control-policy

Use **pki certificate access-control-policy** to create a certificate-based access control policy and enter its view, or enter the view of an existing certificate-based access control policy.

Use **undo pki certificate access-control-policy** to remove a certificate-based access control policy.

Syntax

pki certificate access-control-policy *policy-name*

undo pki certificate access-control-policy *policy-name*

Default

No certificate-based access control policies exist.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a policy name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A certificate-based access control policy contains a set of access control rules that permit or deny access to the device based on the attributes in the requesting client's certificate.

Examples

Create a certificate-based access control policy named **mypolicy** and enter its view.

```
<Sysname> system-view
[Sysname] pki certificate access-control-policy mypolicy
[Sysname-pki-cert-acp-mypolicy]
```

Related commands

display pki certificate access-control-policy

rule

pki certificate attribute-group

Use **pki certificate attribute-group** to create a certificate attribute group and enter its view, or enter the view of an existing certificate attribute group.

Use **undo pki certificate attribute-group** to remove a certificate attribute group.

Syntax

pki certificate attribute-group *group-name*

undo pki certificate attribute-group *group-name*

Default

No certificate attribute groups exist.

Views

System view

Predefined user roles

network-admin

Parameters

group-name: Specifies a group name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A certificate attribute group is a set of attribute rules configured by using the **attribute** command. Each attribute rule defines a matching criterion for an attribute in the issuer name, subject name, or alternative subject name field of certificates.

A certificate attribute group must be associated with an access control rule (a permit or deny statement configured by using the **rule** command). If a certificate attribute group does not have any attribute rules, the system determines that the all certificates match the associated access control rule.

Examples

Create a certificate attribute group named **mygroup** and enter its view.

```
<Sysname> system-view
[Sysname] pki certificate attribute-group mygroup
[Sysname-pki-cert-attribute-group-mygroup]
```

Related commands

attribute

display pki certificate attribute-group

rule

pki delete-certificate

Use **pki delete-certificate** to remove certificates from a PKI domain.

Syntax

pki delete-certificate domain *domain-name* { **ca** | **local** | **peer** [**serial** *serial-num*] }

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 10.

Table 10 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"

Character name	Symbol	Character name	Symbol
Colon	:	Apostrophe	'

ca: Specifies the CA certificate.

local: Specifies the local certificates.

peer: Specifies the peer certificates.

serial *serial-num*: Specifies a peer certificate by its serial number, a case-insensitive string of 1 to 127 characters. If you do not specify a serial number, this command removes all peer certificates in the PKI domain.

Usage guidelines

When you remove the CA certificate in a PKI domain, the system also removes the local certificates, peer certificates, and the CRL in the PKI domain.

To delete a specific peer certificate in a PKI domain, perform the following steps:

1. Execute the **display pki certificate** command to determine the serial number of the peer certificate.
2. Execute the **pki delete-certificate domain** *domain-name* **peer serial** *serial-num* command.

Examples

Remove the CA certificate in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki delete-certificate domain aaa ca
Local certificates, peer certificates and CRL will also be deleted while deleting the CA certificate.
Confirm to delete the CA certificate? [Y/N]:y
[Sysname]
```

Remove the local certificates in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki delete-certificate domain aaa local
[Sysname]
```

Remove all peer certificates in PKI domain **aaa**.

```
<Sysname> system-view
[Sysname] pki delete-certificate domain aaa peer
[Sysname]
```

Display information about all peer certificates in PKI domain **aaa**, and remove a peer certificate with the specified serial number.

```
<Sysname> system-view
[Sysname] display pki certificate domain aaa peer
Total peer certificates: 1

Serial Number: 9a0337eb2156ba1f5476e4d754a5a9f7
Subject  Name: CN=abc
[Sysname] pki delete-certificate domain aaa peer serial 9a0337eb2156ba1f5476e4d754a5a9f7
```

Related commands

display pki certificate

pki domain

Use **pki domain** to create a PKI domain and enter its view, or enter the view of an existing PKI domain.

Use **undo pki domain** to remove a PKI domain.

Syntax

pki domain *domain-name*

undo pki domain *domain-name*

Default

No PKI domains exist.

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 11.

Table 11 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

When you remove a PKI domain, the certificates and the CRL in the domain are also removed.

Examples

Create a PKI domain named **aaa** and enter its view.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa]
```

pki entity

Use **pki entity** to create a PKI entity and enter its view, or enter the view of an existing PKI entity.

Use **undo pki entity** to remove a PKI entity.

Syntax

pki entity *entity-name*

undo pki entity *entity-name*

Default

No PKI entities exist.

Views

System view

Predefined user roles

network-admin

Parameters

entity-name: Specifies a name for a PKI entity, a case-insensitive string of 1 to 31 characters.

Usage guidelines

A PKI entity includes the identity information that can be used by a CA to identify a certificate applicant. You can configure multiple attributes for a PKI entity, such as common name, organization, organization unit, locality, state, country, FQDN, and IP address. The information will be included as subject contents in the certificate issued by the CA.

Examples

Create a PKI entity named **en** and enter its view.

```
<Sysname> system-view
[Sysname] pki entity en
[Sysname-pki-entity-en]
```

Related commands

pki domain

pki export

Use **pki export** to export the CA certificate and the local certificates in a PKI domain.

Syntax

pki export domain *domain-name* **der** { **all** | **ca** | **local** } **filename** *filename*

pki export domain *domain-name* **p12** { **all** | **local** } **passphrase** *p12-key* **filename** *filename*

pki export domain *domain-name* **pem** { { **all** | **local** } [{ **3des-cbc** | **aes-128-cbc** | **aes-192-cbc** | **aes-256-cbc** | **des-cbc** } *pem-key*] | **ca** } [**filename** *filename*]

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 12.

Table 12 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.

Character name	Symbol	Character name	Symbol
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

der: Specifies the DER certificate file format, including PKCS#7.

p12: Specifies the PKCS#12 certificate file format.

pem: Specifies the PEM certificate file format.

all: Specifies both CA and local certificates. The RA certificate is excluded.

ca: Specifies the CA certificate.

local: Specifies the local certificates or the local certificates and their private keys.

passphrase *p12-key*: Specifies a password for encrypting the private key of a local PKCS12 certificate.

3des-cbc: Specifies 3DES_CBC for encrypting the private key of a local certificate.

aes-128-cbc: Specifies 128-bit AES_CBC for encrypting the private key of a local certificate.

aes-192-cbc: Specifies 192-bit AES_CBC for encrypting the private key of a local certificate.

aes-256-cbc: Specifies 256-bit AES_CBC for encrypting the private key of a local certificate.

des-cbc: Specifies DES_CBC for encrypting the private key of a local certificate.

pem-key: Specifies a password for encrypting the private key of a local certificate in PEM format.

filename *filename*: Specifies the name of the file for storing the certificate. The file name is a case-insensitive string. If you do not specify a file name when you export certificates in PEM format, this command displays the certificates on the terminal.

Usage guidelines

When you export the CA certificate, the following conditions might exist:

- If the PKI domain has only one CA certificate, this command exports the CA certificate to a file or displays it on the terminal.
- If the PKI domain has a CA certificate chain, this command exports the certificate chain to a file or displays it on the terminal.

When you export a local certificate to a local file, the local file name might be different from the file name specified in the command. The file name depends on the usage of the key pair contained in the certificate.

The following example uses **certificate** as the file name for saving an exported local certificate.

- If the local certificate contains an RSA signing key pair, the local file name is **certificate-signature**.
- If the local certificate contains an RSA encryption key pair, the local file name is **certificate-encryption**.
- If the local certificate contains a general purpose RSA, ECDSA, or DSA key pair, the local file name is **certificate**.

If the PKI domain has two local certificates, the local certificates are exported as follows:

- If you specify a file name, the two local certificates are exported to two different files.

- If you do not specify a file name, the local certificates are displayed on the terminal, separated by system prompts.

When you export all certificates, the following conditions might exist:

- If the PKI domain has only the CA certificate or local certificates, the result is the same as when you export the CA certificate or local certificates separately.
- If the PKI domain has both the CA certificate and local certificates, you get the following results:
  - If you specify a file name, each local certificate is exported to a separate file with their associated CA certificate chain.
  - If you do not specify a file name, the local certificates and CA certificate or CA certificate chain are displayed on the terminal, separated by system prompts.

When you export all certificates in PKCS12 format, the PKI domain must have a local certificate. If the domain does not have a local certificate, the export operation fails.

When you export the local certificates or all certificates in PEM format, you must specify the cryptographic algorithm and the challenge password for the private key. If you do not specify the cryptographic algorithm and the challenge password, this command does not export the private keys of the local certificates. If you specify the cryptographic algorithm and the password, and the local certificates have their private keys, this command can export the local certificates with their private keys. If the local certificates do not have their private keys, the export operation fails.

When you export the local certificates, if the key pair in the PKI domain is changed and no longer matches the key in the local certificates, the export operation fails.

When you export the local certificates or all certificates, if the PKI domain has two local certificates, failure of exporting one local certificate does not affect export of the other.

The specified file name can contain an absolute path. If the specified path does not exist, the export operation fails.

Examples

Export the CA certificate in the PKI domain to a file named **cert-ca.der** in DER format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 der ca filename cert-ca.der
```

Export the local certificates in the PKI domain to a file named **cert-lo.der** in DER format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 der local filename cert-lo.der
```

Export all certificates in the PKI domain to a file named **cert-all.p7b** in DER format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 der all filename cert-all.p7b
```

Export the CA certificate in the PKI domain to a file named **cacert** in PEM format.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem ca filename cacert
```

Export the local certificates and their private keys in the PKI domain to a file named **local.pem** in PEM format. For the private keys, the cryptographic algorithm is DES_CBC and the password is 111.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem local des-cbc 111 filename local.pem
```

Export the all certificates in the PKI domain to a file named **all.pem** in PEM format. No cryptographic algorithm or password is specified, and the private keys are not exported.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem all filename all.pem
```

Display the local certificates and their private keys in the PKI domain on the terminal in PEM format. For the private keys, the cryptographic algorithm is DES_CBC and the password is 111.

```
<Sysname> system-view
[Sysname] pki export domain domain1 pem local des-cbc 111

Related commands

pki domain

pki import

Use **pki import** to import the CA certificate, local certificates, or peer certificates for a PKI domain.

Syntax

pki import domain *domain-name* { **der** { **ca** | **local** | **peer** } **filename** *filename* | **p12 local filename** *filename* | **pem** { **ca** | **local** | **peer** } [**filename** *filename*] }

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 13.

Table 13 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"

Character name	Symbol	Character name	Symbol
Colon	:	Apostrophe	'

der: Specifies the DER certificate file format, including PKCS#7.

p12: Specifies the PKCS#12 certificate file format.

pem: Specifies the PEM certificate file format.

ca: Specifies the CA certificate.

local: Specifies the local certificates.

peer: Specifies the peer certificates.

filename *filename*: Specifies a certificate file name, a case-insensitive string. For a certificate in PEM format, you can also choose to copy and paste the certificate contents on the terminal instead of importing from a file.

Usage guidelines

Use this command to import a certificate in the following situations:

- The CRL repository is not specified or the CA server does not support SCEP.
- The certificate is packed with the server generated key pair in a single file. Only certificate files in PKCS12 or PEM format can contain key pairs.

Before you import certificates, complete the following tasks:

- Use FTP or TFTP to upload the certificate files to the storage media of the device. If FTP or TFTP is not available, display and copy the contents of a certificate to a file on the device. Make sure the certificate is in PEM format because only certificates in PEM format can be imported by this means.
- For the local certificates or peer certificates to be imported, the correct CA certificate chain must exist. The CA certificate chain can be stored on the device, or carried in the local certificates or peer certificates. If the PKI domain, the local certificates, or the peer certificates do not have the CA certificate chain, you must import the CA certificate first. To import a local or peer certificate, a CA certificate chain must exist in the PKI domain, or be carried in the local or peer certificate. If not, obtain it first.

When you import the local or peer certificates:

- If the local or peer certificates contain the CA certificate chain, you can import the CA certificate and the local or peer certificates at the same time. If the CA certificate already exists in a PKI domain, the system prompts you whether to overwrite the existing CA certificate.
- If the local or peer certificates do not contain the CA certificate chain, but the CA certificate already exists in a PKI domain, you can directly import the certificates.

You can import the CA certificate to a PKI domain when either of the following conditions is met:

- The CA certificate to be imported is the root CA certificate or contains the certificate chain with the root certificate.
- The CA certificate contains a certificate chain without the root certificate, but can form a complete certificate chain with an existing CA certificate on the device.

Contact the CA administrator to get information as prompted in the following scenarios:

- The system prompts you to confirm the certificate's fingerprint in the following situation:
  - The certificate file to be imported contains the root certificate, but the root certificate does not exist in any PKI domains on the device.
  - The **root-certificate fingerprint** command is not configured in the PKI domain to which the certificate file is to be imported.

- The system prompts you to enter the challenge password used for encrypting the private key if the local certificate to be imported contains a key pair.

When you import a local certificate file that contains a key pair, you can choose to update the domain with the key pair. Depending on the purpose of the key pair, the following conditions might apply:

- If the purpose of the key pair is general, the device uses the key pair to replace the local key pair that is found in this order:
  a. General-purpose key pair.
  b. Signature key pair.
  c. Encryption key pair.
- If the purpose of the key pair is signature, the device uses the key pair to replace the local key pair that is found in this order:
  a. General-purpose key pair.
  b. Signature key pair.
- If the purpose of the key pair is encryption, the device searches the domain for an encryption key pair.

If a matching key pair is found, the device asks whether you want to overwrite the existing key pair on the device. If no match is found, the device asks you to enter a key pair name (defaulting to the PKI domain name). Then, it generates the key pair according to the key algorithm and the purpose defined in the certificate file.

The import operation automatically updates or generates the correct key pair. When you perform the import operation, be sure to save the configuration file to avoid data loss.

Examples

Import CA certificate file **rootca_pem.cer** in PEM format to PKI domain **aaa**. The certificate file contains the root certificate.

```
<Sysname> system-view
[Sysname] pki import domain aaa pem ca filename rootca_pem.cer
The trusted CA's finger print is:
    MD5  fingerprint:FFFF 3EFF FFFF 37FF FFFF 137B FFFF 7535
    SHA1 fingerprint:FFFF FF7F FF2B FFFF 7618 FF4C FFFF 0A7D FFFF FF69
Is the finger print correct?(Y/N):y
[Sysname]
```

Import CA certificate file **aca_pem.cer** in PEM format to PKI domain **bbb**. The certificate file does not contain the root certificate.

```
<Sysname> system-view
[Sysname] pki import domain bbb pem ca filename aca_pem.cer
[Sysname]
```

Import local certificate file **local-ca.p12** in PKCS12 format to PKI domain **bbb**. The certificate file contains a key pair.

```
<Sysname> system-view
[Sysname] pki import domain bbb p12 local filename local-ca.p12
Please input challenge password:
******
[Sysname]
```

Import the local certificate in PEM format to PKI domain **bbb** by copying and pasting the contents of the certificate. The certificate contains the key pair and the CA certificate chain.

```
<Sysname> system-view
[Sysname] pki import domain bbb pem local
Enter PEM-formatted certificate.
```

```
End with a Ctrl+c on a line by itself.

pki request-certificate

Use **pki request-certificate** to submit a local certificate request or generate a certificate request in PKCS#10 format.

Syntax

pki request-certificate domain *domain-name* [**password** *password*] [**pkcs10** [**filename** *filename*]]

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 14.

Table 14 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

password *password*: Sets the password for certificate revocation, a case-sensitive string of 1 to 31 characters. The password is contained in the certificate request and must be provided if the certificate is revoked.

pkcs10: Displays BASE64-encoded PKCS#10 certificate request information, which can be used to request a certificate by an out-of-band means, like phone, disk, or email.

filename *filename*: Specifies a local file for saving the certificate request in PKCS#10 format. The *filename* argument is case-insensitive.

Usage guidelines

If SCEP fails, you can perform one of the following tasks:

- Use the **pkcs10** keyword to print the BASE64-encoded request information.
- Use the **pkcs10 filename** *filename* option to save the request information to a local file and transfer the file to the CA by using an out-of-band means. The file name can contain an absolute path. If the specified path does exist, the request information cannot be saved.

This command is not saved in the configuration file.

Examples

Display information about the certificate request in PKCS#10 format.

```
<Sysname> system-view
[Sysname] pki request-certificate domain aaa pkcs10

```
Request certificate of domain openca successfully
```

Related commands

display pki certificate

pki retrieve-certificate

Use **pki retrieve-certificate** to obtain a certificate from the certificate distribution server.

Syntax

pki retrieve-certificate domain *domain-name* { **ca** | **local** | **peer** *entity-name* }

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 15.

Table 15 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

ca: Specifies the CA certificate.

local: Specifies the local certificates.

peer *entity-name*: Specifies a peer entity by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

In online mode:

- You can obtain the CA certificate through the SCEP protocol. If a CA certificate already exists locally, do not obtain the CA certificate again. To obtain a new CA certificate, use the **pki delete-certificate** command to remove the CA certificate and local certificates, and then obtain the CA certificate again.
- You can obtain local certificates or peer certificates through the LDAP protocol. If a PKI domain already has local certificates or peer certificates, you can still perform the obtain operation and the obtained local certificates or peer certificates overwrite the existing ones. If RSA is used, a PKI domain can have two local certificates, one for signing and the other for encryption. Certificates for different purposes do not overwrite each other.

The obtained CA certificate, local certificates, and peer certificates are automatically verified before they are saved locally. If the verification fails, they are not saved.

This command is not saved in the configuration file.

Examples

Obtain the CA certificate from the certificate distribution server. (This operation requires the user to confirm the fingerprint of the root CA certificate.)

```
<Sysname> system-view
[Sysname] pki retrieve-certificate domain aaa ca
The trusted CA's finger print is:
    MD5  fingerprint:5C41 E657 A0D6 ECB4 6BD6 1823 7473 AABC
    SHA1 fingerprint:1616 E7A5 D89A 2A99 9419 1C12 D696 8228 87BC C266
Is the finger print correct?(Y/N):y
```

Obtain the local certificates from the certificate distribution server.

```
<Sysname> system-view
[Sysname] pki retrieve-certificate domain aaa local
```

Obtain the certificate of the peer entity **en1** from the certificate distribution server.

```
<Sysname> system-view
[Sysname] pki retrieve-certificate domain aaa peer en1
```

Related commands

`display pki certificate`

`pki delete-certificate`

pki retrieve-crl

Use **`pki retrieve-crl`** to obtain CRLs and save them locally.

Syntax

`pki retrieve-crl domain` *`domain-name`*

Views

System view

Predefined user roles

network-admin

Parameters

`domain-name`: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 16.

Table 16 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

Usage guidelines

CRLs are used to verify the validity of the local certificates and the peer certificates in a PKI domain. To obtain CRLs, a PKI domain must have the correct CA certificate.

The URL of the CRL repository is specified by using the **crl url** command.

The device can obtain CRLs from the CRL repository through the HTTP, LDAP, or SCEP protocol. Which protocol is used depends on the configuration of the CRL repository in the PKI domain:

- If the specified URL of the CRL repository is in HTTP format, the device obtains CRLs through the HTTP protocol.
- If the specified URL of the CRL repository is in LDAP format, the device obtains CRLs through the LDAP protocol. If the specified URL does not have a host name, for example, ldap:///CN=8088,OU=test,U=rd,C=cn, you must specify the LDAP server's URL for the PKI domain by using the **ldap server** command. The device can obtain the complete URL of the LDAP repository by combining the URLs of the LDAP server and of the CRL repository.
- If the PKI domain is not configured with the CRL repository, the device looks up the local certificates and then the CA certificate for the CRL repository. If a CRL repository is found, the device obtains CRLs from the CRL repository. If no CRL repository is found, the device obtains CRLs through the SCEP protocol.

Examples

Obtain CRLs from the CRL repository.

```
<Sysname> system-view
[Sysname] pki retrieve-crl domain aaa
```

Related commands

crl url

ldap server

pki storage

Use **pki storage** to specify the storage path for the certificates or CRLs.

Use **undo pki storage** to restore the default.

Syntax

pki storage { **certificates** | **crls** } *dir-path*

undo pki storage { **certificates** | **crls** }

Default

Certificates and CRLs are stored in the **PKI** directory on the storage media of the device. The **PKI** directory is automatically created when a certificate is successfully requested, obtained, or imported for the first time.

Views

System view

Predefined user roles

network-admin

Parameters

certificates: Specifies a storage path for certificates.

crls: Specifies a storage path for CRLs.

dir-path: Specifies a storage path, a case-sensitive string, which cannot start with a slash (/) or contain two dots plus a slash (../). The *dir-path* argument specifies an absolute path or a relative path, and the path must exist.

Usage guidelines

The specified storage path must be on the master device.

If the path to be specified does not exist, use the **mkdir** command to create the path first.

Certificate files use the .cer or .p12 file extension. CRL files use the .crl file extension. After you change the storage path for certificates or CRLs, the certificate files and CRL files in the original path are moved to the new path.

Examples

Specifies **flash:/pki-new** as the storage path for certificates.

```
<Sysname> system-view
[Sysname] pki storage certificates flash:/pki-new
```

Specifies **pki-new** as the storage path for CRLs.

```
<Sysname> system-view
[Sysname] pki storage crls pki-new
```

pki validate-certificate

Use **pki validate-certificate** to verify the validity of certificates.

Syntax

pki validate-certificate domain *domain-name* { **ca** | **local** }

Views

System view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters. The domain name cannot contain the special characters listed in Table 17.

Table 17 Special characters

Character name	Symbol	Character name	Symbol
Tilde	~	Dot	.
Asterisk	*	Left angle bracket	<
Backslash	\	Right angle bracket	>
Vertical bar	|	Quotation marks	"
Colon	:	Apostrophe	'

ca: Specifies the CA certificate.

local: Specifies the local certificates.

Usage guidelines

Generally, certificates are automatically verified when you request, obtain, or import them, or when an application uses PKI.

You can also use this command to manually verify a certificate in the following aspects:

- Whether the certificate is issued by a trusted CA.
- Whether the certificate has expired.

- Whether the certificate is revoked. This check is performed only if CRL checking is enabled.

When CRL checking is enabled:

- To verify the local certificates, if the PKI domain has no CRLs, the device looks up the locally saved CRLs. If a correct CRL is found, the device loads the CRL to the PKI domain. If no correct CRL is found locally, the device obtains a correct CRL from the CA server and saves it locally.
- To verify the CA certificate, CRL checking is performed for the CA certificate chain from the current CA to the root CA.

Examples

Verify the validity of the CA certificate in PKI domain **aaa**.

```
<Sysname> system-view

Related commands

crl check

pki domain

public-key dsa

Use **public-key dsa** to specify a DSA key pair for certificate request.

Use **undo public-key** to restore the default.

Syntax

public-key dsa name *key-name* [**length** *key-length*]

undo public-key

Default

No key pair is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

name *key-name*: Specifies a key pair by its name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

length *key-length*: Specifies the key length, in bits. In non-FIPS mode, the value range is 512 to 2048, and the default is 1024. In FIPS mode, the value must be 2048. A longer key means higher security but more public key calculation time.

Usage guidelines

You can specify a nonexistent key pair in this command. A key pair can be obtained in any of the following ways:

- Use the **public-key local create** command to generate a key pair.
- An application, like IKE using digital signature authentication, triggers the device to generate a key pair.
- Use the **pki import** command to import a certificate containing a key pair.

A PKI domain can have key pairs using only one type of cryptographic algorithm (DSA, ECDSA, or RSA).

If you configure a DSA key pair for a PKI domain multiple times, the most recent configuration takes effect.

The **length** *key-length* option takes effect only if you specify a nonexistent key pair. The device will automatically create the key pair by using the specified name and length before submitting a certificate request. The **length** *key-length* option is ignored if the specified key pair already exists or is already contained in an imported certificate.

Examples

Specify 2048-bit DSA key pair **abc** for certificate request.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key dsa name abc length 2048
```

Related commands

pki import

public-key local create

public-key ecdsa

Use **public-key ecdsa** to specify an ECDSA key pair for certificate request.

Use **undo public-key** to restore the default.

Syntax

In non-FIPS mode:

public-key ecdsa name *key-name* [**secp192r1** | **secp256r1** | **secp384r1** | **secp521r1**]

undo public-key

In FIPS mode:

public-key ecdsa name *key-name* [**secp256r1** | **secp384r1** | **secp521r1**]

undo public-key

Default

No key pair is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

name *key-name*: Specifies a key pair by its name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

secp192r1: Uses the secp192r1 curve to generate the key pair.

secp256r1: Uses the secp256r1 curve to generate the key pair.

secp384r1: Uses the secp384r1 curve to generate the key pair.

secp521r1: Uses the secp521r1 curve to generate the key pair.

Usage guidelines

You can specify a nonexistent key pair for a PKI domain.

A key pair can be obtained in any of the following ways:

- Use the **public-key local create** command to generate a key pair.
- An application, like IKE using digital signature authentication, triggers the device to generate a key pair.
- Use the **pki import** command to import a certificate containing a key pair.

A PKI domain can have key pairs using only one type of cryptographic algorithm (DSA, ECDSA, or RSA).

If you configure an ECDSA key pair for a PKI domain multiple times, the most recent configuration takes effect.

The specified elliptic curve takes effect only if you specify a nonexistent key pair. The device will automatically create the key pair by using the specified name and curve before submitting a certificate request. The curve parameter is ignored if the specified key pair already exists or is already contained in an imported certificate.

If you do not specify an elliptic curve, the secp192r1 curve is used by default in non-FIPS mode and the secp256r1 curve is used by default in FIPS mode.

Examples

Specify 384-bit ECDSA key pair **abc** for certificate request.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key ecdsa name abc secp384r1
```

Related commands

pki import

public-key local create

public-key rsa

Use **public-key rsa** to specify an RSA key pair for certificate request.

Use **undo public-key** to restore the default.

Syntax

public-key rsa { { **encryption name** *encryption-key-name* [**length** *key-length*] | **signature name** *signature-key-name* [**length** *key-length*] } * | **general name** *key-name* [**length** *key-length*] }

undo public-key

Default

No key pair is specified for certificate request.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

encryption: Specifies a key pair for encryption.

name *encryption-key-name*: Specifies a key pair name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

signature: Specifies a key pair for signing.

name *signature-key-name*: Specifies a key pair name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

general: Specifies a key pair for both signing and encryption.

name *key-name*: Specifies a key pair name, a case-insensitive string of 1 to 64 characters. The key pair name can contain only letters, digits, and hyphens (-).

length *key-length*: Specifies the key length, in bits. In non-FIPS mode, the value range is 512 to 4096, and the default is 1024. In FIPS mode, the value must be a multiple of 256 in the range of 2048 to 4096, and the default is 2048. A longer key means higher security but more public key calculation time.

Usage guidelines

You can specify a nonexistent key pair in this command. You can get a key pair in any of the following ways:

- Use the **public-key local create** command to generate a key pair.
- An application, like IKE using digital signature authentication, triggers the device to generate a key pair.
- Use the **pki import** command to import a certificate containing a key pair.

A PKI domain can have key pairs using only one type of cryptographic algorithm (DSA, ECDSA, or RSA).

A PKI domain can have two RSA key pairs of different purposes: one is the signing key pair, and the other is the encryption key pair. If you configure an RSA signing key pair or RSA encryption key pair multiple times, the most recent configuration takes effect. The RSA signing key pair and encryption key pair do not overwrite each other.

If you specify a signing key pair and an encryption key pair separately, their key length can be different.

The **length** *key-length* option takes effect only if you specify a nonexistent key pair. The device will automatically create the key pair by using the specified name and length before submitting a certificate request. The **length** *key-length* option is ignored if the specified key pair already exists or is already contained in an imported certificate.

Examples

Specify 2048-bit general purpose RSA key pair **abc** for certificate request.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key rsa general name abc length 2048
```

Specify the following RSA key pairs for certificate request:

- 2048-bit RSA encryption key pair **rsa1**.
- 2048-bit RSA signing key pair **sig1**.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] public-key rsa encryption name rsa1 length 2048
[Sysname-pki-domain-aaa] public-key rsa signature name sig1 length 2048
```

Related commands

pki import

public-key local create

root-certificate fingerprint

Use **root-certificate fingerprint** to set the fingerprint for verifying the root CA certificate.

Use **undo root-certificate fingerprint** to restore the default.

Syntax

In non-FIPS mode:

root-certificate fingerprint { **md5** | **sha1** } *string*

undo root-certificate fingerprint

In FIPS mode:

root-certificate fingerprint sha1 *string*

undo root-certificate fingerprint

Default

No fingerprint is set for verifying the root CA certificate.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

md5: Sets an MD5 fingerprint.

sha1: Sets an SHA1 fingerprint.

string: Sets the fingerprint in hexadecimal notation. If you specify the **MD5** keyword, the fingerprint is a string of 32 characters. If you specify the **SHA1** keyword, the fingerprint is a string of 40 characters.

Usage guidelines

If you set the certificate request mode to auto for a PKI domain that does not have a CA certificate, you must configure the fingerprint for root CA certificate verification. When an application (for example, IKE) triggers the device to request local certificates, the device automatically performs the following operations:

1. Obtains the CA certificate from the CA server.
2. Compares the fingerprint contained in the root CA certificate with the fingerprint configured in the PKI domain, if either of the following conditions exists:
   - The obtained CA certificate is a root certificate.
   - The obtained CA certificate is a certificate chain and contains a root certificate that does not exist on the device.

   If the two fingerprints do not match, or if no fingerprint is configured in the PKI domain, the device rejects the CA certificate and the local certificate request fails.

The fingerprint configured by this command is also used for root CA certificate verification when the device performs the following operations:

- Imports the CA certificate as requested by the **pki import** command.
- Obtains the CA certificate as requested by the **pki retrieve-certificate** command.

The device compares the fingerprint contained in the root CA certificate with the fingerprint configured in the PKI domain, if either of the following conditions exists:

- The CA certificate to be imported or obtained is a root certificate that does not exist on the device.
- The CA certificate to be imported or obtained is a certificate chain and contains a root certificate that does not exist on the device.

If the two fingerprints do not match, the device rejects the CA certificate. If no fingerprint is configured in the PKI domain, the device prompts you to manually verify the fingerprint of the root CA certificate.

Examples

Specify an MD5 fingerprint for verifying the root CA certificate. (This feature is supported only in non-FIPS mode.)

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] root-certificate fingerprint md5
12EF53FA355CD23E12EF53FA355CD23E
```

Specify an SHA1 fingerprint for verifying the root CA certificate.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] root-certificate fingerprint sha1

network-admin

Parameters

id: Assigns an ID to the access control rule, in the range of 1 to 16. The default setting is the smallest unused ID in this range.

deny: Denies the certificates that match the associated attribute group.

permit: Permits the certificates that match the associated attribute group.

group-name: Specifies a certificate attribute group by its name, a case-insensitive string of 1 to 31 characters.

Usage guidelines

When you create an access control rule, you can associate it with a nonexistent certificate attribute group.

The system determines that a certificate matches an access control rule when either of the following conditions exists:

- The associated certificate attribute group does not exist.
- The associated certificate attribute group does not contain any attribute rules.
- The certificate matches all attribute rules in the associated certificate attribute group.

You can configure multiple access control rules for an access control policy. A certificate matches the rules one by one, starting with the rule with the smallest ID. When a match is found, the match process stops, and the system performs the access control action defined in the access control rule.

Examples

Create rule 1 to permit all certificates that match certificate attribute group **mygroup**.

```
<Sysname> system-view
[Sysname] pki certificate access-control-policy mypolicy
[Sysname-pki-cert-acp-mypolicy] rule 1 permit mygroup
```

Related commands

attribute

display pki certificate access-control-policy

pki certificate attribute-group

source

Use **source** to specify the source IP address for PKI protocol packets.

Use **undo source** to restore the default.

Syntax

source { **ip** | **ipv6** } { *ip-address* | **interface** *interface-type interface-number* }

undo source

Default

The source IP address of PKI protocol packets is the IP address of their outgoing interface.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

ip *ip-address*: Specifies a source IPv4 address.

ipv6 *ip-address*: Specifies a source IPv6 address.

interface *interface-type interface-number*: Specifies an interface by its type and number. The interface's primary IP address or the lowest IPv6 address will be used as the source IP address for PKI protocol packets.

Usage guidelines

Use this command to specify the source IP address for PKI protocol packets. You can also specify a source interface if the IP address is dynamically obtained.

Make sure there is a route between the source IP address and the CA server.

You can specify only one source IP address in a PKI domain. If you execute this command multiple times, the most recent configuration takes effect.

Examples

Specify **111.1.1.8** as the source IP address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] source ip 111.1.1.8
```

Specify **1::8** as the source IPv6 address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain 1
[Sysname-pki-domain-1] source ipv6 1::8
```

Use the IP address of VLAN-interface 1 as the source IP address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] source ip interface vlan-interface 1
```

Use the IPv6 address of VLAN-interface 1 as the source IPv6 address for PKI protocol packets.

```
<Sysname> system-view
[Sysname] pki domain 1
[Sysname-pki-domain-1] source ipv6 interface vlan-interface 1
```

state

Use **state** to set the state or province name for a PKI entity.

Use **undo state** to restore the default.

Syntax

state *state-name*

undo state

Default

No state name or province name is set for a PKI entity.

Views

PKI entity view

Predefined user roles

network-admin

Parameters

state-name: Specifies a state or province by its name, a case-sensitive string of 1 to 63 characters. No comma can be included.

Examples

Set the state name to **countryA** for PKI entity **en**.

```
<Sysname> system-view
```

```
[Sysname] pki entity en
[Sysname-pki-entity-en] state countryA
```

usage

Use **usage** to specify the extensions for certificates.

Use **undo usage** to remove certificate extensions.

Syntax

usage { **ike** | **ssl-client** | **ssl-server** } *

undo usage [**ike** | **ssl-client** | **ssl-server**] *

Default

No extensions for certificates are specified. A certificate can be used for IKE, SSL clients, and SSL servers.

Views

PKI domain view

Predefined user roles

network-admin

Parameters

ike: Specifies the IKE certificate extension so IKE peers can use the certificates.

ssl-client: Specifies the SSL client certificate extension so the SSL client can use the certificates.

ssl-server: Specifies the SSL server certificate extension so the SSL server can use the certificates.

Usage guidelines

If you do not specify any keywords for the **undo usage** command, this command removes all certificate extensions.

The extension options contained in a certificate depends on the CA policy, and might be different from those specified in the PKI domain.

Examples

Specify the IKE certificate extension.

```
<Sysname> system-view
[Sysname] pki domain aaa
[Sysname-pki-domain-aaa] usage ike
```

Contents

IPsec commands

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

ah authentication-algorithm

Use **ah authentication-algorithm** to specify authentication algorithms for the AH protocol.

Use **undo ah authentication-algorithm** to restore the default.

Syntax

In non-FIPS mode:

ah authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

undo ah authentication-algorithm

In FIPS mode:

ah authentication-algorithm { **sha1**| **sha256** | **sha384** | **sha512** } *

undo ah authentication-algorithm

Default

AH does not use any authentication algorithms.

Views

IPsec transform set view

Predefined user roles

network-admin

Parameters

aes-xcbc-mac: Specifies the HMAC-AES-XCBC-96 algorithm, which uses a 128-bit key. This keyword is available only for IKEv2.

md5: Specifies the HMAC-MD5-96 algorithm, which uses a 128-bit key.

sha1: Specifies the HMAC-SHA1-96 algorithm, which uses a 160-bit key.

sha256: Specifies the HMAC-SHA256 algorithm, which uses a 256-bit key.

sha384: Specifies the HMAC-SHA384 algorithm, which uses a 384-bit key.

sha512: Specifies the HMAC-SHA512 algorithm, which uses a 512-bit key.

Usage guidelines

In non-FIPS mode, you can specify multiple AH authentication algorithms for one IPsec transform set, and the algorithm specified earlier has a higher priority.

For a manual or IKEv1-based IPsec policy, the first specified AH authentication algorithm takes effect. To make sure an IPsec tunnel can be established successfully, the IPsec transform sets specified at both ends of the tunnel must have the same first AH authentication algorithm.

Examples

Specify HMAC-SHA1 as the AH authentication algorithm for IPsec transform set **tran1**.

```
<Sysname> system-view
```

```
[Sysname] ipsec transform-set tran1
[Sysname-ipsec-transform-set-tran1] ah authentication-algorithm sha1
```

description

Use **description** to configure a description for an IPsec policy, IPsec policy template, or IPsec profile.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

No description is configured for an IPsec policy, IPsec policy template, or IPsec profile.

Views

IPsec policy view

IPsec policy template view

IPsec profile view

Predefined user roles

network-admin

Parameters

text: Specifies a description, a case-sensitive string of 1 to 80 characters.

Usage guidelines

If the system has multiple IPsec policies, IPsec policy templates, or IPsec profiles, you can use this command to configure different descriptions for them to distinguish them.

Examples

Configure the description for IPsec policy **policy1** as **CenterToA**.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 1 isakmp
[Sysname-ipsec-policy-isakmp-policy1-1] description CenterToA
```

display ipsec { ipv6-policy | policy }

Use **display ipsec** { **ipv6-policy** | **policy** } to display information about IPsec policies.

Syntax

display ipsec { **ipv6-policy** | **policy** } [*policy-name* [*seq-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipv6-policy: Displays information about IPv6 IPsec policies.

policy: Displays information about IPv4 IPsec policies.

policy-name: Specifies an IPsec policy by its name, a case-insensitive string of 1 to 63 characters.

seq-number: Specifies an IPsec policy entry by its sequence number in the range of 1 to 65535.

Usage guidelines

If you do not specify any parameters, this command displays information about all IPsec policies.

If you specify an IPsec policy name and a sequence number, this command displays information about the specified IPsec policy entry. If you specify an IPsec policy name without any sequence number, this command displays information about all IPsec policy entries with the specified name.

Examples

Display information about all IPv4 IPsec policies.

```
<Sysname> display ipsec policy

Table 1 Command output

Field	Description
IPsec Policy	IPsec policy name.
Interface	Interface applied with the IPsec policy.
Sequence number	Sequence number of the IPsec policy entry.
Mode	Negotiation mode of the IPsec policy: • **Manual**—Manual mode. • **ISAKMP**—IKE negotiation mode. • **Template**—IPsec policy template mode.
The policy configuration is incomplete	IPsec policy configuration incomplete. Possible causes include: • The ACL is not configured. • The IPsec transform set is not configured. • The ACL does not have any **permit** statements. • The IPsec transform set configuration is not complete. • The peer IP address of the IPsec tunnel is not specified. • The SPI and key of the IPsec SA do not match those in the IPsec policy.
Description	Description of the IPsec policy.
Traffic Flow Confidentiality	Whether Traffic Flow Confidentiality (TFC) padding is enabled.
Security data flow	ACL used by the IPsec policy.
Selector mode	Data flow protection mode of the IPsec policy: **standard**, **aggregation**, or **per-host**.
Local address	Local end IP address of the IPsec tunnel (available only for the IKE-based IPsec policy).
Remote address	Remote end IP address or host name of the IPsec tunnel.
Transform set	Transform set used by the IPsec policy.
IKE profile	IKE profile used by the IPsec policy.

Field	Description
IKEv2 profile	IKEv2 profile used by the IPsec policy.
SA duration(time based)	Time-based IPsec SA lifetime, in seconds.
SA duration(traffic based)	Traffic-based IPsec SA lifetime, in kilobytes.
SA idle time	Idle timeout of the IPsec SA, in seconds.
AH string-key	AH string key. This field displays ****** if the key is configured and it is empty if the key is not configured.
AH authentication hex key	AH authentication hexadecimal key. This field displays ****** if the key is configured and it is empty if the key is not configured.
ESP string-key	ESP string key. This field displays ****** if the key is configured and it is empty if the key is not configured.
ESP encryption hex key	ESP encryption hexadecimal key. This field displays ****** if the key is configured and it is empty if the key is not configured.
ESP authentication hex key	ESP authentication hexadecimal key. This field displays ****** if the key is configured and it is empty if the key is not configured.

ipsec { ipv6-policy | policy }

display ipsec { ipv6-policy-template | policy-template }

Use **display ipsec** { **ipv6-policy-template** | **policy-template** } to display information about IPsec policy templates

Syntax

display ipsec { **ipv6-policy-template** | **policy-template** } [*template-name* [*seq-number*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

ipv6-policy-template: Displays information about IPv6 IPsec policy templates.

policy-template: Displays information about IPv4 IPsec policy templates.

template-name: Specifies an IPsec policy template by its name, a case-insensitive string of 1 to 63 characters.

seq-number: Specifies an IPsec policy template entry by its sequence number in the range of 1 to 65535.

Usage guidelines

If you do not specify any parameters, this command displays information about all IPsec policy templates.

If you specify an IPsec policy template name and a sequence number, this command displays information about the specified IPsec policy template entry. If you specify an IPsec policy template

name without any sequence number, this command displays information about all IPsec policy template entries with the specified name.

Examples

Display information about all IPv4 IPsec policy templates.

```
<Sysname> display ipsec policy-template
-----------------------------------------------
IPsec Policy Template: template
-----------------------------------------------

  --------------------------------
  Sequence number: 1
  --------------------------------
Description: This is policy template
Traffic Flow Confidentiality: Disabled
Security data flow :
Selector mode: standard
Local address:
IKE profile:
IKEv2 profile:
Remote address: 162.105.10.2
Transform set:  testprop
IPsec SA local duration(time based): 3600 seconds
IPsec SA local duration(traffic based): 1843200 kilobytes
SA idle time:
```

Display information about all IPv6 IPsec policy templates.

ipsec profile

display ipsec sa

Use **display ipsec sa** to display information about IPsec SAs.

Syntax

display ipsec sa [**brief** | **count** | **interface** *interface-type interface-number* | { **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *profile-name* | **remote** [**ipv6**] *ip-address*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

brief: Displays brief information about all IPsec SAs.

count: Displays the number of IPsec SAs.

interface *interface-type interface-number*: Specifies an interface by its type and number.

ipv6-policy: Displays detailed information about IPsec SAs created by using a specified IPv6 IPsec policy.

policy: Displays detailed information about IPsec SAs created by using a specified IPv4 IPsec policy.

policy-name: Specifies an IPsec policy by its name, a case-insensitive string of 1 to 63 characters.

seq-number: Specifies an IPsec policy entry by its sequence number. The value range is 1 to 65535.

profile: Displays detailed information about IPsec SAs created by using a specified IPsec profile.

profile-name: Specifies an IPsec profile by its name, a case-insensitive string of 1 to 63 characters.

remote *ip-address*: Specifies an IPsec SA by its remote end IP address.

ipv6: Specifies an IPsec SA by its remote end IPv6 address. If this keyword is not specified, the specified remote end IP address is an IPv4 address.

Usage guidelines

If you do not specify any parameters, this command displays detailed information about all IPsec SAs.

Examples

Display brief information about IPsec SAs.

```
<Sysname> display ipsec sa brief
-------------------------------------------------------------------------
Interface/Global   Dst Address      SPI         Protocol  Status
-------------------------------------------------------------------------
Vlan100            10.1.1.1         400         ESP       Active
Vlan100            255.255.255.255  4294967295  ESP       Active
Vlan100            100::1/64        500         AH        Active

Table 5 Command output

Field	Description
Interface	Interface where the IPsec SA belongs.
IPsec policy	Name of the IPsec policy.
IPsec profile	Name of the IPsec profile.
Sequence number	Sequence number of the IPsec policy entry.
Mode	Negotiation mode used by the IPsec policy: • **Manual**—Manual mode. • **ISAKMP**—IKE negotiation mode. • **Template**—IPsec policy template mode.
Tunnel id	IPsec tunnel ID.
Encapsulation mode	Encapsulation mode, transport or tunnel.
Perfect Forward Secrecy	Perfect Forward Secrecy (PFS) used by the IPsec policy for negotiation: • 768-bit Diffie-Hellman group (**dh-group1**). • 1024-bit Diffie-Hellman group (**dh-group2**). • 1536-bit Diffie-Hellman group (**dh-group5**). • 2048-bit Diffie-Hellman group (**dh-group14**). • 2048-bit and 256_bit subgroup Diffie-Hellman group (**dh-group24**). • 256-bit ECP Diffie-Hellman group (**dh-group19**). • 384-bit ECP Diffie-Hellman group (**dh-group20**).
Extended Sequence Numbers enable	Whether Extended Sequence Number (ESN) is enabled.
Traffic Flow Confidentiality enable	Whether Traffic Flow Confidentiality (TFC) padding is enabled.
Inside VRF	This field is not supported in the current software version.

Field	Description
	VPN instance to which the protected data flow belongs.
Path MTU	Path MTU of the IPsec SA.
Tunnel	Local and remote addresses of the IPsec tunnel.
local address	Local end IP address of the IPsec tunnel.
remote address	Remote end IP address of the IPsec tunnel.
Flow	Information about the data flow protected by the IPsec tunnel.
sour addr	Source IP address of the data flow.
dest addr	Destination IP address of the data flow.
port	Port number.
protocol	Protocol type: **ip** or **ipv6**.
SPI	SPI of the IPsec SA.
Connection ID	Identifier of the IPsec SA.
Transform set	Security protocol and algorithms used by the IPsec transform set.
SA duration (kilobytes/sec)	IPsec SA lifetime, in kilobytes or seconds.
SA remaining duration (kilobytes/sec)	Remaining IPsec SA lifetime, in kilobytes or seconds.
Max received sequence-number	Max sequence number in the received packets.
Max sent sequence-number	Max sequence number in the sent packets.
Anti-replay check enable	Whether anti-replay checking is enabled.
Status	Status of the IPsec SA, which can only be **Active**.
No duration limit for this SA	The manual IPsec SAs do not have lifetime.

Related commands

`ipsec sa global-duration`

`reset ipsec sa`

display ipsec statistics

Use **`display ipsec statistics`** to display IPsec packet statistics.

Syntax

`display ipsec statistics` [**`tunnel-id`** *`tunnel-id`*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

tunnel-id *tunnel-id*: Specifies an IPsec tunnel by its ID. The value range for the *tunnel-id* argument is 0 to 4294967295. You can use the **display ipsec tunnel brief** command to view the IDs of established IPsec tunnels.

Usage guidelines

If you do not specify any parameters, this command displays statistics for all IPsec packets.

Examples

Display statistics for all IPsec packets.

```
<Sysname> display ipsec statistics
  IPsec packet statistics:
    Received/sent packets: 47/64
    Received/sent bytes: 3948/5208
    Dropped packets (received/sent): 0/45

    Dropped packets statistics
      No available SA: 0
      Wrong SA: 0
      Invalid length: 0
      Authentication failure: 0
      Encapsulation failure: 0
      Decapsulation failure: 0
      Replayed packets: 0
      ACL check failure: 45
      MTU check failure: 0
      Loopback limit exceeded: 0
      Crypto speed limit exceeded: 0
```

Display statistics for the packets of IPsec tunnel 1.

```
<Sysname> display ipsec statistics tunnel-id 1
  IPsec packet statistics:
    Received/sent packets: 5124/8231
    Received/sent bytes: 52348/64356
    Dropped packets (received/sent): 0/0

    Dropped packets statistics
      No available SA: 0
      Wrong SA: 0
      Invalid length: 0
      Authentication failure: 0
      Encapsulation failure: 0
      Decapsulation failure: 0
      Replayed packets: 0
      ACL check failure: 0
      MTU check failure: 0
```

```
Loopback limit exceeded: 0
Crypto speed limit exceeded: 0
```

Table 6 Command output

Field	Description
Received/sent packets	Number of received/sent IPsec-protected packets.
Received/sent bytes	Number of bytes of received/sent IPsec-protected packets.
Dropped packets (received/sent)	Number of dropped IPsec-protected packets (received/sent).
No available SA	Number of packets dropped due to lack of available IPsec SA.
Wrong SA	Number of packets dropped due to wrong IPsec SA.
Invalid length	Number of packets dropped due to invalid packet length.
Authentication failure	Number of packets dropped due to authentication failure.
Encapsulation failure	Number of packets dropped due to encapsulation failure.
Decapsulation failure	Number of packets dropped due to decapsulation failure.
Replayed packets	Number of dropped replayed packets.
ACL check failure	Number of packets dropped due to ACL check failure.
MTU check failure	Number of packets dropped due to MTU check failure.
Loopback limit exceeded	Number of packets dropped due to loopback limit exceeded.
Crypto speed limit exceeded	Number of packets dropped due to crypto speed limit exceeded.

Related commands

`reset ipsec statistics`

display ipsec transform-set

Use **`display ipsec transform-set`** to display information about IPsec transform sets.

Syntax

`display ipsec transform-set` [*`transform-set-name`*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

`transform-set-name`: Specifies an IPsec transform set by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

If you do not specify an IPsec transform set, this command displays information about all IPsec transform sets.

Examples

Display information about all IPsec transform sets.

```
<Sysname> display ipsec transform-set
IPsec transform set: mytransform
  State: incomplete
  Encapsulation mode: tunnel
  ESN: Enabled
  PFS:
  Transform: ESP

IPsec transform set: completeTransform
  State: complete
  Encapsulation mode: transport
  ESN: Enabled
  PFS:
  Transform: AH-ESP
  AH protocol:
    Integrity: SHA1
  ESP protocol:
    Integrity: SHA1
    Encryption: AES-CBC-128
```

Table 7 Command output

Field	Description
IPsec transform set	Name of the IPsec transform set.
State	Whether the IPsec transform set is complete.
Encapsulation mode	Encapsulation mode used by the IPsec transform set: **transport** or **tunnel**.
ESN	Whether Extended Sequence Number (ESN) is enabled.
PFS	Perfect Forward Secrecy (PFS) used by the IPsec policy for negotiation: • 768-bit Diffie-Hellman group (**dh-group1**). • 1024-bit Diffie-Hellman group (**dh-group2**). • 1536-bit Diffie-Hellman group (**dh-group5**). • 2048-bit Diffie-Hellman group (**dh-group14**). • 2048-bit and 256_bit subgroup Diffie-Hellman group (**dh-group24**). • 256-bit ECP Diffie-Hellman group (**dh-group19**). • 384-bit ECP Diffie-Hellman group (**dh-group20**).
Transform	Security protocols used by the IPsec transform set: AH, ESP, or both. If both protocols are configured, IPsec uses ESP before AH.
AH protocol	AH settings.
ESP protocol	ESP settings.
Integrity	Authentication algorithm used by the security protocol.
Encryption	Encryption algorithm used by the security protocol.

Related commands

ipsec transform-set

display ipsec tunnel

Use **display ipsec tunnel** to display information about IPsec tunnels.

Syntax

display ipsec tunnel { **brief** | **count** | **tunnel-id** *tunnel-id* }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

brief: Displays brief information about IPsec tunnels.

count: Displays the number of IPsec tunnels.

tunnel-id *tunnel-id*: Specifies an IPsec tunnel by its ID. The value range for the *tunnel-id* argument is 0 to 4294967295.

Usage guidelines

IPsec is a Layer 3 VPN technology that transmits data in a secure channel established between two endpoints (such as two security gateways). Such a secure channel is usually called an IPsec tunnel.

Examples

Display brief information about all IPsec tunnels.

```
<Sysname> display ipsec tunnel brief
-------------------------------------------------------------------------------
Tunn-id   Src Address     Dst Address     Inbound SPI   Outbound SPI  Status
-------------------------------------------------------------------------------
0         --              --              1000          2000          Active
                                          3000          4000
1         1.2.3.1         2.2.2.2         5000          6000          Active
                                          7000          8000
```

Table 8 Command output

Field	Description
Src Address	Source IP address of the IPsec tunnel. For IPsec SAs created by using IPsec profiles, this field displays two hyphens (**--**).
Dst Address	Destination IP address of the IPsec tunnel. For IPsec SAs created by using IPsec profiles, this field displays two hyphens (**--**).
Inbound SPI	Valid SPI in the inbound direction of the IPsec tunnel. If the tunnel uses two security protocols, two SPIs in the inbound direction are displayed in two lines.
Outbound SPI	Valid SPI in the outbound direction of the IPsec tunnel. If the tunnel uses two security protocols, two SPIs in the outbound direction are displayed in two lines.
Status	Status of the IPsec SA, which can only be **Active**.

Display the number of IPsec tunnels.

```
<Sysname> display ipsec tunnel count
Total IPsec Tunnel Count: 2
```

Display detailed information about all IPsec tunnels.

```
<Sysname> display ipsec tunnel
Tunnel ID: 0
Status: Active
Perfect forward secrecy:
Inside vpn-instance:
SA's SPI:
    outbound:  2000        (0x000007d0)   [AH]
    inbound:   1000        (0x000003e8)   [AH]
    outbound:  4000        (0x00000fa0)   [ESP]
    inbound:   3000        (0x00000bb8)   [ESP]
Tunnel:
    local  address:
    remote address:
Flow:

Tunnel ID: 1
Status: Active
Perfect forward secrecy:
Inside vpn-instance:
SA's SPI:
    outbound:  6000        (0x00001770)   [AH]
    inbound:   5000        (0x00001388)   [AH]
    outbound:  8000        (0x00001f40)   [ESP]
    inbound:   7000        (0x00001b58)   [ESP]
Tunnel:
    local  address: 1.2.3.1
    remote address: 2.2.2.2
Flow:
    as defined in ACL3100
```

Display detailed information about IPsec tunnel 1.

```
<Sysname> display ipsec tunnel tunnel-id 1
Tunnel ID: 1
Status: Active
Perfect forward secrecy:
Inside vpn-instance:
SA's SPI:
    outbound:  6000        (0x00001770)   [AH]
    inbound:   5000        (0x00001388)   [AH]
    outbound:  8000        (0x00001f40)   [ESP]
    inbound:   7000        (0x00001b58)   [ESP]

    local  address: 1.2.3.1
    remote address: 2.2.2.2
```

```
Flow:
    as defined in ACL 3100
```

Table 9 Command output

Field	Description
Tunnel ID	IPsec ID, used to uniquely identify an IPsec tunnel.
Status	IPsec tunnel status, which can only be **Active**.
Perfect forward secrecy	Perfect Forward Secrecy (PFS) used by the IPsec policy for negotiation: • 768-bit Diffie-Hellman group (**dh-group1**). • 1024-bit Diffie-Hellman group (**dh-group2**). • 1536-bit Diffie-Hellman group (**dh-group5**). • 2048-bit Diffie-Hellman group (**dh-group14**). • 2048-bit and 256_bit subgroup Diffie-Hellman group (**dh-group24**). • 256-bit ECP Diffie-Hellman group (**dh-group19**). • 384-bit ECP Diffie-Hellman group (**dh-group20**).
Inside vpn-instance	This field is not supported in the current software version. VPN instance to which the IPsec-protected data belongs.
SA's SPI	SPIs of the inbound and outbound SAs.
Tunnel	Local and remote addresses of the IPsec tunnel.
local address	Local end IP address of the IPsec tunnel.
remote address	Remote end IP address of the IPsec tunnel.
Flow	Information about the data flow protected by the IPsec tunnel, including source IP address, destination IP address, source port, destination port, and protocol.
as defined in ACL 3001	Range of data flow protected by the IPsec tunnel that is established manually. This information shows that the IPsec tunnel protects all data flows defined by ACL 3001.

encapsulation-mode

Use **encapsulation-mode** to set the encapsulation mode that the security protocol uses to encapsulate IP packets.

Use **undo encapsulation-mode** to restore the default.

Syntax

encapsulation-mode { **transport** | **tunnel** }

undo encapsulation-mode

Default

IP packets are encapsulated in tunnel mode.

Views

IPsec transform set view

Predefined user roles

network-admin

Parameters

transport: Uses the transport mode for IP packet encapsulation.

tunnel: Uses the tunnel mode for IP packet encapsulation.

Usage guidelines

IPsec supports the following encapsulation modes:

- **Transport mode**—The security protocols protect the upper layer data of an IP packet. Only the transport layer data is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are placed after the original IP header. You can use the transport mode when end-to-end security protection is required (the secured transmission start and end points are the actual start and end points of the data). The transport mode is typically used for protecting host-to-host communications.
- **Tunnel mode**—The security protocols protect the entire IP packet. The entire IP packet is used to calculate the security protocol headers. The calculated security protocol headers and the encrypted data (only for ESP encapsulation) are encapsulated in a new IP packet. In this mode, the encapsulated packet has two IP headers. The inner IP header is the original IP header. The outer IP header is added by the network device that provides the IPsec service. You must use the tunnel mode when the secured transmission start and end points are not the actual start and end points of the data packets (for example, when two gateways provide IPsec but the data start and end points are two hosts behind the gateways). The tunnel mode is typically used for protecting gateway-to-gateway communications.

The IPsec transform sets at both ends of the IPsec tunnel must have the same encapsulation mode.

Examples

Configure IPsec transform set **tran1** to use the transport mode for IP packet encapsulation.

```
<Sysname> system-view
[Sysname] ipsec transform-set tran1
[Sysname-ipsec-transform-set-tran1] encapsulation-mode transport
```

Related commands

ipsec transform-set

esn enable

Use **esn enable** to enable the Extended Sequence Number (ESN) feature.

Use **undo esn enable** to disable the ESN feature.

Syntax

esn enable [**both**]

undo esn enable

Default

The ESN feature is disabled.

Views

IPsec transform set view

Predefined user roles

network-admin

Parameters

both: Specifies IPsec to support both extended sequence number and traditional sequence number. If you do not specify this keyword, IPsec only supports extended sequence number.

Usage guidelines

The ESN feature extends the sequence number length from 32 bits to 64 bits. This feature prevents the sequence number space from being exhausted when large volumes of data are transmitted at high speeds over an IPsec SA. If the sequence number space is not exhausted, the IPsec SA does not need to be renegotiated.

This feature must be enabled at both the initiator and the responder.

Examples

Enable the ESN feature in IPsec transform set **tran1**.

```
<Sysname> system-view
[Sysname] ipsec transform-set tran1
[Sysname-ipsec-transform-set-tran1] esn enable
```

Related commands

display ipsec transform-set

esp authentication-algorithm

Use **esp authentication-algorithm** to specify authentication algorithms for ESP.

Use **undo esp authentication-algorithm** to restore the default.

Syntax

In non-FIPS mode:

esp authentication-algorithm { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

undo esp authentication-algorithm

In FIPS mode:

esp authentication-algorithm { **sha1**| **sha256** | **sha384** | **sha512** } *

undo esp authentication-algorithm

Default

ESP does not use any authentication algorithms.

Views

IPsec transform set view

Predefined user roles

network-admin

Parameters

aes-xcbc-mac: Specifies the HMAC-AES-XCBC-96 algorithm, which uses a 128-bit key. This keyword is available only for IKEv2.

md5: Specifies the HMAC-MD5-96 algorithm, which uses a 128-bit key.

sha1: Specifies the HMAC-SHA1-96 algorithm, which uses a 160-bit key.

sha256: Specifies the HMAC-SHA256 algorithm, which uses a 256-bit key.

sha384: Specifies the HMAC-SHA384 algorithm, which uses a 384-bit key.

sha512: Specifies the HMAC-SHA512 algorithm, which uses a 512-bit key.

Usage guidelines

In non-FIPS mode, you can specify multiple ESP authentication algorithms for one IPsec transform set, and the algorithm specified earlier has a higher priority.

For a manual or IKEv1-based IPsec policy, the first specified ESP authentication algorithm takes effect. To make sure an IPsec tunnel can be established successfully, the IPsec transform sets specified at both ends of the tunnel must have the same first ESP authentication algorithm.

Examples

Configure IPsec transform set **tran1** to use the HMAC-SHA1 algorithm as the ESP authentication algorithm.

```
<Sysname> system-view
[Sysname] ipsec transform-set tran1
[Sysname-ipsec-transform-set-tran1] esp authentication-algorithm sha1
```

Related commands

ipsec transform-set

esp encryption-algorithm

Use **esp encryption-algorithm** to specify encryption algorithms for ESP.

Use **undo esp encryption-algorithm** to restore the default.

Syntax

In non-FIPS mode:

esp encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **camellia-cbc-128** | **camellia-cbc-192** | **camellia-cbc-256** | **des-cbc** | **gmac-128** | **gmac-192** | **gmac-256** | **gcm-128** | **gcm-192** | **gcm-256** | **null** } *

undo esp encryption-algorithm

In FIPS mode:

esp encryption-algorithm { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **gmac-128** | **gmac-192** | **gmac-256** | **gcm-128** | **gcm-192** | **gcm-256** }*

undo esp encryption-algorithm

Default

ESP does not use any encryption algorithms.

Views

IPsec transform set view

Predefined user roles

network-admin

Parameters

3des-cbc: Specifies the 3DES algorithm in CBC mode, which uses a 168-bit key.

aes-cbc-128: Specifies the AES algorithm in CBC mode, which uses a 128-bit key.

aes-cbc-192: Specifies the AES algorithm in CBC mode, which uses a 192-bit key.

aes-cbc-256: Specifies the AES algorithm in CBC mode, which uses a 256-bit key.

aes-ctr-128: Specifies the AES algorithm in CTR mode, which uses a 128-bit key. This keyword is available only for IKEv2.

aes-ctr-192: Specifies the AES algorithm in CTR mode, which uses a 192-bit key. This keyword is available only for IKEv2.

aes-ctr-256: Specifies the AES algorithm in CTR mode, which uses a 256-bit key. This keyword is available only for IKEv2.

camellia-cbc-128: Specifies the Camellia algorithm in CBC mode, which uses a 128-bit key. This keyword is available only for IKEv2.

camellia-cbc-192: Specifies the Camellia algorithm in CBC mode, which uses a 192-bit key. This keyword is available only for IKEv2.

camellia-cbc-256: Specifies the Camellia algorithm in CBC mode, which uses a 256-bit key. This keyword is available only for IKEv2.

des-cbc: Specifies the DES algorithm in CBC mode, which uses a 64-bit key.

gmac-128: Specifies the GMAC algorithm, which uses a 128-bit key. This keyword is available only for IKEv2.

gmac-192: Specifies the GMAC algorithm, which uses a 192-bit key. This keyword is available only for IKEv2.

gmac-256: Specifies the GMAC algorithm, which uses a 256-bit key. This keyword is available only for IKEv2.

gcm-128: Specifies the GCM algorithm, which uses a 128-bit key. This keyword is available only for IKEv2.

gcm-192: Specifies the GCM algorithm, which uses a 192-bit key. This keyword is available only for IKEv2.

gcm-256: Specifies the GCM algorithm, which uses a 256-bit key. This keyword is available only for IKEv2.

null: Specifies the NULL algorithm, which means encryption is not performed.

Usage guidelines

You can specify multiple ESP encryption algorithms for one IPsec transform set, and the algorithm specified earlier has a higher priority.

For a manual or IKEv1-based IPsec policy, the first specified ESP encryption algorithm takes effect. To make sure an IPsec tunnel can be established successfully, the IPsec transform sets specified at both ends of the tunnel must have the same first ESP encryption algorithm.

GCM and GMAC algorithms are combined mode algorithms. GCM algorithms provide encryption and authentication services. GMAC algorithms only provide authentication service. Combined mode algorithms can be used only when ESP is used alone without AH. Combined mode algorithms cannot be used together with ordinary ESP authentication algorithms.

Examples

Configure IPsec transform set **tran1** to use the AES-CBC-128 algorithm as the ESP encryption algorithm.

```
<Sysname> system-view
[Sysname] ipsec transform-set tran1
[Sysname-ipsec-transform-set-tran1] esp encryption-algorithm aes-cbc-128
```

Related commands

ipsec transform-set

ike-profile

Use **ike-profile** to specify an IKE profile for an IPsec policy, IPsec policy template, or IPsec profile.

Use **undo ike-profile** to restore the default.

Syntax

ike-profile *profile-name*

undo ike-profile

Default

No IKE profile is specified for an IPsec policy, IPsec policy template, or IPsec profile.

Views

IPsec policy view

IPsec policy template view

IPsec profile view

Predefined user roles

network-admin

Parameters

profile-name: Specifies an IKE profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

If no IKE profile is specified for an IPsec policy, IPsec policy template, or IPsec profile, the device selects an IKE profile configured in system view for negotiation. If no IKE profile is configured in system view, the device uses the global IKE settings.

The IKE profile specified for an IPsec policy, IPsec policy template, or IPsec profile defines the parameters used for IKE negotiation.

You can specify only one IKE profile for an IPsec policy, IPsec policy template, or IPsec profile.

Examples

Specify IKE profile **profile1** for IPsec policy **policy1**.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 10 isakmp
[Sysname-ipsec-policy-isakmp-policy1-10] ike-profile profile1
```

Related commands

ike profile

ikev2-profile

Use **ikev2-profile** to specify an IKEv2 profile for an IPsec policy or IPsec policy template.

Use **undo ikev2-profile** to restore the default.

Syntax

ikev2-profile *profile-name*

undo ikev2-profile

Default

No IKEv2 profile is specified.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Parameters

profile-name: Specifies an IKEv2 profile by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

The IKEv2 profile specified for an IPsec policy or IPsec policy template defines the parameters used for IKEv2 negotiation.

You can specify only one IKEv2 profile for an IPsec policy or IPsec policy template. On the initiator, an IKEv2 profile is required. On the responder, an IKEv2 profile is optional. If you do not specify an IKEv2 profile, the responder can use any IKEv2 profile for negotiation.

Examples

Specify IKEv2 profile **profile1** for IPsec policy **policy1**.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 10 isakmp
[Sysname-ipsec-policy-isakmp-policy1-10] ikev2-profile profile1
```

Related commands

display ipsec ipv6-policy

display ipsec policy

ikev2 profile

ipsec { ipv6-policy | policy }

Use **ipsec** { **ipv6-policy** | **policy** } to create an IPsec policy entry and enter its view, or enter the view of an existing IPsec policy entry.

Use **undo ipsec** { **ipv6-policy** | **policy** } to delete an IPsec policy.

Syntax

ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* [**isakmp** | **manual**]

undo ipsec { **ipv6-policy** | **policy** } *policy-name* [*seq-number*]

Default

No IPsec policies exist.

Views

System view

Predefined user roles

network-admin

Parameters

ipv6-policy: Specifies an IPv6 IPsec policy.

policy: Specifies an IPv4 IPsec policy.

policy-name: Specifies a name for the IPsec policy, a case-insensitive string of 1 to 63 characters.

seq-number: Specifies a sequence number for the IPsec policy entry, in the range of 1 to 65535.

isakmp: Establishes IPsec SAs through IKE negotiation.

manual: Establishes IPsec SAs manually.

Usage guidelines

When you create an IPsec policy, you must specify the SA setup mode (**isakmp** or **manual**). When you enter the view of an existing IPsec policy, you do not need to specify the SA setup mode.

You cannot change the SA setup mode of an existing IPsec policy.

An IPsec policy is a set of IPsec policy entries that have the same name but different sequence numbers. In the same IPsec policy, an IPsec policy entry with a smaller sequence number has a higher priority.

If you specify the *seq-number* argument, the **undo** command deletes the specified IPsec policy entry. If you do not specify this argument, the **undo** command deletes the specified IPsec policy.

An IPv4 IPsec policy and IPv6 IPsec policy can have the same name.

Examples

Create an IKE-based IPsec policy entry and enter the IPsec policy view. The policy name is **policy1** and the sequence number is 100.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 isakmp
[Sysname-ipsec-policy-isakmp-policy1-100]
```

Create a manual IPsec policy entry and enter the IPsec policy view. The policy name is **policy1** and the sequence number is 101.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 101 manual
[Sysname-ipsec-policy-manual-policy1-101]
```

ipsec apply

ipsec { ipv6-policy | policy } isakmp template

Use **ipsec** { **ipv6-policy** | **policy** } **isakmp template** to create an IKE-based IPsec policy entry by using an IPsec policy template.

Use **undo ipsec** { **ipv6-policy** | **policy** } to delete an IPsec policy.

Syntax

ipsec { **ipv6-policy** | **policy** } *policy-name seq-number* **isakmp template** *template-name*

undo ipsec { **ipv6-policy** | **policy** } *policy-name* [*seq-number*]

Default

No IPsec policies exist.

Views

System view

Predefined user roles

network-admin

Parameters

ipv6-policy: Specifies an IPv6 IPsec policy.

policy: Specifies an IPv4 IPsec policy.

policy-name: Specifies a name for the IPsec policy, a case-insensitive string of 1 to 63 characters.

seq-number: Specifies a sequence number for the IPsec policy, in the range of 1 to 65535. A smaller number indicates a higher priority.

isakmp template *template-name*: Specifies an IPsec policy template by its name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

If you specify the *seq-number* argument, the **undo** command deletes the specified IPsec policy entry. If you do not specify this argument, the **undo** command deletes the specified IPsec policy.

An interface applied with an IPsec policy that is configured by using an IPsec policy template cannot initiate an SA negotiation, but it can respond to a negotiation request. The parameters not defined in the template are determined by the initiator. When the remote end's information (such as the IP address) is unknown, this method allows the remote end to initiate negotiations with the local end.

Examples

Create an IPsec policy entry by using IPsec policy template **temp1**, and specify the IPsec policy name as **policy2** and the sequence number as 200.

```
<Sysname> system-view
[Sysname] ipsec policy policy2 200 isakmp template temp1
```

Related commands

display ipsec { **ipv6-policy** | **policy** }

ipsec { **ipv6-policy-template** | **policy-template** }

ipsec { ipv6-policy | policy } local-address

Use **ipsec** { **ipv6-policy** | **policy** } **local-address** to bind an IPsec policy to a source interface.

Use **undo ipsec** { **ipv6-policy** | **policy** } **local-address** to remove the binding between an IPsec policy and a source interface.

Syntax

ipsec { **ipv6-policy** | **policy** } *policy-name* **local-address** *interface-type interface-number*

undo ipsec { **ipv6-policy** | **policy** } *policy-name* **local-address**

Default

No IPsec policy is bound to a source interface.

Views

System view

Predefined user roles

network-admin

Parameters

ipv6-policy: Specifies an IPv6 IPsec policy.

policy: Specifies an IPv4 IPsec policy.

policy-name: Specifies an IPsec policy name, a case-insensitive string of 1 to 63 characters.

local-address *interface-type interface-number*: Specifies the shared source interface by its type and number.

Usage guidelines

For high availability, two interfaces can operate in backup mode. After an IPsec policy is applied to the two interfaces, they negotiate with their peers to establish IPsec SAs separately. When one interface fails and a link failover occurs, the other interface needs to take some time to renegotiate SAs, resulting in service interruption.

To solve these problems, bind a source interface to an IPsec policy and apply the policy to both interfaces. This enables the two physical interfaces to use the same source interface to negotiate IPsec SAs. As long as the source interface is up, the negotiated IPsec SAs will not be removed and will keep working, regardless of link failover.

After an IPsec policy is applied to a service interface and IPsec SAs have been established, if you bind the IPsec policy to a source interface, the existing IPsec SAs are deleted.

Only an IKE-based IPsec policy can be bound to a source interface.

An IPsec policy can be bound to only one source interface. If you execute this command multiple times, the most recent configuration takes effect.

A source interface can be bound to multiple IPsec policies.

As a best practice, use a stable interface, such as a Loopback interface, as a source interface.

Examples

Bind IPsec policy **map** to source interface Loopback 11.

```
<Sysname> system-view
[Sysname] ipsec policy map local-address loopback 11
```

Related commands

ipsec { **ipv6-policy** | **policy** }

ipsec { ipv6-policy-template | policy-template }

Use **ipsec** { **ipv6-policy-template** | **policy-template** } to create an IPsec policy template entry and enter its view, or enter the view of an existing IPsec policy template entry.

Use **undo ipsec** { **ipv6-policy-template** | **policy-template** } to delete an IPsec policy template.

Syntax

ipsec { **ipv6-policy-template** | **policy-template** } *template-name seq-number*

undo ipsec { **ipv6-policy-template** | **policy-template** } *template-name* [*seq-number*]

Default

No IPsec policy templates exist.

Views

System view

Predefined user roles

network-admin

Parameters

ipv6-policy-template: Specifies an IPv6 IPsec policy template.

policy-template: Specifies an IPv4 IPsec policy template.

template-name: Specifies a name for the IPsec policy template, a case-insensitive string of 1 to 63 characters.

seq-number: Specifies a sequence number for the IPsec policy template entry, in the range of 1 to 65535. A smaller number indicates a higher priority.

Usage guidelines

The configurable parameters for an IPsec policy template are similar to the parameters that you use when you configure an IKE-based IPsec policy. However, all parameters except for the IPsec transform sets and the IKE peer are optional for an IPsec policy template.

An IPsec policy template is a set of IPsec policy template entries that have the same name but different sequence numbers.

With the *seq-number* argument specified, the **undo** command deletes an IPsec policy template entry.

An IPv4 IPsec policy template and an IPv6 IPsec policy template can have the same name.

Examples

Create an IPsec policy template entry and enter the IPsec policy template view. The template name is **template1** and the sequence number is 100.

```
<Sysname> system-view
[Sysname] ipsec policy-template template1 100
[Sysname-ipsec-policy-template-template1-100]
```

Related commands

display ipsec { **ipv6-policy-template** | **policy-template** }

ipsec { **ipv6-policy** | **policy** }

ipsec { **ipv6-policy** | **policy** } **isakmp template**

ipsec anti-replay check

Use **ipsec anti-replay check** to enable IPsec anti-replay checking.

Use **undo ipsec anti-replay check** to disable IPsec anti-replay checking.

Syntax

ipsec anti-replay check

undo ipsec anti-replay check

Default

IPsec anti-replay checking is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

IPsec packet de-encapsulation involves complicated calculation. De-encapsulation of replayed packets is not necessary but consumes large amounts of resources and degrades performance, resulting in DoS. IPsec anti-replay checking, when enabled, is performed before the de-encapsulation process, reducing resource waste.

In some situations, service data packets are received in a different order than their original order. The IPsec anti-replay feature drops them as replayed packets, which impacts communications. If this happens, disable IPsec anti-replay checking or adjust the size of the anti-replay window as required.

Only IPsec SAs negotiated by IKE support anti-replay checking. Manually created IPsec SAs do not support anti-replay checking. Enabling or disabling IPsec anti-replay checking does not affect manually created IPsec SAs.

Examples

Enable IPsec anti-replay checking.

```
<Sysname> system-view
[Sysname] ipsec anti-replay check
```

Related commands

ipsec anti-replay window

ipsec anti-replay window

Use **ipsec anti-replay window** to set the anti-replay window size.

Use **undo ipsec anti-replay window** to restore the default.

Syntax

ipsec anti-replay window *width*

undo ipsec anti-replay window

Default

The anti-replay window size is 64.

Views

System view

Predefined user roles

network-admin

Parameters

width: Specifies the size for the anti-replay window. It can be 64, 128, 256, 512, or 1024 packets.

Usage guidelines

Service data packets might be received in a very different order than their original order, and the IPsec anti-replay feature might drop them as replayed packets, affecting normal communications. If this happens, disable IPsec anti-replay checking or adjust the size of the anti-replay window as required.

Changing the anti-replay window size affects only the IPsec SAs negotiated later.

Examples

Set the size of the anti-replay window to 128.

```
<Sysname> system-view
[Sysname] ipsec anti-replay window 128
```

Related commands

ipsec anti-replay check

ipsec apply

Use **ipsec apply** to apply an IPsec policy to an interface.

Use **undo ipsec apply** to remove an IPsec policy application from an interface.

Syntax

ipsec apply { **ipv6-policy** | **policy** } *policy-name*

undo ipsec apply { **ipv6-policy** | **policy** }

Default

No IPsec policy is applied to an interface.

Views

Interface view

Predefined user roles

network-admin

Parameters

ipv6-policy: Specifies an IPv6 IPsec policy.

policy: Specifies an IPv4 IPsec policy.

policy-name: Specifies an IPsec policy name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

On an interface, you can apply a maximum of two IPsec policies: one IPv4 IPsec policy and one IPv6 IPsec policy.

An IKE-based IPsec policy can be applied to multiple interfaces. As a best practice, apply an IKE-based IPsec policy to only one interface. A manual IPsec policy can be applied to only one interface.

Examples

Apply IPsec policy **policy1** to VLAN-interface 100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] ipsec apply policy policy1
```

Related commands

display ipsec { **ipv6-policy** | **policy** }

ipsec { **ipv6-policy** | **policy** }

ipsec decrypt-check enable

Use **ipsec decrypt-check enable** to enable ACL checking for de-encapsulated IPsec packets.

Use **undo ipsec decrypt-check** to disable ACL checking for de-encapsulated IPsec packets.

Syntax

ipsec decrypt-check enable

undo ipsec decrypt-check enable

Default

ACL checking for de-encapsulated IPsec packets is enabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

In tunnel mode, the IP packet encapsulated in an inbound IPsec packet might not be under the protection of the ACL specified in the IPsec policy. After being de-encapsulated, such packets bring threats to the network security. In this scenario, you can enable ACL checking for de-encapsulated IPsec packets. All packets failing the checking are discarded, improving the network security.

Examples

Enable ACL checking for de-encapsulated IPsec packets.

```
<Sysname> system-view
[Sysname] ipsec decrypt-check enable
```

ipsec df-bit

Use **ipsec df-bit** to configure the DF bit for the outer IP header of IPsec packets on an interface.

Use **undo ipsec df-bit** to restore the default.

Syntax

ipsec df-bit { **clear** | **copy** | **set** }

undo ipsec df-bit

Default

The DF bit is not configured for the outer IP header of IPsec packets on an interface. The global DF bit setting is used.

Views

Interface view

Predefined user roles

network-admin

Parameters

clear: Clears the DF bit in the outer IP header. IPsec packets can be fragmented.

copy: Copies the DF bit setting of the original IP header to the outer IP header.

set: Sets the DF bit in the outer IP header. IPsec packets cannot be fragmented.

Usage guidelines

This command is effective only when the IPsec encapsulation mode is tunnel mode. It is not effective in transport mode because the outer IP header is not added in transport mode.

This command does not change the DF bit for the original IP header of IPsec packets.

If multiple interfaces use an IPsec policy that is bound to a source interface, you must use the same DF bit setting on these interfaces.

Packet fragmentation and reassembly might cause packet forwarding to be delayed. You can set the DF bit to avoid the forwarding delay. However, to prevent the IPsec packets from being discarded, you must make sure the path MTU is larger than the IPsec packet size. As a best practice, clear the DF bit if you cannot make sure the path MTU is larger than the IPsec packet size.

Examples

Set the DF bit in the outer IP header of IPsec packets on VLAN-interface100.

```
<Sysname> system-view
[Sysname] interface vlan-interface 100
[Sysname–Vlan-interface100] ipsec df-bit set
```

Related commands

ipsec global-df-bit

ipsec fragmentation

Use **ipsec fragmentation** to configure the IPsec fragmentation feature.

Use **undo ipsec fragmentation** to restore the default.

Syntax

ipsec fragmentation { **after-encryption** | **before-encryption** }

undo ipsec fragmentation

Default

The device fragments packets before IPsec encapsulation.

Views

System view

Predefined user roles

network-admin

Parameters

after-encryption: Fragments packets after IPsec encapsulation.

before-encryption: Fragments packets before IPsec encapsulation.

Usage guidelines

If you configure the device to fragment packets before IPsec encapsulation, the device predetermines the encapsulated packet size before the actual encapsulation. If the encapsulated packet size exceeds the MTU of the output interface and the DF bit is not set, the device fragments the packet before encapsulation. If the packet's DF bit is set, the device drops the packet and sends an ICMP error message.

If you configure the device to fragment packets after IPsec encapsulation, the device directly encapsulates the packets and fragments the encapsulated packets in subsequent service modules.

Examples

Configure the device to fragment packets after IPsec encapsulation.

```
<Sysname>system-view
[Sysname] ipsec fragmentation after-encryption
```

ipsec global-df-bit

Use **ipsec global-df-bit** to configure the DF bit for the outer IP header of IPsec packets on all interfaces.

Use **undo ipsec global-df-bit** to restore the default.

Syntax

ipsec global-df-bit { **clear** | **copy** | **set** }

undo ipsec global-df-bit

Default

The DF bit setting of the original IP header is copied to the outer IP header for IPsec packets.

Views

System view

Predefined user roles

network-admin

Parameters

clear: Clears the DF bit in the outer IP header. IPsec packets can be fragmented.

copy: Copies the DF bit setting of the original IP header to the outer IP header.

set: Sets the DF bit in the outer IP header. IPsec packets cannot be fragmented.

Usage guidelines

This command is effective only when the IPsec encapsulation mode is tunnel mode. It is not effective in transport mode because the outer IP header is not added in transport mode.

This command does not change the DF bit for the original IP header of IPsec packets.

Packet fragmentation and reassembly might cause packet forwarding to be delayed. You can set the DF bit to avoid the forwarding delay. However, to prevent IPsec packets from being discarded, you must make sure the path MTU is larger than the IPsec packet size. As a best practice, clear the DF bit if you cannot make sure the path MTU is larger than the IPsec packet size.

Examples

Set the DF bit in the outer IP header of IPsec packets on all interfaces.

```
<Sysname> system-view
[Sysname] ipsec global-df-bit set
```

Related commands

ipsec df-bit

ipsec limit max-tunnel

Use **ipsec limit max-tunnel** to set the maximum number of IPsec tunnels.

Use **undo ipsec limit max-tunnel** to restore the default.

Syntax

ipsec limit max-tunnel *tunnel-limit*

undo ipsec limit max-tunnel

Default

The number of IPsec tunnels is not limited.

Views

System view

Predefined user roles

network-admin

Parameters

tunnel-limit: Specifies the maximum number of IPsec tunnels, in the range of 1 to 4294967295.

Usage guidelines

To maximize concurrent performance of IPsec when memory is sufficient, increase the maximum number of IPsec tunnels. To ensure service availability when memory is insufficient, decrease the maximum number of IPsec tunnels.

Examples

Set the maximum number of IPsec tunnels to 5000.

```
<Sysname> system-view
[Sysname] ipsec limit max-tunnel 5000
```

Related commands

ike limit

ipsec logging packet enable

Use **ipsec logging packet enable** to enable logging for IPsec packets.

Use **undo ipsec logging packet enable** to disable logging for IPsec packets.

Syntax

ipsec logging packet enable

undo ipsec logging packet enable

Default

Logging for IPsec packets is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

After logging for IPsec packets is enabled, the device outputs a log when an IPsec packet is discarded. IPsec packets might be discarded due to lack of inbound SA, AH/ESP authentication failure, or ESP encryption failure. A log contains the source and destination IP addresses, SPI, and sequence number of the packet, and the reason it was discarded.

Examples

Enable logging for IPsec packets.

```
<Sysname> system-view
[Sysname] ipsec logging packet enable
```

ipsec profile

Use **ipsec profile** to create an IPsec profile and enter its view, or enter the view of an existing IPsec profile.

Use **undo ipsec profile** to delete an IPsec profile.

Syntax

ipsec profile *profile-name* [**manual**]

undo ipsec profile *profile-name*

Default

No IPsec profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

profile-name: Specifies a name for the IPsec profile, a case-insensitive string of 1 to 63 characters.

manual: Specifies the IPsec SA setup mode as manual.

Usage guidelines

When you create an IPsec profile, you must specify the IPsec SA setup mode (**manual**). When you enter the view of an existing IPsec profile, you do not need to specify the IPsec SA setup mode.

A manual IPsec profile is similar to a manual IPsec policy. It is used exclusively for IPsec protection for application protocols, including OSPFv3 and RIPng.

Examples

Create a manual IPsec profile named **profile1**.

```
<Sysname> system-view
[Sysname] ipsec profile profile1 manual
[Sysname-ipsec-profile-manual-profile1]
```

Related commands

display ipsec profile

ipsec redundancy enable

Use **ipsec redundancy enable** to enable IPsec redundancy.

Use **undo ipsec redundancy enable** to disable IPsec redundancy.

Syntax

ipsec redundancy enable

undo ipsec redundancy enable

Default

IPsec redundancy is disabled.

Views

System view

Predefined user roles

network-admin

Usage guidelines

With IPsec redundancy enabled, the system synchronizes the following information from the active device to the standby device at configurable intervals:

- Lower bound values of the IPsec anti-replay window for inbound packets.
- IPsec anti-replay sequence numbers for outbound packets.

The synchronization ensures uninterrupted IPsec traffic forwarding and anti-replay protection when the active device fails.

To configure synchronization intervals, use the **redundancy replay-interval** command.

Examples

Enable IPsec redundancy.

```
<Sysname> system-view
[Sysname] ipsec redundancy enable
```

Related commands

redundancy replay-interval

ipsec sa global-duration

Use **ipsec sa global-duration** to configure the global IPsec SA lifetime.

Use **undo ipsec sa global-duration** to restore the default.

Syntax

ipsec sa global-duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

undo ipsec sa global-duration { **time-based** | **traffic-based** }

Default

The time-based global IPsec SA lifetime is 3600 seconds, and the traffic-based global lifetime is 1843200 kilobytes.

Views

System view

Predefined user roles

network-admin

Parameters

time-based *seconds*: Specifies the time-based global lifetime for IPsec SAs, in the range of 180 to 604800 seconds.

traffic-based *kilobytes*: Specifies the traffic-based global lifetime for IPsec SAs, in the range of 2560 to 4294967295 kilobytes. When traffic on an SA reaches this value, the SA expires.

Usage guidelines

You can also configure IPsec SA lifetimes in IPsec policy view or IPsec policy template view. The device prefers the IPsec SA lifetimes configured in IPsec policy view or IPsec policy template view over the global IPsec SA lifetimes.

When IKE negotiates IPsec SAs, it uses the local lifetime settings or those proposed by the peer, whichever are smaller.

An IPsec SA can have both a time-based lifetime and a traffic-based lifetime. The IPsec SA expires when either lifetime expires. Before the IPsec SA expires, IKE negotiates a new IPsec SA, which takes over immediately after its creation.

Examples

Configure the global IPsec SA lifetime as 7200 seconds.

```
<Sysname> system-view
[Sysname] ipsec sa global-duration time-based 7200
```

Configure the global IPsec SA lifetime as 10240 kilobytes.

```
[Sysname] ipsec sa global-duration traffic-based 10240
```

Related commands

display ipsec sa

sa duration

ipsec sa idle-time

Use **ipsec sa idle-time** to enable the global IPsec SA idle timeout feature and set the idle timeout. If no traffic matches an IPsec SA within the idle timeout interval, the IPsec SA is deleted.

Use **undo ipsec sa idle-time** to disable the global IPsec SA idle timeout feature.

Syntax

ipsec sa idle-time *seconds*

undo ipsec sa idle-time

Default

The global IPsec SA idle timeout feature is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

seconds: Specifies the IPsec SA idle timeout in the range of 60 to 86400 seconds.

Usage guidelines

This feature applies only to IPsec SAs negotiated by IKE.

The IPsec SA idle timeout can also be configured in IPsec policy view, IPsec policy template view, or IPsec profile view, which takes precedence over the global IPsec SA timeout.

Examples

Enable the global IPsec SA idle timeout feature and set the IPsec SA idle timeout to 600 seconds.

```
<Sysname> system-view
[Sysname] ipsec sa idle-time 600
```

Related commands

display ipsec sa

sa idle-time

ipsec transform-set

Use **ipsec transform-set** to create an IPsec transform set and enter its view, or enter the view of an existing IPsec transform set.

Use **undo ipsec transform-set** to delete an IPsec transform set.

Syntax

ipsec transform-set *transform-set-name*

undo ipsec transform-set *transform-set-name*

Default

No IPsec transform sets exist.

Views

System view

Predefined user roles

network-admin

Parameters

transform-set-name: Specifies a name for the IPsec transform set, a case-insensitive string of 1 to 63 characters.

Usage guidelines

An IPsec transform set, part of an IPsec policy, defines the security parameters for IPsec SA negotiation, including the security protocol, encryption algorithms, authentication algorithms, and encapsulation mode.

Examples

Create an IPsec transform set named **tran1** and enter its view.

```
<Sysname> system-view
[Sysname] ipsec transform-set tran1
[Sysname-transform-set-tran1]
```

Related commands

display ipsec transform-set

local-address

Use **local-address** to configure the local IP address for the IPsec tunnel.

Use **undo local-address** to restore the default.

Syntax

local-address { *ipv4-address* | **ipv6** *ipv6-address* }

undo local-address

Default

The primary IPv4 address of the interface to which the IPsec policy is applied is used as the local IPv4 address. The first IPv6 address of the interface to which the IPsec policy is applied is used as the local IPv6 address.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Parameters

ipv4-address: Specifies the local IPv4 address for the IPsec tunnel.

ipv6 *ipv6-address*: Specifies the local IPv6 address for the IPsec tunnel.

Usage guidelines

The remote IP address on the IKE negotiation initiator must be the same as the local address on the IKE negotiation responder.

Examples

Configure local address 1.1.1.1 for the IPsec tunnel.

```
<Sysname> system-view
[Sysname] ipsec policy map 1 isakmp
[Sysname-ipsec-policy-isakmp-map-1] local-address 1.1.1.1
```

Related commands

remote-address

pfs

Use **pfs** to enable the Perfect Forward Secrecy (PFS) feature for an IPsec transform set.

Use **undo pfs** to restore the default.

Syntax

In non-FIPS mode:

pfs { **dh-group1** | **dh-group2** | **dh-group5** | **dh-group14** | **dh-group24** | **dh-group19** | **dh-group20** }

undo pfs

In FIPS mode:

pfs { **dh-group14** | **dh-group19** | **dh-group20** }

undo pfs

Default

The PFS feature is disabled for the IPsec transform set.

Views

IPsec transform set view

Predefined user roles

network-admin

Parameters

dh-group1: Uses 768-bit Diffie-Hellman group.

dh-group2: Uses 1024-bit Diffie-Hellman group.

dh-group5: Uses 1536-bit Diffie-Hellman group.

dh-group14: Uses 2048-bit Diffie-Hellman group.

dh-group24: Uses 2048-bit and 256-bit subgroup Diffie-Hellman group.

dh-group19: Uses 256-bit ECP Diffie-Hellman group. This keyword is available only for IKEv2.

dh-group20: Uses 384-bit ECP Diffie-Hellman group. This keyword is available only for IKEv2.

Usage guidelines

In terms of security and required calculation time, the following groups are in descending order: 384-bit ECP Diffie-Hellman group (**dh-group20**), 256-bit ECP Diffie-Hellman group (**dh-group19**), 2048-bit and 256-bit subgroup Diffie-Hellman group (**dh-group24**), 2048-bit Diffie-Hellman group (**dh-group14**), 1536-bit Diffie-Hellman group (**dh-group5**), 1024-bit Diffie-Hellman group (**dh-group2**), and 768-bit Diffie-Hellman group (**dh-group1**).

If IKEv1 is used, the security level of the Diffie-Hellman group of the initiator must be higher than or equal to that of the responder. This restriction does not apply to IKEv2.

The end without the PFS feature performs IKE negotiation according to the PFS requirements of the peer end.

Examples

Enable PFS using 2048-bit Diffie-Hellman group for IPsec transform set **tran1**.

```
<Sysname> system-view
[Sysname] ipsec transform-set tran1
[Sysname-ipsec-transform-set-tran1] pfs dh-group14
```

protocol

Use **protocol** to specify a security protocol for an IPsec transform set.

Use **undo protocol** to restore the default.

Syntax

protocol { **ah** | **ah-esp** | **esp** }

undo protocol

Default

The IPsec transform set uses the ESP protocol.

Views

IPsec transform set view

Predefined user roles

network-admin

Parameters

ah: Specifies the AH protocol.

ah-esp: Specifies using the ESP protocol first and then using the AH protocol.

ah: Specifies the AH protocol.

Usage guidelines

The two tunnel ends must use the same security protocol in the IPsec transform set.

Examples

Specify the AH protocol for the IPsec transform set.

```
<Sysname> system-view
[Sysname] ipsec transform-set tran1
[Sysname-ipsec-transform-set-tran1] protocol ah
```

qos pre-classify

Use **qos pre-classify** to enable the QoS pre-classify feature.

Use **undo qos pre-classify** to disable the QoS pre-classify feature.

Syntax

qos pre-classify

undo qos pre-classify

Default

The QoS pre-classify feature is disabled. QoS uses the new IP header of IPsec packets to perform traffic classification.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Usage guidelines

The QoS pre-classify feature enables QoS to classify packets by using the IP header of the original IP packets.

Examples

Enable the QoS pre-classify feature.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 manual
[Sysname-ipsec-policy-manual-policy1-100] qos pre-classify
```

redundancy replay-interval

Use **redundancy replay-interval** to set the anti-replay window lower bound value synchronization interval for inbound packets and the sequence number synchronization interval for outbound packets.

Use **undo redundancy replay-interval** to restore the default.

Syntax

redundancy replay-interval inbound *inbound-interval* **outbound** *outbound-interval*

undo redundancy replay-interval

Default

The active device synchronizes the anti-replay window lower bound value every time it receives 1000 packets and synchronizes the sequence number every time it sends 100000 packets.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Parameters

inbound *inbound-interval*: Specifies the interval at which the active device synchronizes the lower bound value of the IPsec anti-replay window to the standby device. This interval is expressed in the number of received packets, in the range of 0 to 1000. If you set the value to 0, the lower bound value of the anti-replay window will not be synchronized.

outbound *outbound-interval*: Specifies the interval at which the active device synchronizes the IPsec anti-replay sequence number to the standby device. This interval is expressed in the number of sent packets, in the range of 1000 to 100000.

Usage guidelines

The intervals take effect only after you enable IPsec redundancy by using the **ipsec redundancy enable** command.

A short interval improves the anti-replay information consistency between the active device and the standby device, but it sacrifices the forwarding performance of the devices.

Examples

Set the anti-replay window lower bound value synchronization interval for inbound packets to 800. Set the sequence number synchronization interval for outbound packets to 50000.

```
<Sysname> system-view

remote-address

Use **remote-address** to configure the remote IP address for the IPsec tunnel.

Use **undo remote-address** to restore the default.

Syntax

remote-address { [**ipv6**] *host-name* | *ipv4-address* | **ipv6** *ipv6-address* }

undo remote-address

Default

No remote IP address is configured for the IPsec tunnel.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Parameters

ipv6: Specifies the remote address or host name of an IPv6 IPsec tunnel. To specify the remote address or host name of an IPv4 IPsec tunnel, do not specify this keyword.

hostname: Specifies the remote host name, a case-insensitive string of 1 to 253 characters. The host name can be resolved to an IP address by the DNS server.

ipv4-address: Specifies a remote IPv4 address.

ipv6-address: Specifies a remote IPv6 address.

Usage guidelines

This remote IP address configuration is required on the IKE negotiation initiator and optional on the responder if the responder uses an IPsec policy template.

A manual IPsec policy does not support DNS. Therefore, you must specify a remote IP address rather than a remote host name for the manual IPsec policy.

If you configure a remote host name, make sure the local end can always resolve the host name into the latest IP address of the remote end.

- If a DNS server is used for resolution, the local end queries the remote IP address again from the DNS server after the previously cached remote IP address expires. This mechanism ensures that the local end can always obtain the latest remote IP address.
- If a static DNS entry is used for resolution, you must reconfigure the **remote-address** command whenever the remote IP address changes. Without the reconfiguration, the local end cannot obtain the latest remote IP address.

For example, the local end has a static DNS entry which maps the host name **test** to the IP address 1.1.1.1. Configure the following commands:

Configure the remote host name to **test** for the IPsec tunnel in the IPsec policy **policy1**.

```
[Sysname] ipsec policy policy1 1 isakmp
[Sysname-ipsec-policy-isakmp-policy1-1] remote-address test
```

Change the IP address for the host **test** to 2.2.2.2.

```
[Sysname] ip host test 2.2.2.2
```

In this case, you must reconfigure the remote host name for the IPsec policy **policy1** so that the local end can obtain the latest IP address of the remote host.

Reconfigure the remote host name to **test** for the IPsec tunnel in the IPsec policy **policy1**.

```
[Sysname] ipsec policy policy1 1 isakmp
[Sysname -ipsec-policy-isakmp-policy1-1] remote-address test
```

Examples

Specify remote IP address 10.1.1.2 for the IPsec tunnel.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 10 manual
[Sysname-ipsec-policy-manual-policy1-10] remote-address 10.1.1.2
```

Related commands

ip host (*Layer 3—IP Services Command Reference*)

local-address

reset ipsec sa

Use **reset ipsec sa** to clear IPsec SAs.

Syntax

reset ipsec sa [{ **ipv6-policy** | **policy** } *policy-name* [*seq-number*] | **profile** *policy-name* | **remote** { *ipv4-address* | **ipv6** *ipv6-address* } | **spi** { *ipv4-address* | **ipv6** *ipv6-address* } { **ah** | **esp** } *spi-num*]

Views

User view

Predefined user roles

network-admin

Parameters

{ **ipv6-policy** | **policy** } *policy-name* [*seq-number*]: Clears IPsec SAs for the specified IPsec policy.

- **ipv6-policy**: Specifies an IPv6 IPsec policy.
- **policy**: Specifies an IPv4 IPsec policy.
- *policy-name*: Specifies the name of the IPsec policy, a case-insensitive string of 1 to 63 characters.
- *seq-number*: Specifies the sequence number of an IPsec policy entry, in the range of 1 to 65535. If you do not specify this argument, all the entries in the IPsec policy are specified.

profile *profile-name*: Clears IPsec SAs for the IPsec profile specified by its name, a case-insensitive string of 1 to 63 characters.

remote: Clears IPsec SAs for the specified remote address.

ipv4-address: Specifies a remote IPv4 address.

ipv6 *ipv6-address*: Specifies a remote IPv6 address.

spi { *ipv4-address* | **ipv6** *ipv6-address* } { **ah** | **esp** } *spi-num*: Clears IPsec SAs matching the specified SA triplet: the remote address, the security protocol, and the SPI.

- *ipv4-address*: Specifies a remote IPv4 address.
- **ipv6** *ipv6-address*: Specifies a remote IPv6 address.
- **ah**: Specifies the AH protocol.
- **esp**: Specifies the ESP protocol.

spi-num: Specifies the security parameter index in the range of 256 to 4294967295.

Usage guidelines

If you do not specify any parameters, this command clears all IPsec SAs.

If you specify an SA triplet, this command clears the IPsec SA matching the triplet, and all the other IPsec SAs that were established during the same negotiation process, including the corresponding IPsec SA in the other direction, and the inbound and outbound IPsec SAs using the other security protocol (AH or ESP).

An outbound SA is uniquely identified by an SA triplet and an inbound SA is uniquely identified by an SPI. To clear IPsec SAs by specifying a triplet in the outbound direction, you should provide the remote IP address, the security protocol, and the SPI, where the remote IP address can be any valid

address if the SAs are established by IPsec profiles. To clear IPsec SAs by specifying a triplet in the inbound direction, you should provide the SPI and use any valid values for the other two parameters.

After a manual IPsec SA is cleared, the system automatically creates a new SA based on the parameters of the IPsec policy. After IKE negotiated SAs are cleared, the system creates new SAs only when IKE negotiation is triggered by packets.

Examples

Clear all IPsec SAs.

```
<Sysname> reset ipsec sa
```

Clear the inbound and outbound IPsec SAs for the triplet of SPI 256, remote IP address 10.1.1.2, and security protocol AH.

```
<Sysname> reset ipsec sa spi 10.1.1.2 ah 256
```

Clear all IPsec SAs for remote IP address 10.1.1.2.

```
<Sysname> reset ipsec sa remote 10.1.1.2
```

Clear all IPsec SAs for entry 10 of IPsec policy **policy1**.

```
<Sysname> reset ipsec sa policy policy1 10
```

Clear all IPsec SAs for IPsec policy **policy1**.

```
<Sysname> reset ipsec sa policy policy1
```

reset ipsec statistics

Use **reset ipsec statistics** to clear IPsec packet statistics.

Syntax

reset ipsec statistics[**tunnel-id** *tunnel-id*]

Views

User view

Predefined user roles

network-admin

Parameters

tunnel-id *tunnel-id*: Clears IPsec packet statistics for the specified IPsec tunnel. The value range for the *tunnel-id* argument is 0 to 4294967295. If you do not specify this option, the command clears all IPsec packet statistics.

Examples

Clear IPsec packet statistics.

```
<Sysname> reset ipsec statistics
```

Related commands

reverse-route dynamic

Use **reverse-route dynamic** to enable IPsec reverse route inject (RRI).

Use **undo reverse-route dynamic** to disable IPsec RRI.

Syntax

reverse-route dynamic

undo reverse-route dynamic

Default

IPsec RRI is disabled.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Usage guidelines

IPsec RRI is usually used on a gateway device at the headquarters side in an IPsec VPN. After IPsec RRI is enabled for an IPsec policy or an IPsec policy template on a gateway device, the gateway device automatically creates a static route upon IPsec SA creation according to this IPsec policy or IPsec policy template. In the static route, the destination IP address is the protected peer private network, and the next hop is the IP address of the remote tunnel interface.

When you enable IPsec RRI for an IPsec policy, the device deletes all IPsec SAs that are created according to this IPsec policy. Upon IPsec SAs are renegotiated, the static routes are created.

When you disable IPsec RRI for an IPsec policy, the device deletes all IPsec SAs that are created according to this IPsec policy, and the associated static routes.

To display the static routes created by RRI, use the **display ip routing-table** command.

Examples

Enable IPsec RRI to create a static route according to the IPsec SA negotiated by the specified IPsec policy. The destination IP address is the protected peer private network 3.0.0.0/24, and the next hop is the IP address (1.1.1.2) of the remote tunnel interface.

```
<Sysname> system-view
[Sysname] ipsec policy 1 1 isakmp
[Sysname-ipsec-policy-isakmp-1-1] reverse-route dynamic
[Sysname-ipsec-policy-isakmp-1-1] quit
```

Display the routing table. You can see a created static route. (Other information is not shown.)

```
[Sysname] display ip routing-table

Destinations : 1        Routes : 1

Destination/Mask    Proto  Pre  Cost         NextHop         Interface
3.0.0.0/24          Static 60   0            1.1.1.2         Vlan100
```

reverse-route preference

Use **reverse-route preference** to set the preference of the static routes created by IPsec RRI.

Use **undo reverse-route preference** to restore the default.

Syntax

reverse-route preference *number*

undo reverse-route preference

Default

The preference for the static routes created by IPsec RRI is 60.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Parameters

number: Specifies a preference value. The value range is 1 to 255. A smaller value represents a higher preference.

Usage guidelines

When you change this preference in an IPsec policy, the device deletes all IPsec SAs created according to this IPsec policy, and the associated static routes.

Examples

Change the preference to 100 for static routes created by IPsec RRI.

```
<Sysname> system-view
[Sysname] ipsec policy 1 1 isakmp
[Sysname-ipsec-policy-isakmp-1-1] reverse-route preference 100
```

Related commands

ipsec policy

ipsec policy-template

reverse-route tag

Use **reverse-route tag** to set a route tag for the static routes created by IPsec RRI.

Use **undo reverse-route tag** to restore the default.

Syntax

reverse-route tag *tag-value*

undo reverse-route tag

Default

The route tag value is 0 for the static routes created by IPsec RRI.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Parameters

tag-value: Specifies a tag value. The value range is 1 to 4294967295.

Usage guidelines

The tag value set by this command helps in implementing flexible route control through routing policies.

When you change this tag value in an IPsec policy, the device deletes all IPsec SAs created by this IPsec policy, and all associated static routes.

Examples

Set the tag value to 50 for the static routes created by IPsec RRI.

```
<Sysname>system-view
[Sysname] ipsec policy 1 1 isakmp
[Sysname-ipsec-policy-isakmp-1-1] reverse-route tag 50
```

ipsec policy-template

sa duration

Use **sa duration** to set an SA lifetime.

Use **undo sa duration** to remove an SA lifetime.

Syntax

sa duration { **time-based** *seconds* | **traffic-based** *kilobytes* }

undo sa duration { **time-based** | **traffic-based** }

Default

The SA lifetime of an IPsec policy, IPsec policy template, or IPsec profile is the current global SA lifetime.

Views

IPsec policy view

IPsec policy template view

IPsec profile view

Predefined user roles

network-admin

Parameters

time-based *seconds*: Specifies the time-based SA lifetime in the range of 180 to 604800 seconds.

traffic-based *kilobytes*: Specifies the traffic-based SA lifetime in the range of 2560 to 4294967295 kilobytes.

Usage guidelines

IKE prefers the SA lifetime of the IPsec policy, IPsec policy template, or IPsec profile over the global SA lifetime configured by the **ipsec sa global-duration** command. If the IPsec policy, IPsec policy template, or IPsec profile is not configured with the SA lifetime, IKE uses the global SA lifetime for SA negotiation.

During SA negotiation, IKE selects the shorter SA lifetime between the local SA lifetime and the remote SA lifetime.

Examples

Set the SA lifetime to 7200 seconds for IPsec policy **policy1**.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 isakmp
[Sysname-ipsec-policy-isakmp-policy1-100] sa duration time-based 7200
```

Set the SA lifetime to 20 MB for IPsec policy **policy1**. The IPsec SA expires after transmitting 20480 kilobytes.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 isakmp
[Sysname-ipsec-policy-isakmp-policy1-100] sa duration traffic-based 20480
```

Related commands

ipsec sa global-duration

sa hex-key authentication

Use **sa hex-key authentication** to configure an authentication key for a manual IPsec SA.

Use **undo sa hex-key authentication** to delete an authentication key for a manual IPsec SA.

Syntax

sa hex-key authentication { **inbound** | **outbound** } { **ah** | **esp** } { **cipher** | **simple** } *string*

undo sa hex-key authentication { **inbound** | **outbound** } { **ah** | **esp** }

Default

No hexadecimal authentication keys are configured for manual IPsec SAs.

Views

IPsec policy view

IPsec profile view

Predefined user roles

network-admin

Parameters

inbound: Specifies a hexadecimal authentication key for the inbound SA.

outbound: Specifies a hexadecimal authentication key for the outbound SA.

ah: Uses AH.

esp: Uses ESP.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its plaintext form is case insensitive and must be a 16-byte hexadecimal string for HMAC-MD5 and a 20-byte hexadecimal string for HMAC-SHA1. Its encrypted form is a case-sensitive string of 1 to 85 characters.

Usage guidelines

This command applies only to manual IPsec policies and IPsec profiles.

You must set an authentication key for both the inbound and outbound SAs.

The local inbound SA must use the same authentication key as the remote outbound SA, and the local outbound SA must use the same authentication key as the remote inbound SA.

In an IPsec profile to be applied to an IPv6 routing protocol, the local authentication keys of the inbound and outbound SAs must be identical.

The keys for the IPsec SAs at the two tunnel ends must be input in the same format (either in hexadecimal or character format). Otherwise, they cannot establish an IPsec tunnel.

If you execute this command multiple times for the same protocol and direction, the most recent configuration takes effect.

Examples

Configure plaintext authentication keys **0x112233445566778899aabbccddeeff00** and **0xaabbccddeeff001100aabbccddeeff00** for the inbound and outbound SAs that use AH.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 manual
[Sysname-ipsec-policy-manual-policy1-100] sa hex-key authentication inbound ah simple
112233445566778899aabbccddeeff00
[Sysname-ipsec-policy-manual-policy1-100] sa hex-key authentication outbound ah simple
aabbccddeeff001100aabbccddeeff00
```

sa hex-key encryption

Use **sa encryption-hex** to configure an encryption key for a manual IPsec SA.

Use **undo sa encryption-hex** to delete an encryption key for a manual IPsec SA.

Syntax

sa hex-key encryption { **inbound** | **outbound** } **esp** { **cipher** | **simple** } *string*

undo sa hex-key encryption { **inbound** | **outbound** } **esp**

Default

No hexadecimal encryption keys are configured for manual IPsec SAs.

Views

IPsec policy view

IPsec profile view

Predefined user roles

network-admin

Parameters

inbound: Specifies a hexadecimal encryption key for the inbound SA.

outbound: Specifies a hexadecimal encryption key for the outbound SA.

esp: Uses ESP.

cipher: Specifies a key in encrypted form.

simple: Specifies a key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the key. Its encrypted form is a case-sensitive string of 1 to 117 characters. Its plaintext form is a case-insensitive hexadecimal string and the key length varies by algorithm.

The following matrix shows the key length for the algorithms:

Algorithm	Key length (bytes)
DES-CBC	8
3DES-CBC	24
AES128-CBC	16
AES192-CBC	24
AES256-CBC	32

Usage guidelines

This command applies only to manual IPsec policies and IPsec profiles.

You must set an encryption key for both the inbound and outbound SAs.

The local inbound SA must use the same encryption key as the remote outbound SA, and the local outbound SA must use the same encryption key as the remote inbound SA.

In an IPsec profile to be applied to an IPv6 routing protocol, the local encryption keys of the inbound and outbound SAs must be identical.

The keys for the IPsec SAs at the two tunnel ends must be configured in the same format (either in hexadecimal or character format). Otherwise, they cannot establish an IPsec tunnel.

If you execute this command multiple times for the same direction, the most recent configuration takes effect.

Examples

Configure plaintext encryption keys **0x1234567890abcdef** and **0xabcdefabcdef1234** for the inbound and outbound IPsec SAs that use ESP.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 manual
[Sysname-ipsec-policy-manual-policy1-100] sa hex-key encryption inbound esp simple
1234567890abcdef
[Sysname-ipsec-policy-manual-policy1-100] sa hex-key encryption outbound esp simple
abcdefabcdef1234
```

sa idle-time

Use **sa idle-time** to set the IPsec SA idle timeout. If no traffic matches an IPsec SA within the idle timeout interval, the IPsec SA is deleted.

Use **undo sa idle-time** to restore the default.

Syntax

sa idle-time *seconds*

undo sa idle-time

Default

An IPsec policy, IPsec policy template, or IPsec profile uses the global IPsec SA idle timeout.

Views

IPsec policy view

IPsec policy template view

IPsec profile view

Predefined user roles

network-admin

Parameters

seconds: Specifies the IPsec SA idle timeout in the range of 60 to 86400 seconds.

Usage guidelines

This feature applies only to IPsec SAs negotiated by IKE and takes effect after the **ipsec sa idle-time** command is configured.

The IPsec SA idle timeout configured by this command takes precedence over the global IPsec SA timeout configured by the **ipsec sa idle-time** command. If the IPsec policy, IPsec policy template, or IPsec profile is not configured with the SA idle timeout, IKE uses the global SA idle timeout.

Examples

Set the IPsec SA idle timeout to 600 seconds for IPsec policy **map**.

```
<Sysname> system-view
[Sysname] ipsec policy map 100 isakmp
[Sysname-ipsec-policy-isakmp-map-100] sa idle-time 600
```

Related commands

display ipsec sa

ipsec sa idle-time

sa spi

Use **sa spi** to configure an SPI for IPsec SAs.

Use **undo sa spi** to remove the SPI.

Syntax

sa spi { **inbound** | **outbound** } { **ah** | **esp** } *spi-number*

undo sa spi { **inbound** | **outbound** } { **ah** | **esp** }

Default

No SPI is configured for IPsec SAs.

Views

IPsec policy view

IPsec profile view

Predefined user roles

network-admin

Parameters

inbound: Specifies an SPI for inbound SAs.

outbound: Specifies an SPI for outbound SAs.

ah: Uses AH.

esp: Uses ESP.

spi-number: Specifies a security parameters index (SPI) in the range of 256 to 4294967295.

Usage guidelines

This command applies only to manual IPsec policies and IPsec profiles.

You must configure an SPI for both inbound and outbound SAs, and make sure the SAs in each direction are unique: For an outbound SA, make sure its triplet (remote IP address, security protocol, and SPI) is unique. For an inbound SA, make sure its SPI is unique.

The local inbound SA must use the same SPI as the remote outbound SA, and the local outbound SA must use the same SPI as the remote inbound SA.

When you configure an IPsec profile for an IPv6 routing protocol, follow these guidelines:

- The local inbound and outbound SAs must use the same SPI.
- The IPsec SAs on the devices in the same scope must have the same SPI. The scope is defined by protocols. For OSPFv3, the scope consists of OSPFv3 neighbors or an OSPFv3 area. For RIPng, the scope consists of directly-connected neighbors or a RIPng process.

Examples

Set the SPI for the inbound SA to 10000 and the SPI for the outbound SA to 20000 in a manual IPsec policy.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 manual
[Sysname-ipsec-policy-manual-policy1-100] sa spi inbound ah 10000
[Sysname-ipsec-policy-manual-policy1-100] sa spi outbound ah 20000
```

Related commands

display ipsec sa

sa string-key

Use **sa string-key** to set a key string (a key in character format) for manual IPsec SAs.

Use **undo sa string-key** to remove the key string.

Syntax

sa string-key { **inbound** | **outbound** } { **ah** | **esp** } [**cipher** | **simple**] *string*

undo sa string-key { **inbound** | **outbound** } { **ah** | **esp** }

Default

No key string is configured for manual IPsec SAs.

Views

IPsec policy view

IPsec profile view

Predefined user roles

network-admin

Parameters

inbound: Sets a key string for inbound IPsec SAs.

outbound: Sets a key string for outbound IPsec SAs.

ah: Uses AH.

esp: Uses ESP.

cipher: Specifies a key string in encrypted form.

simple: Specifies a key string in plaintext form. For security purposes, the key string specified in plaintext form will be stored in encrypted form.

string: Specifies the key string. Its encrypted form is a case-sensitive string of 1 to 373 characters. Its plaintext form is a case-sensitive string of 1 to 255 characters. Using the key string, the system automatically generates keys that meet the algorithm requirements. When the protocol is ESP, the system automatically generates keys for the authentication algorithm and encryption algorithm.

Usage guidelines

This command applies only to manual IPsec policies and IPsec profiles.

You must set a key for both inbound and outbound SAs.

The local inbound SA must use the same key as the remote outbound SA, and the local outbound SA must use the same key as the remote inbound SA.

The keys for the IPsec SAs at the two tunnel ends must be input in the same format (either in hexadecimal or character format). Otherwise, they cannot establish an IPsec tunnel.

When you configure an IPsec profile for an IPv6 routing protocol, follow these guidelines:

- The local inbound and outbound SAs must use the same key.
- The IPsec SAs on the devices in the same scope must have the same key. The scope is defined by protocols. For OSPFv3, the scope consists of OSPFv3 neighbors or an OSPFv3 area. For RIPng, the scope consists of directly-connected neighbors or a RIPng process.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

Configure the inbound and outbound SAs that use AH to use plaintext keys **abcdef** and **efcdab**, respectively.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 100 manual
[Sysname-ipsec-policy-manual-policy1-100] sa string-key inbound ah simple abcdef
[Sysname-ipsec-policy-manual-policy1-100] sa string-key outbound ah simple efcdab
```

In an IPv6 IPsec policy, configure the inbound and outbound SAs that use AH to use plaintext key **abcdef**.

```
<Sysname> system-view
[Sysname] ipsec ipv6-policy policy1 100 manual
```

```
[Sysname-ipsec-ipv6-policy-manual-policy1-100] sa string-key inbound ah simple abcdef
[Sysname-ipsec-ipv6-policy-manual-policy1-100] sa string-key outbound ah simple abcdef
```

Related commands

display ipsec sa

sa hex-key

security acl

Use **security acl** to specify an ACL for an IPsec policy or IPsec policy template.

Use **undo security acl** to restore the default.

Syntax

security acl [**ipv6**] { *acl-number* | **name** *acl-name* } [**aggregation** | **per-host**]

undo security acl

Default

An IPsec policy or IPsec policy template does not use any ACL.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Parameters

ipv6: Specifies an IPv6 ACL.

acl-number: Specifies an ACL by its number in the range of 3000 to 3999.

name *acl-name*: Specifies an ACL by its name, a case-insensitive string of 1 to 63 characters.

aggregation: Specifies the data protection mode as aggregation. The device does not support protecting IPv6 data flows in aggregation mode.

per-host: Specifies the data protection mode as per-host.

Usage guidelines

An IKE-based IPsec policy supports the following data flow protection modes:

- **Standard mode**—One IPsec tunnel protects one data flow. The data flow permitted by an ACL rule is protected by one IPsec tunnel that is established solely for it. The standard mode is used if you do not specify the aggregation or the per-host mode.
- **Aggregation mode**—One IPsec tunnel protects all data flows permitted by all the rules of an ACL. This mode is only used to communicate with old-version devices.
- **Per-host mode**—One IPsec tunnel protects one host-to-host data flow. One host-to-host data flow is identified by one ACL rule and protected by one IPsec tunnel established solely for it. This mode consumes more system resources when multiple data flows exist between two subnets to be protected.

A manual IPsec policy supports only the aggregation mode.

Examples

Specify IPv4 advanced ACL 3001 for IPsec policy **policy1**.

```
<Sysname> system-view
[Sysname] acl advanced 3001
[Sysname-acl-ipv4-adv-3001] rule permit tcp source 10.1.1.0 0.0.0.255 destination
10.1.2.0 0.0.0.255
[Sysname-acl-ipv4-adv-3001] quit
[Sysname] ipsec policy policy1 100 manual
[Sysname-ipsec-policy-manual-policy1-100] security acl 3001
```

Specify IPv4 advanced ACL 3002 for IPsec policy **policy2** and specify the data protection mode as aggregation.

```
<Sysname> system-view
[Sysname] acl advanced 3002
[Sysname-acl-ipv4-adv-3002] rule 0 permit ip source 10.1.2.1 0.0.0.255 destination
10.1.2.2 0.0.0.255
[Sysname-acl-ipv4-adv-3002] rule 1 permit ip source 10.1.3.1 0.0.0.255 destination
10.1.3.2 0.0.0.255
[Sysname-acl-ipv4-adv-3002] quit
[Sysname] ipsec policy policy2 1 isakmp
[Sysname-ipsec-policy-isakmp-policy2-1] security acl 3002 aggregation
```

Parameters

auth-failure: Specifies notifications about authentication failures.

decrypt-failure: Specifies notifications about decryption failures.

encrypt-failure: Specifies notifications about encryption failures.

global: Specifies notifications globally.

invalid-sa-failure: Specifies notifications about invalid-SA failures.

no-sa-failure: Specifies notifications about SA-not-found failures.

policy-add: Specifies notifications about events of adding IPsec policies.

policy-attach: Specifies notifications about events of applying IPsec policies to interfaces.

policy-delete: Specifies notifications about events of deleting IPsec policies.

policy-detach: Specifies notifications about events of removing IPsec policies from interfaces.

tunnel-start: Specifies notifications about events of creating IPsec tunnels.

tunnel-stop: Specifies notifications about events of deleting IPsec tunnels.

Usage guidelines

If you do not specify any keywords, this command enables or disables all SNMP notifications for IPsec.

To generate and output SNMP notifications for a specific IPsec failure type or event type, perform the following tasks:

1. Enable SNMP notifications for IPsec globally.
2. Enable SNMP notifications for the failure type or event type.

Examples

Enable SNMP notifications for IPsec globally.

```
<Sysname> system-view
[Sysname] snmp-agent trap enable ipsec global
```

Enable SNMP notifications for events of creating IPsec tunnels.

```
[Sysname] snmp-agent trap enable ipsec tunnel-start
```

tfc enable

Use **tfc enable** to enable Traffic Flow Confidentiality (TFC) padding.

Use **undo tfc enable** to disable TFC padding.

Syntax

tfc enable

undo tfc enable

Default

TFC padding is disabled.

Views

IPsec policy view

IPsec policy template view

Predefined user roles

network-admin

Usage guidelines

TFC padding can hide the length of the original packet, and might affect the packet encapsulation and de-encapsulation performance. This feature takes effect on UDP packets encapsulated by ESP in transport mode and on original IP packets encapsulated by ESP in tunnel mode.

Examples

Enable TFC padding for IPsec policy **policy1**.

```
<Sysname> system-view
[Sysname] ipsec policy policy1 10 isakmp
[Sysname-ipsec-policy-isakmp-policy1-10] tfc enable
```

Related commands

display ipsec ipv6-policy

display ipsec policy

transform-set

Use **transform-set** to specify an IPsec transform set for an IPsec policy, IPsec policy template, or IPsec profile.

Use **undo transform-set** to remove the IPsec transform set specified for an IPsec policy, IPsec policy template, or IPsec profile.

Syntax

transform-set *transform-set-name*&<1-6>

undo transform-set [*transform-set-name*]

Default

No IPsec transform set is specified for an IPsec policy, IPsec policy template, or IPsec profile.

Views

IPsec policy view

IPsec policy template view

IPsec profile view

Predefined user roles

network-admin

Parameters

transform-set-name&<1-6>: Specifies a space-separated list of up to six IPsec transform sets by their names, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You can specify only one IPsec transform set for a manual IPsec policy. If you execute this command multiple times, the most recent configuration takes effect.

You can specify a maximum of six IPsec transform sets for an IKE-based IPsec policy. During an IKE negotiation, IKE searches for a fully matched IPsec transform set at the two ends of the IPsec tunnel. If no match is found, no SA can be set up, and the packets expecting to be protected will be dropped.

If you do not specify the *transform-set-name* argument, the **undo transform-set** command removes all IPsec transform sets specified for the IPsec policy, IPsec policy template, or IPsec profile.

Examples

Specify IPsec transform set **prop1** for IPsec policy **policy1**.

```
<Sysname> system-view
[Sysname] ipsec transform-set prop1
[Sysname-ipsec-transform-set-prop1] quit
```

```
[Sysname] ipsec policy policy1 100 manual
[Sysname-ipsec-policy-manual-policy1-100] transform-set prop1
```

IKE commands

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

authentication-algorithm

Use **authentication-algorithm** to specify an authentication algorithm for an IKE proposal.

Use **undo authentication-algorithm** to restore the default.

Syntax

In non-FIPS mode:

authentication-algorithm { **md5** | **sha** | **sha256** | **sha384** | **sha512** }

undo authentication-algorithm

In FIPS mode:

authentication-algorithm { **sha**| **sha256** | **sha384** | **sha512** }

undo authentication-algorithm

Default

In non-FIPS mode:

The IKE proposal uses the HMAC-SHA1 authentication algorithm.

In FIPS mode:

The IKE proposal uses the HMAC-SHA256 authentication algorithm.

Views

IKE proposal view

Predefined user roles

network-admin

Parameters

md5: Specifies the HMAC-MD5 algorithm.

sha: Specifies the HMAC-SHA1 algorithm.

sha256: Specifies the HMAC-SHA256 algorithm.

sha384: Specifies the HMAC-SHA384 algorithm.

sha512: Specifies the HMAC-SHA512 algorithm.

Examples

Specify HMAC-SHA1 as the authentication algorithm for IKE proposal 1.

```
<Sysname> system-view
[Sysname] ike proposal 1
[Sysname-ike-proposal-1] authentication-algorithm sha
```

Related commands

display ike proposal

authentication-method

Use **authentication-method** to specify an authentication method to be used in an IKE proposal.

Use **undo authentication-method** to restore the default.

Syntax

authentication-method { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

undo authentication-method

Default

The IKE proposal uses the preshared key authentication method.

Views

IKE proposal view

Predefined user roles

network-admin

Parameters

dsa-signature: Specifies the DSA signature authentication method.

ecdsa-signature: Specifies the ECDSA signature authentication method.

pre-share: Specifies the preshared key authentication method.

rsa-signature: Specifies the RSA signature authentication method.

Usage guidelines

Preshared key authentication does not require certificates as signature authentication does, and it is usually used in a simple network. Signature authentication provides higher security, and it is usually deployed in a large-scale network, such as a network with many branches. In a network with many branches, using preshared key authentication requires the headquarters to configure a preshared key for each branch. Using signature authentication only requires the headquarters to configure one PKI domain.

Authentication methods configured on both IKE ends must match.

To use the RSA, DSA, or ECDSA signature authentication method, make sure the IKE peer can obtain certificates from a CA.

If you specify the preshared key authentication method, you must configure the preshared key on both IKE ends.

Examples

Specify the preshared key authentication method for IKE proposal 1.

```
<Sysname> system-view
[Sysname] ike proposal 1
[Sysname-ike-proposal-1] authentication-method pre-share
```

Related commands

display ike proposal

ike keychain

pre-shared-key

certificate domain

Use **certificate domain** to specify a PKI domain for signature authentication.

Use **undo certificate domain** to remove a PKI domain for signature authentication.

Syntax

certificate domain *domain-name*

undo certificate domain *domain-name*

Default

No PKI domains are specified for signature authentication.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

domain-name: Specifies the name of a PKI domain, a case-insensitive string of 1 to 31 characters.

Usage guidelines

You can specify a maximum of six PKI domains for an IKE profile by executing this command multiple times.

IKE uses the specified PKI domains for enrollment, authentication, certificate issuing, validation, and signature. If you do not specify any PKI domains, IKE uses all PKI domains configured on the device.

Follow these restrictions and guidelines for the device to obtain the CA certificate during IKE negotiation:

- On the initiator:
  - If the IKE profile has a PKI domain and the automatic certificate request mode is configured for the PKI domain, the initiator automatically obtains the CA certificate.
  - If the IKE profile has no PKI domain, you must manually obtain the CA certificate.
- On the responder:
  - If main mode is used in IKE phase 1, the responder does not automatically obtain the CA certificate. You must manually obtain the CA certificate.
  - If aggressive mode is used in IKE phase 1, the responder automatically obtains the CA certificate if the following conditions are met:
    - A matching IKE profile is found.
    - An PKI domain is specified in the IKE profile.
    - The automatic certificate request mode is configured for the PKI domain.

    If the conditions are not met, you must manually obtain the CA certificate.

IKE first automatically obtains the CA certificate, and then requests a local certificate. If the CA certificate already exists locally, IKE automatically requests a local certificate.

Examples

Specify PKI domain **abc** for IKE profile 1.

```
<Sysname> system-view
[Sysname] ike profile 1
[Sysname-ike-profile-1] certificate domain abc
```

Related commands

authentication-method

pki domain

description

Use **description** to configure a description for an IKE proposal.

Use **undo description** to restore the default.

Syntax

description *text*

undo description

Default

An IKE proposal does not have a description.

Views

IKE proposal view

Predefined user roles

network-admin

Parameters

text: Specifies the description, a case-sensitive string of 1 to 80 characters.

Usage guidelines

When multiple IKE proposals exist, you configure different descriptions for them to distinguish them.

Examples

Configure a description of **test** for IKE proposal 1.

```
<Sysname> system-view
[Sysname] ike proposal 1
[Sysname-ike-proposal-1] description test
```

dh

Use **dh** to specify the DH group to be used for key negotiation in IKE phase 1.

Use **undo dh** to restore the default.

Syntax

In non-FIPS mode:

dh { **group1** | **group14** | **group19** | **group2** | **group20** | **group24** | **group5** }

undo dh

In FIPS mode:

dh { **group14** | **group19** | **group20** | **group24** }

undo dh

Default

In non-FIPS mode:

The 768-bit Diffie-Hellman group (**group1**) is used.

In FIPS mode:

The 2048-bit Diffie-Hellman group (**group14**) is used.

Views

IKE proposal view

Predefined user roles

network-admin

Parameters

group1: Uses the 768-bit Diffie-Hellman group.

group14: Uses the 2048-bit Diffie-Hellman group.

group19: Uses the 256-bit Diffie-Hellman group.

group2: Uses the 1024-bit Diffie-Hellman group.

group20: Uses the 384-bit Diffie-Hellman group.

group24: Uses the 2048-bit Diffie-Hellman group with the 256-bit prime order subgroup.

group5: Uses the 1536-bit Diffie-Hellman group.

Usage guidelines

A DH group with a higher group number provides higher security but needs more time for processing. To achieve the best trade-off between processing performance and security, choose a proper Diffie-Hellman group for your network.

Examples

Specify the 2048-bit Diffie-Hellman group **group1** to be used for key negotiation in IKE phase 1 in IKE proposal 1.

```
<Sysname> system-view
[Sysname] ike proposal 1
[Sysname-ike-proposal-1] dh group14
```

Related commands

display ike proposal

display ike proposal

Use **display ike proposal** to display configuration information about all IKE proposals.

Syntax

display ike proposal

Views

Predefined user roles

network-admin

network-operator

Usage guidelines

This command displays the configuration information about all IKE proposals in descending order of proposal priorities. If no IKE proposal is configured, this command displays the default IKE proposal.

Examples

Display the configuration information about all IKE proposals.

```
<Sysname> display ike proposal
 Priority Authentication Authentication Encryption  Diffie-Hellman Duration
             method       algorithm    algorithm       group      (seconds)
------------------------------------------------------------------------------
 1        RSA-SIG            SHA1        DES-CBC     Group 1        5000
 11       PRE-SHARED-KEY     SHA1        DES-CBC     Group 1        50000
 default  PRE-SHARED-KEY     SHA1       DES-CBC     Group 1        86400
```

Table 10 Command output

Field	Description
Priority	Priority of the IKE proposal
Authentication method	Authentication method used by the IKE proposal.
Authentication algorithm	Authentication algorithm used in the IKE proposal: • **MD5**—HMAC-MD5 algorithm. • **SHA1**—HMAC-SHA1 algorithm. • **SHA256**—HMAC-SHA256 algorithm. • **SHA384**—HMAC-SHA384 algorithm. • **SHA512**—HMAC-SHA512 algorithm.
Encryption algorithm	Encryption algorithm used by the IKE proposal: • **3DES-CBC**—168-bit 3DES algorithm in CBC mode. • **AES-CBC-128**—128-bit AES algorithm in CBC mode. • **AES-CBC-192**—192-bit AES algorithm in CBC mode. • **AES-CBC-256**—256-bit AES algorithm in CBC mode. • **DES-CBC**—56-bit DES algorithm in CBC mode.
Diffie-Hellman group	DH group used in IKE negotiation phase 1.
Duration (seconds)	IKE SA lifetime (in seconds) of the IKE proposal

ike proposal

display ike sa

Use **display ike sa** to display information about IKE SAs.

Syntax

display ike sa [**verbose** [**connection-id** *connection-id* | **remote-address** [**ipv6**] *remote-address*]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

verbose: Displays detailed information.

connection-id *connection-id*: Displays detailed information about IKE SAs by connection ID in the range of 1 to 2000000000.

remote-address: Displays detailed information about IKE SAs with the specified remote address.

ipv6: Specifies an IPv6 address.

remote-address: Remote IP address.

Usage guidelines

If you do not specify any parameters, this command displays summary information about all IKE SAs.

Examples

Display summary information about all IKE SAs.

```
<Sysname> display ike sa
    Connection-ID  Remote          Flag        DOI
  -----------------------------------------------------------
      1            202.38.0.2      RD          IPsec
Flags:
RD--READY RL--REPLACED FD-FADING RK-REKEY
```

Table 11 Command output

Field	Description
Connection-ID	Identifier of the IKE SA.
Remote	Remote IP address of the SA.
Flags	Status of the SA: • **RD--READY**—The SA has been established. • **RL--REPLACED**—The SA has been replaced by a new one and will be deleted later. • **FD-FADING**—The SA is in use, but it is about to expire and will be deleted soon. • **RK-REKEY**—The SA is a Rekey SA. • **Unknown**—The SA status is unknown.
DOI	Interpretation domain to which the SA belongs. **IPsec**—The SA belongs to an IPsec DOI.

Display detailed information about all IKE SAs.

```
<Sysname> display ike sa verbose

```

Table 12 Command output

Field	Description
Connection ID	Identifier of the IKE SA.

Field	Description
Outside VPN	This field is not supported in the current software version. MPLS L3VPN instance to which the receiving interface belongs.
Inside VPN	This field is not supported in the current software version. MPLS L3VPN instance to which the protected data belongs.
Profile	Name of the matching IKE profile found in the IKE SA negotiation. If no matching profile is found, this field displays nothing.
Transmitting entity	Role of the IKE negotiation entity: **Initiator** or **Responder**.
Local IP	IP address of the local gateway.
Local ID type	Identifier type of the local gateway.
Local ID	Identifier of the local gateway.
Remote IP	IP address of the remote gateway.
Remote ID type	Identifier type of the remote gateway.
Remote ID	Identifier of the remote security gateway.
Authentication-method	Authentication method used by the IKE proposal.
Authentication-algorithm	Authentication algorithm used by the IKE proposal: • **MD5**—HMAC-MD5 algorithm. • **SHA1**—HMAC-SHA1 algorithm. • **SHA256**—HMAC-SHA256 algorithm. • **SHA384**—HMAC-SHA384 algorithm. • **SHA512**—HMAC-SHA512 algorithm.
Encryption-algorithm	Encryption algorithm used by the IKE proposal: • **3DES-CBC**—168-bit 3DES algorithm in CBC mode. • **AES-CBC-128**—128-bit AES algorithm in CBC mode. • **AES-CBC-192**—192-bit AES algorithm in CBC mode. • **AES-CBC-256**—256-bit AES algorithm in CBC mode. • **DES-CBC**—56-bit DES algorithm in CBC mode.
Life duration(sec)	Lifetime of the IKE SA in seconds.
Remaining key duration(sec)	Remaining lifetime of the IKE SA in seconds.
Exchange-mode	IKE negotiation mode in phase 1: **Main** or **Aggressive**.
Diffie-Hellman group	DH group used for key negotiation in IKE phase 1.
NAT traversal	Whether a NAT gateway is detected.
Extend authentication	Whether extended authentication for clients is enabled.
Assigned IP address	IP address assigned to the remote peer. This field is not displayed if no IP address is assigned.

display ike statistics

Use **display ike statistics** to display IKE statistics.

Syntax

display ike statistics

Views

Any view

```

Related commands

reset ike statistics

dpd

Use **dpd** to configure IKE DPD.

Use **undo dpd** to disable IKE DPD.

Syntax

dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

undo dpd interval

Default

IKE DPD is disabled.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies a DPD triggering interval in the range of 1 to 300 seconds.

retry *seconds*: Specifies the DPD retry interval in the range of 1 to 60 seconds. The default is 5 seconds.

on-demand: Triggers DPD on demand. The device triggers DPD if it has IPsec traffic to send and has not received any IPsec packets from the peer for the specified interval.

periodic: Triggers DPD at regular intervals. The device triggers DPD at the specified interval.

Usage guidelines

DPD is triggered periodically or on-demand. As a best practice, use the on-demand mode when the device communicates with a large number of IKE peers. For an earlier detection of dead peers, use the periodic triggering mode, which consumes more bandwidth and CPU.

When DPD settings are configured in both IKE profile view and system view, the DPD settings in IKE profile view apply. If DPD is not configured in IKE profile view, the DPD settings in system view apply.

It is a good practice to set the triggering interval longer than the retry interval so that a DPD detection does not occur during a DPD retry.

Examples

Configure DPD to be triggered every 10 seconds and every 5 seconds between retries if the peer does not respond.

```
<Sysname> system-view
[Sysname] ike profile 1
[Sysname-ike-profile-1] dpd interval 10 retry 5 on-demand
```

Related commands

ike dpd

encryption-algorithm

Use **encryption-algorithm** to specify an encryption algorithm for an IKE proposal.

Use **undo encryption-algorithm** to restore the default.

Syntax

In non-FIPS mode:

encryption-algorithm { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **des-cbc** }

undo encryption-algorithm

In FIPS mode:

encryption-algorithm { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** }

undo encryption-algorithm

Default

In non-FIPS mode:

An IKE proposal uses the 56-bit DES encryption algorithm in CBC mode.

In FIPS mode:

An IKE proposal uses the 128-bit AES encryption algorithm in CBC mode.

Views

IKE proposal view

Predefined user roles

network-admin

Parameters

3des-cbc: Specifies the 3DES algorithm in CBC mode. The 3DES algorithm uses a 168-bit key for encryption.

aes-cbc-128: Specifies the AES algorithm in CBC mode. The AES algorithm uses a 128-bit key for encryption.

aes-cbc-192: Specifies the AES algorithm in CBC mode. The AES algorithm uses a 192-bit key for encryption.

aes-cbc-256: Specifies the AES algorithm in CBC mode. The AES algorithm uses a 256-bit key for encryption.

des-cbc: Specifies the DES algorithm in CBC mode. The DES algorithm uses a 56-bit key for encryption.

Examples

Use the 128-bit AES algorithm in CBC mode as the encryption algorithm for IKE proposal 1.

```
<Sysname> system-view
[Sysname] ike proposal 1
[Sysname-ike-proposal-1] encryption-algorithm aes-cbc-128
```

Related commands

display ike proposal

exchange-mode

Use **exchange-mode** to select an IKE negotiation mode for phase 1.

Use **undo exchange-mode** to restore the default.

Syntax

In non-FIPS mode:

exchange-mode { **aggressive** | **main** }

undo exchange-mode

In FIPS mode:

exchange-mode main

undo exchange-mode

Default

Main mode is used for phase 1.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

aggressive: Specifies the aggressive mode.

main: Specifies the main mode.

Usage guidelines

As a best practice, specify the **aggressive** mode at the local end if the following conditions are met:

- The local end, for example, a dialup user, obtains an IP address automatically.
- Preshared key authentication is used.

Examples

Specify that IKE negotiation operates in main mode.

```
<Sysname> system-view
[Sysname] ike profile 1
[Sysname-ike-profile-1] exchange-mode main
```

Related commands

display ike proposal

ike dpd

Use **ike dpd** to configure global IKE DPD.

Use **undo ike dpd** to disable global IKE DPD.

Syntax

ike dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

undo ike dpd interval

Default

Global IKE DPD is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies a DPD triggering interval in the range of 1 to 300 seconds.

retry *seconds*: Specifies the DPD retry interval in the range of 1 to 60 seconds. The default is 5 seconds.

on-demand: Triggers DPD on demand. The device triggers DPD if it has IPsec traffic to send and has not received any IPsec packets from the peer for the specified interval.

periodic: Triggers DPD at regular intervals. The device triggers DPD at the specified interval.

Usage guidelines

DPD is triggered periodically or on-demand. As a best practice, use the on-demand mode when the device communicates with a large number of IKE peers. For an earlier detection of dead peers, use the periodical triggering mode, which consumes more bandwidth and CPU.

When DPD settings are configured in both IKE profile view and system view, the DPD settings in IKE profile view apply. If DPD is not configured in IKE profile view, the DPD settings in system view apply.

It is a good practice to set the triggering interval longer than the retry interval so that a DPD detection does not occur during a DPD retry.

Examples

Configure DPD to be triggered every 10 seconds and every 5 seconds between retries if the peer does not respond.

```
<Sysname> system-view
[Sysname] ike dpd interval 10 retry 5 on-demand
```

Related commands

dpd

ike identity

Use **ike identity** to specify the global identity used by the local end during IKE negotiations.

Use **undo ike identity** to restore the default.

Syntax

ike identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* }| **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

undo ike identity

Default

The IP address of the interface where the IPsec policy applies is used as the IKE identity.

Views

System view

Predefined user roles

network-admin

Parameters

address { *ipv4-address* | **ipv6** *ipv6-address* }: Uses an IPv4 or IPv6 address as the identity.

dn: Uses the DN in the digital signature as the identity.

fqdn *fqdn-name*: Uses the FQDN name as the identity. The *fqdn-name* argument is a case-sensitive string of 1 to 255 characters, for example, www.test.com. If you do not specify this argument, the device name configured by using the **sysname** command is used as the local FQDN.

user-fqdn *user-fqdn-name*: Uses the user FQDN name as the identity. The *user-fqdn-name* argument is a case-sensitive string of 1 to 255 characters, for example, abc@test.com. If you do not specify this argument, the device name configured by using the **sysname** command is used as the user FQDN.

Usage guidelines

The global local identity can be used for all IKE SA negotiations. The local identity (set by the **local-identity** command for an IKE profile) can be used only for IKE SA negotiations that use the IKE profile.

If the local authentication method is signature authentication, you can set an identity of any type. If the local authentication method is preshared key authentication, you cannot set the DN as the identity.

The **ike signature-identity from-certificate** command sets the local device to always use the identity information obtained from the local certificate for signature authentication. If the **ike signature-identity from-certificate** command is not set, the **local-identity** command configuration, if configured, takes precedence over the **ike identity** command configuration.

Examples

Specify IP address 2.2.2.2 as the identity.

```
<sysname> system-view
[sysname] ike identity address 2.2.2.2
```

Related commands

local-identity

ike signature-identity from-certificate

ike invalid-spi-recovery enable

Use **ike invalid-spi-recovery enable** to enable invalid security parameter index (SPI) recovery.

Use **undo ike invalid-spi-recovery enable** to disable invalid SPI recovery.

Syntax

ike invalid-spi-recovery enable

undo ike invalid-spi-recovery enable

Default

Invalid SPI recovery is disabled.

network-admin

Usage guidelines

IPsec "black hole" occurs when one IPsec peer fails (for example, a peer can fail if a reboot occurs). One peer fails and loses its SAs with the other peer. When an IPsec peer receives a data packet for which it cannot find an SA, an invalid SPI is encountered. The peer drops the data packet and tries to send an SPI invalid notification to the data originator. This notification is sent by using the IKE SA. When no IKE SA is available, the notification is not sent. The originating peer continues sending the data by using the IPsec SA that has the invalid SPI, and the receiving peer keeps dropping the traffic.

The invalid SPI recovery feature enables the receiving peer to set up an IKE SA with the originator so that an SPI invalid notification can be sent. Upon receiving the notification, the originating peer deletes the IPsec SA that has the invalid SPI. If the originator has data to send, new SAs will be set up.

Use caution when you enable the invalid SPI recovery feature, because using this feature can result in a DoS attack. Attackers can make a great number of invalid SPI notifications to the same peer.

Examples

Enable invalid SPI recovery.

```
<Sysname> system-view
[Sysname] ike invalid-spi-recovery enable
```

ike keepalive interval

Use **ike keepalive interval** to set the IKE keepalive interval.

Use **undo ike keepalive interval** to restore the default.

Syntax

ike keepalive interval *interval*

undo ike keepalive interval

Default

No IKE keepalives are sent.

Views

System view

Predefined user roles

network-admin

Parameters

interval: Specifies the number of seconds between IKE keepalives, in the range of 20 to 28800.

Usage guidelines

To detect the status of the peer, configure IKE DPD instead of the IKE keepalive feature, unless IKE DPD is not supported on the peer.

The keepalive timeout time configured at the local must be longer than the keepalive interval configured at the peer. Because more than three consecutive packets are rarely lost on a network, you can set the keepalive timeout time to three times as long as the keepalive interval.

Examples

Set the keepalive interval to 200 seconds

```
<Sysname> system-view
[Sysname] ike keepalive interval 200
```

Related commands

ike keepalive timeout

ike keepalive timeout

Use **ike keepalive timeout** to set the IKE keepalive timeout time.

Use **undo ike keepalive timeout** to restore the default.

Syntax

ike keepalive timeout *seconds*

undo ike keepalive timeout

Default

The IKE keepalive timeout time is not set.

Views

System view

Predefined user roles

network-admin

Parameters

seconds: Specifies the number of seconds between IKE keepalives. The value range for this argument is 20 to 28800.

Usage guidelines

If the local end receives no keepalive packets from the peer during the timeout time, the IKE SA is deleted along with the IPsec SAs it negotiated.

The keepalive timeout time configured at the local end must be longer than the keepalive interval configured at the peer. Because more than three consecutive packets are rarely lost on a network, you can set the keepalive timeout time to three times as long as the keepalive interval.

Examples

Set the keepalive timeout time to 20 seconds.

```
<Sysname> system-view
[Sysname] ike keepalive timeout 20
```

Related commands

ike keepalive interval

ike keychain

Use **ike keychain** to create an IKE keychain and enter its view, or enter the view of an existing IKE keychain.

Use **undo ike keychain** to delete an IKE keychain.

Syntax

ike keychain *keychain-name*

undo ike keychain *keychain-name*

Default

No IKE keychains exist.

Views

System view

Predefined user roles

network-admin

Parameters

keychain-name: Specifies an IKE keychain name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

To use preshared key authentication, you must create and specify an IKE keychain for the IKE profile.

Examples

Create IKE keychain **key1** and enter its view.

```
<Sysname> system-view
[Sysname] ike keychain key1
[Sysname-ike-keychain-key1]
```

Related commands

authentication-method

pre-shared-key

ike limit

Use **ike limit** to set the maximum number of half-open or established IKE SAs.

Use **undo ike limit** to restore the default.

Syntax

ike limit { **max-negotiating-sa** *negotiation-limit* | **max-sa** *sa-limit* }

undo ike limit { **max-negotiating-sa** | **max-sa** }

Default

There is no limit to the maximum number of half-open or established IKE SAs.

Views

System view

Predefined user roles

network-admin

Parameters

max-negotiating-sa *negotiation-limit*: Specifies the maximum number of half-open IKE SAs and IPsec SAs. The value range for the *negotiation-limit* argument is 1 to 99999.

max-sa *sa-limit*: Specifies the maximum number of established IKE SAs. The value range for the *sa-limit* argument is 1 to 99999.

Usage guidelines

The supported maximum number of half-open IKE SAs depends on the device's processing capability. Adjust the maximum number of half-open IKE SAs to make full use of the device's processing capability without affecting the IKE SA negotiation efficiency.

The supported maximum number of established IKE SAs depends on the device's memory space. Adjust the maximum number of established IKE SAs to make full use of the device's memory space without affecting other applications in the system.

Examples

Set the maximum number of half-open IKE SAs and IPsec SAs to 200.

```
<Sysname> system-view
[Sysname] ike limit max-negotiating-sa 200
```

Set the maximum number of established IKE SAs to 5000.

```
<Sysname> system-view
[Sysname] ike limit max-sa 5000
```

ike nat-keepalive

Use **ike nat-keepalive** to set the NAT keepalive interval.

Use **undo ike nat-keepalive** to restore the default.

Syntax

ike nat-keepalive *seconds*

undo ike nat-keepalive

Default

The NAT keepalive interval is 20 seconds.

Views

System view

Predefined user roles

network-admin

Parameters

seconds: Specifies the NAT keepalive interval in seconds, in the range of 5 to 300.

Usage guidelines

This command takes effect only for a device that resides in the private network behind a NAT gateway. The device behind the NAT gateway needs to send NAT keepalives to its peer to keep the NAT session alive, so that the peer can access the device.

The NAT keepalive interval must be shorter than the NAT session lifetime.

Examples

Set the NAT keepalive interval to 5 seconds.

```
<Sysname> system-view
[Sysname] ike nat-keepalive 5
```

ike profile

Use **ike profile** to create an IKE profile and enter its view, or enter the view of an existing IKE profile.

Use **undo ike profile** to delete an IKE profile.

Syntax

ike profile *profile-name*

undo ike profile *profile-name*

Default

No IKE profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

profile-name: Specifies an IKE profile name, a case-insensitive string of 1 to 63 characters.

Examples

Create IKE profile 1 and enter its view.

```
<Sysname> system-view
[Sysname] ike profile 1
[Sysname-ike-profile-1]
```

ike proposal

Use **ike proposal** to create an IKE proposal and enter its view, or enter the view of an existing IKE proposal.

Use **undo ike proposal** to delete an IKE proposal.

Syntax

ike proposal proposal-number

undo ike proposal *proposal-number*

Default

An IKE proposal exists, which has the lowest priority and uses the following settings:

- **Encryption algorithm**—DES-CBC in non-FIPS mode and AES-CBC-128 in FIPS mode.
- **Authentication algorithm**—HMAC-SHA1 in non-FIPS mode and SHA256 in FIPS mode.
- **Authentication method**—Preshared key authentication.
- **DH group**—768-bit Diffie-Hellman group in non-FIPS mode and 2048-bit Diffie-Hellman group in FIPS mode.
- **IKE SA lifetime**—86400 seconds.

You cannot change the settings of the default IKE proposal.

Views

System view

Predefined user roles

network-admin

Parameters

proposal-number: Specifies an IKE proposal number in the range of 1 to 65535. The lower the number, the higher the priority of the IKE proposal.

Usage guidelines

During IKE negotiation:

- The initiator sends its IKE proposals to the peer.
  - If the initiator is using an IPsec policy with an IKE profile, the initiator sends all IKE proposals specified for the IKE profile to the peer. An IKE proposal specified earlier for the IKE profile has a higher priority.
  - If the initiator is using an IPsec policy with no IKE profile, the initiator sends all its IKE proposals to the peer. An IKE proposal with a smaller number has a higher priority.
- The peer searches its own IKE proposals for a match. The search starts from the IKE proposal with the highest priority and proceeds in descending order of priority until a match is found. The matching IKE proposals are used to establish the IKE SA. If all user-defined IKE proposals are mismatched, the two peers use their default IKE proposals to establish the IKE SA.

Examples

Create IKE proposal 1 and enter its view.

```
<Sysname> system-view
[Sysname] ike proposal 1
[Sysname-ike-proposal-1]
```

Related commands

display ike proposal

ike signature-identity from-certificate

Use **ike signature-identity from-certificate** to configure the local device to obtain the identity information from the local certificate for signature authentication.

Use **undo ike signature-identity from-certificate** to restore the default.

Syntax

ike signature-identity from-certificate

undo ike signature-identity from-certificate

Default

The local end uses the identity information specified by the **local-identity** or **ike identity** command for signature authentication.

Views

System view

Predefined user roles

network-admin

Usage guidelines

This command requires the local device to always use the identity information in the local certificate for signature authentication, regardless of the **local-identity** or **ike identity** configuration.

Configure this command when the aggressive mode and signature authentication are used and the device interconnects with a Comware 5-based peer device. Comware 5 supports only DN for signature authentication.

If the **ike signature-identity from-certificate** command is not configured, the **local-identity** command configuration, if configured, takes precedence over the **ike identity** command configuration.

Examples

Configure the local device to always obtain the identity information from the local certificate for signature authentication.

```
<Sysname> system-view
[sysname] ike signature-identity from-certificate
```

Related commands

local-identity

ike identity

keychain

Use **keychain** to specify an IKE keychain for preshared key authentication.

Use **undo keychain** to remove an IKE keychain.

Syntax

keychain *keychain-name*

undo keychain *keychain-name*

Default

No IKE keychain is specified for preshared key authentication.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

keychain-name: Specifies an IKE keychain name, a case-insensitive string of 1 to 63 characters.

Usage guidelines

You can specify a maximum of six IKE keychains for an IKE profile. An IKE keychain specified earlier has a higher priority.

Examples

Specify IKE keychain **abc** for IKE profile **1**.

```
<Sysname> system-view
[Sysname] ike profile 1
[Sysname-ike-profile-1] keychain abc
```

Related commands

ike keychain

local-identity

Use **local-identity** to configure the local ID, the ID that the device uses to identify itself to the peer during IKE negotiation.

Use **undo local-identity** to restore the default.

Syntax

local-identity { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **fqdn** [*fqdn-name*] | **user-fqdn** [*user-fqdn-name*] }

undo local-identity

Default

No local ID is configured for an IKE profile. An IKE profile uses the local ID configured in system view by using the **ike identity** command. If the local ID is not configured in system view, the IKE profile uses the IP address of the interface to which the IPsec policy is applied as the local ID.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

address { *ipv4-address* | **ipv6** *ipv6-address* }: Uses an IPv4 or IPv6 address as the local ID.

dn: Uses the DN in the local certificate as the local ID.

fqdn *fqdn-name*: Uses an FQDN as the local ID. The *fqdn-name* argument is a case-sensitive string of 1 to 255 characters, such as www.test.com. If you do not specify this argument, the device name configured by using the **sysname** command is used as the local FQDN.

user-fqdn *user-fqdn-name*: Uses a user FQDN as the local ID. The *user-fqdn-name* argument is a case-sensitive string of 1 to 255 characters, such as adc@test.com. If you do not specify this argument, the device name configured by using the **sysname** command is used as the user FQDN.

Usage guidelines

For digital signature authentication, the device can use any type of ID. For preshared key authentication, the device can use any type of ID other than the DN.

In digital signature authentication, if the local ID is an IP address that is different from the IP address in the local certificate, the device uses its FQDN instead. The FQDN is the device name configured by using the **sysname** command.

The initiator uses the local ID to identify itself to the responder. The responder compares the initiator's ID with the peer IDs configured by the **match remote** command to look for a matching IKE profile.

An IKE profile can have only one local ID.

An IKE profile with no local ID specified uses the local ID configured by using the **ike identity** command in system view.

Examples

Set the local ID to IP address **2.2.2.2**.

```
<Sysname> system-view
[Sysname] ike profile prof1
[Sysname-ike-profile-prof1] local-identity address 2.2.2.2
```

Related commands

match remote

ike identity

match local address (IKE keychain view)

Use **match local address** to specify a local interface or IP address to which an IKE keychain can be applied.

Use **undo match local address** to restore the default.

Syntax

match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } }

undo match local address

Default

An IKE keychain can be applied to any local interface or IP address.

Views

IKE keychain view

Predefined user roles

network-admin

Parameters

interface-type interface-number: Specifies a local interface. It can be any Layer 3 interface.

ipv4-address: Specifies the IPv4 address of a local interface.

ipv6 *ipv6-address*: Specifies the IPv6 address of a local interface.

Usage guidelines

Use this command to specify which address or interface can use the IKE keychain for IKE negotiation. Specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for this command. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.

You can specify a maximum of six IKE keychains for an IKE profile. An IKE keychain specified earlier has a higher priority. To give an IKE keychain a higher priority, you can configure this command for the keychain. For example, suppose you specified IKE keychain A before specifying IKE keychain B, and you configured the peer ID 2.2.0.0/16 for IKE keychain A and the peer ID 2.2.2.0/24 for IKE keychain B. For the local interface with the IP address 3.3.3.3 to negotiate with the peer 2.2.2.6, IKE keychain A is preferred because IKE keychain A was specified earlier. To use IKE keychain B, you can use this command to restrict the application scope of IKE keychain B to address 3.3.3.3.

Examples

Create IKE keychain **key1**.

```
<Sysname> system-view
[Sysname] ike keychain key1
```

Apply IKE keychain **key1** to IP address 2.2.2.2.

```
[sysname-ike-keychain-key1] match local address 2.2.2.1
```

match local address (IKE profile view)

Use **match local address** to specify a local interface or IP address to which an IKE profile can be applied.

Use **undo match local address** to restore the default.

Syntax

match local address { *interface-type interface-number* | { *ipv4-address* | **ipv6** *ipv6-address* } }

undo match local address

Default

An IKE profile can be applied to any local interface or IP address.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

interface-type interface-number: Specifies a local interface. It can be any Layer 3 interface.

ipv4-address: Specifies the IPv4 address of a local interface.

ipv6 *ipv6-address*: Specifies the IPv6 address of a local interface.

Usage guidelines

Use this command to specify which address or interface can use the IKE profile for IKE negotiation. Specify the local address configured in IPsec policy or IPsec policy template view (using the **local-address** command) for this command. If no local address is configured, specify the IP address of the interface that uses the IPsec policy.

An IKE profile configured earlier has a higher priority. To give an IKE profile that is configured later a higher priority, you can configure this command for the profile. For example, suppose you configured IKE profile A before configuring IKE profile B, and you configured the **match remote identity address range 2.2.2.1 2.2.2.100** command for IKE profile A and the **match remote identity address range 2.2.2.1 2.2.2.10** command for IKE profile B. For the local interface with the IP address 3.3.3.3 to negotiate with the peer 2.2.2.6, IKE profile A is preferred because IKE profile A was configured earlier. To use IKE profile B, you can use this command to restrict the application scope of IKE profile B to address 3.3.3.3.

Examples

Create IKE profile **prof1**.

```
<Sysname> system-view
[Sysname] ike profile prof1
```

Apply IKE profile **prof1** to IP address 2.2.2.2.

```
[sysname-ike-profile-prof1] match local address 2.2.2.1
```

match remote

Use **match remote** to configure a peer ID for IKE profile matching.

Use **undo match remote** to delete a peer ID for IKE profile matching.

Syntax

match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } | **fqdn** *fqdn-name* | **user-fqdn** *user-fqdn-name* } }

undo match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } | **fqdn** *fqdn-name* | **user-fqdn** *user-fqdn-name* } }

Default

No peer ID is configured for IKE profile matching.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

certificate *policy-name*: Uses the DN in the peer's digital certificate as the peer ID for IKE profile matching. The *policy-name* argument is a string of 1 to 31 characters.

identity: Uses the specified information as the peer ID for IKE profile matching. The specified information is configured on the peer by using the **local-identity** command.

- **address** *ipv4-address* [*mask* | *mask-length*]: Uses an IPv4 host address or an IPv4 subnet address as the peer ID for IKE profile matching. The *mask-length* argument is in the range of 0 to 32. If you do not specify a mask or mask length, the 32-bit mask is used.
- **address range** *low-ipv4-address high-ipv4-address*: Uses a range of IPv4 addresses as the peer ID for IKE profile matching. The end address must be higher than the start address.
- **address ipv6** *ipv6-address* [*prefix-length*]: Uses an IPv6 host address or an IPv6 subnet address as the peer ID for IKE profile matching. The *prefix-length* argument is in the range of 0 to 128. If you do not specify a prefix length, the 128-bit prefix is used.
- **address ipv6 range** *low-ipv6-address high-ipv6-address*: Uses a range of IPv6 addresses as the peer ID for IKE profile matching. The end address must be higher than the start address.
- **fqdn** *fqdn-name*: Uses the peer's FQDN as the peer ID for IKE profile matching. The *fqdn-name* argument is a case-sensitive string of 1 to 255 characters, such as www.test.com.
- **user-fqdn** *user-fqdn-name*: Uses the peer's user FQDN as the peer ID for IKE profile matching. The *user-fqdn-name* argument is a case-sensitive string of 1 to 255 characters, such as adc@test.com.

Usage guidelines

When an end needs to select an IKE profile, it compares the peer's ID received with the peer IDs of its local IKE profiles. If a match is found, it uses the IKE profile with the matching peer ID for IKE negotiation.

Each IKE profile must have at least one peer ID configured. To make sure only one IKE profile is matched for a peer, do not configure the same peer ID for two or more IKE profiles. If you configure the same peer ID for two or more IKE profiles, which IKE profile is selected for IKE negotiation is unpredictable.

For an IKE profile, you can configure multiple peer IDs. A peer ID configured earlier has a higher priority.

Examples

Create IKE profile **prof1**.

```
<Sysname> system-view
[Sysname] ike profile prof1
```

Configure a peer ID with the identity type of FQDN and the value of **www.test.com**.

```
[Sysname-ike-profile-prof1] match remote identity fqdn www.test.com
```

Configure a peer ID with the identity type of IP address and the value of **10.1.1.1**.

```
[Sysname-ike-profile-prof1] match remote identity address 10.1.1.1
```

Related commands

local-identity

pre-shared-key

Use **pre-shared-key** to configure a preshared key.

Use **undo pre-shared-key** to delete a preshared key.

Syntax

In non-FIPS mode:

pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** { **cipher** | **simple** } *string*

undo pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* }

In FIPS mode:

pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* } **key** [**cipher** *string*]

undo pre-shared-key { **address** { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] } | **hostname** *host-name* }

Default

No preshared key is configured.

Views

IKE keychain view

Predefined user roles

network-admin

Parameters

address: Specifies a peer by its address.

ipv4-address: Specifies the IPv4 address of the peer.

mask: Specifies the mask in dotted decimal notation. The default mask is 255.255.255.255.

mask-length: Specifies the mask length in the range of 0 to 32. The default mask length is 32.

ipv6: Specifies an IPv6 peer.

ipv6-address: Specifies the IPv6 address of the peer.

prefix-length: Specifies the prefix length in the range of 0 to 128. The default prefix length is 128.

hostname *host-name*: Specifies a peer by its hostname, a case-sensitive string of 1 to 255 characters.

key: Specifies a preshared key.

cipher: Specifies a preshared key in encrypted form.

simple: Specifies a preshared key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

string: Specifies the preshared key. The key is case sensitive. In non-FIPS mode, its plaintext form is a string of 1 to 128 characters and its encrypted form is a string of 1 to 201 characters. In FIPS mode, its plaintext form is a string of 1 to 128 characters and its encrypted form is a string of 15 to 201 characters.

Usage guidelines

The address option or the hostname option specifies the peer with which the device can use the preshared key to perform IKE negotiation.

Two peers must be configured with the same preshared key to pass preshared key authentication.

In FIPS mode, if you do not specify the **cipher** *string* option, you specify a plaintext preshared key in interactive mode. The key is a case-sensitive string of 15 to 128 characters, and it must contain uppercase and lowercase letters, digits, and special characters other than the question mark (?). In non-FIPS mode, this command does not support configuring a preshared key in interactive mode.

Examples

Create IKE keychain **key1** and enter IKE keychain view.

```
<Sysname> system-view
[Sysname] ike keychain key1
```

Set the preshared key to be used for IKE negotiation with peer 1.1.1.2 to **123456TESTplat&!**.

```
[Sysname-ike-keychain-key1] pre-shared-key address 1.1.1.2 255.255.255.255 key simple
123456TESTplat&!
```

Related commands

authentication-method

keychain

priority (IKE keychain view)

Use **priority** to specify a priority for an IKE keychain.

Use **undo priority** to restore the default.

Syntax

priority *priority*

undo priority

Default

The priority of an IKE keychain is 100.

Views

IKE keychain view

Predefined user roles

network-admin

Parameters

priority *priority*: Specifies a priority number in the range of 1 to 65535. The lower the priority number, the higher the priority.

Usage guidelines

To determine the priority of an IKE keychain, the device examines the existence of the **match local address** command before examining the priority number. An IKE keychain with the **match local address** command configured has a higher priority than an IKE keychain that does not have the **match local address** command configured.

Examples

Set the priority to 10 for IKE keychain **key1**.

```
<Sysname> system-view
[Sysname] ike keychain key1
[Sysname-ike-keychain-key1] priority 10
```

priority (IKE profile view)

Use **priority** to specify a priority for an IKE profile.

Use **undo priority** to restore the default.

Syntax

priority *priority*

undo priority

Default

The priority of an IKE profile is 100.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

priority *priority*: Specifies a priority number in the range of 1 to 65535. The smaller the priority number, the higher the priority.

Usage guidelines

To determine the priority of an IKE profile, the device examines the existence of the **match local address** command before examining the priority number. An IKE profile with the **match local address** command configured has a higher priority than an IKE profile that does not have the **match local address** command configured.

Examples

Set the priority to 10 for IKE profile **prof1**.

```
<Sysname> system-view
[Sysname] ike profile prof1
[Sysname-ike-profile-prof1] priority 10
```

proposal

Use **proposal** to specify IKE proposals for an IKE profile.

Use **undo proposal** to restore the default.

Syntax

proposal *proposal-number*&<1-6>

undo proposal

Default

No IKE proposals are specified for an IKE profile and the IKE proposals configured in system view are used for IKE negotiation.

Views

IKE profile view

Predefined user roles

network-admin

Parameters

proposal-number&<1-6>: Specifies a space-separated list of up to six IKE proposals by their numbers in the range of 1 to 65535. An IKE proposal specified earlier has a higher priority.

Usage guidelines

When acting as the initiator, the device sends the specified IKE proposals to its peer for IKE negotiation. When acting as the responder, the device uses the IKE proposals configured in system view to match the IKE proposals received from the initiator.

Examples

Specify IKE proposal **10** for IKE profile **prof1**.

```
<Sysname> system-view
[Sysname] ike profile prof1
[Sysname-ike-profile-prof1] proposal 10
```

Related commands

reset ike sa

Use **reset ike sa** to delete IKE SAs.

Syntax

reset ike sa [**connection-id** *connection-id*]

Views

User view

Predefined user roles

network-admin

Parameters

connection-id *connection-id*: Specifies the connection ID of the IKE SA to be cleared, in the range of 1 to 2000000000.

Usage guidelines

When you delete an IKE SA, the device automatically sends a notification to the peer.

Examples

Display the current IKE SAs.

```
<Sysname> display ike sa
    Connection-ID  Remote            Flag        DOI
  -------------------------------------------------------------
      1            202.38.0.2        RD          IPsec
      2            202.38.0.3        RD          IPsec
Flags:
RD--READY RL--REPLACED FD-FADING RK-REKEY
```

Delete the IKE SA with the connection ID **2**.

```
<Sysname> reset ike sa connection-id 2
```

Display the current IKE SAs.

```
<Sysname> display ike sa

reset ike statistics

Use **reset ike statistics** command to clear IKE MIB statistics.

Syntax

reset ike statistics

Views

User view

Predefined user roles

network-admin

Examples

Clears IKE MIB statistics.

```
<Sysname> reset ike statistics
```

Related commands

snmp-agent trap enable ike

sa duration

Use **sa duration** to set the IKE SA lifetime for an IKE proposal.

Use **undo sa duration** to restore the default.

Syntax

sa duration *seconds*

undo sa duration

Default

The IKE SA lifetime is 86400 seconds for an IKE proposal.

Views

IKE proposal view

Predefined user roles

network-admin

Parameters

seconds: Specifies the IKE SA lifetime in seconds, in the range of 60 to 604800.

Usage guidelines

Before an IKE SA expires, IKE negotiates a new SA. The new SA takes effect immediately after it is negotiated. The old IKE SA will be cleared when it expires.

If the communicating peers are configured with different IKE SA lifetime settings, the smaller setting takes effect.

Examples

Set the IKE SA lifetime to 600 seconds for IKE **proposal 1**.

```
<Sysname> system-view
[Sysname] ike proposal 1
[Sysname-ike-proposal-1] sa duration 600
```

Related commands

display ike proposal

snmp-agent trap enable ike

Use **snmp-agent trap enable ike** command to enable SNMP notifications for IKE.

Use **undo snmp-agent trap enable ike** to disable SNMP notifications for IKE.

Syntax

snmp-agent trap enable ike [**attr-not-support** | **auth-failure** | **cert-type-unsupport** | **cert-unavailable** | **decrypt-failure** | **encrypt-failure** | **global** | **invalid-cert-auth** | **invalid-cookie** | **invalid-id** | **invalid-proposal** | **invalid-protocol** | **invalid-sign** | **no-sa-failure** | **proposal-add** | **proposal–delete** | **tunnel-start** | **tunnel-stop** | **unsupport-exch-type**] *

undo snmp-agent trap enable ike [**attr-not-support** | **auth-failure** | **cert-type-unsupport** | **cert-unavailable** | **decrypt-failure** | **encrypt-failure** | **global** | **invalid-cert-auth** | **invalid-cookie** | **invalid-id** | **invalid-proposal** | **invalid-protocol** | **invalid-sign** | **no-sa-failure** | **proposal-add** | **proposal–delete** | **tunnel-start** | **tunnel-stop** | **unsupport-exch-type**] *

Default

All SNMP notifications for IKE are disabled.

Views

System view

Predefined user roles

network-admin

Parameters

attr-not-support: Specifies notifications about attribute-unsupported failures.

auth-failure: Specifies notifications about authentication failures.

cert-type-unsupport: Specifies notifications about certificate-type-unsupported failures.

cert-unavailable: Specifies notifications about certificate-unavailable failures.

decrypt-failure: Specifies notifications about decryption failures.

encrypt-failure: Specifies notifications about encryption failures.

global: Specifies notifications globally.

invalid-cert-auth: Specifies notifications about invalid-certificate-authentication failures.

invalid-cookie: Specifies notifications about invalid-cookie failures.

invalid-id: Specifies notifications about invalid-ID failures.

invalid-proposal: Specifies notifications about invalid-IKE-proposal failures.

invalid-protocol: Specifies notifications about invalid-protocol failures.

invalid-sign: Specifies notifications about invalid-signature failures.

no-sa-failure: Specifies notifications about SA-not-found failures.

proposal-add: Specifies notifications about events of adding IKE proposals.

proposal-delete: Specifies notifications about events of deleting IKE proposals.

tunnel-start: Specifies notifications about events of creating IKE tunnels.

tunnel-stop: Specifies notifications about events of deleting IKE tunnels.

unsupport-exch-type: Specifies notifications about negotiation-type-unsupported failures.

Usage guidelines

If you do not specify any keywords, this command enables or disables all SNMP notifications for IKE.

To generate and output SNMP notifications for a specific IKE failure type or event type, perform the following tasks:

1. Enable SNMP notifications for IKE globally.
2. Enable SNMP notifications for the failure type or event type.

Examples

Enable SNMP notifications for IKE globally.

```
<Sysname> system-view
[Sysname] snmp-agent trap enable ike global
```

Enable SNMP notifications for events of creating IKE tunnels.

```
[Sysname] snmp-agent trap enable ike tunnel-start
```

IKEv2 commands

address

Use **address** to specify the IP address or IP address range of an IKEv2 peer.

Use **undo address** to restore the default.

Syntax

address { *ipv4-address* [*mask* | *mask-length*] | **ipv6** *ipv6-address* [*prefix-length*] }

undo address

Default

The IKEv2 peer's IP address or IP address range is not specified.

Views

IKEv2 peer view

Predefined user roles

network-admin

Parameters

ipv4-address: Specifies the IPv4 address of the IKEv2 peer.

mask: Specifies the subnet mask of the IPv4 address.

mask-length: Specifies the subnet mask length of the IPv4 address, in the range of 0 to 32.

ipv6 *ipv6-address*: Specifies the IPv6 address of the IKEv2 peer.

prefix-length: Specifies the prefix length of the IPv6 address, in the range of 0 to 128.

Usage guidelines

Both the initiator and the responder can look up an IKEv2 peer by IP address in IKEv2 negotiation.

The IP addresses of different IKEv2 peers in the same IKEv2 keychain cannot be the same.

Examples

Create an IKEv2 keychain named **key1**.

```
<Sysname> system-view
[Sysname] ikev2 keychain key1
```

Create an IKEv2 peer named **peer1**.

```
[Sysname-ikev2-keychain-key1] peer peer1
```

Specify the IKEv2 peer's IP address 3.3.3.3 with subnet mask 255.255.255.0.

```
[Sysname-ikev2-keychain-key1-peer-peer1] address 3.3.3.3 255.255.255.0
```

Related commands

ikev2 keychain

peer

authentication-method

Use **authentication-method** to specify the local or remote identity authentication method.

Use **undo authentication-method** to remove the local or remote identity authentication method.

Syntax

authentication-method { **local** | **remote** } { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

undo authentication-method local

undo authentication-method remote { **dsa-signature** | **ecdsa-signature** | **pre-share** | **rsa-signature** }

Default

No local or remote identity authentication method is specified.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

local: Specifies the local identity authentication method.

remote: Specifies the remote identity authentication method.

dsa-signature: Specifies the DSA signatures as the identity authentication method.

ecdsa-signature: Specifies the ECDSA signatures as the identity authentication method.

pre-share: Specifies the preshared key as the identity authentication method.

rsa-signature: Specifies the RSA signatures as the identity authentication method.

Usage guidelines

The local and remote identity authentication methods must both be specified and they can be different.

You can specify only one local identity authentication method. You can specify multiple remote identity authentication methods by executing this command multiple times when there are multiple remote ends whose authentication methods are unknown.

If you use RSA, DSA, or ECDSA signature authentication, you must specify PKI domains for obtaining certificates. You can specify PKI domains by using the **certificate domain** command in IKEv2 profile view. If you do not specify PKI domains in IKEv2 profile view, the PKI domains configured by the **pki domain** command in system view will be used.

If you specify the preshared key method, you must specify a preshared key for the IKEv2 peer in the keychain used by the IKEv2 profile.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Specify the preshared key and RSA signatures as the local and remote authentication methods, respectively.

```
[Sysname-ikev2-profile-profile1] authentication local pre-share
[Sysname-ikev2-profile-profile1] authentication remote rsa-signature
```

Specify PKI domain **genl** as the PKI domain for obtaining certificates.

```
[Sysname-ikev2-profile-profile1] certificate domain genl
```

Specify IKEv2 keychain **keychain1**.

```
[Sysname-ikev2-profile-profile1] keychain keychain1
```

Related commands

display ikev2 profile

certificate domain (IKEv2 profile view)

keychain (IKEv2 profile view)

certificate domain

Use **certificate domain** to specify a PKI domain for signature authentication in IKEv2 negotiation.

Use **undo certificate domain** to remove a PKI domain for signature authentication in IKEv2 negotiation.

Syntax

certificate domain *domain-name* [**sign** | **verify**]

undo certificate domain *domain-name*

Default

PKI domains configured in system view are used for signature authentication.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

domain-name: Specifies a PKI domain by its name, a case-insensitive string of 1 to 31 characters.

sign: Uses the local certificate in the PKI domain to generate a signature.

verify: Uses the CA certificate in the PKI domain to verify the remote end's certificate.

Usage guidelines

If you do not specify the **sign** or **verify** keyword, the PKI domain is used for both **sign** and **verify** purposes. You can specify a PKI domain for each purpose by executing this command multiple times. If you specify the same PKI domain for both purposes, the later configuration takes effect. For example, if you execute **certificate domain abc sign** and **certificate domain abc verify** successively, the PKI domain **abc** will be used only for verification.

If the local end uses RSA, DSA, or ECDSA signature authentication, you must specify a PKI domain for signature generation. If the remote end uses RSA, DSA, or ECDSA signature authentication, you must specify a PKI domain for verifying the remote end's certificate. If you do not specify PKI domains, the PKI domains configured in system view will be used.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
```

```
[Sysname] ikev2 profile profile1
```

Specify PKI domain **abc** for signature. Specify PKI domain **def** for verification.

```
[Sysname-ikev2-profile-profile1] certificate domain abc sign
[Sysname-ikev2-profile-profile1] certificate domain def verify
```

Related commands

authentication-method

pki domain

config-exchange

Use **config-exchange** to enable configuration exchange.

Use **undo config-exchange** to disable configuration exchange.

Syntax

config-exchange { **request** | **set** { **accept** | **send** } }

undo config-exchange { **request** | **set** { **accept** | **send** } }

Default

Configuration exchange is disabled.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

request: Enables the device to send request messages carrying the configuration request payload during the IKE_AUTH exchange.

set: Specifies the configuration set payload exchange.

accept: Enables the device to accept the configuration set payload carried in Info messages.

send: Enables the device to send Info messages carrying the configuration set payload.

Usage guidelines

The configuration exchange feature enables the local and remote ends to exchange configuration data, such as gateway address, internal IP address, and route. The exchange includes data request and response, and data push and response. The enterprise center can push IP addresses to branches. The branches can request IP addresses, but the requested IP addresses cannot be used.

You can specify both **request** and **set** for the device.

If you specify **request** for the local end, the remote end will respond if it can obtain the requested data.

If you specify **set send** for the local end, you must specify **set accept** for the remote end.

The device with **set send** specified pushes an IP address after the IKEv2 SA is set up if it does not receive any configuration request from the peer.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Enable the local end to add the configuration request payload to the request message of IKE_AUTH exchange.

```
[Sysname-ikev2-profile-profile1] config-exchange request
```

Related commands

display ikev2 profile

dh

Use **dh** to specify DH groups to be used in IKEv2 key negotiation.

Use **undo group** to restore the default.

Syntax

In non-FIPS mode:

dh { **group1** | **group14** | **group2** | **group24** | **group5** | **group19** | **group20** } *

undo dh

In FIPS mode:

dh { **group14** | **group19** | **group20** } *

undo dh

Default

No DH group is specified for an IKEv2 proposal.

Views

IKEv2 proposal view

Predefined user roles

network-admin

Parameters

group1: Uses the 768-bit Diffie-Hellman group.

group2: Uses the 1024-bit Diffie-Hellman group.

group5: Uses the 1536-bit Diffie-Hellman group.

group14: Uses the 2048-bit Diffie-Hellman group.

group24: Uses the 2048-bit Diffie-Hellman group with the 256-bit prime order subgroup.

group19: Uses the 256-bit ECP Diffie-Hellman group.

group20: Uses the 384-bit ECP Diffie-Hellman group.

Usage guidelines

A DH group with a higher group number provides higher security but needs more time for processing. To achieve the best trade-off between processing performance and security, choose proper DH groups for your network.

You must specify a minimum of one DH group for an IKEv2 proposal. Otherwise, the proposal is incomplete and useless.

You can specify multiple DH groups for an IKEv2 proposal. A group specified earlier has a higher priority.

Examples

Specify DH group 1 for IKEv2 proposal 1.

```
<Sysname> system-view
[Sysname] ikev2 proposal 1
[Sysname-ikev2-proposal-1] dh group1
```

Predefined user roles

network-admin

network-operator

Parameters

policy-name: Specifies an IKEv2 policy by its name, a case-insensitive string of 1 to 63 characters.

default: Specifies the default IKEv2 policy.

Usage guidelines

If you do not specify any parameters, this command displays the configuration of all IKEv2 policies.

Examples

Display the configuration of all IKEv2 policies.

```
<Sysname> display ikev2 policy
IKEv2 policy: 1
  Priority: 100
  Match local address: 1.1.1.1
  Match local address ipv6: 1:1::1:1
  Match VRF:
  Proposal: 1
  Proposal: 2
IKEv2 policy: default
  Match VRF:
  Proposal: default
```

Table 13 Command output

Field	Description
IKEv2 policy	Name of the IKEv2 policy.
Priority	Priority of the IKEv2 policy.
Match local address	IPv4 address to which the IKEv2 policy can be applied.
Match local address ipv6	IPv6 address to which the IKEv2 policy can be applied.

Field	Description
Match VRF	This field is not supported in the current software version. VPN instance to which the IKEv2 policy can be applied.
Proposal	IKEv2 proposal that the IKEv2 policy uses.

network-operator

Parameters

profile-name: Specifies an IKEv2 profile by its name, a case-insensitive string of 1 to 63 characters. If you do not specify an IKEv2 profile, this command displays the configuration of all IKEv2 profiles.

Examples

Display the configuration of all IKEv2 profiles.

```
<Sysname> display ikev2 profile
IKEv2 profile: 1
  Priority: 100
  Match criteria:
    Local address 1.1.1.1
    Local address Vlan-interface100
    Local address 1:1::1:1
    Remote identity ipv4 address 3.3.3.3/32
    VRF vrf1
  Inside-vrf:
  Local identity: address 1.1.1.1
  Local authentication method: pre-share
  Remote authentication methods: pre-share
  Keychain: Keychain1
  Sign certificate domain:
     Domain1
     abc
  Verify certificate domain:
     Domain2
     yy
```

```
SA duration: 500
DPD: Interval 32, retry 23, periodic
Config-exchange: Request, Set send, Set accept
NAT keepalive: 10
AAA authorization: Domain domain1, username ikev2
```

Table 14 Command output

Field	Description
IKEv2 profile	Name of the IKEv2 profile.
Priority	Priority of the IKEv2 profile.
Match criteria	Criteria for looking up the IKEv2 profile.
Inside-vrf	This field is not supported in the current software version. Inside VRF instance.
Local identity	ID of the local end.
Local authentication method	Method that the local end uses for authentication.
Remote authentication methods	Methods that the remote end uses for authentication.
Keychain	IKEv2 keychain that the IKEv2 profile uses.
Sign certificate domain	PKI domain used for signature generation.
Verify certificate domain	PKI domain used for verifying the remote end's certificate.
SA duration	Lifetime of the IKEv2 SA.
DPD	DPD settings: • Detection interval in seconds. • Retry interval in seconds. • Detection mode, on demand or periodically. If DPD is disabled, this field displays **Disabled**.
Config-exchange	Configuration exchange settings: • **Request**—The local end sends request messages carrying the configuration request payload during the IKE_AUTH exchange. • **Set accept**—The local end accepts the configuration set payload carried in Info messages. • **Set send**—The local end sends Info messages carrying the configuration set payload.
NAT keepalive	NAT keepalive interval in seconds.
AAA authorization	This field is not supported in the current software version. AAA authorization settings: • ISP domain name. • Username.

Use **`display ikev2 proposal`** to display the IKEv2 proposal configuration.

Syntax

display ikev2 proposal [*name* | **default**]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

name: Specifies an IKEv2 proposal by its name, a case-insensitive string of 1 to 63 characters.

default: Specifies the default IKEv2 proposal.

Usage guidelines

This command displays IKEv2 proposals in descending order of priorities. If you do not specify any parameters, this command displays the configuration of all IKEv2 proposals.

Examples

Display the configuration of all IKEv2 proposals.

```
<Sysname> display ikev2 proposal
IKEv2 proposal : 1
  Encryption: 3DES-CBC AES-CBC-128 AES-CTR-192 CAMELLIA-CBC-128
  Integrity: MD5 SHA256 AES-XCBC-MAC
  PRF: MD5 SHA256 AES-XCBC-MAC
  DH Group: MODP1024/Group2 MODP1536/Group5

IKEv2 proposal : default
  Encryption: AES-CBC-128 3DES-CBC
  Integrity: SHA1 MD5
  PRF: SHA1 MD5
  DH Group: MODP1536/Group5 MODP1024/Group2
```

Table 15 Command output

Field	Description
IKEv2 proposal	Name of the IKEv2 proposal.
Encryption	Encryption algorithms that the IKEv2 proposal uses.
Integrity	Integrity protection algorithms that the IKEv2 proposal uses.
PRF	PRF algorithms that the IKEv2 proposal uses.
DH Group	DH groups that the IKEv2 proposal uses.

Related commands

ikev2 proposal

display ikev2 sa

Use **display ikev2 sa** to display the IKEv2 SA information.

Syntax

display ikev2 sa [**count** | [{ **local** | **remote** } { *ipv4-address* | **ipv6** *ipv6-address* }] [**verbose** [**tunnel** *tunnel-id*]]]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

count: Displays the number of IKEv2 SAs.

local: Displays IKEv2 SA information for a local IP address.

remote: Displays IKEv2 SA information for a remote IP address.

ipv4-address: Specifies a local or remote IPv4 address.

ipv6 *ipv6-address*: Specifies a local or remote IPv6 address.

verbose: Displays detailed information. If you do not specify this keyword, the command displays the summary information.

tunnel *tunnel-id*: Displays detailed IKEv2 SA information for an IPsec tunnel. The *tunnel-id* argument specifies an IPsec tunnel by its ID in the range of 1 to 2000000000.

Usage guidelines

If you do not specify any parameters, this command displays summary information about all IKEv2 SAs.

Examples

Display summary information about all IKEv2 SAs.

```
<Sysname> display ikev2 sa
     Tunnel ID          Local             Remote             Status
  ----------------------------------------------------------------------
     1                  1.1.1.1/500       1.1.1.2/500        EST
     2                  2.2.2.1/500       2.2.2.2/500        EST
  Status:
  IN-NEGO: Negotiating, EST: Established, DEL: Deleting
```

Display summary IKEv2 SA information for the remote IP address 1.1.1.2.

```
<Sysname> display ikev2 sa remote 1.1.1.2
     Tunnel ID          Local             Remote             Status
  ----------------------------------------------------------------------
     1                  1.1.1.1/500       1.1.1.2/500        EST
  Status:
  IN-NEGO: Negotiating, EST: Established, DEL: Deleting
```

Table 16 Command output

Field	Description
Tunnel ID	ID of the IPsec tunnel to which the IKEv2 SA belongs.
Local	Local IP address of the IKEv2 SA.
Remote	Remote IP address of the IKEv2 SA.

Field	Description
Status	Status of the IKEv2 SA: • **IN-NEGO (Negotiating)**—The IKEv2 SA is under negotiation. • **EST (Established)**—The IKEv2 SA has been set up. • **DEL (Deleting)**—The IKEv2 SA is about to be deleted.

Display detailed information about all IKEv2 SAs.

dpd

Use **dpd** to configure IKEv2 DPD.

Use **undo dpd** to disable IKEv2 DPD.

Syntax

dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

undo dpd interval

Default

IKEv2 DPD is disabled. The global IKEv2 DPD settings are used.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies a DPD triggering interval in the range of 10 to 3600 seconds.

retry *seconds*: Specifies the DPD retry interval in the range of 2 to 60 seconds. The default is 5 seconds.

on-demand: Triggers DPD on demand. The device triggers DPD if it has IPsec traffic to send and has not received any IPsec packets from the peer for the specified interval.

periodic: Triggers DPD at regular intervals. The device triggers DPD at the specified interval.

Usage guidelines

DPD is triggered periodically or on-demand. As a best practice, use the on-demand mode when the device communicates with a large number of IKEv2 peers. For an earlier detection of dead peers, use the periodic triggering mode, which consumes more bandwidth and CPU.

The triggering interval must be longer than the retry interval, so that the device will not trigger a new round of DPD during a DPD retry.

Examples

Configure on-demand IKEv2 DPD. Set the DPD triggering interval to 10 seconds and the retry interval to 5 seconds.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
[Sysname-ikev2-profile-profile1] dpd interval 10 retry 5 on-demand
```

Related commands

ikev2 dpd

encryption

Use **encryption** to specify encryption algorithms for an IKEv2 proposal.

Use **undo encryption** to restore the default.

Syntax

In non-FIPS mode:

encryption { **3des-cbc** | **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** | **camellia-cbc-128** | **camellia-cbc-192** | **camellia-cbc-256** | **des-cbc** } *

undo encryption

In FIPS mode:

encryption { **aes-cbc-128** | **aes-cbc-192** | **aes-cbc-256** | **aes-ctr-128** | **aes-ctr-192** | **aes-ctr-256** } *

undo encryption

Default

No encryption algorithm is specified for an IKEv2 proposal.

Views

IKEv2 proposal view

Predefined user roles

network-admin

Parameters

3des-cbc: Specifies the 3DES algorithm in CBC mode, which uses a 168-bit key.

aes-cbc-128: Specifies the AES algorithm in CBC mode, which uses a 128-bit key.

aes-cbc-192: Specifies the AES algorithm in CBC mode, which uses a 192-bit key.

aes-cbc-256: Specifies the AES algorithm in CBC mode, which uses a 256-bit key.

aes-ctr-128: Specifies the AES algorithm in CTR mode, which uses a 128-bit key.

aes-ctr-192: Specifies the AES algorithm in CTR mode, which uses a 192-bit key.

aes-ctr-256: Specifies the AES algorithm in CTR mode, which uses a 256-bit key.

camellia-cbc-128: Specifies the Camellia algorithm in CBC mode, which uses a 128-bit key.

camellia-cbc-192: Specifies the Camellia algorithm in CBC mode, which uses a 192-bit key.

camellia-cbc-256: Specifies the Camellia algorithm in CBC mode, which uses a 256-bit key.

des-cbc: Specifies the DES algorithm in CBC mode, which uses a 56-bit key.

Usage guidelines

You must specify a minimum of one encryption algorithm for an IKEv2 proposal. Otherwise, the proposal is incomplete and useless. You can specify multiple encryption algorithms for an IKEv2 proposal. An algorithm specified earlier has a higher priority.

Examples

Specify the 168-bit 3DES algorithm in CBC mode as the encryption algorithm for IKE proposal **prop1**.

```
<Sysname> system-view
[Sysname] ikev2 proposal prop1
[Sysname-ikev2-proposal-prop1] encryption 3des-cbc
```

Related commands

ikev2 proposal

hostname

Use **hostname** to specify the host name of an IKEv2 peer.

Use **undo hostname** to restore the default.

Syntax

hostname *name*

undo hostname

Default

The IKEv2 peer's host name is not specified.

Views

IKEv2 peer view

Predefined user roles

network-admin

Parameters

name: Specifies the host name of the IKEv2 peer, a case-insensitive string of 1 to 253 characters.

Usage guidelines

Only the initiator can look up an IKEv2 peer by host name in IKEv2 negotiation, and the initiator must use an IPsec policy rather than an IPsec profile.

Examples

Create an IKEv2 keychain named **key1**.

```
<Sysname> system-view
[Sysname] ikev2 keychain key1
```

Create an IKEv2 peer named **peer1**.

```
[Sysname-ikev2-keychain-key1] peer peer1
```

Specify host name **test** of the IKEv2 peer.

```
[Sysname-ikev2-keychain-key1-peer-peer1] hostname test
```

Related commands

ikev2 keychain

peer

identity

Use **identity** to specify the ID of an IKEv2 peer.

Use **undo identity** to restore the default.

Syntax

identity { **address** { *ipv4-address* | **ipv6** { *ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* }

undo identity

Default

The IKEv2 peer's ID is not specified.

Views

IKEv2 peer view

Predefined user roles

network-admin

Parameters

ipv4-address: Specifies the IPv4 address of the peer.

ipv6 *ipv6-address*: Specifies the IPv6 address of the peer.

fqdn *fqdn-name*: Specifies the FQDN of the peer. The *fqdn-name* argument is a case-sensitive string of 1 to 255 characters, such as www.test.com.

email *email-string*: Specifies the email address of the peer. The *email-string* argument is a case-sensitive string of 1 to 255 characters in the format defined by RFC 822, such as esec@test.com.

key-id *key-id-string*: Specifies the remote gateway's key ID. The *key-id-string* argument is a case-sensitive string of 1 to 255 characters, and is usually a vendor-specific string for doing proprietary types of identification.

Usage guidelines

Only the responder can look up an IKEv2 peer by ID in IKEv2 negotiation. The initiator does not know the peer ID when initiating the IKEv2 negotiation, so it cannot use an ID for IKEv2 peer lookup.

Examples

Create an IKEv2 keychain named **key1**.

```
<Sysname> system-view
[Sysname] ikev2 keychain key1
```

Create an IKEv2 peer named **peer1**.

```
[Sysname-ikev2-keychain-key1] peer peer1
```

Specify IPv4 address 1.1.1.2 as the ID of the IKEv2 peer.

```
[Sysname-ikev2-keychain-key1-peer-peer1] identity address 1.1.1.2
```

Related commands

ikev2 keychain

peer

identity local

Use **identity local** to configure the local ID, the ID that the device uses to identify itself to the peer during IKEv2 negotiation..

Use **undo identity local** to restore the default.

Syntax

identity local { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **dn** | **email** *email-string* | **fqdn** *fqdn-name* | **key-id** *key-id-string* }

undo identity local

Default

No local ID is configured. The IP address of the interface to which the IPsec policy is applied is used as the local ID.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

address { *ipv4-address* | **ipv6** *ipv6-address* }: Uses an IPv4 or IPv6 address as the local ID.

dn: Uses the DN in the local certificate as the local ID.

email *email-string*: Uses an email address as the local ID. The *email-string* argument is a case-sensitive string of 1 to 255 characters in the format defined by RFC 822, such as sec@abc.com.

fqdn *fqdn-name*: Uses an FQDN as the local ID. The *fqdn-name* argument is a case-sensitive string of 1 to 255 characters, such as www.test.com.

key-id *key-id-string*: Uses the device's key ID as the local ID. The *key-id-string* argument is a case-sensitive string of 1 to 255 characters, and is usually a vendor-specific string for doing proprietary types of identification.

Usage guidelines

Peers exchange local IDs for identifying each other in negotiation.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Use IP address 2.2.2.2 as the local ID.

```
[Sysname-ikev2-profile-profile1] identity local address 2.2.2.2
```

Related commands

peer

ikev2 cookie-challenge

Use **ikev2 cookie-challenge** to enable the cookie challenging feature.

Use **undo ikev2 cookie-challenge** to disable the cookie challenging feature.

Syntax

ikev2 cookie-challenge *number*

undo ikev2 cookie-challenge

Default

The cookie challenging feature is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

number: Specifies the threshold for triggering the cookie challenging feature. The value range for this argument is 0 to 1000 half-open IKE SAs.

Usage guidelines

When an IKEv2 responder maintains a threshold number of half-open IKE SAs, it starts the cookie challenging mechanism. The responder generates a cookie and includes it in the response sent to the initiator. If the initiator initiates a new IKE_SA_INIT request that carries the correct cookie, the responder considers the initiator valid and proceeds with the negotiation. If the carried cookie is incorrect, the responder terminates the negotiation.

This feature can protect the responder against DoS attacks which aim to exhaust the responder's system resources by using a large number of IKE_SA_INIT requests with forged source IP addresses.

Examples

Enable the cookie challenging feature and set the threshold to 450.

```
<Sysname> system-view
[Sysname] ikev2 cookie-challenge 450
```

ikev2 dpd

Use **ikev2 dpd** to configure global IKEv2 DPD.

Use **undo ikev2 dpd** to disable global IKEv2 DPD.

Syntax

ikev2 dpd interval *interval* [**retry** *seconds*] { **on-demand** | **periodic** }

undo ikev2 dpd interval

Default

The global IKEv2 DPD feature is disabled.

Views

System view

Predefined user roles

network-admin

Parameters

interval *interval*: Specifies a DPD triggering interval in the range of 10 to 3600 seconds.

retry *seconds*: Specifies the DPD retry interval in the range of 2 to 60 seconds. The default is 5 seconds.

on-demand: Triggers DPD on demand. The device triggers DPD if it has IPsec traffic to send and has not received any IPsec packets from the peer for the specified interval.

periodic: Triggers DPD at regular intervals. The device triggers DPD at the specified interval.

Usage guidelines

DPD is triggered periodically or on-demand. As a best practice, use the on-demand mode when the device communicates with a large number of IKEv2 peers. For an earlier detection of dead peers, use the periodic triggering mode, which consumes more bandwidth and CPU.

The triggering interval must be longer than the retry interval, so that the device will not trigger a new round of DPD during a DPD retry.

You can configure IKEv2 DPD in both IKEv2 profile view and system view. The IKEv2 DPD settings in IKEv2 profile view apply. If you do not configure IKEv2 DPD in IKEv2 profile view, the IKEv2 DPD settings in system view apply.

Examples

Configure the device to trigger IKEv2 DPD if it has IPsec traffic to send and has not received any IPsec packets from the peer for 15 seconds.

```
<Sysname> system-view
[Sysname] ikev2 dpd interval 15 on-demand
```

Configure the device to trigger IKEv2 DPD every 15 seconds.

```
<Sysname> system-view
[Sysname] ikev2 dpd interval 15 periodic
```

Related commands

dpd (IKEv2 profile view)

ikev2 keychain

Use **ikev2 keychain** to create an IKEv2 keychain and enter its view, or enter the view of an existing IKEv2 keychain.

Use **undo ikev2 keychain** to delete an IKEv2 keychain.

Syntax

ikev2 keychain *keychain-name*

undo ikev2 keychain *keychain-name*

Default

No IKEv2 keychains exist.

Views

System view

Predefined user roles

network-admin

Parameters

keychain-name: Specifies a name for the IKEv2 keychain. The keychain name is a case-insensitive string of 1 to 63 characters and cannot contain a hyphen (-).

Usage guidelines

An IKEv2 keychain is required on both ends if either end uses preshared key authentication. The preshared key configured on both ends must be the same.

You can configure multiple IKEv2 peers in an IKEv2 keychain.

Examples

Create an IKEv2 keychain named **key1** and enter IKEv2 keychain view.

```
<Sysname> system-view
[Sysname] ikev2 keychain key1
[Sysname-ikev2-keychain-key1]
```

ikev2 nat-keepalive

Use **ikev2 nat-keepalive** to set the NAT keepalive interval.

Use **undo ikev2 nat-keepalive** to restore the default.

Syntax

ikev2 nat-keepalive *seconds*

undo ikev2 nat-keepalive

Default

The NAT keepalive interval is 10 seconds.

Views

System view

Predefined user roles

network-admin

Parameters

seconds: Specifies the NAT keepalive interval in seconds, in the range of 5 to 3600.

Usage guidelines

This command takes effect when the device resides in the private network behind a NAT device. The device must send NAT keepalive packets regularly to its peer to keep the NAT session alive, so that the peer can access the device.

The NAT keepalive interval must be shorter than the NAT session lifetime.

Examples

Set the NAT keepalive interval to 5 seconds.

```
<Sysname> system-view
[Sysname] ikev2 nat-keepalive 5
```

ikev2 policy

Use **ikev2 policy** to create an IKEv2 policy and enter its view, or enter the view of an existing IKEv2 policy.

Use **undo ikev2 policy** to delete an IKEv2 policy.

Syntax

ikev2 policy *policy-name*

undo ikev2 policy *policy-name*

Default

An IKEv2 policy named **default** exists, which uses the default IKEv2 proposal and matches any local addresses.

Views

System view

Predefined user roles

network-admin

Parameters

policy-name: Specifies a name for the IKEv2 policy. The policy name is a case-insensitive string of 1 to 63 characters.

Usage guidelines

Each end must have an IKEv2 policy for the IKE_SA_INIT exchange. The initiator looks up an IKEv2 policy by the IP address of the interface to which the IPsec policy is applied. The responder looks up an IKEv2 policy by the IP address of the interface that receives the IKEv2 packet. An IKEv2 policy uses IKEv2 proposals to define the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups to be used for negotiation.

You can configure multiple IKEv2 policies. An IKEv2 policy must have a minimum of one IKEv2 proposal. Otherwise, the policy is incomplete.

If the initiator uses an IPsec policy that is bound to a source interface, the initiator looks up an IKEv2 policy by the IP address of the source interface.

You can set priorities to adjust the match order of IKEv2 policies that have the same match criteria.

If no IKEv2 policy is configured, the default IKEv2 policy is used. You cannot enter the view of the default IKEv2 policy, nor modify it.

Examples

Create an IKEv2 policy named **policy1** and enter IKEv2 policy view.

```
<Sysname> system-view
[Sysname] ikev2 policy policy1
[Sysname-ikev2-policy-policy1]
```

Related commands

display ikev2 policy

ikev2 profile

Use **ikev2 profile** to create an IKEv2 profile and enter its view, or enter the view of an existing IKEv2 profile.

Use **undo ikev2 profile** to delete an IKEv2 profile.

Syntax

ikev2 profile *profile-name*

undo ikev2 profile *profile-name*

Default

No IKEv2 profiles exist.

Views

System view

Predefined user roles

network-admin

Parameters

profile-name: Specifies a name for the IKEv2 profile. The profile name is a case-insensitive string of 1 to 63 characters.

Usage guidelines

An IKEv2 profile contains the IKEv2 SA parameters that are not negotiated, such as the identity information and authentication methods of the peers, and the matching criteria for profile lookup.

Examples

Create an IKEv2 profile named **profile1** and enter IKEv2 profile view.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
[Sysname-ikev2-profile-profile1]
```

Related commands

display ikev2 profile

ikev2 proposal

Use **ikev2 proposal** to create an IKEv2 proposal and enter its view, or enter the view of an existing IKEv2 proposal.

Use **undo ikev2 proposal** to delete an IKEv2 proposal.

Syntax

ikev2 proposal *proposal-name*

undo ikev2 proposal *proposal-name*

Default

An IKEv2 proposal named **default** exists.

The default IKEv2 proposal has the lowest priority and uses the following settings in non-FIPS mode:

- **Encryption algorithm**—AES-CBC-128 and 3DES.
- **Integrity protection algorithm**—HMAC-SHA1 and HMAC-MD5.
- **PRF algorithm**—HMAC-SHA1 and HMAC-MD5.
- **DH group**—Group 5 and group 2.

The default IKEv2 proposal has the lowest priority and uses the following settings in FIPS mode:

- **Encryption algorithm**—AES-CBC-128 and AES-CTR-128.
- **Integrity protection algorithm**—HMAC-SHA1 and HMAC-SHA256.
- **PRF algorithm**—HMAC-SHA1 and HMAC-SHA256.
- **DH group**—Group 14 and group 19.

Views

System view

Predefined user roles

network-admin

Parameters

proposal-name: Specifies a name for the IKEv2 proposal. The proposal name is a case-insensitive string of 1 to 63 characters and cannot be **default**.

Usage guidelines

An IKEv2 proposal contains security parameters used in IKE_SA_INIT exchanges, including the encryption algorithms, integrity protection algorithms, PRF algorithms, and DH groups.

An IKEv2 proposal must have a minimum of one set of security parameters, including one encryption algorithm, one integrity protection algorithm, one PRF algorithm, and one DH group.

In an IKEv2 proposal, you can specify multiple parameters of the same type. The parameters of different types combine and form multiple sets of security parameters. If you want to use only one set of security parameters, configure only one set of security parameters for the IKEv2 proposal.

Examples

Create an IKEv2 proposal named **prop1**. Specify encryption algorithm AES-CBC-128, integrity protection algorithm SHA1, PRF algorithm SHA1, and DH group 2.

```
<Sysname> system-view
[Sysname] ikev2 proposal prop1
[Sysname-ikev2-proposal-prop1] encryption aes-cbc-128
[Sysname-ikev2-proposal-prop1] integrity sha1
[Sysname-ikev2-proposal-prop1] prf sha1
```

```
[Sysname-ikev2-proposal-prop1] dh group2
```

Related commands

integrity

Use **integrity** to specify integrity protection algorithms for an IKEv2 proposal.

Use **undo integrity** to restore the default.

Syntax

In non-FIPS mode:

integrity { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

undo integrity

In FIPS mode:

integrity { **sha1** | **sha256** | **sha384** | **sha512** } *

undo integrity

Default

No integrity protection algorithm is specified for an IKEv2 proposal.

Views

IKEv2 proposal view

Predefined user roles

network-admin

Parameters

aes-xcbc-mac: Uses the HMAC-AES-XCBC-MAC algorithm.

md5: Uses the HMAC-MD5 algorithm.

sha1: Uses the HMAC-SHA1 algorithm.

sha256: Uses the HMAC-SHA256 algorithm.

sha384: Uses the HMAC-SHA384 algorithm.

sha512: Uses the HMAC-SHA512 algorithm.

Usage guidelines

You must specify a minimum of one integrity protection algorithm for an IKEv2 proposal. Otherwise, the proposal is incomplete and useless. You can specify multiple integrity protection algorithms for an IKEv2 proposal. An algorithm specified earlier has a higher priority.

Examples

Create an IKEv2 proposal named **prop1**.

```
<Sysname> system-view
[Sysname] ikev2 proposal prop1
```

Specify HMAC-SHA1 and HMAC-MD5 as the integrity protection algorithms, with HMAC-SHA1 preferred.

```
[Sysname-ikev2-proposal-prop1] integrity sha1 md5
```

Related commands

ikev2 proposal

keychain

Use **keychain** to specify an IKEv2 keychain for preshared key authentication.

Use **undo keychain** to restore the default.

Syntax

keychain *keychain-name*

undo keychain

Default

No IKEv2 keychain is specified for an IKEv2 profile.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

keychain-name: Specifies an IKEv2 keychain by its name. The keychain name is a case-insensitive string of 1 to 63 characters and cannot contain a hyphen (-).

Usage guidelines

An IKEv2 keychain is required on both ends if either end uses preshared key authentication. You can specify only one IKEv2 keychain for an IKEv2 profile.

You can specify the same IKEv2 keychain for different IKEv2 profiles.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Specify IKEv2 keychain **keychain1**.

```
[Sysname-ikev2-profile-profile1] keychain keychain1
```

match local (IKEv2 profile view)

Use **match local** to specify a local interface or a local IP address to which an IKEv2 profile can be applied.

Use **undo match local** to remove a local interface or a local IP address to which an IKEv2 profile can be applied.

Syntax

match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

undo match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

Default

An IKEv2 profile can be applied to any local interface or IP address.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

address: Specifies a local interface or IP address to which an IKEv2 profile can be applied.

interface-type interface-number: Specifies a local interface by its type and number. It can be any Layer 3 interface.

ipv4-address: Specifies the IPv4 address of a local interface.

ipv6 *ipv6-address*: Specifies the IPv6 address of a local interface.

Usage guidelines

Use this command to specify which address or interface can use the IKEv2 profile for IKEv2 negotiation. The interface is the interface that receives IKEv2 packets. The IP address is the IP address of the interface that receives IKEv2 packets.

An IKEv2 profile configured earlier has a higher priority. To give an IKEv2 profile that is configured later a higher priority, you can configure the **priority** command or this command for the profile. For example, suppose you configured IKEv2 profile A before configuring IKEv2 profile B, and you configured the **match remote identity address range 2.2.2.1 2.2.2.100** command for IKEv2 profile A and the **match remote identity address range 2.2.2.1 2.2.2.10** command for IKEv2 profile B. For the local interface with the IP address 3.3.3.3 to negotiate with the peer 2.2.2.6, IKEv2 profile A is preferred because IKEv2 profile A was configured earlier. To use IKEv2 profile B, you can use this command to restrict the application scope of IKEv2 profile B to IPv4 address 3.3.3.3.

You can specify multiple applicable local interfaces or IP addresses for an IKEv2 profile.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Apply IKEv2 profile **profile1** to the interface whose IP address is 2.2.2.2.

```
[Sysname-ikev2-profile-profile1] match local address 2.2.2.2
```

Related commands

match remote

match local address (IKEv2 policy view)

Use **match local address** to specify a local interface or a local address that an IKEv2 policy matches.

Use **undo match local address** to remove a local interface or a local address that an IKEv2 policy matches.

Syntax

match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

undo match local address { *interface-type interface-number* | *ipv4-address* | **ipv6** *ipv6-address* }

Default

No local interface or local address is specified, and the IKEv2 policy matches any local interface or local address.

Views

IKEv2 policy view

Predefined user roles

network-admin

Parameters

interface-type interface-number: Specifies a local interface by its type and number. It can be any Layer 3 interface.

ipv4-address: Specifies the IPv4 address of a local interface.

ipv6 *ipv6-address*: Specifies the IPv6 address of a local interface.

Usage guidelines

IKEv2 policies with this command configured are looked up before those that do not have this command configured.

Examples

Configure IKEv2 policy **policy1** to match local address 3.3.3.3.

```
<Sysname> system-view
[Sysname] ikev2 policy policy1
[Sysname-ikev2-policy-policy1] match local address 3.3.3.3
```

Related commands

display ikev2 policy

match remote

Use **match remote** to configure a peer ID that an IKEv2 profile matches.

Use **undo match remote** to delete a peer ID that an IKEv2 profile matches.

Syntax

match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* | *mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range** *low-ipv6-address high-ipv6-address* } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* } }

undo match remote { **certificate** *policy-name* | **identity** { **address** { { *ipv4-address* [*mask* |*mask-length*] | **range** *low-ipv4-address high-ipv4-address* } | **ipv6** { *ipv6-address* [*prefix-length*] | **range**

low-ipv6-address high-ipv6-address } } | **fqdn** *fqdn-name* | **email** *email-string* | **key-id** *key-id-string* } }

Default

No matching peer ID is configured for the IKEv2 profile.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

certificate *policy-name*: Uses the information in the peer's digital certificate as the peer ID for IKEv2 profile matching. The *policy-name* argument specifies a certificate-based access control policy by its name, a case-insensitive string of 1 to 31 characters.

identity: Uses the specified information as the peer ID for IKEv2 profile matching. The specified information is configured on the peer by using the **identity local** command.

- **address** *ipv4-address* [*mask* | *mask-length*]: Uses an IPv4 host address or an IPv4 subnet address as the peer ID for IKEv2 profile matching. The value range for the *mask-length* argument is 0 to 32. If you do not specify a mask or mask length, the 32-bit mask is used.
- **address range** *low-ipv4-address high-ipv4-address*: Uses a range of IPv4 addresses as the peer ID for IKEv2 profile matching. The end address must be higher than the start address.
- **address ipv6** *ipv6-address* [*prefix-length*]: Uses an IPv6 host address or an IPv6 subnet address as the peer ID for IKEv2 profile matching. The value range for the *prefix-length* argument is 0 to 128. If you do not specify a prefix length, the 128-bit prefix is used.
- **address ipv6 range** *low-ipv6-address high-ipv6-address*: Uses a range of IPv6 addresses as the peer ID for IKEv2 profile matching. The end address must be higher than the start address.
- **fqdn** *fqdn-name*: Uses the peer's FQDN as the peer ID for IKEv2 profile matching. The *fqdn-name* argument is a case-sensitive string of 1 to 255 characters, such as www.test.com.
- **email** *email-string*: Uses peer's email address as the peer ID for IKEv2 profile matching. The *email-string* argument is a case-sensitive string of 1 to 255 characters in the format defined by RFC 822, such as sec@abc.com.
- **key-id** *key-id-string*: Uses the peer's key ID as the peer ID for IKEv2 profile matching. The *key-id-string* argument is a case-sensitive string of 1 to 255 characters, and is usually a vendor-specific string for doing proprietary types of identification.

Usage guidelines

The device compares the received peer ID with the peer IDs configured in local IKEv2 profiles. If a match is found, it uses the IKEv2 profile with the matching peer ID for IKEv2 negotiation.

If the device has the **match remote** and **match local address** commands configured, it uses the IKEv2 profile that matches all the criteria configured by the commands.

To make sure only one IKEv2 profile is matched for a peer, do not configure the same peer ID for two or more IKEv2 profiles. If you configure the same peer ID for two or more IKEv2 profiles, which IKEv2 profile is selected for IKEv2 negotiation is unpredictable.

You can configure an IKEv2 profile to match multiple peer IDs. A peer ID configured earlier has a higher priority.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Configure the IKEv2 profile to match the peer ID that is FQDN name **www.test.com**.

```
[Sysname-ikev2-profile-profile1] match remote identity fqdn www.test.com
```

Configure the IKEv2 profile to match the peer ID that is IP address 10.1.1.1.

```
[Sysname-ikev2-profile-profile1]match remote identity address 10.1.1.1
```

Related commands

identity local

match local address

nat-keepalive

Use **nat-keepalive** to set the NAT keepalive interval.

Use **undo nat-keepalive** to restore the default.

Syntax

nat-keepalive *seconds*

undo nat-keepalive

Default

The NAT keepalive interval set in system view is used.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

seconds: Specifies the NAT keepalive interval in seconds, in the range of 5 to 3600.

Usage guidelines

This command takes effect when the device resides in the private network behind a NAT device. The device must send NAT keepalive packets regularly to its peer to keep the NAT session alive, so that the peer can access the device.

The NAT keepalive interval must be shorter than the NAT session lifetime.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Set the NAT keepalive interval to 1200 seconds.

```
[Sysname-ikev2-profile-profile1]nat-keepalive 1200
```

Related commands

display ikev2 profile

ikev2 nat-keepalive

peer

Use **peer** to create an IKEv2 peer and enter its view, or enter the view of an existing IKEv2 peer.

Use **undo peer** to delete an IKEv2 peer.

Syntax

peer *name*

undo peer *name*

Default

No IKEv2 peers exist.

Views

IKEv2 keychain view

Predefined user roles

network-admin

Parameters

name: Specifies a name for the IKEv2 peer. The peer name is a case-insensitive string of 1 to 63 characters.

Usage guidelines

An IKEv2 peer contains a preshared key and the criteria for looking up the peer. The criteria for peer lookup includes the peer's host name, IP address, IP address range, and ID. The IKEv2 negotiation initiator uses the peer's host name, IP address, or IP address range to look up its peer. The responder uses the peer's IP address, IP address range, or ID to look up its peer.

Examples

Create an IKEv2 keychain named **key1** and enter IKEv2 keychain view.

```
<Sysname> system-view
[Sysname] ikev2 keychain key1
```

Create an IKEv2 peer named **peer1**.

```
[Sysname-ikev2-keychain-key1] peer peer1
```

Related commands

address

hostname

identity

ikev2 keychain

pre-shared-key

Use **pre-shared-key** to configure a preshared key.

Use **undo pre-shared-key** to delete a preshared key.

Syntax

pre-shared-key [**local** | **remote**] { **ciphertext** | **plaintext** } *string*

undo pre-shared-key [**local** | **remote**]

Default

No preshared key exists.

Views

IKEv2 peer view

Predefined user roles

network-admin

Parameters

`local`: Specifies a preshared key for certificate signing.

`remote`: Specifies a preshared key for certificate authentication.

`ciphertext`: Specifies a preshared key in encrypted form.

`plaintext`: Specifies a preshared key in plaintext form. For security purposes, the key specified in plaintext form will be stored in encrypted form.

`string`: Specifies the preshared key. The key is case sensitive. In non-FIPS mode, its plaintext form is a string of 1 to 128 characters and its encrypted form is a string of 1 to 201 characters. In FIPS mode, its plaintext form is a string of 15 to 128 characters and its encrypted form is a string of 15 to 201 characters.

Usage guidelines

If you specify the **`local`** or **`remote`** keyword, you configure an asymmetric key. If you specify neither the **`local`** nor the **`remote`** keyword, you configure a symmetric key.

To delete a key by using the **undo** command, you must specify the correct key type. For example, if you configure a key by using the **`pre-shared-key local`** command, you cannot delete the key by using the **`undo pre-shared-key`** or **`undo pre-shared-key remote`** command.

If you execute this command multiple times, the most recent configuration takes effect.

Examples

- On the initiator:

  # Create an IKEv2 keychain named **key1**.

  ```
  <Sysname> system-view
  [Sysname] ikev2 keychain key1
  ```

  # Create an IKEv2 peer named **peer1**.

  ```
  [Sysname-ikev2-keychain-key1] peer peer1
  ```

  # Configure **111-key** as the symmetric plaintext preshared key.

  ```
  [Sysname-ikev2-keychain-key1-peer-peer1] pre-shared-key plaintext 111-key
  [Sysname-ikev2-keychain-key1-peer-peer1] quit
  ```

  # Create an IKEv2 peer named **peer2**.

  ```
  [Sysname-ikev2-keychain-key1] peer peer2
  ```

  # Configure asymmetric plaintext preshared keys. The key for certificate signing is **111-key-a** and the key for certificate authentication is **111-key-b**.

  ```
  [Sysname-ikev2-keychain-key1-peer-peer2] pre-shared-key local plaintext 111-key-a
  [Sysname-ikev2-keychain-key1-peer-peer2] pre-shared-key remote plaintext 111-key-b
  ```

- On the responder:

  # Create an IKEv2 keychain named **telecom**.

  ```
  <Sysname> system-view
  [Sysname] ikev2 keychain telecom
  ```

  # Create an IKEv2 peer named **peer1**.

```
[Sysname-ikev2-keychain-telecom] peer peer1
```

Configure **111-key** as the symmetric plaintext preshared key.

```
[Sysname-ikev2-keychain-telecom-peer-peer1] pre-shared-key plaintext 111-key
[Sysname-ikev2-keychain-telecom-peer-peer1] quit
```

Create an IKEv2 peer named **peer2**.

```
[Sysname-ikev2-keychain-telecom] peer peer2
```

Configure asymmetric plaintext preshared keys. The key for certificate signing is **111-key-b** and the key for certificate authentication is **111-key-a**.

```
[Sysname-ikev2-keychain-telecom-peer-peer2] pre-shared-key local plaintext
111-key-b
[Sysname-ikev2-keychain-telecom-peer-peer2] pre-shared-key remote plaintext
111-key-a
```

prf

Use **prf** to specify pseudo-random function (PRF) algorithms for an IKEv2 proposal.

Use **undo prf** to restore the default.

Syntax

In non-FIPS mode:

prf { **aes-xcbc-mac** | **md5** | **sha1** | **sha256** | **sha384** | **sha512** } *

undo prf

In FIPS mode:

prf { **sha1** | **sha256** | **sha384** | **sha512** } *

undo prf

Default

An IKEv2 proposal uses the integrity protection algorithms as the PRF algorithms.

Views

IKEv2 proposal view

Predefined user roles

network-admin

Parameters

aes-xcbc-mac: Uses the HMAC-AES-XCBC-MAC algorithm.

md5: Uses the HMAC-MD5 algorithm.

sha1: Uses the HMAC-SHA1 algorithm.

sha256: Uses the HMAC-SHA256 algorithm.

sha384: Uses the HMAC-SHA384 algorithm.

sha512: Uses the HMAC-SHA512 algorithm.

Usage guidelines

You can specify multiple PRF algorithms for an IKEv2 proposal. An algorithm specified earlier has a higher priority.

Examples

Create an IKEv2 proposal named **prop1**.

```
<Sysname> system-view
[Sysname] ikev2 proposal prop1
```

Specify HMAC-SHA1 and HMAC-MD5 as the PRF algorithms, with HMAC-SHA1 preferred.

```
[Sysname-ikev2-proposal-prop1] prf sha1 md5
```

ikev2 proposal

reset ikev2 sa

Use **reset ikev2 sa** to delete IKEv2 SAs.

Syntax

reset ikev2 sa [[{ **local** | **remote** } { *ipv4-address* | **ipv6** *ipv6-address* }] | **tunnel** *tunnel-id*] [**fast**]

Views

User view

Predefined user roles

network-admin

Parameters

local: Deletes IKEv2 SAs for a local IP address.

remote: Deletes IKEv2 SAs for a remote IP address.

ipv4-address: Specifies a local or remote IPv4 address.

ipv6 *ipv6-address*: Specifies a local or remote IPv6 address.

tunnel *tunnel-id*: Deletes IKEv2 SAs for an IPsec tunnel. The *tunnel-id* argument specifies an IPsec tunnel by its ID in the range of 1 to 2000000000.

fast: Notifies the peers of the deletion and deletes IKEv2 SAs directly before receiving the peers' responses. If you do not specify this keyword, the device notifies the peers of the deletion and deletes IKEv2 SAs after it receives the peers' responses.

Usage guidelines

Deleting an IKEv2 SA will also delete the child SAs negotiated through the IKEv2 SA.

If you do not specify any parameters, this command deletes all IKEv2 SAs and the child SAs negotiated through the IKEv2 SAs.

Examples

Display information about IKEv2 SAs.

```
<Sysname> display ikev2 sa
     Tunnel ID          Local             Remote             Status
  ------------------------------------------------------------------------
     1                  1.1.1.1/500       1.1.1.2/500        EST
     2                  2.2.2.1/500       2.2.2.2/500        EST
  Status:
  IN-NEGO: Negotiating, EST: Established, DEL: Deleting
```

Delete the IKEv2 SA whose remote IP address is 1.1.1.2.

```
<Sysname> reset ikev2 sa remote 1.1.1.2
```

Display information about IKEv2 SAs again. Verify that the IKEv2 SA is deleted.

```
<Sysname> display ikev2 sa
     Tunnel ID          Local             Remote             Status
  ------------------------------------------------------------------------
     2                  2.2.2.1/500       2.2.2.2/500        EST
  Status:
  IN-NEGO: Negotiating, EST: Established, DEL: Deleting
```

Examples

Clear IKEv2 statistics.

```
<Sysname> reset ikev2 statistics
```

Related commands

display ikev2 statistics

sa duration

Use **sa duration** to set the IKEv2 SA lifetime.

Use **undo sa duration** to restore the default.

Syntax

sa duration *seconds*

undo sa duration

Default

The IKEv2 SA lifetime is 86400 seconds.

Views

IKEv2 profile view

Predefined user roles

network-admin

Parameters

seconds: Specifies the IKEv2 SA lifetime in seconds, in the range of 120 to 86400.

Usage guidelines

An IKEv2 SA can be used for subsequent IKEv2 negotiations before its lifetime expires, saving a lot of negotiation time. However, the longer the lifetime, the higher the possibility that attackers collect enough information and initiate attacks.

Two peers can have different IKEv2 SA lifetime settings, and they do not perform lifetime negotiation. The peer with a shorter lifetime always initiates the rekeying.

Examples

Create an IKEv2 profile named **profile1**.

```
<Sysname> system-view
[Sysname] ikev2 profile profile1
```

Set the IKEv2 SA lifetime to 1200 seconds.

```
[Sysname-ikev2-profile-profile1] sa duration 1200
```

SSH commands

The device supports the FIPS mode that complies with NIST FIPS 140-2 requirements. Support for features, commands, and parameters might differ in FIPS mode and non-FIPS mode. For more information about FIPS mode, see *Security Configuration Guide*.

SSH server commands

display ssh server

Use **display ssh server** on an SSH server to display the SSH server status or sessions.

Syntax

display ssh server { **session** | **status** }

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

session: Specifies the SSH server sessions.

status: Specifies the SSH server status.

Examples

Display the SSH server status.

```
<Sysname> display ssh server status
 Stelnet server: Disable
 SSH version : 2.0
 SSH authentication-timeout : 60 second(s)
 SSH server key generating interval : 0 hour(s)
 SSH authentication retries : 3 time(s)
 SFTP server: Disable
 SFTP server Idle-Timeout: 10 minute(s)
 NETCONF server: Disable
 SCP server: Disable
 SSH Server PKI domain name: aaa
```

Table 1 Command output

Field	Description
Stelnet server	Whether the Stelnet server is enabled.
SSH version	SSH protocol version. When the SSH supports SSH1, the protocol version is 1.99. Otherwise, the protocol version is 2.
SSH authentication-timeout	Authentication timeout timer.

Field	Description
SSH server key generating interval	Minimum interval for updating the RSA server key pair.
SSH authentication retries	Maximum number of authentication attempts for SSH users.
SFTP server	Whether the SFTP server is enabled.
SFTP server Idle-Timeout	SFTP connection idle timeout timer.
NETCONF server	Whether NETCONF over SSH is enabled.
SCP server	Whether the SCP server is enabled.
SSH Server PKI domain name	Name of the PKI domain specified for the SSH server.

Display the SSH server sessions.

```
<Sysname> display ssh server session
UserPid   SessID Ver   Encrypt    State          Retries  Serv     Username
 184       0     2.0   aes128-cbc Established    1        Stelnet  abc@123
```

Table 2 Command output

Field	Description
UserPid	User process ID.
SessID	Session ID.
Ver	Protocol version of the SSH server.
Encrypt	Encryption algorithm used on the SSH server.
State	Session state: • **Init**—Initialization. • **Ver-exchange**—Version negotiation. • **Keys-exchange**—Key exchange. • **Auth-request**—Authentication request. • **Serv-request**—Session service request. • **Established**—The session is established. • **Disconnected**—The session is terminated.
Retries	Number of authentication failures.
Serv	Service type: • SCP. • SFTP. • Stelnet. • NETCONF.
Username	Username that the client uses to log in to the server.

display ssh user-information

Use **display ssh user-information** to display information about SSH users on an SSH server.

Syntax

display ssh user-information [*username*]

Views

Any view

Predefined user roles

network-admin

network-operator

Parameters

username: Specifies an SSH username, a case-sensitive string of 1 to 80 characters. If you do not specify an SSH user, this command displays information about all SSH users.

Usage guidelines

This command displays information only about SSH users that are configured by using the **ssh user** command on the SSH server.

Examples

Display information about all SSH users.

```
<Sysname> display ssh user-information
 Total ssh users:2
 Username            Authentication-type  User-public-key-name  Service-type
 yemx                password                                   Stelnet|SFTP
 test                publickey            pubkey                SFTP
```

Table 3 Command output

Field	Description
Total ssh users	Total number of SSH users.
Authentication-type	Authentication methods: • Password authentication. • Publickey authentication. • Password-publickey authentication. • Any authentication.
User-public-key-name	Public key name of the user. This field is empty if the authentication method is password authentication.
Service-type	Service types: • Stelnet. • SFTP. • SCP. • NETCONF. If multiple service types are available for an SSH user, they are separated by vertical bars (|).

Related commands

ssh user

free ssh

Use **free ssh** to disconnect SSH sessions.

Syntax
