Parameter Description	*acl-id*: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of *acl-id* is 100–199 and 1300–1999. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. **host** *source*: Indicates that IP packets sent from a host with the specified source IP address are filtered. **any**: Indicates that IP packets sent from any host are filtered. *source source-wildcard:* Indicates that IP packets sent from hosts in the specified IP network segment are filtered. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. **url-group** *url-group-id*: Indicates that this ACE is associated with the URL group of a packet. For details about the URL group, see the configuration guide of application identification.
Command Mode	Standard IP ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered IP ACL in global configuration mode. It cannot be used to add ACEs to a named IP ACL.

- Add ACEs to an extended IP ACL.

Use either of the following methods to add ACEs to an extended IP ACL.

Command	[*sn*] { **deny** | **permit** } *protocol* { *source source-wildcard* | **any** | **host** *source* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any** | **host** *destination* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**url-group** *url-group-id*]
Parameter Description	*sn*: Indicates the sequence number of an ACE. The value range is from 1 to 2,147,483,647. The sequence number determines the priority of the ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a new ACE will be 110 by default. You can adjust the increment using a command. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. *protocol*: Indicates the IP protocol number. The value range is from 0 to 255. To facilitate usage, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. **host** *source*: Indicates that IP packets sent from a host with the specified source IP address are filtered. *source source-wildcard:* Indicates that IP packets sent from hosts in the specified IP network segment are filtered.

	host *destination:* Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the **any** keyword is configured, IP packets sent to any host are filtered. *destination destination-wildcard:* Indicates that IP packets sent to hosts in a specified IP network segment are filtered. **any**: Indicates that IP packets sent to or from any host are filtered. **lt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is smaller than the port number specified by this parameter. **eq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is equal to the port number specified by this parameter. **gt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is larger than the port number specified by this parameter. **neq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is not equal to the port number specified by this parameter. **range** *lower upper*: Indicates that the TCP or UDP packet containing a Layer 4 destination port number in the specified range is to be matched. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. **url-group** *url-group-id*: Indicates that this ACE is associated with the URL group of a packet. For details about the URL group, see the configuration guide of application identification.
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs in extended IP ACL configuration mode. The ACL can be a named or numbered ACL.

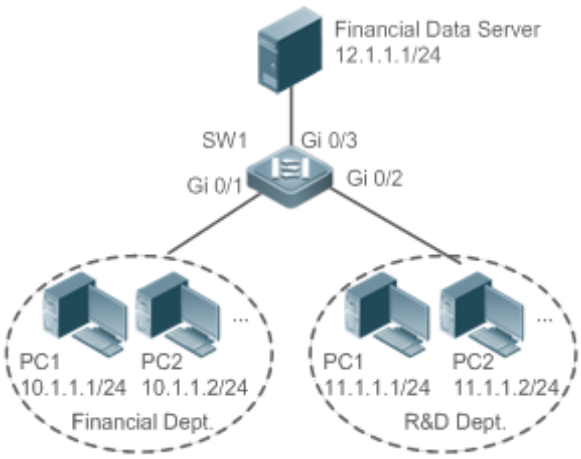
Command	**access-list** *acl-id* { **deny** | **permit** } *protocol* { *source source-wildcard* | **any** | **host** *source* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any** | **host** *destination* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**url-group** *url-group-id*]
Parameter Description	*acl-id*: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of *acl-id* is 100–199 and 2000–1999. *sn*: Indicates the sequence number of an ACE. The value range is from 1 to 2,147,483,647. The sequence number determines the priority of the ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the current ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a new ACE will be 110 by default. You can adjust the increment using a command. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE.

	protocol: Indicates the IP protocol number. The value range is from 0 to 255. To facilitate usage, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. **host** *source*: Indicates that IP packets sent from a host with the specified source IP address are filtered. *source source-wildcard:* Indicates that IP packets sent from hosts in the specified IP network segment are filtered. **host** *destination:* Indicates that IP packets sent to a host with the specified destination IP address are filtered. If the **any** keyword is configured, IP packets sent to any host are filtered. *destination destination-wildcard:* Indicates that IP packets sent to hosts in a specified IP network segment are filtered. **any**: Indicates that IP packets sent to or from any host are filtered. **lt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is smaller than the port number specified by this parameter. **eq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is equal to the port number specified by this parameter. **gt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is larger than the port number specified by this parameter. **neq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is not equal to the port number specified by this parameter. **range** *lower upper*: Indicates that the TCP or UDP packet containing a Layer 4 destination port number in the specified range is to be matched. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. For details about the time range, see the configuration manual of the time range. **url-group** *url-group-id*: Indicates that this ACE is associated with the URL group of a packet. For details about the URL group, see the configuration guide of application identification.
Command Mode	Extended IP ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered IP ACL in extended IP ACL configuration mode. It cannot be used to add ACEs to a named extended IP ACL.

Rearranging Sequence Numbers of ACEs

Command	**ip access-list resequence** { *acl-id* | *acl-name* } *start-sn inc-sn*
Parameter Description	*acl-id*: Indicates the numbered standard or extended IP ACL. *acl-name*: Indicates the named standard or extended IP ACL. *start-sn*: Indicates that the start value of the sequence number is configured. *inc-sn*: Indicates that the sequence number increment is configured.
Command Mode	Global configuration mode

Usage Guide	In practice, ACEs may be added to or deleted from a standard or extended IP ACL several times. After a given period of time, the sequence numbers are irregular. You can use this command to rearrange sequence numbers of ACEs to regularize them.



Applying an IP ACL

Command	**ip access-group** { *acl-id* | *acl-name* } { **in** | **out** }
Parameter Description	*acl-id*: Indicates that a numbered standard or extended IP ACL will be applied to the interface. *acl-name*: Indicates that a named standard or extended IP ACL will be applied to the interface. **in**: Indicates that this ACL controls incoming IP packets of the interface. **out**: Indicates that this ACL controls outgoing IP packets of the interface. **reflect:** Indicates that the reflexive ACL is enabled.
Command Mode	Interface configuration mode
Usage Guide	This command makes an IP ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring an IP ACL to Prohibit Departments Except the Financial Department from Accessing the Financial Data Server

Scenario Figure 1-3	
Configuration Steps	● Configure an IP ACL. ● Add ACEs to the IP ACL. ● Apply the IP ACL to the outbound direction of the interface connected to the financial data server.
SW1	`sw1(config)#ip access-list standard 1`

	sw1(config-std-nacl)#permit 10.1.1.0 0.0.0.255 sw1(config-std-nacl)#deny 11.1.1.1 0.0.0.255 sw1(config-std-nacl)#exit sw1(config)#int gigabitEthernet 0/3 sw1(config-if-GigabitEthernet 0/3)#ip access-group 1 out
Verification	● On a PC of the R&D department, ping the financial data server. Verify that the ping operation fails. ● On a PC of the financial department, ping the financial data server. Verify that the ping operation succeeds.
SW1	sw1(config)#show access-lists ip access-list standard 1 10 permit 10.1.1.0 0.0.0.255 20 deny 11.1.1.0 0.0.0.255 sw1(config)#show access-group ip access-group 1 out Applied On interface GigabitEthernet 0/3

1.4.2 Configuring an Extended MAC ACL

Configuration Effect

Configure and apply an extended MAC ACL to an interface to control all incoming and outgoing IPv4 packets of this interface. You can permit or deny specific Layer 2 packets on a network to control users' access to network resources based on Layer 2 packets.

Notes

N/A

Configuration Step

↘ **Configuring an Extended MAC ACL**

- Mandatory. Configure an extended MAC ACL if you want to control users' access to network resources based on the Layer 2 packet header, for example, the MAC address of each user's PC.

- You can configure this ACL on an access device, an aggregation device, or a core device based on user distribution. The MAC extended ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an Extended MAC ACL

- Optional. An ACL may contain no ACE or multiple ACEs. If no ACE is configured, all incoming L2 Ethernet packets of the device are denied by default.

Rearranging Sequence Numbers of ACEs

- Optional. Rearrange sequence numbers of ACEs in an ACL to regularize them.

Applying an Extended MAC ACL

- Mandatory. Apply an extended MAC ACL to a specified interface to make the ACL take effect.
- You can apply an extended MAC ACL on a specified interface of an access device, an aggregation device, or a core device based on user distribution.

Verification

Use the following methods to verify the configuration of the extended MAC ACL:

- If an extended MAC ACL is configured to permit or deny some IP packets, run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, an extended MAC ACL is configured to prevent a device interface from receiving IP packets (Ethernet type is 0x0800), run the **ping** command for verification.
- If an extended MAC ACL is configured to permit or deny some non-IP packets such as ARP packets, run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- You can also construct Layer 2 packets matching some specified characteristics to check whether the extended MAC ACL takes effect. Typically, prepare two PCs, construct and send Layer 2 packets on one PC, enable packet obtaining on another PC, and check whether packets are forwarded as expected (forwarded or blocked) according to the action specified in the ACEs.

Related Commands

Configuring an Extended MAC ACL

Command	**mac access-list extended** { *acl-name* | *acl-id* }
Parameter Description	*acl-name*: Indicates the name of an extended MAC ACL. If this parameter is specified, a named ACL is created. The value is a string of 1 to 99 characters. It cannot start with numerals (0–9), or cannot be **in** or **out**. *acl-id*: Indicates the ID that uniquely identifies an MAC extended ACL. If this parameter is specified, a numbered ACL is created. The value range of *acl-id* is 700–799.
Command	Global configuration mode

Mode	
Usage Guide	Run this command to configure an extended MAC ACL and enter the extended MAC ACL configuration mode. You can configure an extended MAC ACL to control users' access to network resources by checking Layer 2 information of Ethernet packets.

Adding ACEs to an Extended MAC ACL

Use either of the following methods to add ACEs to an extended MAC ACL:

- Add ACEs in extended MAC ACL configuration mode.

Command	[*sn*] { **deny** | **permit** } { *source-mac-address source-mac-mask* | **any** | **host** *source-mac-address* } { *destination-mac-address destination-mac-mask* | **any** | **host** *destination-mac-address* } [*ethernet-type*] **[cos** [*cos*] **[inner** *cos*]]
Parameter Description	*sn*: Indicates the sequence number of an ACE. The value range is from 1 to 2,147,483,647. The sequence number determines the priority of the ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a new ACE will be 110 by default. You can adjust the increment using a command. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. **any**: Indicates that Layer 2 packets sent from any host are filtered. **host** *source-mac-addr*: Indicates that IP packets sent from a host with the specified source MAC address are filtered. *source-mac-mask*: Indicates that bits of the source MAC address are inverted. **any**: Indicates that Layer 2 packets sent to any host are filtered. **host** *destination-mac-addr*: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. *destination-mac-mask*: Indicates that bits of the destination MAC address are inverted. *ethernet-type*: Indicates that Layer 2 packets of the specified Ethernet type are filtered. **cos** *cos*: Indicates that Layer 2 packets with the specified class of service (CoS) field in the outer tag are filtered. **inner** *cos*: Indicates that Layer 2 packets with the specified CoS field in the inner tag are filtered. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range.
Command Mode	Extended MAC ACL configuration mode
Usage Guide	Run this command to add ACEs in extended MAC ACL configuration mode. The ACL can be a named or numbered ACL.

- Add ACEs to an extended MAC ACL in global configuration mode.

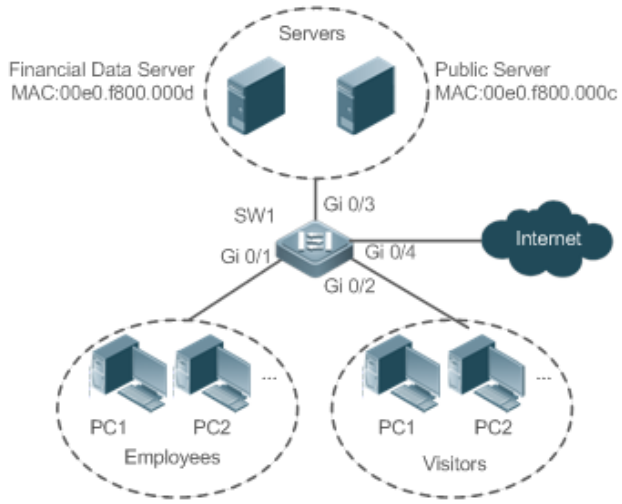
Command	**access-list** *acl-id* { **deny** | **permit** } { *source-mac-address source-mac-mask* | **any** |

	host *source-mac-address* } { *destination-mac-address destination-mac-mask* | **any** | **host** *destination-mac-address* } [*ethernet-type*] [**cos** [*cos*] [**inner** *cos*]
Parameter Description	*acl-id*: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of *acl-id* is 700–799. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. **host** *source-mac-addr*: Indicates that IP packets sent from a host with the specified source MAC address are filtered. *source-mac-mask*: Indicates that bits of the source MAC address are inverted. **any**: Indicates that Layer 2 packets sent to any host are filtered. **host** *destination-mac-addr*: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. *destination-mac-mask*: Indicates that bits of the destination MAC address are inverted. *ethernet-type*: Indicates that Layer 2 packets of the specified Ethernet type are filtered. **cos** *cos*: Indicates that Layer 2 packets with the specified cos field in the outer tag are filtered. **inner** *cos*: Indicates that Layer 2 packets with the specified cos field in the inner tag are filtered. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range.
Command Mode	Global configuration mode
Usage Guide	Run this command to add ACEs to a numbered extended MAC ACL in global configuration mode. It cannot be used to add ACEs to a named extended MAC ACL.

Rearranging Sequence Numbers of ACEs

Command	**mac access-list resequence** { *acl-id* | *acl-name* } *start-sn inc-sn*
Parameter Description	*acl-id*: Indicates the numbered extended MAC ACL. *acl-name*: Indicates the named extended MAC ACL. *start-sn*: Indicates that the start value of the sequence number is configured. *inc-sn*: Indicates that the sequence number increment is configured.
Command Mode	Global configuration mode
Usage Guide	In practice, ACEs may be added to or deleted from an extended MAC ACL several times. After a given period of time, the sequence numbers are irregular. You can use this command to rearrange sequence numbers of ACEs to regularize them.

Applying an Extended MAC ACL



Command	**mac access-group** { *acl-id* | *acl-name* } { **in** | **out** }
Parameter Description	*acl-id*: Indicates that a numbered extended MAC ACL will be applied to the interface. *acl-name*: Indicates that a named extended MAC ACL will be applied to the interface. **in**: Indicates that this ACL controls incoming Layer 2 packets of the interface. **out**: Indicates that this ACL controls outgoing Layer 2 packets of the interface.

Command Mode	Interface configuration mode
Usage Guide	This command makes an extended MAC ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring an Extended MAC ACL to Restrict Resources Accessed by Guests

Scenario Figure 1-4	
Configuration Steps	● Configure an extended MAC ACL. ● Add ACEs to the extended MAC ACL. ● Apply the extended MAC ACL to the outbound direction of the interface connected to the guest area so that guests are allowed to access Internet and the public server of the company, but prohibited from accessing the financial data server of the company. That is, visitors cannot access the server with the MAC address of 00e0.f800.000d.

SW1	`sw1(config)#mac access-list extended 700`
	`sw1(config-mac-nacl)#deny any host 00e0.f800.000d`
	`sw1(config-mac-nacl)#permit any any`
	`sw1(config-mac-nacl)#exit`
	`sw1(config)#int gigabitEthernet 0/2`
	`sw1(config-if-GigabitEthernet 0/2)#mac access-group 700in`

Verification	● On a guest's PC, ping the financial data server. Verify that the ping operation fails. ● On a guest's PC, ping the public resource server. Verify that the ping operation

	succeeds. ● On a guest's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.

SW1	`sw1(config)#show access-lists`
	`mac access-list extended 700`
	` 10 deny any host 00e0.f800.000d etype-any`
	`20 permit any any etype-any`
	`sw1(config)#show access-group`
	`mac access-group 700in`
	`Applied On interface GigabitEthernet 0/2`

1.4.3 Configuring an Extended Expert ACL

Configuration Effect

Configure and apply an extended expert ACL to an interface to control incoming and outgoing packets of the interface based on Layer 2 and Layer 3 information, and allow or prohibit specific packets on a network. In addition, you can configure an extended expert ACL to control all Layer 2 packets based on the VLAN to permit or deny the access of users in some network segments to network resources. Typically, you can use an extended expert ACL if you want to incorporate ACEs of the IP ACL and MAC extended ACL into one ACL.

Configuration Step

↘ **Configuring an Extended Expert ACL**

- Mandatory. Configure an extended expert ACL if you want to control users' access to network resources based on the Layer 2 packet header, for example, VLAN ID.
- You can configure this ACL on an access device, an aggregation device, or a core device based on user distribution. The extended expert ACL takes effect only on the local device, and does not affect other devices on the network.

↘ **Adding ACEs to an Expert Extended ACL**

- Optional. An ACL may contain no ACE or multiple ACEs. If no ACE is configured, all incoming packets of the device are denied by default.

↘ **Rearranging Sequence Numbers of ACEs**

- Optional. Rearrange sequence numbers of ACEs in an ACL to regularize them.

↘ **Applying an Extended Expert ACL**

- Mandatory. Apply an extended expert ACL to a specified interface to make this ACL take effect.
- You can apply an extended expert ACL in the inbound or outbound direction of a specified interface of an access device, an aggregation device, or a core device based on user distribution.

Verification

Use the following methods to verify the configuration of the extended expert ACL:

- Use the following methods to verify the configuration of the expert extended ACL:
- If IP address-based access rules are configured in an expert extended ACL to permit or deny some IP packets, run the **ping** command to verify whether these rules take effect.
- If MAC address-based access rules are configured in an expert extended ACL to permit or deny some L2 packets (e.g. ARP packets), also run the **ping** command to check whether ACEs of this ACL takes effect on the specified interface. For example, to filter out ARP packets, run the **ping** command for verification.
- If VLAN ID-based access rules are configured in an expert extended ACL to permit or deny some L2 packets in some network segments (e.g., to prevent communication between VLAN 1 users and VLAN 2 users), ping PCs of VLAN 2 on a PC of VLAN 1. If the ping operation fails, the rules take effect.

Related Commands

Configuring an Expert Extended ACL

Command	**expert access-list extended** { *acl-name* | *acl-id* }
Parameter Description	*acl-name*: Indicates the name of an expert extended ACL. If this parameter is specified, a named ACL is created. The value is a string of 1 to 99 characters. It cannot start with numerals (0–9), or cannot be **in** or **out**. *acl-id*: Indicates the ID of an extended expert ACL. If this parameter is specified, a numbered ACL is created. The value range of *acl-id* is 2700-2899.
Command Mode	Configuration mode
Usage Guide	Run this command to configure an extended expert ACL and enter the extended expert ACL configuration mode.

Adding ACEs to an Extended Expert ACL

Use either of the following methods to add ACEs to an extended expert ACL:

- Add ACEs in extended expert ACL configuration mode.

Command	[*sn*] { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos*] [**inner** *cos*]]] [**VID** [*vid*] [**inner** *vid*]] { *source source-wildcard* | **any** | **host** *source* } { *source-mac-address source-mac-mask* | **any** | **host** *source-mac-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any**

	| **host** *destination* } { **any** | **host** *destination-mac-address* }] [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*]
Parameter Description	*sn*: Indicates the sequence number of an ACE. The value range is from 1 to 2,147,483,647. The sequence number determines the priority of the ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a new ACE will be 110 by default. You can adjust the increment using a command. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. *protocol*: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate usage, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. *ethernet-type*: Indicates that Layer 2 packets of the specified Ethernet type are filtered. **cos** *cos*: Indicates that Layer 2 packets with the specified cos field in the outer tag are filtered. **inner cos** *in*: Indicates that Layer 2 packets with the specified cos field in the inner tag are filtered. **VID** *vid*: Indicates that Layer 2 packets with the specified VLAN ID field in the outer tag are filtered. **inner** *vid*: Indicates that Layer 2 packets with the specified VLAN ID field in the inner tag are filtered. *source source-wildcard:* Indicates that IP packets sent from hosts in the specified IP network segment are filtered. **host** *source*: Indicates that IP packets sent from a host with the specified source IP address are filtered. **any**: Indicates that IP packets sent from any host are filtered. **host** *source-mac-address*: Indicates that IP packets sent from a host with the specified source MAC address are filtered. **any**: Indicates that Layer 2 packets sent to any host are filtered. *destination destination-wildcard:* Indicates that IP packets sent to hosts in a specified IP network segment are filtered. **host** *destination*: Indicates that IP packets sent to a host with the specified destination IP address are filtered. **any**: Indicates that IP packets sent to any host are filtered. **host** *destination-mac-address*: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. **any**: Indicates that Layer 2 packets sent to any host are filtered. **lt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is smaller than the port number specified by this parameter. **eq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to

	be matched is equal to the port number specified by this parameter. **gt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is larger than the port number specified by this parameter. **neq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is not equal to the port number specified by this parameter. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range.
Command Mode	Extended expert ACL configuration mode
Usage Guide	Run this command to add ACEs in extended expert ACL configuration mode. The ACL can be a named or numbered ACL.

- Add ACEs to an extended expert ACL in global configuration mode.

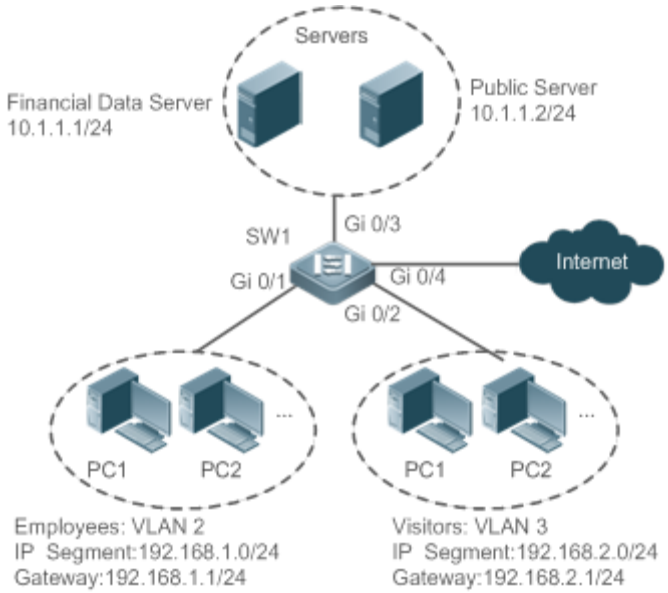
Command	**access-list** *acl-id* { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos*] [**inner** *cos*]]] [**VID** [*vid*] [**inner** *vid*]] { *source source-wildcard* | **any** | **host** *source* } { *source-mac-address source-mac-mask* | **any** | **host** *source-mac-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any** | **host** *destination* } { **any** | **host** *destination-mac-address* }] [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*]
Parameter Description	*acl-id*: Indicates the ID of a numbered ACL. It uniquely identifies an ACL. The value range of *acl-id* is 2700-2899. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. *protocol*: Indicates the IP protocol number. The value ranges from 0 to 255. To facilitate usage, the system provides frequently-used abbreviations to replace the specific IP protocol numbers, including eigrp, gre, icmp, igmp, ip, ipinip, nos, ospf, tcp, and udp. *ethernet-type*: Indicates that Layer 2 packets of the specified Ethernet type are filtered. **cos** *cos*: Indicates that Layer 2 packets with the specified cos field in the outer tag are filtered. **inner** *cos*: Indicates that Layer 2 packets with the specified cos field in the inner tag are filtered. **VID** *vid*: Indicates that Layer 2 packets with the specified VLAN ID field in the outer tag are filtered. **inner** *vid*: Indicates that Layer 2 packets with the specified VLAN ID field in the inner tag are filtered. *source source-wildcard:* Indicates that IP packets sent from hosts in the specified IP network segment are filtered. **host** *source*: Indicates that IP packets sent from a host with the specified source IP address are filtered. **any**: Indicates that IP packets sent from any host are filtered. **host** *source-mac-address*: Indicates that IP packets sent from a host with the specified source MAC address are filtered. **any**: Indicates that Layer 2 packets sent to any host are filtered. *destination destination-wildcard:* Indicates that IP packets sent to hosts in a specified

	IP network segment are filtered. **host** *destination*: Indicates that IP packets sent to a host with the specified destination IP address are filtered. **any**: Indicates that IP packets sent to any host are filtered. **host** *destination-mac-address*: Indicates that IP packets sent to a host with the specified destination MAC address are filtered. **any**: Indicates that Layer 2 packets sent to any host are filtered. **lt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is smaller than the port number specified by this parameter. **eq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is equal to the port number specified by this parameter. **gt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is larger than the port number specified by this parameter. **neq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is not equal to the port number specified by this parameter. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range.
Command Mode	Extended expert ACL configuration mode
Usage Guide	Run this command to add ACEs to a numbered extended expert ACL in global configuration mode. It cannot be used to add ACEs to a named extended expert ACL.

Rearranging Sequence Numbers of ACEs

Command	**expert access-list resequence** { *acl-id* | *acl-name* } *start-sn inc-sn*
Parameter Description	*acl-id*: Indicates the numbered extended expert ACL. *acl-name*: Indicates the named extended expert ACL. *start-sn*: Indicates that the start value of the sequence number is configured. *inc-sn*: Indicates that the sequence number increment is configured.
Command Mode	Global configuration mode
Usage Guide	In practice, ACEs may be added to or deleted from an extended expert ACL several times. After a given period of time, the sequence numbers are irregular. You can use this command to rearrange sequence numbers of ACEs to regularize them.

Applying an Extended Expert ACL



Command	**expert access-group** { *acl-id* **|** *acl-name* } { **in** | **out** }
Parameter Description	● *acl-id*: Indicates that a numbered extended expert ACL will be applied to the interface. ● *acl-name*: Indicates that a named extended expert ACL will be applied to the interface. ● **in**: Indicates that this ACL controls incoming L2 packets of the interface. ● **out**: Indicates that this ACL controls outgoing L2 packets of the interface.
Command	Interface configuration mode

Mode	
Usage Guide	This command makes an extended expert ACL take effect on the incoming or outgoing packets of a specified interface.

Configuration Example

The following configuration example describes only ACL-related configurations.

Configuring an Extended Expert ACL to Restrict Resources Accessed by Guests (Guests and Employees Cannot Communicate with Each Other, and Guests Can Access the Public Server but Not the Financial Data Server of the Company)

Scenario Figure 1-5	
Configuration Steps	● Configure an extended expert ACL. ● Add an ACE to deny packets sent from PCs in the guest area (VLAN 3) to employee PCs in VLAN 2. ● Add an ACE to prevent guests from accessing the financial data server of the company. ● Add an ACE to permit all packets. ● Apply the ACL to the inbound direction of the interface of the switch that connects to the guest area.

SW1	`sw1(config)#expert access-list extended 2700`
	`sw1(config-exp-nacl)#deny ip any any 192.168.1.0 0.0.0.255 any`
	`sw1(config-exp-nacl)#deny ip any any host 10.1.1.1 any`
	`sw1(config-exp-nacl)#pemit any any any any`
	`sw1(config-exp-nacl)#exit`
	`sw1(config)#int gigabitEthernet 0/2`

	`sw1(config-if-GigabitEthernet 0/2)#expert access-group 2700 in`
Verification	● On a guest's PC, ping the financial data server. Verify that the ping operation fails. ● On a guest's PC, ping the public server. Verify that the ping operation succeeds. ● On a guest's PC, ping the gateway address 192.168.1.1 of an employee. Verify that the ping operation fails. ● On a guest's PC, access the Internet, for example, visit the Baidu website. Verify that the webpage can be opened.

SW1	`sw1(config)#show access-lists`
	`expert access-list extended 2700`
	` 10 deny ip any any 192.168.1.0 0.0.0.255 any`
	`20 deny ip any any host 10.1.1.1 any`
	` 30 permit ip any any any any`
	
	`sw1(config)#show access-group`
	`expert access-group 2700 in`
	`Applied On interface GigabitEthernet 0/2`

1.4.4 Configuring an IPv6 ACL

Configuration Effect

Configure and apply an IPv6 ACL to an interface to control all incoming and outgoing IPv6 packets of this interface. You can permit or deny specific IPv6 packets on a network to control IPv6 users' access to network resources.

Configuration Step

↘ Configuring an IPv6 ACL

- Mandatory. Configure an IP ACL to control IPv4 users' access to network resources.
- You can configure this ACL on an access device, an aggregation device, or a core device based on user distribution. The IPv6 ACL takes effect only on the local device, and does not affect other devices on the network.

↘ Adding ACEs to an IPv6 ACL

- Optional. An ACL may contain no ACE or multiple ACEs. If no ACE is configured, all incoming IPv6 packets of the device are denied by default.

Rearranging Sequence Numbers of ACEs

- Optional. Rearrange sequence numbers of ACEs in an ACL to regularize them.

Applying an IPv6 ACL

- Mandatory. Apply an IPv6 ACL to a specified interface on a device to make this ACL take effect.
- You can apply an IPv6 ACL on a specified interface/VXLAN of an access device, an aggregation device, or a core device based on user distribution.

Verification

Use the following methods to verify the configuration of the IPv6 ACL:

- Run the **ping** command to verify that the IPv6 ACL takes effect on the specified interface. For example, if an IPv6 ACL is configured to prohibit a host with a specified IP address or hosts in a specified IPv6 address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.
- Access network resources, for example, visit an IPv6 website, to check whether the IPv6 ACL takes effect on the specified interface.

Related Commands

Configuring an IPv6 ACL

Command	**ipv6 access-list** *acl-name*
Parameter Description	*acl-name*: Indicates the name of an IPv6 ACL. If this parameter is specified, a named ACL is created. The value is a string of 1 to 99 characters. It cannot start with numerals (0–9), or cannot be **in** or **out**.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an IPv6 ACL and enter the IPv6 configuration mode.

Adding ACEs to an IPv6 ACL

- To filter TCP or UDP packets, add ACEs to an IPv6 ACL as follows.

Command	[*sn*] { **deny** | **permit** } *ipv6-protocol* { *source-ipv6-prefix/prefix-length* | **any** | **host** *source-ipv6-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix/prefix-length* | **any** | **host** *destination-ipv6-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**flow-label** *flow-label*] [**time-range** *time-range-name*]
Parameter Description	*sn*: Indicates the sequence number of an ACE. The value range is from 1 to 2,147,483,647. The sequence number determines the priority of the ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number

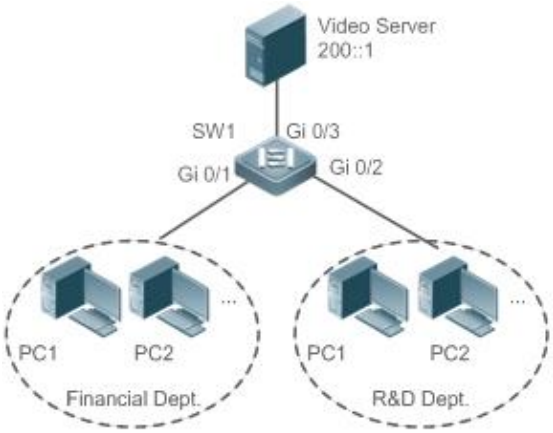
	when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a new ACE will be 110 by default. You can adjust the increment using a command. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. *ipv6-protocol*: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate usage, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp. *source-ipv6-prefix/prefix-length:* Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered. **host** *source-ipv6-address* : Indicates that IPv6 packets sent from a host with the specified source IP address are filtered. **any**: Indicates that IPv6 packets sent from any host are filtered. *destination-ipv6-prefix/prefix-length*: Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered. **any**: Indicates that IPv6 packets sent to any host are filtered. **lt** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is smaller than the port number specified by this parameter. **eq** *port*: Indicates that the Layer 4 destination port number in TCP or UDP packets to be matched is equal to the port number specified by this parameter. **gt** *port*: Indicates that the Layer destination port number in TCP or UDP packets to be matched is larger than the port number specified by this parameter. **neq** *port*: Indicates that the Layer destination port number in TCP or UDP packets to be matched is not equal to the port number specified by this parameter. **range** *lower upper*: Indicates that TCP or UDP packets with the Layer destination port number in the specified range are filtered. **flow-label** *flow-label*: Indicates that IPv6 packets with the specified the flow label field in the header are filtered. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range.
Command Mode	IPv6 ACL configuration mode
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

- To filter IPv6 packets except for the TCP or UDP packets, add ACEs to an IPv6 ACL as follows.

Command	[*sn*] { **deny** | **permit** } *ipv6-protocol* { *source-ipv6-prefix/prefix-length* | **any** | **host** *source-ipv6-address* } { *destination-ipv6-prefix*/*prefix-length* | **any** | **host** *destination-ipv6-address* } [**flow-label** *flow-label*] [**time-range** *time-range-name*]
Parameter Description	*sn*: Indicates the sequence number of an ACE. The value ranges from 1 to 2,147,483,647. The sequence number determines the priority of the ACE in the ACL. A

	smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a new ACE will be 110 by default. You can adjust the increment using a command. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. *ipv6-protocol*: Indicates the IPv6 protocol number. The value ranges from 0 to 255. To facilitate usage, the system provides frequently-used abbreviations of IPv6 protocol numbers to replace the specific IP protocol numbers, including icmp, ipv6, tcp, and udp. *source-ipv6-prefix/prefix-length:* Indicates that IP packets sent from hosts in the specified IPv6 network segment are filtered. **host** *source-ipv6-address*: Indicates that IPv6 packets sent from a host with the specified source IP address are filtered. **any**: Indicates that IPv6 packets sent from any host are filtered. *destination-ipv6-prefix/prefix-length:* Indicates that IPv6 packets sent from hosts in the specified IPv6 network segment are filtered. **host** *destination-ipv6-address* : Indicates that IPv6 packets sent to a host with the specified destination IP address are filtered. **any**: Indicates that IPv6 packets sent to any host are filtered. **flow-label** *flow-label*: Indicates that IPv6 packets with the specified the flow label field in the header are filtered. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range.
Command Mode	IPv6 ACL configuration mode
Usage Guide	Run this command to add ACEs in IPv6 ACL configuration mode.

↘ Rearranging Sequence Numbers of ACE



Command	**ipv6 access-list resequence** *acl-name start-sn inc-sn*
Parameter Description	*acl*-name: Indicates the IPv6 ACL name. *start-sn*: Indicates that the start value of the sequence number is configured. *inc-sn*: Indicates that the sequence number increment is configured.
Command Mode	Global configuration mode
Usage Guide	In practice, ACEs may be added to or deleted from an IPv6 extended ACL several times. After a given period of time, the sequence numbers are irregular. You can use this command to rearrange sequence numbers of ACEs to regularize them.

↘ Applying an IPv6 ACL

Command	**ipv6 traffic-filter** *acl-name* { **in** | **out** }
Parameter Description	*acl-name*: Indicates the name of an IPv6 ACL. **in**: Indicates that this ACL controls incoming IPv6 packets of the interface. **out**: Indicates that this ACL controls outgoing IPv6 packets of the interface.
Command Mode	Interface configuration mode
Usage Guide	This command makes an IPv6 ACL take effect on the incoming or outgoing packets of the specified interface.

Configuration Example

Configuring an IPv6 ACL to Prohibit the R&D Department from Accessing the Video Server

Scenario Figure 1-6	
Configuration Steps	● Configure an IPv6 ACL. ● Add an ACE to the IPv6 ACL to prevent access to the video server. ● Add an ACE to the IPv6 ACL to permit all IPv6 packets. ● Apply the IPv6 ACL to the incoming direction of the interface connected to the R&D department.

SW1	`sw1(config)#ipv6 access-list dev_deny_ipv6video`
	`sw1(config-ipv6-nacl)#deny ipv6 any host 200::1`
	`sw1(config-ipv6-nacl)#permit ipv6 any any`
	`sw1(config-ipv6-nacl)#exit`
	`sw1(config)#int gigabitEthernet 0/2`
	`sw1(config-if-GigabitEthernet 0/2)# ipv6 traffic-filter dev_deny_ipv6videoin`

Verification	● On a PC of the R&D department, ping the video server. Verify that the ping operation fails.
SW1	`sw1(config)#show access-lists`

	ipv6 access-list dev_deny_ipv6video 10 deny ipv6 any host 200::1 20 permit ipv6 any any sw1(config)#show access-group ipv6 traffic-filter dev_deny_ipv6video in Applied On interface GigabitEthernet 0/2

1.4.5 Configuring a Security Channel

Configuration Effect

Configure a security channel to enable packets matching the security channel rules not to be checked by access control applications. Configure the security channel if an access control application (such as 802.1X) is enabled on an uplink interface of a user, but the user should be allowed to log in to a website to download some resources (for example, downloading the authentication client) before 802.1X authentication.

Configuration Step

↘ Configuring an ACL

- Mandatory. Configure an ACL before configuring the security channel.
- You can configure this ACL on an access device, an aggregation device, or a core device based on user distribution. The configurations take effect only on the local device, and do not affect other devices on the network.

↘ Adding ACEs to an ACL

- Optional. An ACL may contain no ACE or multiple ACEs. If no ACE is configured for an ACL, the security channel does not take effect.

↘ Configuring a Security Channel on a Specified Interface or Globally

- Configure a security channel on an interface to make this security channel take effect on the interface. Configure a global security channel to make this security channel take effect globally. You must configure the interface-based or global security channel.
- You can configure a security channel on an access device, an aggregation device, or a core device based on user distribution.

Configuring an Excluded Interface for the Global Security Channel

- Optional. Configure an interface as the excluded interface for the global security channel if the global security channel is required not to take effect on this interface.

Configuring an Access Control Application

- Optional. You can enable 802.1X or web-based authentication to verify the security channel function.
- You can configure the access control function on an access device, an aggregation device, or a core device based on user distribution.

Verification

On a PC that is subject to the control of an access control application, ping the resources (devices or servers) that are allowed to be not checked by the access control application to verify the configuration of the security channel.

Related Commands

Configuring an ACL

For details about how to configure an ACL, see the earlier descriptions about the IP ACL, MAC extended ACL, expert extended ACL, or IPv6 ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.

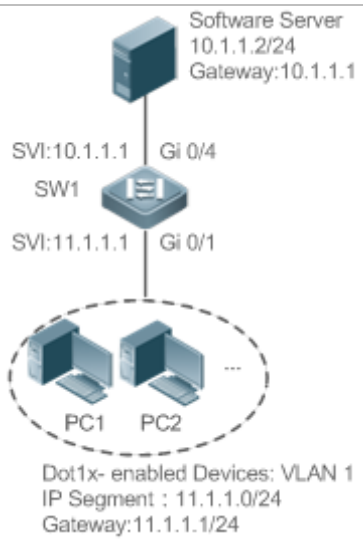
Configuring a Security Channel on an Interface

Command	**security access-group** { *acl-id* | *acl-name* }
Parameter Description	*acl-id*: Indicates that ID of the ACL that is configured as the security channel. *acl-name*: Indicates that name of the ACL that is configured as the security channel.
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure a specified ACL as the security channel on the specified interface.

Configuring a Global Security Channel

Command	**security global access-group** { *acl-id* | *acl-name* }
Parameter Description	*acl-id*: Indicates that ID of the ACL that is configured as the security channel. *acl-name*: Indicates that name of the ACL that is configured as the security channel.
Command	Global configuration mode

Mode	
Usage Guide	Run this command to configure the specified ACL as the global security channel.



Configuring an Excluded Interface for the Global Security Channel

Command	**security uplink enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure the specified interface as the excluded interface of the global security channel.

Configuration Example

The following configuration example describes only ACL-related configurations.

Enabling DOT1X Authentication and Configuring a Security Channel to Allow Users to Download the SU Software from the Server Before Authentication

Scenario Figure 1-7	
Configuration Steps	● Configure an extended expert ACL named **exp_ext_esc**. ● Add an ACE to allow packets to the destination host at 10.1.1.2. ● Add an ACE to permit DHCP packets. ● Add an ACE to permit ARP packets. ● On the interface where 802.1X authentication is enabled, configure the ACL **exp_ext_esc** as the security channel.

SW1	`sw1(config)#expert access-list extendedexp_ext_esc`
	`sw1(config-exp-nacl)# permit ip any any host 10.1.1.2 any`
	`sw1(config-exp-nacl)# permit 0x0806 any any any any any`

	sw1(config-exp-nacl)# permit tcp any any any any eq 67 sw1(config-exp-nacl)# permit tcp any any any any eq 68 sw1(config)#int gigabitEthernet 0/1 sw1(config-if-GigabitEthernet 0/1)# security access-group exp_ext_esc
Verification	● On a PC of the sales department, ping the server of the sales department. Verify that the ping operation succeeds. ● On the PCs of R&D departments 1 and 2, ping the server of the sales department. Verify that the ping operations fail.
	sw1#show access-lists expert access-list extended exp_ext_esc 10 permit ip any any host 10.1.1.2 any 20 permit arp any any any any any 30 permit tcp any any any any eq 67 40 permit tcp any any any any eq 68…… sw1#show running-config interface gigabitEthernet 0/1 Building configuration... Current configuration : 59 bytes interface GigabitEthernet 0/1 security access-group exp_ext_esc

1.4.6 Configuring ACEs Based on the Time Range

Configuration Effect

Configure the time range for ACEs to make the ACEs take effect or to become invalid in a specified period of time.

Configuration Step

↘ **Configuring an ACL**

- Mandatory. Configure an ACL before configuring ACEs based on the time range.

- You can configure this ACL on an access device, an aggregation device, or a core device based on user distribution. The configurations take effect only on the local device, and do not affect other devices on the network.

Adding an ACE with the Time Range Specified

- Mandatory. Specify the time range when adding an ACE.

Applying an ACL

- Mandatory. Apply the ACL to a specified interface to make ACEs take effect in the specified time range.
- You can apply an IP ACL on a specified interface of an access device, an aggregation device, or a core device based on user distribution.

Verification

In the time range during which the configured ACE takes effect or becomes invalid, run the **ping** command or construct packets matching the ACE to check whether the ACE takes effect or becomes invalid.

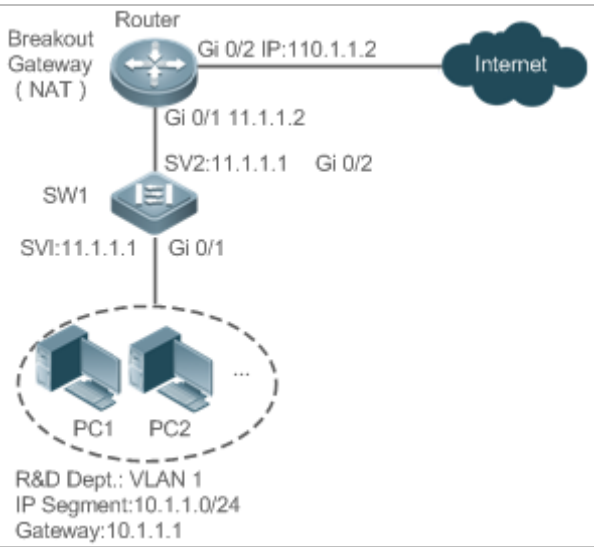
Related Commands

Configuring an ACL

For details on how to configure an ACL, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.

Adding an ACE with the Time Range Specified

For details on how to configure an ACE, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.



Applying an ACL

For details on how to apply an ACL, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.

Configuration Example

The following configuration example describes only ACL-related configurations.

Adding an ACE with the Time Range Specified to Allow the R&D Department to Access the Internet Between 12:00 and 13:30 Every Day

Scenario **Figure 14-8**	
Configuration Steps	● Configure a time range named **access-internet**, and add an entry of the time range between 12:00 and 13:30 every day. ● Configure an IP ACL named **ip_std_internet_acl**. ● Add an ACE to allow packets with the source IP address in the network segment 10.1.1.0/24, and associate this ACE with the time zone **access-internet**. ● Add an ACE to deny packets with the source IP address the network segment 10.1.1.0/24. Access to the Internet is not allowed except in the specified time range. ● Add an ACE to permit all packets. ● Apply the ACL to the outbound direction of the interface connected to the egress gateway.

SW1	`Hostname(config)# time-range access-internet`
	`Hostname(config-time-range)# periodic daily 12:00 to 13:30`
	`Hostname(config-time-range)# exit`
	`sw1(config)# ip access-list standard ip_std_internet_acl`
	`sw1(config-std-nacl)# permit 10.1.1.0 0.0.0.255 time-range access-internet`
	`sw1(config-std-nacl)# deny 10.1.1.0 0.0.0.255`
	`sw1(config-std-nacl)# permit any`
	`sw1(config-std-nacl)# exit`
	`sw1(config)#int gigabitEthernet 0/2`
	`sw1(config-if-GigabitEthernet 0/2)# ip access-group ip_std_internet_acl out`

Verification	● Within the time range between 12:00 and 13:30, visit the Baidu website on a PC of the R&D department. Verify that the website can be opened normally. ● Beyond the time range between 12:00 and 13:30, visit the Baidu website on a PC

	of the R&D department. Verify that the website cannot be opened.

SW1	`sw1#show time-range`
	
	`time-range entry: access-internet (inactive)`
	`  periodic Daily 12:00 to 13:30`
	
	`sw1#show access-lists`
	
	`ip access-list standard ip_std_internet_acl`
	` 10 permit 10.1.1.0 0.0.0.255 time-range access-internet (inactive)`
	` 20 deny 10.1.1.0 0.0.0.255`
	` 30 permit any`
	
	`sw1#show access-group`
	`ip access-group ip_std_internet_acl out`
	`Applied On interface GigabitEthernet 0/2`

1.4.7 Configuring Comments for ACLs

Configuration Effect

During network maintenance, if many ACLs are configured without any comments, it is difficult to distinguish these ACLs. You can configure comments for ACLs to better understand usage of ACLs.

Configuration Step

↘ **Configuring an ACL**

- Mandatory. Configure an ACL before configuring a security channel.
- You can configure this ACL on an access device, an aggregation device, or a core device based on user distribution. The configurations take effect only on the local device, and do not affect other devices on the network.

↘ **Configuring Comments for ACLs**

- Optional. Configure comments for ACLs so that it is easy to manage and understand the configured ACLs.

↘ **Adding ACEs to an ACL**

- Optional. An ACL may contain no ACE or multiple ACEs. If no ACE is configured, the security channel does not take effect.

Configuring Comments for ACEs

- Optional. To facilitate understanding of a configured ACL, you can configure comments for ACEs in addition to comments for the ACL.

Verification

Run the **show access-lists** command on the device to display the comments configured for ACLs.

Related Commands

Configuring an ACL

For details about how to configure an ACL, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.

Configuring a Comment for an ACL

Use either of the following two methods to configure a comment for an ACL.

Command	**list-remark** *comment*
Parameter Description	*comment*: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	ACL configuration mode
Usage Guide	Run this command to configure the comment for a specified ACL.

Command	**access-list** *acl-id* **list-remark** *comment*
Parameter Description	*acl-id*: Indicates the ID of an ACL. *comment*: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	Configuration mode
Usage Guide	Run this command to configure the comment for a specified ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.

Configuring Comments for ACEs

Use either of the following two methods to configure a comment for an ACE.

Command	**remark** *comment*
Parameter Description	*comment*: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	ACL configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE. If *sn* is not configured, the comment is configured for the last ACE.

Command	**access-list** *acl-id* [*sn*] **remark** *comment*
Parameter Description	*acl-id*: Indicates the ID of an ACL. *sn*: Indicates the sequence number of an ACE for which a comment is required. *comment*: Indicates the comment. The value is a string of 1 to 100 characters. A comment longer than 100 characters will be truncated to 100 characters.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the comment for a specified ACE. If *sn* is not configured, the comment is configured for the last ACE.

1.5 Monitoring

Clearing

Command	Description
clear counters access-list [*acl-id* | *acl-name*]	Clears the ACL packet matching counters.
clear access-list counters [*acl-id* | *acl-name*]	Clears statistics on denied packets.

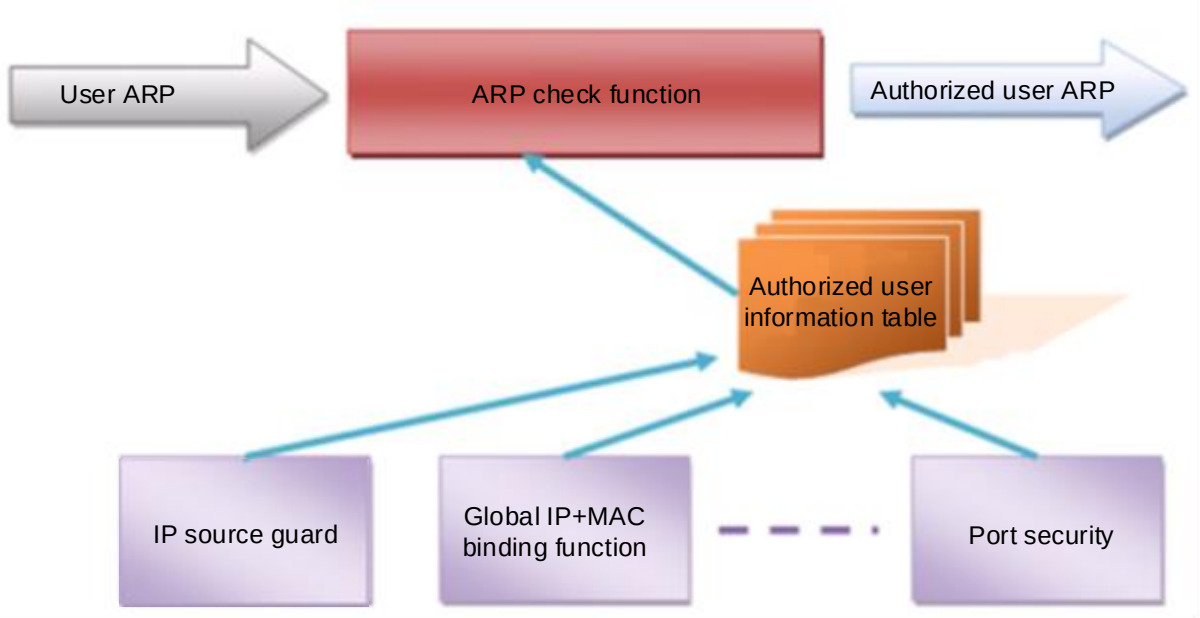
Displaying

Command	Description
show access-lists [*acl-id* | *acl-name*] [**summary**]	Displays basic ACLs.
show access-group [**interface** *interface-name*] | **wlan** *wlan-id*	Displays the ACL applied to an interface.
show ip access-group [**interface** *interface-name* | **wlan** *wlan-id*]	Displays the IP ACL applied to an interface.
show mac access-group [**interface** *interface-name*| **wlan** *wlan-id*]	Displays the extended MAC ACL applied to an interface.

show expert access-group [**interface** *interface-name* | **wlan** *wlan-id*]	Displays the extended expert ACL applied to an interface.
show ipv6 traffic-filter [**interface** *interface-name*]	Displays the IPv6 ACL applied to an interface.

Debugging

⚠ System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.



Command	Description
debug acl acld event	Debugs the ACL running process.
debug acl acld client-show	Debugs ACL clients.
debug acl acld acl-show	Debugs ACLs created by all ACL clients.

1 Configuring ARP Check

1.1 Overview

The Address Resolution Protocol (ARP) check filters all ARP packets on interfaces (including wired Layer 2 switching interfaces, Layer 2 aggregate interfaces, and Layer 2 encapsulation sub-interfaces, as well as WLAN interfaces) and discards unauthorized ARP packets, so as to effectively prevent ARP spoofing through networks and to promote network stability. On devices supporting ARP check, unauthorized ARP packets ion networks will be ignored according to authorized user information (IP-based or IP-MAC information) generated by security application modules such as IP source guard, global IP+MAC binding, 802.1X authentication, Global Security Network (GSN) binding, web-based authentication, and port security.

Figure 5-1

In Figure 5-1, security modules generate authorized user information (IP-based or IP-MAC based information). ARP check uses the information to detect whether the Sender IP field or the <Sender IP, Sender MAC> fields in all ARP packets on interfaces match those in the list of authorized user information. If not, such ARP packets will be discarded.

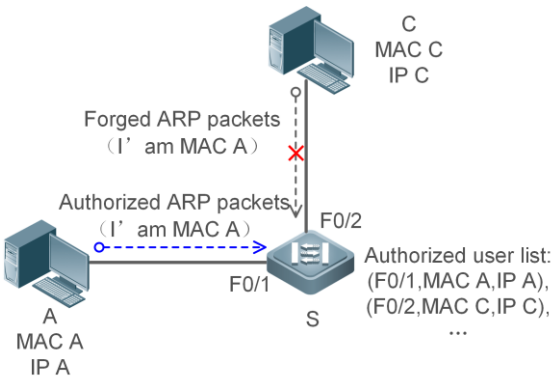
Protocols and Standards

RFC826: An Ethernet Address Resolution Protocol or Converting Network Protocol Addresses

1.2 Applications

Application	Description
Filtering ARP Packets on a Network	Unauthorized users on a network launch attacks using forged ARP packets.

1.2.1 Filtering ARP Packets on a Network



Scenario

ARP check enables the device to check ARP packets from untrusted interfaces and filter out ARP packets with addresses not matching the results assigned by the DHCP server.

In Figure 5-2, the device checks ARP packets sent by DHCP clients.

The interface receiving ARP packets, and the MAC address and IP address of the sender that sends ARP packets must be consistent with DHCP packets sent by the device for detection.

Figure 5-2

Remarks:	S is an access device. A and C are user PCs.

Deployment

- Enable DHCP snooping on S to realize DHCP monitoring.
- Set all the downlink interfaces on S as DHCP untrusted interfaces.
- Enable IP source guard and ARP check on all untrusted interfaces of S to realize ARP packet filtering.

1.3 Features

Basic Concepts

Compatible Security Modules

ARP check can be used with the following security modules:

- IP-based mode: port security and IP source guard manually configured
- IP-MAC-based mode: port security, global IP+MAC binding, 802.1X authorization, IP source guard, GSN binding, and web-based authentication

Two Modes of APR Check

ARP check can be enabled or disabled. It is enabled by default.

1 Enabling ARP check

ARP check enables the device to check ARP packets based on IP-based or IP-MAC-based binding information provided by the following modules:

- Global IP-MAC binding
- 802.1X authorization
- IP source guard
- GSN binding
- Port security
- Web-based authentication
- IP+MAC binding or IP binding of port security

⚠ When only ARP Check is enabled on an interface, the device allows all packets to pass through. On the device enabled with ARP check and the above-mentioned modules, if user information cannot be generated, all ARP packets from this interface will be discarded.

⚠ When ARP check and VRRP are enabled on an interface, if the physical IP address and virtual IP address of the interface can be used as the gateway address, configure the device to allow packets from the physical IP address and virtual IP address to pass. Otherwise, ARP packets sent to the gateway will be filtered out.

2 Disabling ARP check

ARP packets on an interface are not checked.

Overview

Feature	Description
Filtering ARP Packets	Check the source IP and source MAC addresses of ARP packets to filter out unauthorized ARP packets.

1.3.2 Filtering ARP Packets

Enable ARP check on specified interfaces to filter unauthorized ARP packets.

Working Principle

A device matches the source IP and source MAC addresses of ARP packets received on its interfaces with authorized user information of the device. If information matches, packets are forwarded. Otherwise, they will be discarded.

Related Configuration

↘ Enabling ARP Check on Interfaces

By default, ARP check is disabled on interfaces.

Use the **arp-check** command to enable ARP check.

Unless otherwise specified, ARP check is typically configured on interfaces of access devices.

1.4 Configuration

Configuration	Description and Command	
Configuring ARP Check	(Mandatory) It is used to enable APR check.	
	arp-check	Enables ARP check.

1.4.1 Configuring ARP Check

Configuration Effect

Unauthorized ARP packets are filtered out.

Notes

- When ARP check is enabled, the number of policies or users of related security applications may decrease.
- ARP check cannot be configured on mirrored destination interfaces.
- ARP check cannot be configured on the trusted interface of DHCP snooping.
- ARP check cannot be configured on global IP+MAC excluded interfaces.
- ARP check can be enabled only on wired switching interfaces, Layer aggregate interfaces, Layer 2 encapsulation sub-interfaces, as well as WLAN interfaces. Enable ARP check for the wired service in interface configuration mode, while for the wireless service in WLAN security configuration mode.
- For fit APs in wired access mode, ARP check needs to be enabled in all-AP configuration mode.

Configuration Steps

Enabling ARP Check

Mandatory. The function is disabled by default. To use the ARP check function, an administrator needs to run a command to enable it.

Verification

- Use the **show running-config** command to display the system configuration.
- Use the **show interfaces** { *interface-type interface-number* } **arp-check list** command to display filtering entries.

Related Commands

Enabling ARP Check

Command	**arp-check**
Parameter Description	N/A
Command	Interface configuration mode, WLAN security configuration mode, or all-AP configuration mode
Usage Guide	This command is used to generate ARP filtering information according to authorized user information about security application modules to filter out unauthorized ARP packets on a network. When the ARP check function is enabled in all-AP configuration mode, the function is enabled on wired interfaces of all APs.

Configuration Example

The following configuration example introduces only the configuration related to ARP check.

Enabling ARP Check on Interfaces

Configuration Steps	• Enable ARP check. Restricted ARP packets must match entries of IP source guard, port security, or global IP+MAC binding.
	Hostname# configure terminal Hostname(config)#address-bind 192.168.1.3 00d0.f800.0003 Hostname(config)#address-bind install Hostname(config)#ip source binding 00d0.f800.0002 vlan 1 192.168.1.4 interface gigabitethernet 0/1 Hostname(config)# interface gigabitethernet 0/1 Hostname(config-if-GigabitEthernet 0/1)# arp-check Hostname(config-if-GigabitEthernet 0/1)#ip verify source port-security Hostname(config-if-GigabitEthernet 0/1)#exit Hostname(config)#interface gigabitethernet 0/4 Hostname(config-if-GigabitEthernet 0/4)# arp-check Hostname(config-if-GigabitEthernet 0/4)#exit Hostname(config)#interface gigabitethernet 0/5 Hostname(config-if-GigabitEthernet 0/5)# arp-check Hostname(config-if-GigabitEthernet 0/5)#end Hostname# configure terminal Hostname(config)#wlan-config 1 TEST-SSID Hostname(config-wlan)#end Hostname# configure terminal Hostname(config)#wlansec 1 Hostname(config-wlansec)# ip verify source port-security Hostname(config-wlansec)#arp-check Hostname(config-wlansec)#end Hostname# configure terminal Hostname(config)# ip source binding 0026.c79f.6e4c vlan 1 172.168.131.1 wlan 1
Verification	• Use the **show interfaces arp-check list** command to display effective ARP check entries on interfaces.
	Hostname# show interfaces arp-check list INTERFACE SENDER MAC SENDER IP POLICY SOURCE ---------- ---------- ---------- ---------- GigabitEthernet 0/1 00d0.f800.0003 192.168.1.3 address-bind

```

Common Errors

If ARP packets on an interface need to be checked but APR check is disabled, APR check will not take effect.

1.5 Monitoring

Displaying

Command	Description
show interfaces [*interface-type interface-number*] **arp-checklist**	Displays effective ARP check entries on interfaces.
show wlan [*wlan-id*] **arp-checklist**	Displays effective ARP check entries based on a WLAN.

1 Configuring Gateway-targeted ARP Anti-spoofing

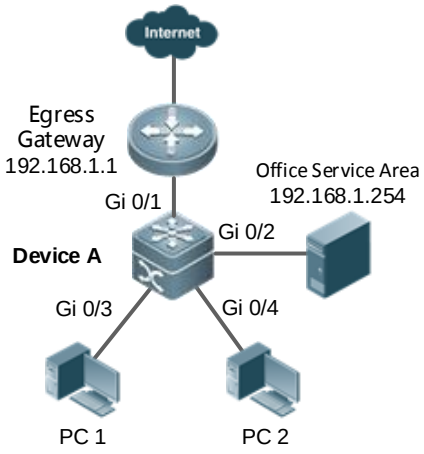
1.1 Overview

Gateway-targeted Address Resolution Protocol (ARP) anti-spoofing effectively prevents gateway-targeted ARP spoofing by checking whether the source IP addresses of ARP packets (Sender IP fields of ARP packets) on the logical interface are the configured gateway IP addresses.

Protocols and Standards

RFC 826: Ethernet Address Resolution Protocol

1.2 Applications



Application	Description
Gateway-targeted ARP Anti-spoofing	ARP spoofing packets with forged gateway addresses and intranet server IP addresses are blocked so that users can access the Internet.

1.2.1 Gateway-targeted ARP Anti-spoofing

Scenario

- PCs access the office server through the access device (Device A) and connect to the Internet through the gateway.
- If any malicious user hosts use forged gateway IP addresses or server IP addresses for ARP spoofing, the other user hosts cannot access the Internet or the server.
- ARP spoofing packets with forged gateway addresses and intranet server IP addresses must be blocked so that users can access the Internet.

Figure 1-1 Typical Topology of Gateway-targeted ARP Anti-spoofing

Deployment

Enable gateway-targeted ARP anti-spoofing on interfaces (Gi 0/3 and Gi 0/4 in this example) of the access device (Device A) that are directly connected to PCs. The gateway address is the intranet gateway address and the intranet server address.

1.3 Features

Basic Concepts

ARP

ARP, a TCP/IP protocol, obtains physical addresses based on IP addresses.

A host broadcasts ARP request packets to all hosts on the network and receives the returned packets to determine physical addresses of the target IP addresses, and saves IP addresses and hardware addresses in the local ARP cache, which are queried in response to future request packets. For ARP, all the hosts on a network trust each other. Each host on the network can independently send ARP response packets; the other hosts receive the response packets and record them in the local ARP cache without detecting authenticity. In this way, attackers can send forged ARP response packets to target hosts so that packets sent from these hosts cannot reach the target host or reach the non-target host, thereby causing ARP spoofing.

Gateway-targeted ARP Spoofing

When User A sends an ARP packet requesting the media access control (MAC) address of a gateway, User B on the same VLAN also receives this packet, and User B can send an ARP response packet. In the ARP response packet, the gateway IP address is the source IP address of the packet, and User B's MAC address is the source MAC address. When receiving the ARP response packet, User A considers User B's device as the gateway, so all the packets sent from User A to the gateway during communication will be sent to User B. In this way, User A's communication information is intercepted, thereby causing ARP spoofing.

Overview

Feature	Description
Gateway-targeted ARP Anti-spoofing	Blocks ARP spoofing packets with forged gateway address and intranet server IP addresses to ensure that users can access the Internet.

1.3.1 Gateway-targeted ARP Anti-spoofing

Working Principle

Gateway-targeted Anti-spoofing

Gateway-targeted ARP anti-spoofing effectively prevents gateway-targeted ARP spoofing by checking whether the source IP addresses of ARP packets on the logical interface are the configured gateway IP addresses. If an ARP packet uses the gateway address as the source IP address, the packet will be discarded to prevent users from receiving incorrect ARP response packets. If not, the packet will not be handled. In this way, only the devices connected to the device can send ARP packets of the gateway, and forged ARP response packets sent from the other PCs are filtered by the device.

Related Configuration

Configuring the Gateway-targeted Anti-spoofing Address

- By default, no gateway-targeted ARP anti-spoofing address is configured.
- Run the **anti-arp-spoofing ip** command to configure the gateway-targeted ARP anti-spoofing address.

1.4 Configuration

Configuration	Description and Command	
Configuring Gateway-targeted Anti-spoofing	⚠ Optional.	
	anti-arp-spoofing ip	Configures gateway-targeted ARP anti-spoofing on the logical interface and specifies the gateway IP address.

1.4.1 Configuring Gateway-targeted Anti-spoofing

Configuration Effect

Enable gateway-targeted ARP anti-spoofing.

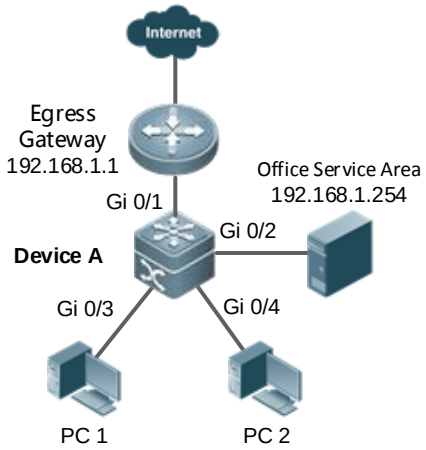
Configuration Steps

Configuring Gateway-targeted ARP Anti-spoofing

- Gateway-targeted ARP anti-spoofing is mandatory. It must be enabled.

Verification

- Run the **show running-config** command to check the configuration.
- Run the **show anti-arp-spoofing** command to display all data of gateway-targeted ARP anti-spoofing.



Related Commands

Configuring Gateway-targeted ARP Anti-spoofing

Command	**anti-arp-spoofing ip** *ipv4-address*
Parameter Description	*ipv4-address*: Indicates the IPv4 address of the gateway.
Command Mode	Interface configuration mode or wireless security configuration mode
Usage Guide	This configuration is supported only on Layer 2 interfaces. This configuration is supported on wireless ACs in wireless security configuration mode only.

Configuration Example

Configuring Gateway-targeted ARP Anti-spoofing

Scenario **Figure 1-2**	
	PCs access the office server through the access device (Device A) and connect to the Internet through the gateway. If any malicious user hosts use forged gateway IP addresses or server IP addresses to perform ARP spoofing, the other user hosts cannot access the Internet or the server. The ARP spoofing packets with forged gateway addresses and intranet server IP addresses must be blocked so that users can access the Internet.
Configuration Steps	Enable gateway-targeted ARP anti-spoofing on the interfaces connected to the PCs.

	`DeviceA# configure terminal`
	`DeviceA(config)# interface range gigabitethernet 0/3-4`
	`DeviceA(config-if-range)# anti-arp-spoofing ip 192.168.1.1`
	`DeviceA(config-if-range)# anti-arp-spoofing ip 192.168.1.254`

Verification	Run the **show anti-arp-spoofing** command to check for data of gateway-targeted ARP anti-spoofing.

	`DeviceA# show anti-arp-spoofing`
	`NO PORT IP STATUS`
	`----- ---------- ---------- ----------`
	`3 Gi0/3 192.168.1.1 active`
	`4 Gi0/3 192.168.1.254 active`
	`5 Gi0/4 192.168.1.1 active`
	`6 Gi0/4 192.168.1.254 active`

1.5 Monitoring

Displaying

Command	Description
show anti-arp-spoofing	Displays all data on gateway-targeted ARP spoofing prevention.

1 Configuring Global IP-MAC Binding

1.1 Overview

Global IP-MAC binding is configured manually to verify bindings between IP addresses and MAC addresses in input packets. If a specified IP address is bound to a MAC address, the device receives only the IP packets containing matched IP address and MAC address, and discards other packets.

Global IP-MAC binding can be used to strictly verify the source of input packets. Note that this feature takes precedence over 802.1X authentication, port security, and access control list (ACL).

1.2 Applications

N/A

1.3 Features

Basic Concepts

IPv6 Address Binding Mode

IPv6 address binding has three modes: compatible, loose, and strict. The default mode is strict. If IPv4-MAC binding is not configured, the IPv6 address binding mode does not take effect, and all IPv4 and IPv6 packets are allowed to pass through. If IPv4-MAC binding is configured, the IPv6 address binding mode takes effect, and the device forwards IPv4 and IPv6 packets based on forwarding rules described in the following table.

Mode	IPv4 Packet Forwarding Rule	IPv6 Packet Forwarding Rule
Strict	Packets matching the IPv4-MAC binding are forwarded.	Packets matching the global IPv6-MAC binding are forwarded.
Loose	Packets matching the IPv4-MAC binding are forwarded.	If IPv6-MAC binding is configured, packets matching the IPv6-MAC binding are forwarded. If IPv6-MAC binding does not exist, all IPv6 packets are forwarded.
Compatible	Packets matching the IPv4-MAC binding are forwarded.	If the IPv6 packets contain a MAC address matching the MAC address in the IPv4-MAC binding, the IPv6 packets are forwarded. Packets matching the global IPv6-MAC binding are forwarded.

IPv4-MAC binding entries in the preceding table can be generated through global IP-MAC binding or other access security functions, such as port security and IP source guard. Similarly, IPv6-MAC binding can be also generated through global IP-MAC binding or other access security functions, such as port security and IPv6 source guard.

Overview

Feature	Description
Configuring an IPv6 Address Binding Mode	Changes IPv6 packet forwarding rules.

1.3.1 Configuring an IPv6 Address Binding Mode

Working Principle

After the IPv6-MAC binding is configured and access security functions are enabled, IPv6 packets are forwarded based on the IPv6 address binding mode. IPv6 address binding has three modes: compatible, loose, and strict.

Related Configuration

↘ Configuring an IPv6 Address Binding Mode

By default, the IPv6 address binding mode is strict.

Run the **address-bind ipv6-mode** command to specify an IPv6 address binding mode.

1.4 Configuration

Configuration	Description and Command	
Configuring an IPv6 Address Binding Mode	⚠ (Optional) It is used to configure an IPv6 address binding mode.	
	address-bind ipv6-mode	Configures an IPv6 address binding mode.

1.4.1 Configuring an IPv6 Address Binding Mode

Configuration Effect

Change the IPv6 address binding mode so as to change forwarding rules for IPv6 packets.

Configuration Step

↘ Configuring the IPv6 Address Binding Mode

Optional. Perform this configuration when you want to change forwarding rules for IPv6 packets.

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

↘ Configuring an IPv6 Address Binding Mode

Command	**address-bind ipv6-mode** { **compatible** | **loose** | **strict** }
Parameter Description	**compatible**: Indicates the compatible mode. **loose**: Indicates the loose mode. **strict**: Indicates the strict mode.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Configuration Example

Configuring an IPv6 Address Binding Mode

Configuration Steps	● Configure global IP-MAC binding. ● Enable address binding. ● Set the IPv6 address binding mode to compatible.

	`Hostname# configure terminal`
	`Enter configuration commands, one per line. End with CNTL/Z.`
	`Hostname(config)# address-bind ipv6-mode compatible`

Verification	Run the **show running-config** command to display the configuration on the device.

1 Configuring IP Source Guard

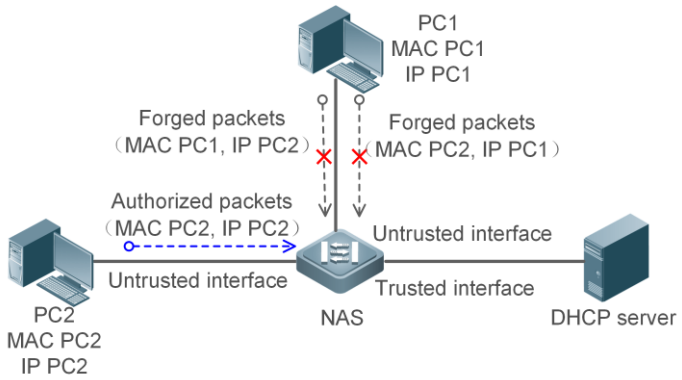
1.1 Overview

The IP source guard function realizes hardware-based IP packet filtering. This ensures that only the users having their information in the binding database can access networks normally, preventing users from forging IP packets.

1.2 Applications

Application	Description
IP/MAC Spoofing Attack	On a network, users use unauthorized IP addresses and malicious users launch attacks by forging IP packets.

1.2.1 IP/MAC Spoofing Attack Defense



Scenario

The device checks IP packets from DHCP untrusted interfaces. Forged IP packets will be filtered out based on the address or IP and MAC addresses.

In Figure 1-1, the device checks IP packets sent by DHCP clients.

- The Source IP Address fields of IP packets should match DHCP-assigned IP addresses.
- The Source MAC Address fields of Layer 2 packets should match MAC addresses in DHCP request packets from clients.

Figure 1-1

Deployment

- Enable DHCP snooping on the NAS to realize DHCP monitoring.
- Set all downlink interfaces on the NAS as DHCP untrusted interfaces.
- Enable IP source guard on the NAS to realize IP packet filtering.

- Configure the IP-MAC mode for IP source guard on the NAS, which filters IP packets based on IP and MAC addresses.

1.3 Features

Basic Concepts

Source IP Address

Source IP address field of an IP packet.

Source MAC Address

Source MAC address field of an IP packet.

IP-based Filtering

Only source IP addresses of all IP packets (except DHCP packets) passing through an interface are checked. It is the default filtering policy of IP source guard.

IP-MAC based Filtering

Both source IP addresses and source MAC addresses of all IP packets are checked, and only those user packets with these IP addresses and MAC addresses existing in the binding database are allowed to pass through.

Address Binding Database

It is the basis for security control of IP source guard. Data in the address binding database comes from the DHCP snooping binding database or statically configured. When IP source guard is enabled, data of the DHCP snooping binding database is synchronized to the address binding database of IP source guard, so that IP packets can be filtered strictly through IP source guard on a device with DHCP snooping enabled.

Excluded VLAN

By default, when IP source guard is enabled on an interface, it is valid for all the VLANs on the interface. You can specify excluded VLANs, where the device does not check or filter IP packets. At most 32 excluded VLANs can be specified for an interface.

Overview

Feature	Description
Checking Source Address Fields of Packets	Filter IP packets passing through interfaces by IP-based or IP-MAC-based filtering.

1.3.1 Checking Source Address Fields of Packets

The device filters IP packets passing through interfaces based on source IP addresses or both source IP addresses and source MAC addresses to prevent malicious attacks by forging packets. When there is no need to check and filter IP packets within a VLAN, an excluded VLAN can be specified to allow such packets to pass through.

Working Principle

When IP source guard is enabled, the device checks source addresses of packets passing through an interface. The interface can be a wired switching interface, a Layer 2 aggregate interface, or a Layer 2 encapsulation sub-interface, or a WLAN interface. Such packets will pass through the interface only when source address fields of the packets match DHCP snooping binding entries, or the statically configured user set. There are two matching modes.

IP-based Filtering

Packets are allowed to pass through an interface only when source IP address fields of the packets belong to the address binding database.

IP-MAC-based Filtering

Packets are allowed to pass through an interface only when both Layer 2 source MAC addresses and Layer 3 source IP addresses of packets match an entry in the address binding database.

Specifying an Excluded VLAN

Packets within such a VLAN are allowed to pass through an interface without being checked or filtered.

Related Configuration

Enabling IP Source Guard on an Interface

- By default, IP source guard is disabled on interfaces.
- It can be enabled by using the **ip verify source** command.

IP source guard needs to be used with DHCP snooping. Therefore, DHCP snooping should also be enabled. DHCP snooping can be enabled on devices at any time, either before or after IP source guard is enabled.

Configuring Static Binding

- By default, authorized users passing IP source guard check are all from the binding database of DHCP snooping.
- Bound users can be added using the **ip source binding** command.

Specifying an Excluded VLAN

- By default, IP source guard is valid for all the VLANs on an interface.
- Excluded VLANs can be specified by using the **ip verify source exclude-vlan** command.

Excluded VLANs can be specified only after IP source guard is enabled on an interface. Specified excluded VLANs will be deleted automatically when IP source guard is disabled on an interface.

The above-mentioned interface can be a wired switching interface, a Layer 2 aggregate interface, a Layer 2 encapsulation sub-interface, or a WLAN interface.

1.4 Configuration

Configuration	Description and Command	
Configuring IP Source Guard	(Mandatory) It is used to enable IP source guard.	
	ip verify source	Enables IP source guard on an interface.

Configuration	Description and Command	
	ip source binding	Configures static binding.
	Ip verify source exclude-vlan	Specifies an excluded VLAN for IP source guard.

1.4.1 Configuring IP Source Guard

Configuration Effect

Check the source IP addresses of input IP packets.

Notes

- When IP source guard is enabled, IP packet forwarding may be affected. Typically, IP source guard is used with DHCP snooping.
- IP source guard cannot be configured on the trusted interfaces controlled by DHCP snooping.
- IP source guard cannot be configured on the global IP+MAC excluded interfaces.
- IP source guard can be configured and enabled only on the wired switching interface, a Layer 2 aggregate interface, a Layer 2 encapsulation sub-interface, or a WLAN interface. In a wired access scenario, this function is configured in interface configuration mode. In a wireless access scenario, this function is configured in WLAN security configuration mode.
- For a Fit AP in a wired access scenario, IP Source Guard is configured and enabled in all-AP configuration mode.

Configuration Step

- Enable DHCP snooping.
- Enable IP source guard.

Verification

Use monitoring commands to display the address binding database of IP source guard.

Related Commands

↘ Enabling IP Source Guard on an Interface

Command	**ip verify source** [**port-security**]
Parameter Description	**port-security**: Enables IP-MAC-based filtering.
Configuration Mode	Interface configuration mode, WLAN security configuration mode, or all-AP configuration mode
Usage Guide	Detection of users based on IP address or both IP and MAC addresses can be realized by enabling IP source guard for an interface. In all-AP configuration mode, once IP source guard is enabled, it is valid for all wired interfaces of the AP.

↘ Configuring Static Binding

Command	**ip source binding** *mac-address* **vlan** *vlan-id* [*ip-address* { **interface** *interface-type interface-number* | **wlan** *wlan-id* | **ip-mac** | **ip-only** }

Parameter Description	**mac-address**: Indicates the MAC address of static binding. **vlan-id**: Indicates the VLAN ID of static binding. It also refers to the outer VLAN ID of a QINQ-termination user. **ip-address**: The IP address of a static binding *interface-type interface-number*: Indicates the port ID (PID) of static binding. **wlan-id**: Indicates the WLAN ID of static binding. **ip-mac**: Indicates the IP-MAC-based mode. **ip-only**: Indicates the IP-based mode.
Configuration Mode	Global configuration mode
Usage Guide	Through this command, authorized users can pass the check of IP source guard but not being controlled by DHCP. For a fit AP in a wireless scenario, an AC cannot access static information about users that are connected to a wired interface of a wireless AP.

Specifying an Excluded VLAN for IP Source Guard

Command	**ip verify source exclude-vlan** *vlan-id*
Parameter Description	*vlan-id*: Indicates the ID of an excluded VLAN where the device enabled with IP source guard does not check or filter such packets.
Configuration Mode	Interface configuration mode or WLAN security configuration mode
Usage Guide	By using this command, the device does not check or filter packets from the specified VLANs on an interface where IP source guard is enabled.

Configuration Example

Enabling IP Source Guard on an Interface

Configuration Steps	● Enable DHCP snooping. ● Enable IP source guard.

	`Hostname(config)# interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# ip verify source`
	`Hostname(config-if-GigabitEthernet 0/1)# exit`
	`Hostname(config)# wlansec 1`
	`Hostname(config-wlansec)# ip verify source port-security`
	`Hostname(config-wlansec)# end`

Verification	Display the address filtering table of IP source guard.
	`Hostname# show ip verify source`

Configuring Static Binding

Configuration Steps	● Enable DHCP snooping. ● Enable IP source guard. ● Configure static binding.

	Hostname# configure terminal Hostname(config)# ip source binding 00d0.f801.0101 vlan 1 192.168.4.243 interface GigabitEthernet 0/3 Hostname(config)# end
Verification	Display the address filtering table of IP source guard.
	Hostname# show ip verify source NO. INTERFACE FilterType FilterStatus IPADDRESS MACADDRESS VLAN TYPE ----- ---------- ---------- ---------- ---------- ---------- ---- ---------- 1 GigabitEthernet 0/3 UNSET Inactive-restrict-off 192.168.4.243 00d0.f801.0101 1 Static 2 GigabitEthernet 0/1 IP-ONLY Active Deny-All 3 WLAN 1 IP-MAC Active Deny-All

↘ Enabling IP Source Guard on an Interface and Specifying an Excluded VLAN

Configuration Steps	● Enable DHCP snooping. ● Enable IP source guard.
	Hostname(config)# interface GigabitEthernet 0/1 Hostname(config-if-GigabitEthernet 0/1)# ip verify source Hostname(config-if-GigabitEthernet 0/1)# ip verify source exclude-vlan 1 Hostname(config-if)# exit Hostname(config)# wlansec 1 Hostname(config-wlansec)# ip verify source Hostname(config-wlansec)# ip verify source exclude-vlan 1 Hostname(config-wlansec)# end
Verification	Display the configuration of excluded VLANs specified on an interface.
	Hostname# show running-config

Common Errors

- IP source guard is enabled on a trusted interface of DHCP snooping.
- Specify an excluded VLAN before IP source guard is enabled.

1.5 Monitoring

Displaying

Command	Description
show ip verify source [**interface** *interface-type interface-number* | **wlan** *wlan-id*]	Displays the address filtering table of IP source guard.

Command	Description
show ip source binding	Displays the address binding database of IP source guard.

1 Configuring IPv6 Source Guard

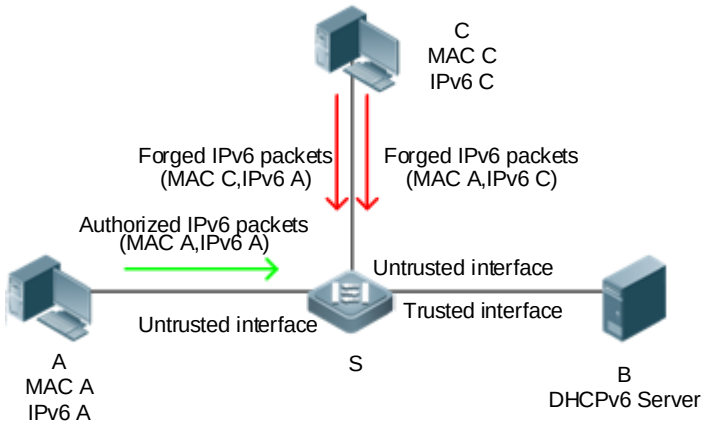
1.1 Overview

The IPv6 source guard function realizes hardware-based IPv6 packet filtering. This ensures that only the users having their information in the binding database can access networks normally, preventing users from forging IPv6 packets.

1.2 Applications

Application	Description
IPv6/MAC Spoofing Attack Defense	On a network, malicious users launch attacks by forging IPv6 packets.

1.2.1 IPv6/MAC Spoofing Attack Defense



Scenario

The device checks IPv6 packets from DHCPv6 untrusted interfaces. Forged IPv6 packets will be filtered out based on the IPv6 address only or both IPv6 and MAC addresses.

In Figure 1-1, the device checks IPv6 packets sent by DHCPv6 clients.

- The Source IPv6 Address fields of IPv6 packets should match DHCPv6-assigned IPv6 addresses.
- The Source MAC Address fields of Layer 2 packets should match MAC addresses delivered through DHCPv6 snooping.

Figure 1-1

Remarks	S is an access device. A and C are PCs. B is the DHCPv6 server under control.

Deployment

- Enable DHCPv6 snooping on S to implement DHCPv6 packet monitoring.

- Configure all downlink interfaces on S as DHCPv6 untrusted interfaces.
- Enable IPv6 source guard on S to realize IPv6 packet filtering.
- Configure the IPv6-MAC mode for IPv6 source guard on S, which filters IPv6 packets based on IPv6 and MAC addresses.

1.3 Features

Basic Concepts

Source IPv6 Address

Source IPv6 address field of an IPv6 packet.

Source MAC Address

Source MAC address field of an IPv6 packet.

IPv6-based Filtering

Only source IPv6 addresses of all IPv6 packets (except DHCPv6 packets) passing through an interface are checked. It is the default filtering policy of IPv6 source guard.

IPv6-MAC-based Filtering

Both source IPv6 addresses and source MAC addresses of all IPv6 packets are checked, and only those user packets with these IPv6 addresses and MAC addresses existing in the binding database are allowed to pass through.

Address Binding Database

It is the basis for security control of IPv6 source guard. Data in the address binding database comes from the DHCPv6 snooping binding database or statically configured. When IPv6 source guard is enabled, data of the DHCPv6 snooping binding database is synchronized to the address binding database of IPv6 source guard, so that IPv6 packets can be filtered strictly through IPv6 source guard on a device with DHCPv6 snooping enabled.

Overview

Feature	Description
Checking Source Address Fields of Packets	Filters IPv6 packets passing through interfaces based on IPv6-based or IPv6-MAC-based filtering.

1.3.1 Checking Source Address Fields of Packets

The device filters IPv6 packets passing through interfaces based on source IPv6 addresses or both source IPv6 addresses and source MAC addresses to prevent malicious attacks by forging packets.

Working Principle

When IPv6 source guard is enabled, the device checks source addresses of packets passing through an interface. The interface can be a wired switching interface, a Layer 2 aggregate interface, or a Layer 2 encapsulation sub-interface, or a WLAN interface. Such packets will pass through the interface only when source address fields of the packets match DHCPv6 snooping binding entries, or the statically configured user set. There are two matching modes.

IPv6-based Filtering

Packets are allowed to pass through an interface only when source IPv6 address fields of the packets belong to the address binding database.

IPv6-MAC-based Filtering

Packets are allowed to pass through an interface only when both Layer 2 source MAC addresses and Layer 3 source IPv6 addresses of packets match an entry in the address binding database.

Related Configuration

Enabling IPv6 Source Guard on an Interface

- By default, IPv6 source guard is disabled on interfaces.
- It can be enabled by using the **ipv6 verify source** command.

IPv6 source guard needs to be used with DHCPv6 snooping. Therefore, DHCPv6 snooping should also be enabled. DHCPv6 snooping can be enabled on devices at any time, either before or after IPv6 source guard is enabled.

Configuring a Static Binding

- By default, authorized users passing IPv6 source guard check are all from the binding database of DHCPv6 snooping.
- Bound users can be added using the **ipv6 source binding** command.

1.4 Configuration

Configuration	Description and Command	
Configuring IPv6 Source Guard	(Mandatory) It is used to enable IPv6 source guard.	
	ipv6 verify source	Enables IPv6 source guard on an interface.
	ipv6 source binding	Configures a static binding.

1.4.1 Configuring IPv6 Source Guard

Configuration Effect

Check the source IPv6 addresses of input IPv6 packets.

Notes

IPv6 source guard should be used with DHCPv6 snooping. IPv6 source guard can take effect when configured on the untrusted interfaces controlled by DHCPv6 snooping. However, when IPv6 source guard is configured on trusted interfaces or interfaces on a VLAN that is not controlled by DHCPv6 snooping, this function cannot take effect.

Configuration Steps

- Enable DHCPv6 snooping.
- Enable IPv6 source guard.

Verification

Use monitoring commands to display the address binding database of IPv6 source guard.

Related Commands

Enabling IPv6 Source Guard on an Interface

Command	**ipv6 verify source** [**port-security**]
Parameter Description	**port-security**: Enables IPv6-MAC-based filtering.
Command Mode	WLAN security configuration mode
Usage Guide	Detection of users based on IPv6 address or both IPv6 and MAC addresses can be realized by enabling IPv6 source guard. After IPv6 source guard is enabled, packets with source IPv6 addresses as link-local addresses and unspecified addresses are filtered. On an IPv6 network, these two types of packets need to be permitted, so additional security rules are required to allow them to pass through.

Configuring a Static Binding

Command	**ipv6 source binding** *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-id* | **wlan** *wlan-id* | **ipv6-mac** | **ipv6-only** }
Parameter Description	*mac-address*: Indicates the MAC address of a static binding. *vlan-id*: Indicates the VLAN ID of a static binding. *ipv6-address*: Indicates the IPv6 address of a static binding. *interface-id*: Indicates the interface of a static binding. *wlan-id*: Indicates the WLAN ID of a static binding. **ipv6-mac**: Indicates the IPv6-MAC-based mode. **ipv6-only**: Indicates the IPv6-based mode.
Command Mode	Global configuration mode
Usage Guide	Through this command, authorized users can pass the check of IPv6 source guard but not being controlled by DHCPv6.

Configuration Example

Enabling IPv6 Source Guard on an Interface

Configuration Steps	● Enable DHCPv6 snooping.
	● Configure ACEs for a secure channel permit packets in which source IPv6 addresses are link-local addresses or 0.0.0.0.
	`Hostname(config)# ipv6 access-list v6-list`
	`Hostname(config-ipv6-nacl)# permit ipv6 fe80::/10 any`
	`Hostname(config-ipv6-nacl)# permit ipv6 ::/128 any`
	`Hostname(config-ipv6-nacl)# exit`
	`Hostname(config)# security global access-group v6-list`
	● Enable IPv6 source guard.

	Hostname(config)# wlansec 1 Hostname(config-wlansec)# ipv6 verify source Hostname(config-wlansec)# end
Verification	● Display the address filtering table of IPv6 source guard.
	Hostname# show ipv6 source binding

↘ Configuring a Static Binding

Configuration Steps	● Enable DHCPv6 snooping. ● Enable IPv6 source guard. ● Configure a static binding.
	Hostname# configure terminal Hostname(config)# ipv6 source binding 0001.0002.0006 vlan 1 2008::1 ip-mac Hostname(config)# end
Verification	● Display the address filtering table of IPv6 source guard.
	Hostname# show ipv6 source binding

Common Errors

- IPv6 source guard is enabled on a trusted interface of DHCPv6 snooping.

1 Configuring CPP

1.1 Overview

Malicious attacks are often found on networks. Network devices are busy in processing forged management and protocol packets, so real management and protocol packets cannot be processed in a timely manner. Such attacks damage device security and network stability. The CPU Protect Policy (CPP) function protects CPU resources and important packets by means of packet identification and rate limiting.

Protocols and Standards

N/A

1.2 Applications

Application	Description
Rate Limiting	Limits the rate of specified packets.

1.2.1 Rate Limiting

Scenario

The access controller (AC) provides packet identification and rate limiting to protect processors.

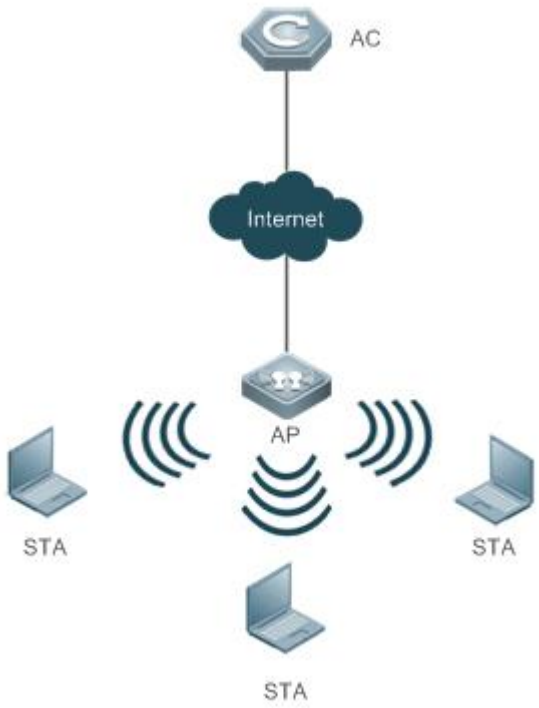

Figure 3-1 shows the networking topology of CPP.

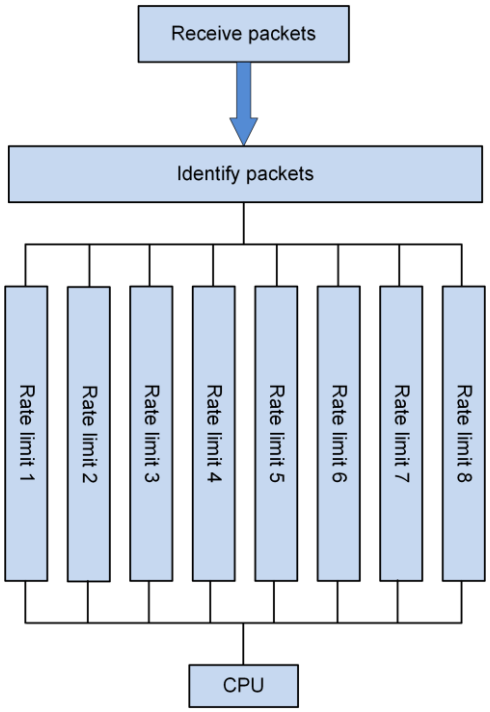
1 An access point (AP) accesses the AC.

2 Multiple stations (STAs) access the AP.

3 Attacks of specified packets may occur on STAs on a network. The AC must be able to protect their CPU.

Figure 3-1 Networking Topology



Deployment

Apply CPP to the AC to limit the rate of specified packets.

1.3 Features

Figure 3-2 Working Principle

Basic Concepts

Identifying Packets

All packets that are sent to the AC for protocol processing must be classified (such as ARP packets, BPDUs, and 802.1X packets) through packet identification.

Rate Limiting

An administrator can configure the rate limit for packets of each type, effectively suppressing high-rate attack packets on a network.

Overview

Feature	Description
Identifying Packets	All packets that are sent to CPU are classified through packet identification.
Rate	High-rate attack packets are suppressed by rate limiting.

1.3.1 Identifying Packets

All packets that are sent to CPU are classified through packet identification.

Working Principle

Identifying Packets

The CPP-enabled device classifies packets and automatically applies the packet identification function by default.

1.3.2 Rate Limiting

An administrator can configure the rate limit for packets of each type, effectively suppressing high-rate attack packets on a network.

Working Principle

Rate Limiting

Packets that have been identified and classified are rate-limited, and packets that exceed the rate limit are discarded.

1.4 Configuration

Configuration	Description and Command	
Configuring the Rate Limit for Specified Packets	⚠ (Optional) It is used to set the rate limit for specified packets.	
	cpu-protect type	Sets the rate limit for specified packets
Configuring the Rate Limit for Wireless Management Packets	⚠ (Optional) It is used to set the rate limit for wireless management packets.	
	mgmt-ratelimit disable	Enables or disables rate limiting of wireless management packets.
	mgmt-ratelimit per-cti pps *value*	Configures the CTI-based rate limit for wireless management packets.

	mgmt-ratelimit total pps *value*	Configures the AC-based rate limit for wireless management packets.

1.4.1 Configuring the Rate Limit for Specified Packets

Configuration Effect

Configure the rate limit for various types of packets.

Notes

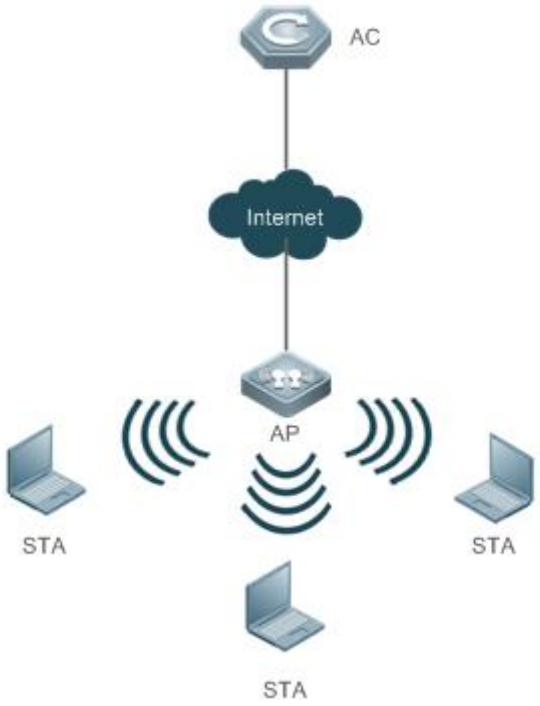
N/A

Configuration Step

Configuring the Rate limit for Specified Packets

- Optional.
- Enable CPP on all ACs unless otherwise specified.
- You can adjust the default rate limit for packets of each type as needed.

Command	**cpu-protect type** { **arp** | **bpdu** | **capwap-disc** | **d1x** | **dhcp-option82** | **dhcp-relay-client** | **dhcp-realy-server** | **dhcps** | **igmp** | **ipmc** | **ipv6-nans** | **lldp** | **ospf** | **ospfv3** | **pim** | **pppoe** | **rip** | **ripng** | **tcp80 | tcp443** | **vrrp** } **pps** *value*
Parameter Description	**arp**: Specifies the Address Resolution Protocol (ARP) packet. **bpdu**: Specifies the IEEE Bridge Protocol Data Unit (BPDU). **capwap-disc**: Specifies the Control And Provisioning of Wireless Access Points (CAPWAP) discovery packet. **d1x**: Specifies the 802.1X Extensible Authentication Protocol over LAN (EAPOL) packet. **dhcp-option82**: Specifies the Dynamic Host Configuration Protocol (DHCP) Option 82 packet. **dhcp-relay-client**: Specifies the DHCP client's packet. **dhcp-relay-server**: Specifies the DHCP server's packet. **dhcps**: Specifies the DHCP snooping packet. **igmp**: Specifies the Internet Group Management Protocol (IGMP) packet. **ipmc**: Specifies the IPv4 multicast packet. **ipv6-nans**: Specifies the IPv6 neighbor discovery packet. **lldp**: Specifies the Link Layer Discovery Protocol Data Unit (LLDPDU). **ospf**: Specifies the Open Shortest Path First (OSPF) packet. **ospfv3**: Specifies the OSPFv3 packet. **pppoe**: Specifies the Point to Point Protocol over Ethernet (PPPoE) packet. **pim**: Specifies the Protocol Independent Multicast (PIM) packet. **rip**: Specifies the IPv4 Routing Information Protocol (RIP) packet. **ripng**: Specifies the IPv6 RIP packet. **tcp80**: Specifies the web-based authentication redirection packet. **Tcp443**: Specifies the Hyper Text Transfer Protocol over Secure Socket Layer (HTTPS) packet. **vrrp**: Specifies the Virtual Router Redundancy Protocol (VRRP) packet. **pps** *value*: Specifies the upper limit of packets per second. The value range is from 0 to 148810, in pps.



Defaults	The default values vary with the product model.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show cpu-protect summary** command to display the configuration.

Configuration Example

Configuring the Rate Limit for ARP Packets as 200 pps

Scenario Figure 3-3	
Configuration Steps	Configure the rate limit for ARP packets on the AC.
AC	`Hostname#configure terminal` `Hostname(config)#cpu-protect type arp pps 200`
Verification	After the rate limit for ARP packets is configured on the AC, the system limits the rate for ARP packets arriving at the CPU based on the new rate limit. ● Run the **show cpu-protect summary** command to check configured parameters. ● Run the **show cpu-protect type arp** command to display statistics about the received ARP packets.

1.4.2 Configuring the Rate Limit for Wireless Management Packets

Configuration Effect

Configure the rate limit for wireless management packets.

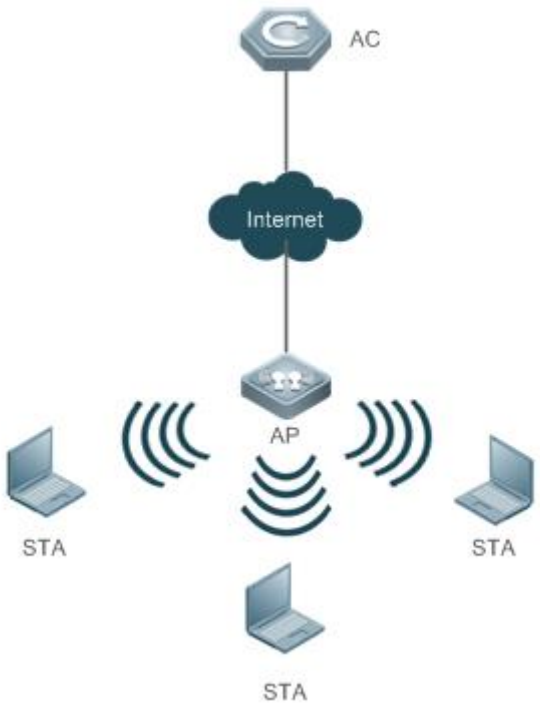
Notes

N/A

Configuration Step

↘ Configuring the Rate Limit for Wireless Management Packets

- Optional. This function is supported only on the AC. By default, the CTI-based rate limit is 8 pps. Different ACs adopt different default AC-based rate limits.
- Enable the rate limiting function for wireless management packets on all ACs unless otherwise specified.
- You can adjust the default rate limit based on the CTI or the AC as needed.



Command	**mgmt-ratelimit** { **disable** | **per-cti pps** *value* | **total pps** *value* }
Parameter Description	**disable**: Disables rate limiting for wireless management packets. It is enabled by default. **per-cti pps** *value*: Configures the CTI-based rate limit. The value range is from 1 to 10000, in pps. The default value is 8 pps. **total pps** *value*: Configures the AC-based rate limit. The value range is from 1 to 10000, in pps. Default values vary with different ACs.
Defaults	The rate limiting function is enabled by default. The default CTI-based rate limit is 8 pps. The default AP-based rate limit varies with different ACs.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the rate limit of wireless management packets.

Configuration Example

Configuring the AC-based Rate Limit for Wireless Management Packets as 100 pps

Scenario Figure 3-4	
Configuration Steps	Configure the AC-based rate limit for wireless management packets.
AC	`Hostname#configure terminal` `Hostname(config)#mgmt-ratelimit total pps 200`
Verification	After the AC-based rate limit is set, the system filters wireless management packets based on the

	new rate limit. ● Run the **show running-config** command to display the rate limit of wireless management packets. ● Run the **show mgmt-ratelimit summary** command to display statistics about ARP packets.

show mgmt-ratelimit summary	Displays statistics about AP-based wireless management packets.

1 Configuring NFPP

1.1 Overview

The Network Foundation Protection Policy (NFPP) provides attack defense for devices.

Some malicious attacks are always found on a network. These attacks bring heavy burdens to devices, resulting in high CPU usage and abnormal device running. The following attacks often occur:

Denial of service (DoS) attacks may greatly consume the memory, entries, or other resources of a device to cause system services to be unavailable.

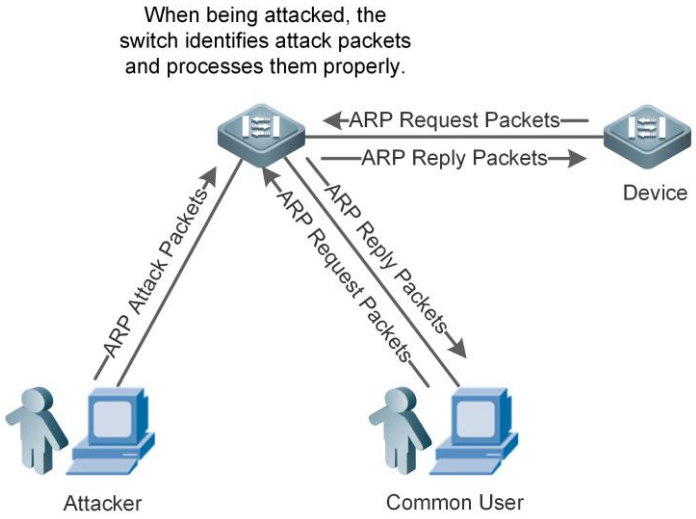
Massive attack traffic is sent to the CPU, occupying the entire bandwidth of packets sent to the CPU. In this case, normal protocol traffic and management traffic cannot be processed by the CPU, causing protocol flapping or management failures. Forwarding on the data plane will also be affected and the entire network will become abnormal.

A great number of attack packets directed to the CPU consume many CPU resources, resulting in a highly loaded CPU and thereby causing device management failures or abnormal running.

NFPP can effectively protect the system against these attacks. When attacks occur, NFPP protects proper running of various system services and keeps a low CPU load, thereby ensuring stable running of the entire network.

1.2 Applications

Application	Description
Attack Detection and Rate Limiting	Due to various malicious attacks such as ARP attacks and IP scanning attacks on a network, the CPU cannot process normal protocol and management traffic, causing protocol flapping or management failures. The NFPP attack detection and rate limiting function is used to limit the rate of attack traffic or isolate attack traffic so that the network can be recovered.
Centralized Rate Limiting and Distribution	Because normal service traffic is heavy, you need to classify and prioritize the traffic. When a large number of packets are directed to the CPU, the CPU will be highly loaded, thereby causing device management or device running failures. The centralized rate limiting and distribution function is used to increase the priority of such traffic so that devices can run stably.



1.2.1 Attack Detection and Rate Limiting

Scenario

NFPP supports attack detection and rate limiting for various types of packets, including Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP), and Dynamic Host Configuration Protocol (DHCP) packets. It also allows users to define packet matching characteristics and corresponding attack detection and rate limiting policies. The attack detection and rate limiting function takes effect based on each type of packets. ARP packets are used as an example here.

If an attacker sends ARP attack packets in the case of limited CPU capability, a large number of CPU resources will be consumed for processing these ARP packets. If the attacker's ARP packet rate exceeds the maximum ARP bandwidth specified in the CPU Protect Policy (CPP) of the device, normal ARP packets will be lost. As shown in Figure 4-1, common users will fail to access the network, and the device will fail to send ARP Reply packets to other devices.

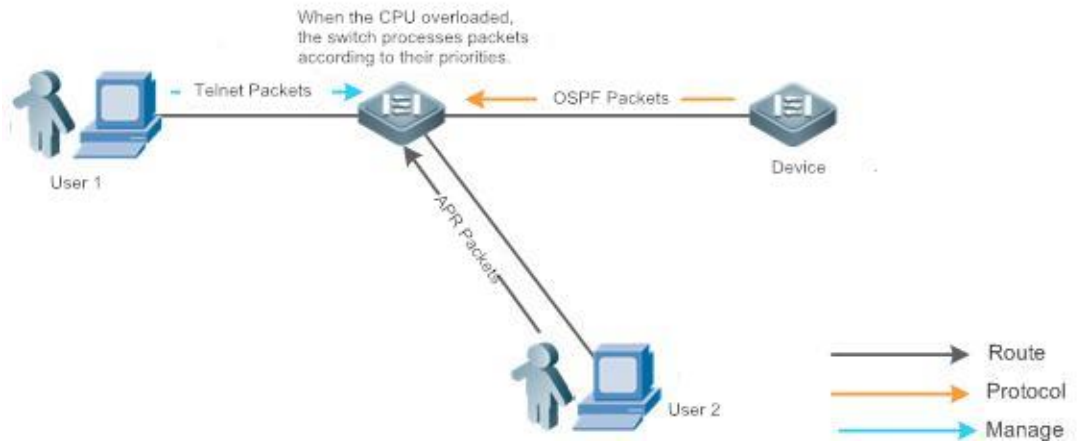
Figure 4-1

Deployment

- By default, the ARP attack detection and rate limiting function is enabled, and corresponding policies configured. If an attacker's ARP packet rate exceeds the rate limit, the packets will be discarded. If the packet rate exceeds the attack threshold, a monitored user will be generated and prompt information will be output.
- If an attacker's ARP packet rate exceeds the rate limit defined in CPP and affects normal ARP Reply packets, you can enable attack isolation to discard ARP attack packets based on an ACL and recover the network.

For details about the CPP configuration, refer to *Configuring CPP*.

To maximize the use of NFPP attack defense, change the rate limits for various services in CPP based on the application environment or use the configuration recommended by the system. You can run the **show cpu-protect summary** command to display the configuration.



1.2.2 Centralized Rate Limiting and Distribution

Scenario

A device classifies services defined in CPP into three types: management, routing, and protocol packets. Each type of services has independent bandwidth. Different types of services cannot share their bandwidth. Traffic exceeding the bandwidth threshold is discarded. By such service classification, service packets of a certain type can be processed first.

As shown in Figure 4-2, the device receives a large number of Telnet packets, OSPF packets, and ARP packets, causing CPU overload. In this case, the CPU cannot process all packets, and a large number of packets are placed in the queue, causing various problems such as occasional Telnet disconnection, OSPF protocol flapping, and ARP access failure.

Figure 4-2

Deployment

- By default, CPU centralized protection is enabled to assign an independent bandwidth and bandwidth ratio to each type of services. At the time, the CPU first processes Telnet packets to ensure nonstop connection of the Telnet service, and then processes OSPF packets to maintain OSPF protocol stability, and finally processes ARP packets.
- If the preceding problems occur in default configurations, you can accordingly adjust the bandwidth and bandwidth ratio for various types of services.

1.3 Features

Basic Concepts

ARP Anti-attack

On local area networks (LANs), IP addresses are converted to MAC addresses through ARP, which is significant for safeguarding network security. A large number of unauthorized ARP packets are sent to the gateway through the network, causing a failure for the gateway to provide services for normal hosts. Such packets are called ARP-based DoS attacks. To prevent such attacks, limit the rate of ARP packets and detect and isolate the attack source.

IP Anti-scanning

Attackers start scanning active hosts on a network before initiating hacker attacks and network virus intrusions. Therefore, many scanning packets rapidly occupy the network bandwidth, causing network communication failures.

To solve this problem, Layer 3 devices provide IP attack defense to prevent scanning by hackers and Blaster Worm viruses and reduce the CPU load. There are mainly two types of IP attacks:

- Scanning destination IP address changes: This type of scanning is the most harmful to networks. It consumes network bandwidth and increases device burden, and also serves as a precursor to many hacker attack methods.
- Sending IP packets to nonexistent destination IP addresses at a high rate: This type of attack is primarily designed to burden the device's CPU. For a Layer 3 device, if the destination IP address exists, the packet will be directly forwarded by the switching chip without consuming the device's CPU resources. However, if the destination IP address does not exist, the IP packet will be sent to the CPU, which will then send an ARP Request packet to query the MAC address corresponding to the destination IP address. If many packets are sent to the CPU, it will consume CPU resources. The harm caused by this type of attack is much less than that of the first type.

To prevent the latter type of attacks, limit the rate of IP packets and detect and isolate the attack source.

ICMP Attack Defense

ICMP is a common approach for diagnosing network failures. After receiving an ICMP echo request from a host, the device returns an ICMP echo reply. The preceding process requires the CPU to process the packets, consuming some CPU resources. If an attacker sends a large number of ICMP echo requests to the destination device, massive CPU resources will be consumed on the device, and the device may even fail to work properly. This type of attacks is called ICMP flood. To prevent this type of attacks, limit the rate of ICMP packets and detect and isolate the attack source.

DHCP Attack Defense

DHCP is widely used on LANs to dynamically assign IP addresses. It greatly affects network security. The most common DHCP attacks, also called DHCP exhaustion attacks, use forged MAC addresses to broadcast DHCP Request packets. Various attack tools on the live network can initiate such attacks. A network attacker can send a large number of DHCP Request packets to use up the address space provided by the DHCP server within a period. In this case, authorized hosts will fail to request IP addresses and thereby fail to access the network. To prevent this type of attacks, limit the rate of DHCP packets and detect and isolate the attack source.

DHCPv6 Attack Defense

DHCP version 6 (DHCPv6) is widely used on LANs to dynamically assign IPv6 addresses. Both DHCP version 4 (DHCPv4) and DHCPv6 have security problems. Attacks to DHCPv4 also apply to DHCPv6. A network attacker can send a large number of DHCPv6 Request packets to use up the address space provided by the DHCPv6 server within a period. In this case, authorized hosts will fail to request IPv6 addresses and therefore fail to access the network. To prevent this type of attacks, limit the rate of DHCPv6 packets and detect and isolate the attack source.

ND Attack Defense

Neighbor Discovery (ND) is mainly used on IPv6 networks to perform address resolution, router discovery, prefix discovery, and redirection. ND uses five types of packets: Neighbor Solicitation (NS), Neighbor Advertisement (NA), Router Solicitation (RS), Router Advertisement (RA), and Redirect.

ND snooping monitors ND packets on a network to filter unauthorized ND packets. It also monitors IPv6 hosts on a network and binds the monitored IPv6 hosts to interfaces to prevent IPv6 address from being used in unauthorized manner. ND snooping requires ND packets to be sent to the CPU. If ND packets are sent at a high rate, the CPU will be attacked. Therefore, ND attack defense must be provided to limit the rate of ND packets.

Overview

Feature	Description
Host-based Rate Limiting and Attack Identification	Limit the rate according to the host-based rate limit and identify host attacks on a network.
Interface-based Rate Limiting and Attack Identification	Limit the rate according to the interface-based rate limit and identify interface attacks.
Configuring the Monitoring Period	Monitor host attackers in a specified period.
Configuring the Isolation Period	Isolate host attackers or interface attackers in a specified period.
Configuring Trusted Hosts	Trust a host. That is, the trusted host is not monitored.
Centralized Rate Limiting and Distribution	Classify and prioritize packets.

1.3.1 Host-based Rate Limiting and Attack Identification

Limit the rate of attack packets of hosts and identify the attacks.

Identify ARP scanning.

Identify IP scanning.

Working Principle

Hosts can be identified based on the source IP address, VLAN ID, and interface, or based on the link-layer source MAC address, VLAN ID, and interface. Each host has a rate limit and an attack threshold (also called alarm threshold). The rate limit must be smaller than the attack threshold. If the attack packet rate exceeds the rate limit of a host, the host discards the packets beyond the rate limit. If the attack packet rate exceeds the attack threshold of a host, the host identifies host attacks, logs them, and sends trap packets.

ARP scanning attacks may occur if ARP packets beyond the scanning threshold received in the configured period meet either of the following conditions:

- The link-layer source MAC address is fixed but the source IP address changes.
- The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes.

Among IP packets beyond the scanning threshold received in the configured period, if the source IP address remains the same while the destination IP address continuously changes, IP scanning attack may occur.

When the NFPP-enabled device detects a specific type of attack packets of a service, it sends an alarm to the administrator. If the attack traffic persists, the NFPP-enabled device will not resend the alarm within 60 seconds after generating an alarm.

To prevent CPU resource consumption caused by frequent logging, the NFPP-enabled device writes attack detection logs to the buffer, obtains them from the buffer at a specified rate, and generates them. The NFPP-enabled device does not limit the rate of trap packets.

Only ARP attack defense and IP anti-scanning support anti-scanning.

1.3.2 Interface-based Rate Limiting and Attack Identification

Limit the rate of interface-based attack packets and identify the attacks.

Working Principle

Each interface has a rate limit and an attack threshold. The rate limit must be smaller than the attack threshold. If the packet rate exceeds the rate limit on an interface, the interface discards the packets. If the packet rate exceeds the attack threshold on an interface, the interface records the attacks in logs and sends trap packets.

1.3.3 Configuring the Monitoring Period

Configure the monitoring period for attackers.

Working Principle

Monitored hosts provide information about attackers in the current system. If the isolation period is 0 (that is, no isolation), the attack defense module automatically performs software monitoring on attackers in the configured

monitoring period. Within the monitoring period, you can view entries of a monitored host. If attack packets are received from this host before aging of the monitoring period, update the monitoring period of the host; otherwise, when the monitoring period is set to 0, entries of the monitored host will be deleted. When the isolation time is configured as a non-0 value, the attack defense module automatically isolates the host monitored by the software.

1.3.4 Configuring the Isolation Period

Configure the isolation period for attackers.

Working Principle

Isolation is performed based on the attack defense policy after attacks are detected. Isolation is implemented using the filtering function of a software ACL to ensure that these attacks are not sent to the CPU, thereby ensuring proper running of the device.

Isolation involves host-based and interface-based isolation. When an attacker is isolated, a policy will be configured in an ACL. When ACLs are exhausted and isolation fails, logs will be generated to remind the administrator.

1.3.5 Configuring Trusted Hosts

Configure trusted hosts.

Working Principle

If you do not want to monitor a host, you can configure the host to be trusted. This trusted host will be allowed to send packets of specified types to the CPU.

1.3.6 Centralized Rate Limiting and Distribution

Set the rate thresholds and percentages for management, routing, and protocol packets.

Working Principle

Services defined in the CPP are classified into three types: management, routing, and protocol packets. Each type of services has an independent bandwidth. Different types of services cannot share their bandwidths. Traffic exceeding the bandwidth threshold is discarded. By such service classification, service packets of a certain type can be processed first.

NFPP allows the administrator to flexibly assign bandwidth for three types of packets based on the actual network situation so that protocol and management packets can be first processed. Processing of protocol packets ensures proper running of the protocol, and processing of management packets helps the administrator perform proper management, thereby ensuring proper running of important device functions and improving attack defense capabilities of the device.

After packets are classified and rate-limited, all types of packets are centralized in a queue. When one type of service features a lower processing efficiency, packets of this service will be placed in the queue and may finally use up resources of the queue. NFPP allows the administrator to configure the percentages of these three types of packets in the queue. When the queue length occupied by one type of packets exceeds the product of the total queue length and the percentage of this type of packets, these packets are discarded. This effectively prevents one type of packets from exclusively occupying queue resources.

Packet Type	Service Type Defined in CPP
Protocol	tp-guard, dot1x, rldp, rerp, slow-packet, bpdu, gvrp, ripng, dvmrp, igmp, mpls, ospf, pim, pimv6, rip, vrrp, ospf3, dhcp-relay-s, dhcp-relay-c, option82, tunnel-bpdu, and tunnel-gvrp
Route	unknown-ipmc, unknown-ipmcv6, ttl1, ttl0, udp-helper, ip4-packet-other, ip6-packet-other, and non-ip-packet-other
Manage	ip4-packet-local, ip6-packet-local, and arp

For the definitions of service types, see *Configuring CPP*.

1.4 Configuration

Configuration	Description and Command	
Configuring ARP Attack Defense_Configuring_ARP_Guard	(Mandatory) It is used to configure global ARP attack defense.	
	arp-guard enable	Enables global attack detection.
	arp-guard monitor-period	Configures the monitoring period.
	arp-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	arp-guard rate-limit	Configures the global rate limit.
	arp-guard attack-threshold	Configures the global attack threshold.
	arp-guard scan-threshold	Configures the global host-based scanning threshold.
	(Optional) It is used to configure ARP isolation and ARP attack defenseguard.	
	arp-guard isolate-period	Configures the global isolation period.
	arp-guard trusted-host	Configures trusted hosts.
	nfpp arp-guard enable	Enables attack detection for an interface.
	nfpp arp-guard policy	Configures the rate limit and attack threshold for an interface.
	nfpp arp-guard scan-threshold	Configures the stage-by-stage scanning threshold for an interface.
	nfpp arp-guard isolate-period	Configures the isolation period for an interface.
Configuring IP Anti-scanning_Configuring_IP_Anti-scanning	(Mandatory) It is used to configure the global IP anti-scanning function.	
	ip-guard enable	Enables global attack detection.
	ip-guard monitor-period	Configures the monitoring period.
	ip-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	ip-guard rate-limit	Configures the global rate limit.
	ip-guard attack-threshold	Configures the global attack threshold.
	ip-guard scan-threshold	Configures the global host-based scanning threshold.
	(Optional) It is used to configure IP trusted hosts, IP isolation and interface-based IP anti-scanning.	

Configuration	Description and Command	
	ip-guard isolate-period	Configures the global isolation period.
	ip-guard trusted-host	Configures trusted hosts.
	nfpp ip-guard enable	Enables attack detection for an interface.
	nfpp ip-guard policy	Configures the rate limit and attack threshold for an interface.
	nfpp ip-guard scan-threshold	Configures the stage-by-stage scanning threshold for an interface.
	nfpp ip-guard isolate-period	Configures the isolation period for an interface.
Configuring ICMP Attack Defense_Configuring_ICMP_Guard	(Mandatory) It is used to configure global ICMP attack defense.	
	icmp-guard enable	Enables global attack detection.
	icmp-guard monitor-period	Configures the monitoring period.
	icmp-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	icmp-guard rate-limit	Configures the global rate limit.
	icmp-guard attack-threshold	Configures the global attack threshold.
	(Optional) It is used to configure ICMP trusted hosts, ICMP isolation and interfaceport-based ICMP attack defenseguard.	
	icmp-guard isolate-period	Configures the global isolation period.
	icmp-guard trusted-host	Configures trusted hosts.
	nfpp icmp-guard enable	Enables attack detection for an interface.
	nfpp icmp-guard policy	Configures the rate limit and attack threshold for an interface.
	nfpp icmp-guard isolate-period	Configures the isolation period for a port.
Configuring DHCP Attack Defense_Configuring_DHCP_Guard	(Mandatory) It is used to configure the global DHCP attack defenseguard function.	
	dhcp-guard enable	Enables global attack detection.
	dhcp-guard monitor-period	Configures the monitoring period.
	dhcp-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	dhcp-guard rate-limit	Configures the global rate limit.
	dhcp-guard attack-threshold	Configures the global attack threshold.
	(Optional) It is used to configure DHCP isolation and interface-based DHCP attack defense.	
	dhcp-guard isolate-period	Configures the global isolation period.
	dhcp-guard trusted-host	Configures trusted hosts.
	nfpp dhcp-guard enable	Enables attack detection for an interface.
	nfpp dhcp-guard policy	Configures the rate limit and attack threshold for an interface.
	nfpp dhcp-guard isolate-period	Configures the isolation period for an interface.
Configuring DHCPv6	(Mandatory) It is used to configure global DHCPv6 attack defense.	

Configuration	Description and Command	
Attack Defense_Configuring_DHCPv6_Guard	**dhcpv6-guard enable**	Enables global attack detection.
	dhcpv6-guard monitor-period	Configures the monitoring period.
	dhcpv6-guard monitored-host-limit	Configures the maximum number of monitored hosts.
	dhcpv6-guard rate-limit	Configures the global rate limit.
	dhcpv6-guard attack-threshold	Configures the global attack threshold.
	⚠ (Optional) It is used to configure DHCPv6 isolation and DHCPv6 attack defense.	
	dhcpv6-guard isolate-period	Configures the global isolation period.
	dhcpv6-guard trusted-host	Configures trusted hosts.
	nfpp dhcpv6-guard enable	Enables attack detection for an interface.
	nfpp dhcpv6-guard policy	Configures the rate limit and attack threshold for an interface.
	nfpp dhcpv6-guard isolate-period	Configures the isolation period for an interface.
Configuring ND Attack Defense_Configuring_ND_Guard	⚠ (Mandatory) It is used to configure the global ND attack defenseguard function.	
	nd-guard enable	Enables global attack detection.
	nd-guard rate-limit	Configures the global rate limit.
	nd-guard attack-threshold	Configures the global attack threshold.
	⚠ (Optional) It is used to configure interface-based ND attack defense.	
	nd-guard trusted-host	Configures trusted hosts.
	nfpp nd-guard enable	Enables attack detection for an interface.
	nfpp nd-guard policy	Configures the rate limit and attack threshold for an interface.
Configuring Centralized Rate Limiting and Distribution_Configuring_Centralized_Rate	⚠ (Optional) It is used to set the rate thresholds and percentages for management, routing, and protocol packets.	
	cpu-protect sub-interface pps	Configures the maximum bandwidth for each type of packets.
	cpu-protect sub-interface percent	Configures the maximum percentage of each type of packets in the queue.
Configuring NFPP Log Information_Configuring_NFPP_Log	⚠ (Mandatory) It is used to set log information.	
	log-buffer entries	Configures the capacity of NFPP log buffer.
	log-buffer logs	Configures the rate when logs are obtained from the log buffer to generate system messages.
	⚠ (Optional) It is used to configure logs to be recorded.	
	logging vlan	Configures the device to record logs of a specified VLAN.
	logging interface	Configures the device to record logs of a specified interface.

1.4.1 Configuring ARP Attack Defense

Configuration Effect

- ARP attacks are identified based on hosts or physical interfaces. Host-based ARP attack identification can be based on the source IP address, VLAN ID, and interface, or based on the link-layer source MAC address, VLAN ID, and interface. Each type of attack identification has a rate limit and an alarm threshold. If the ARP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ARP packet rate exceeds the alarm threshold, the system generates alarms and sends trap packets. In host-based attack identification, the system also isolates the attack source.
- ARP attack defense can also detect ARP scanning attacks. ARP scanning attacks indicate that the link-layer source MAC address is fixed but the source IP address changes, or that the link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes. Because attacks may be identified incorrectly, the hosts that may initiate ARP scanning are not isolated and are notified of the administrator for reference only.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes precedence over that in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.
- ARP attack defense prevents only ARP DoS attacks to the device, but not ARP spoofing or ARP attacks on a network.

Configuration Step

↘ Enabling Attack Detection

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.
- If ARP attack defense is disabled, the system automatically clears monitored hosts, scanned hosts, and port isolation entries.

Command	**arp-guard enable**
Parameter Description	N/A
Defaults	ARP attack defense is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp arp-guard enable**
Parameter Description	N/A
Defaults	ARP attack defense is configured in global configuration mode, but not in interface configuration mode.

Command Mode	Interface configuration mode
Usage Guide	ARP attack defense configured in interface configuration mode takes precedence over that configured in global configuration mode.

Configuring the Isolation Period

- (Optional) Isolation is disabled by default.
- If the packet rate of attackers exceeds the rate limit, configure the isolation period for the device to directly discard packets and therefore save bandwidth resources.
- The AC supports the global configuration mode and interface configuration mode.
- If the isolation period is changed to 0, attackers on the corresponding interface are deleted, instead of being monitored by software.

Command	**arp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. **permanent**: Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp arp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400.The value 0 indicates no isolation. **permanent**: Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is used as the attacker monitoring period, and the configured monitoring period does not take effect.
- The AC supports the global configuration mode.

Command	**arp-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period, in seconds. The value ranges from 180 to 86400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Configure the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- The AC supports the global configuration mode.
- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system generates the log "% NFPP_ARP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**arp-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts. The value range is from 1 to 4294967295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Configuring the Attack Threshold

- Mandatory.
- To achieve the best ARP attack defense effect, you are advised to configure the host-based rate limit and alarm threshold based on the following rules:

  Source IP address-based rate limit < source IP address-based alarm threshold < source MAC address-based rate limit < source MAC address-based alarm threshold
- The AC supports the global configuration mode and interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system generates the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system generates the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system generates the log "%NFPP_ARP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes precedence over source IP address-based rate limiting, while the latter takes precedence over interface-based rate limiting.
- In NFPP configuration mode, run the **arp-guard rate-limit** {**per-src-ip** | **per-src-mac**} *pps* command to configure rate limits of hosts identified based on the source IP address, VLAN ID, and interface or based on the link-layer source MAC address, VLAN ID, and interface.

- In NFPP configuration mode, run the **arp-guard attack-threshold** {**per-src-ip** | **per-src-mac**} *pps* command to configure attack thresholds of hosts identified based on the source IP address, VLAN ID, and interface or based on the link-layer source MAC address, VLAN ID, and interface.
- In interface configuration mode, run the **nfpp arp-guard policy** {**per-src-ip | per-src-mac**} *rate-limit-pps attack-threshold-pps* command to configure rate limits and attack thresholds of hosts identified based on the source IP address, VLAN ID, and interface or based on the link-layer source MAC address, VLAN ID, and interface on an interface.

Command	**arp-guard rate-limit** { **per-src-ip** | **per-src-mac** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Limits the rate for each source IP address. **per-src-mac:** Limits the rate of packets from each source MAC address. **per-port:** Limits the rate for each interface. *pps*: Indicates the rate limit. The value range is from 1 to 9999.
Defaults	The default rate limit varies with the product model.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**arp-guard attack-threshold** { **per-src-ip** | **per-src-mac | per-port** } *pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-src-mac:** Configures the attack threshold for each source MAC address. **per-port:** Configures the attack threshold for each interface. *pps*: Indicates the attack threshold, in packets per second (pps). The value range is from 1 to 9999.
Defaults	The default attack threshold varies with the product model.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Command	**nfpp arp-guard policy** { **per-src-ip | per-src-mac | per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-ip:** Configures the rate limit and attack threshold for each source IP address. **per-src-mac:** Configures the rate limit and attack threshold for each source MAC address. **per-port:** Configures the rate limit and attack threshold for each interface. *rate-limit-pps*: Indicates the rate limit. The value range is from 1 to 9999. *attack-threshold-pps*: Indicates the attack threshold. The value range is from 1 to 9999.
Defaults	By default, no rate limit and attack threshold are configured for an interface, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring the Scanning Threshold

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.

- The ARP scanning table stores only the latest 256 records. When the ARP scanning table is full, the latest record will overwrite the earliest record.
- ARP scanning attack may occur if ARP packets received within 10 seconds meet either of the following conditions:
  - The link-layer source MAC address is fixed but the source IP address changes.
  - The link-layer source MAC address and source IP address are fixed but the destination IP address continuously changes, and the change count exceeds the scanning threshold.

Command	**arp-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold. The value range is from 1 to 9999.
Defaults	The default scanning threshold is 100, in the unit of 10 seconds.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp arp-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold. The value range is from 1 to 9999.
Defaults	By default, no interface-based ARP scanning threshold is configured and the global ARP scanning threshold is used.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring Trusted Hosts

- Optional. No trusted host is configured by default.
- For ARP attack defense, you can configure only a maximum of 500 IP addresses and MAC addresses not to be monitored.
- The AC supports the global configuration mode.
- If any entry matching a trusted host (the IP addresses and MAC addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system generates the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system generates the log "%ERROR: Failed to delete trusted host 1.1.1.1 0000.0000.1111." to notify the administrator.
- If you fail to add a trusted host, the system generates the log "%ERROR: Failed to add trusted host 1.1.1.1 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system generates the log "%ERROR: Trusted host 1.1.1.1 0000.0000.1111 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system generates the log "%ERROR: Trusted host 1.1.1.1 0000.0000.1111 is not found." to notify the administrator.

Command	**arp-guard trusted-host** *ip mac*
Parameter Description	*ip*: Indicates the IP address. *mac*: Indicates the MAC address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, configure the host to be trusted. The trusted host can send ARP packets to the CPU. In this case, the device does not rate-limit such packets or generate alarms.

Verification

When a network host sends ARP attack packets to a device configured with ARP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets (not matching the trusted host configuration) exceeds the attack threshold or scanning threshold, attack information is displayed.
- If the rate of attack packets matches the trusted host configuration, no information is displayed.

Configuration Example

CPU Protection Based on ARP Attack Defense

Scenario	● ARP host attacks exist in the system, and some hosts cannot properly establish ARP sessions. ● ARP scanning exists in the system, causing a high CPU usage. ● ARP packet traffic of some hosts is heavy in the system, and these packets need to be allowed.
Configuration Steps	● Set the host-based attack threshold to 5 pps. ● Set the ARP scanning threshold to 10 pps. ● Set the isolation period to 180 pps. ● Configure trusted hosts.

	`Hostname# configure terminal`
	`Hostname(config)# nfpp`
	`Hostname(config-nfpp)#arp-guard rate-limit per-src-mac 5`
	`Hostname(config-nfpp)#arp-guard attack-threshold per-src-mac 10`
	`Hostname(config-nfpp)#arp-guard isolate-period 180`
	`Hostname(config-nfpp)#arp-guard trusted-host 1.1.1.1 0000.0000.1111`

Verification	● Run the **show nfpp arp-guard summary** command to display the configuration.

	`Hostname# show nfpp arp-guard summary`
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)`
	`Interface Status Isolate-period Rate-limit Attack-threshold Scan-threshold`
	`Global Disable 180 4/5/100 8/10/200 15`

	Maximum count of monitored hosts: 1000 Monitor period: 600s
	● Run the **show nfpp arp-guard hosts** command to display monitored hosts.
	Hostname# show nfpp arp-guard hosts If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface IP address MAC address remain-time(s) ---- --------- ---------- ---------- -------------- 1 Gi0/43 5.5.5.16 - 175 Total: 1 host
	● Run the **show nfpp arp-guard scan** command to display scanned hosts.
	Hostname# show nfpp arp-guard scan VLAN interface IP address MAC address timestamp ---- --------- ---------- ---------- --------- 1 Gi0/5 - 001a.a9c2.4609 2013-4-30 23:50:32 1 Gi0/5 192.168.206.2 001a.a9c2.4609 2013-4-30 23:50:33 1 Gi0/5 - 001a.a9c2.4609 2013-4-30 23:51:33 1 Gi0/5 192.168.206.2 001a.a9c2.4609 2013-4-30 23:51:34 Total: 4 record(s)
	● Run the **show nfpp arp-guard trusted-host** command to display trusted hosts.
	Hostname# show nfpp arp-guard trusted-host IP address mac ---------- ---- 1.1.1.1 0000.0000.1111 Total: 1 record(s)

1.4.2 Configuring IP Anti-scanning

Configuration Effect

- IP attacks are identified based on hosts or interfaces. In host-based IP attack identification, IP attacks are identified based on the source IP address, VLAN ID, and interface. Each type of attack identification has a rate limit and an alarm threshold. If the IP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the IP packet rate exceeds the alarm threshold, the system generates alarms and sends trap packets. In host-based attack identification, the system also isolates the attack source.
- IP guard can also detect IP scanning attacks. IP anti-scanning applies to IP packet attacks as follows: the destination IP address continuously changes but the source IP address remains the same, and the destination IP address is not the IP address of the local device.
- IP anti-scanning applies to IP packet attacks where the destination IP address is not the local IP address. CPP limits the rate of IP packets where the destination IP address is the local IP address.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes precedence over that in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Step

Enabling Attack Detection

- Mandatory. Attack detection is enabled by default.
- The AC supports the global configuration mode and interface configuration mode.
- If IP anti-scanning is disabled, the system automatically clears monitored hosts.

Command	**ip-guard enable**
Parameter Description	N/A
Defaults	IP anti-scanning is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp ip-guard enable**
Parameter Description	N/A
Defaults	IP anti-scanning is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	IP anti-scanning configured in interface configuration mode takes precedence over that configured in global configuration mode.

Configuring the Isolation Period

- Optional. Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit of CPP, configure the isolation period for the device to directly discard packets and therefore save bandwidth resources.
- The AC supports the global configuration mode and interface configuration mode.
- If the isolation period is changed to 0, attackers on the corresponding interface is deleted, instead of being monitored by software.

Command	**ip-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. **permanent**: Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp ip-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. The value 0 indicates no isolation. **permanent**: Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is used as the attacker monitoring period, and the configured monitoring period does not take effect.
- The AC supports the global configuration mode.

Command	**ip-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period, in seconds. The value ranges from 180 to 86400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is changed to 0, attackers on the corresponding interface is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- The AC supports the global configuration mode.
- If the number of monitored hosts reaches 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system generates the log "% NFPP_IP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**ip-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts. The value range is from 1 to 4294967295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command	NFPP configuration mode

Mode	
Usage Guide	N/A

Configuring the Attack Threshold

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system generates the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system generates the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system generates the log "%NFPP_IP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes precedence over interface-based rate limiting.
- In NFPP configuration mode, run the **ip-guard rate-limit** { **per-src-ip** | **per-port** } *pps* command to configure the global rate limit.
- In NFPP configuration mode, run the **ip-guard attack-threshold** { **per-src-ip** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attacks exist.
- In interface configuration mode, run the **nfpp ip-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on an interface.

Command	**ip-guard rate-limit** { **per-src-ip** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Limits the rate for each source IP address. **per-port:** Limits the rate for each interface. *pps*: Indicates the rate limit. The value range is from 1 to 9999.
Defaults	**per-src-ip**: 20 pps. **per-port**: 1000 pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**ip-guard attack-threshold** { **per-src-ip** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-port:** Configures the attack threshold for each interface. *pps*: Indicates the attack threshold, in pps. The value range is from 1 to 9999.
Defaults	**per-src-ip**: 20 pps. **per-port**: 1500 pps.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Command	**nfpp ip-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-port:** Configures the attack threshold for each interface. *rate-limit-pps*: Indicates the rate limit. The value range is from 1 to 9999. *attack-threshold-pps*: Indicates the attack threshold. The value range is from 1 to 9999.
Defaults	By default, no rate limit and attack threshed are configured for an interface, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring the Scanning Threshold

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.
- IP scanning attack may occur if IP packets received within 10 seconds meet the following conditions:
  - The source IP address remains the same.
  - The destination IP address continuously changes and is not the local IP address, and the change count exceeds the scanning threshold.

Command	**ip-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold. The value range is from 1 to 9999.
Defaults	The default scanning threshold is 100 pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp ip-guard scan-threshold** *pkt-cnt*
Parameter Description	*pkt-cnt*: Indicates the scanning threshold. The value range is from 1 to 9999.
Defaults	By default, no port-based IP scanning threshold is configured and the global IP scanning threshold is used.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For IP anti-scanning, you can configure a maximum of 500 IP addresses not to be monitored.
- The AC supports the global configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.

- If the table of trusted hosts is full, the system generates the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system generates the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If you fail to add a trusted host, the system generates the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the trusted host you want to add already exists, the system generates the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system generates the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.

Command	**ip-guard trusted-host** *ip mask*
Parameter Description	*ip*: Indicates the IP address. *mask*: Indicates the mask of an IP address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, configure the host to be trusted. The trusted host can send ARP packets to the CPU. In this case, the device does not rate-limit such packets or generate alarms.

Verification

When a network host sends IP attack packets to a device configured with IP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets (not matching the trusted host configuration) exceeds the attack threshold or scanning threshold, attack information is displayed.
- If the rate of attack packets matches the trusted host configuration, no information is displayed.

Configuration Example

CPU Protection Based on IP Attack Defense

Scenario	• IP host attacks exist in the system, and packets of some hosts cannot be properly routed or forwarded. • IP scanning exists in the system, causing a high CPU usage. • Traffic of some hosts is heavy in the system, and the traffic needs to be allowed.
Configuration Steps	• Configure the host-based attack threshold. • Configure the IP scanning threshold. • Set the isolation period to a non-zero value. • Configure trusted hosts.

	`Hostname# configure terminal`
	`Hostname(config)# nfpp`
	`Hostname(config-nfpp)#ip-guard rate-limit per-src-ip 20`
	`Hostname(config-nfpp)#ip-guard attack-threshold per-src-ip 30`

	Hostname(config-nfpp)#ip-guard isolate-period 180 Hostname(config-nfpp)#ip-guard trusted-host 192.168.201.46 255.255.255.255
Verification	● Run the **show nfpp ip-guard summary** command to display the configuration.
	Hostname# show nfpp ip-guard summary (Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.) 	● Run the show nfpp ip-guard hosts command to display monitored hosts.
	Hostname# show nfpp ip-guard hosts If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface IP address Reason remain-time(s) ---- --------- ---------- ------ -------------- 1 Gi0/5 192.168.201.47 ATTACK 160 Total: 1 host
	● Run the **show nfpp ip-guard trusted-host** command to display trusted hosts.
	Hostname# show nfpp ip-guard trusted-host IP address mask ---------- ---- 192.168.201.46 255.255.255.255 Total: 1 record(s)

1.4.3 Configuring ICMP Attack Defense

Configuration Effect

- ICMP attacks are identified based on hosts or interfaces. In host-based attack identification, ICMP attacks are identified based on the source IP address, VLAN ID, and interface. Each type of attack identification has a rate limit and an alarm threshold. If the ICMP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ICMP packet rate exceeds the alarm threshold, the system generates alarms and sends trap packets. In host-based attack identification, the system also isolates the attack source.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes precedence over that in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Step

Enabling Attack Detection

- (Mandatory) Attack detection is enabled by default.
- The AC supports the global configuration mode and interface configuration mode.
- If ICMP attack defense is disabled, the system automatically clears monitored hosts.

Command	**icmp-guard enable**
Parameter Description	N/A
Defaults	ICMP attack defense is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp icmp-guard enable**
Parameter Description	N/A
Defaults	ICMP attack defense is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	ICMP attack defense configured in interface configuration mode takes precedence over that in global configuration mode.

Configuring the Isolation Period

- Optional. Isolation is disabled by default.
- If the packet rate of attackers exceeds the rate limit of the CPP, configure the isolation period for the device to directly discard packets and therefore save bandwidth resources.
- The AC supports the global configuration mode and interface configuration mode.
- If the isolation period is changed to 0, attackers under the corresponding port is deleted, instead of being monitored by software.

Command	**icmp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into the global isolation period and interface-based isolation period (local isolation period). For an interface, if the interface-based isolation period is not configured, the global isolation period is used; otherwise, the interface-based isolation period is used.

Command	**nfpp icmp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is used as the attacker monitoring period, and the configured monitoring period does not take effect.
- The AC supports the global configuration mode.

Command	**icmp-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period, in seconds. The value ranges from 180 to 86400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs isolation against attackers monitored by software and configures the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers on the corresponding interface is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- The AC supports the global configuration mode.
- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to be smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system generates the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**icmp-guard monitored-host-limit** *number*
Parameter	*number*: Indicates the maximum number of monitored hosts. The value range is from 1 to

Description	4294967295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to be smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted. If the table of monitored hosts is full, the system generates the log "% NFPP_ICMP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Configuring the Attack Threshold

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system generates the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system generates the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system generates the log "%NFPP_ICMP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source IP address-based rate limiting takes precedence over interface-based rate limiting.
- In NFPP configuration mode, run the **icmp-guard rate-limit** { **per-src-ip** | **per-port** } *pps* command to configure the global rate limit.
- In NFPP configuration mode, run the **icmp-guard attack-threshold** { **per-src-ip** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attacks exist.
- In interface configuration mode, run the **nfpp icmp-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on an interface.

Command	**icmp-guard rate-limit** { **per-src-ip**	**per-port** } *pps*
Parameter Description	**per-src-ip:** Limits the rate for each source IP address. **per-port:** Limits the rate for each interface. *pps*: Indicates the rate limit. The value range is from 1 to 9999.
Defaults	For the AC, see the specification and limitation document. For the AP: **per-src-ip**: 200 pps **per-port**: 400 pps
Command Mode	NFPP configuration mode

Usage Guide	N/A

Command	**icmp-guard attack-threshold** { **per-src-ip** | **per-port** } *pps*
Parameter Description	**per-src-ip:** Configures the attack threshold for each source IP address. **per-port:** Configures the attack threshold for each interface. *pps*: Indicates the attack threshold, in pps. The value range is from 1 to 9999.
Defaults	For the AC, see the specification and limitation document. For the AP: **per-src-ip**: 200 pps **per-port**: 400 pps
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp icmp-guard policy** { **per-src-ip | per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-ip:** Configures the rate limit and attack threshold for each source IP address. **per-port:** Configures the rate limit and attack threshold for each interface. *rate-limit-pps*: Indicates the rate limit. The value range is from 1 to 9999. *attack-threshold-pps*: Indicates the attack threshold. The value range is from 1 to 9999.
Defaults	By default, no rate limit and attack threshed are configured for an interface, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring Trusted Hosts

- Optional. No trusted host is configured by default.
- For ICMP anti-scanning, you can configure a maximum of 500 IP addresses not to be monitored.
- The AC supports the global configuration mode.
- If any entry matching a trusted host (IP addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system generates the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system generates the log "%ERROR: Failed to delete trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If you fail to add a trusted host, the system generates the log "%ERROR: Failed to add trusted host 1.1.1.0 255.255.255.0." to notify the administrator.
- If the trusted host you want to add already exists, the system generates the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system generates the log "%ERROR: Trusted host 1.1.1.0 255.255.255.0 is not found." to notify the administrator.

Command	**icmp-guard trusted-host** *ip mask*
Parameter Description	*ip*: Indicates the IP address. *mask*: Indicates the mask of an IP address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, configure the host to be trusted. The trusted host can send ICMP packets to the CPU. In this case, the device does not rate-limit such packets or generate alarms. You can configure the mask so that no host in one network segment is monitored. You can configure a maximum of 500 trusted hosts.

Verification

When a network host sends ICMP attack packets to a device configured with ICMP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets (not matching the trusted host configuration) exceeds the attack threshold or scanning threshold, attack information is displayed.
- If the rate of attack packets matches the trusted host configuration, no information is displayed.

Configuration Example

CPU Protection Based on ICMP Attack Defense

Scenario	● ICMP host attacks exist in the system, and some hosts cannot ping devices. ● Traffic of some hosts is heavy in the system, and the traffic needs to be allowed.
Configuration Steps	● Configure the host-based attack threshold. ● Set the isolation period to a non-zero value. ● Configure trusted hosts.

	`Hostname# configure terminal`
	`Hostname(config)# nfpp`
	`Hostname(config-nfpp)#icmp-guard rate-limit per-src-ip 20`
	`Hostname(config-nfpp)#icmp-guard attack-threshold per-src-ip 30`
	`Hostname(config-nfpp)#icmp-guard isolate-period 180`
	`Hostname(config-nfpp)#icmp-guard trusted-host 192.168.201.46 255.255.255.255`

Verification	● Run the **show nfpp icmp-guard summary** command to display the configuration.

	`Hostname# show nfpp icmp-guard summary`
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)`
	`Interface Status Isolate-period Rate-limit Attack-threshold`
	`Global Disable 180 20/-/400 30/-/400`
	
	`Maximum count of monitored hosts: 1000`
	`Monitor period: 600s`

	● Run the **show nfpp icmp-guard hosts** command to display monitored hosts.

	`Hostname# show nfpp icmp-guard hosts`
	`If col_filter 1 shows '*', it means "hardware do not isolate host".`
	` VLAN  interface  IP address  remain-time(s)`
	` ----  ---------  ----------  --------------`
	`  1  Gi0/5  192.168.201.47  160`
	`Total: 1 host`

	● Run the **show nfpp icmp-guard trusted-host** command to display trusted hosts.

	`Hostname# show nfpp icmp-guard trusted-host`
	`IP address  mask`
	`----------  ----`
	`192.168.201.46  255.255.255.255`
	`Total: 1 record(s)`

1.4.4 Configuring DHCP Attack Defense

Configuration Effect

DHCP attacks are identified based on hosts or interfaces. In host-based attack identification, DHCPv6 attacks are identified based on the link-layer source IP address, VLAN ID, and interface. Each type of attack identification has a rate limit and an alarm threshold. If the DHCP packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCP packet rate exceeds the alarm threshold, the system generates alarms and sends trap packets. In host-based attack identification, the system also isolates the attack source.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes precedence over that in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Step

↘ Enabling Attack Detection

- Mandatory. Attack detection is enabled by default.
- The AC supports the global configuration mode and interface configuration mode.
- If DHCP attack defense is disabled, the system automatically clears monitored hosts.

Command	**dhcp-guard enable**
Parameter Description	N/A
Defaults	DHCP attack defense is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp dhcp-guard enable**
Parameter Description	N/A
Defaults	DHCP attack defense is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	DHCP attack defense configured in interface configuration mode takes precedence over that configured in global configuration mode.

Configuring the Isolation Period

- Optional. Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit of CPP, configure the isolation period for the device to directly discard packets and therefore save bandwidth resources.
- The AC supports the global configuration mode and interface configuration mode.
- If the isolation period is changed to 0, attackers on the corresponding interface is deleted, instead of being monitored by software.

Command	**dhcp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into the global isolation period and port-based isolation period (local isolation period). For an interface, if the interface-based isolation period is not configured, the global isolation period is used; otherwise, the interface-based isolation period is used.

Command	**nfpp dhcp-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is used as the attacker monitoring period, and the configured monitoring period does not take effect.
- The AC supports the global configuration mode.

Command	**dhcp-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period, in seconds. The value ranges from 180 to 86400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs isolation against attackers monitored by software and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers on the corresponding interface is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.
- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- The AC supports the global configuration mode.
- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to be smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system generates the log "% NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**dhcp-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts. The value range is from 1 to 4294967295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to be smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted. If the table of monitored hosts is full, the system generates the log "% NFPP_DHCP_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Configuring the Attack Threshold

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system generates the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system generates the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system generates the log "%NFPP_DHCP_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes precedence over port-based rate limiting.
- In NFPP configuration mode: run the **dhcp-guard rate-limit** { **per-src-mac** | **per-port** } *pps* command to configure the global rate limit.
- In NFPP configuration mode: run the **dhcp-guard attack-threshold** { **per-src-mac** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attacks exist.
- In interface configuration mode: run the **nfpp dhcp-guard policy** { **per-src-mac | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on an interface.

Command	**dhcp-guard rate-limit** { **per-src-mac** | **per-port** } *pps*
Parameter Description	**per-src-mac:** Limits the rate for each source MAC address. **per-port:** Limits the rate for each interface. *pps*: Indicates the rate limit. The value range is from 1 to 9999.
Defaults	For the AC, The default rate limit varies with the product model. For the AP, the default rate limit for packets based on source MAC address is 5 pps, and the default rate limit for packets based on interfaces is 150 pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**dhcp-guard attack-threshold** { **per-src-mac** | **per-port** } *pps*
Parameter Description	**per-src-mac:** Configures the attack threshold for each source MAC address. **per-port:** Configures the attack threshold for each interface. *pps*: Indicates the attack threshold, in pps. The value range is from 1 to 9999.
Defaults	For the AC, the default rate limit varies with the product model. For the AP, the default rate limit for packets based on source MAC address is 10 pps, and the default rate limit for packets based on interfaces is 300 pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp dhcp-guard policy** { **per-src-mac	per-port** } *rate-limit-pps attack-threshold-pps*
Parameter	**per-src-mac:** Configures the rate limit and attack threshold for each source MAC address**.**

Description	**per-port:** Configures the rate limit and attack threshold for each interface. *rate-limit-pps*: Indicates the rate limit. The value range is from 1 to 9999. *attack-threshold-pps*: Indicates the attack threshold. The value range is from 1 to 9999.
Defaults	By default, no rate limit and attack threshed are configured for an interface, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring Trusted Hosts

- Optional. No trusted host is configured by default.
- For DHCP attack defense, you can configure a maximum of 500 MAC addresses not to be monitored.
- The AC supports the global configuration mode.
- If any entry matching a trusted host (MAC addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system generates the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system generates the log "%ERROR: Failed to delete trusted host 0000.0000.1111." to notify the administrator.
- If you fail to add a trusted host, the system generates the log "%ERROR: Failed to add trusted host 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system generates the log "%ERROR: Trusted host 0000.0000.1111 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system generates the log "%ERROR: Trusted host 0000.0000.1111 is not found." to notify the administrator.

Command	**dhcp-guard trusted-host** *mac*
Parameter Description	*mac*: Indicates the MAC address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, configure the host to be trusted. In this case, the device does not rate-limit such packets or generate alarms.

Verification

When a network host sends DHCP attack packets to a device configured with DHCP attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets (not matching the trusted host configuration) exceeds the attack threshold or scanning threshold, attack information is displayed.
- If the rate of attack packets matches the trusted host configuration, no information is displayed.

Configuration Example

CPU Protection Based on DHCP Attack Defense

Scenario	● DHCP host attacks exist in the system, and some hosts fail to request IP addresses. ● DHCP traffic of some hosts is heavy in the system, and the traffic need to be allowed.
Configuration Steps	● Configure the host-based attack threshold. ● Set the isolation period to a non-zero value. ● Configure trusted hosts.

	`Hostname# configure terminal`
	`Hostname(config)# nfpp`
	`Hostname(config-nfpp)#dhcp-guard rate-limit per-src-mac 8`
	`Hostname(config-nfpp)#dhcp-guard attack-threshold per-src-mac 16`
	`Hostname(config-nfpp)#dhcp-guard isolate-period 180`
	`Hostname(config-nfpp)#dhcp-guard trusted-host 0000.0000.1111`

Verification	Run the **show nfpp dhcp-guard summary** command to display the configuration.

	`Hostname# show nfpp dhcp-guard summary`
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)`
	`Interface Status Isolate-period Rate-limit Attack-threshold`
	`Global Disable 180 -/8/150 -/16/300`
	
	`Maximum count of monitored hosts: 1000`
	`Monitor period: 600s`

	Run the **show nfpp dhcp-guard hosts** command to display monitored hosts.

	`Hostname# show nfpp dhcp-guard hosts`
	`If col_filter 1 shows '*', it means "hardware do not isolate host".`
	` VLAN interface MAC address remain-time(s)`
	` ---- --------- ----------- --------------`
	` *1 Gi0/5 001a.a9c2.4609 160`
	`Total: 1 host`

	Run the **show nfpp dhcp-guard trusted-host** command to display trusted hosts.

	`Hostname# show nfpp dhcp-guard trusted-host`
	`mac`
	`----`
	`0000.0000.1111`
	`Total: 1 record(s)`

1.4.5 Configuring DHCPv6 Attack Defense

Configuration Effect

DHCPv6 attacks are identified based on hosts or interfaces. In host-based attack identification, DHCPv6 attacks are identified based on the link-layer source IP address, VLAN ID, and interface. Each type of attack identification has a

rate limit and an alarm threshold. If the DHCPv6 packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the DHCPv6 packet rate exceeds the alarm threshold, the system generates alarms and sends trap packets.

In host-based attack identification, the system also isolates the attack source.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes precedence over that in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Step

Enabling Attack Detection

- Mandatory. Attack detection is enabled by default.
- The AC supports the global configuration mode and interface configuration mode.
- If DHCPv6 attack defense is disabled, the system automatically clears monitored hosts.

Command	**dhcpv6-guard enable**
Parameter Description	N/A
Defaults	DHCPv6 attack defense is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp dhcpv6-guard enable**
Parameter Description	N/A
Defaults	DHCPv6 attack defense is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	DHCPv6 attack defense configured in interface configuration mode takes precedence over that configured in global configuration mode.

Configuring the Isolation Period

- Optional. Isolation is disabled by default.
- If the packet traffic of attackers exceeds the rate limit of CPP, configure the isolation period for the device to directly discard packets and therefore save bandwidth resources.
- The AC supports the global configuration mode and interface configuration mode.
- If the isolation period is changed to 0, attackers on the corresponding interface is deleted, instead of being monitored by software.

Command	**dhcpv6-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	The default global isolation period is 0, that is, no isolation.
Command Mode	NFPP configuration mode
Usage Guide	The attacker isolation period falls into the global isolation period and port-based isolation period (local isolation period). For an interface, if the interface-based isolation period is not configured, the global isolation period is used; otherwise, the interface-based isolation period is used.

Command	**nfpp dhcpv6-guard isolate-period** [*seconds* | **permanent**]
Parameter Description	*seconds*: Indicates the isolation period, in seconds. It can be set to 0 or any value from 30 to 86400. The value 0 indicates no isolation. **permanent:** Indicates permanent isolation.
Defaults	By default, a global isolation period is used, but no local isolation period is configured.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Monitoring Period

- Mandatory.
- If the isolation period is configured, it is used as the attacker monitoring period, and the configured monitoring period does not take effect.
- The AC supports the global configuration mode.

Command	**dhcpv6-guard monitor-period** *seconds*
Parameter Description	*seconds*: Indicates the monitoring period, in seconds. The value ranges from 180 to 86400.
Defaults	The default monitoring period is 600 seconds.
Command Mode	NFPP configuration mode
Usage Guide	If the isolation period is 0, the system performs software monitoring on detected attackers. The timeout period is the monitoring period. During software monitoring, if the isolation period is set to a non-zero value, the system automatically performs isolation against attackers monitored by software and sets the timeout period as the monitoring period. The monitoring period is valid only when the isolation period is 0. If the isolation period is changed to 0, attackers on the corresponding interface is deleted, instead of being monitored by software.

Configuring the Maximum Number of Monitored Hosts

- Mandatory.

- Increase the maximum number of monitored hosts. As the number of actually monitored hosts increases, more CPU resources are used to handle monitored hosts.
- The AC supports the global configuration mode.
- If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted.
- If the table of monitored hosts is full, the system generates the log "% NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Command	**dhcpv6-guard monitored-host-limit** *number*
Parameter Description	*number*: Indicates the maximum number of monitored hosts. The value range is from 1 to 4294967295.
Defaults	The maximum number of monitored hosts is 1000 by default.
Command Mode	NFPP configuration mode
Usage Guide	If the number of monitored hosts exceeds 1000 (default value), the administrator can set the maximum number of monitored hosts to a value smaller than 1000. In this case, the system does not delete monitored hosts but displays the message "%ERROR: The value that you configured is smaller than current monitored hosts 1000, please clear a part of monitored hosts." The message notifies the administrator that the configuration does not take effect and that some monitored hosts need to be deleted. If the table of monitored hosts is full, the system generates the log "% NFPP_DHCPV6_GUARD-4-SESSION_LIMIT: Attempt to exceed limit of 1000 monitored hosts." to notify the administrator.

Configuring the Attack Threshold

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system generates the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system generates the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system generates the log "%NFPP_DHCPV6_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- Source MAC address-based rate limiting takes precedence over interface-based rate limiting.
- In NFPP configuration mode, run the **dhcpv6-guard rate-limit** { **per-src-mac** | **per-port** } *pps* command to configure the global rate limit.

- In NFPP configuration mode, run the **dhcpv6-guard attack-threshold** { **per-src-mac** | **per-port** } *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attacks exist.
- In interface configuration mode, run the **nfpp dhcpv6-guard policy** { **per-src-mac | per-port** } *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on an interface.

Command	**dhcpv6-guard rate-limit** { **per-src-mac** | **per-port** } *pps*
Parameter Description	**per-src-mac:** Limits the rate for each source MAC address. **per-port:** Limits the rate for each interface. *pps*: Indicates the rate limit. The value range is from 1 to 9999.
Defaults	For the AC, the default rate limit varies with the product model. For the AP, the default rate limit for packets based on source MAC address is 5 pps, and the default rate limit for packets based on interfaces is 150 pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nfpp dhcpv6-guard policy** { **per-src-mac** | **per-port** } *rate-limit-pps attack-threshold-pps*
Parameter Description	**per-src-mac:** Configures the rate limit and attack threshold for each source MAC address. **per-port:** Configures the rate limit and attack threshold for each interface. *rate-limit-pps*: Indicates the rate limit. The value range is from 1 to 9999. *attack-threshold-pps*: Indicates the attack threshold. The value range is from 1 to 9999.
Defaults	By default, no rate limit and attack threshed are configured for a port, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Configuring Trusted Hosts

- (Optional) No trusted host is configured by default.
- For DHCPv6 attack defense, you can configure a maximum of 500 MAC addresses not to be monitored.
- The AC supports the global configuration mode.
- If any entry matching a trusted host (MAC addresses are the same) exists in the table of monitored hosts, the system automatically deletes this entry.
- If the table of trusted hosts is full, the system generates the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system generates the log "%ERROR: Failed to delete trusted host 0000.0000.1111." to notify the administrator.
- If you fail to add a trusted host, the system generates the log "%ERROR: Failed to add trusted host 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system generates the log "%ERROR: Trusted host 0000.0000.1111 has already been configured." to notify the administrator.

- If the trusted host you want to delete does not exist, the system generates the log "%ERROR: Trusted host 0000.0000.1111 is not found." to notify the administrator.

Command	**dhcpv6-guard trusted-host** *mac*
Parameter Description	*mac*: Indicates the MAC address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, configure the host to be trusted. This trusted host can send DCHPv6 packets to the CPU. In this case, the device does not rate-limit such packets or generate alarms.

Verification

When a network host sends DHCPv6 attack packets to a device configured with DHCPv6 attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets (not matching the trusted host configuration) exceeds the attack threshold or scanning threshold, attack information is displayed.
- If the rate of attack packets matches the trusted host configuration, no information is displayed.

Configuration Example

CPU Protection Based on DHCPv6 Attack Defense

Scenario	• DHCPv6 host attacks exist in the system, and DHCPv6 neighbor discovery fails on some hosts. • DHCPv6 traffic of some hosts is heavy in the system, and the traffic needs to be allowed.
Configuration Steps	• Configure the host-based attack threshold. • Set the isolation period to a non-zero value. • Configure trusted hosts.

	`Hostname# configure terminal`
	`Hostname(config)# nfpp`
	`Hostname(config-nfpp)#dhcpv6-guard rate-limit per-src-mac 8`
	`Hostname(config-nfpp)#dhcpv6-guard attack-threshold per-src-mac 16`
	`Hostname(config-nfpp)#dhcpv6-guard isolate-period 180`
	`Hostname(config-nfpp)#dhcpv6-guard trusted-host 0000.0000.1111`

Verification	Run the **show nfpp dhcpv6-guard summary** command to display the configuration.

	`Hostname# show nfpp dhcpv6-guard summary`
	`(Format of column Rate-limit and Attack-threshold is per-src-ip/per-src-mac/per-port.)`
	`Interface Status Isolate-period Rate-limit Attack-threshold`
	`Global Disable 180 -/8/150 -/16/300`
	
	`Maximum count of monitored hosts: 1000`

	Monitor period: 600s
	Run the **show nfpp dhcpv6-guard hosts** command to display monitored hosts.
	Hostname# show nfpp dhcpv6-guard hosts If col_filter 1 shows '*', it means "hardware do not isolate host". VLAN interface MAC address remain-time(s) ---- --------- ----------- -------------- *1 Gi0/5 001a.a9c2.4609 160 Total: 1 host
	Run the **show nfpp dhcpv6-guard trusted-host** command to display trusted hosts.
	Hostname# show nfpp dhcpv6-guard trusted-host mac ---- 0000.0000.1111 Total: 1 record(s)

1.4.6 Configuring ND Attack Defense

Configuration Effect

- AR ND attack defense classifies ND packets into three types:

  (1) NS and NA

  (2) RS

  (3) RA and Redirect

  The first type of packets are used for address resolution. The second type of packets are used by hosts to discover the gateway. The third type of packets are related to routing: RA packets are used to advertise the gateway and prefix, while Redirect packets are used to advertise a better next hop.

- Only interface-based ND packet attack identification is supported. You can configure the rate limits and alarm thresholds for these three types of packets. If the ND packet rate exceeds the rate limit, the packets beyond the rate limit are discarded. If the ND packet rate exceeds the alarm threshold, the system generates alarms and sends trap packets.

Notes

- For a command that is configured both in global configuration mode and interface configuration mode, the configuration in interface configuration mode takes precedence over that in global configuration mode.
- Isolation is disabled by default. If isolation is enabled, attackers will occupy entries of the security module.

Configuration Step

↘ Enabling Attack Detection

- Mandatory. Attack detection is enabled by default.
- The AC supports the global configuration mode and interface configuration mode.

Command	**nd-guard enable**
Parameter	-

Description	
Defaults	ND attack defense is enabled by default.
Command Mode	NFPP configuration mode
Usage Guide	-

Command	**nfpp nd-guard enable**
Parameter Description	-
Defaults	ND attack defense is configured in global configuration mode, but not in interface configuration mode.
Command Mode	Interface configuration mode
Usage Guide	ND attack defense configured in interface configuration mode takes precedence over that configured in global configuration mode.

Configuring the Attack Threshold

- Mandatory.
- The AC supports the global configuration mode and interface configuration mode.
- If the configured rate limit is greater than the attack threshold, the system generates the log "%ERROR: rate limit is higher than attack threshold 500pps." to notify the administrator.
- If the configured attack threshold is smaller than the rate limit, the system generates the log "%ERROR: attack threshold is smaller than rate limit 300pps." to notify the administrator.
- If the memory cannot be allocated to detected attackers, the system generates the log "%NFPP_ND_GUARD-4-NO_MEMORY: Failed to alloc memory." to notify the administrator.
- In NFPP configuration mode, run the **nd-guard rate-limit per-port** [**ns-na** | **rs** | **ra-redirect**] *pps* command to configure the global rate limit.
- In NFPP configuration mode, run the **nd-guard attack-threshold per-port** [**ns-na** | **rs** | **ra-redirect**] *pps* command to configure the global attack threshold. That is, when the packet rate exceeds the attack threshold, it is considered that attacks exist.
- In interface configuration mode: run the **nfpp nd-guard policy per-port** [**ns-na** | **rs** | **ra-redirect**] *rate-limit-pps attack-threshold-pps* command to configure the local rate limit and attack threshold on an interface.

Command	**nd-guard rate-limit per-port** [**ns-na**	**rs**	**ra-redirect**] *pps*
Parameter Description	**ns-na:** Indicates NS and NA packets. **rs:** Indicates RS packets. **ra-redirect:** Indicates RA and Redirect packets. *pps:* Indicates the rate limit. The value range is from 1 to 9999.
Defaults	For the AC, the default attack threshold varies with the product model. For the AP, the default attack threshold for NS, NA, RS, RA, and Redirect packets is 15 pps.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Command	**nd-guard attack-threshold per-port** [**ns-na** | **rs** | **ra-redirect**] *pps*
Parameter Description	**ns-na:** Indicates NS and NA packets. **rs:** Indicates RS packets. **ra-redirect:** Indicates RA and Redirect packets. *pps*: Indicates the attack threshold, in pps. The value range is from 1 to 9999.
Defaults	For the AC, the default attack threshold varies with the product model. For the AP, the default attack threshold for NS, NA, RS, RA, and Redirect packets is 30 pps.
Command Mode	NFPP configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit.

Command	**nfpp nd-guard policy per-port** [**ns-na** | **rs** | **ra-redirect**] *rate-limit-pps attack-threshold-pps*
Parameter Description	**ns-na:** Indicates NS and NA packets. **rs:** Indicates RS packets. **ra-redirect:** Indicates RA and Redirect packets. *rate-limit-pps*: Indicates the rate limit. The value range is from 1 to 9999. *attack-threshold-pps*: Indicates the attack threshold. The value range is from 1 to 9999.
Defaults	By default, no rate limit and attack threshed are configured for an interface, and the global rate limit and attack threshold are used.
Command Mode	Interface configuration mode
Usage Guide	The attack threshold must be equal to or greater than the rate limit. ND snooping classifies interfaces into two types: untrusted interfaces (connecting the host) and trusted interfaces (connecting to the gateway). As the traffic volume on a trusted interface is greater than that on an untrusted interface, the rate limit for a trusted interface is higher than that for an untrusted interface. If ND snooping is enabled for a trusted interface, ND snooping sets the rate limit to 800 pps and the attack threshold to 900 pps for the three types of packets on the interface by advertising ND attack defense. ND attack defense treats the rate limit configured for ND snooping and that configured by the administrator in the same way. The value configured later overwrites the value configured earlier and is stored in the configuration file. The attack threshold configured for ND snooping is treated in a similar way.

Configuring Trusted Hosts

- Optional. No trusted host is configured by default.
- For ND guard, you can configure a maximum of 500 MAC addresses not to be monitored.
- Support the global configuration mode on the AC or AP.
- If the table of trusted hosts is full, the system generates the log "%ERROR: Attempt to exceed limit of 500 trusted hosts." to notify the administrator.
- If the administrator fails to delete a trusted host, the system generates the log "%ERROR: Failed to delete trusted host 0000.0000.1111." to notify the administrator.

- If you fail to add a trusted host, the system generates the log "%ERROR: Failed to add trusted host 0000.0000.1111." to notify the administrator.
- If the trusted host you want to add already exists, the system generates the log "%ERROR: Trusted host 0000.0000.1111 has already been configured." to notify the administrator.
- If the trusted host you want to delete does not exist, the system generates the log "%ERROR: Trusted host 0000.0000.1111 is not found." to notify the administrator.

Command	**nd-guard trusted-host** *mac*
Parameter Description	*mac*: Indicates the MAC address.
Defaults	No trusted host is configured by default.
Command Mode	NFPP configuration mode
Usage Guide	If you do not want to monitor a host, configure the host to be trusted. This trusted host can send ND packets to the CPU. In this case, the device does not rate-limit such packets or generate alarms.

Verification

When a network host sends ND attack packets to a device configured with ND attack detection and rate limiting, check whether these packets can be sent to the CPU.

- If the rate of packets (not matching the trusted host configuration) exceeds the attack threshold or scanning threshold, attack information is displayed.
- If the rate of attack packets matches the trusted host configuration, no information is displayed.

Configuration Example

CPU Protection Based on ND Attack Defense

Scenario	● ND host attacks exist in the system, and neighbor discovery fails on some hosts. ● ND traffic of some hosts is heavy in the system, and the traffic needs to be allowed.
Configuration Steps	● Configure the host-based attack threshold.

	`Hostname# configure terminal`
	`Hostname(config)# nfpp`
	`Hostname(config-nfpp)# nd-guard rate-limit per-port ns-na 30`
	`Hostname(config-nfpp)# nd-guard attack-threshold per-port ns-na 50`
	`Hostname(config-nfpp)#nd-guard trusted-host 0000.0000.1111`

Verification	● Run the **show nfpp nd-guard summary** command to display the configuration.

	`Hostname# show nfpp nd-guard summary`
	`(Format of column Rate-limit and Attack-threshold is NS-NA/RS/RA-REDIRECT.)`
	`Interface Status Rate-limit Attack-threshold`
	`Global Disable 30/15/15`

	● Run the **show nfpp nd-guard trusted-host** command to display trusted hosts.

	Hostname# show nfpp nd-guard trusted-host mac ---- 0000.0000.1111 Total: 1 record(s)

1.4.7 Configuring Centralized Rate Limiting and Distribution

Configuration Effect

Configure centralized rate limiting and distribution so that management and protocol packets are first processed when the network is busy.

Notes

The valid percentage range of a type of packets must be equal to or smaller than 100% minus the percentage of the sum of the other two types.

Configuration Step

Configuring the Maximum Bandwidth for Each Type of Packets

- Mandatory. Management, routing, and protocol packets share the same default bandwidth. For details, see *Product Features*.
- The AC supports the global configuration mode.

Command	**cpu-protect sub-interface** { **manage** | **protocol** | **route** } **pps** *pps_value*
Parameter Description	**manage**: Specifies management packets. **protocol**: Specifies protocol packets. **route**: Specifies routing packets. *pps_value*: Indicates the rate limit. The value range is from 1 to 500000.
Defaults	For the AC, the default attack threshold varies with the product model. For the AP, the default rate limit of management, protocol, and routing packets is 3000 pps.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Maximum Percentage of Each Type of Packets in the Queue

- Mandatory. By default, management packets occupy 30% of the bandwidth, routing packets occupy 40%, and protocol packets occupy 25%.
- The AC supports the global configuration mode.

Command	**cpu-protect sub-interface** { **manage** | **protocol** | **route** } **percent** *percent_value*
Parameter Description	**manage**: Specifies management packets. **protocol**: Specifies protocol packets. **route**: Specifies routing packets. *percent_value*: Indicates the percentage of a type of packets in the queue. The value range is from 1 to 100.

Defaults	**manage**: 30% **protocol**: 25% **route**: 40%
Command Mode	Global configuration mode
Usage Guide	The valid percentage range of a type of packets must be equal to or smaller than 100% minus the percentage of the sum of the other two types.

Configuration Example

↘ Prioritizing Packets Sent to the CPU Through Centralized Distribution

Scenario	Various types of mass packets exist on a network and belong to different centralized types.
Configuration Steps	● Configure the maximum bandwidth for each type of packets. ● Configure the maximum percentage of each type of packets in the queue.

	`Hostname# configure terminal`
	`Hostname(config)# cpu-protect sub-interface manage pps 5000`
	`Hostname(config)# cpu-protect sub-interface manage percent 25`

Verification	Omitted.

1.4.8 Configuring NFPP Log Information

Configuration Effect

The NFPP-enabled device obtains a log from the dedicated log buffer at a certain rate, generates a system message, and clears this log from the dedicated log buffer.

Notes

Logs are continuously generated in the log buffer, even if attacks are stopped.

Configuration Step

↘ Configuring the Log Buffer Capacity

- Mandatory.
- If the log buffer is full, new logs are discarded and a corresponding prompt is displayed.
- If the log buffer overflows, subsequent logs are discarded and an entry with all attributes marked with a hyphen (-) is displayed in the log buffer. The administrator needs to increase the log buffer capacity or the system message generation rate.
- The AC supports the global configuration mode.

Command	**log-buffer entries** *number*
Parameter Description	*number*: Indicates the buffer size, which is expressed in the number of logs. The value range is from 0 to 1024.
Defaults	The default buffer size is 256.

Command Mode	NFPP configuration mode
Usage Guide	N/A

Configuring the System Message Generation Rate

- Mandatory.
- The system message generation rate depends on the time segment length and the number of system messages generated in the time segment.
- If both of the preceding two parameters are set to 0, system messages are immediately generated for logs but are not stored in the log buffer.
- The AC supports the global configuration mode.

Command	**log-buffer logs** *number_of_message* **interval** *length_in_seconds*
Parameter Description	*number_of_message*: Indicates the number of system messages. The value range is from 0 to 1024. The value 0 indicates that all logs are recorded in the log buffer and no system message is generated. *length_in_seconds*: Indicates the time segment length. The value range is from 0 to 86400 (1 day). The value 0 indicates that logs are not recorded in the log buffer but system messages are instantly generated. If ***number_of_message*** and ***length_in_seconds*** are 0, logs are not recorded in the log buffer but system messages are instantly generated. *number_of_message/length_in_second:* Indicates the system message generation rate.
Defaults	The default value of **number_of_message** is 1 and the default value of **length_in_seconds** is 30.
Command Mode	NFPP configuration mode
Usage Guide	N/A

Enabling Log Filtering

- Optional. Log filtering is disabled by default.
- Logs can be filtered based on an interface or VLAN.
- If log filtering is enabled, logs not meeting the filtering rule are discarded.
- The AC supports the global configuration mode.

Command	**logging vlan** *vlan-range*
Parameter Description	*vlan-range*: Records logs in a specified VLAN range, for example, 1-3,5 for example.
Defaults	All logs are recorded by default.
Command Mode	NFPP configuration mode
Usage Guide	This command is used to filter logs so that only logs in the specified VLAN range are recorded. For interface-based and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

Command	**logging interface** *interface-id*
Parameter	*interface-id*: Records logs of a specified interface.

Description	
Defaults	All logs are recorded by default.
Command Mode	NFPP configuration mode
Usage Guide	Run this command to filter logs so that only logs of the specified interface are recorded. For interface-based and VLAN-based log filtering, if either rule is met, logs are recorded in the log buffer.

Configuration Example

↘ CPU Protection Based on ND Attack Defense

Scenario	If there are too many attackers, log generation will affect the usage of user interfaces and must be restricted.
Configuration Steps	● Configure the log buffer capacity. ● Configure the system message generation rate. ● Configure VLAN-based log filtering.

	`Hostname# configure terminal`
	`Hostname(config)# nfpp`
	`Hostname(config-nfpp)#log-buffer entries 1024`
	`Hostname(config-nfpp)#log-buffer logs 3 interval 5`
	`Hostname(config-nfpp)#logging interface vlan 1`

Verification	Run the **show nfpp log summary** command to display the configuration.

	`Hostname# show nfpp log summary`
	`Total log buffer size : 1024`
	`Syslog rate : 3 entry per 5 seconds`
	`Logging:`
	`  VLAN 1`

	Run the **show nfpp log buffer** command to display logs in the log buffer.

	`Hostname# show nfpp log buffer`
	`Protocol VLAN Interface  IP address  MAC address  Reason Timestamp`
	`-------- ---- ---------  ----------  -----------  ------ ---------`
	`ARP  1  Gi0/5  192.168.206.2  001a.a9c2.4609  SCAN 2013-5-1 5:4:24`

1.5 Monitoring

Clearing

Command	Description
clear nfpp arp-guard scan	Clears the ARP attack defense scanning table.
clear nfpp arp-guard hosts	Clears monitored hosts in ARP attack defense.

Command	Description
clear nfpp ip-guard hosts	Clears monitored hosts in IP attack defense.
clear nfpp icmp-guard hosts	Clears monitored hosts in IMCP attack defense.
clear nfpp dhcp-guard hosts	Clears monitored hosts in DHCP attack defense.
clear nfpp dhcpv6-guard hosts	Clears monitored hosts in DHCPv6 attack defense.
clear nfpp log	Clears logs.

Displaying

Command	Description
show nfpp arp-guard summary	Displays configuration parameters of ARP attack defense.
show nfpp arp-guard hosts	Displays monitored hosts of ARP attack defense.
show nfpp arp-guard scan	Displays the ARP attack defense scanning table.
show nfpp arp-guard trusted-host	Displays trusted hosts in ARP attack defense.
show nfpp ip-guard summary	Displays configuration parameters of IP attack defense.
show nfpp ip-guard hosts	Displays monitored hosts in IP attack defense.
show nfpp ip-guard trusted-host	Displays trusted hosts in IP attack defense.
show nfpp icmp-guard summary	Displays configuration parameters of ICMP attack defense.
show nfpp icmp-guard hosts	Displays monitored hosts in ICMP attack defense.
show nfpp icmp-guard trusted-host	Displays trusted hosts in ARP attack defense.
show nfpp dhcp-guard summary	Displays configuration parameters of DHCP attack defense.
show nfpp dhcp-guard hosts	Displays monitored hosts in DHCP attack defense.
show nfpp dhcp-guard trusted-host	Displays trusted hosts in DHCP attack defense.
show nfpp dhcpv6-guard summary	Displays configuration parameters of DHCPv6 attack defense.
show nfpp dhcpv6-guard hosts	Displays monitored hosts in DHCPv6 attack defense.
show nfpp dhcpv6-guard trusted-host	Displays trusted hosts in DHCPv6 attack defense.
show nfpp nd-guard summary	Displays configuration parameters of ND attack defense.
show nfpp nd-guard trusted-host	Displays trusted hosts in ND attack defense.
show nfpp log summary	Displays NFPP logs.
show nfpp log buffer [**statistics**]	Displays the NFPP log buffer.

1 Configuring Password Policy

1.1 Overview

The password policy is provided for local authentication of the device, and is used to control users' login passwords and login status.

Protocols and Standards

N/A

1.2 Features

Basic Concepts

Minimum Password Length

An administrator can set the minimum length for user passwords according to system security requirements. If the input password is shorter than the minimum password length, the system does not allow the user to set this password but displays a prompt, asking the user to specify another password of an appropriate length.

Strong Password Detection

The less complex a password is, the more likely the password is cracked. For example, a password that is the same as the corresponding account or a simple password that contains only characters or digits may be easily cracked. To ensure security, an administrator can enable the strong password detection function to ensure that the configured passwords are correctly configured. After the strong password detection function is enabled, a prompt will be displayed for the following types of passwords:

1 Passwords that are the same as corresponding accounts

2 Simple passwords that contain characters or digits only

Special Password Character Detection

Special characters include space, tilde (~), apostrophe (`), exclamation mark (!), at sign (@), number sign (#), dollar sign ($), percent (%), caret (^), ampersand (&), asterisk (*), parentheses (()), underscore (_), plus sign (+), hyphen (-), equal sign (=), braces ({}), vertical bar (|), brackets ([]), backslash (\), colon (:), quotation marks ("), semicolon (;), single quotation mark ('), angle brackets (<>), comma (,), period (.), and slash (/). If a password contains these special characters, the password is weak and may be easily cracked. To ensure security, an administrator can enable the special password character detection function to ensure that the configured passwords do not contain any special character. After the special password character detection function is enabled, a prompt will be displayed for passwords containing special characters.

Password Lifecycle

The password lifecycle defines the validity time of a user password. When the service time of a password exceeds the lifecycle, the user needs to change the password.

If the user inputs a password that has already expired during login, the system will display a message, indicating that the password has expired and the user needs to reset the password. If the new password input during password resetting does not meet system requirements or the new passwords consecutively input twice are different, the system will ask the user to input the new password once again.

Limitation on Repeated Use of Passwords

When changing the password, a user will set a new password while the old password will be recorded as historical records. If the new password input by the user has been used previously, the system displays an error message and asks the user to specify another password.

The maximum number of password historical records per user can be configured. When the number of password historical records of a user is greater than the maximum number configured for this user, the new password historical record will overwrite the user's oldest password historical record.

Storage of Encrypted Passwords

An administrator can enable storage of encrypted passwords considering security. When an administrator runs the **show running-config** command to display the configuration or run the **write** command to save configuration files, various configured passwords are displayed in cipher text format. If the administrator disables storage of encrypted passwords next time, the passwords that use the cipher text format will not be restored to cleartext passwords.

1.3 Configuration

Configuration	Description and Command	
Configuring the Password Security Policy	⚠ (Optional configuration) It is used to configure a combination of parameters related to the password security policy.	
	password policy life-cycle	Configures the password lifecycle.
	password policy min-size	Configures the minimum length of user passwords.
	password policy no-repeat-times	Configures the number of times for repeated use of latest passwords.
	password policy strong	Enables the strong password detection function.
	service password-encryption	Enables storage of encrypted passwords.

1.3.1 Configuring the Password Security Policy

Configuration Effect

Provide a password security policy for local authentication of the device. You can configure different password security policies to implement password security management.

Notes

The configured password security policy is valid for global passwords (configured using **enable password** and **enable secret**) and local user passwords (configured using the **username** *name* **password** *password* command). It is invalid for passwords in line mode.

Configuration Step

Configuring the Password Lifecycle

- Optional.
- Perform this configuration on each device unless otherwise specified.

Configuring the Minimum Length of User Passwords

- Optional.
- Perform this configuration on each device unless otherwise specified.

Setting the Number of Times for Repeated Use of Latest Passwords

- Optional.
- Perform this configuration on each device unless otherwise specified.

Enabling the Strong Password Detection Function

- Optional.
- Perform this configuration on each device unless otherwise specified.

Enabling torage of Encrypted Passwords

- Optional.
- Perform this configuration on each device unless otherwise specified.

Verification

Configure a local user on the device, and configure a valid password and an invalid password for the user.

- When you configure the valid password, the device correctly adds the password.
- When you configure the invalid password, the device displays a corresponding error log.

Related Commands

Configuring the Password Lifecycle

Command Syntax	**password policy life-cycle** *days*
Parameter Description	*days*: Indicates the password lifecycle, in days. The value range is from 1 to 65535.
Command Mode	Global configuration mode
Usage Guide	The password lifecycle is used to define the validity period of user passwords. If the user logs in with a password whose service time already exceeds the lifecycle, a prompt is displayed, asking the user to change the password.

Configuring the Minimum Length of User Passwords

Command	**password policy min-size** *length*

Syntax	
Parameter Description	*length*: Indicates the minimum length of passwords. The value range is from 1 to 31.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the minimum length of passwords. If the minimum length of passwords is not configured, users can input a password of any length.

Setting the Number of Times for Repeated Use of Latest Passwords

Command Syntax	**password policy no-repeat-times** *times*
Parameter Description	*times*: Indicates the number of times for repeated use of latest passwords. The value range is from 1 to 31.
Command Mode	Global configuration mode
Usage Guide	After this function is enabled, all old passwords used in recent times will be recorded as password historical records. If the new password input by the user has been used previously, the system displays an error prompt and the password change fails. You can configure the maximum number of password historical records per user. When the number of password historical records of a user is greater than the maximum number configured for the user, the new password historical record will overwrite the user's oldest password historical record.

Enabling the Strong Password Detection Function

Command Syntax	**password policy strong**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After the strong password detection function is enabled, a prompt is displayed for the following types of passwords: 1. Passwords that are the same as corresponding accounts 2. Simple passwords that contain characters or digits only

Setting the Storage of Encrypted Passwords

Command Syntax	**service password-encryption**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Before storage of encrypted passwords is enabled, all passwords will be displayed and stored in cleartext format, unless the passwords are configured in cipher text format. You can enable storage of encrypted passwords considering security. When you run the **show running-config** command to

	display the configuration or run the **write** command to save configuration files, various configured passwords are displayed in cipher text format. If you disable storage of encrypted passwords next time, the passwords that use the cipher text format will not be restored to cleartext passwords.

Checking Configured Password Security Policy Information

Command Syntax	**show password policy**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Use this command to display the password security policy configured on the device.

Configuration Examples

The following configuration example describes the configuration related to a password security policy.

Configuring Password Security Check on the Device

Typical Application	There are the following password security requirements on a network: 1. The passwords has a minimum of eight characters. 2. The password lifecycle is 90 days. 3. Passwords are stored and transmitted in cipher text format. 4. The number of times for repeated use of recent passwords is 3. 5. Passwords cannot be the same as user names, and cannot contain simple characters or digits only.

Configuration Steps	● Set the minimum length of passwords to 8.
	● Set the password lifecycle to 90 days.
	● Enable storage of encrypted passwords.
	● Set the number of times for repeated use of recent passwords to 3.
	● Enable the strong password detection function.
	`Hostname# configure terminal`
	`Hostname(config)# password policy min-size 8`
	`Hostname(config)# password policy life-cycle 90`
	`Hostname(config)# service password-encryption`
	`Hostname(config)# password policy no-repeat-times 3`
	`Hostname(config)# password policy strong`

Verification	When you create a user and the corresponding password after configuring the password security policy, the system will perform detection according to the password security policy.
	● Run the **show password policy** command to display configured password security policy information.
	`Hostname# show password policy`
	`Global password policy configurations:`
	`Password encryption: Enabled`

	Password strong-check: Enabled Password min-size: Enabled (8 characters) Password life-cycle: Enabled (90 days) Password no-repeat-times: Enabled (max history record: 3)

Common Errors

The time configured for providing a pre-warning notification about password expiry is greater than the password lifecycle.

1.4 Monitoring

Displaying

Command	Function
show password policy	Displays configured password security policy information.

1 Configuring SSH

1.1 Overview

A Secure Shell (SSH) connection is similar to a Telnet connection except that all data transmitted over SSH is encrypted. When a user on an insecure network logs into a device remotely, SSH helps ensure information security and powerful authentication, protecting the device against attacks such as IP address spoofing and cleartext password interception.

An SSH-capable device can be connected to multiple SSH clients. In addition, the device can also function as an SSH client, and allows users to set up an SSH connection with an SSH server. In this way, the local device can securely log in to a remote device through SSH to implement management.

The device can work as either the SSH server or an SSH client, and supports SSHv1 and SSHv2. It supports IPv4 and IPv6 SSH.

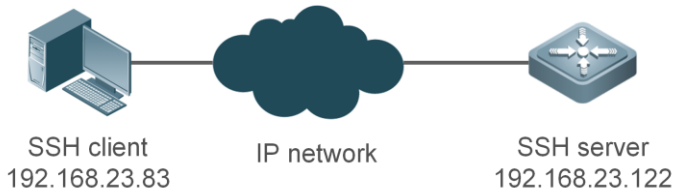
Unless otherwise specified, SSH in this document refers to SSHv2.

Protocols and Standards

- RFC 4251: The Secure Shell (SSH) Protocol Architecture
- RFC 4252: The Secure Shell (SSH) Authentication Protocol
- RFC 4253: The Secure Shell (SSH) Transport Layer Protocol
- RFC 4254: The Secure Shell (SSH) Connection Protocol
- RFC 4419: Diffie-Hellman Group Exchange for the Secure Shell (SSH) Transport Layer Protocol
- RFC 4716: The Secure Shell (SSH) Public Key File Format
- RFC 4819: Secure Shell Public Key Subsystem
- RFC 3526: More Modular Exponential (MODP) Diffie-Hellman groups for Internet Key Exchange (IKE)
- RFC 2409: The Internet Key Exchange (IKE)
- RFC 1950: ZLIB Compressed Data Format Specification version 3.3
- draft-ietf-secsh-filexfer-05: SSH File Transfer Protocol
- draft-ylonen-ssh-protocol-00: The version of the SSH Remote Login Protocol is 1.5. Comware implements the SSH server functions, but not the SSH client functions.

1.2 Applications

Application	Description
SSH Device Management	Use SSH to manage devices.
SSH Local Line Authentication	Use local line password authentication for SSH user authentication.
SSH AAA Authentication	Use the authentication, authorization and accounting (AAA) mode for SSH user authentication.
SSH Public Key Authentication	Use public key authentication for SSH user authentication.



Application	Description
SSH File Transfer	Use Secure Copy (SCP) commands on the SSH client to exchange data with the SSH server.
SSH Client Application	Use the SSH client to securely log in to a remote device for management.

1.2.1 SSH Device Management

Scenario

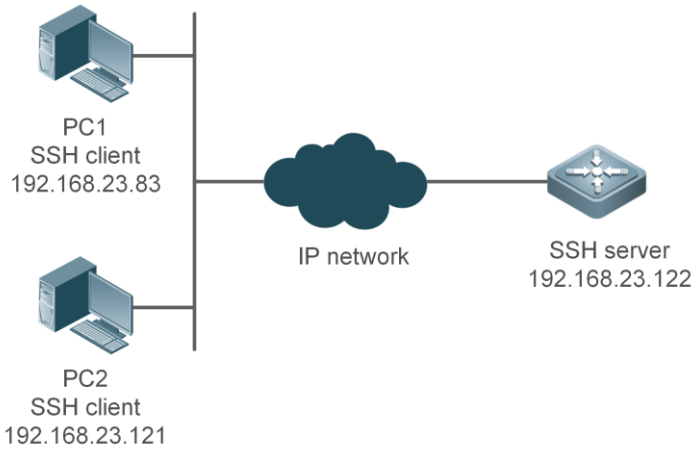
To use SSH to manage devices, ensure that the SSH server is enabled. By default, the SSH server is disabled. The Telnet component that comes with the Windows system does not support SSH. Therefore, a third-party client software must be used. Well-compatible software includes PuTTY, Linux, and SecureCRT. PuTTY is used as an example to introduce the configuration of the SSH client. Figure 1-1 shows the network topology.

Figure 1-1 Networking Topology of SSH Device Management

Deployment

Configure the SSH client as follows:

- Start the PuTTY software.
- On the **Session** option tab of PuTTY, enter the host IP address of the SSH server and SSH port number 22, and select the connection type of SSH.
- On the **SSH** option tab of PuTTY, select preferred SSH protocol version 2.
- On the **SSH authentication** option tab of PuTTY, select the authentication method of **Attempt "keyboard-interactive" auth**.
- Click **Open** to connect to the SSH server.
- Enter the correct user name and password to access the terminal login interface.



1.2.2 SSH Local Line Authentication

Scenario

SSH clients can use the local line password authentication mode, as shown in Figure 1-2. To ensure security of data exchange, PC 1 and PC 2 function as the SSH clients, and use the SSH protocol to log in to the network device where the SSH server is enabled. The requirements are as follows:

- SSH users use the local line password authentication mode.
- Five lines, including Line 0 to Line 4, are activated concurrently. The login password is **passzero** for Line 0 and **pass** for the remaining lines. Any user name can be used.

Figure 1-2 Networking Topology of SSH Local Line Password Authentication

Deployment

- Configure the SSH server as follows:

1 Enable the SSH server globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2.

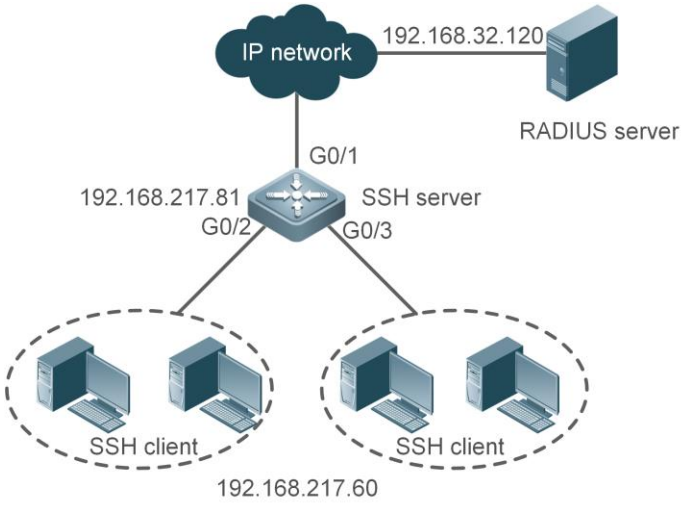
2 Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH clients, compares the decrypted cleartext with the password stored on the server, and returns a message about authentication success or failure. SSHv1 uses an RSA key, whereas SSHv2 adopts a Rivest-Shamir-Adleman (RSA) or Digital Signature Algorithm (DSA) key.

3 Configure the IP address of FastEthernet 0/1 on the SSH server. The SSH client is connected to the SSH server using this IP address. The routes from the SSH clients to the SSH server are reachable.

- Configure the SSH client as follows:

Diversified SSH client software is available, including PuTTY, Linux, and OpenSSH. PuTTY is used as an example to explain the method for configuring the SSH clients.

1 Open the PuTTY connection tab, and select SSHv1 for authenticated login. The method is similar if SSHv2 is selected.



2 Set the IP address and connected port ID of the SSH server. As shown in the network topology, the IP address of the server is 192.168.23.122, and the port ID is 22. Click **Open** to start the connection. Because the current authentication mode does not require a user name, you can enter any user name, which cannot be empty. (In this example, the user name is "anyname".)

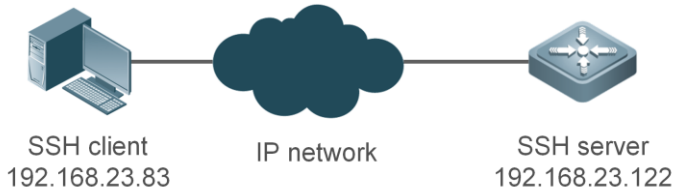
1.2.3 SSH AAA Authentication

Scenario

SSH users can use the AAA authentication mode for user authentication, as shown in Figure 1-3. To ensure security of data exchange, PCs function as the SSH clients and use SSH to log in to the network device where the SSH server is enabled. To better perform security management, the AAA authentication mode is used for user login on the SSH clients. Two authentication methods, including RADIUS server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The RADIUS server authentication method is preferred. If the RADIUS server does not respond, local authentication is used.

Figure 1-3 Networking Topology of SSH AAA Authentication

Deployment



- Configure reachable routes from the SSH clients to the SSH server and from the SSH server to the RADIUS server.
- Configure the SSH server on the network device.
- Configure AAA parameters on the network device. When the AAA authentication mode is used, method lists are created to define identity authentication and types, and applied to a specified service or interface.

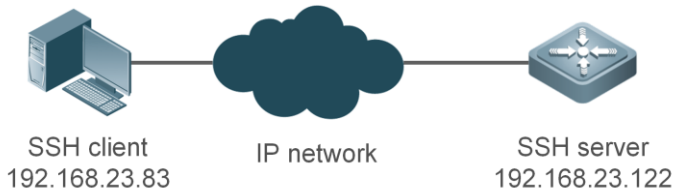
1.2.4 SSH Public Key Authentication

Scenario

SSH clients can use public keys for authentication, and the public key algorithm can be RSA or DSA, as shown in Figure 1-4. SSH is configured on the client so that a secure connection is set up between the SSH client and the SSH server.

Figure 1-4 Network Topology for Public Key Authentication of SSH Users

Deployment



- To implement public key authentication for the client, configure the client to generate a key pair (RSA or DSA), configure the public key on the SSH server, and select the public key authentication mode.
- After the key is generated on the client, the SSH server will copy the file of the public key from the client to the flash memory and associates the file with the SSH user name. Each user can be associated with one RSA public key and one DSA public key.

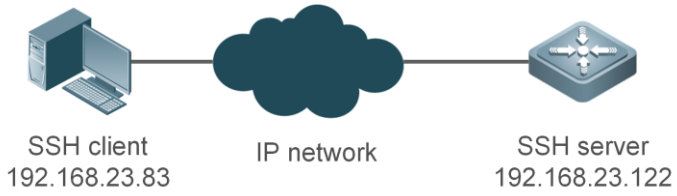
1.2.5 SSH File Transfer

Scenario

The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server, as shown in Figure 1-5.

Figure 1-5 Networking Topology of SSH File Transfer

Deployment



- Enable the SCP service on the server.
- On the client, use SCP commands to upload files to the server, or download files from the server.

1.2.6 SSH Client Application

Scenario

The SSH service is enabled on a remote SSH server, and the **ssh** command is used on the local client to set up an SSH connection with the server for secure data transmission, as shown in Figure 1-6.

Figure 1-6 Networking Topology of SSH Client Application

Deployment

- Enable the SSH service on the server.
- On the client, run the **ssh** command to set up an SSH connection with the server for secure data transmission.

1.3 Features

Basic Concepts

↘ User Authentication Mechanism

- Password authentication

During password authentication, a client sends a user authentication request and encrypted user name and password to the server. The server decrypts the received information, compares the decrypted information with those stored on the server, and then returns a message indicating successful or failed authentication.

- Public key authentication

During public key authentication, digital signature algorithms such as RSA and DSA are used to authenticate a client. The client sends a public key authentication request to the server. The request contains information including the user name, public key, and public key algorithm. On receiving the request, the server checks whether the public key is correct. If not, the server directly sends an authentication failure message. If so, the server performs digital signature authentication on the client, and returns a message indicating successful or failed authentication.

Public key authentication is applicable only to SSHv2 clients.

SSH Communication

To ensure secure communication, interaction between an SSH server and an SSH client involves the following seven stages:

- Connection setup

The server listens on port 22 to the connection request from the client. After originating a socket initial connection request, the client sets up a TCP socket connection with the server.

- Version negotiation

If the connection is set up successfully, the server sends a version negotiation packet to the client. On receiving the packet, the client analyzes the packet and returns a selected protocol version to the server. The server analyzes the received information to determine whether version negotiation is successful.

- Key exchange and algorithm negotiation

If version negotiation is successful, key exchange and algorithm negotiation are performed. The server and client exchange the algorithm negotiation packet with each other, and determine the final algorithm based on their capacity. In addition, the server and the client work together to generate a session key and a session ID according to the key exchange algorithm and host key, which will be applied to subsequent user authentication, data encryption, and data decryption.

- User authentication

After the encrypted channel is set up, the client sends an authentication request to the server. The server repeatedly conducts authentication for the client until the authentication succeeds or the server shuts down the connection because the maximum number of authentication attempts is reached.

- Session request

After successful authentication, the client sends a session request to the server. The server waits and processes the client request. After the session request is successfully processed, SSH enters the session interaction stage.

- Session interaction

After the session request is successfully processed, SSH enters the session interaction stage. Encrypted data can be transmitted and processed in both directions. The client sends a command to be executed to the client. The server decrypts, analyzes, and processes the received command, and then sends the encrypted execution result to the client. The client decrypts the execution result.

- Session ending

When the interaction between the server and the client is terminated, the socket connection is terminated and the session is ended.

Overview

Feature	Description
SSH Server	Enable the SSH server function on a network device for setting up a secure connection with the SSH client.
SCP Service	After the SCP service is enabled, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, ensuring security.
SSH Client	The SSH client is used to set up a secure connection with a remote network device enabled with the SSH server.

1.3.1 SSH Server

Enable the SSH server function on a network device for setting up a secure connection with the SSH client. You can also disable the SSH server function to disconnect all SSH clients.

Working Principle

For details about the working principle of the SSH server, see "SSH Communication" In practice, after enabling the SSH server, you can configure the following parameters according to application requirements:

- Version: Configure the SSH version as SSHv1 or SSHv2 to connect SSH clients.
- Authentication timeout: The SSH server starts the timer after receiving a user connection request. The SSH server is disconnected from the client when the authentication succeeds or the authentication timeout is reached.
- Maximum re-authentication count: The SSH server starts authenticating the client after receiving its connection request. If authentication does not succeed after the maximum re-authentication count is reached, the system displays a message indicating the authentication failure.
- Public key authentication: The public key algorithm can be RSA or DSA. It provides a secure connection between the client and the server. The public key file on the client is associated with the user name. In addition, the public key authentication mode is configured on the client, and the corresponding private key file is specified. In this way, when the client attempts to log in to the server, public key authentication can be implemented to set up a secure connection.

Related Configuration

Enabling the SSH Server

By default, the SSH server is disabled.

In global configuration mode, run the [**no**] **enable service ssh-server** command to enable or disable the SSH server.

To generate the SSH key, you also need to enable the SSH server.

Specifying the SSH Version

By default, the SSH server supports both SSHv1 and SSHv2, that is, it can connect to SSHv1 or SSHv2 clients.

Run the **ip ssh version** command to configure the SSH version supported by the SSH server.

If only SSHv1 or SSHv2 is configured, only the SSHv1 or SSHv2 client can be connected to the SSH server.

Configuring the Authentication Timeout

By default, the user authentication timeout is 120s.

Run the **ip ssh time-out** command to configure the user authentication timeout of the SSH server. Use the **no** form of this command to restore the default timeout. The SSH server starts the timer after receiving a user connection request. If authentication does not succeed before the timeout is reached, authentication times out and fails.

Configuring the Maximum Re-authentication Count

By default, the maximum re-authentication count is 3.

Run the **ip ssh authentication-retries** command to configure the maximum re-authentication count on the SSH server. Use the **no** form of this command to restore the default re-authentication count. If authentication still does not succeed when the maximum re-authentication count is reached, user authentication fails.

Specifying the SSH Encryption Mode

By default, the encryption mode supported by the SSH server is compatible. That is, the device supports Cipher Block Chaining (CBC), counter (CTR), and other encryption modes.

Run the **ip ssh cipher-mode** command to configure the encryption mode supported by the SSH server. Use the **no** form of this command to restore the default encryption mode supported by the SSH server.

Specifying the SSH Message Authentication Algorithm

By default, the message authentication algorithms supported by the SSH server are as follows:

(1) For SSHv1, no algorithm is supported.

(2) For SSHv2, MD5, SHA1, SHA1-96, MD5-96, SHA2-256, and SHA2-512 are supported.

Run the **ip ssh hmac-algorithm** command to configure the message authentication algorithm supported by the SSH server. Use the **no** form of the command to restore the default message authentication algorithm supported by the SSH server.

Configuring the DH Key Exchange Algorithm on the SSH Server

By default, Ruijie's SSHv2 server supports diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, and diffie-hellman-group1-sha1 for key exchange, while the SSHv1 server dose not support any of them. Run the **ip ssh key-exchange** command to configure the Diffie-Hellman(DH) key exchange algorithm supported by the SSH server. Use the **no** form of this command to restore the default setting.

Setting a Monitoring Port ID for the SSH Server

The default port ID is 22.

Run the **ip ssh port** command to set a monitoring port ID for the SSH server. Use the **no ip ssh port** or **ip ssh port 22** command to restore the default setting.

Configuring an ACL for the SSH Server

By default, an ACL does not filter traffic of all connections on the SSH server.

Run the {**ip**| **ipv6** }**ssh access-class** command to configure an ACL to filter traffic of all connections on the SSH server. Use the **no** form of this command to restore the default setting.

Enabling the Public Key Authentication on the SSH Server

Run the **ip ssh peer** command to associate the public key file on the client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

1.3.2 SCP Service

The SSH server provides the SCP service to implement secure file transfer between the server and client.

Working Principle

- SCP supports online file transfer. It runs on port 22 based on the Berkeley Software Distribution (BSD) Remote Copy Protocol (RCP), whereas RCP provides encryption and authentication functions based on SSH. RCP implements file transfer, and SSH implements authentication and encryption.
- Assume that the SCP service is enabled on the server. When you use an SCP client to upload or download files, the SCP client first analyzes command parameters, sets up a connection with a remote server, and starts another SCP process based on this connection. This process may run in source or sink mode. The process running in source mode is the data provider, and the process running in sink mode is the destination of data. The process running in source mode reads and sends files to the peer end through the SSH connection. The process running in sink mode receives files through the SSH connection.

Related Configuration

Enabling the SCP Server

By default, the SCP server function is disabled.

Run the **ip scp server enable** command to enable SCP server on a network device.

Configuring the Transmission Path for Files of the SCP Server

The default transmission path is **flash:/**.

Run the **ip scp server topdir {flash:/***path* **| flash2:/***path* **| usb0:/***path* **| usb1:/***path* **| sd0:/***path* **| sata0:/***path* **| tmp:/***path* **}** command to configure the transmission path to upload files to or download files from the SCP server.

1.3.3 SSH Client

The SSH client is used to set up a secure connection with a remote network device on which the SSH server runs.

Working Principle

For details about the working principle of the SSH client, see "SSH Communication"

Related Configuration

Specifying the Source Interface of the SSH Client

By default, the source address of SSH packets is queried based on the destination address.

Run the **ip ssh source-interface** *interface-name* command to specify the source interface of the SSH client.

Establishing a Session with the SSH Server

Run the **ssh** command to log in to a remote device that supports the SSH server.

Restoring an Established SSH Session

- Run the **ssh-session** *session-id* command to restore an established SSH session.

Disconnecting a Suspended SSH Session

- Run the **disconnect ssh-session** *session-id* command to disconnect a specified SSH session.

1.4 Configuration

Configuration	Description and Command	
Configuring the SSH Server	(Mandatory) It is used to enable the SSH server.	
	enable service ssh-server	Enables the SSH server.
	disconnect ssh [**vty**] *session-id*	Disconnects an established SSH session.
	crypto key generate { **rsa** | **dsa** }	Generates an SSH key.
	crypto key zeroize { **dsa** | **rsa** }	Deletes an SSH key.
	ip ssh version { **1** | **2** }	Specifies the SSH version.
	ip ssh time-out *time*	Configures the SSH authentication timeout.
	ip ssh authentication-retries *retry times*	Configures the maximum re-authentication count.
	ip ssh cipher-mode { **cbc** | **ctr** | **others** | **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes192-cbc** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **blowfish-cbc** | **des-cbc** }	Specifies the SSH encryption mode.
	ip ssh hmac-algorithm { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }	Specifies the SSH message authentication algorithm.
	ip ssh key-exchange { **dh_group_exchange_sha1** | **dh_group14_sha1** | **dh_group1_sha1** }	Configures the DH key exchange algorithm supported by the SSH server.
	ip ssh port *port*	Sets a monitoring port ID for the SSH server.
	{ **ip** | **ipv6** } **ssh access-class** { *access-list-number* | *access-list-name* }	Configures an ACL for the SSH server.
	ip ssh peer *test* **public-key rsa flash** *:rsa.pub*	Associates an RSA public key file with a user.
	ip ssh peer *test* **public-key dsa flash***:dsa.pub*	Associates a DSA public key file with a user.
Configuring the SCP Service	Mandatory.	
	ip scp server enable	Enables the SCP server.

Configuration	Description and Command	
	ip scp server topdir { **flash:/***path* | **flash2:/***path* | **usb0:/***path* | **usb1:/***path* | **sd0:/***path* | **sata0:/***path* | **tmp:/***path* }	Configures the transmission path for files of the SCP server.
Configuring the SSH Client	(Optional) It is used to set up a secure connection with a remote network device that supports the SSH server.	
	ip ssh source-interface *interface-name*	Specifies the source interface of the SSH client.
	ssh [**-v** { **1** | **2** }] [**-c** { **3des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** }] [**-l** *username*] [**-m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha1-96** | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** }] [**-p** *port-num*] { *ip-addr* | *hostname* } [**/source** { **ip** *A.B.C.D* | **ipv6** *X:X:X:X::X* | **interface** *interface-name* }]	Establishes an encrypted session with a remote network device.

1.4.1 Configuring the SSH Server

Configuration Effect

- Enable the SSH server on a network device for setting up a secure connection with the SSH client. All interactive data is encrypted before being transmitted.
- You can use diversified SSH user authentications modes, including local line password authentication, AAA authentication, and public key authentication.
- You can generate or delete an SSH key.
- You can specify the SSH version.
- You can configure the SSH authentication timeout.
- You can configure the maximum re-authentication count.
- You can specify the SSH encryption mode.
- You can specify the SSH message authentication algorithm.
- You can specify an ACL for filtering traffic on the SSH server.

Notes

- Before configuring a device as the SSH server, ensure that communication is smooth on the network that the device resides, and the administrator can access the device management interface to perform the configuration.
- The **no crypto key generate** command does not exist. You need to run the **crypto key zeroize** command to delete a key.
- The SSH module does not support hot standby. Therefore, for the device that supports hot standby on the supervisor modules, if no SSH key file exist on the new active module after failover, you must run the **crypto key generate** command to configure the device to re-generate a key before using SSH.

Configuration Step

Enabling the SSH Server

- Mandatory.
- By default, the SSH server is disabled. In global configuration mode, enable the SSH server and configure the device to generate an SSH key so that the SSH server status changes to ENABLE.

Specifying the SSH Version

- Optional.
- By default, the SSH server supports SSHv1 and SSHv2, that is, it can connect to SSHv1 or SSHv2 clients.

Configuring the SSH Authentication Timeout

- Optional.
- By default, the SSH authentication timeout is 120s. You can configure the user authentication timeout as required. The value range is from 1 to 120, in seconds.

Configuring the Maximum Re-authentication Count

- Optional.
- Configure the maximum re-authentication count to prevent unauthorized behaviors such as malicious guessing. By default, the maximum re-authentication count is 3, that is, a user is allowed to enter the user name and password three times for authentication. You can configure the maximum re-authentication count as required. The value range is from 0 to 5.

Specifying the SSH Encryption Mode

- Optional.
- Specify the encryption mode supported by the SSH server. By default, the encryption mode supported by the SSH server is compatible. That is, the device supports CBC, CTR, and other encryption modes.

Specifying the SSH Message Authentication Algorithm

- Optional.
- Specify the message authentication algorithm supported by the SSH server. By default, the message authentication algorithms supported by the SSH server are as follows: (1) For SSHv1, no algorithm is supported. (2) For SSHv2, four algorithms, including MD5, SHA1, SHA1-96, and MD5-96, are supported.

Configuring an ACL for the SSH Server

- Optional.
- Configure an ACL for the SSH server. By default, an ACL is not used to filter traffic of all connections of the SSH server. You can configure an ACL to filter traffic of all connections of the SSH server.

Enabling Public Key Authentication for SSH Users

- Optional.

- Only SSHv2 supports authentication based on the public key. This configuration associates a public key file on the client with a user name. When a client is authenticated upon login, a public key file is specified based on the user name.

Verification

- Run the **show ip ssh** command to display the current SSH version, port number, encryption mode, message authentication algorithm, authentication timeout, and maximum re-authentication count of the SSH server.
- Run the **show crypto key mypubkey** command to display public information about the public key to verify whether the key has been generated.
- Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If so, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.

Related Commands

Enabling the SSH Server

Command	**enable service ssh-server**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To disable the SSH server, run the **no enable service ssh-server** command in global configuration mode. After this command is executed, the SSH server status changes to DISABLE.

Disconnecting an Established SSH Session

Command	**disconnect ssh** [**vty**] *session-id*
Parameter Description	**vty**: Indicates an established virtual teletype terminal (VTY) session. *session-id*: Indicates the ID of an established SSH session. The value range is from 0 to 35.
Command Mode	Privileged EXEC mode
Usage Guide	Specify an SSH session ID to disconnect the established SSH session. Alternatively, specify a VTY session ID to disconnect a specified SSH session. Only SSH sessions can be disconnected.

Generating an SSH Key

Command	**crypto key generate** { **rsa** | **dsa** }
Parameter Description	**rsa**: Generates an RSA key. **dsa**: Generates a DSA key.
Command Mode	Global configuration mode
Usage Guide	The **no crypto key generate** command does not exist. You need to run the **crypto key zeroize** command to delete a key. SSHv1 uses an RSA key, whereas SSHv2 uses an RSA or DSA key. If an RSA key is generated, both SSHv1 and SSHv2 are supported. If only a DSA key is generated, only SSHv2 can use the key.

Deleting a Key

Command	**crypto key zeroize** { **dsa** | **rsa** }
Parameter Description	**dsa**: Deletes a DSA key. **rsa**: Deletes an RSA key.
Command Mode	Global configuration mode
Usage Guide	This command is used to delete the public key of the SSH server. After the public key is deleted, the SSH server status is **DISABLE**. To disable the SSH server, use the **no** form of this command.

Specifying the SSH Version

Command	**ip ssh version** {**1** | **2** }
Parameter Description	**1**: Indicates that the SSH server only receives connection requests sent by SSHv1 clients. **2**: Indicates that the SSH server only receives connection requests sent by SSHv2 clients.
Command Mode	Global configuration mode
Usage Guide	Run the **no ip ssh version** command to restore the default settings. By default, the SSH server supports both SSHv1 and SSHv2.

Configuring the SSH Authentication Timeout

Command	**ip ssh time-out** *time*
Parameter Description	*time*: Indicates the SSH authentication timeout. The value range is from 1 to 120, in seconds.
Command Mode	Global configuration mode
Usage Guide	Run the **no ip ssh time-out** command to restore the default SSH authentication timeout, which is 120s.

Configuring the Maximum Re-authentication Count

Command	**ip ssh authentication-retries** *retry times*
Parameter Description	*retry times*: Indicates the maximum re-authentication count. The value range is from 0 to 5.
Command Mode	Global configuration mode
Usage Guide	Run the **no ip ssh authentication-retries** command to restore the default re-authentication count. The default value is 3.

Specifying the SSH Encryption Mode

Command	**ip ssh cipher-mode** { **cbc** | **ctr** | **others** | **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes192-cbc** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **blowfish-cbc** | **des-cbc** }
Parameter Description	**cbc**: Sets the encryption mode supported by the SSH server to CBC. Corresponding algorithms include DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, and Blowfish-CBC. **ctr**: Sets the encryption mode supported by the SSH server to CTR. Corresponding algorithms include AES128-CTR, AES192-CTR, and AES256-CTR.

	others: Sets the encryption mode supported by the SSH server to others. The corresponding algorithm is RC4.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the encryption mode supported by the SSH server. On Ruijie devices, the SSHv1 server supports DES-CBC, 3DES-CBC, and Blowfish-CBC encryption algorithms; the SSHv2 server supports AES128-CTR, AES192-CTR, AES256-CTR, DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blowfish-CBC, and RC4 encryption algorithms. These algorithms can be grouped into three encryption modes: CBC, CTR, and others. As the cryptography continuously develops, encryption algorithms in CBC and others modes are proved to be decrypted in a limited period of time. Therefore, organizations or companies that have high security requirements can set the encryption mode supported by the SSH server to CTR to enhance security of the SSH server. If the complete set of CBC, CTR, and GCM is configured and their subsets are also configured, for example, if **ip ssh cipher cbc 3des-cbc** is configured, the configuration result indicates the CBC mode.

Specifying the SSH Message Authentication Algorithm Supported by the SSH Server

Command	**ip ssh hmac-algorithm** { **md5** | **md5-96** | **sha1** | **sha1-96** }
Parameter Description	**md5**: Indicates the MD5 algorithm supported by the SSH server. **md5-96**: Indicates the MD5-96 algorithm supported by the SSH server. **sha1**: Indicates the SHA1 algorithm supported by the SSH server. **sha1-96**: Indicates the SHA1-96 algorithm supported by the SSH server.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the message authentication algorithm supported by the SSH server. On Ruijie devices, the SSHv1 server does not support any message authentication algorithm; the SSHv2 server supports the MD5, SHA1, SHA1-96, and MD5-96 message authentication algorithms. You can select message authentication algorithms supported by the SSH server as required.

Configuring the DH Key Exchange Algorithm Supported by the SSH Server

Command	**ip ssh key-exchange** { **dh_group_exchange_sha1** | **dh_group14_sha1** | **dh_group1_sha1** }
Parameter Description	**dh_group_exchange_sha1**: Indicates diffie-hellman-group-exchange-sha1 for key exchange. The key has 2048 bytes, which cannot be edited. **dh_group14_sha1**: Indicates diffie-hellman-group14-sha1 for key exchange. The key has 2048 bytes. **dh_group1_sha1**: Indicates diffie-hellman-group1-sha1 for key exchange. The key has 1024 bytes.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure a DH key exchange method on the SSH server. Ruijie's SSHv1 server does not support DH key exchange method, while the SSHv2 server supports diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, and diffie-hellman-group1-sha1 for key exchange.

Setting a Monitoring Port ID for the SSH Server

Command	**ip ssh port** *port*
Parameter Description	*port*: Indicates the monitoring port ID of the SSH server. The value range is from 1025 to 65535.
Command Mode	Global configuration mode
Usage Guide	Use the **no ip ssh port** or **ip ssh port 22** command to restore the default monitoring port ID of the SSH server.

Configuring an ACL for the SSH Server

Command	{ **ip**| **ipv6** } **ssh access-class** { *access-list-number* | *access-list-name* }
Parameter Description	*access-list-number*: Specifies the ACL ID. The value range of IP standard ACLs is 1–99 or 1300–1999; the value range of IP extended ACLs is 100–199 or 2000–2699. *access-list-name*: Specifies the ACL name. It is supported by IPv4 and IPv6.
Command Mode	Global configuration mode
Usage Guide	Run the **ssh access-class** command to configure an ACL to filter traffic of all connections of the SSH server. In line mode, an ACL is used to filter traffic on a specific line only. However, an ACL on the SSH server is used to filter traffic of all SSH connections.

Configuring RSA Public Key Authentication

Command	**ip ssh peer** *username* **public-key rsa** *filename*
Parameter Description	*username*: Indicates the user name. **rsa**: Indicates that the public key type is RSA. *filename*: Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the RSA public key file associated with a user. For SSHv1 and SSHv2, only SSHv2 supports authentication based on the public key. This command associates the public key file on a client with the user name. When the client is authenticated upon login, a public key file is specified based on the user name.

Configuring DSA Public Key Authentication

Command	**ip ssh peer** *username* **public-key dsa** *filename*
Parameter Description	*username*: Indicates the user name. **dsa**: Indicates that the public key type is DSA. *filename*: Indicates the name of a public key file.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the DSA key file associated with a user. For SSHv1 and SSHv2, only SSHv2 supports authentication based on the public key. This command associates the public key file on a client with the user name. When the client is authenticated upon

	login, a public key file is specified based on the user name.

Configuration Example

The following configuration examples describe only configurations related to SSH.

Generating a Public Key on the SSH Server

Configuration Steps	Run the **crypto key generate** { **rsa** | **dsa** } command to configure the SSH server to generate a RSA public key.

SSH Server	`Hostname#configure terminal`
	`Hostname(config)# crypto key generate rsa`
	`Choose the size of the rsa key modulus in the range of 512 to 2048 and the size of the dsa key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes.`
	
	`How many bits in the modulus [512]:`
	● If the RSA key is generated successfully, the following information is displayed:
	`% Generating 512 bit RSA1 keys ...[ok]`
	`% Generating 512 bit RSA keys ...[ok]`
	● If the RSA key fails to be generated, the following information is displayed:
	`% Generating 512 bit RSA1 keys ...[fail]`
	`% Generating 512 bit RSA keys ...[fail]`

Verification	Run the **show crypto key mypubkey rsa** command to display public information about the RSA key. If public information about the RSA key exists, the RSA key has been generated.

SSH Server	`Hostname(config)#show crypto key mypubkey rsa`
	`% Key pair was generated at: 1:49:47 UTC Jan 4 2013`
	`Key name: RSA1 private`
	`Usage: SSH Purpose Key`
	`Key is not exportable.`
	`Key Data:`
	`AAAAAwEA AQAAAHJM 6izXt1pp rUSOEGZ/ UhFpRRrW nngP4BU7 mG836apf jajSYwcU 8O3LojHL ayJ8G4pG 7j4T4ZSf FKg09kfr 92JpRNHQ gbwaPc5/ 9UnTtX9t qFIKDj1j 0dKBcCfN tr0r/CT+ cs5tlGKV S0ICGifz oB+pYaE=`
	
	`% Key pair was generated at: 1:49:47 UTC Jan 4 2013`
	`Key name: RSA private`
	`Usage: SSH Purpose Key`
	`Key is not exportable.`
	`Key Data:`
	`AAAAAwEAAQAAAHJfLwKnzOgO F3RlKhTN /7PmQYoE v0a2VXTX 8ZCa7Sll EghLDLJc w3T5JQXk Rr3iBD5s b1EeOL4b 21ykZt/u UetQ0Q80 sISgIfZ9 8o5No3Zz MPM0LnQR`

	G4c7/28+ GOHzYkTk 4IiQuTIL HRgtbyEYXCFaaxU=

Specifying the SSH Version

Configuration Steps	Run the **ip ssh version** { **1** | **2** } command to set the version supported by the SSH server to SSHv2.
SSH Server	Hostname#configure terminal Hostname(config)#ip ssh version 2
Verification	Run the **show ip ssh** command to display the SSH version supported by the SSH server.
SSH Server	Hostname(config)#show ip ssh SSH Enable - version 2.0 SSH Port: 22 SSH Cipher Mode: cbc,ctr,others SSH HMAC Algorithm: md5-96,md5,sha1-96,sha1,sha2-256,sha2-512 Authentication timeout: 120 secs Authentication retries: 3 SSH SCP Server: disabled

Configuring the SSH Authentication Timeout

Configuration Steps	Run the **ip ssh time-out** *time* command to set the SSH authentication timeout to 100s.
SSH Server	Hostname#configure terminal Hostname(config)#ip sshtime-out100
Verification	Run the **show ip ssh** command to display the configured SSH authentication timeout.
SSH Server	Hostname(config)#show ip ssh SSH Enable - version 2.0 SSH Port: 22 SSH Cipher Mode: cbc,ctr,others SSH HMAC Algorithm: md5-96,md5,sha1-96,sha1,sha2-256,sha2-512 Authentication timeout: 100 secs Authentication retries: 3 SSH SCP Server: disabled

Configuring the Maximum Re-authentication Count

Configuration Steps	Run the **ip ssh authentication-retries** *retry times* command to set the maximum re-authentication count on the SSH server to 2.
SSH Server	Hostname#configure terminal Hostname(config)#ip ssh authentication-retries 2
Verification	Run the **show ip ssh** command to display the configured maximum re-authentication count.

SSH Server	`Hostname(config)#show ip ssh`
	`SSH Enable - version 2.0`
	`SSH Port: 22`
	`SSH Cipher Mode: cbc,ctr,others`
	`SSH HMAC Algorithm: md5-96,md5,sha1-96,sha1,sha2-256,sha2-512`
	`Authentication timeout: 120 secs`
	`Authentication retries: 2`
	`SSH SCP Server: disabled`

Specifying the SSH Encryption Mode

Configuration Steps	Run the **ip ssh cipher-mode** { **cbc** | **ctr** | **others** | **3des-cbc** | **aes128-cbc** | **aes128-ctr** | **aes192-cbc** | **aes192-ctr** | **aes256-cbc** | **aes256-ctr** | **blowfish-cbc** | **des-cbc** } command to set the encryption mode supported by the SSH server to CTR.
SSH Server	`Hostname#configure terminal` `Hostname(config)# ip ssh cipher-mode ctr`
Verification	Select the CTR encryption mode on the SSH client, and check whether you can successfully log in to the SSH server from the SSH client.

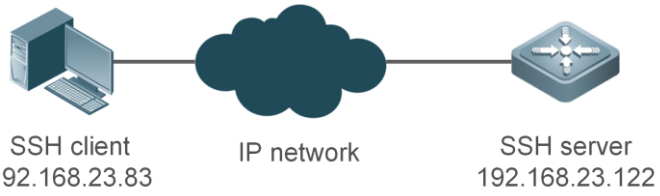
Specifying the SSH Message Authentication Algorithm

Configuration Steps	Run the **ip ssh hmac-algorithm** {**md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** } command to set the message authentication algorithm supported by the SSH server to SHA1.
SSH Server	`Hostname#configure terminal` `Hostname(config)# ip ssh hmac-algorithmsha1`
Verification	Select the SHA1 message authentication algorithm on the SSH client, and check whether you can successfully log in to the SSH server from the SSH client.

Configuring the DH Key Exchange Algorithm Supported by the SSH Server

Configuration Steps	Run the **ip ssh key-exchange** { **dh_group_exchange_sha1** | **dh_group14_sha1** | **dh_group1_sha1** } command to configure a key exchange method on the SSH server.
SSH Server	`Hostname# configure terminal` `Hostname(config)# ip ssh key-exchange dh_group14_sha1`
Verification	Choose diffie-hellman-group14-sha1 on the client terminal and check whether you can log in successfully.

Setting a Monitoring Port ID for the SSH Server

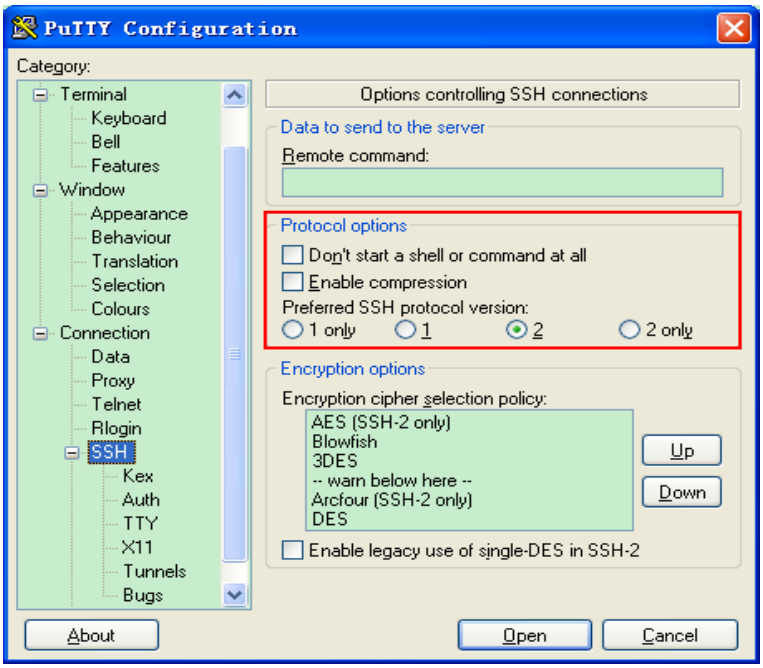


Command	**ip ssh port** *port*
Parameter Description	*port*: Indicates the monitoring port ID of the SSH server. The value range is from 1025 to 65535.
Command Mode	Global configuration mode
Usage Guide	Use the **no ip ssh port** or **ip ssh port 22** command to restore the default monitoring port ID of the

	SSH server.

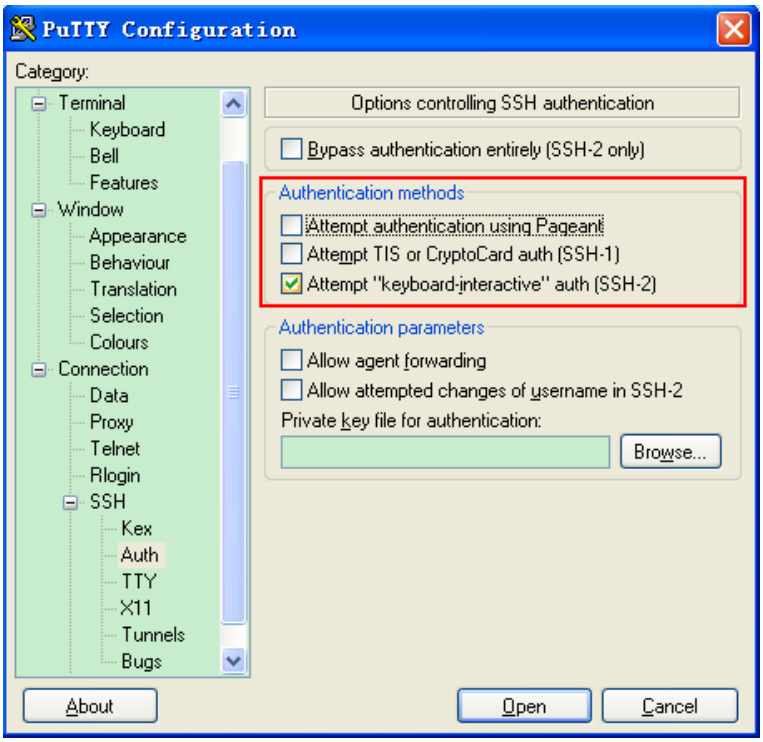
Configuring Public Key Authentication

Configuration Steps	Run the **ip ssh peer** *username* **public-key** { **rsa** | **dsa** | **ecc**} *filename* command to associate a public key file of the client with a user name. When the client is authenticated upon login, a public key file (for example, RSA) is specified based on the user name.
SSH Server	`Hostname#configure terminal` `Hostname(config)# ip ssh peer test public-key rsaflash:rsa.pub`
Verification	Configure the public key authentication login mode on the SSH client and specify the private key file. Check whether you can successfully log in to the SSH server from the SSH client. If so, the public key file on the client is successfully associated with the user name, and public key authentication succeeds.



Configuring SSH Device Management

Scenario Figure1-6	 You can use SSH to manage devices only when the SSH server is enabled. By default, this function is disabled. The Telnet component that comes with the Windows does not support SSH. Therefore, a third-party client software must be used. Well-compatible client software includes PuTTY, Linux, and SecureCRT. PuTTY is used as an example to introduce the configuration of the SSH client.
Configuration Steps	• Start the PuTTY software. • On the **Session** option tab of PuTTY, enter the host IP address 192.168.23.122 and SSH port number 22, and select the connection type SSH. • On the **SSH** option tab of PuTTY, select the preferred SSH protocol version 2. • On the **SSH authentication** option tab of PuTTY, select the authentication method **Attempt "keyboard-interactive" auth**. • Click **Open** to connect to the SSH server. • Enter the correct user name and password to access the terminal login interface.
SSH Client	Figure 1-7



Host Name (or IP address) indicates the IP address of the host to be logged in. In this example, the IP address is **192.168.23.122**. **Port** indicates the port ID 22, that is, default listening port ID. The value of **Connection type** is **SSH**.

Figure 1-8

As shown in Figure 1-8, select **2** as the preferred SSH protocol version in the **Protocol options** pane because SSHv2 is used for login.

Figure 1-9

As shown in Figure 1-8, select **Attempt "keyboard-interactive" auth** as the authentication method for authentication based on the user name and password.

Click **Open** to connect to the configured server host, as shown in Figure 1-10.

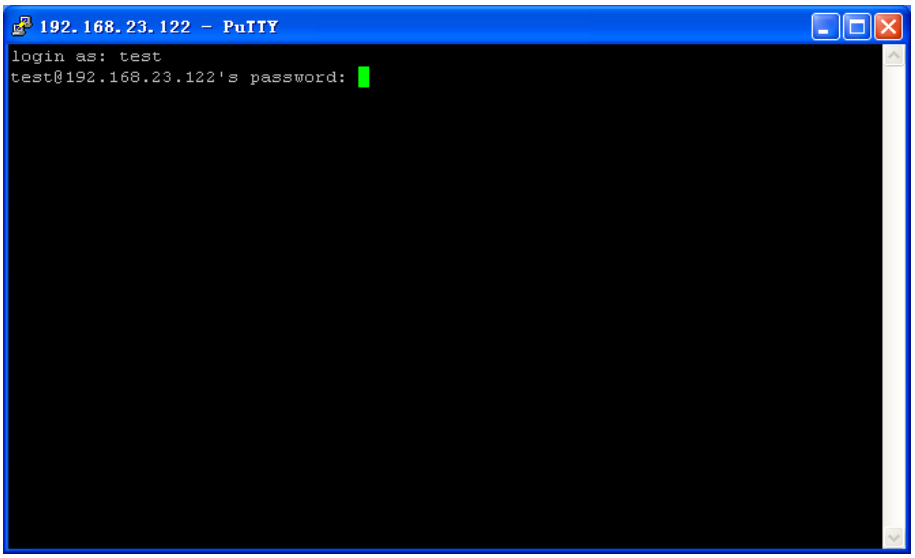


Figure 1-10

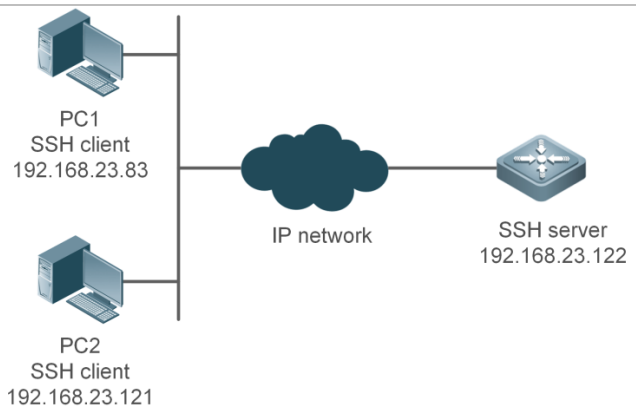
The **PuTTY Security Alert** box indicates that you are logging in to the client of the server at 192.168.23.122, and asks you whether to receive the key sent from the server.

If you select **Yes**, a login dialog box is displayed, as shown in Figure 1-11.

Figure 1-11

Enter the correct user name and password,. You can log in to the SSH terminal interface, as shown in Figure 1-12.

Figure 1-12

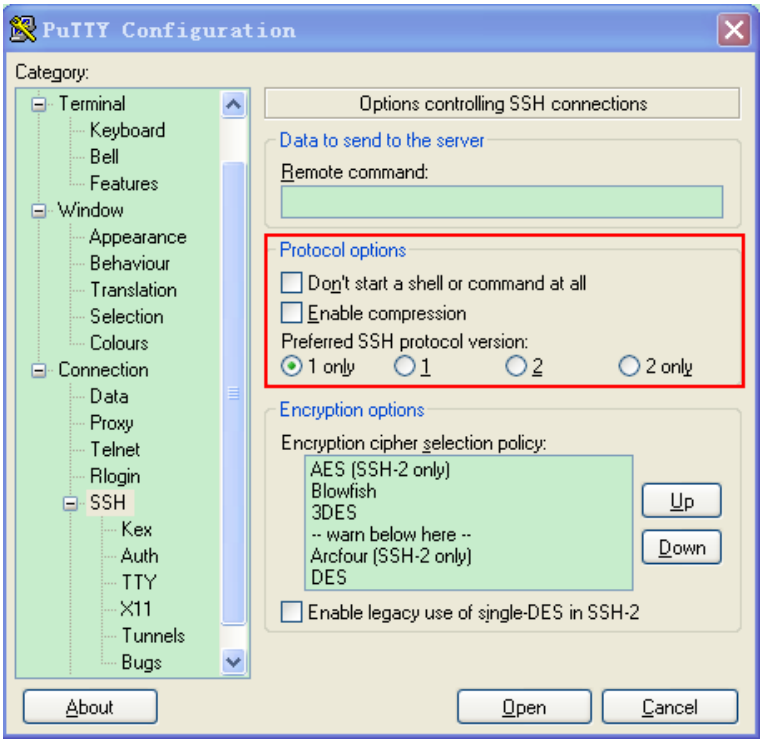


Verification	● Run the **show ip ssh** command to display the effective configuration on the SSH server. ● Run the **show ssh** command to display information about every SSH connection that has been established.

```
Hostname#show ip ssh
SSH Enable - version 1.99
SSH Port:               22
SSH Cipher Mode:        cbc,ctr,others
SSH HMAC Algorithm:     md5-96,md5,sha1-96,sha1,sha2-256,sha2-512
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:         disabled
Hostname#show ssh
```

	Connection Version Encryption Hmac State Username 0 2.0 aes256-cbc hmac-sha1 Session started test

Configuring SSH Local Line Authentication



Scenario **Figure 1-13**	 SSH users can use the local line password for user authentication, as shown in Figure 1-13. To ensure security of data exchange, PC 1 and PC 2 function as SSH clients, and use SSH to log in to the network device where the SSH server is enabled. The requirements are as follows: ● SSH users use the local line password authentication mode. ● Five lines, including Line 0 to Line 4, are activated concurrently. The login password is **passzero** for Line 0 and **pass** for the remaining lines. Any user name can be used.
Configuration Steps	Configure the SSH server as follows: ● Enable the SSH server globally. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2. ● Configure the key. With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted plain text with the password stored on the server, and returns a message indicating successful or failed authentication. SSHv1 uses the RSA key, whereas SSHv2 uses the RSA or DSA key. ● Configure the IP address of GigabitEthernet 0/1 on the SSH server. The SSH client is connected to the SSH server based on this IP address. The route from the SSH client to the SSH server is reachable. Configure the SSH client as follows: ● Diversified SSH client software is available, including PuTTY, Linux, and SecureCRT. PuTTY is used as an example to explain the method for configuring the SSH client. For details, see "Configuration Steps."

SSH Server	Before configuring the SSH-related function, ensure that the route from the SSH user to the network segment of the SSH server is reachable. The interface IP address is shown in Figure 1-14. The detailed procedure for configuring IP addresses and routes is omitted.
	`Hostname(config)# enable service ssh-server`
	`Hostname(config)#crypto key generate rsa`
	`% You already have RSA keys.`
	`% Do you really want to replace them? [yes/no]:`
	`Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take`

```
a few minutes.
How many bits in the modulus [512]:
% Generating 512 bit RSA1 keys ...[ok]
% Generating 512 bit RSA keys ...[ok]
Hostname(config)#interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)#ip address 192.168.23.122
255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)#exit
Hostname(config)#line vty 0
Hostname(config-line)#password passzero
Hostname(config-line)#privilege level 15
Hostname(config-line)#login
Hostname(config-line)#exit
Hostname(config)#line vty1 4
Hostname(config-line)#password pass
Hostname(config-line)#privilege level 15
Hostname(config-line)#login
Hostname(config-line)#exit
```

SSH Client (PC1/PC2)

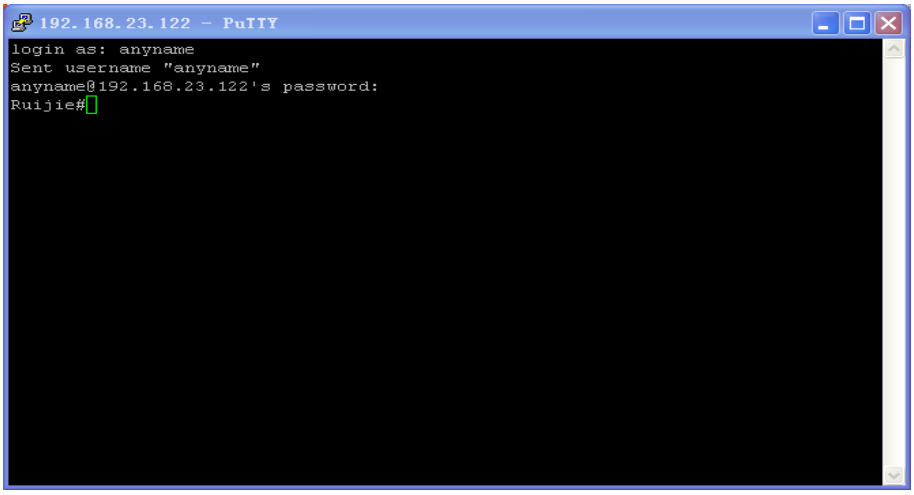


Figure 1-14

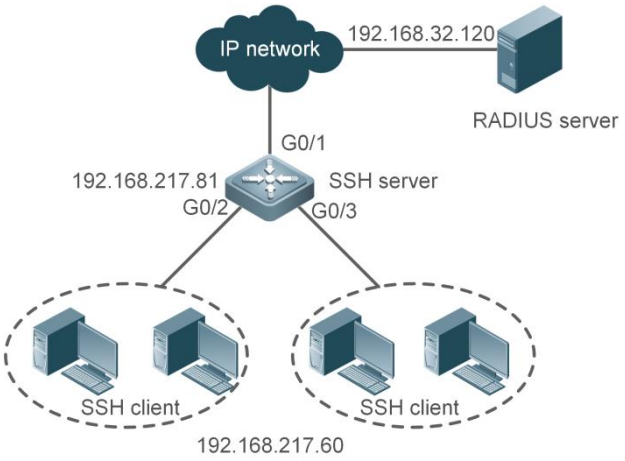
Set the IP address and port ID of the SSH server. As shown in the network topology, the IP address of the server is 192.168.23.122, and the port ID is 22. For details, see Configuring SSH Device Management. Click **Open** to start the SSH server. Because the current authentication mode does not require a user name, you can enter any user name, but cannot leave the user name unspecified. In this example, the user name is **anyname**.



Verification

- Run the **show running-config** command to display the current configuration.

	● Verify that the SSH client configuration is correct.
SSH Server	Hostname#show running-config Building configuration... ! enable secret 5 1eyy2$xs28FDw4s2q0tx97 enable service ssh-server ! interface GigabitEthernet 0/1 ip address 192.168.23.122 255.255.255.0 ! line vty 0 privilege level 15 login password passzero line vty 1 4 privilege level 15 login password pass ! end
SSH Client	Set up a connection and enter the correct password. The login password is **passzero** for Line 0 and **pass** for the remaining lines. Then the SSH server operation interface is displayed, as shown in Figure 1-15. Figure 1-15  Hostname#show users Line User Host(s) Idle Location ---------- ---------- ---------- ---------- ---------- * 0 con 0 --- idle 00:00:00 --- 1 vty 0 --- idle 00:08:02 192.168.23.83 2 vty 1 --- idle 00:00:58

	192.168.23.121

Configuring AAA Authentication of SSH Users

Scenario **Figure 1-16**	 SSH users can use the AAA authentication mode for user authentication, as shown in Figure 1-16. To ensure security of data exchange, the PC functions as the SSH client, and uses SSH to log in to the network device where the SSH server is enabled. To better perform security management, the AAA authentication mode is used on the user login interface of the SSH client. Two authentication methods, including RADIUS server authentication and local authentication, are provided in the AAA authentication method list to ensure reliability. The RADIUS server authentication method is preferred. If the RADIUS server does not respond, select the local authentication method.
Configuration Steps	● The route from the SSH client to the SSH server is reachable, and the route from the SSH server to the RADIUS server is also reachable. ● Configure the SSH server on the network device. The configuration method is already described in the previous example, and therefore omitted here. ● Perform AAA configuration on the network device. When the AAA authentication mode is used, method lists are created to define the identity authentication and types, and applied to a specified service or interface.
SSH Server	Hostname(config)# enable service ssh-server Hostname(config)#crypto key generate rsa % You already have RSA keys. % Do you really want to replace them? [yes/no]: Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes. How many bits in the modulus [512]: % Generating 512 bit RSA1 keys ...[ok] % Generating 512 bit RSA keys ...[ok] Hostname(config)#crypto key generate dsa Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes.

```
How many bits in the modulus [512]:
% Generating 512 bit DSA keys ...[ok]

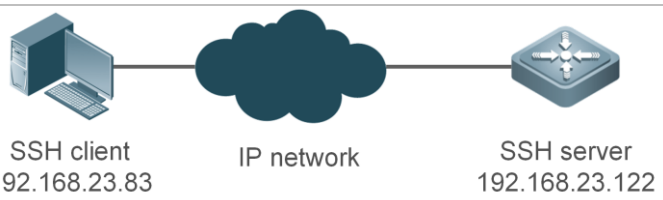
End
```

On the SSH client, choose **System Management** > **Device Management**, and add the device IP address **192.168.217.81** and the device key **aaaradius**.

Choose **Security Management** > **Device Management Rights**, and set the rights of the login user.

Choose **Security Management** > **Device Administrator**, and add the user name **user** and password **pass**.

Configure the SSH client and set up a connection with the SSH server. For details, see the previous example.



Enter the user name **user** and password **pass**. Verify that you can log in to the SSH server successfully.

```
Hostname#show users
    Line          User          Host(s)               Idle       Location

```

Configuring Public Key Authentication of SSH Users

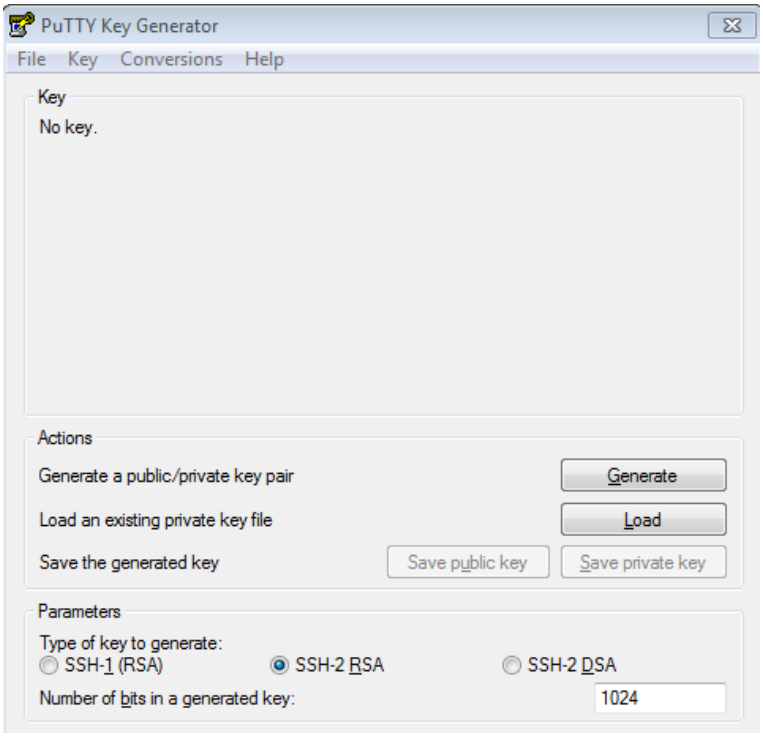
Scenario

Figure 1-17

SSH users can use the public key for user authentication, and the public key algorithm is RSA or DSA, as shown in Figure 1-17. SSH is configured on the client so that for setting up a secure connection with the SSH server.

Configuration Steps

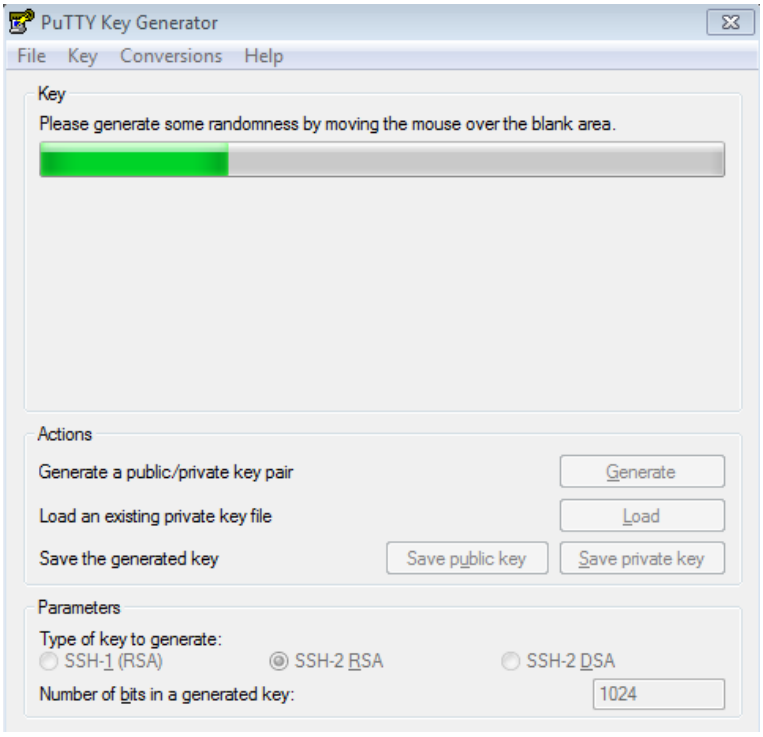
- To implement public key authentication on the client, configure the device to generate a key pair (for example, RSA key) on the client, place the public key on the SSH server, and select the public key authentication mode.



After the key pair is generated on the client, you must save and upload the public key file to the server and complete server-related settings before you can continue to configure the client and connect the client to the server.

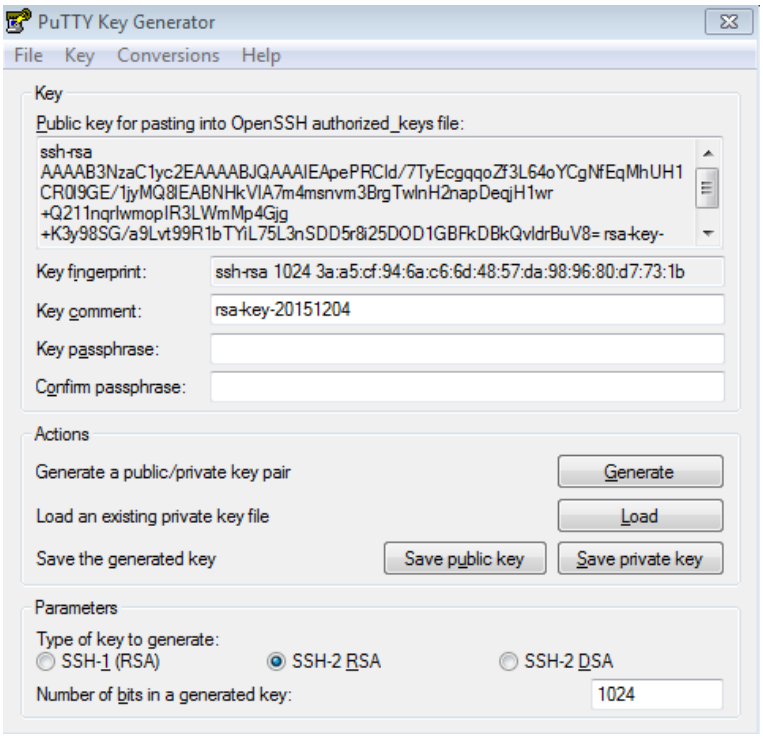
- After the key is generated on the client, copy the public key file from the client to the flash memory of the SSH server, and associate the file with an SSH user name. A user can be associated with one RSA public key and one DSA public key.

SSH Client



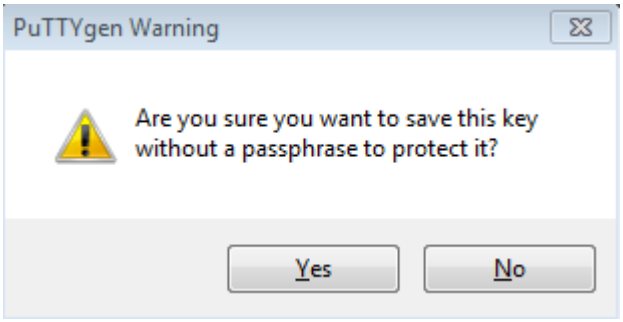
Run **puttygen.exe** on the client. Select **SSH-2 RSA** in the **Parameters** pane, and click **Generate** to generate a key, as shown in Figure 1-18.

Figure 1-18



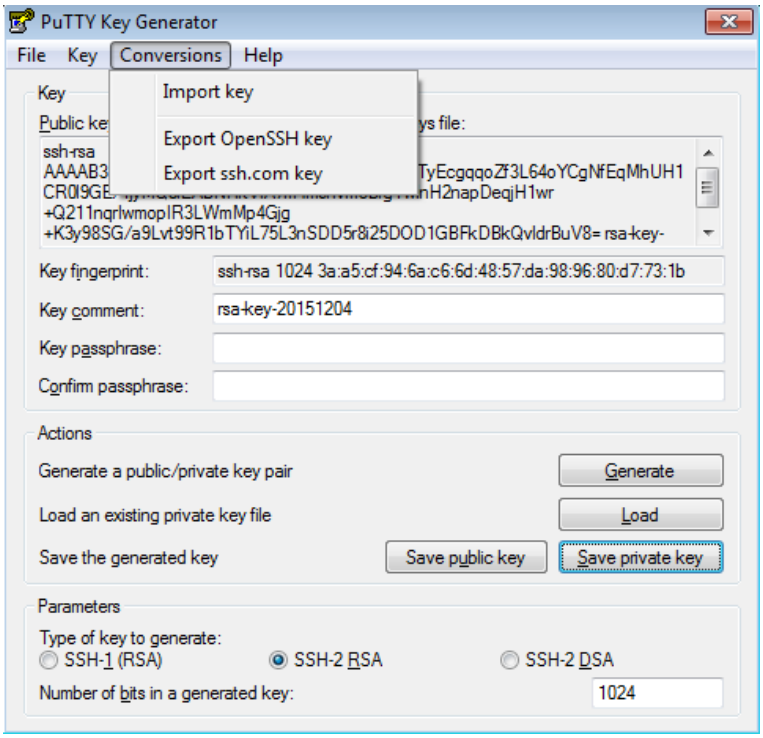
When a key is being generated, you need to constantly move the mouse over a blank area outside the green progress bar; otherwise, the progress bar does not move and key generation stops, as shown in Figure 1-19.

Figure 1-19



To ensure security of RSA public key authentication, the length of the generated RSA key pair must be equal to or larger than 768 bits. In this example, the length is set to 1024 bits.

Figure 1-20

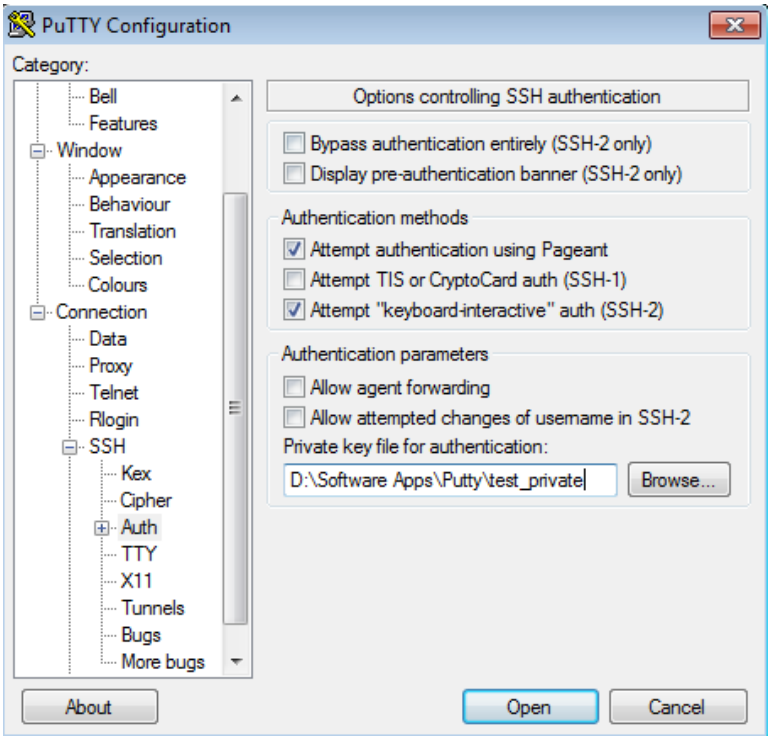


After the key pair is generated, click **Save public key**, enter the public key name **test_key.pub**, select the storage path, and click **Save**. Then click **Save private key**. The following dialog box is displayed. Select **Yes**, enter the public key name **test_private**, and click **Save**.

Figure 1-21

You must select the OpenSSH key file; otherwise, the key file cannot be used. **puttygen.exe** can be used to generate a key file in OpenSSH format, but the file cannot be directly used by the PuTTY client. You must use **puttygen.exe** to convert the private key to the PuTTY format. The public key file stored on the server uses the OpenSSH format and does not need to be converted, as shown in Figure 18-21.

Figure 1-22



SSH Server

```
Hostname#configure terminal
Hostname(config)# ip ssh peer test public-key rsaflash:test_key.pub
```

Verification

- After completing basic configurations of the client and server, specify the private key file **test_private** on the PuTTY client, and set the host IP address to **192.168.23.122** and port ID to **22** to set up a connection between the client and the server. In this way, the client can use the public key authentication mode to log in to the network device.

Figure 1-23

Common Errors

The **no crypto key generate** command is used to delete a key.

1.4.2 Configuring the SCP Service

Configuration Effect

After the SCP function is enabled on a network device, you can directly download files from the network device and upload local files to the network device. In addition, all interactive data is encrypted, ensuring security.

Notes

The SSH server must have been enabled.

Configuration Step

Enabling the SCP Server

- Mandatory.
- By default, the SCP server is disabled. Run the **ip scp server enable** command to enable the SCP server in global configuration mode.

Configuring the Transmission Path for Files of the SCP Server

- Optional.
- The default transmission path is **flash:/**. Run the **ip scp server topdir** { **flash:***/path* | **flash2:***/path* | **usb0:***/path* | **usb1:***/path* | **sd0:***/path* | **sata0:***/path* | **tmp:***/path* } command to configure the transmission path to upload files to or download files from the SCP server.

Verification

Run the **show ip ssh** command to check whether the SCP server is enabled.

Related Commands

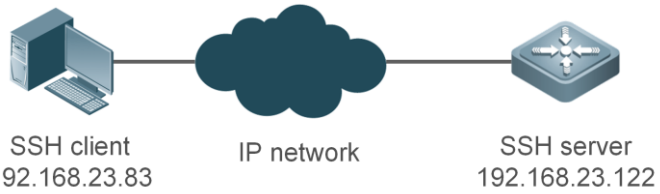
Enabling the SCP Server

Command	**ip scp server enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command is used to enable the SCP server. Run the **no ip scp server enable** command to disable the SCP server.

Configuring the Transmission Path for Files of the SCP Server

Command	**ip scp server topdir** { **flash:***/path* | **flash2:***/path* | **usb0:***/path* | **usb1:***/path* | **sd0:***/path* | **sata0:***/path* | **tmp:***/path* }
Parameter	N/A

Description	
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the transmission path to upload files to or download files from the SCP server. Run the **no ip scp server topdir** command to restore the default transmission path.



Configuration Example

Enabling the SCP Server

Configuration Steps	Run the **ip scp server enable** command to enable the SCP server.
	`Hostname#configure terminal` `Hostname(config)#ip scp server enable`
Verification	● Run the **show ip ssh** command to check whether the SCP server is enabled.

	`Hostname(config)#show ipssh`
	`Hostname(config)#show ip ssh`
	`SSH Enable - version 1.99`
	`SSH Port:  22`
	`SSH Cipher Mode:  cbc,ctr,others`
	`SSH HMAC Algorithm:  md5-96,md5,sha1-96,sha1,sha2-256,sha2-512`
	`Authentication timeout: 120 secs`
	`Authentication retries: 3`
	`SSH SCP Server: enabled`

Configuring SSH File Transfer

Scenario Figure 1-24	 The SCP service is enabled on the server, and SCP commands are used on the client to transfer data to the server.

Configuration Steps	● Enable the SCP service on the server.
	The SCP server uses SSH threading. When connecting to a network device for SCP transmission, the client occupies a VTY session. You can find that the user type is SSH by running the **show user** command.
	● On the client, use SCP commands to upload files to the server, or download files from the server.
	`Syntax of the SCP command:`
	`scp [-1246BCpqrv] [-c cipher] [-F ssh_config] [-iidentity_file]`
	`  [-l limit] [-o ssh_option] [-P port] [-S program]`

	[[user@]host1:]file1 [...] [[user@]host2:]file2 Descriptions of some options: -1: Uses SSHv1 (If not specified, SSHv2 is used by default); -2: Uses SSHv2 (by default); -C: Uses compressed transmission. -c: Specifies the encryption algorithm to be used. -r:Transmits the whole directory; -i: Specifies the key file to be used. -l: Limits the transmission speed (unit: Kbit/s). For other parameters, see the filescp.0. Most options are related to terminals. Few options are supported on both terminals and servers. SCP servers do not support d-p-q-r options. When these options are used, the system displays messages.
SSH Server	Hostname#configure terminal Hostname(config)# ip scp server enable
Verification	● File transmission example in the Ubuntu 7.10 system: Set the username of a client to **test** and copy the **config.text** file from the network device with the IP address of 192.168.195.188 to the ***/root*** directory on the local device.
	root@dhcpd:~#scp test@192.168.23.122:/config.text /root/config.text test@192.168.195.188's password: config.text 100% 1506 1.5KB/s 00:00 Read from remote host 192.168.195.188: Connection reset by peer

1.4.3 Configuring the SSH Client

Configuration Effect

On the network device that supports the SSH server, enable the SSH server, and specify the user authentication method and supported SSH versions. Then you can use the built-in SSH client of the device to set up a secure connection with the SSH server, implementing remote device management.

Notes

- The SSH server must have been configured on the remote device that supports the SSH server.
- The SSH client must communicate with the SSH server properly.

Configuration Step

↘ Specifying the Source Interface of the SSH Client

- Optional. This configuration must be performed on the SSH client.

↘ Establishing a Session with the SSH Server

- Optional. Use the **ssh** command on the client to set up a connection with a remote server.
- Before using this command, enable the SSH server and configure the SSH key and authentication mode on the server.

Restoring an Established SSH Session

- Optional. Run the related command to restore a disconnected session if necessary.

Disconnecting a Suspended SSH Session

- Optional. This configuration must be performed on the SSH client if you need to disconnect a specified SSH session.

Verification

Run the **show ssh-sessions** command to display information about established sessions of SSH clients.

Related Commands

Specifying the Source Interface of the SSH Client

Command	**ip ssh source-interface** *interface-name*
Parameter Description	*interface-name*: Specifies an interface, the IP address of which will be used as the source address of an SSH client session.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify an interface, the IP address of which will be used as the global source address of an SSH client session. When the **ssh** command is used to connect to an SSH server, the global configuration will be used if the source interface or source address is not specified for this connection. Run the **no ip ssh source-interface** command to restore the default setting.

Establishing a Session with the SSH Server

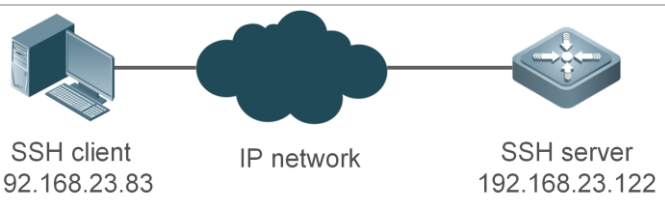
Command	**ssh** [**-v** { **1** | **2** }] [**-c** { **3des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** }] [**-l** *username*] [**-m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha1-96** | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** }] [**-p** *port-num*] { *ip-addr* | *hostname* } [**/source** { **ip** *A.B.C.D* | **ipv6** *X:X:X:X::X* | **interface** *interface-name* }]
Parameter Description	N/A
Command Mode	User EXEC mode
Usage Guide	The **ssh** command is used to set up a secure and encrypted connection from the local device (an SSH client) to another device (an SSH server) or any other server that supports SSHv1 or SSHv2. This connection provides a mechanism similar to the Telnet connection except that all data transmitted over this connection is encrypted. Based on authentication and encryption, the SSH client can set up a secure connection on an insecure network. ⚠ SSHv1 supports only DES (56-bit key) and 3DES (168-bit key) encryption algorithms. ⚠ SSHv2 supports the following Advanced Encryption Standards (AES) algorithms: ASE128-CBC, AES192-CBC, AES256-CBC, AES128-CTR, AES192-CTR, and AES256-CTR. ⚠ SSHv1 does not support the Hashed Message Authentication Code (HMAC). ⚠ If an SSH version is selected an a non-matched encryption or authentication algorithm is

	specified, the non-matched algorithm will be ignored when a connection is set up.

Recovering an Established SSH Client Session

Command	**ssh-session** *session-id*
Parameter Description	*session-id*: Indicates the ID of an established SSH client session.
Command Mode	User EXEC mode
Usage Guide	This command is used to restore the established SSH client session. When the **ssh** command is used to initiate an SSH client session, you can press **Ctrl+Shift+6+X** to temporarily exit the session. To restore this session, run the **ssh-session** command. In addition, if the session is already established, you can run the **show ssh-sessions** command to display information about the established session.

Disconnecting a Suspended SSH Session



Command	**disconnect ssh-session** *session-id*
Parameter Description	*session-id*: Indicates the ID of a suspended SSH client session.
Command Mode	User EXEC mode
Usage Guide	You can specify an SSH client session ID to disconnect the specified SSH client session.

Configuration Example

Specifying the Source Interface of the SSH Client

Configuration Steps	Run the **ip ssh source-interface** *interface-name* command to specify an interface, the IP address of which will be used as the global source address of an SSH client session.
	`Hostname#configure terminal` `Hostname(config)#ipsshsource-interface gigabitethernet 0/1`
Verification	N/A

Establishing a Session with the SSH Server

Scenario **Figure 1-25**	 The SSH server function is enabled on the server. The **ssh** command is used on the client to set up a secure connection with the server.
Configuration Steps	● Enable the SSH server on the server. ● Configure the SSH key on the server. ● Configure the authentication mode of the SSH server, and use the local line authentication

	mode for Line 0 to Line 4. ● Configure the IP address of Gi 0/1 of the SSH server. The client will use this address as the source address to connect to the SSH server. ● Configure the SSH client and specify the source address of the SSH client. By default, the SSH server supports two SSH versions: SSHv1 and SSHv2. With this key, the SSH server decrypts the encrypted password received from the SSH client, compares the decrypted cleartext with the password stored on the server, and returns a message indicating successful or failed authentication. SSHv1 uses an RSA key, whereas SSHv2 uses an RSA or DSA key. The authentication mode used by the SSH server is local line authentication. The local user name is **admin**, and the password is 123456. The SSH client is connected to the SSH server based on this IP address. The routes from the SSH clients to the SSH server are reachable. Configure the IP address of Gi 0/1 of the SSH server. The client will use this address as the source address to connect to the SSH server.

SSH Server	`Hostname#configure terminal`
	`Hostname(config)#enable service ssh-server`
	`Hostname(config)#crypto key generate rsa`
	`% You already have RSA keys.`
	`% Do you really want to replace them? [yes/no]:`
	`Choose the size of the key modulus in the range of 360 to 2048 for your Signature Keys. Choosing a key modulus greater than 512 may take a few minutes.`
	`How many bits in the modulus [512]:`
	`% Generating 512 bit RSA1 keys ...[ok]`
	`% Generating 512 bit RSA keys ...[ok]`
	`Hostname(config)#line vty 0 4`
	`Hostname(config-line)#login local`
	`Hostname(config-line)#exit`
	`Hostname(config)#username admin password 123456`
	`Hostname(config)#username admin privilege 15`
	`Hostname(config-line)#exit`
	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet0/1)#ip address 192.168.23.122 255.255.255.0`
	`Hostname(config-if-GigabitEthernet0/1)#exit`

SSH Client	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet0/1)#ip address 192.168.23.83 255.255.255.0`
	`Hostname(config-if-GigabitEthernet0/1)#exit`
	`Hostname(config)# ip ssh source-interface gigabitEthernet 0/1`

Verification	• Run the **show running-config| include username** and **show ip ssh** commands to check whether the SSH server configuration is correct. • On the SSH client, set up a connection with a remote SSH server. After the connection is set up, enter the correct password **123456**. The SSH server operation interface is displayed. Check the login user on the console of the SSH client.
	`Hostname(config)#sh running-config	include username` `username admin password admin` `username admin privilege 15` `Hostname(config)#sh running-config	begin line` `line con 0` `line vty 0 4` `login local` `!` `!` `end`
	• Check whether the SSH client configuration is correct.

	`Hostname#ssh -l admin 192.168.23.122`
	`%Trying 192.168.23.122, 22,...open`
	`admin@192.168.23.122's password:`
	`Hostname#`
	`Hostname#sh users`
	`Line User Host(s) Idle Location`
	`0 con 0 idle 00:00:00`
	`* 1 vty 0 admin idle 00:00:36 192.168.217.20`

1.5 Monitoring

Displaying

Description	Command
show ipssh	Displays the effective SSH server configuration.
show ssh	Displays the established SSH connection.
show crypto key mypubkey	Displays public information about the SSH public key.
show ssh-sessions	Displays the established SSH client session.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ssh	Debugs SSH sessions.
debug ssh client	Debugs SSH client sessions.

Configuring Reliability

1. Configuring VRRP
2. Configuring Supervisor Module Redundancy
3. Configuring WLAN Hot Standby
4. Configuring Virtual AC
5. Configuring RIPT
6. Configuring Track

1 Configuring VRRP

1.1 Overview

The Virtual Router Redundancy Protocol (VRRP) is a fault-tolerant routing protocol.

VRRP adopts the active/standby design to ensure that when the master fails, the backup routing device can seamlessly take over functions without affecting internal and external data communication, and without the need to modify internal network parameters. Multiple routing devices in a VRRP group are mapped to a single virtual router. VRRP ensures that only one routing device at a time represents the virtual router for packet transmission. Hosts send packets to this virtual router, and the router forwarding the packets is seleced as the master. If the master becomes unable to function due to any reason, one backup device is selected to replace the original master. VRRP makes it appear to hosts on a LAN that only one router device is being used, and even in the event of failure of the current first-hop router being used, connectivity can be maintained.

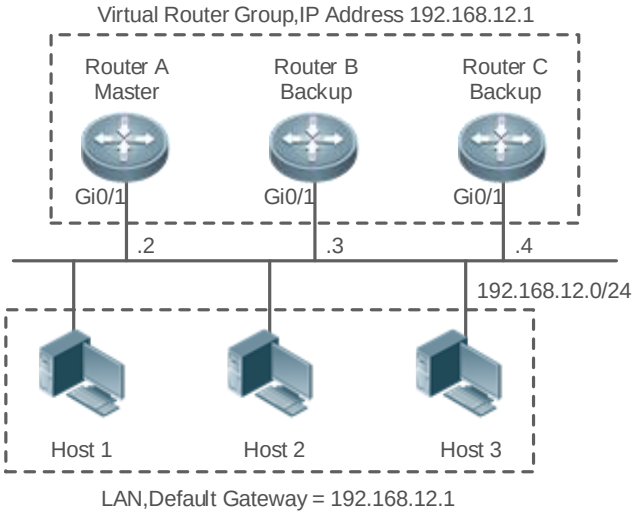
- VRRP is applicable to LANs where redundancy of routing egresses is required.

Protocols and Standards

- RFC 2338: Virtual Router Redundancy Protocol
- RFC 3768: Virtual Router Redundancy Protocol (VRRP)
- RFC 5798: Virtual Router Redundancy Protocol (VRRP) Version 3 for IPv4 and IPv6

1.2 Applications

Application	Description
Routing Redundancy	Configure routing devices on a LAN as one VRRP group to achieve routing redundancy.
Load Balancing	Configure routing devices on a LAN as multiple VRRP groups to achieve traffic load balancing.



1.2.1 Routing Redundancy

Scenario

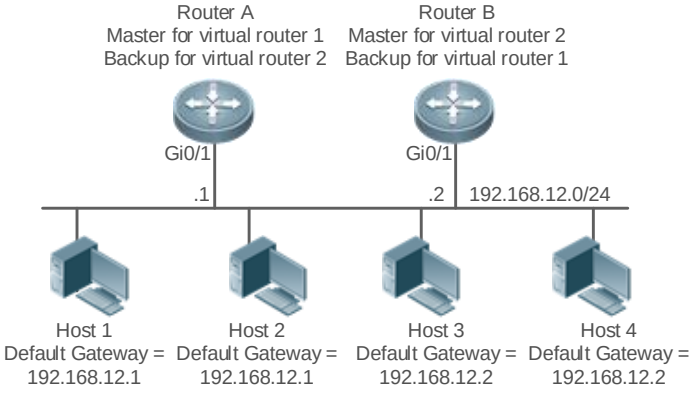
Configure a VRRP group on routers of a LAN, where hosts use the virtual IP address of the group as the default gateway address.

- Packets from Host 1, Host 2 and Host 3 to other networks are forwarded by the elected master (Router A in Figure 1-1).
- If Router A fails, the master will be re-elected between Router B and Router C to forward packets, achieving simple routing redundancy.

Figure 1-1

Deployment

- Router A, Router B and Router C are connected to the LAN through Ethernet interfaces.
- On Router A, Router B, and Router C, VRRP is configured on Ethernet interfaces connected to the LAN.
- These Ethernet interfaces are in the same VRRP group whose virtual IP address is 192.168.12.1.
- The gateway address for Host 1, Host 2, and Host 3 is the IP address of the VRRP group, namely, 192.168.12.1.



1.2.2 Load Balancing

Scenario

Configure multiple VRRP groups on routers of a LAN. Hosts on the LAN use virtual IP addresses of the groups as their gateways, and each router backs up for other routers in different groups.

- Packets from Host 1 and Host 2 to other networks with the default gateway address as the virtual IP address of virtual router 1 are forwarded by the master of virtual router 1 (Router A in Figure 1-2).
- Packets from Host 3 and Host 4 to other networks with the default gateway address as the virtual IP address of virtual router 2 are forwarded by the master of virtual router 2 (Router B in Figure 1-2).
- Routing redundancy is achieved on Router A and Router B, and LAN traffic is shared to achieve load balancing.

Figure 1-2

Deployment

- Router A and Router B are connected to the LAN through Ethernet interfaces.
- On Router A and Router B, two virtual routers are configured on the Ethernet interfaces connected to the LAN.
- Router A uses the IP address 192.168.12.1 of Ethernet interface Gi0/1 as the IP address of virtual router 1. For virtual router 1, Router A becomes the master and Router B becomes the backup.
- Router B uses the IP address 192.168.12.2 of Ethernet interface Gi0/1 as the IP address of virtual router 2. For virtual router 2, Router B becomes the master and Router A becomes the backup.
- On the LAN, Host 1 and Host 2 use the IP address 192.168.12.1 of virtual router 1 as the default gateway address, while Host 3 and Host 4 use the IP address 192.168.12.2 of virtual router 2 as the default gateway address.

1.3 Features

Basic Concepts

Virtual Router

A virtual router, also called a VRRP group, is regarded as a default gateway for hosts on a LAN, which involves the Virtual Router Identifier (VRID) and a set of virtual IP addresses.

Virtual IP Address

The virtual IP address is the IP address of a virtual router. A virtual router can be configured with one or more IP addresses.

IP Address Owner

If a VRRP group has the virtual IP address as that of an Ethernet interface on one router, the router is regarded as the virtual IP address owner. In such case, the router priority is 255. If the corresponding Ethernet interface is available, the VRRP group will be in master state automatically. The IP address owner receives and processes the packets with the destination IP address as that of the virtual router.

Virtual MAC Address

The virtual MAC address of a VRRP group is an IEEE 802 MAC address, in the format of 00-00-5E-00-01-{VRID} with the first five octets assigned and the last two as a group VRID. A VRRP group responds to an Address Resolution Protocol (ARP) request packet with its virtual MAC address but not the actual MAC address.

Master Router

In a VRRP group, only the master responds to ARP request packets and forwards IP packets. If the router is the IP address owner, it becomes the master router.

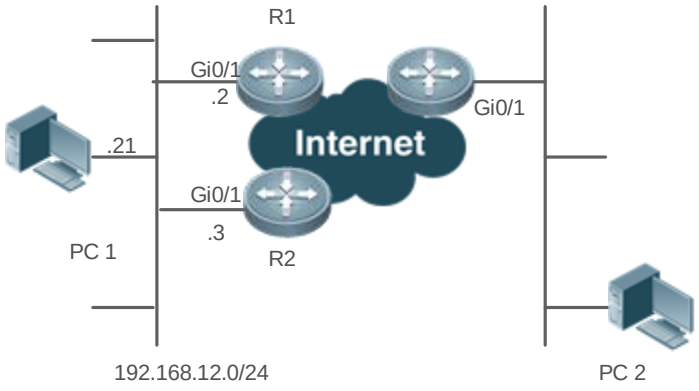
Backup Router

In a VRRP group, backup routers only monitor the state of the master but do not respond to ARP request packets or forward IP packets. When the master fails, backup routers will compete for the master role.

Preemption Mode

If a VRRP group runs in preemption mode, a backup router with a higher priority will replace the master with a lower priority.

Overview



Feature	Description
VRRP	VRRP achieves redundancy for default gateways of terminals on a multi-access media (for example, Ethernet). It enables a backup router to forward packets when the master router is Down, providing transparent switching and enhancing the network service quality.

1.3.1 VRRP

When the master router is faulty, VRRP achieves migration of functions from the master router to a backup without affecting internal and external data communication or changing the LAN configuration.

Working Principle

Figure 1-3 Working Principle of VRRP

Working Mode of VRRP

RFC 2338, RFC 3768, and RFC 5798 define the format and operating mechanism of VRRP packets. Multicast VRRP packets are sent periodically with specified destination addresses by the master router to advertise normal operation or for master election. VRRP allows a router on a LAN to automatically replace the master who forwards IP packets when the master fails. This helps achieve hot standby and fault tolerance of IP-based routing as well as ensure communication continuity and reliability for hosts on the LAN. A VRRP group achieves redundancy through multiple routers. However, only one router acts as the master to forward packets while the others are backup routers. Switching in a VRRP group is completely transparent to hosts on a LAN.

Master Election Process

RFC standards define the master election process as follows:

- VRRP provides a simple mechanism for master election. First, routers in a VRRP group compare the VRRP priorities configured on connected interfaces. The router with the highest priority is elected as the master. If the priorities are the same, they compare the primary IP addresses. The router with the largest IP address is elected as the master.
- After the master router is elected, the other routers become backup routers (and enter the backup state) and monitor the state of the master router through VRRP packets the master router sends. If the master router is

operational, it regularly sends VRRP multicast packets known as Advertisement packets to notify the backup routers of its status. If the backup routers do not receive such packets within a given period of time, all of them will enter the master state. In such case, master election is repeated. In this way, a router with the highest priority will be elected as a new master, achieving VRRP backup.

Once the master router of a VRRP group is elected, it is responsible for forwarding packets for hosts on a LAN.

Communication Process

Figure 1-3 Working Principle of VRRP shows the VRRP communication process. R1 and R2 are connected to the LAN segment 192.168.12.0/24 through the VRRP-enabled Ethernet interfaces Gi0/1. Hosts on the LAN use the virtual IP address of the VRRP group as the default gateway address. Only the virtual router is recognized by the hosts. The master router in the group, however, is unknown. For example, when PC 1 plan to communicate with PC 2, PC 1 sends packets to the default gateway with the virtual IP address. The master router in the group receives the packets and forwards them to PC 2. In this process, PC 1 only detects the virtual router but not R1 or R2. The master router in the group is elected between R1 and R2. When the master fails, it will be replaced automatically by the other router.

Related Configuration

Enabling VRRP

By default, VRRP is disabled on an interface.

In interface configuration mode, run the **vrrp** *group* **ip** *ipaddress* [**secondary**] or **vrrp** *group* **ipv6** *ipv6-address* command to set the VRID and virtual IP address to enable VRRP.

VRRP must be enabled on an interface.

Configuring the IPv4 VRRP Authentication String

By default, VRRP is in non-authentication mode.

Run the **vrrp group authentication** *string* command to set an authentication string in MD5 authentication mode or a cleartext password for an IPv4 VRRP group. In cleartext authentication mode, a password contains up to 8 bytes.

Members of a VRRP group can communicate with each other only when they use the same authentication mode. In cleartext authentication mode, all routers in a VRRP group should have the same authentication password. The cleartext authentication password cannot guarantee security but only prevents or prompts VRRP configuration errors.

Configuring the VRRP Advertisement Interval

By default, the advertisement interval of the master router is 1 second.

Run the **vrrp** [**ipv6**] *group* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* } command to change the interval.

When the VRRP learning timer is not configured, the same advertisement interval should be set for a VRRP group. Otherwise, routers in backup state will discard received VRRP packets.

Configuring the VRRP Preemption Mode

By default, a VRRP group operates in preemption mode.

To enable the preemption mode for a VRRP group, run the **vrrp** [**ipv6**] *group* **preempt** [**delay** *seconds*] command. The value of **delay** *seconds* is 0 by default.

If a VRRP group works in preemption mode, a router will become the mater of the group when it finds that its priority is higher than that of the master. If a VRRP group operates in non-preemption mode, a router will not become the master even when it finds that its priority is higher than that of the master. When the VRRP group uses the IP address of an Ethernet interface, the device that the Ethernet interface belongs to has the highest priority and automatically becomes the master in the group. The optional parameter **delay** *seconds* defines the delay before a backup VRRP router declares its master role.

Enabling the IPv6 VRRP Accept Mode

By default, the Accept mode is disabled for an IPv6 VRRP group.

To enable the Accept mode, run the **vrrp ipv6** *group* **accept_mode** command.

When the Accept mode is enabled, an IPv6 VRRP virtual router in master state receives and processes packets destined for the virtual router IP address; when the Accept mode is disabled, the virtual router discards such packets except Neighbor Advertisement (NA) packets and Neighbor Solicitation (NS) packets. Besides, an IPv6 VRRP master in owner state receives and processes packets destined for the virtual router IP address by default regardless of whether the Accept mode is configured.

Configuring the VRRP Router Priority

By default, router priorities in a VRRP group are all 100.

To adjust the priority, run the **vrrp** [**ipv6**] *group* **priority** *level* command.

If a router in preemption mode has the group's virtual IP address and the highest priority, it becomes the master, while the other routers with lower priorities in the group become backup (or monitoring) routers.

Configuring the VRRP Tracked Interface

By default, no interface is tracked by a VRRP group.

To configure such an interface, run the **vrrp** *group* **track** { *interface-type interface-number* | **bfd** *interface-type interface-number ipv4-addess* } [*priority*] or **vrrp ipv6** ***group*** **track** *interface-type interface-number* [*priority*] command.

After an interface to be monitored by a VRRP group is configured, the router priority will be adjusted dynamically based on the interface status. Once the interface becomes unavailable, the priority of the router in the group will be reduced by a set value, and another functional router with a higher priority in this group will become the master.

To trace the link layer protocol status of an interface, configure the **link** parameter. Otherwise, the network layer protocol status of the interface is traced.

Configuring the VRRP Tracked IP Address

By default, no IP address is tracked by a VRRP group.

To configure such an address, run the **vrrp** *group* **track** *ip-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] or **vrrp ipv6** *group* **track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type interface-number* } } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*] command.

After an IP address to be monitored by a VRRP group is configured, the router priority will be adjusted dynamically based on address accessibility. Once the address is inaccessible (the **ping** command fails), the priority of the router in the group will be reduced by a set value, and another router with a higher priority in this group will become the master.

Configuring the VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group.

To enable it, run the **vrrp** [**ipv6**] *group* **timers learn** command.

After the learning timer is configured, a VRRP backup router learns the advertisement interval of NA packets from the master. The backup router calculates the interval for determining a failure of the master based on the learning timer but not the local advertisement interval. This command ensures that advertisement intervals between backup routers and the master are synchronized.

Configuring the Description for a VRRP Group

By default, no description is configured for a VRRP group.

To configure such a string, run the **vrrp** [**ipv6**] *group* **description** *text* command.

The description helps distinguish a VRRP group. A description has up to 80 bytes. If the description has more than 80 bytes, the system displays the message about incorrect configuration.

Configuring the Delay for a VRRP Group

By default, no delay is configured for a VRRP group.

To configure the delay for a VRRP Group, run the **vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* } command. The delay range of two types is from 0 to 60, in seconds.

The command configures the delay of starting a VRRP group on an interface. There are two types of VRRP delay: delay after system startup and delay after an interface becomes active. You may configure them respectively or simultaneously. After the delay is configured for a VRRP group on an interface, the VRRP group does not start when the system starts up or the interface becomes active. Instead, the VRRP group starts after the delay, ensuring that the non-preemption configuration is effective. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP group will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface.

Configuring the IPv4 VRRP Version

By default, IPv4 adopts the VRRPv2 standard.

To specify the version for IPv4 VRRP, run the **vrrp** *group* **version** { **2** | **3** } command.

When the parameter value is set to 2, VRRPv2 is adopted; when the parameter value is set to 3, VRRPv3 is adopted.

Specifying a Sub-VLAN of a Super-VLAN to Receive the IPv4 VRRP Packets

By default, IPv4 VRRP packets are sent to the first Up interface of a sub-VLAN in a super-VLAN.

To specify the first Up interface of a sub-VLAN in a super-VLAN to receive IPv4 VRRP packets, run the **vrrp detection-vlan first-subvlan** command; to specify a sub-VLAN, run the **vrrp detection-vlan** *subvlan-id* command. If VRRP and VRRP Plus are enabled simultaneously on an interface of a super-VLAN, VRRP packets are sent to all Up interfaces of the sub-VLANs in the super-VLAN.

You can configure the IPv4 VRRP protocol packets to be sent only to the first Up interface of a sub-VLAN or a specified sub-VLAN in a super-VLAN. This reduces the number of VRRP protocol packets, and prevents device performance and network bandwidth from being affected. In this case, routers constituting an IPv4 VRRP group should be interconnected within the first Up interface of a sub-VLAN or a specified sub-VLAN of the super-VLAN.

1.4 Configuration

Configuration	Description and Command	
Configuring IPv4 VRRP	(Mandatory) It is used to enable IPv4 VRRP.	
	vrrp *group* **ip** *ipaddress* [**secondary**]	Enables IPv4 VRRP.
	(Optional) It is used to configure IPv4 VRRP parameters.	
	vrrp *group* **authentication** *string*	Configures the IPv4 VRRP authentication string.
	vrrp *group* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* } [**multiplier** *interval*]	Configures the IPv4 VRRP advertisement interval.
	vrrp *group* **preempt** [**delay** *seconds*]	Configures the IPv4 VRRP preemption mode.
	vrrp *group* **priority** *level*	Configures the IPv4 VRRP router priority.
	vrrp *group* **track** *interface-type interface-number* [*priority*]	Configures the IPv4 VRRP tracked interface.
	vrrp *group* **track** *ip-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*]	Configures the IPv4 VRRP tracked IP address.
	vrrp *group* **timers learn**	Configures the IPv4 VRRP learning timer.
	vrrp *group* **description** *text*	Configures the IPv4 VRRP group description.
	vrrp delay { **minimum** *min-seconds* | **reload** *reload-seconds* }	Configures the IPv4 VRRP delay.
	vrrp *group* **version** { **2** | **3** }	Configures the IPv4 VRRP version.
	vrrp detection-vlan { **first-subvlan** | *subvlan-id* }	Configures the IPv4 VRRP protocol packets to be sent only to the first Up interface of a sub-VLAN or a specified sub-VLAN in the super-VLAN.
Configuring IPv6 VRRP	(Mandatory) It is used to enable IPv6 VRRP.	
	vrrp *group* **ipv6** *ipv6-address*	Enables IPv6 VRRP in interface configuration mode.
	(Optional) It is used to configure IPv6 VRRP parameters.	
	vrrp ipv6 *group* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }	Configures the IPv6 advertisement interval.
	vrrp ipv6 *group* **preempt** [**delay** *seconds*]	Configures the IPv6 VRRP preemption mode.
	vrrp ipv6 *group* **accept_mode**	Enables the Accept mode for an IPv6 VRRP group.

Configuration	Description and Command	
	vrrp ipv6 *group* **priority** *level*	Configures the IPv6 VRRP router priority.
	vrrp ipv6 *group* **track** *interface-type interface-number* [**link**] [*interface–priority*]	Configures the IPv6 VRRP tracked interface.
	vrrp ipv6 *group* **track** { *ipv6-global-address* | { *ipv6-linklocal-address interface-type interface-number* } } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*]	Configures the IPv6 VRRP tracked IP address.
	vrrp ipv6 *group* **timers learn**	Configures the IPv6 VRRP learning timer.
	vrrp ipv6 *group* **description** *text*	Configures the IPv6 VRRP group description.
	vrrp delay { **minimum** *min-seconds* | **reload** *reload-seconds* }	Configures the IPv6 VRRP delay.
Configuring VRRP and MSTP	The configuration is the same as IPv4 VRRP configuration.	

1.4.1 Configuring IPv4 VRRP

Configuration Effect

- Configure a VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IP address.
- Configure multiple VRRP groups on an interface to achieve load balancing and offer more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor failures, change interface priorities, and realize failover dynamically.

Notes

- To achieve VRRP, routers in a VRRP group should be configured with the same virtual IPv4 address.
- To achieve backup between multiple IPv4 VRRP groups, configure multiple IPv4 VRRP groups with the same VRRP configuration on different interfaces and configure different priorities for the groups so that they back up each other.
- Enable VRRP on Layer 3 interfaces.

Configuration Steps

Enabling IPv4 VRRP

By default, IPv4 VRRP is disabled on an interface. You can enable it as needed.

Configuring the IPv4 VRRP Authentication String

By default, VRRP is in non-authentication mode. You can enable cleartext authentication as needed.

Configuring the IPv4 VRRP Advertisement Interval

By default, the master router sends advertisement packets every 1s. You can modify the interval as needed.

Configuring the IPv4 VRRP Preemption Mode

By default, a VRRP group operates in preemption mode without a delay.

Configuring the IPv4 VRRP Router Priority

The default router priority for a VRRP group is 100. You can modify the priority as needed.

Configuring the IPv4 VRRP Tracked Interface

By default, an IPv4 VRRP group does not monitor any interface and the value of priority change is 10. To detect faults through interface monitoring, perform this configuration.

Configuring the IPv4 VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group. Enable this function if backup routers need to learn the master's advertisement interval.

Configuring the Description for an IPv4 VRRP Group

By default, no description is configured for a VRRP group. To help distinguish VRRP groups, configure descriptions.

Configuring the IPv4 VRRP Delay

By default, the IPv4 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

Configuring the IPv4 VRRP Version

By default, IPv4 adopts the VRRPv2 standard. To change it, use the corresponding command.

Setting the Sending Mode of IPv4 VRRP Packets in a Super-VLAN

By default, IPv4 VRRP packets are only sent to the first Up interface of a sub-VLAN in a super-VLAN. However, it is possible to configure them to be sent to a specific sub-VLAN in the super-VLAN.

Verification

Run the **show vrrp** command to verify the configuration.

Related Commands

Enabling IPv4 VRRP

Command	**vrrp** *group* **ip** *ipaddress* [**secondary**]
Parameter Description	*group*: Indicates the VRID of a VRRP group. The value range depends on product models. *ipaddress*: Indicates the IP address of a VRRP group. **secondary**: Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

Configuring the IPv4 VRRP Authentication String

Command	**vrrp** *group* **authentication** *string*
Parameter Description	*group*: Indicates the VRID of a VRRP group. *string*: Indicates the authentication string of a VRRP group (a cleartext password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The cleartext authentication password cannot guarantee security but only prevents or prompts VRRP configuration errors. This command is only applicable to VRRPv2 but not VRRPv3. Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP) packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

Configuring the IPv4 VRRP Advertisement Interval

Command	**vrrp** *group* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }
Parameter Description	*group*: Indicates the VRID of a VRRP group. *advertise-interval*: Indicates the advertisement interval of a VRRP group, in seconds. ***csec*** *centisecond-interval:* Indicates the interval for the master router in a VRRP group to send VRRP packets. It is an integer from 50 to 99, in centiseconds. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is 1s.
Command Mode	Interface configuration mode
Usage Guide	If a router is elected as the master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority, and other information. As defined by RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40s. Therefore, if the interval is larger than 40s, the maximum interval of 40s will be applied, though the configuration is effective.

Configuring the IPv4 VRRP Preemption Mode

Command	**vrrp** *group* **preempt** [**delay** *seconds*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. **delay** *seconds*: Indicates the preemption delay for the master router to declare its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	If a VRRP group runs in preemption mode, a router with a higher priority will replace the master with a lower priority. If a VRRP group runs in non-preemption mode, a router with the priority higher than that of the master remains backup. When the VRRP group uses the IP address of an Ethernet interface, the device to which the Ethernet interface belongs has the highest priority and automatically becomes the master in the group.

Configuring the IPv4 VRRP Router Priority

Command	**vrrp** *group* **priority** *level*

Parameter Description	*group*: Indicates the VRID of a VRRP group. *level*: Indicates the priority of an interface in a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the VRRP router priority.

Configuring the IPv4 VRRP Tracked Interface

Command	**vrrp** *group* **track** *interface-type interface-number* [*priority*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. *interface-type interface-number*: Indicates the interface to be tracked. *priority*: Indicates the step of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	A tracked interface must be a routable Layer 3 logical interface, for example, a routed interface, an SVI, a loopback interface, or a tunnel interface. The priority of the router that has the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

Configuring the IPv4 VRRP Tracked IP Address

Command	**vrrp** *group* **track** *ipv4-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. *ipv4-addres*: Indicates the IPv4 address to be tracked. ***interval*** *interval-value*: Indicates the probe interval, in seconds. The default value is 3s. ***timeout*** *timeout-value*: Indicates the probe timeout interval of waiting for response, in seconds. If no response is received within the timeout interval, the device considers that the destination is inaccessible. The default value is 1s. **retry** *retry-value*: Indicates the probe retry count. If no response is received after the probe retry count, the device considers that the destination is inaccessible. The default value is 3. *priority*: Indicates the step of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	To monitor a host, specify its IPv4 address for an IPv4 VRRP group. If a VRRP group owns the IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

Configuring the IPv4 VRRP Learning Timer

Command	**vrrp** *group* **timers learn**
Parameter Description	*group*: Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode

Usage Guide	After the learning timer is configured, a VRRP backup router learns the advertisement interval of NA packets from the master. The backup router calculates the interval for determining a failure of the master based on the learning timer but not the local advertisement interval. This command ensures that advertisement intervals between backup routers and the master are synchronized.

Configuring the Description for an IPv4 VRRP Group

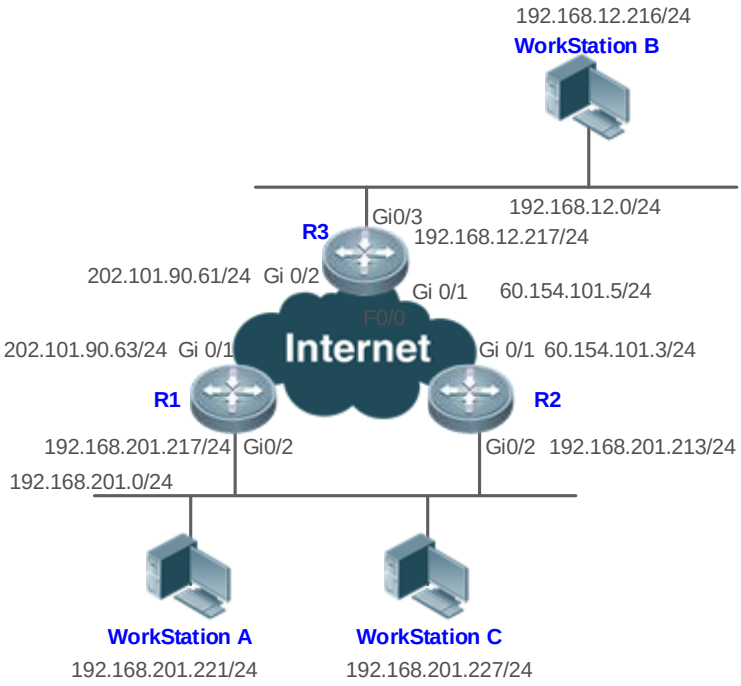
Command	**vrrp** *group* **description** *text*
Parameter Description	*group*: Indicates the VRID of a VRRP group. *text*: Indicates the description of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	The description helps distinguish a VRRP group. A description has up to 80 bytes. If the description has more than 80 bytes, the system displays the message about incorrect configuration.

Configuring the IPv4 VRRP Delay

Command	**vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* }
Parameter Description	**minimum** *min-seconds*: Indicates the VRRP delay after an interface state changes. **reload** *reload-seconds*: Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group does not start when the system starts up or the interface becomes active. Instead, the VRRP group starts after the delay, ensuring that the non-preemption configuration is effective. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP group will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface. The value range of the delay of two types is from 0 to 60, in seconds.

Configuring the IPv4 VRRP Version

Command	**vrrp** *group* **version** { **2** | **3** }
Parameter Description	**2**: Indicates VRRPv2. **3**: Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is defined in RFC 3768 and VRRPv3 in RFC 5798. This command is only applicable to IPv4 VRRP.



Specifying a Sub-VLAN of a Super-VLAN to Receive IPv4 VRRP Packets

Command	**vrrp detection-vlan** { **first-subvlan** | *subvlan-id* }
Parameter Description	**first-subvlan**: Sends IPv4 VRRP packets only to the first Up interface of a sub-VLAN in a super-VLAN. *subvlan-id*: Sends packets to a specified sub-VLAN.
Command Mode	Interface configuration mode

Usage Guide	This command is used to specify a sub-VLAN of a super-VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a super-VLAN using the following three methods. Packets are sent to the first Up interface of a sub-VLAN in a super-VLAN, or to a specified sub-VLAN interface in a super-VLAN, or to all the sub-VLAN interfaces in a super-VLAN. If VRRP and VRRP Plus are enabled simultaneously on a super-VLAN interface, VRRP packets are sent to all Up interfaces of sub-VLANs in the super-VLAN. This command is configured on a VLAN interface and effective only to super-VLAN interfaces.

Configuration Example

↘ Configuring an IPv4 VRRP Group and Tracked Interface

Scenario **Figure 1-4**	
Configuration Steps	● Configure a VRRP group between R1 and R2. The cluster of WorkStation A and WorkStation C (192.168.201.0/24) uses the virtual IP address 192.168.201.1 of the VRRP group as the gateway address to communicate with WorkStation B (192.168.12.0 /24). ● Configure GigabitEthernet 0/1 on R1 as the tracked interface. ● Configure routing functions on R3.

R3	`R3#configure terminal`
	`R3(config)#interface GigabitEthernet 0/3`
	`R3(config-if-GigabitEthernet 0/3)#no switchport`
	`R3(config-if-GigabitEthernet 0/3)#ip address 192.168.12.217 255.255.255.0`
	`R3(config-if-GigabitEthernet 0/3)#exit`
	`R3(config)#interface GigabitEthernet 0/1`
	`R3(config-if-GigabitEthernet 0/1)#no switchport`
	`R3(config-if-GigabitEthernet 0/1)#ip address 60.154.101.5 255.255.255.0`
	`R3(config-if-GigabitEthernet 0/1)#exit`
	`R3(config)#interface GigabitEthernet 0/2`
	`R3(config-if-GigabitEthernet 0/2)#no switchport`

	R3(config-if-GigabitEthernet 0/2)#ip address 202.101.90.61 255.255.255.0 R3(config-if-GigabitEthernet 0/2)#exit R3(config)#router ospf R3(config-router)#network 202.101.90.0 0.0.0.255 area 10 R3(config-router)#network 192.168.12.0 0.0.0.255 area 10 R3(config-router)#network 60.154.101.0 0.0.0.255 area 10
R1	R1#configure terminal R1(config)#interface GigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)#ip address 192.168.201.217 255.255.255.0 R1(config-if-GigabitEthernet 0/2)#vrrp 1 priority 120 R1(config-if-GigabitEthernet 0/2)#vrrp 1 timers advertise 3 R1(config-if-GigabitEthernet 0/2)#vrrp 1 ip 192.168.201.1 R1(config-if-GigabitEthernet 0/2)#vrrp 1 track GigabitEthernet 0/1 30 R1(config-if-GigabitEthernet 0/2)#exit R1(config)#interface GigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)#ip address 202.101.90.63 255.255.255.0 R1(config-if-GigabitEthernet 0/1)#exit R1(config)#router ospf R1(config-router)#network 202.101.90.0 0.0.0.255 area 10 R1(config-router)#network 192.168.201.0 0.0.0.255 area 10
R2	R2#configure terminal R2(config)#interface GigabitEthernet 0/2 R2(config-if-GigabitEthernet 0/2)#ip address 192.168.201.213 255.255.255.0 R2(config-if-GigabitEthernet 0/2)#vrrp 1 ip 192.168.201.1 R2(config-if-GigabitEthernet 0/2)#vrrp 1 timers advertise 3 R2(config-if-GigabitEthernet 0/2)#exit R2(config)#interface GigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)#no switchport R2(config-if-GigabitEthernet 0/1)#ip address 60.154.101.3 255.255.255.0 R2(config-if-GigabitEthernet 0/1)#exit R2(config)#router ospf R2(config-router)#network 60.154.101.0 0.0.0.255 area 10 R2(config-router)#network 192.168.201.0 0.0.0.255 area 10
Verification	Run the **show vrrp** command to verify the configuration. ● Check whether R1 used as the master reduces its VRRP priority from 30 to 90 when GigabitEthernet0/1 connected to the Wide Area Network (WAN) is unavailable. If so, R2 becomes the master. ● Check whether R1 changes its VRRP priority from 30 to 120 when GigabitEthernet 0/1 connected to the WAN recovers. If so, R1 is re-elected as the master.
R1	R1#show vrrp GigabitEthernet 0/2 - Group 1 State is Master Virtual IP address is 192.168.201.1 configured

	Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 120 Master Router is 192.168.201.217 (local), priority is 120 Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 0/1 priority decrement=30
R2	R2#show vrrp GigabitEthernet 0/2 - Group 1 State is Backup Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 100 Master Router is 192.168.201.217 , priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec

Common Errors

- Different virtual IP addresses are configured on routers in a VRRP group, resulting in multiple master routers in the group.
- Different VRRP advertisement intervals are configured on routers in a VRRP group and the learning timer is not configured, resulting in multiple master routers in the group.
- Different VRRP versions are configured on routers in a VRRP group, resulting in multiple master routers in the group.
- For VRRPv2, Ethernet interfaces of the routers in a VRRP group are all in cleartext authentication mode but use inconsistent authentication strings, resulting in multiple master routers in the group.

Configuration Example

Configuring Multiple IPv4 VRRP Groups

Scenario **Figure 1-5**	
Configuration Steps	● The user workstation cluster (192.168.201.0/24) uses the VRRP group constituted by R1 and R2. The gateway for partial workstations (WorkStation A for example) points to the virtual IP address 192.168.201.1 of VRRP group 1, while that for other partial workstations (WorkStation C for example) points to the virtual IP address 192.168.201.2 of VRRP group 2. IPv4 multicast routing is enabled on all devices. ● R1 acts as the master router in VRRP group 2 and as a backup router in VRRP group 1. ● R2 acts as a backup router in VRRP group 2 and as the master router in VRRP group 1.

R3	`R3#configure terminal`
	`R3(config)#interface GigabitEthernet 0/3`
	`R3(config-if-GigabitEthernet 0/3)#no switchport`
	`R3(config-if-GigabitEthernet 0/3)#ip address 192.168.12.217 255.255.255.0`
	`R3(config-if-GigabitEthernet 0/3)#exit`
	`R3(config)#interface GigabitEthernet 0/1`
	`R3(config-if-GigabitEthernet 0/1)#no switchport`
	`R3(config-if-GigabitEthernet 0/1)#ip address 60.154.101.5 255.255.255.0`
	`R3(config-if-GigabitEthernet 0/1)#exit`
	`R3(config)#interface GigabitEthernet 0/2`
	`R3(config-if-GigabitEthernet 0/2)#no switchport`
	`R3(config-if-GigabitEthernet 0/2)#ip address 202.101.90.61 255.255.255.0`
	`R3(config-if-GigabitEthernet 0/2)#exit`
	`R3(config)#router ospf`
	`R3(config-router)#network 202.101.90.0 0.0.0.255 area 10`
	`R3(config-router)#network 192.168.12.0 0.0.0.255 area 10`
	`R3(config-router)#network 60.154.101.0 0.0.0.255 area 10`

R1	`R1#configure terminal`
	`R1(config)#interface GigabitEthernet 0/2`
	`R1(config-if-GigabitEthernet 0/2)#ip address 192.168.201.217 255.255.255.0`
	`R1(config-if-GigabitEthernet 0/2)#vrrp 1 timers advertise 3`

	R1(config-if-GigabitEthernet 0/2)#vrrp 1 ip 192.168.201.1 R1(config-if-GigabitEthernet 0/2)#vrrp 2 priority 120 R1(config-if-GigabitEthernet 0/2)#vrrp 2 timers advertise 3 R1(config-if-GigabitEthernet 0/2)#vrrp 2 ip 192.168.201.2 R1(config-if-GigabitEthernet 0/2)#vrrp 2 track GigabitEthernet 0/1 30 R1(config-if-GigabitEthernet 0/2)#exit R1(config)#interface GigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)#ip address 202.101.90.63 255.255.255.0 R1(config-if-GigabitEthernet 0/1)#exit R1(config)#router ospf R1(config-router)#network 202.101.90.0 0.0.0.255 area 10 R1(config-router)#network 192.168.201.0 0.0.0.255 area 10
R2	R2#configure terminal R2(config)#interface GigabitEthernet 0/2 R2(config-if-GigabitEthernet 0/2)#ip address 192.168.201.213 255.255.255.0 R2(config-if-GigabitEthernet 0/2)#vrrp 1 ip 192.168.201.1 R2(config-if-GigabitEthernet 0/2)#vrrp 1 timers advertise 3 R2(config-if-GigabitEthernet 0/2)#vrrp 1 priority 120 R2(config-if-GigabitEthernet 0/2)#vrrp 2 ip 192.168.201.2 R2(config-if-GigabitEthernet 0/2)#vrrp 2 timers advertise 3 R2(config-if-GigabitEthernet 0/2)#exit R2(config)#interface GigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)#ip address 60.154.101.3 255.255.255.0 R2(config-if-GigabitEthernet 0/1)#exit R2(config)#router ospf R2(config-router)#network 60.154.101.0 0.0.0.255 area 10 R2(config-router)#network 192.168.201.0 0.0.0.255 area 10
Verification	Run the **show vrrp** command to verify the configuration. ● Check whether R1 used as the master router in the group 2 reduces its VRRP group priority from 30 to 90 when it finds that GigabitEthernet 0/1 connected to a WAN is unavailable. If so, R2 in VRRP group 2 becomes the master router. ● Check whether R1 increases its VRRP group priority from 30 to 120 when it finds that GigabitEthernet 0/1 connected to a WAN becomes available again. If so, R1 becomes the master router again in VRRP group 2.
R1	R1#show vrrp GigabitEthernet 0/2 - Group 1 State is Backup Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 100

	Master Router is 192.168.201.213 , priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec GigabitEthernet 0/2 - Group 2 State is Master Virtual IP address is 192.168.201.2 configured Virtual MAC address is 0000.5e00.0102 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 120 Master Router is 192.168.201.217 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 0/1 priority decrement=30
R2	R2#show vrrp GigabitEthernet 0/2 - Group 1 State is Master Virtual IP address is 192.168.201.1 configured Virtual MAC address is 0000.5e00.0101 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 120 Master Router is 192.168.201.213 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec GigabitEthernet 0/2 - Group 2 State is Backup Virtual IP address is 192.168.201.2 configured Virtual MAC address is 0000.5e00.0102 Advertisement interval is 3 sec Preemption is enabled min delay is 0 sec Priority is 100 Master Router is 192.168.201.217 , priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec

Common Errors

- Different virtual IP addresses are configured on routers in a VRRP group, resulting in multiple master routers in the group.

- Different VRRP advertisement intervals are configured on routers in a VRRP group and the learning timer is not configured, resulting in multiple master routers in the group.
- Different VRRP versions are configured on routers in a VRRP group, resulting in multiple master routers in the group.
- For VRRPv2, the Ethernet interfaces of routers in a VRRP group are all in cleartext authentication mode but use inconsistent authentication strings, resulting in multiple master routers in the group.

1.4.2 Configuring IPv6 VRRP

Configuration Effect

- Configure an IPv6 VRRP group on an interface of a specific LAN segment by setting the VRID and virtual IPv6 address.
- Configure multiple IPv6 VRRP groups on an interface to achieve load balancing and achieve more stable and reliable network services.
- Configure the VRRP tracked interfaces to monitor failures, change interface priorities, and realize failover dynamically.

Notes

- To achieve VRRP, routers in a VRRP group should be configured with the same virtual IPv6 address.
- To achieve backup for multiple IPv6 VRRP groups, configure multiple IPv6 VRRP groups with identical VRRP configuration on an interface and configure different priorities for them so that they back up each other.
- VRRP must be enabled on Layer 3 interfaces.
- To use the IPv6 VRRP function on an N18000 with a CB line card inserted, enable the IPv6 VRRP function in global configuration mode first.

Configuration Steps

↘ Enabling IPv6 VRRP in Interface Configuration Mode

By default, IPv6 VRRP is not enabled on an interface. You can enable it as needed.

↘ Configuring the IPv6 VRRP Advertisement Interval

By default, the master router sends advertisement packets every 1s. You can modify the interval as needed.

↘ Configuring the IPv6 VRRP Preemption Mode

By default, a VRRP group operates in preemption mode without a delay.

↘ Enabling the Accept Mode for an IPv6 VRRP Group

By default, the Accept mode is disabled for an IPv6 VRRP group. To configure an IPv6 VRRP group in master state to receive and process packets with the destination IP address as that of the virtual router, enable the Accept mode.

↘ Configuring the IPv6 VRRP Router Priority

The default router priority for a VRRP group is 100. You can modify the priority as needed.

Configuring the IPv6 VRRP Tracked Interface

By default, no tracked interface is configured. You can modify the interval as needed.

Configuring the IPv6 VRRP Tracked IP Address

By default, no tracked IPv6 address is configured and the value of priority change is 10. You can configure this function as needed.

Configures the IPv6 VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group. Enable this function if the backup routers need to learn the master's advertisement interval.

Configuring the Description for an IPv6 VRRP Group

By default, no description is configured for a VRRP group. To help distinguish VRRP groups, configure descriptions.

Configuring the IPv4 VRRP Delay

By default, the IPv6 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

Verification

Run the **show vrrp** command to verify the configuration.

Related Commands

Enabling IPv6 VRRP

Command	**vrrp** *group* **ipv6** *ipv6-address*
Parameter Description	*group*: Indicates the VRID of a VRRP group. The value range depends on product models. *ipv6-address*: Indicates the IPv6 address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	IPv6 and IPv4 VRRP groups share a VRID range from 1 to 255. One VRID is applicable to an IPv4 VRRP group and an IPv6 VRRP group simultaneously. The first configured address should be a link-local address, which can be deleted only after other virtual addresses.

Configuring the IPv6 VRRP Advertisement Interval

Command	**vrrp ipv6** *group* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }
Parameter Description	*group*: Indicates the VRID of a VRRP group. *advertise-interval*: Indicates the advertisement interval of a VRRP group, in seconds. ***csec*** *centisecond-interval:* Indicates the interval for the master router in a VRRP group to send VRRP packets. It is an integer from 50 to 99, in centiseconds. No default value is provided. The command is only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is 1s.
Command Mode	Interface configuration mode
Usage Guide	If a router is elected as the master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority, and other information.

	As defined by RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40s. Therefore, if the interval is larger than 40s, the maximum interval of 40s will be applied, though the configuration is effective.

Configuring the Preemption Mode

Command	**vrrp ipv6** *group* **preempt** [**delay** *seconds*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. **delay** *seconds*: Indicates the preemption delay for the master router to declare its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	If a VRRP group runs in preemption mode, a router with a higher priority will replace the master with a lower priority. If a VRRP group runs in non-preemption mode, a router with the priority higher than that of the master remains backup. When the VRRP group uses the IP address of an Ethernet interface, the device to which the Ethernet interface belongs has the highest priority and automatically becomes the master in the group.

Enabling the Accept Mode for an IPv6 VRRP Group

Command	**vrrp ipv6** *group* **accept_mode**
Parameter Description	*group*: Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	By default, an IPv6 VRRP group in master state is not permitted to receive packets with the destination IPv6 address as that of the VRRP group. However, it receives NA and NS packets regardless of whether the Accept mode is configured. Besides, the IP address owner in master state receives and processes the packets with the destination IPv6 address as that of the VRRP group regardless of whether the Accept mode is configured.

Configuring the IPv6 VRRP Router Priority

Command	**vrrp ipv6** *group* **priority** *level*
Parameter Description	*group*: Indicates the VRID of a VRRP group. *level*: Indicates the priority of a VRRP router.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the VRRP router priority.

Configuring the IPv6 VRRP Tracked Interface

Command	**vrrp ipv6** *group* **track** *interface-type interface-number* [*priority*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. *interface-type interface-number*: Indicates the interface to be tracked. *priority*: Indicates the step of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command	Interface configuration mode

Mode	
Usage Guide	A tracked interface must be a routable Layer 3 logical interface, for example, a routed interface, an SVI, a loopback interface, or a tunnel interface. The priority of the router that has the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

Configuring the IPv6 VRRP Tracked IP Address

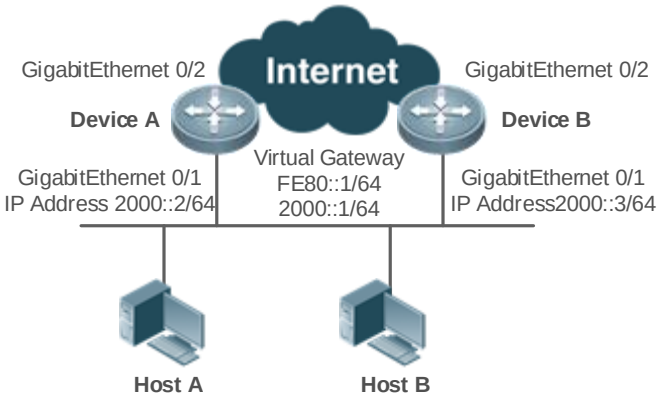
Command	**vrrp ipv6** *group* **track** { *ipv6-global-address* | *ipv6-linklocal-address interface-type interface-number* } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. *ipv6-global-addres*: Indicates the IPv6 global unicast address. *ipv6-linklocal-address*: Indicates the IPv6 link-local address. *interface-type interface-number*: Indicates the interface to be tracked. ***interval*** *interval-value*: Indicates the probe interval, in seconds. The default value is 3s. ***timeout*** *timeout-value*: Indicates the probe timeout interval of waiting for response, in seconds. If no response is received within the timeout interval, the device considers that the destination is inaccessible. The default value is 1s. **retry** *retry-value*: Indicates the probe retry count. If no response is received after the probe retry count, the device considers that the destination is inaccessible. The default value is 3. *priority*: Indicates the step of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	To monitor a host, specify its IPv6 address for an IPv6 VRRP group. If the host IP address being tracked is a link-local address, specify a network interface. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

Configures the IPv6 VRRP Learning Timer

Command	**vrrp ipv6** *group* **timers learn**
Parameter Description	*group*: Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	After the learning timer is configured, a VRRP backup router learns the advertisement interval of NA packets from the master. The backup router calculates the interval for determining a failure of the master based on the learning timer but not the local advertisement interval. This command ensures that advertisement intervals between backup routers and the master are synchronized.

Configuring the Description for an IPv6 VRRP Group

Command	**vrrp ipv6** *group* **description** *text*
Parameter Description	*group*: Indicates the VRID of a VRRP group. *text*: Indicates the description of a VRRP group.
Command	Interface configuration mode



Mode	
Usage Guide	The description helps distinguish a VRRP group. A description has up to 80 bytes. If the description has more than 80 bytes, the system displays the message about incorrect configuration.

Configuring the IPv4 VRRP Delay

Command	**vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* }
Parameter Description	**minimum** *min-seconds*: Indicates the VRRP delay after an interface state changes. **reload** *reload-seconds*: Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode
Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group does not start when the system starts up or the interface becomes active. Instead, the VRRP group starts after the delay, ensuring that the non-preemption configuration is effective. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP group will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface. The value range of the delay of two types is from 0 to 60, in seconds.

Configuration Example

Configuring an IPv6 VRRP Group and Tracked Interface

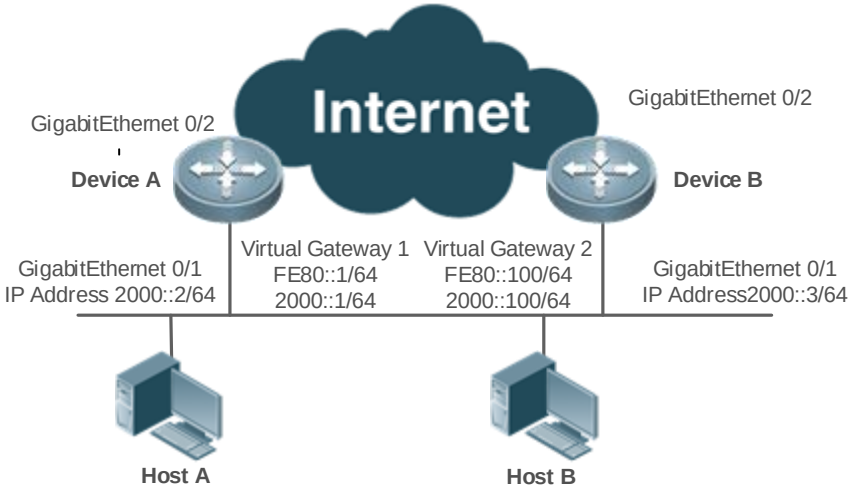
Scenario **Figure 1-6**	
Configuration Steps	● Host A and Host B access the Internet resources through the default gateway address 2000::1/64. ● Device A and Device B belong to IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively. ● Device A tracks GigabitEthernet 0/2 connected to the Internet. When GigabitEthernet 0/2 is unavailable, Device A reduces its priority and Device B acts as a gateway.

DeviceA	`Device A#configure terminal`
	`Device A(config)#interface GigabitEthernet 0/1`
	`Device A(config-if-GigabitEthernet 0/1)#no switchport`
	`Device A(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64`
	`Device A(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1`
	`Device A(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1`
	`Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120`

	Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 track GigabitEthernet 0/2 50 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode
DeviceB	Device B#configure terminal Device B(config)#interface GigabitEthernet 0/1 Device B(config-if-GigabitEthernet 0/1)#no switchport Device B(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 Device B(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 Device B(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode
Verification	Run the **show ipv6 vrrp** command to verify the configuration. ● Check whether Device A used as the master router reduces its VRRP group priority from 50 to 70 when it finds that GigabitEthernet 0/2 connected to a WAN is unavailable. If so, Device B becomes the master. ● Check whether Device A increases its VRRP group priority from 50 to 120 when it finds that GigabitEthernet 0/2 connected to a WAN becomes available again. If so, Device A becomes the master again.
DeviceA	Device A#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec Tracking state of 1 interface, 1 up: up GigabitEthernet 0/2 priority decrement=50
DeviceB	Device B#show ipv6 vrrp 1 GigabitEthernet 0/1 - Group 1 State is Backup Virtual IPv6 address is as follow: FE80::1 2000::1

```
Virtual MAC address is 0000.5e00.0201
Advertisement interval is 3 sec
Accept_Mode is enabled
Preemption is enabled
min delay is 0 sec
Priority is 100
Master Router is FE80::1234, priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.82 sec
```

Common Errors



- Different virtual IP addresses are configured on routers in a VRRP group, resulting in multiple master routers in the group.
- Different VRRP advertisement intervals are configured on routers in a VRRP group and the learning timer is not configured, resulting in multiple master routers in the group.

Configuration Example

Configuring Multiple IPv6 VRRP Groups

Scenario

Figure 1-7

Configuration Steps

- Host A and Host B access the Internet resources through gateway addresses of 2000::1/64 and 2000::100/64 respectively.
- Device A and Device B belong to IPv6 VRRP group 1, and their virtual addresses are 2000::1/64 and FE80::1 respectively.
- Device A and Device B belong to IPv6 VRRP group 2 of a virtual IPv6 router, and their virtual addresses are 2000::100/64 and FE80::100 respectively.
- Device A and Device B act as gateways and forward flows. They back up to each other.

DeviceA

```
Device A#configure terminal
Device A(config)#interface GigabitEthernet 0/1
Device A(config-if-GigabitEthernet 0/1)#no switchport
Device A(config-if-GigabitEthernet 0/1)#ipv6 address 2000::2/64
```

	Device A(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 Device A(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 120 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode Device A(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100 Device A(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 100 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3 Device A(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode
DeviceB	Device B#configure terminal Device B(config)#interface GigabitEthernet 0/1 Device B(config-if-GigabitEthernet 0/1)#no switchport Device B(config-if-GigabitEthernet 0/1)#ipv6 address 2000::3/64 Device B(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 FE80::1 Device B(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2000::1 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 priority 100 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 timers advertise 3 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 1 accept_mode Device B(config-if-GigabitEthernet 0/1)#vrrp 2 ipv6 FE80::100 Device B(config-if-GigabitEthernet 0/1)# vrrp 2 ipv6 2000::100 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 priority 120 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 timers advertise 3 Device B(config-if-GigabitEthernet 0/1)#vrrp ipv6 2 accept_mode
Verification	● Run the **show ipv6 vrrp** command to verify the configuration.
DeviceA	Device A#show ipv6 vrrp GigabitEthernet 0/1 - Group 1 State is Master Virtual IPv6 address is as follows: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::1234 (local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec GigabitEthernet 0/1 - Group 2 State is Backup Virtual IPv6 address is as follows:

	FE80::100 2000::100 Virtual MAC address is 0000.5e00.0202 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::5678, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec
DeviceB	Device B#show ipv6 vrrp GigabitEthernet 0/1 - Group 1 State is Backup Virtual IPv6 address is as follow: FE80::1 2000::1 Virtual MAC address is 0000.5e00.0201 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 100 Master Router is FE80::1234, priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.82 sec GigabitEthernet 0/1 - Group 2 State is Master Virtual IPv6 address is as follows: FE80::100 2000::100 Virtual MAC address is 0000.5e00.0202 Advertisement interval is 3 sec Accept_Mode is enabled Preemption is enabled min delay is 0 sec Priority is 120 Master Router is FE80::5678(local), priority is 120 Master Advertisement interval is 3 sec Master Down interval is 10.59 sec

Common Errors

- Different virtual IP addresses are configured on routers in a VRRP group, resulting in multiple master routers in the group.

- Different VRRP advertisement intervals are configured on routers in a VRRP group and the learning timer is not configured, resulting in multiple master routers in the group.

1.4.3 Configuring VRRP and MSTP

Configuration Effect

VRRP and MSTP can be configured simultaneously, achieving link-level and gateway-level backup and improving network robustness.

Notes

- Configure routers in a VRRP group with the same virtual IPv4 address.
- Enable VRRP on a Layer 3 interface.

Configuration Steps

↘ Enabling IPv4 VRRP

By default, IPv4 VRRP is not enabled on an interface. You can enable it as needed.

↘ Configuring the IPv4 VRRP Authentication String

By default, VRRP is in a non-authentication mode. To enable cleartext password authentication for VRRP, perform this configuration.

↘ Configuring the IPv4 VRRP Advertisement Interval

By default, the master router sends advertisement packets every 1s. You can modify the interval as needed.

↘ Configuring the IPv4 VRRP Preemption Mode

By default, VRRP groups work in preemption mode without a delay.

↘ Configuring the IPv4 VRRP Router Priority

The default router priority for a VRRP group is 100. You can modify the priority as needed.

↘ Configuring the IPv4 VRRP Tracked Interface

By default, an IPv4 VRRP group does not monitor any interface. To detect faults through interface monitoring, perform this configuration.

↘ Configuring the IPv4 VRRP Learning Timer

By default, the learning timer is disabled for a VRRP group. Enable this function if backup routers need to learn the master's advertisement interval.

↘ Configuring the Description for an IPv4 VRRP Group

By default, no description is configured for a VRRP group. To help distinguish VRRP groups, configure descriptions.

↘ Configuring the IPv4 VRRP Delay

By default, the IPv4 VRRP delay is not configured. To guarantee an effective non-preemption mode, configure the delay.

Configuring the IPv4 VRRP Version

By default, IPv4 adopts the VRRPv2 standard. To change it, use the corresponding command.

Specifying a Sub-VLAN of a Super-VLAN to Receive the IPv4 VRRP Packets

By default, IPv4 VRRP packets are only sent to the first Up interface of a sub-VLAN in a super-VLAN. However, it is possible to configure them to be sent to a specific sub-VLAN in the super-VLAN.

Verification

Run the **show vrrp** command to verify the configuration.

Related Commands

Enabling IPv4 VRRP

Command	**vrrp** *group* **ip** *ipaddress* [**secondary**]
Parameter Description	*group*: Indicates the VRID of a VRRP group. The value range depends on product models. *ipaddrss*: Indicates the IP address of a VRRP group. **secondary**: Indicates the secondary IP address of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	If no virtual IP address is specified, routers cannot join a VRRP group. If no secondary IP address is applied, the configured IP address will be the primary IP address of a VRRP group.

Configuring the IPv4 VRRP Authentication String

Command	**vrrp** *group* **authentication** *string*
Parameter Description	*group*: Indicates the VRID of a VRRP group. *string*: Indicates the authentication string of a VRRP group (a cleartext password consists of 8 bytes at most).
Command Mode	Interface configuration mode
Usage Guide	In a VRRP group, the same authentication password should be configured for routers. The cleartext authentication password cannot guarantee security but only prevents or prompts VRRP configuration errors. This command is only applicable to VRRPv2 but not VRRPv3. Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP) packets. If VRRPv2 is chosen for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

Configuring the IPv4 VRRP Advertisement Interval

Command	**vrrp** *group* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }
Parameter Description	*group*: Indicates the VRID of a VRRP group. *advertise-interval*: Indicates the advertisement interval of a VRRP group, in seconds. ***csec*** *centisecond-interval:* Indicates the interval for the master router in a VRRP group to send VRRP packets. It is an integer from 50 to 99, in centiseconds. No default value is provided. The command is

	only effective for VRRPv3 packets. If it is configured for VRRPv2 packets, the default interval is 1s.
Command Mode	Interface configuration mode
Usage Guide	If a router is elected as the master in a VRRP group, it sends VRRP advertisement packets at the set interval to announce its VRRP state, priority, and other information. As defined by RFC standards, if an IPv4 VRRP group adopts VRRPv3 for sending multicast packets, the maximum advertisement interval is 40s. Therefore, if the interval is larger than 40s, the maximum interval of 40s will be applied, though the configuration is effective.

Configuring the IPv4 VRRP Preemption Mode

Command	**vrrp** *group* **preempt** [**delay** *seconds*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. **delay** *seconds*: Indicates the preemption delay for the master router to declare its status. The default value is 0 second.
Command Mode	Interface configuration mode
Usage Guide	If a VRRP group runs in preemption mode, a router with a higher priority will replace the master with a lower priority. If a VRRP group runs in non-preemption mode, a router with the priority higher than that of the master remains backup. When the VRRP group uses the IP address of an Ethernet interface, the device to which the Ethernet interface belongs has the highest priority and automatically becomes the master in the group.

Configuring the IPv4 VRRP Router Priority

Command	**vrrp** *group* **priority** *level*
Parameter Description	*group*: Indicates the VRID of a VRRP group. *level*: Indicates the priority of an interface in a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	This command is used to manually configure the priority of a VRRP group.

Configuring the IPv4 VRRP Tracked Interface

Command	**vrrp** *group* **track** *interface-type interface-number* [*priority*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. *interface-type interface-number*: Indicates the interface to be tracked. *priority*: Indicates the step of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	A tracked interface must be a routable Layer 3 logical interface, for example, a routed interface, an SVI, a loopback interface, or a tunnel interface. The priority of the router that has the virtual IP address associated with a VRRP group must be 255, and no tracked interface can be configured on it.

Configuring the IPv4 VRRP Tracked IP Address

Command	**vrrp** *group* **track** *ipv4-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] [*priority*]
Parameter Description	*group*: Indicates the VRID of a VRRP group. *ipv4-addres*: Indicates the IPv4 address to be tracked. ***interval*** *interval-value*: Indicates the probe interval, in seconds. The default value is 3s. ***timeout*** *timeout-value*: Indicates the probe timeout interval of waiting for response, in seconds. If no response is received within the timeout interval, the device considers that the destination is inaccessible. The default value is 1s. **retry** *retry-value*: Indicates the probe retry count. If no response is received after the probe retry count, the device considers that the destination is inaccessible. The default value is 3. *priority*: Indicates the step of VRRP priority change when the state of a monitored interface changes. The default value is 10.
Command Mode	Interface configuration mode
Usage Guide	To monitor a host, specify its IPv4 address for an IPv4 VRRP group. If a VRRP group owns the actual IP address of an Ethernet interface, the group priority is 255, and no monitored IP address can be configured.

Configuring the IPv4 VRRP Learning Timer

Command	**vrrp** *group* **timers learn**
Parameter Description	*group*: Indicates the VRID of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	After the learning timer is configured, a VRRP backup router learns the advertisement interval of NA packets from the master. The backup router calculates the interval for determining a failure of the master based on the learning timer but not the local advertisement interval. This command ensures that advertisement intervals between backup routers and the master are synchronized.

Configuring the Description for an IPv4 VRRP Group

Command	**vrrp** *group* **description** *text*
Parameter Description	*group*: Indicates the VRID of a VRRP group. *text*: Indicates the description of a VRRP group.
Command Mode	Interface configuration mode
Usage Guide	The description helps distinguish a VRRP group. A description has up to 80 bytes. If the description has more than 80 bytes, the system displays the message about incorrect configuration.

Configuring the IPv4 VRRP Delay

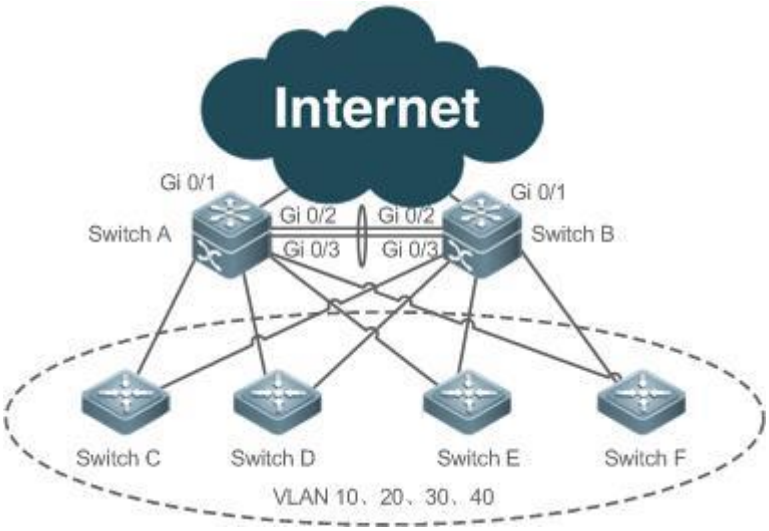
Command	**vrrp delay** { **minimum** *min-seconds* | **reload** *reload-seconds* }
Parameter Description	**minimum** *min-seconds*: Indicates the VRRP delay after an interface state changes. **reload** *reload-seconds*: Indicates the VRRP delay after the system starts.
Command Mode	Interface configuration mode

Usage Guide	After the delay is configured for a VRRP group on an interface, the VRRP group does not start when the system starts up or the interface becomes active. Instead, the VRRP group starts after the delay, ensuring that the non-preemption configuration is effective. If the interface receives a VRRP packet during the delay, the delay will be canceled and the VRRP group will be started immediately. This configuration will be effective for both IPv4 and IPv6 VRRP groups of an interface. The value range of the delay of two types is from 0 to 60, in seconds.

Configuring the IPv4 VRRP Version

Command	**vrrp** *group* **version** { **2** | **3** }
Parameter Description	**2**: Indicates VRRPv2. **3**: Indicates VRRPv3.
Command Mode	Interface configuration mode
Usage Guide	Considering compatibility between VRRPv2 and VRRPv3, specify a standard for IPv4 VRRP based on the actual network condition. VRRPv2 is defined in RFC 3768 and VRRPv3 in RFC 5798. This command is only applicable to IPv4 VRRP.

Specifying a Sub-VLAN of a Super-VLAN to Receive IPv4 VRRP Packets



Command	**vrrp detection-vlan** { **first-subvlan** | *subvlan-id* }
Parameter Description	**first-subvlan**: Sends IPv4 VRRP packets only to the first Up interface of a sub-VLAN in a super-VLAN. *subvlan-id*: Sends packets to a specified sub-VLAN.
Command Mode	Interface configuration mode
Usage Guide	This command is used to specify a sub-VLAN of a super-VLAN to receive the IPv4 VRRP packets. IPv4 VRRP packets are sent in a super-VLAN using the following three methods. Packets are sent to the first Up interface of a sub-VLAN in a super-VLAN, or to a specified sub-VLAN interface in a super-VLAN, or to all the sub-VLAN interfaces in a super-VLAN. If VRRP and VRRP Plus are enabled simultaneously on a super-VLAN interface, VRRP packets are sent to all Up interfaces of sub-VLANs in the super-VLAN. This command is configured on a VLAN interface and effective only to super-VLAN interfaces.

Configuration Example

Configuring VRRP and MSTP

Scenario

Figure 1-8

Configuration Steps

- Configure MSTP on switches A, B, C, D, E and F. Configure VLAN-MSTI mapping (mapping VLAN 10 and VLAN 20 to MSTI 1, VLAN 30 and VLAN 40 to MSTI 2, and the rest VLANs to MSTI 0), and configure gateways (Switch A and Switch B in this example) as the root bridges of corresponding MSTIs.
- Add the SVIs of all VLANs to corresponding VRRP groups, and configure gateways as the master and backup routers for corresponding VRRP groups.

Gateway	VLAN ID	SVI	VRRP Group	Virtual IP Address	State
Switch A	10	192.168.10.2	VRRP group 10	192.168.10.1	Master
Switch B		192.168.10.3			Backup
Switch A	20	192.168.20.2	VRRP group 20	192.168.20.1	Master
Switch B		192.168.20.3			Backup
Switch A	30	192.168.30.2	VRRP group 30	192.168.30.1	Backup
Switch B		192.168.30.3			Master
Switch A	40	192.168.40.2	VRRP group 40	192.168.40.1	Backup
Switch B		192.168.40.3			Master

- Configure the uplink interface (Gi 0/1 of Switch A and Switch B) of master routers as a monitored interface of the master router.
- Create VLANs. Create VLAN 10, VLAN 20, VLAN 30, and VLAN 40 on Switch A and Switch B.
- Configure MST regions. Map VLAN 10 and VLAN 20 to MSTI 1, VLAN 30 and VLAN 40 to

	MSTI 2, and the rest VLANs to MSTI 0. ● Configure Switch A as the root bridge for MST 0 and MST 1, and Switch B as the root bridge for MST 2. ● Enable MSTP. ● Configure SVIs of all the VLANs, add the SVIs to corresponding VRRP groups, and configure virtual IP addresses for the groups. ● Configure master routers and backup routers for all the groups. ● Configure uplink interfaces of master routers as monitored ports of VRRP groups. Monitored interfaces must be Layer 3 interfaces. ● Configure Internet interfaces of core routers as aggregate interfaces.

SwitchA	`//Create VLAN 10, VLAN 20, VLAN 30 and VLAN 40 on Switch A.`
	`SwitchA#configure terminal`
	`Enter configuration commands, one per line. End with CNTL/Z.`
	`SwitchA(config)#vlan range 10,20,30,40`
	`SwitchA(config-vlan-range)#exit`

Common Errors

- Different virtual IP addresses are configured on routers in a VRRP group, resulting in multiple master routers in the group.
- Different VRRP advertisement intervals are configured on routers in a VRRP group and the learning timer is not configured, resulting in multiple master routers in the group.
- Different VRRP versions are configured on routers in a VRRP group, resulting in multiple master routers in the group.
- For VRRPv2, Ethernet interfaces of routers in a VRRP group are all in cleartext authentication mode and use inconsistent authentication strings, resulting in multiple master routers in the group.

1.5 Monitoring

Displaying

Command	Description
show [**ipv6**] **vrrp** [**brief** | *group*]	Displays brief or detailed information about IPv4/IPv6 VRRP.
show [**ipv6**] **vrrp interface** *type number* [**brief**]	Displays information about an IPv4/IPv6 VRRP group on a specified interface.
show vrrp [**brief** | *group*]	Displays brief or detailed information about IPv4 VRRP.
show vrrp interface *type number* [**brief**]	Displays information about an IPv4 VRRP group on a specified interface.

show vrrp packet statistics [*interface-type interface-number*]	Displays statistics on VRRP packets.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug [**ipv6**] **vrrp**	Debugs VRRP errors, events, packets, and status.
debug [**ipv6**] **vrrp errors**	Debugs VRRP errors.
debug [**ipv6**] **vrrp events**	Debugs VRRP events.
debug vrrp packets [**acl** *acl-id* **|** [**icmp | protocol**] **interface** *type number* [*group*]] **debug ipv6 vrrp packets** [**acl** *acl-name* **|** [**icmp | protocol**] **interface** *type number* [*group*]]	Debugs VRRP packets.
debug [**ipv6**] **vrrp state**	Debugs the VRRP status.

1 Configuring Supervisor Module Redundancy

1.1 Overview

Supervisor module redundancy is a mechanism that adopts real-time backup (also called hot standby) of the service running status of supervisor modules to improve device availability.

In a network device where the control plane is separated from the forwarding plane, the control plane runs on a supervisor module and the forwarding plane runs on line cards. The control plane information of the active supervisor module is backed up to the standby supervisor module in real time during device running. When the active supervisor module is shut down as expected (for example, due to software upgrade) or unexpectedly (for example, due to software or hardware exception), the device can automatically and rapidly switch to the standby supervisor module without user configuration loss, thereby ensuring normal operation of the network. The forwarding plane continues with packet forwarding during switching. Forwarding is not stopped and no link flapping occurs during restart of the control plane.

The supervisor module redundancy technology brings the following benefits to network services:

1 Improving network availability

The supervisor module redundancy technology sustains data forwarding and status information about user sessions during switching.

2 Preventing neighbors from detecting link flapping

The forwarding plane is not restarted during switching. Therefore, neighbors cannot detect the status change of a link from Down to Up.

3 Preventing route flapping

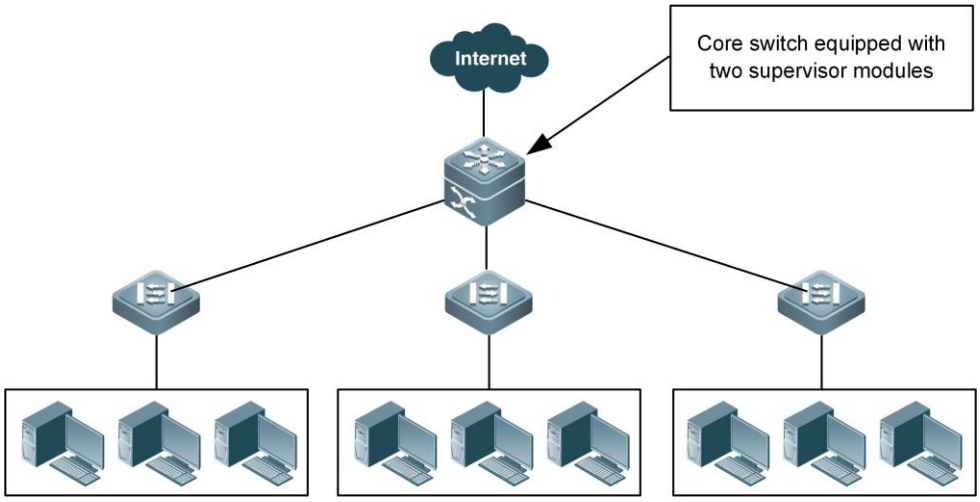
The forwarding plane sustains forwarding communication during switching, and the control plane rapidly constructs a new forwarding table. This process prevents route flapping.

4 Preventing loss of user sessions

User sessions that are created prior to switching are not lost because the session status is synchronized in real time.

1.2 Applications

Application	Description
Redundancy of Supervisor Modules	On a core switch where two supervisor modules are installed, the redundancy technology can improve network stability and system availability.



1.2.1 Redundancy of Supervisor Modules

Scenario

In Figure 1-1, in this network topology, if the core switch malfunctions, networks connected to the core switch may break down. To improve the network stability, two supervisor modules need to be configured on the core switch to implement redundancy. The active supervisor module manages the entire system and the standby supervisor module backs up

information about service running status of the active supervisor module in real time. When manual switching is performed or forcible switching is performed due to a failure on the active supervisor module, the standby supervisor module immediately takes over functions of the active supervisor module. The forwarding plane can proceed with data forwarding and the system availability is enhanced.

Figure 1-1

Deployment

For modular devices, the system is equipped with the active/standby backup mechanism. The system supports plug-and-play as long as active and standby supervisor modules conform to redundancy conditions.

For fixed devices, each device is equivalent to one supervisor module and one line card. The virtual switching unit (VSU) composed of multiple fixed devices also has the active and standby backup mechanism.

1.3 Features

Basic Concepts

Active and Standby Supervisor Modules

On a device where two supervisor modules are installed, the system elects one supervisor module as the active supervisor module. The other supervisor module functions as the backup supervisor module. When the active supervisor module malfunctions or proactively requests switching, the standby supervisor module takes over functions of the active supervisor module and becomes the new active supervisor module, which is called the standby supervisor module. Typically, the standby supervisor module does not participate in device management but monitors the running status of the active supervisor module.

Globally Active Supervisor Module, Globally Standby Supervisor Module, Globally Candidate Supervisor Module

In a VSU composed of two or more modular devices, each device has two supervisor modules, with the active supervisor module managing the entire chassis and the standby supervisor module functioning as a backup. For a VSU, there are two or more supervisor modules. One active supervisor module is elected out of the supervisor modules to manage the entire VSU, one standby supervisor module is elected as the backup of the VSU, and other supervisor modules are used as candidate supervisor modules. A candidate supervisor module replaces the active or standby

supervisor module and runs as the active or standby supervisor module when the original active or standby supervisor module malfunctions. In most cases, candidate supervisor modules do not participate in backup. To differentiate active and standby supervisor modules in a chassis from those in a VSU, the active, standby, and candidate supervisor modules in a VSU are called globally active, standby, and candidate supervisor modules respectively. The redundancy mechanism of supervisor modules takes effect on the globally active and standby supervisor module. Therefore, the active and standby supervisor modules in the VSU are globally ones.

In a VSU composed of two or more fixed devices, each fixed device is equivalent to one supervisor module and one line card. The system elects one device as the globally active supervisor module and one device as the globally standby supervisor module, and other devices serve as globally candidate supervisor modules.

↘ Prerequisites for Redundancy of Supervisor Modules

In a device system, hardware and software of all supervisor modules must be compatible so that supervisor modules in redundancy mode function properly.

Batch synchronization is required between the active and standby supervisor modules during startup so that the two supervisor modules are in the same state. Redundancy of supervisor modules is ineffective prior to synchronization.

↘ Redundancy Status of Supervisor Modules

The active supervisor module experiences the following status changes during active/standby backup:

- alone: In this state, only one supervisor module is running in the system, or active/standby switching is not complete, and redundancy is not established between the new active and standby supervisor modules.
- batch: In this state, redundancy is established between the active and standby supervisor modules and batch backup is being performed.
- realtime: The active supervisor module enters this state after the batch backup between active and standby supervisor modules is complete. Real-time backup is performed between the active and standby supervisor modules, and manual switching can be performed only in this state.

Overview

Feature	Description
Election of Active and Standby Supervisor Modules	The device can automatically select active and standby supervisor modules based on the status of the system. Manual selection is also supported.
Information Synchronization of Supervisor Modules	For supervisor modules in redundancy mode, the active supervisor module synchronizes status information and configuration files to the standby supervisor module in real time.

1.3.1 Election of Active and Standby Supervisor Modules

Working Principle

↘ Automatically Selecting Active and Standby Supervisor Modules for Modular Devices

You can install or remove supervisor modules during device running. The device, based on the current condition of the system, automatically selects an engine for running, without affecting normal data switching. The following cases may occur and the active supervisor module is selected accordingly:

- If only one supervisor module is installed during device startup, the device selects this supervisor module as the active supervisor module regardless of whether it is installed into the M1 slot or M2 slot.
- If two supervisor modules are installed during device startup, the supervisor module in the M1 slot is selected as the active supervisor module and the supervisor module in the M2 slot is selected as the standby supervisor module to serve as a backup by default, and relevant prompts are output.
- If one supervisor module is installed during device startup and another supervisor module is installed during device running, the supervisor module that is inserted later is used as the standby supervisor module to serve as a backup regardless of whether it is inserted into the M1 slot or M2 slot, and relevant prompts are output.
- Assume that two supervisor modules are installed during device startup and one supervisor module is removed during device running (or one supervisor module malfunctions). If the removed supervisor module is the standby supervisor module prior to removal (or failure), only a prompt is displayed after removal (or malfunction), indicating that the standby supervisor module is removed (or fails to run). If the removed supervisor module is the active supervisor module prior to removal (or failure), the other supervisor module becomes the active supervisor module and relevant prompts are output.

↘ Manually Selecting Active and Standby Supervisor Modules

You can manually select active and standby supervisor modules, which are selected as follows:

- In standalone mode, you can manually perform active/standby switching. The supervisor modules take effect after reset.
- In VSU mode, you can manually perform active/standby switching to make the globally standby supervisor module become the globally active supervisor module. If a VSU has only two supervisor modules, the original globally active supervisor module becomes the new globally standby supervisor module after reset. If there are more than two supervisor modules, one globally candidate supervisor module is elected as the new globally standby supervisor module and the original globally active supervisor module becomes a globally candidate supervisor module after reset.

Related Configuration

↘ Manually Performing Active/Standby Switching

- By default, the device can automatically select the active supervisor module.
- In standalone and VSU modes, you can run the **redundancy forceswitch** command to perform manual switching.

1.3.2 Information Synchronization of Supervisor Modules

Working Principle

- Status synchronization

The active supervisor module synchronizes its running status to the standby supervisor module in real time so that the standby supervisor module can take over functions of the active supervisor module at any time, without causing any obvious changes.

- Configuration synchronization

There are two system configuration files during device running: running-config and startup-config. running-config is a system configuration file dynamically generated during running and changes with the service configuration.

startup-config is a system configuration file imported during device startup. You can run the **write** command to write running-config into startup-config or run the **copy** command to perform the copy operation.

For some functions that are not directly related to non-stop forwarding, synchronization of system configuration files can ensure consistent user configuration during switching.

In the case of redundancy of dual supervisor modules, the active supervisor module periodically synchronizes startup-config and running-config files to the standby supervisor module and all candidate supervisor modules. Configuration synchronization is also triggered in the following operations:

1. The running-config file is synchronized when the device switches from the global configuration mode to privileged EXEC mode.
2. The startup-config file is synchronized when the **write** or **copy** command is executed to save the configuration.
3. Information configured over the Simple Network Management Protocol (SNMP) is not automatically synchronized and the synchronization of the running-config file needs to be triggered by running commands on the CLI.

Related Configuration

- By default, the startup-config and running-config files are automatically synchronized once per hour.

1.4 Configuration

Configuration	Description and Command	
Configuring Manual Active/Standby Switching	Optional.	
	show redundancy states	Displays the hot standby status.
	redundancy forceswitch	Manually performs active/standby switching.
Resetting Supervisor Modules	Optional.	
	redundancy reload	Resets the standby supervisor module or resets both the active and standby supervisor modules.

1.4.1 Configuring Manual Active/Standby Switching

Configuration Effect

The original active supervisor module is reset and the standby supervisor module becomes the new active supervisor module.

If there are more than two supervisor modules in the system, the original standby supervisor module becomes the active supervisor module, one supervisor module is elected out of candidate supervisor modules to serve as the new standby supervisor module, and the original active supervisor module becomes a candidate supervisor module after reset.

Notes

To ensure that data forwarding is not affected during switching, batch synchronization needs to be first performed between the active and standby supervisor modules so that the two supervisor modules are in the same state. That is, manual switching can be performed only when redundancy of supervisor modules is in real-time backup state. In

addition, to ensure synchronization of complete configuration files, service modules temporarily forbid manual active/standby switching during synchronization. Therefore, the following conditions need to be met simultaneously for manual switching:

- Manual active/standby switching is performed on the active supervisor module and a standby supervisor module is available.

Configuration Steps

- Optional.
- Perform the configuration on the active supervisor module.

Verification

Run the **show redundancy states** command to check whether the active and standby supervisor modules are switched.

1.4.2 Resetting Supervisor Modules

Configuration Effect

Resetting only the standby supervisor module does not affect data forwarding, and forwarding is not interrupted or user session information is not lost during reset of the standby supervisor module.

In standalone mode, running the **redundancy reload shelf** command will cause simultaneous reset of all supervisor modules and line cards in the chassis. In VSU mode, the device of a specified ID is reset when this command is

executed. If there are two or more devices in the system and the device to be reset is the device where the globally active supervisor module resides, the system performs active/standby switching.

Notes

In VSU mode, if the supervisor modules of the system do not enter the real-time backup state, resetting the device where the globally active supervisor module resides will cause the reset of the entire VSU.

Configuration Steps

Optional. Perform the reset when the supervisor modules or device runs abnormally.

Related Commands

Command	**redundancy reload** { **peer** | **shelf** [*switchid*] }
Parameter Description	**peer**: Resets only the standby supervisor module. **shelf** [*switchid*]: Indicates that the active and standby supervisor modules are set in standalone mode, and the ID of the device to be reset needs to be specified in VSU mode.
Command Mode	Privileged EXEC mode
Usage Guide	In standalone mode, **redundancy reload shelf** is used to reset the device. In VSU mode, **redundancy reload shelf** *switchid* is used to reset the device of a specified device ID.

Configuration Example

Resetting a Device in VSU Mode

Configuration Steps	In privileged EXEC mode of the globally active supervisor module, reset the device with the ID of 2.

	`Hostname# redundancy reload shelf 2`
	`This operation will reload the device 2. Are you sure to continue? [N/y] y`
	`Preparing to reload device 2!`

Verification	Check whether the relevant supervisor module or device is restarted.

1.5 Monitoring

Displaying

Command	Description
show redundancy states	Displays the redundancy status of dual supervisor modules.

1 Configuring WLAN Hot Standby

1.1 Overview

Wireless LAN (LAN) hot standby is a wireless dual-host hot standby function.

The WLAN hot standby function enables switchover over the Control and Provisioning of Wireless Access Points (CAPWAP) tunnels between access controllers (ACs) and access points (APs) within several milliseconds when the AC is unreachable or faulty, thus ensuring uninterrupted services for associated stations (STAs) to the maximum extent.

Working modes of WLAN hot standby include the active/standby (A/S) mode and the active/active (A/A) mode.

WLAN hot standby is applicable to a reliability-sensitive wireless network.

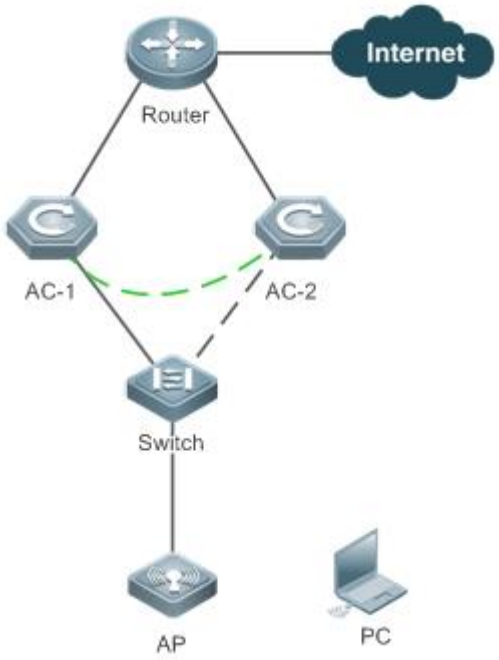
Protocols and Standards

N/A

1.2 Applications

Application	Description
1+1 A/S Networking	Two ACs are deployed. AC-1 and AC-2 are configured as hot standby ACs working in A/S mode.
1+1 A/A Networking	Two ACs are deployed. AC-1 and AC-2 are configured as hot standby ACs working in A/A mode.
N+1 A/S Networking	N+1 ACs are deployed and configured as hot standby ACs working in A/S mode.
Hierarchical AC Networking	A special N+1 networking mode is adopted in hierarchical AC scenarios.

1.2.1 1+1 A/S Networking



Scenario

On a wireless network, two ACs are deployed. One AC works as the active AC and provides services to external entities. The other AC works as the standby AC and receives data synchronized from the active AC.

When the active AC is unreachable due to some reasons (for example, the AC is upgraded and restarted or the power supply of the equipment room is interrupted), the standby AC can take over services from the active AC to ensure that the wireless network is not affected.

As shown in Figure 1-1, when AC-1 is unreachable but the switch and other devices work normally, AC-2 takes over services from AC-1. The wireless network is not affected and can still provide wireless services normally.

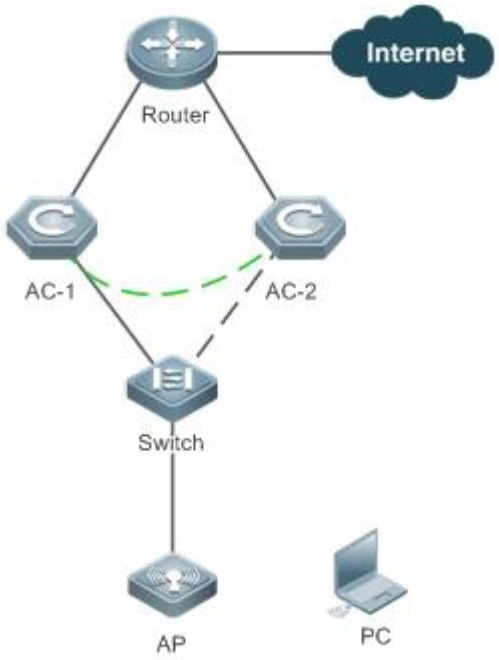
Figure 1-1

Remarks	The router functions as the gateway of STAs. The switch is an aggregation device that functions as the gateway of APs.

Deployment

- Enable the WLAN hot standby function on AC-1 and AC-2, and configure a hot standby instance.
- Add the AP group to which the AP belongs to the WLAN hot standby instance.

1.2.2 1+1 A/A Networking



Scenario

On a wireless network, two ACs are deployed. Both ACs work as the active ACs and provide services to external entities. Both ACs work as the standby AC of the peer AC and receive data synchronized from the peer AC.

When one AC is unreachable due to some reasons (for example, the AC is upgraded and restarted or the power supply of the equipment room is interrupted), the other AC can take over services from the unreachable AC to ensure that the wireless network is not affected.

As shown in Figure 1-2, when AC-1 is unreachable but the switch and other devices work normally, AC-2 takes over services from AC-1. The wireless network is not affected and can still provide wireless services normally.

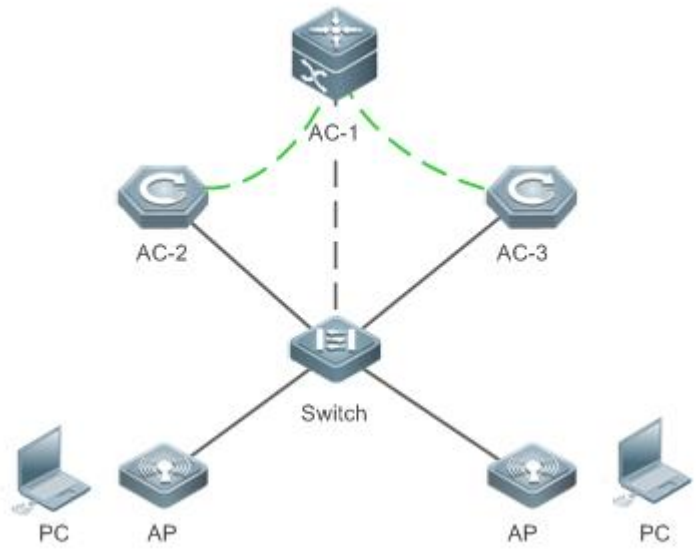
Figure 1-2

Remarks	The router functions as the gateway of STAs. The switch is an aggregation device that functions as the gateway of APs.

Deployment

- Enable the WLAN hot standby function on AC-1 and AC-2, and configure two hot standby instances.
- Add the AP group to which the AP belongs evenly to the two WLAN hot standby instances.

1.2.3 N+1 A/S Networking



Scenario

On the wireless network, N+1 ACs are deployed. *N* ACs work as the active ACs and provide services to external entities. The other AC works as the standby AC and receives data synchronized from the active ACs.

When one active AC is unreachable (for example, the AC is upgraded and restarted or the power supply of the equipment room is interrupted), the standby AC can take over services from the active AC to ensure that the wireless network is not affected.

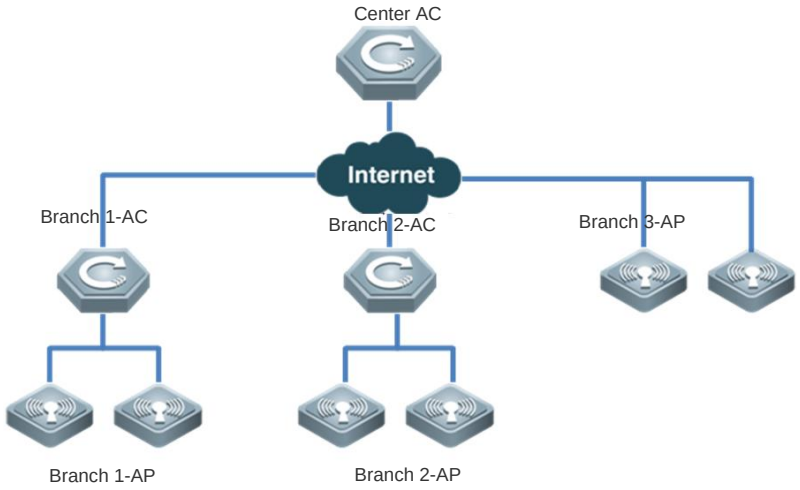
As shown in Figure 1-3, when AC-2 is unreachable but the switch, APs, and other devices work normally, AC-1 takes over services from AC-2. The wireless network is not affected and can still provide wireless services normally.

Figure 1-3

Remarks	The router functions as the gateway of STAs. The switch is an aggregation device that functions as the gateway of APs.

⚠ The N+1 A/S networking mode is not compatible with the 1+1 A/A networking mode.

Deployment



- Enable the WLAN hot standby function on AC-1, and configure two hot standby instances. Enable the WLAN hot standby function on AC-2 and AC-3, and configure a hot standby instance respectively on AC-2 and AC-3.
- Add the AP group to which the AP belongs to the WLAN hot standby instance.

1.2.4 Hierarchical AC Networking

Scenario

Hierarchical AC is a centralized management and distributed forwarding model. In this model, ACs are classified into the center AC and branch ACs. A high-performance AC is deployed at the center, and low-end ACs are deployed at braches. The following figure shows the model.

Figure 1-1

Deployment

- Enable the WLAN hot standby function and configure two hot standby instances on the center AC. Enable the WLAN hot standby function and configure one hot standby instance on Branch 1-AC and Branch 2-AC.
- Configure the center AC and branch ACs.
- Add the AP groups to which the APs belong to the corresponding WLAN hot standby instances.

1.3 Features

Basic Concepts

AC Keepalive Channel

After the hot standby function is enabled, the active AC periodically sends a keepalive packet to the standby AC, and the standby AC determines whether the active AC works normally based on the received keepalive packet. If the standby AC does not receive the packet in five consecutive keepalive periods, the standby AC determines that the active AC is faulty, and then notifies APs to activate the standby CAPWAP tunnel.

The keepalive period between ACs is 10s by default and is configurable.

Active CAPWAP Tunnel

To support the hot standby function, an AP must set up CAPWAP tunnels with two ACs that are configured with the hot standby relationship. The CAPWAP tunnel between the AP and the active AC is activated, and is called active CAPWAP tunnel.

Standby CAPWAP Tunnel

The CAPWAP tunnel between an AP and the standby AC is called standby CAPWAP tunnel. The standby CAPWAP tunnel is not used for communication between the AP and AC.

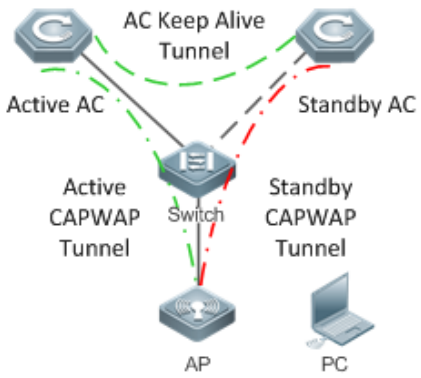
Hot Standby Instance

In A/A mode, the role of an AC varies according to APs. An AC that sets up an active CAPWAP tunnel with an AP serves as the active AC of the AP. An AC that sets up a standby CAPWAP tunnel with an AP serves as the standby AC of the AP. The AC with different roles must perform different backup operations, so different hot standby instances must be configured on the AC.

Overview

Feature	Description
Configuring	Enable the hot standby function to synchronize data.
Configuring Hierarchical AC	Configure WLAN hot standby connections in hierarchical AC networking.

1.3.1 Configuring Hot Standby



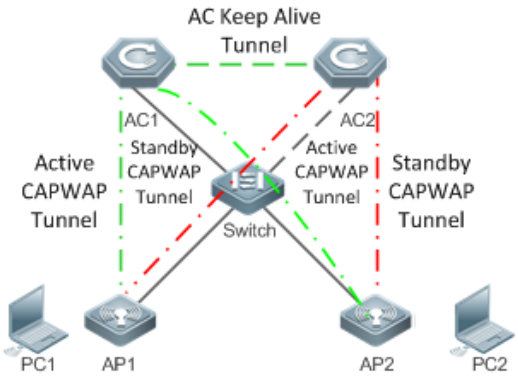
Configure addresses of hot standby neighbors and instances, and bind AP groups, DHCP address pool, and VRRP groups with the corresponding instances so that the hot standby function is enabled on the AP groups, DHCP address pool, and VRRP groups to support data synchronization and switchover.

Working Principle

The WLAN hot standby detection packet is a UDP packet, and the port ID is 7425. The control channel packet is a TCP packet, and the port ID is 6435. The data channel packet is a TCP packet, and the port ID is 6425. The heartbeat keepalive packet is an IP packet by default and can be configured as the UDP packet, the protocol field is 0, and the port ID is 7435.

WLAN hot standby enables switchover of the CAPWAP tunnels between ACs and APs within several milliseconds when an AC is unreachable or faulty, thus ensuring uninterrupted services for associated STAs to the maximum extent. Figure 1-4 shows the working principle of the WLAN hot standby function.

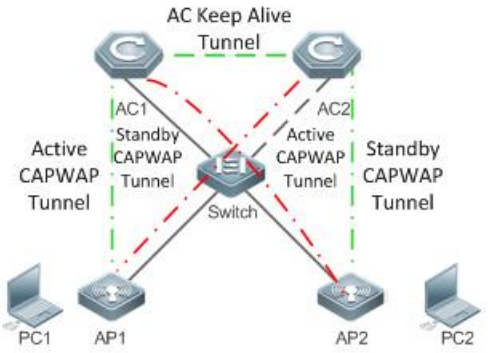
Figure 1-4 WLAN Hot Standby



- Two ACs determine the active and standby roles through negotiation, and the keepalive mechanism is used between ACs.
- The AP sets up an active CAPWAP tunnel with the active AC and a standby CAPWAP tunnel with the standby AC.
- A STA is associated with the AP.
- The user communicates with external entities through the active CAPWAP tunnel.

- When the active AC is faulty, the standby AC detects the keepalive timeout event and immediately notifies the AP.
- The standby CAPWAP tunnel is activated, and the standby AC becomes the active AC.
- User's services are restored after the standby CAPWAP tunnel is activated.
- When the original active AC is restored, it sets up the hot standby relationship with the new active AC again. Then the original active AC becomes the standby AC and sets up a standby CAPWAP tunnel with the AP. In this way, ensuring service continuity.

Working modes of WLAN hot standby include the A/S mode and the A/A mode.



In A/S mode, one AC is the active AC, and the other AC is the standby AC. The active AC processes all services and transfers service status information to the standby AC for backup. The standby AC does not process services, and only backs up service data. In A/S mode, all the APs set up active CAPWAP tunnels with the active AC and standby CAPWAP tunnels with the standby AC. When both ACs work normally, all services are processed by the active AC. When the active AC is faulty, the standby AC takes over all services.

Figure 1-5 WLAN Hot Standby in A/S Mode

In A/A mode, both ACs are active ACs and process services, and serve as the standby AC of the other AC and back up service status information of the other AC. In A/A mode, some APs set up active CAPWAP tunnels with AC1, and standby CAPWAP tunnels with AC2. Other APs set up active CAPWAP tunnels with AC2, and standby CAPWAP tunnels with AC1. When both ACs work normally, the two ACs process services of APs with which active CAPWAP tunnels are set up. When AC1 is faulty, APs that set up active CAPWAP tunnels with AC1 switch over services to standby CAPWAP tunnels, and then AC2 processes services of all APs.

Figure 1-6 WLAN Hot Standby in A/A Mode

1.3.2 Configuring Hierarchical AC

Working Principle

Hierarchical AC is a special N+1 networking mode. In normal cases, the center AC is a high-performance AC and deployed at the center and branch ACs are deployed at branches. Hierarchical AC ensures unified upgrade, disaster recovery, unified management, and license sharing.

In hierarchical AC scenarios, the cold mode is added, which indicates lightweight data backup. In cold mode, most data backup with the peer is forbidden and only little data transmission is reserved. When traffic of the center AC is heavy, configure the working mode as cold to reduce the load of the center AC. In cold mode, when a branch AC is faulty, STAs need to be re-associated and STAs' IP addresses need to be obtained again for authentication. In cold mode, unified upgrade, unified management, and license sharing are reserved.

1.4 Configuration

Configuration	Description and Command	
Configuring the Hot Standby Function	(Mandatory) It is used to enable the hot standby function.	
	wlan hot-backup	Configures a hot standby neighbor.
	instance	Configures a hot standby instance.
	wlan hot-backup enable	Enables the hot standby function.
	(Optional) It is used to adjust the hot standby connection parameters.	
	local-ip	Configures the IP address of the local AC for the hot standby function.
	work-mode	Configures the hot standby working mode.
	hello-interval	Configures the heartbeat keepalive period for the hot standby function.
	kplv-pkt	Configures the format of the heartbeat keepalive packet for hot standby.

Configuration	Description and Command	
	priority level	Configures the priorities of instances.
	ap-group	Binds an AP group with an instance.
	dhcp-pool	Binds a DHCP address pool with an instance.
	dhcpv6-pool	Binds a DHCPv6 address pool with an instance.
	vrrp interface group	Binds a VRRP group with an instance.
	description	Configures the description for a hot standby peer.
Configuring Hierarchical AC	(Mandatory) It is used to enable the hierarchical AC function.	
	wlan hot-backup [**center** | **branch**]	Configures Hierarchical AC Roles.
	(Optional) It is used to set the lightweight backup mode.	
	work-mode cold	Configures Hierarchical AC Roles.

1.4.1 Configuring the Hot Standby Function

Configuration Effect

- Configure a hot standby connection to provide the hot standby service for other modules.

Notes

- After the hot standby function is enabled, the hot standby related configurations cannot be modified.

Configuration Step

Configuring Basic Information about Hot Standby

- Mandatory. The configuration is performed on the AC.
- Run the **wlan hot-backup** command to configure a hot standby neighbor. Unless otherwise specified, you must configure a hot standby neighbor on both ACs. Enter the hot standby configuration mode, and configure the working mode and instance for the hot standby function.
- In the hot standby configurations, the peer IP address is the loopback IP address of the peer AC. Ensure that the loopback IP address is correctly configured; otherwise, hot standby may become unavailable. In addition, configure routes to ensure that loopback IP addresses of the local and peer ends can be pinged successfully from each other.
- Run the **instance** command to configure an instance. Unless otherwise specified, you must configure the same instance on both ACs.

Command	**wlan hot-backup** *ip-address*
Parameter Description	*ip-address*: Indicates the IP address of the peer AC.
Defaults	No hot standby neighbor is configured.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**instance** *instance-id*
Parameter Description	*instance-id*: Indicates the ID of the instance.
Defaults	N/A
Command Mode	Hot standby configuration mode
Usage Guide	The value range is 0 to 65,535. In hierarchical AC scenarios, the value is 0-0.

Adjusting Hot Standby Parameters

- Optional. The configuration is performed on the AC.
- Run the **local-ip** command to configure the IP address of the local AC for hot standby. By default, the IP address of Loopback 0 on the AC is used. You can configure another IP address of the AC for setting up a hot standby relationship with the peer AC.
- Run the **work-mode** command to configure the hot standby working mode. Hot standby is switched to the quick switchover mode only when necessary, for example, in the onsite test environment. Two hot standby working modes are available:
  - Quick switchover mode: It is used in performance switchover scenarios that require sensitive detection and quick switchover, such as system demonstration and performance test. The default detection period is 10 ms.
  - Normal switchover mode: It is used in real-world application scenarios that require stable running and avoid hot standby flapping. The default detection period is 2s.
- Run the **hello-interval** command to configure the heartbeat keepalive period for the hot standby function. If quick switchover is required, you can set a short heartbeat keepalive period to accelerate hot standby detection and switchover. A shorter heartbeat keepalive period indicates that disconnection can be detected faster and it is easier to trigger a switchover. A longer heartbeat keepalive period indicates that the hot standby relationship is more stable.
- Run the **kplv-pkt** command to configure the format of heartbeat keepalive packets. If Network Address Translation (NAT) is deployed between ACs, IP packets are not allowed to be routed to the NAT device, which is limited by the intermediate NAT device. You can run this command to change the format of heartbeat keepalive packets to the UDP packets to ensure that the heartbeat channel is set up for hot standby.
- Run the **priority level** command to configure the priority of an instance. If an AC must be preferentially selected as the active AC, the hot standby priority of this AC must be increased. If an AC is required to support the switchback function, the hot standby priority of this AC must be set to 7.
- If the priority of an AC is high, the AC will be preferentially selected as the active AC when the hot standby connection is set up for the first time. If the AC with the priority of 7 is selected as the standby AC and completes batch backup of data, a hot standby switchback will be performed and this AC will be changed to the active AC again. To perform hot standby switchback, ensure that all APs that are connected to the peer AC also set up connections to the local AC. If this condition is met and the AC with the priority of 7 is selected as the standby AC, a hot standby switchback will be performed within the minimum switchover time (10 minutes by default, which is configurable) after batch backup is completed. Otherwise, a switchback will be performed forcibly 45 minutes after batch backup is completed. Some STAs may go offline due to the forced switchback.

Command	**local-ip** *ip-address*

Parameter Description	*ip-address*: indicates the IP address of the local AC.
Defaults	The IP address of Loopback 0 is used by default.
Command Mode	Hot standby configuration mode
Usage Guide	When the IP address of the local AC changes, the hot standby connection will be ended, and then the new IP address of the local AC will be used to set up a hot standby connection.

Command	**work-mode** [**normal** | **quick-switch** | **cold**]
Parameter Description	**normal**: Indicates the normal switchover mode. **quick-switch**: Indicates the quick switchover mode. **cold**: Indicates lightweight backup in HAC scenarios.
Defaults	normal
Command Mode	Hot standby configuration mode
Usage Guide	N/A

Command	**hello-interval** *hellointerval*
Parameter Description	*hellointerval*: Indicates the heartbeat keepalive period, in milliseconds. The value range is from 10 to 600000.
Defaults	The default value is related to the working mode. In normal mode, the default value is 2s (2000 ms). In quick switchover mode, the default value is 10 ms. After the hierarchical AC function is configured, the default value is 30s (30000 ms).
Command Mode	Hot backup configuration mode
Usage Guide	The value range is from 10 to 600000. In hierarchical AC scenarios, the value range is from 30000 to 600000.

Command	**kplv-pkt** [**ip** | **udp**]
Parameter Description	**ip**: Indicates that the heartbeat keepalive packet is an IP packet. **udp**: Indicates that the heartbeat keepalive packet is a UDP packet.
Defaults	IP packet
Command Mode	Hot standby configuration mode
Usage Guide	N/A

Command	**description** *name*
Parameter Description	*name*: Indicates the name of the hot standby peer.
Defaults	No name is configured.
Command	Hot standby configuration mode

Mode	
Usage Guide	N/A

Command	**priority level** *priority*
Parameter Description	*priority*: indicates the hot standby priority.
Defaults	The hot standby priority is 4 by default. In hierarchical AC scenarios, the hot standby priority is 7 for a branch AC.
Command Mode	Hot standby instance mode
Usage Guide	The value range is from 0 to 7. The default priority is 4, and the highest priority is 7. In hierarchical AC scenarios, the hot standby priority is 7 for a branch AC.

Binding the Hot Standby Function to an Instance

- Optional. The configuration is performed on the AC.
- Run the **ap-group** command to bind an AP group to a hot standby instance. After the AP group is bound to the hot standby instance, data of STAs associated with APs in the AP group can be synchronized from the active AC to the standby AC.
- Run the **dhcp-pool** command to bind a DHCP address pool with a hot standby instance. If IP addresses of STAs are on the hot standby AC, you need to bind the DHCP address pool to realize synchronization of DHCP entries between the active and standby ACs. After the DHCP address pool is bound to the instance, allocated IP addresses in this DHCP address pool can be synchronized from the active AC to the standby AC.
- Run the **dhcpv6-pool** command to bind a DHCPv6 address pool to a hot standby instance. If IP addresses of STAs are on the hot standby AC, you need to bind the DHCPv6 address pool to realize synchronization of DHCPv6 entries between the active and standby ACs. After the DHCPv6 address pool is bound to the instance, allocated IP addresses in this DHCPv6 address pool can be synchronized from the active AC to the standby AC.
- Run the **vrrp interface** command to bind a VRRP group to an instance if 802.1X or web-based authentication must support the hot standby function. After a VRRP group is bound to an instance, the virtual IP addresses in this VRRP group will determine the active/standby relationship based on the hot standby status.

Command	**ap-group** *ap-group*
Parameter Description	*ap-group*: Indicates the name of an AP group.
Defaults	No AP group is bound.
Command Mode	Hot standby instance mode
Usage Guide	N/A

Command	**dhcp-pool** *pool-name*
Parameter Description	*pool-name*: Indicates the name of a DHCP address pool.
Defaults	No DHCP address pool is bound.

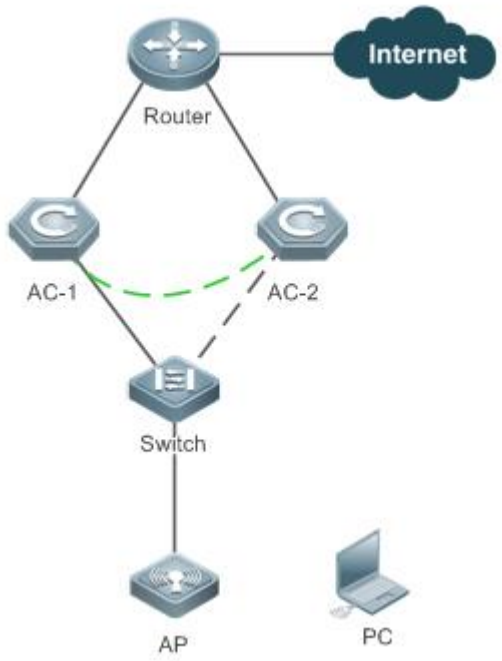
Command Mode	Hot standby instance mode
Usage Guide	You can run the **show wlan hot-backup dhcp-pool config** command to check the binding configuration of a DHCP address pool.

Command	**dhcpv6-pool** *pool-name*
Parameter Description	*pool-name*: Indicates the name of a DHCPv6 address pool.
Defaults	No DHCPv6 address pool is bound.
Command Mode	Hot standby instance mode
Usage Guide	You can run the **show wlan hot-backup dhcpv6-pool config** command to check the binding configuration of a DHCPv6 address pool.

Command	**vrrp interface** *interface-name* **group** *vrrp-group*
Parameter Description	*interface-name*: Indicates the interface corresponding to the VRRP group. *vrrp-group*: Indicates the ID of a VRRP group.
Defaults	No VRRP group is bound.
Command Mode	Hot standby instance mode
Usage Guide	You can run the **show wlan hot-backup vrrp config** command to check the binding configuration of a VRRP group.

Enabling Hot Standby

- Mandatory. The configuration is performed on the AC.
- Unless otherwise specified, the hot standby function must be enabled on both ACs; otherwise, the hot standby function cannot take effect.
- You must ensure consistency in configurations of the two ACs that establish the hot standby relationship. In particular, the configuration sequence of interface-mapping configured in AP group configuration mode must be the same on both ACs.

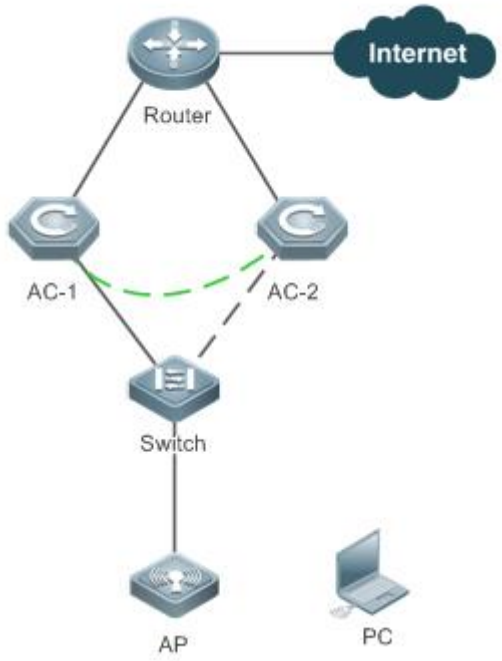


Command	**wlan hot-backup enable**
Parameter Description	N/A
Defaults	The hot standby function is disabled by default.
Command Mode	Hot standby configuration mode
Usage Guide	N/A

Verification

On the two ACs, check whether the hot standby connection is set up normally, and whether the hot standby status is normal.

Configuration Example



1+1 A/S Networking

Scenario **Figure 1-7**	
Configuration Steps	● Configure the peer IP addresses, including the IP address 192.168.1.100 of AC-1 and the IP address 192.168.1.200 of AC-2. ● Configure a hot standby instance. In the 1+1 A/S networking mode, configure only one instance on the two ACs, respectively. Note that the instance IDs configured on both ACs must be the same. ● Configure the priority of AC-1 for the hot standby instance. ● Configure the associated AP group. Bind the associated AP group **apg-a** to instance 10 on both ACs. ● Configure the VRRP group. In 1+1 A/S networking mode, both ACs have only one instance, and the two instances are in pairs. Therefore, you only need to configure one VRRP group, for example, VRRP group 1. Configure VRRP group 1 on the interface of VLAN 2 on two ACs, respectively. ● Enable the hot standby function.

AC-1	`AC-1# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC-1(config)# wlan hot-backup 192.168.1.200`
	`AC-1(config-hotbackup)# context 10`
	`AC-1(config-hotbackup-ctx)# priority level 7`
	`AC-1(config-hotbackup-ctx)# ap-group apg-a`
	`AC-1(config-hotbackup-ctx)# vrrp interface vlan 2 group 1`
	`AC-1(config-hotbackup-ctx)# exit`
	`AC-1(config-hotbackup)# wlan hot-backup enable`

AC-2	AC-2# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-2(config)# wlan hot-backup 192.168.1.100 AC-2(config-hotbackup)# context 10 AC-2(config-hotbackup-ctx)# ap-group apg-a AC-2(config-hotbackup-ctx)# vrrp interface vlan 2 group 1 AC-2(config-hotbackup-ctx)# exit AC-2(config-hotbackup)# wlan hot-backup enable
Verification	After the hot standby relationship is set up between AC-1 and AC-2, check the hot standby configuration.
AC-1	AC-1# show wlan hot-backup wlan hot-backup peer list: ip address hot-backup state description ------------------- ------------------- ------------------- ------------ 192.168.1.200 Enable CHANNEL_UP AC-1# show wlan hot-backup 192.168.1.200 wlan hot-backup 192.168.1.200 hot-backup : Enable connect state : CHANNEL_UP hello-interval : 2000 kplv-pkt : ip ! context 10 hot-backup role : PAIR-ACTIVE hot-backup rdnd state : REALTIME-SYN hot-backup priority : 7
AC-2	AC-2# show wlan hot-backup wlan hot-backup peer list: ip address hot-backup state description ------------------- ------------------- ------------------- ------------ 192.168.1.100 Enable CHANNEL_UP AC-2# show wlan hot-backup 192.168.1.100 wlan hot-backup 192.168.1.100 hot-backup : Enable connect state : CHANNEL_UP hello-interval : 1000 kplv-pkt : ip ! context 10 hot-backup role : PAIR-STANDBY hot-backup rdnd state : REALTIME-SYN hot-backup priority : 4

1+1 A/A Networking

Scenario **Figure 1-8**	
Configuration Steps	● Configure the peer IP addresses, including the IP address 192.168.1.100 of AC-1 and the IP address 192.168.1.200 of AC-2. ● Configure the instances and bind AP groups to instances. In 1+1 A/A networking mode, two instances must be configured and respectively bound to two AP groups on each of the two ACs. ● Configure VRRP groups. In 1+1 A/A networking mode, configure two instances on each of the two ACs. Assume that VRRP group 1 is configured on interfaces of VLAN 1 on AC-1 and AC-2, and VRRP group 2 is configured on interfaces of VLAN 2 on AC-1 and AC-2. Bind VRRP group 1 to instance 10, and VRRP group 2 to instance 20. ● Configure hot standby priorities. For instance 10, AC-1 is the active AC and therefore should be configured with the highest priority. For instance 20, AC-2 is the active AC and therefore should be configured with the highest priority. ● Enable the hot standby function.
AC-1	AC-1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-1(config)# wlan hot-backup 192.168.1.200 AC-1(config-hotbackup)# context 10 AC-1(config-hotbackup-ctx)# ap-group apg-a AC-1(config-hotbackup-ctx)# vrrp interface vlan 1 group 1 AC-1(config-hotbackup-ctx)# priority level 7 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# context 20 AC-1(config-hotbackup-ctx)# ap-group apg-b AC-1(config-hotbackup-ctx)# vrrp interface vlan 2 group 2 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable

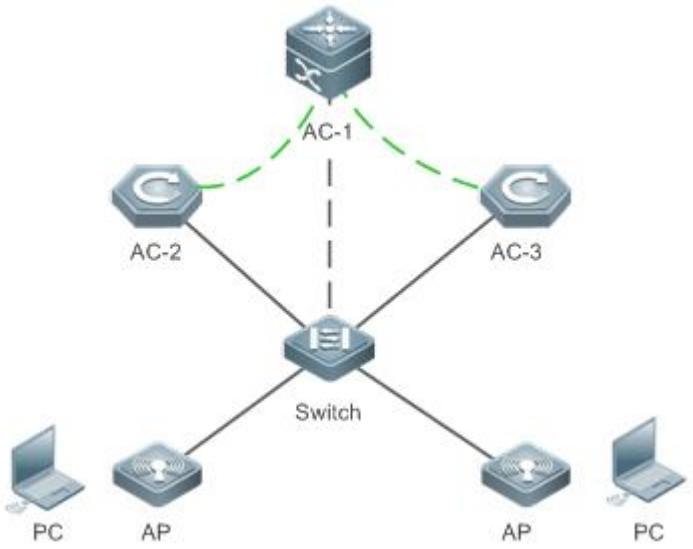
AC-2

```
AC-2# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
AC-2(config)# wlan hot-backup 192.168.1.100
AC-2(config-hotbackup)# context 10
AC-2(config-hotbackup-ctx)# ap-group apg-a
AC-2(config-hotbackup-ctx)# vrrp interface vlan 1 group 1
AC-2(config-hotbackup-ctx)# exit
AC-2(config-hotbackup)# context 20
AC-2(config-hotbackup-ctx)# ap-group apg-b
AC-2(config-hotbackup-ctx)# vrrp interface vlan 2 group 2
AC-2(config-hotbackup-ctx)# priority level 7
AC-2(config-hotbackup-ctx)# exit
AC-2(config-hotbackup)# wlan hot-backup enable
```

Verification

After the hot standby relationship is set up between AC-1 and AC-2, check the hot standby configurations.

AC-1



```
AC-1# show wlan hot-backup
wlan hot-backup peer list:
ip address           hot-backup           state                description
-------------------- -------------------- -------------------- ------------
192.168.1.200        Enable               CHANNEL_UP
AC-1# show wlan hot-backup 192.168.1.200
wlan hot-backup 192.168.1.200
  hot-backup     : Enable
  connect state  : CHANNEL_UP
  hello-interval : 2000
  kplv-pkt       : ip
  !
  context 10
    hot-backup role        : PAIR-ACTIVE
    hot-backup rdnd state  : REALTIME-SYN
    hot-backup priority    : 7
  !
  context 20
    hot-backup role        : PAIR-STANDBY
    hot-backup rdnd state  : REALTIME-SYN
    hot-backup priority    : 4
```

AC-2

```
AC-2# show wlan hot-backup
wlan hot-backup peer list:
ip address           hot-backup           state                description
-------------------- -------------------- -------------------- -----------
192.168.1.100        Enable               CHANNEL_UP

N+1 A/S Networking

Scenario **Figure 1-9**	
Configuration Steps	● Configure the peer IP addresses, including the IP address 192.168.1.100 of AC-1, IP address 192.168.1.200 of AC-2, and IP address 192.168.1.300 of AC-3. Configure two peer IP address on AC-1, and different peer IP addresses correspond to different instances. ● Configure the instances and bind AP groups to the instances. In N+1 A/S networking mode, one instance is configured on each of *N* ACs, and bound to the corresponding AP group. On the standby AC (AC-1 in this example), *N* instances must be configured and bound to AP groups on the corresponding active ACs. The AP groups configured on the *N* active ACs cannot conflict with each other. ● Configure VRRP groups. In N+1 A/S networking mode, one VRRP group must be configured on each of *N* active ACs, and *N* VRRP groups must be configured on the standby AC. ● Configure hot standby priorities. In N+1 A/S networking mode, the priorities of instances on the *N* active ACs must be set to the highest priority, and the priorities of instances on the standby AC can be set to the default value 4.

AC-1	AC-1# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC-1(config)# wlan hot-backup 192.168.1.200 AC-1(config-hotbackup)# context 10 AC-1(config-hotbackup-ctx)# ap-group apg-a AC-1(config-hotbackup-ctx)# vrrp interface vlan 1 group 1 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable AC-1(config-hotbackup)# exit AC-1(config)# wlan hot-backup 192.168.1.300 AC-1(config-hotbackup)# context 20 AC-1(config-hotbackup-ctx)# ap-group apg-b AC-1(config-hotbackup-ctx)# ap-group apg-c AC-1(config-hotbackup-ctx)# vrrp interface vlan 2 group 2 AC-1(config-hotbackup-ctx)# exit AC-1(config-hotbackup)# wlan hot-backup enable

Common Errors

- N/A

1.4.2 Configuring Hierarchical AC

Configuration Effect

Establish hot standby connections in hierarchical AC scenarios.

Notes

- The hierarchical AC roles (center AC and branch ACs) must be configured.
- After the hot standby function is enabled for a branch, the hierarchical AC role and working mode cannot be changed.
- In hierarchical AC scenarios, changing the forwarding mode may lead to disconnection and reconnection of the hot standby channel. The hot standby channel cannot be established in central forwarding mode.
- In hierarchical AC scenarios, the quick switchover mode is not supported and the minimum value of **hello-interval** is 30s.

Configuration Steps

↘ Configuring Hierarchical AC Roles

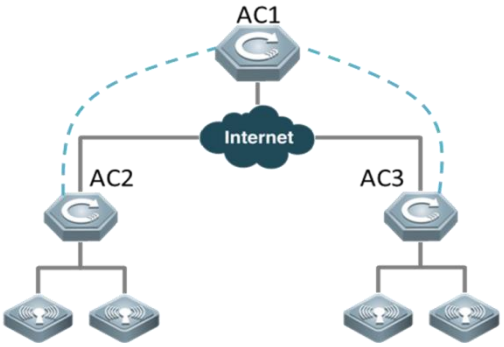
Hierarchical AC roles must be configured in hierarchical AC scenarios.

Command	**wlan hot-backup** [**center** | **branch**]
Parameter Description	**center**: Indicates the center AC. **branch**: Indicates the branch AC.
Defaults	No hierarchical AC role is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring the Cold Mode in Hierarchical AC Scenarios

- Configure the cold mode on branch ACs that require lightweight backup.

- In cold mode, most data backup with the peer is forbidden and only little data transmission is reserved. When traffic of the center AC is heavy, configure the working mode as cold to reduce the load of the center AC. In cold mode, when a branch AC is faulty, STAs need to be re-associated and STAs' IP addresses need to be obtained again for authentication.



Command	**work-mode cold**
Parameter Description	N/A
Defaults	The working mode is normal by default.
Command Mode	Hot standby configuration mode
Usage Guide	N/A

Verification

On the center AC and branch ACs, check whether the hot standby connection is normally established and the hot standby status is normal.

Configuration Example

Hierarchical AC Networking

Scenario	
Figure 1-2	
Configuration Steps	• Configure hierarchical AC roles. Configure AC-1 as the center AC and AC-2 and AC-3 as branch ACs. • Configure peer IP addresses. The IP address of center AC-1 is 192.168.1.100, the IP address of branch AC-2 is 192.168.1.200, and the IP address of branch AC-3 is 192.168.1.300. Two peer IP addresses need to be configured on AC-1. Different peer IP addresses correspond to different configuration space. • Configure description of AC-2 as RD-Office and that of AC-3 as HR-Office. • Configure the working mode on AC-3 as cold. • Configure hot standby priorities. In N+1 A/S mode, the highest priority needs to be configured for hot standby instances on branch ACs, and the default priority 4 is configured for the hot standby instances on the center AC.

AC-1	`AC-1# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC-1(config)# wlan hot-backup center`

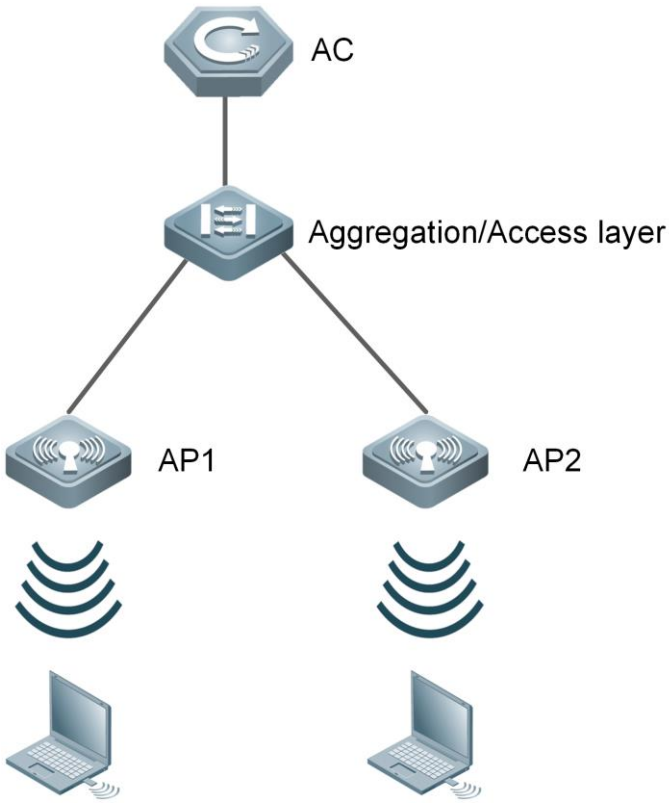
1.5 Monitoring

Displaying

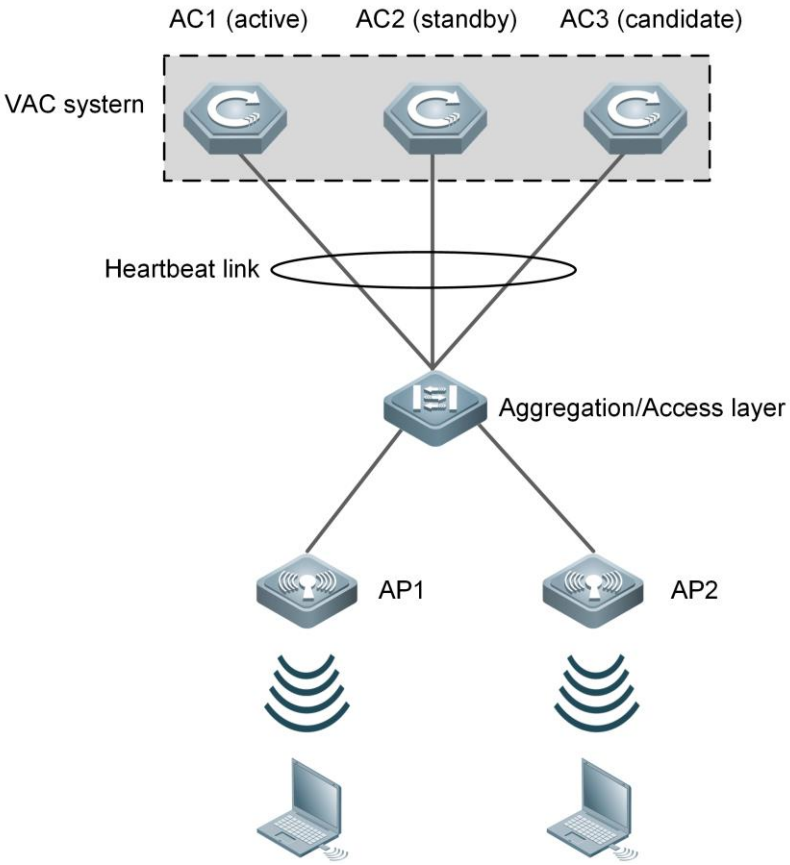
Command	Description
show wlan hot-backup [*ip-address*]	Displays the global AC hot standby configuration.
show wlan hot-backup dhcp-pool config *ip-address*	Displays the instance binding configuration of the DCHP address pool and the neighbor address.
show wlan hot-backup dhcpv6-pool config *ip-address*	Displays the instance binding configuration of the DCHPv6 address pool and the neighbor address.
show wlan hot-backup vrrp config *ip-address*	Displays the binding configuration between VRRP groups and instances for the neighbor addresses.



1 Configuring VAC

1.1 Overview

In an AC+fit AP distributed network, there are thousands of and even tens of thousands of APs. How to guarantee reliability of wireless access is essential on a large-scale network.



In existing AC+fit AP networking mode, an AP discovers the AC through the Control and Provisioning of Wireless Access Points (CAPWAP) protocol. The AP can receive services from the AC only after being successfully registered and associated with the AC. As a result, the process in which an AP detects whether the AC is faulty through CAPWAP keepalive packets is time-consuming. If an AC malfunctions, all APs need to re-register with another AC. The incurred network interruption duration imposes great impact on enterprises. How to shorten the switch time to reduce impact on the network is an issue to be urgently resolved.

Figure 4-1 Conventional Network Architecture

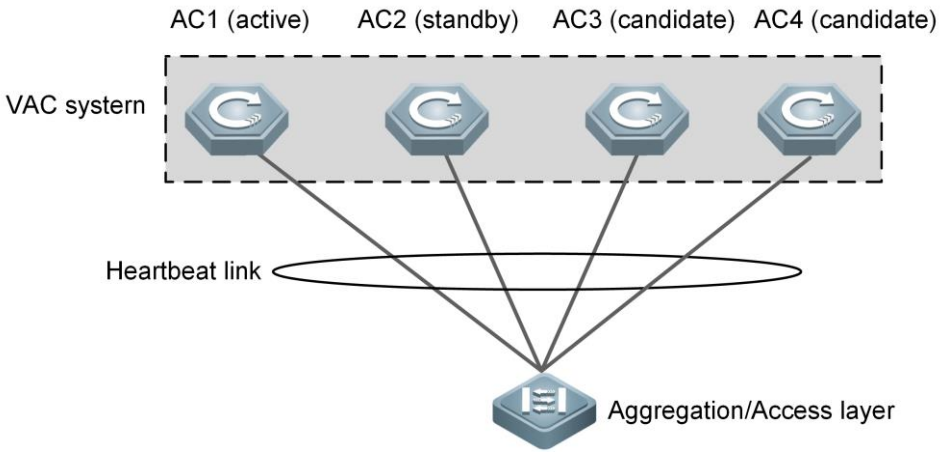
Virtual AC (VAC) is a network system virtualization technology that virtualizes multiple ACs into one virtual device. As shown in Figure 4-2, multiple ACs of the same model can form a VAC system. Compared with the conventional networking mode, this networking simplifies the network topology, reduces network management and maintenance costs, shortens the application recovery time and service interruption time, and improves network resource utilization.

Figure 4-2 VAC Networking Mode

1.2 Applications

Application	Description
Managing Multiple Devices	Multiple physical devices compose one logical device for unified management.
Improving the AC's Reliability	Multiple devices are available for fast switching, thereby improving reliability.

1.2.1 Managing Multiple Devices Uniformly



Scenario

When multiple physical devices compose a VAC system, the VAC system can be considered as one logical device. All configurations are managed on the active device.

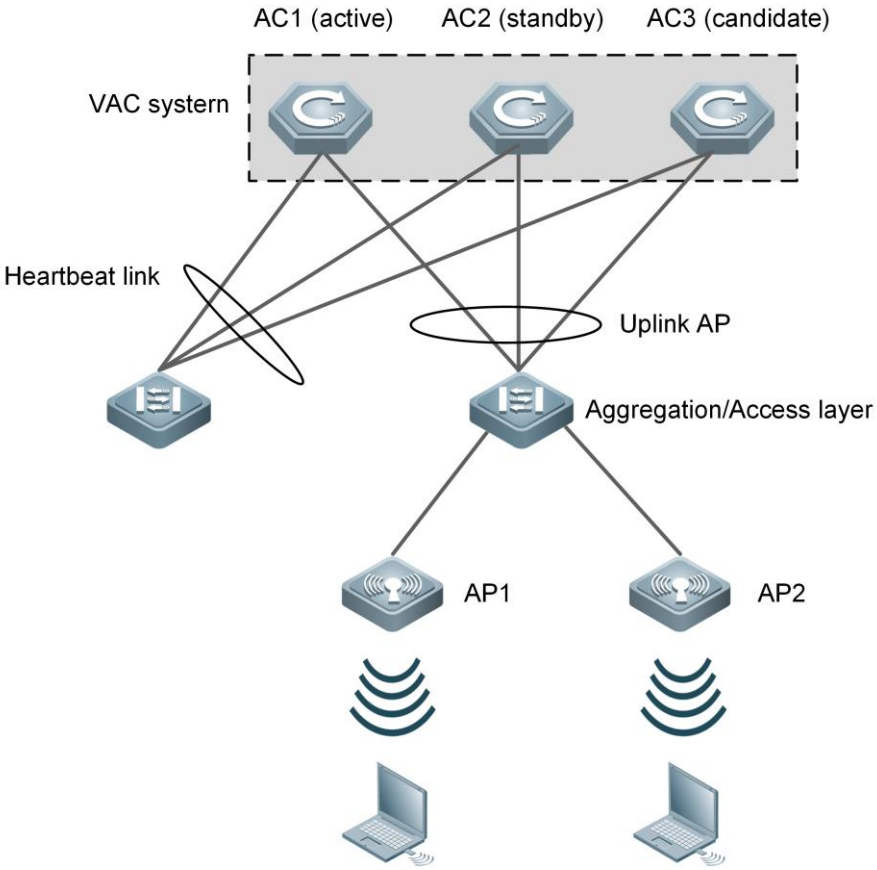
As shown in Figure 4-3, four devices (numbered 1, 2, 3, and 4 from left to right in sequence) constitute a VAC system. Device 1 is the active device, Device 2 is the standby device, and Device 3 and Device 4 are candidate devices.

- Configurations only need to be performed on the active device for device management.

Figure 4-3

Deployment

- The active device is responsible for controlling the VAC system. It runs management plane and control plane protocols and participates in data forwarding.
- The standby device is responsible for running control plane protocols, participating in data forwarding, and taking over the work of the active device when the active device malfunctions.
- Candidate devices are responsible for running control plane protocols and participating in data forwarding. When the standby device malfunctions, a candidate device can take over the work of the standby device and serves as the standby device. A candidate device cannot take over the work of the active device. Therefore, when both the active device and standby device malfunction, the VAC system restarts.
- Control plane protocols back up each other among devices.



1.2.2 Improving the AC's Reliability

Scenario

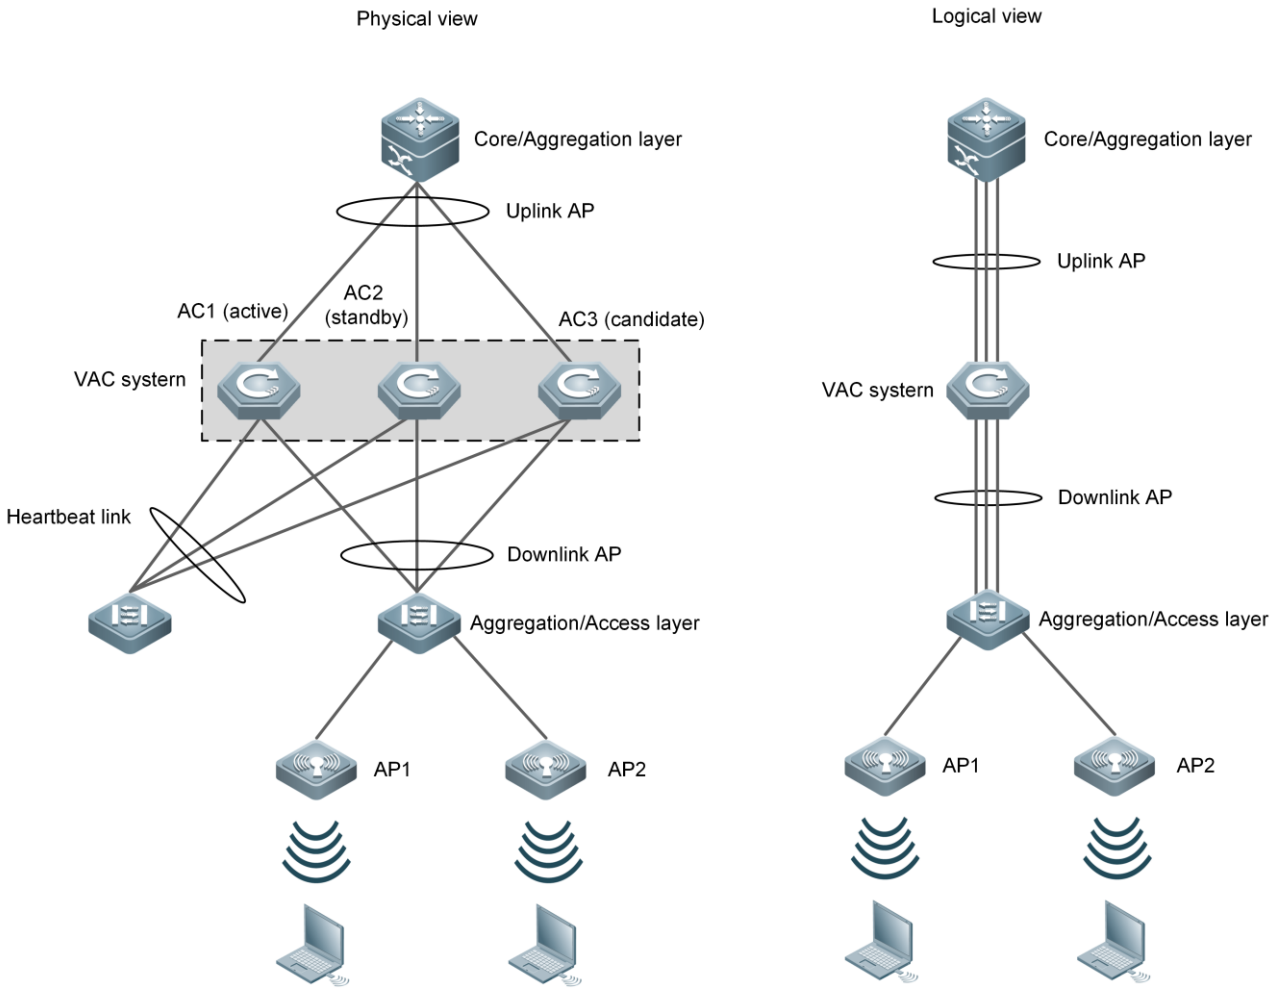
As shown in Figure 4-4, when the AC malfunctions, all APs registered with the AC are disconnected. The APs need to rediscover another AC and complete registration so as to reconnect to the network. All devices in a VAC system are considered as one logical device. A device in the VAC system mutually serves as a backup of other devices. When one device malfunctions, services and data can be rapidly migrated to another device.

- Multiple ACs form a VAC system and the ACs provide redundancy. System management is conducted on the active device.
- A heartbeat link is configured between ACs to provide a data channel and exchange data. ACs are connected to the access/aggregation layer through the uplink AP.
- When one device in a VAC system malfunctions, other devices work properly.

Figure 4-4

Deployment

- The active device is responsible for managing the entire VAC system, running management plane and control plane protocols, and participating in data forwarding.
- The standby device is responsible for participating in data forwarding, running control plane protocols, and taking over the work of the active device when the global active device malfunctions.
- The heartbeat link occupies an independent interface on the AC, and services are not configured on the interface.



1.3 Features

Basic Concepts

↘ VAC System

A VAC system is a single logical entity composed of multiple independent ACs in the conventional network architecture that are connected through internal heartbeat links. A VAC system can be considered as an independent AC for management.

Figure 4-5 VAC System

Domain ID

A VAC system has a unique domain ID. Only devices with the same domain ID can form a VAC system.

Device ID

Each member device in a VAC system has a unique device ID. This device ID facilitates management on member devices. When adding a device to a VAC system, you need to configure a device ID for the device and ensure that the device ID is unique in the VAC system. If device IDs of member devices conflict in a VAC system, one member device is retained according to the priority.

Device Role

When a VAC system is built, one device is elected as the active device, another device is elected as the standby device according to the election protocol mechanism, and other devices serve as candidate devices. The active device is responsible for controlling the entire VAC system, running management plane protocols of the VAC system, running the control plane protocols of the active device, and participating in data forwarding. The standby device and candidate devices run their respective control plane protocols and participate in data forwarding. When the active device fails, the standby device serves as the active device to manage the VAC system.

The active device of a VAC system is elected as follows:

1 The rules for active device election are as follows (if the active device cannot be elected according to the previous rule, the next rule is used):

2 The current running device is elected as the active device preferentially (no device is the active device during startup).

3 A member device with the highest priority is elected as the active device.

4 A member device with a smaller device ID is elected as the active device.

5 A member device with a smaller MAC address is elected as the active device.

6 The VAC system allows a device to be added in hot mode. The system does not perform an active/standby switchover even if a device that joins the VAC system in hot mode has a higher priority than the active device in the VAC system.

7 The startup sequence of member devices may affect election of the active device. Some member devices may not join the VAC system in a timely manner due to slow startup (the VAC system directly conducts convergence if it does not discover a neighbor within 5 minutes). In this case, the member device will join the VAC system in hot mode. Even if its priority is higher than the running active device in the VAC system, the system does not perform an active/standby switchover.

Overview

Feature	Description
Heartbeat Link	Describes features of the heartbeat link of the VAC system.
Topology	Describes the topology of the VAC system.
Dual-Active Detection	Prevents dual active devices in the same VAC system.
Traffic Forwarding	An AP binds multiple physical connections to form a logical connection.
System Management	Manages devices in the VAC system.
Standby Device Preemption	The VAC system supports the standby device preemption function. If a new device that joins the VAC system has a higher priority than the existing standby device in the VAC system, the new device will preempt the standby device role.

1.3.2 Heartbeat Link

Working Principle

↘ Heartbeat Link

The active and standby devices in a VAC system are network entities and need to transmit management information to each other. Heartbeat links are used for transmitting management information (including role election and configuration backup information) and data streams between devices in the VAC system. You can configure one or more heartbeat links between two member devices of a VAC system. Two heartbeat links are recommended for scenarios demanding high reliability.

After the VAC system is established, if one heartbeat link fails, the VAC system automatically adjusts the configuration so that the backup traffic is not transmitted through the failed link.

If all heartbeat links are disconnected, the topology of the VAC system is split, and the standby device automatically becomes the active device. The configurations of the two devices are the same, which will trigger dual-active detection. One of the two active devices will enter the recovery state and the service interface on the device is disabled, preventing the impact on services on the user network.

If the active device malfunctions, the standby device can detect the fault of the active device through the heartbeat link, automatically becomes the active device, and takes over services.

Heartbeat links can be directly connected or connected through a Layer 2 switch.

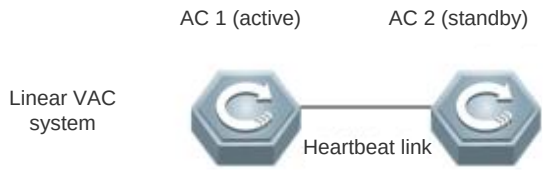
Heartbeat Link Traffic

Data streams transmitted by heartbeat links between devices are classified into the following:

- Data streams flooded in a VLAN
- Data streams to be forwarded between devices, which need to be transmitted through heartbeat links

In addition, heartbeat links also transmit internal management packets of the VAC system, for example, hot standby control plane protocol information, and packets that carry the configuration to be delivered from the active device to other member devices.

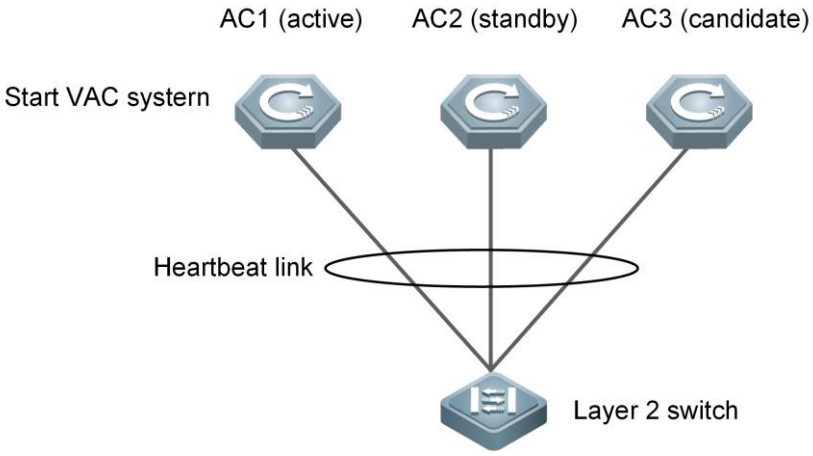
1.3.3 Topology



The VAC system supports the linear and star topologies. Devices are connected through a heartbeat link, which can be considered as a line and the topology is called linear topology. Multiple ACs are connected through a Layer 2 switch and the topology is called star topology.

Working Principle

Topology



In the linear topology, ACs are directly connected through a heartbeat link. A linear VAC system can be composed of only two devices. A VAC system consisting of three or more devices must use the star topology.

Figure 4-6 Linear Topology

As shown in Figure 4-7, ACs can be connected through a Layer 2 switch to form a star topology. This topology reduces the number of interfaces occupied by heartbeat links.

Figure 4-7 Star Topology

Topology Election

Before a VAC system is established, member devices discover their neighbors through a topology discovery protocol, to determine the devices that constitute the VAC system, so as to determine the scope of the management domain. Then, one active device is elected to manage the VAC system and one standby device is elected as the backup of the active device. At this point, the topology of the VAC system is converged. Topology discovery protocol information is transmitted through heartbeat links. The startup time of different devices is different, so the first convergence time of the topology is different.

The rules for active device election are as follows (the first rule is used for active device election; if the active device is not elected according to the first rule, the system goes on with the next rule):

- The device whose topology is converged is elected as the active device preferentially.
- The device with a higher priority is elected as the active device.
- If the active device cannot be determined according to the preceding rules, the device with a smaller device ID is elected as the active device.
- If the active device cannot be determined according to the preceding rules, the device with a smaller MAC address is elected as the active device.

The rules for standby device election are as follows (the first rule is used for standby device election; if the standby device is not elected according to the first rule, the system goes on with the next rule):

- Compare with the ID of the switch connected to the active device. The device that does not reside on the same switch as the active device is preferentially elected as the standby device. If multiple devices are not on the same switch as the active device, the next rule is used.
- The device with a higher priority is elected as the standby device.
- If the standby device cannot be determined according to the preceding rules, the device with a smaller device ID is elected as the standby device.
- If the standby device cannot be determined according to the preceding rules, the device with a smaller MAC address is elected as the standby device.

Topology Combination

When two or more ACs with the same domain ID are connected through heartbeat links, topologies will be combined. One device will restart and join the VAC system in hot mode during topology combination.

The topology combination rules are as follows (the first rule is used; if the optimal topology is not selected according to the first rule, the system goes on with the next rule):

- The user configuration is prior to other configuration. The device configured with the highest priority will prevail.
- If the active device cannot be determined according to the preceding rule, the device with a smaller device ID will prevail.
- If the active device cannot be determined according to the preceding rule, the device with a smaller MAC address will prevail.

Heartbeat Link for a Layer 2 Network

- In a star topology, heartbeat links are not directly connected, and a Layer 2 switch is used to forward management packets carried over the heartbeat links. In a VAC system, management packets of devices cannot be forwarded across VLANs. Therefore, on the Layer 2 switch, interfaces of the heartbeat link of multiple ACs must be configured to be in the same VLAN. You are advised to configure a separate VLAN for interfaces of the heartbeat link on the switch, so as to prevent other interfaces in the same VLAN from interfering with management packet forwarding.

1.3.4 Dual-Active Detection

Working Principle

When the heartbeat link is disconnected, the standby device becomes the active device. If the original active device is still running, there are two active devices. In this case, IP address conflicts and other problems will be incurred on the LAN because they have the same configuration. In this case, the VAC system must detect whether dual active devices coexist, and take measures.

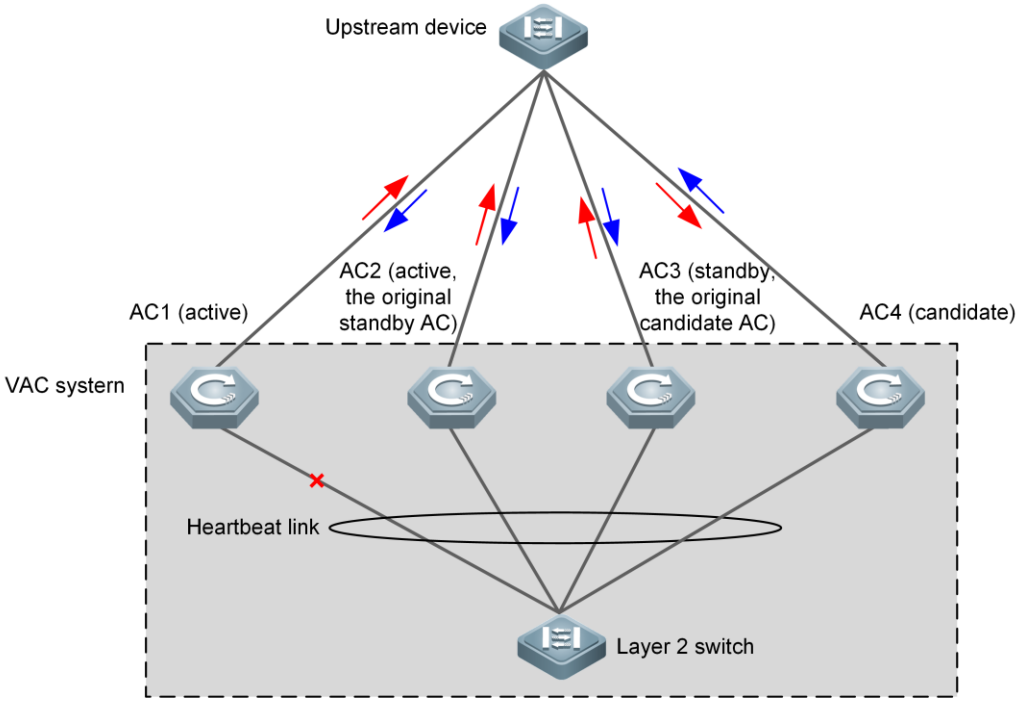
Rules of Dual-Active Detection

1 The device with a higher priority is preferred.

2 If the active device cannot be determined according to the preceding rule, the device with a smaller device ID is preferred.

3 If the active device cannot be determined according to the preceding rules, the device with a smaller MAC address is preferred.

4 If the active device cannot be determined according to the preceding rules, the device with longer startup time will be retained.



⚠ If dual-active detection is not configured, the network will be interrupted after the topology is split.

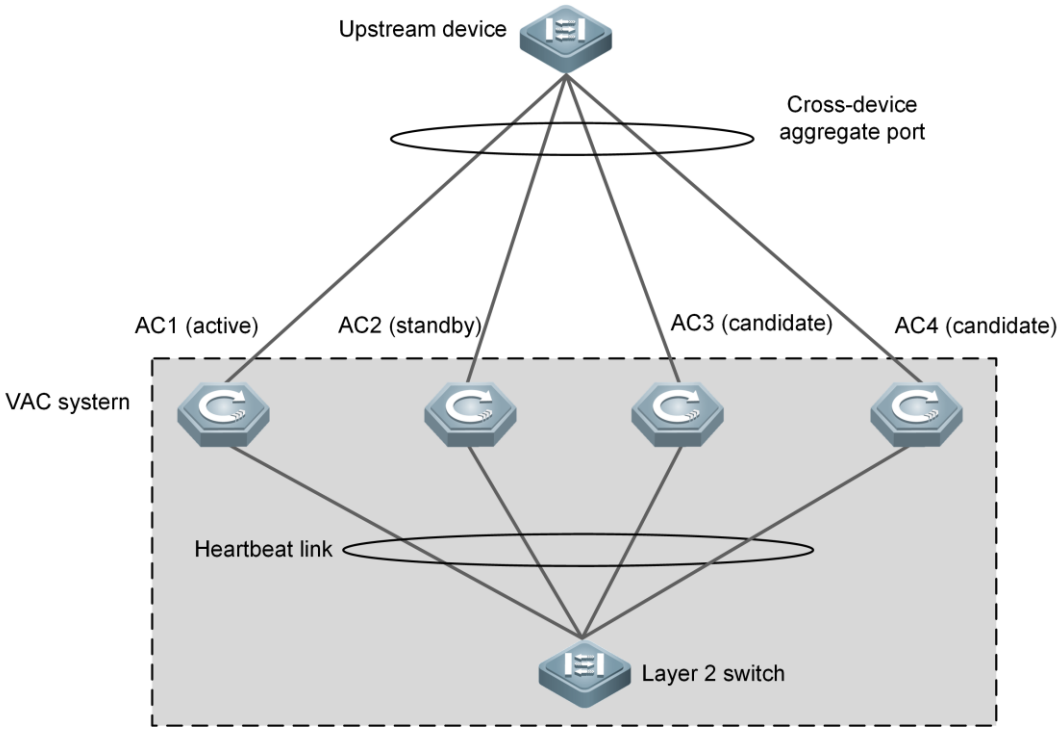
Dual-Active Detection Mode

The VAC system supports the dual-active detection mechanism by using an aggregate interface. Figure 4-8 shows the connection topology. Both the VAC system and upstream device need to support the dual-active detection function of the aggregate interface. When a heartbeat link is disconnected and dual active devices coexist, both active devices send detection packets to each member interface of the aggregate interface. The detection packets are transferred by the upstream device to the other active device. As shown in Figure 4-8, the aggregate interface contains four member

interfaces, each of which is connected to one device in the VAC system. When the topology is split, the four member interfaces send and receive detection packets to detect coexistence of dual active devices. Then the VAC system where one active device resides will be shut down to enter the recovery state, so as to prevent network exceptions.

Figure 4-8 Dual-Active Detection

1.3.5 Traffic Forwarding



Working Principle

Cross-device Aggregate Interface Group

An aggregate interface is formed by binding multiple physical interfaces. The VAC system supports the aggregate interface across member devices.

As shown in Figure 4-9, four ACs compose the VAC system and the upstream device is connected to the VAC system as an aggregate interface. For the upstream device, the aggregate interface is equivalent to a common aggregate interface group.

Figure 4-9 Cross-device Aggregate Interface

Troubleshooting

It is recommended that a peripheral device be physically connected to each device in the VAC system when a cross-device aggregate interface is configured for the VAC system. This can ensure the bandwidth of heartbeat links (the cross-device aggregate interface preferentially selects the member interface as the egress, to prevent transmission of unnecessary traffic through heartbeat links), and improve network reliability (if a device malfunctions, member interfaces on normal devices can work properly).

The possible cross-device aggregate interface failures and incurred impact are described as follows:

- A single link fails.

If a single link of the cross-device aggregate interface fails but other links function properly, the cross-device aggregate interface redistributes traffic among the remaining normal links.

- On the active device, links of all member interfaces of the cross-device aggregate interface fail.

If links of all member interfaces of the cross-device aggregate interface on the active device fail, only member interfaces on other member devices continue to work properly. If the outbound interface of data streams from the aggregate interface to the VAC system is located on the active device, the VAC system forwards the data streams to the outbound interface through heartbeat links.

Control plane protocols run on each device. Therefore, protocol packets transmitted to the VAC system are forwarded to each device for protocol computing through the heartbeat links.

- All links to other member devices fail.

If all links between the cross-device aggregate interface and a member device fail, only member interfaces on other member devices continue to work properly. If the outbound interface of data streams from the aggregate interface to the VAC system is located on the member device, the VAC system forwards the data streams to the outbound interface through heartbeat links.

- All links fail.

If all links of the cross-device aggregate interface fail, the cross-device aggregate interface changes the interface status to Link-Down, just as a common aggregate interface does.

- The active device malfunctions.

If the active device malfunctions, hot standby switching is triggered and the original standby device becomes the active device. Meanwhile, member interfaces on other member devices continue to work properly. When the peer device in the VAC system that is connected to the cross-device aggregate interface detects a link failure, it adjusts the load balancing algorithm to distribute data streams to normal links.

- A member device malfunctions.

If a member device malfunctions, the member link of the aggregate interface connected to the member device is disconnected but other member links still work properly. When the peer device in the VAC system that is connected to the cross-device aggregate interface detects a link failure, it adjusts the traffic balancing algorithm to distribute data streams to normal links.

Traffic Balancing

There may multiple traffic egresses in a VAC system. The aggregate interface and Equal-cost Multi-path Routing (ECMP) have their own traffic balancing algorithms, for example, traffic is balanced based on the source and destination MAC addresses. For details, see the AP and ECMP configuration manuals. In this configuration manual, packets received by the local device can be configured to be preferentially forwarded by the local device. In this way, packets can be forwarded to other devices not through heartbeat links.

1.3.6 System Management

Working Principle

Console Access

The console of the active device in the VAC system is also used to manage multiple devices in the system. On the console of the standby device, CLI commands cannot be executed, but the protocol status of the standby device can be queried and protocol entries can be cleared. On the active device, services can be configured for member devices uniformly. You can also log in to the console of the active device through the serial port of the standby device. In addition, you can redirect to the console of a device by running the **session** command.

Interface Naming

In a running VAC system, multiple devices may use the same interface ID. Therefore, the device ID is introduced to interface naming.

For example, gigabitEthernet 1/0/1 indicates GE interface 1 in slot 0 of the device with the ID of 1; gigabitEthernet 2/0/2 indicates GE interface 2 in slot 0 of the device with the ID of 2.

System Upgrade

In most cases, the main program versions of member devices in the VAC system need to be consistent. However, there are numerous member devices and the upgrade is time-consuming, laborsome, and error-prone if the devices are upgraded in standalone mode. You can complete the system upgrade by using the following two methods:

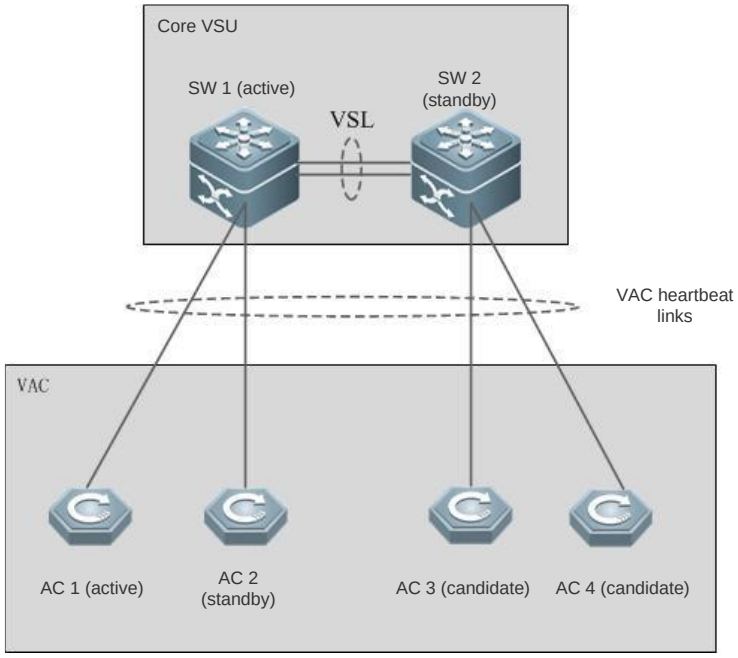
- When the VAC system is established, the system automatically checks the main program version of all member devices. If inconsistency is identified, the system synchronizes the main program of the active device to all member devices.
- After the VAC system is established, the system automatically synchronizes the file downloaded over TFTP to all member devices.

System Logs

System logs can be generated on all member interfaces of the VAC system. System logs generated by the active device are directly generated on the console of the active device, and the format of generated system logs is identical to that of system logs generated in standalone mode. System logs generated by other member devices are also generated on the console of the active device, but the format of generated system logs is different from that of system logs generated in standalone mode because the device ID is generated.

For example, the system log generated in standalone mode is "%DEVICE-6-INSTALL: Install chassis WS5708 on device 1." The system log generated by the member device with the device ID of 2 should be "%DEVICE-6-INSTALL: (2*)Install chassis WS5708 on device 1.

1.3.7 Standby Device Preemption



Working Principle

Standby Device Preemption

The VAC system supports the standby device preemption function. If a new device that joins the VAC system has a higher priority than the existing standby device in the VAC system, the new device will preempt the standby device role.

As shown in Figure 4-10, SW 1 and SW 2 compose a VSU, and ACs 1-4 are connected to the two switches and form a VAC system. The active and standby devices of the VAC system connect to SW 1 and the candidate ACs are connected to SW 2.

Figure 4-10 VSU+VAC

When the core VSU malfunctions, SW 1 is reset, which will result in splitting of the VAC system. AC 1 and AC 2 cannot communicate with external devices, resulting in AP disconnection. AC 3 and AC 4 have no standby devices and will be reset upon splitting. Therefore, when one switch in the VSU malfunctions, all ACs will become unavailable.

The standby device preemption function can solve this problem. ACs with high priority are connected to different switches. In this way, the active and standby devices in the VAC system are connected to different switches. When the VSU malfunctions, one switch is reset, and ACs connected to the other switch can take over services properly, preventing unavailability of all ACs.

1.4 Configuration

Configuration		Description and Command	
Configuring Basic VAC System Parameters in Standalone Mode		(Mandatory) It is used to configure VAC system parameters in standalone mode.	
		virtual-ac domain	Configures the domain ID.
		device	Configures the device ID in the VAC system.
		device priority	Configures the device priority.
		device connect_switch	Configures the ID of the switch connected to the AC.
		vac-port	Enters the heartbeat interface configuration mode.
		port-member interface	Adds a common interface to the heartbeat link interface pool.
		device convert mode	Switches the device from the standalone mode to the VAC mode.
Configuring VAC System Parameters in VAC Mode	Configuring VAC System Attributes	(Optional) It is used to configure device attributes in VAC mode.	
		device domain	Changes the domain ID of the device.
		device renumber	Changes the device ID.
		device description	Configures the device alias.
	Configuring Heartbeat Links	(Optional) It is used to configure heartbeat links.	
		vac-port	Enters the heartbeat interface configuration mode.
		port-member interface	Adds a common interface to the heartbeat link interface pool.
	Configuring Dual-active Detection	(Mandatory) It is used to configure the dual-active detection function.	
		dual-active detection	Configures the dual-active detection function.
		dual-active bfd interface	Configures BFD for an interface.
		dual-active interface	Configures the aggregate interface as the dual-active detection interface.

Configuration		Description and Command	
		dual-active exclude interface	Configures an excluded interface.
	Configuring Standby Device Preemption	**slave preemtive enable**	Configures standby device preemption.

1.4.1 Configuring Basic VAC System Parameters in Standalone Mode

Configuration Effect

Configure VAC-relevant basic parameters, so as to build a VAC system.

Configuration Step

Configuring VAC System Attributes

- Configure the same domain ID for multiple devices that need to compose a VAC system and ensure that the domain ID is unique on the LAN. In addition, configure a device ID for each device in the VAC system.
- (Mandatory) Run the **vitrual-ac domain** *domain_id* command to configure the domain ID.
- Run the **device** device_*id* command to configure a device ID for each device in the VAC system. This command is mandatory. When devices share the same priority, the device with a smaller device ID is preferentially elected as the primary device.
- (Optional) Run the **device** *device_id* **priority** *priority_num* command to configure the device priority. The value range is from 1 to 255. A larger value indicates a higher priority.

Command	**virtual-ac domain** *number*
Parameter Description	*number*: Indicates the virtual domain ID of a VAC system.
Defaults	The default domain ID is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	Only devices with the same domain ID can constitute a VAC system. The domain ID must be unique on a LAN.

Command	**device** *device_id*
Parameter Description	*device_id*: Indicates the ID of a device in the VAC system. The value varies with the product model.
Defaults	The default device ID is 1.
Command Mode	config-vac-domain configuration mode
Usage Guide	The device with a smaller device ID is elected as the active device if two devices are both active devices or if the two devices share the same priority and are just started with their roles not determined. This command can be used to change the ID of an AC only in standalone mode. The changed device ID takes effect only after device restart.

Command	**device** *device_id* **connect_switch** *switch_id*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. *switch_id*: Indicates the device ID. The value range is from 1 to 255.
Defaults	The default switch ID is 1.
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is used to set the ID of the connected switch. If the specified switch ID is different from that of the active device, the device will be preferentially elected as the standby device. This command is available in both standalone and VAC modes. The changed priority takes effect only after the device restart. In VAC mode, *device_id* indicates the ID of the running device. If the device ID does not exist, the priority does not take effect.

Command	**device** *device_id* **priority** *priority_num*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. priority_num: Indicates the device priority. The value range is from 1 to 255.
Defaults	The default priority is 100.
Configuration Mode	config-vac-domain configuration mode
Usage Guide	A larger value indicates a higher priority. The device with a higher priority is elected as the active device. This command is available in both standalone and VAC modes. The changed priority takes effect only after device restart. In VAC mode, *device_id* indicates the ID of the running device. If the device ID does not exist, the configuration does not take effect.

The priority command is used to change the priority only and will not change the device ID. Therefore, a correct device ID must be entered during configuration. For example, the configured device ID is 1. If you enter the **device 2 priority 100** command, the priority does not take effect.

Command	**device convert mode** { **virtual** | **standalone** } [*device_id*]
Parameter Description	**virtual**: Switches to the VAC mode. **standalone**: Switches to the standalone mode. *device_id*: Indicates the ID of the device.
Defaults	The standalone mode is the default mode.
Command Mode	Privileged EXEC mode
Usage Guide	After the **device convert mode virtual** command is run, the software automatically backs up the global configuration file in standalone mode as **standalone.text**, deletes global configuration file **config.text**, and then asks you whether to use **config_vac.text** to replace **config.text**. If the user chooses **yes**, **config_vac.text** replaces **config.text**. Otherwise, the global configuration file **config.text** is not restored, and the related configuration of the VAC system is written to the configuration file **config_vac.dat** before the device is reloaded. After the **device convert mode standalone** command is run, the software automatically backs up

	the global configuration file in standalone mode as **virtuac-ac.text**, deletes global configuration file **config.text**, and then asks the user if **standalone.text** is allowed to replace **config.text**. If the user chooses **yes**, **standalone.text** replaces **config.text**. Otherwise, the global configuration file **config.text** is not restored, and the related configuration of the VAC system is written to the configuration file **config_vac.dat** before the device is reloaded. This command can be run in both standalone and VAC modes. In standalone mode, services are switched to the device itself. In VAC mode, when *device_id* is specified, services are switched to the device specified by *device_id*. When *device_id* is not specified, services are switched to the active device. It is recommended that services be switched to the standby device and active device in sequence.

Configuring Heartbeat Links

- Multiple interfaces need to be configured as heartbeat detection interfaces so as to establish a VAC system.
- (Mandatory) Run the **vac-port** command to enter the heartbeat interface configuration mode.
- (Mandatory) Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to add heartbeat interfaces.
- When the device enters the heartbeat interface configuration mode, you can configure or delete heartbeat interfaces.

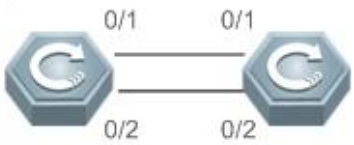
Command	**vac-port**
Parameter Description	N/A
Defaults	N/A
Command Mode	Configuration mode
Usage Guide	This command is available in both standalone and VAC modes.

Command	**port-member interface** *interface-name* [**copper** | **fiber**]
Parameter Description	*interface-name*: Indicates a 2-dimensional interface name, for example, Tengigabitethernet 1/1 and Tengigabitethernet 1/3. **copper**: Indicates the electrical interface. **fiber**: Indicates the optical interface.
Defaults	*N/A*
Command Mode	config-vac-port configuration mode
Usage Guide	This command is used to add member interfaces for heartbeat links. *interface-name* indicates the 2-dimensional interface name in standalone mode. It can be a 10GE or GE interface. The GE interface can be a combo interface. If the medium type is not specified, the GE interface is a GE electrical interface by default. The optical/electrical attribute must be specified for the combo interface. This command is available in both VAC and standalone modes.

⚠ In standalone mode, the heartbeat interface configuration does not take effect immediately. It can take effect only after the device switches to VAC mode and is restarted.

Verification

Run the **show virtual-ac config** [*device_id*] command to display the VAC system configuration on the device in standalone mode.



Command	**show virtual-ac config** [*device_id*]
Parameter Description	*device_id*: Indicates the device ID. If this parameter is specified, only the VAC system configuration of a specific device is displayed.
Command Mode	Privileged EXEC mode
Usage Guide	This command is used to display the VAC system configuration in standalone mode or VAC mode.

The VAC-relevant configuration is applicable to a single physical device, and the configuration is stored in the special configuration file **config_vac.dat**. Therefore, the **show running config** command cannot display VAC system configuration. Only the **show virtual-ac** config command can be executed to display the configuration of the VAC system.

In standalone mode, the running information of the VAC system is empty. When the **show virtual-ac** command is executed, a prompt is displayed, indicating that the standalone mode is used and there is no VAC system running information.

Configuration Example

Configuring Basic VAC System Parameters in Standalone Mode

Scenario **Figure 4-11**	AC 1 Device ID: 1 Priority: 200 AC 2 Device ID: 2 Priority: 100 VAC system  Heartbeat link AC 1 and AC 2 form a VAC system. The domain ID is 100. The device ID and priority of AC 1 are 1 and 200 respectively. Interfaces 0/1 and 0/2 are heartbeat interfaces. The device ID and priority of AC 2 are 2 and 100 respectively. Interfaces 0/1 and 0/2 are heartbeat interfaces.
Configuration Steps	1. Complete the following configuration on AC 1: ● Configure the VAC system attributes and heartbeat interfaces. ● Switch the device from the standalone mode to VAC mode. 2. Complete the following configuration on AC 2: ● Configure the VAC system attributes and heartbeat interfaces. ● Switch the device from the standalone mode to VAC mode.

Device-1	`Hostname# configure terminal`
	`Hostname(config)# virtual-ac domain 100`
	`Hostname(config-vac-domain)#device 1`
	`Hostname(config-vac-domain)#device 1 priority 200`
	`Hostname(config-vac-domain))#exit`
	`Hostname(config)# vac-port`

	Hostname(config-vac-port)#port-member interface GigabitEthernet 0/1 Hostname(config-vac-port)#port-member interface GigabitEthernet 0/2 Hostname(config)#exit
Device-2	Hostname# configure terminal Hostname(config)# virtual-ac domain 100 Hostname(config-vac-domain)# device 2 Hostname(config-vac-domain)# device 2 priority 200 Hostname(config-vac-domain))#exit Hostname(config)# vac-port Hostname(config-vac-port)#port-member interface GigabitEthernet 0/1 Hostname(config-vac-port)#port-member interface GigabitEthernet 0/2 Hostname(config-vac-port)#exit
Verification	● Run the **show virtual-ac config** command to display VAC system attributes of AC 1 and AC 2.
Device-1	Hostname#show virtual-ac config device_id: 1 (mac: 1414.4b5b.54f8) ! virtual-ac domain 100 ! device 1 device 1 priority 200 ! device convert mode virtual ! port-member interface GigabitEthernet 0/1 ! port-member interface GigabitEthernet 0/2 !
Device-2	Hostname#show virtual-ac config device_id: 2 (mac: 00d0.f822.33c0) ! virtual-ac domain 100 ! device 2 device 2 priority 100 ! device convert mode virtual ! port-member interface GigabitEthernet 0/1 ! port-member interface GigabitEthernet 0/2 !

1.4.2 Configuring VAC System Parameters in VAC Mode

1.4.2.1 Configuring VAC System Attributes

Configuration Effect

When devices constitute a VAC system or the VAC system is running, if some parameters need to be modified, you can log in to the console of the active device of the VAC system to modify parameters. You cannot enter the global configuration mode from the console of the standby device.

Notes

Configuration commands take effect only after the switch is restarted except the **device** *device_id* **description** *device*1 command, which takes effect immediately.

Configuration Step

↘ Entering the Domain Configuration Mode

- Optional.
- Run this command in VAC mode to enter the domain configuration mode. Only ACs with the same domain ID can form a VAC system. In VAC mode, you can change or configure the domain ID, device priority, and switch ID only after entering the domain configuration mode.

Command	**virtual-ac domain** *domain_id*
Parameter Description	*domain_id*: Indicates the virtual domain ID of the VAC system.
Defaults	The default domain ID is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	Only two devices with the same domain ID can constitute a virtual device. The domain ID must be unique on a LAN.

↘ Changing the Domain ID of the VAC System

- Optional.
- To change the domain ID of a device, run this command on the console of the active device in the VAC system.

Command	**device** *device_id* **domain** *new_domain_id*
Parameter Description	*device_id*: Indicates the ID of the running device in VAC mode. The value varies with the product model. *new_domain_id*: Indicates the changed domain ID. The value ranges from 1 to 255.
Defaults	The default value is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is available only in VAC mode and the configuration takes effect only after device restart.

↘ Changing the Device ID

- Optional.
- To change the device ID of a device, run this command on the console of the active device in the VAC system.

Command	**device** *device_id* **renumber** *new_device_id*
Parameter Description	*device_id*: Indicates the ID of the running device in VAC mode. The value varies with the product model. *new_device_id*: Indicates the changed device ID.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is available only in VAC mode and the configuration takes effect only after device restart. This command is used only to change the device ID and will not change configuration related to the device ID. In VAC mode, many configurations are related to the device ID, for example, the type of the device installed by running the **install** command, configuration commands in various interface modes, and configuration commands using the interface ID. After the device ID is changed, check whether all configuration is correct.

Changing the Device Priority

- Optional.
- To change the priority of a device, run this command on the console of the active device in the VAC system.
- A larger value indicates a higher priority. The device with a higher priority is elected as the active device.

Command	**device** *device_id* **priority** *priority_num*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. *priority_num*: Indicates the device priority. The value ranges from 1 to 255.
Defaults	The default priority is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	A larger value indicates a higher priority. The device with a higher priority is elected as the active device. This command is available in both standalone and VAC modes. The changed priority takes effect only after the device restart. This command will not change the device ID. In standalone mode, if *device_id* is set to 1 but the **device 2 priority 200** command is executed, the command does not take effect unless *device_id* is changed to 2 and the command is executed again. In VAC mode, *device_id* indicates the ID of the running device. If the device ID does not exist, the priority does not take effect.

Configuring the Device Alias

- Optional.
- To configure an alias for a device, run this command on the console of the active device in the VAC system.
- Run the **device** device_*id* **description** *device1* command to configure the device alias. The device alias can contain a maximum of 32 characters.

Command	**device device**_*id* **description** *dev-name*

Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. *dev_name*: Indicates the device name.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is available in both standalone and VAC modes. The configuration takes effect immediately in VAC mode.

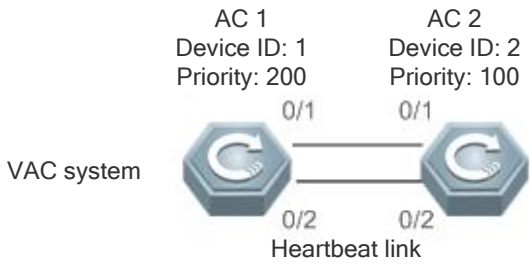
Configuring the ID of the Switch Connected to a Device

- Optional.
- To configure the ID of the switch connected to a device, run this command on the console of the active device in the VAC system.
- Run the **device** *device_id* **connect_switch** *switch_id* command to configure the ID of the switch connected to a device. The value range is from 1 to 255.

Command	**device** *device_id* **connect_switch** *switch_id*
Parameter Description	*device_id*: Indicates the ID of the device with the priority to be configured. switch_id: Indicates the ID of the switch connected to the device.
Defaults	N/A
Command Mode	config-vac-domain configuration mode
Usage Guide	This command is used to set the ID of the connected switch. If the specified switch ID is different from that of the active device, the device will be preferentially elected as the standby device. This command is available in both standalone and VAC modes. The changed switch ID takes effect only after device restart. In VAC mode, *device_id* indicates the ID of the running device. If the device ID does not exist, the configuration does not take effect.

Saving the Configuration File

Run the **exit** command to exit the VAC configuration mode and run the **write** command to save the configuration to the **config_vac.dat** file.



Verification

Run the **show virtual-ac** [**topology | config**] command to display information about the running VAC system, topology, or VAC system parameters.

Command	**show virtual-ac** [**topology	config**]
Parameter Description	Topology: Indicates topology information, that is, VAC system configuration.
Command Mode	Privileged EXEC mode
Usage Guide	This command is used to display the domain ID and the device ID, status, and role of each device.

Configuration Example

Configuring VAC System Attributes

Scenario **Figure 4-12**	 AC 1 and AC 2 form a VAC system. Change the device ID of AC 2 to 3 and priority to 150. Assume that AC 1 is the active device. Complete the configuration on the active device.
Configuration Steps	● Modify the configuration of AC 2.

AC 2	`Hostname#config`
	`Hostname(config)# virtual-ac domain 100`
	`Hostname(config-vac-domain)# device 2 renumber 3`
	`Hostname(config-vac-domain)# device 2 priority 150`
	`Hostname(config-vac-domain)# device 2 description AC3`

Verification	● Run the **show virtual-ac config** command to display the configuration.

AC 1	`Hostname#show virtual-ac config`
	`device_id: 1 (mac: 0x1201aeda0M)`
	`!`
	`virtual-ac domain 100`
	`!`
	`device 1`
	`device 1 priority 100`
	`!`
	`device convert mode virtual`
	`!`
	`port-member interface GigabitEthernet 0/1`
	`!`
	`port-member interface GigabitEthernet 0/2`
	`!`

	`device_id: 3 (mac: 0x1201aeda0E)`
	`!`
	`virtual-ac domain 100`
	`!`
	`device 3`
	`device 3 priority 150`
	`!`
	`device convert mode virtual`
	`!`
	`port-member interface GigabitEthernet 1/1`
	`!`

	port-member interface GigabitEthernet 1/2 ! device 3 description AC3 !

1.4.2.2 Configuring Heartbeat Links

Configuration Effect

When devices constitute a VAC system or the VAC system is running, if common interfaces need to be switched to heartbeat interfaces and vice versa, you can log in to the console of the active device in the VAC system for modification. You cannot enter the global configuration mode from the console of the standby device.

Notes

You can log in to the console of the VAC system through a serial port or in telnet mode, to add or delete heartbeat interfaces.

Configuration Step

Entering the Heartbeat Port Mode

- (Optional) Run the **vac-port** command to enter the heartbeat interface configuration mode.
- When the device enters the heartbeat interface configuration mode, you can add or delete heartbeat interfaces.

Command	**vac-port**
Parameter Description	N/A
Defaults	N/A
Command Mode	Configuration mode
Usage Guide	This command is available in both standalone and VAC modes.

Configuring Heartbeat Interfaces

- (Optional) Run the **port-member interface** *interface-name* [**copper** | **fiber**] command to configure a heartbeat interface.
- Run the **port-member interface** command to add or delete a heartbeat interface.

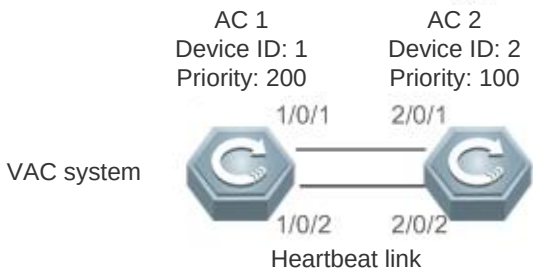
Command	**port-member interface** *interface-name* [**copper | fiber**]
Parameter Description	*interface-name*: Indicates a 2-dimensional interface name, for example, GigabitEthernet 0/1 and GigabitEthernet 0/3. **copper**: Indicates the electrical interface. **fiber**: Indicates the optical interface.
Defaults	N/A
Command Mode	config-vac-port configuration mode
Usage Guide	This command is available in both VAC and standalone modes. In standalone mode, the command configuration needs to be saved and the device where the heartbeat member interface resides

	needs to be restarted for the configuration to take effect. In VAC mode, the command configuration takes effect immediately.

The configured heartbeat member links take effect immediately during the running of the VAC system. Heartbeat interfaces need to be configured on all devices.

To prevent loops from being instantaneously generated when a heartbeat interface is switched to a common interface, the system automatically sets the interface to be in shutdown state when this command is executed. You can reconnect the link and run the **no shutdown** command to enable the interface.

If the VAC system topology is split because a heartbeat interface is switched to a common interface, the heartbeat interface cannot be deleted. You can disconnect the physical interface and then delete the heartbeat interface.



Verification

Run the **show virtual-ac link** [**port**] command to display the running status of the heartbeat interface.

Command	**show virtual-ac link** [**port**]
Parameter Description	**port**: Displays information about a specific interface.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring Heartbeat Links

Scenario Figure 4-13	
Configuration Steps	● Add interface 1/0/3 as a heartbeat interface and remove the heartbeat interface 0/2.

	`Hostname#config`
	`Hostname(config)# vac-port`
	`Hostname(config-vac-port)# port-member interface Gigabitethernet 1/0/3`
	`Hostname(config-vac-port)# no port-member interface Gigabitethernet 1/0/2`

Verification	● Run the **show virtual-ac config** command to display heartbeat links. Assume that AC 1 is the active device. Run the command on the active device.

	`Hostname#show virtual-ac config`
	`device_id: 1 (mac: 0x1201aeda0M)`
	`!`

	Virtual-ac domain 100 ! device 1 device 1 priority 200 ! device convert mode virtual ! port-member interface Gigabitethernet 0/1 ! port-member interface Gigabitethernet 0/3 !
	device_id: 2 (mac: 0x1201aeda0E) ! virtual-ac domain 100 ! device 2 device 2 priority 100 ! device convert mode virtual ! port-member interface Gigabitethernet 0/1 ! port-member interface Gigabitethernet 0/2 !

1.4.2.3 Configuring Dual-active Detection

Configuration Effect

Configure a detection mechanism to prevent dual-active devices.

Notes

- Dual-active detection can be configured only in VAC mode.
- Dual-active detection is configured in global configuration mode and the dual-active detection configuration takes effect immediately on the active device. Run the **show running-config** command to display the configuration.
- BFD-based dual-active detection configuration cannot be displayed by running related BFD commands but by running the **show virtual-ac dual-active summary** command.

Configuration Step

↘ Configuring BFD-based Dual-active Detection

- In BFD-based dual-active detection, a direct link needs to be established between two devices and the interfaces at both ends of the link must be routed interfaces. The following configuration is required on both devices.
- Enter the interface configuration mode of the detection interface and configure the detection interface as a routed interface.

- Exit the interface configuration mode, and run the **virtual-ac domain** *domain_id* command to enter the config-vac-domain configuration mode.
- In config-vac-domain configuration mode, run the **dual-active detection bfd** command to enable BFD, which is optional.
- In config-vac-domain mode, run the **dual-active bfd interface** *interface-name* command to configure the BFD detection interface, which is optional.
- If no BFD detection interface is available after a BFD detection interface is deleted, BFD detection will be unavailable.

Command	**virtual-ac domain** *domain_id*
Parameter Description	*domain_id*: Indicates the virtual domain ID of the VAC system.
Defaults	The default domain ID is 100.
Command Mode	config-vac-domain configuration mode
Usage Guide	Only two devices with the same domain ID can constitute a virtual device. The domain ID must be unique on a LAN.

Command	**dual-active detection** { **aggregateport	bfd** }
Parameter Description	**aggregateport**: Specifies the aggregate interface-based detection. **bfd**: Indicates BFD detection.
Defaults	The dual-active detection function is disabled.
Command Mode	config-vac-domain configuration mode
Usage Guide	This command can be configured only in VAC mode.

Command	**dual-active bfd interface** *interface-name*
Parameter Description	*interface-name*: Indicates the type and ID of the detection interface.
Defaults	N/A
Command Mode	config-vac-domain configuration mode
Usage Guide	BFD detection interfaces must be routed interface and reside on different devices.

BFD detection interfaces must be direct routed interfaces and must reside on different devices.

The configured interface type is unlimited. Dual-active detection links are used to transmit only BFD packets, and traffic is light. Therefore, you are advised to configure a 1000M or 100M interface as the dual-active detection interface.

After a Layer 3 routed interface configured for dual-active detection is switched into a Layer 2 switching interface (by running the **switchport** command on the interface), the BFD dual-active detection configuration is automatically cleared.

You are advised to adopt the direct connection for the BFD link to connect only the active and standby devices.

When a dual-active conflict is detected and one VAC system is enabled to enter the recovery state, you can rectify the fault by eliminating the VSL failure but not by directly resetting the VAC system in recovery state. Otherwise, a dual-active device conflict will be incurred on a network.

Configuring Aggregate Interface-based Dual-active Detection

- To configure aggregate interface-based dual-active detection, configure an aggregate interface and then specify the aggregate interface as the detection interface.
- Run the **port-group** *ap-num* command to add a physical member interface to the aggregate interface.
- Run the **dual-active interface** *interface-name* command to configure the aggregate interface as the dual-active detection interface, which is optional.
- Run the **dad relay enable** command to enable the device to transfer dual-active detection packets on interfaces of upstream and downstream devices, which is optional.
- Disabling the aggregate interface-based dual-active detection will make dual-active detection of the aggregate interface to take ineffective.
- If no detection interface is available after a detection interface is deleted, detection will be unavailable.
- The function of forwarding aggregate interface-based dual-active detection packets is disabled by default.

Command	**virtual-ac domain** *domain_id*
Parameter Description	*domain_id*: Indicates the virtual domain ID of the VAC system.
Defaults	The default domain ID is 100.
Command Mode	Global configuration mode
Usage Guide	Only two devices with the same domain ID can constitute a virtual device. The domain ID must be unique on a LAN.

Command	**dual-active interface** *interface-name*
Parameter Description	*interface-name*: Indicates the type and ID of the detection interface.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	Detection interfaces must belong to an aggregate interface and member interfaces of the aggregate interface must reside on different devices.

It is recommended that physical interfaces that are added to an aggregate interface reside on different devices.

When a dual-active device conflict is detected and one VAC system is enabled to enter the recovery state, you can rectify the fault by eliminating the heartbeat link failure but not by directly resetting the VAC system in recovery state. Otherwise, a dual-active device conflict will be incurred on a network.

Configuring Excluded Interface List in Recovery Mode

- When dual-active devices are detected, one active device must enter the recovery mode. In recovery mode, all service interfaces of the device need to be disabled. To ensure normal use of service interfaces for some special

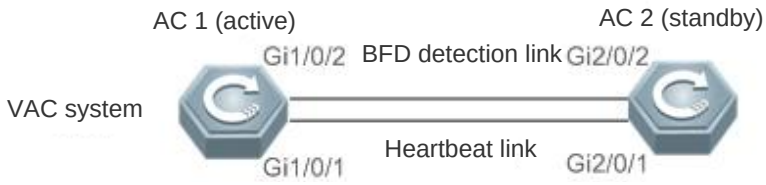
purposes (for example, configuring an interface for logging in to the management device remotely), you can configure some interfaces as excluded interfaces that do not need to be disabled in recovery mode.

- After entering the config-vac-domain configuration mode, run the **dual-active exclude interface** *interface-name* command to specify excluded interfaces that do not need to be disabled in recovery mode, which is optional.

Command	**dual-active exclude interface** *interface-name*
Parameter Description	*interface-name*: Indicates the type and ID of an interface.
Defaults	*N/A*
Command Mode	config-vac-domain configuration mode
Usage Guide	This command can be configured only in VAC mode. Excluded interfaces must be routed interfaces and cannot be heartbeat interfaces. You can configure multiple excluded interfaces.

⚠ Excluded interfaces must be routed interfaces and cannot be heartbeat interfaces.

⚠ After a routed interface is switched into a switching interface (run the **switchport** command on the interface), the excluded interface configuration associated with the routed interface is automatically cleared.



Verification

Run the **show virtual-ac dual-active summary** command to display the dual-active configuration.

Command	**show virtual-ac dual-active summary**
Parameter Description	**smmary**: Displays the summary of dual-active detection.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

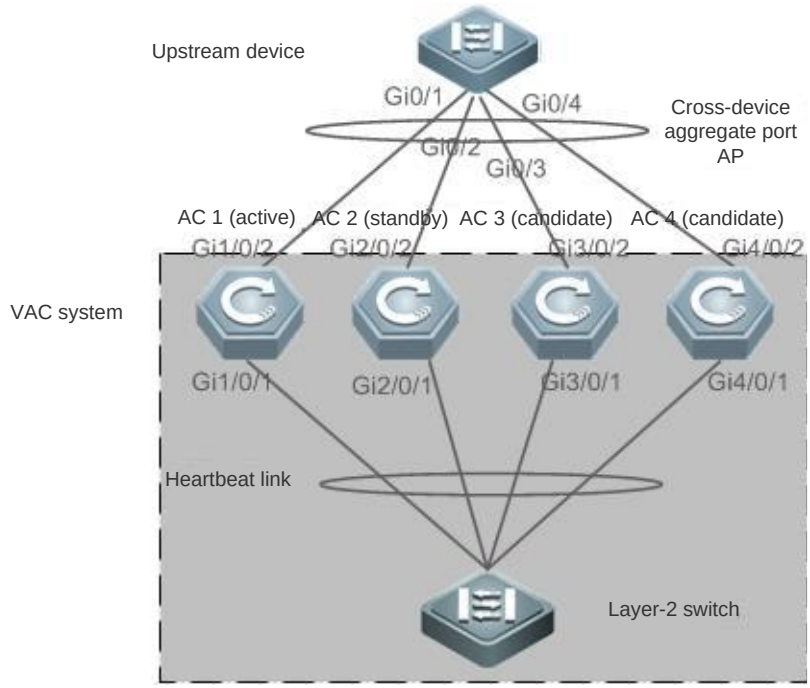
Configuration Example

Configuring BFD-based Dual-active Detection

Scenario **Figure 4-14**	 - Device 1 and Device 2 constitute a VAC system (the domain ID is 100). The priority of Device 1 is 200 and the priority of Device 2 is 150. A connection is established between Gi1/0/1 of Device 1 and Gi2/0/1 of Device 2, which forms the VSL between Device 1 and Device 2. Gi1/0/2 of Device 1 is connected to G2/0/2 of Device 2. G1/0/2 and G2/0/2 are both routed interfaces. - G1/0/2 and G2/0/2 are a pair of BFD dual-active detection interfaces.
Configuration Steps	- Configure G1/0/2 and Port G2/0/2 as routed interfaces. - Enable BFD-based dual-active detection. - Configure G1/0/2 and Port G2/0/2 as BFD detection interfaces.

	Device 1 and Device 2 form a VAC system. Therefore, the configuration can be performed on Device 1 or Device 2. Device 1 is used as an example.

Switch 1	`Hostname(config)# interface GigabitEthernet 1/0/2`
	`Hostname(config-if-GigabitEthernet 1/0/2)# no switchport`
	`Hostname(config)# interface GigabitEthernet 2/0/2`
	`Hostname(config-if-GigabitEthernet 2/0/2)# no switchport`
	`Hostname(config-if)# virtual-ac domain 100`
	`Hostname(config-vac-domain)# dual-active detection bfd`
	`Hostname(config-vac-domain)# dual-active bfd interface GigabitEthernet 1/0/2`
	`Hostname(config-vac-domain)# dual-active bfd interface GigabitEthernet 2/0/2`



Verification	● Check the status of the dual-active detection function. ● Check the BFD-based dual-active detection configuration.

Switch 1	`Hostname# show switch virtual dual-active summary`
	`BFD dual-active detection enabled: Yes`
	`Aggregateport dual-active detection enabled: No`
	`Interfaces excluded from shutdown in recovery mode:`
	`In dual-active recovery mode: NO`
	`Hostname# show switch virtual dual-active bfd`
	`BFD dual-active detection enabled: Yes`
	`BFD dual-active interface configured:`
	`GigabitEthernet 1/0/2: UP`
	`GigabitEthernet 2/0/2: UP`

Common Errors

- A BFD detection interface is not a routed interface.
- Both BFD-based dual-active detection and aggregate interface-based dual-active detection are enabled.

↘ Configuring Aggregate Interface-based Dual-active Detection

Scenario **Figure 4-15**	 AC 1, AC 2, AC 3, and AC 4 form a VAC system (the domain ID is 1). The priority of AC 1 is 200, and the priorities of AC 2, AC 3, and AC4 are all 150. Gi1/0/1, Gi2/0/1, Gi3/0/1, and Gi4/0/1 of the VAC system establish connections with the Layer 2 switch, which form heartbeat links of the VAC system. G0/1, G0/2, G0/3, and G0/4 of the upstream device are connected to G1/0/2, G2/0/2, G3/0/2, and G4/0/2 of the VAC system respectively to form an aggregate interface that involves four member links. The ID of the aggregate interface is 1, and all members are GE SFP interfaces.
Configuration Steps	Configure AG 1 as the dual-active detection interface.

AC 1	`Hostname(config)# virtual-ac domain 100`
	`Hostname(c config-vs-domain)# dual-active detection aggregateport`
	`Hostname(config-vac-domain)# dual-active interface aggregateport 1`

Layer-2 Switch	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#interface  aggregateport 1`
	`Hostname(config-if-AggregatePort 1)#dad relay enable`

Verification	Check the status of the dual-active detection function.

AC 1	`Hostname#show virtual-ac dual-active summary`
	`BFD dual-active detection enabled: No`
	`Aggregateport dual-active detection enabled: Yes`
	`Interfaces excluded from shutdown in recovery mode:`
	`In dual-active recovery mode: No`
	`Hostname#show virtual-ac dual-active aggregateport`
	`Aggregateport dual-active detection enabled: Yes`
	`Aggregateport dual-active interface configured:`
	`  AggregatePort 1: UP`

	GigabitEthernet 1/0/2: UP GigabitEthernet 2/0/2: UP GigabitEthernet 3/0/2: UP GigabitEthernet 4/0/2: UP

Common Errors

A dual-active detection interface is not an aggregate interface.

1.4.2.4 Configuring Standby Device Preemption

Configuration Effect

Configure standby device preemption to reduce the possibility that both active and standby devices fail.

Notes

- The standby device preemption can be configured only in VAC mode.
- Standby device preemption is configured in global configuration mode and the configuration takes effect immediately on the active device. Run the **show running-config** command to display the configuration.

Configuration Step

Configuring Standby Device Preemption

Configuration Steps	Configure standby device preemption.
AC 1	Hostname(config)# virtual-ac domain 100 Hostname(config-vs-domain)# slave preemptive enable
Verification	Check the status of the dual-active detection function.
AC 1	Hostname#show running-config virtual-ac domain 100 slave preemptive enable

1.5 Monitoring

Displaying

Command	Description
show virtual-ac [**topology | config | role**]	Displays information about the running VAC system, topology, or VAC system parameters.
show virtual-ac dual-active summary	Displays the dual-active detection configuration.
show virtual-ac link [**port**]	Displays the heartbeat link running status in VAC mode.
session { **device** *device_id* | **master** }	Redirects to the console of the active device or any device.
show device id	Displays the device ID.

1 Configuring RIPT

1.1 Overview

The Remote Intelligent Perceptive Technology (RIPT) is also known as the smart access point (AP) technology. As a wireless network edge device (as compared with an AC), the smart AP can detect its connection with the access controller (AC) and take over external provisioning of wireless networks seamlessly once the connection fails. The wireless RIPT solution can be deployed on an enterprise branch network where the AC and APs are connected across a Wide Area Network (WAN), ensuring service availability in case of WAN faults. The solution can be also deployed on a Wireless Local Area Network (WLAN) network to reduce dependence on ACs and improve its availability.

Protocols and Standards

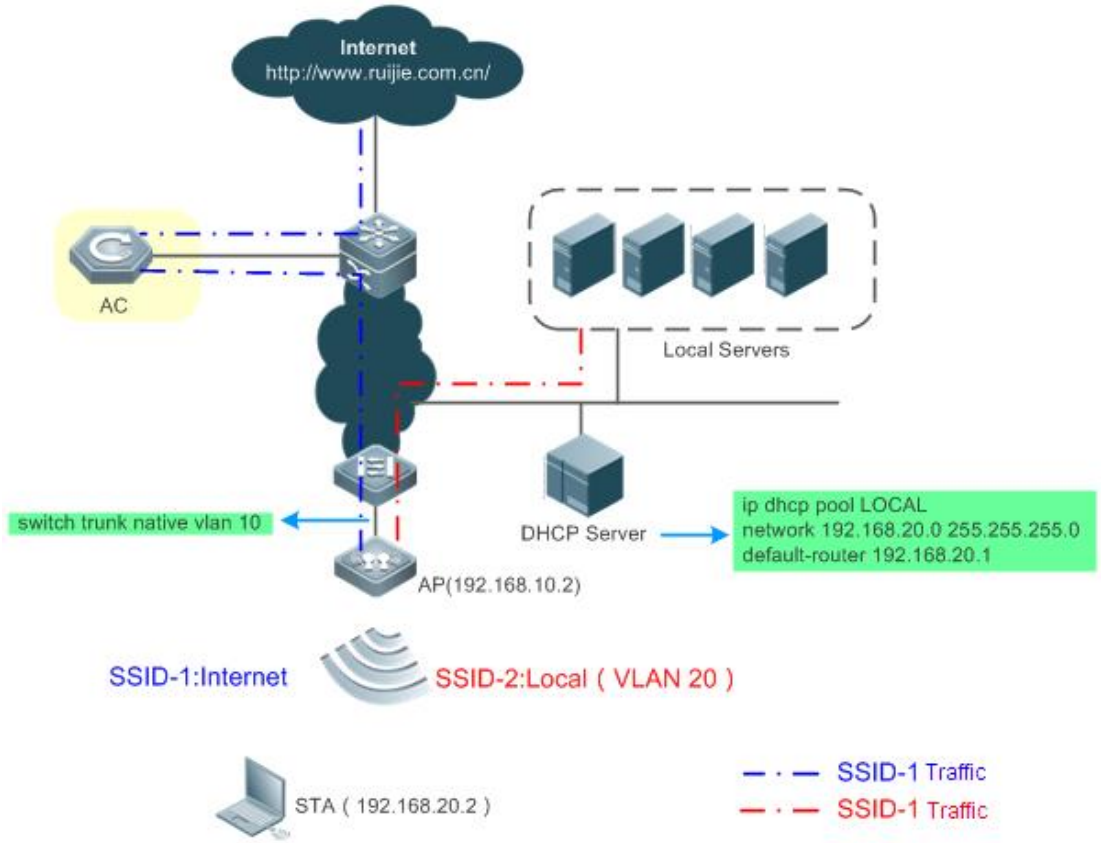
N/A

1.2 Applications

Application	Description
Deploying RIPT on a WLAN Network	Both the AC and APs are deployed on a Local Area Network (LAN).
Deploying RIPT on Enterprise Branch Networks	The AC is deployed in the enterprise headquarters, while APs are deployed in various branches and connected to the AC through a WAN.

1.2.1 Deploying RIPT on a WLAN Network

Scenario



The following two types of WLANs are deployed to meet service requirements:

- WLAN for operators' Internet services: applies centralized forwarding and 802.1X/web authentication mode. There is potential demand for accounting.
- WLAN for LAN resource services: applies local forwarding and Wireless Application Protocol (WAP) or Wi-Fi Protected Access 2 - Pre-Shared Key (WAP2-PSK) authentication mode.

When the AC is unreachable (such as restart upon AC upgrade or outage of the equipment room), the wireless network can still access local resources.

For example, as shown in Figure 3-1, the AC is unreachable while the other devices such as switches and APs are normal. The WLAN service is not affected.

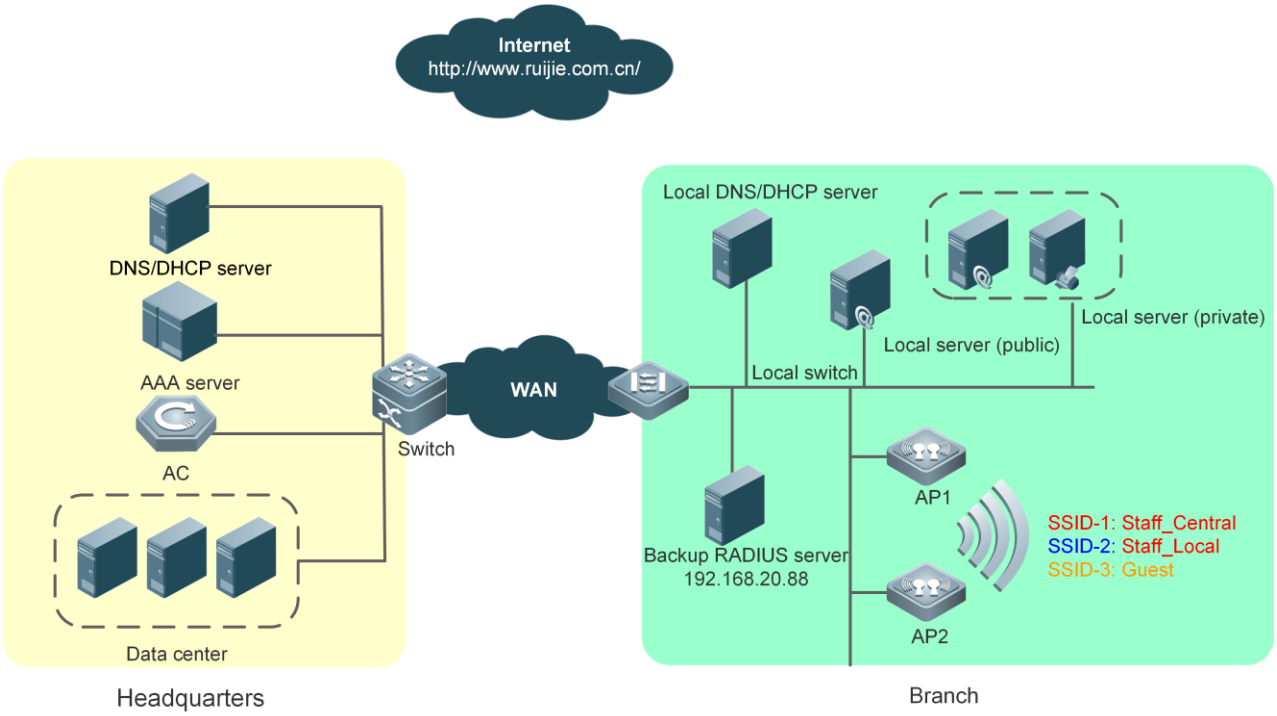
Figure 3-1

Remarks	The DHCP server for allocating an IP address to a STA cannot be configured on the AC. The AC cannot forward data traffic for SSID-2 in local forwarding mode.

Deployment

- Create a WLAN, and configure a forwarding mode and a security policy.
- Enable RIPT on APs.

1.2.2 Deploying RIPT on Enterprise Branch Networks



Scenario

The following are requirements for enterprise branch networks:

- An AC is deployed in the headquarters data center, while some APs and a DHCP server are deployed in the branches to serve STAs.
- A RADIUS server is deployed in the headquarters to perform access authentication for STAs in both the headquarters and all branches. If a backup RADIUS server is not deployed in the branch, access authentication for STAs in the branch fails when APs in the branch are disconnected from the AC of the headquarters (for example, when the WAN fails).
- Traffic for accessing the headquarters data center will pass the WAN between the branch and headquarters, whereas traffic for accessing local resources and Internet resources of the branch is forwarded in the branch instead of passing the WAN.

As shown in Figure 3-2, when the route from a branch AP to the headquarters AC is unreachable, the branch AP can still provide services for local resource access.

Figure 3-2

Remarks	The AC is deployed in the headquarters and connected to APs through the WAN. A DHCP server for IP address allocation is deployed in the branch. STA access authentication will be stopped when the WAN link fails. If 802.1X authentication is adopted, another WLAN can be deployed and the function of SSID enabling upon disconnection can be configured, so that the WLAN can provide network services for new STAs when the AP is disconnected. Free web authentication upon disconnection can be enabled to ensure that STAs passing web-based authentication can access the network when the AP is disconnected.

Deployment

- Deploy a WLAN for employees in the branch to access the headquarters data center, and enable the centralized forwarding mode. STA access authentication is performed in the headquarters.
- Deploy a WLAN for employees in the branch to access Internet and local resources, and enable the local forwarding mode and the 802.1X local authentication. When an AP works in connected mode, the headquarters RADIUS server performs authentication. When the AP works in standalone mode, another WLAN can be deployed and the function of SSID enabling upon disconnection can be configured, so that the WLAN can provide network services for new STAs; or the 802.1X authentication is prohibited for new STAs to ensure security.
- Deploy a WLAN for guests' access to Internet and public resources of the branch, and enable the local forwarding mode and web-based authentication. When an AP works in connected mode, the headquarters RADIUS server performs authentication. When the AP works in standalone mode, free web-based authentication can be enabled to ensure that new STAs can access the network.

- Create an AP group and configure WLAN-VLAN mapping.
- Configure the APs, add them to an AP group, and enable RIPT.

1.3 Features

Basic Concepts

Connected Mode and Standalone Mode

When a CAPWAP tunnel has been established between an AP and an AC, the AP works in connected mode.

When the CAPWAP tunnel between the AP and the AC is terminated, the AP works in standalone mode.

RIPT AP

An RIPT-enabled AP is called an RIPT AP, which is also known as a smart AP.

AC Configuration Change Monitoring

After reestablishing a CAPWAP tunnel in standalone mode with the AC, an RIPT AP should check the AC configuration change, so as to determine whether to maintain the online status of online STAs accordingly. Therefore, the AC configuration should be monitored to determine whether the AC has changed when the RIPT AP is offline.

The configuration is considerred to be changed when one of the following operations is performed:

- The AC enters the configuration mode using a CLI command, or a CLI command has been executed in configuration mode.
- The SET operation has been performed on the AC through the Simple Network Management Protocol (SNMP).

If either of the preceding operations is performed on the AC during AP logout, the AC configuration is considered to be changed. Then online STAs will be brought offline when the AP is reconnected to the AC.

When all the configuration of the AC has been stored in its flash memory, and the AC is restarted (or powered on after power-off) and the configuration file in the flash memory does not change, the configuration of the AC is considered to remain unchanged.

Overview

Feature	Description
Enabling RIPT	The AP automatically detects its connection with the AC. When the connection with the AC is terminated, the AP continues to provide services by smoothly switching to the standalone mode.
Enabling SSID Upon Disconnection	When the AP is disconnected, the WLAN provides SSIDs for STAs to access a network. In normal cases, this function is used with 802.1X authentication.
Enabling Free Web-based Authentication Upon Disconnection	After the AP is disconnected, STAs can access WLANs adopting web-based or MAC address bypass (MAB) authentication without being authenticated through web-based or MAB authentication.
Enabling the AP Standalone Mode	After the AP is disconnected, the AP can provide Wi-Fi services.

1.3.1 Enabling RIPT

An AP enabled with RIPT is an RIPT AP. When the AP detects that its connection with the AC is terminated, the AP automatically switches to the standalone mode. After a connection with the AC is reestablished, the AP switches back to the connected mode.

Working Principle

When the WLAN is set to the local forwarding mode, an RIPT AP has the same working mechanism as a common fit AP in connected mode. The AC performs STA association and authentication. When a new STA goes online, the AC backs up its information in real time to the associated RIPT AP. Then the RIPT AP creates STA information and a backup entry. When detecting that its CAPWAP connection with the AC is terminated, the RIPT AP automatically switches to the standalone mode. Then online STAs will maintain their online status, while new STAs can get online. If the WLAN works in centralized forwarding mode, online STAs will be brought offline and SSID broadcast is automatically disabled.

In standalone mode, the RIPT AP will first detect whether the AC configuration changes after reestablishing a CAPWAP tunnel with the AC. If the configuration of the AC does not change, the RIPT AP synchronies information about all online STAs to the AC, so that the AC reestablishes STA information. Then STA association and authentication are switched back to the AC, while the RIPT AP enters the connected mode. If the configuration of the AC has changed, the RIPT AP disconnects all online STAs, receives the new configuration, and then enters the connected mode.

1.3.2 Enabling SSID Upon Disconnection

When the AP connects to the AC, STAs cannot discover SSID or access a network. When the connection between the AP and AC is ended, the SSID is enabled for STAs to access the network. After the connection between the AP and AC recovers, the SSID becomes unavailable.

This function is a supplement to the RIPT AP enabled with 802.1X authentication. After the RIPT AP is disconnected, network access requests from STAs using 802.1X authentication cannot be processed. To enable STAs to access the network, configure another WLAN and enable this function.

Working Principle

If the function of SSID enabling upon disconnection is configured for STAs after the RIPT AP is disconnected, the WLAN can provide services and allow STA access. After the AP is re-connected, if the function of SSID enabling upon disconnection is configured for the WLAN, the WLAN stops working, STAs are not allowed to access the network, and online STAs become offline.

1.3.3 Enabling Free Web-based Authentication Upon Disconnection

When the AP connects to the AC, STAs can access the network only after passing web-based or MAB authentication. When the connection between the AP and AC is ended, STAs can access the network without passing web-based or MAB authentication. After the connection between the AP and AC is reestablished, STAs can access the network after passing web-based or MAB authentication.

Working Principle

An RIPT AP determines whether free web-based authentication is enabled for the WLAN after the AP is disconnected. If this function is enabled for the WLAN, STAs can directly access the network. After the AP connection is reestablished, STAs can access the network only after passing authentication.

1.3.4 Enabling the AP Standalone Mode

Before the AP establishes a connection with the AC after restart, the AP provides Wi-Fi services before restart. In the case of consistent software version, the AP provides uniform Wi-Fi services for STAs.

Working Principle

When RIPT is enabled on an AP, it can still provide Wi-Fi services normally even if the AP connection is terminated. However, after the AP restarts, it must connect to the AC and receive the configuration issued by the AC before it can provide Wi-Fi services. This function allows the AP to provide Wi-Fi services when the AP connection is terminated, and before the AP restarts and reconnects to the AC.

When the AP reconnects to the AC, if the version number of the AC is the same as that before AP disconnection, the process of restoring the connection is transparent to STAs. If the version number of the AC is different from that before AP disconnection, the AP's configuration is cleared, all STAs go offline, the AP reconnects to the AC, receives the latest configuration from the AC, and provides Wi-Fi services.

1.4 Configuration

Configuration	Description and Command	
Configuring RIPT	(Mandatory) It is used to enable RIPT.	
	ript enable	Enables RIPT.
	(Optional) It is used to configure SSID enabling upon disconnection.	
	enable-ssid at-capwap-down	Enables SSID upon disconnection.
	(Optional) It is used to enable free web-based authentication upon disconnection.	
	free-webauth at-capwap-down	Enables free web-based authentication upon disconnection.
	(Optional) It is used to enable the AP standalone mode.	
	ap-mode standalone	Enable the AP standalone mode.

1.4.1 Configuring RIPT

Networking Requirements

- An RIPT AP can independently work when its connection with the AC is terminated.
- When RIPT is enabled or disabled, the AP proactively terminates its CAPWAP connection with the AC and then reestablishes a new connection. This process occurs when the AP goes online for the first time.
- After SSID enabling is configured upon disconnection, the WLAN works only after the AP connection is ended.
- After free web-based authentication is enabled for a WLAN and the AP is disconnected, STAs can access the network without passing web-based or MAB authentication.

Notes

- Save the configuration before restarting the AC. If the configuration is not saved before the AC is restarted, the restarted AC will use the configuration stored in its flash memory. In this case, the configuration used on the RIPT

AP is different from that being used on the AC after the restart. Such a problem is handled in the same manner as the situation where the AC configuration has changed. Therefore, ensure that the AC configuration is saved before AC restart in the RIPT scenario.

- In 802.1X authentication scenarios, STAs are not allowed to access WLANs adopting 802.1X authentication after the AP connection is terminated.
- Configure the keepalive time of APs. For an RIPT AP, configure its keepalive time according to the status of the connection between the AP and the AC. For details, see **echo-interval** to be executed in AP configuration mode. This prevents instability of the CAPWAP tunnel between the AP and the AC, which may occur as a result of poor network communications between the AP and the AC.
- Ensure that requirements must be met during deployment of the DHCP server. If an RIPT AP or STA acquires its IP address through DHCP and the RIPT AP works in standalone mode, the DHCP server must be reachable for the RIPT AP and STA.

Configuration Steps

Creating a WLAN and Configuring the Local Forwarding Mode

- Mandatory. If the WLAN works in centralized forwarding mode, STAs will be brought offline after the RIPT AP switches to the standalone mode.
- Create the WLAN in global configuration mode on the AC.
- By default, the WLAN works in centralized forwarding mode.
- Run the **tunnel local** command in WLAN configuration mode to set the WLAN to the local forwarding mode.

Enabling RIPT

- Mandatory.
- Run the **ript enable** command to enable RIPT in AP or AP group configuration mode.
- Enabling the RIPT function on an AP does not affect existing services when the AP is connected to the AC.

Command	**ript enable**
Parameter Description	N/A
Defaults	RIPT is disabled.
Command Mode	AP or AP group configuration mode
Configuration Usage	N/A

Enabling or Disabling the AC Configuration Change Monitoring Function

Optional.

Command	**ript-monitor** { **enable** | **disable** }
Parameter Description	**enable**: Enables the AC configuration change monitoring function. **disable**: Disables the AC configuration change monitoring function.
Defaults	The AC configuration change monitoring function is enabled.
Command Mode	Privileged EXEC mode or global configuration mode
Configuration Usage	N/A

Enabling SSID Upon Disconnection

- Optional.
- Perform this operation in WLAN configuration mode.
- If RIPT is not enabled for the AP, this function does not take effect. After the AP connection is ended, SSID signals are not provided.
- Run the **enable-ssid at-capwap-down** command in WLAN configuration mode to enable SSID upon disconnection.

Command	enable-ssid at-capwap-down
Parameter Description	N/A
Defaults	By default, the function of SSID enabling upon disconnection is disabled.
Command Mode	WLAN configuration mode
Usage Guide	This function needs to be enabled only if 802.1X authentication is used.

Enabling Free Web Authentication Upon Disconnection

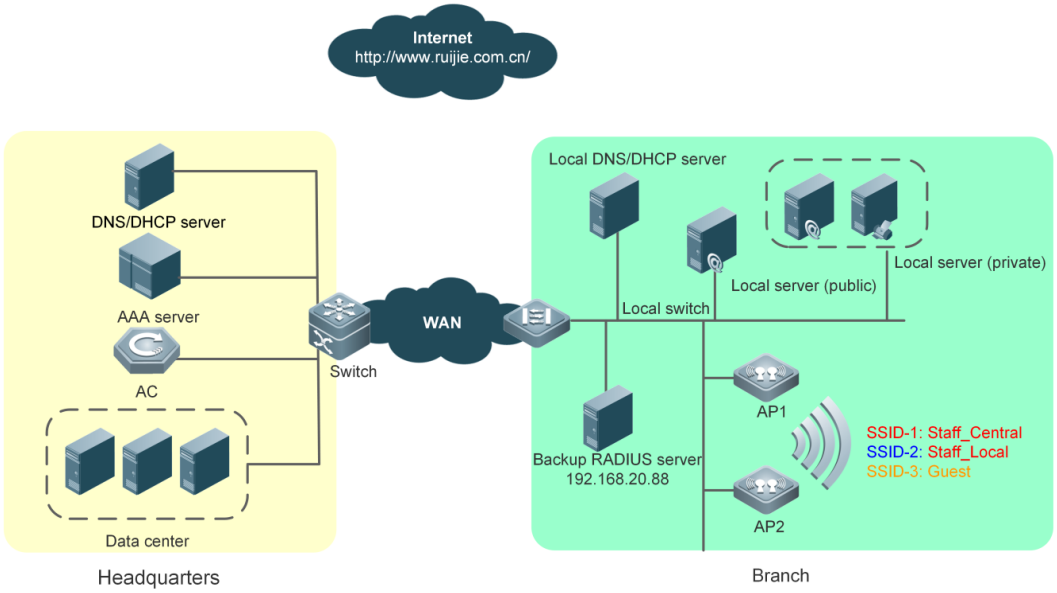
- Optional
- Perform this operation in WLAN configuration mode.
- Free Web authentication after connection interruption is performed only after this function is enabled on WLANs adopting web or MAB authentication.

Command	free-webauth at-capwap-down
Parameter Description	N/A
Defaults	By default, free web authentication upon disconnection is disabled.
Command Mode	WLAN configuration mode
Usage Guide	This function needs to be enabled only on WLANs adopting web or MAB authentication.

Enabling the AP Standalone Mode

Optional

Command	ap-mode standalone
Parameter Description	N/A
Defaults	The AP standalone mode is disabled by default.
Command Mode	AP or AP group configuration mode
Usage Guide	1. RIPT must be enabled. 2. Only OPEN or WPA/WPA2-PSK is supported. 3. The local forwarding mode must be used. 4. After the AC configuration changes, the latest configuration of the AP will take effect after 1 minute.



Verification

- Run the **show ap-config summary ript-enable** command to check whether RIPT and the standalone mode are enabled on the AP.

- Run the **show running-config** command to check whether the functions of SSID enabling upon disconnection and free web authentication upon disconnection are enabled.
- When the AC is correctly connected, STAs can normally go online. When the AC is restarted or disconnected, online STAs can maintain normal communications and new STAs can normally access the network.
- For WLANs with the function of SSID enabling upon disconnection enabled, SSID signals are provided only after the AP connection is ended.
- For WLANs enabled with web authentication and free web authentication upon disconnection, STAs can access the network without web authentication only after the AP connection is ended.
- Before the AP establishes a connection with the AC after restart, the AP provides Wi-Fi services as before restart.

Configuration Example

Configuring RIPT

Scenario **Figure 3-3**	
Configuration Steps	● Create a WLAN and set it to the local forwarding mode. ● Configure an AP group and specify WLAN mapping for the AP group. ● Configure the APs, add them to the AP group, and enable RIPT on the APs. ● For 802.1X authentication, configure SSID enabling upon disconnection. ● For Web authentication, enable free web authentication upon disconnection.

AC	`Hostname# configure terminal`

1.5 Monitoring

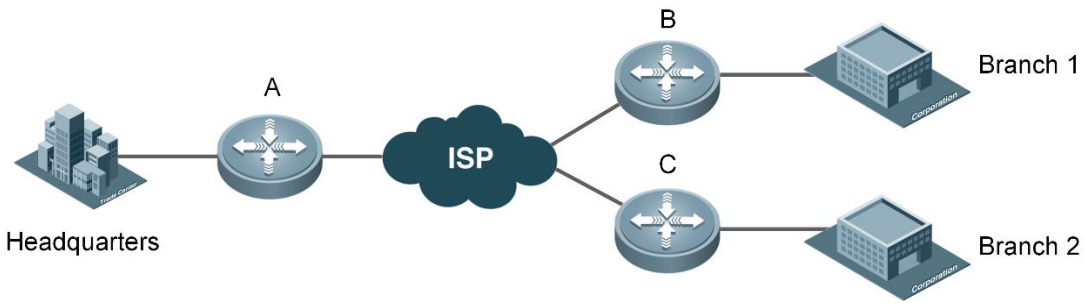
Displaying

Command	Function
show ap-config summary ript-enable	Displays the RIPT configuration of APs.
show ript-monitor	Displays the AC monitoring configuration.

1 Configuring Track

1.1 Overview

The reliable network service (RNS) tests specific services provided by a peer device to monitor service availability, integrity of an end-to-end connection, and service quality. RNS test results can be used to achieve the following effects:



- Learn the network performance in a timely manner and take measures accordingly to handle network performance problems.
- Diagnose and locate network faults.

1.2 Applications

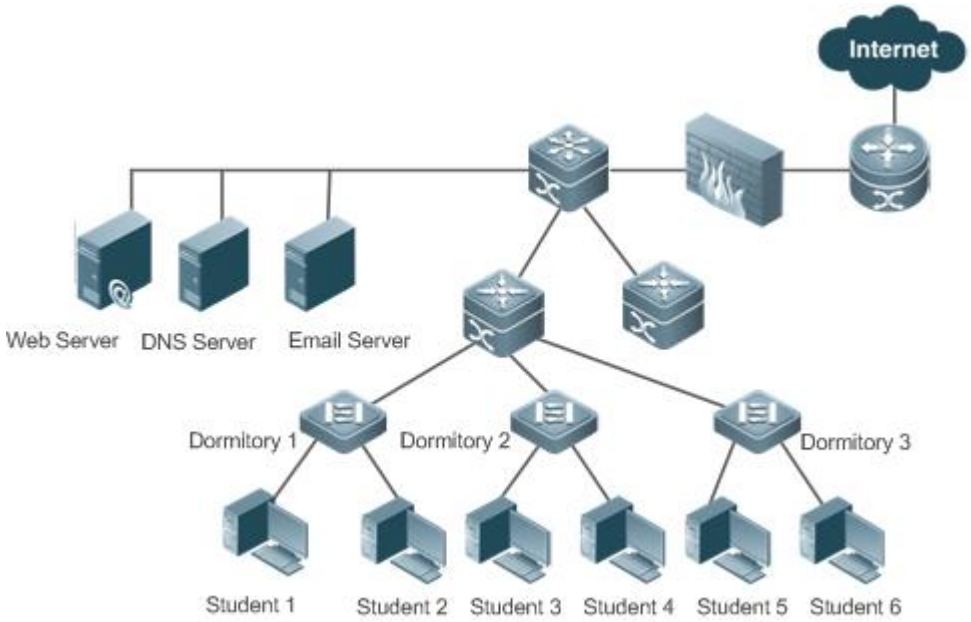
1.2.1 Testing and Evaluating Service Performance

Scenario

As shown in the following figure, a company will deploy a video conference system between the headquarters and branches, and has completed quality of service (QoS) configurations. Before deployment, the company needs to check whether new services can be provisioned normally without affecting existing services. The video conference system is sensitive to the User Datagram Protocol (UDP) delay and UDP transmission jitter of the network. The traditional ping tool can test the Internet Control Message Protocol (ICMP) performance, but cannot effectively evaluate the UDP transmission performance or measure the jitter.

Remarks	A, B, and C are switches.

Deployment



- Configure RNS on the egress switching device of each branch to test the UDP jitter and delay.
- On Switch A, specify the IP address and UDP port of the egress switching device in the headquarters, so UDP packets can be automatically sent and the egress switching device in the headquarters can automatically respond to the UDP packets. The egress switching device of the branch processes the sent and received packets to calculate the UDP jitter. To learn the performance in different periods of time, you also need to configure scheduling functions, such as periodic starting/stopping and repeated running, for the RNS.

1.2.2 Locating Network Faults

Scenario

On the campus network shown in Figure 1-1, Student 1 reports a web server access failure, Student 3 reports an Internet access failure, and Student 6 reports an email sending/receiving failure.

Figure 1-1

Deployment

- The administrator enables the domain name service (DNS) function on the access switch of dormitories to test whether the DNS server is faulty. If DNS fails, an ICMP echo packet is automatically triggered to test whether the web server is reachable.
- When a fault occurs, the administrator only needs to start a test. Then subsequent tests can be automatically triggered. The administrator can check the test results to locate the fault, which greatly reduces the workload for the administrator.

1.3 Features

Basic Concepts

↘ RNS Instance

An RNS instance can be treated as an RNS process. Before performing the RNS, you must create an RNS instance. In the RNS instance, you need to configure RNS parameters, such as the test type, test destination address, and test frequency. The instance ID is globally unique.

Feature	Description
RNS Test	Monitor network connectivity, service availability, integrity of an end-to-end connection, and service quality.
Track	Track test results and notify the related module of the results.

1.3.1 RNS Test

An RNS test is used to monitor network connectivity, service availability, integrity of an end-to-end connection, and service quality. For example, it can be used to test whether the DNS function of the device is normal. The device supports the following types of RNS tests: ICMP echo, DNS, TCP, UDP echo, and HTTP.

Working Principle

ICMP Echo Test

ICMP echo is a basic function of the RNS, and is implemented in compliance with RFC 2925. An ICMP packet is sent to check whether the destination is reachable and to calculate the network response time and packet loss rate.

An ICMP echo request packet is sent to the destination IP address based on the preset test time and frequency. Upon receipt of the ICMP echo request packet, an ICMP echo reply packet is returned from the destination IP address. Through the ICMP echo test, the response time and packet loss rate is calculated based on information related to the received ICMP echo reply packet, for example, the receipt time and number of packets. This helps you learn the network performance and status. The ICMP echo test results and historical information will be recorded, which can be displayed using commands.

For a successful ICMP echo test, the destination device must correctly respond to ICMP echo request packets.

DNS Test

In a DNS test, a DNS client is simulated to send a domain name resolution request to a specified DNS server. You can determine whether the DNS server is available and the domain name resolution speed by checking the domain name resolution result and the time required for domain name resolution. In the DNS test, the domain name resolution process is simulated, but the mapping between the resolved domain name and the IP address is not saved. The DNS test results and historical information will be recorded, which can be displayed using commands.

Procedure for Configuring an RNS Test

1 Create an instance of a specified test type and configure test parameters based on the test type.

2 Start the instance.

3 Use the RNS instance to construct a packet of the specific test type and send the packet to the peer end.

4 Upon receipt of the test packet, the peer end returns a reply packet of a corresponding type.

5 The RNS instance calculates the packet loss rate and round trip time (RTT) depending on whether a reply packet is received and the time of reply packet receipt.

6 Use the **show** or **debug** command to check the test result.

The preceding describes the general procedure for RNS tests.

Related Configuration

Configuring the Test Repeat Interval

By default, the test repeat interval is 60s.

In RNS configuration mode, run the **frequency** *millisecond* command to configure the test repeat interval.

Configure the frequency based on the following formula to ensure correct test calculation.

(**frequency** *milliseconds*) > (**timeout** *milliseconds*) >= (**threshold** *milliseconds*)

Configuring the Test Timeout

The default timeout varies according to the test type. You can run the **show ip rns configuration** command to display the timeout of a specific test type.

In RNS configuration mode, run the **timeout** *milliseconds* command to configure the timeout of an instance.

Configure the timeout based on a formula. For details, see "Usage Guide" of the **frequency** command.

Configure the test time threshold.

Configuring the Test Threshold

By default, the test threshold is 5000 ms.

In RNS configuration mode, run the **threshold** *milliseconds* command to configure the test threshold.

Configure the threshold based on a formula. For details, see "Usage Guide" of the **frequency** command.

Configuring a Tag for the Test

No default configuration is available.

In RNS configuration mode, run the **tag** *text* command to configure a test tag.

You can run the **tag** command to specify a tag to identify the test.

Configuring the Protocol Payload Size

The default protocol payload size varies with the test type. By default, the protocol payload size is the minimum or appropriate size for protocol packets of the corresponding test type.

In RNS configuration mode, run the **request-data-size** *bytes* command to configure the protocol payload size.

Perform this configuration in IP RNS configuration mode.

Configuring the TOS Field of Test Packets

By default, the TOS is 0.

In RNS configuration mode, run the **tos** number command to configure the TOS field in the IPv4 header of RNS test packets.

1.3.2 Track Association

Objects that can be tracked include the test result of an RNS instance, RNS list status, link status on an interface, and track list status. When the track status changes, an action of a module is triggered.

Working Principle

The test result of an RNS instance is tracked as follows:

- Configure a track object for tracking the test result of an RNS instance.
- When the test result of the RNS instance changes, the RNS module sends a status change message to the track module.

- The track module receives the test result. After the preset delay is reached, if the test result remains unchanged, the status of the track object is modified, and the module of the track object is notified of the modification. If the test result is normal within the period, the status of the track object is not modified and the corresponding module is not notified.

Related Configuration

Configuring a Track Object for Tracking the Link Status of An Interface

By default, the function of tracking the link status of an interface is disabled.

Run the **track interface line-protocol** command to configure a track object, which is used to track the link status of an interface.

If the link status of the interface is Up, the status of the track object is Up. If the link status of the interface is Down, the status of the track object is also Down.

Configuring a Track Object for Tracking the Test Result of an RNS Instance

By default, the function of tracking the test result of an RNS instance is disabled.

Run the **track rns** command to configure a track object, which is used to track the test result of an RNS instance. The RNS instance ID range is from 1 to 500.

If the RNS test succeeds, the track object is in Up state. If the RNS test fails, the track object is in Down state.

Configuring a Track Object for Tracking the Test Result of an RNS List

By default, the function of tracking the test result of an RNS list is disabled.

Run the **track rns-list** command to configure a track object, which is used to track the test result of an RNS list. The RNS instance ID range is from 1 to 500.

The result can be the AND or OR operation result of the status of all members. If the result of this track object is set to the OR operation result, and the OR result of the status of all the tracked RNS objects is Up, the status of this track object is Up. If the OR result of the status of all the tracked RNS objects is Down, the status of this track object is also Down. If the result of this track object is set to the AND operation result, and the AND result of the status of all the tracked RNS objects is Up, the status of this track object is Up. If the AND result of the status of all the tracked RNS objects is Down, the status of this track object is also Down.

Configuring a Track Object for Tracking the Status of a Track List

By default, the function of tracking the status of a track list is disabled.

Run the **track list** command to configure a track object, which is used to track the status of a track list. The result can be the AND or OR operation result of the status of all members.

If the result of this track object is set to the OR operation result of the status of all members, when all RNS tests succeed, the track object is in Up state. If one RNS test fails, the track object is in Down state. If the result of this track object is set to the OR operation result of the status of all members, when all RNS tests fail, the track object is in Down state. If one RNS test succeeds, the track object is in Up state.

Configuring a Track List Member

By default, no member is configured for the track list.

Run the **object** command to configure a track list member. The status of the member can be the same as or contrary to that of the corresponding track object.

Adjusting the Delay for Notifying the Status Change of a Track Object

By default, the delay for notifying the status change of a track object is 0.

Run the **delay** command to adjust the delay for track notification, including the delay values for notifying the status change of a track object from Up to Down and from Down to UP. The delay range is from 0 to 180, in seconds.

A longer delay indicates a longer waiting time for the associated track object being notified of the status; a shorter delay indicates a shorter waiting time for the associated track object being notified of the status.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions	(Mandatory) It is used to configure basic function parameters of the RNS.	
	ip rns	Detailed configuration and brief configuration are supported: ● Detailed configuration: An RNS operation object is defined, which is used as the configuration ID for subsequent tests and parameters. ● Brief configuration: Subsequent configuration is not required, and tests can be started in one step. ICMP echo, DNS, and TCP tests can be started in one step.
	ip rns reaction-configuration	Configures the proactive threshold monitoring and triggering mechanism of an RNS test.
	ip rns reaction-trigger	Triggers another type of the RNS test in pending state when the monitoring threshold is exceeded during an RNS test.
	ip rns schedule	Configures the scheduling method, start time, and life time of an RNS test.
	ip rns restart	Restarts an RNS test.
	ip rns reset	Clears all the IP RNS configurations.
Configuring an ICMP Echo Test	(Optional) It is used to implement the ICMP echo test.	
	icmp-echo	Creates an ICMP echo test.
	request-data-size	Configures the protocol payload size.
	frequency	Configures the test repeat interval.
	tag	Configures a tag.
	threshold	Configures the test time threshold.
	timeout	Configures the test timeout.
	tos	Configures the ToS field in the IPv4 header of test packets.
Configuring a DNS Test	(Optional) It is used to implement the DNS test.	
	dns	Creates a DNS test.

Configuration	Description and Command	
	frequency	Configures the test repeat interval.
	tag	Configures a tag.
	threshold	Configures the test time threshold.
	timeout	Configures the test timeout.
	tos	Configures the ToS field in the IPv4 header of test packets.
Configuring Track	(Optional) It is used to configure track association.	
	track rns	Configures a track object for tracking the test result of an RNS instance.
	track rns-list	Configures a track object for tracking the status of an RNS list.
	track interface line-protocol	Configures a track object for tracking the link status of an interface.
	track list	Configures a track object for tracking the status of a track list.
	object	Configures a member object for a track list object.
	delay	Configures the delay for notifying the status change of a track object.

1.4.1 Configuring Basic Functions of the RNS

Configuration Effect

- Detailed configuration: Configures an RNS instance.
- Brief configuration: (Optional) Configure and start an RNS instance at a time.

Notes

- In detailed configuration mode, if you do not configure the test type after entering the IP RNS mode by running the command, the RNS instance will not be created.
- In detailed configuration mode, after configuring an RNS instance, you need to run the **ip rns schedule** command to configure the startup policy; otherwise, the test will not be implemented.

Configuration Step

Defining an RNS Operation Object

- Mandatory.
- Unless otherwise required, define an RNS operation object on each switch.
- Brief configuration is optional.

Configuring the Proactive Threshold Monitoring and Triggering Mechanism for an RNS Test

- Perform this configuration if required.
- Perform this configuration on every switch, unless otherwise required.

Enabling an RNS Instance to Trigger Another RNS Instance

- Perform this configuration if another RNS test in pending state needs to be triggered in the situation where the monitoring threshold is exceeded during an RNS test.
- If scheduling parameters are not configured for the triggered RNS instance, the default schedulingparameters are applied.
- Unless otherwise required, apply this configuration to each switch.

Configuring Scheduling Parameters of an RNS Instance

- Perform this configuration on every switch, unless otherwise required.
- In brief configuration mode, default parameter values are applied, so you do not need to perform this configuration.

Restarting an RNS Instance

- Perform this configuration, or directly run the **ip rns schedule X start-time now** command if an IP RNS instance in pending state needs to be reset.

Clearing Configurations of All RNS Instances

- Perform this configuration if required, for example, when many instances are configured but configurations are found incorrect.

Enabling the IP RNS Server

- This configuration is mandatory for UDP echo tests.
- Unless otherwise required, apply this configuration to each switch.

Verification

Run the **show ip rns configuration** command to display the RNS instance configuration.

Related Commands

Defining an IP RNS Operation Object

Command	**ip rns** *operation-number* [{ **dns** *destination-hostname* **name-server** *ip-address* | **icmp-echo** *destination-ip-address* } [**frequency** *seconds* | **timeout** *milliseconds* | **threshold** *milliseconds*] *]
Command	**ip rns** *operation-number*
Parameter Description	*operation-number*: Indicates the RNS instance ID. The value range is from 1 to 500. For details about parameters, see the configuration of the specific test type.
Command Mode	Global configuration mode
Usage Guide	The device supports only IPv4-related tests, but not IPv6-related tests. A maximum of 500 tests can be configured, depending on the device performance. The test function is only a value-added function. When a large number of tests are configured and consume a lot of system resources, the test function may be temporarily disabled to ensure normal operation of core services, such as route forwarding. Detailed configuration (**ip rns** *operation-number* with mandatory parameters specified**)**: Run this command and enter the IP RNS configuration mode. In this mode, you can define various test types. If the test type is not configured, the RNS test is not created. After configuring an RNS test, you must

	run the **ip rns schedule** command to configure scheduling parameters; otherwise, the test cannot be conducted. After configuring the type of an RNS test, you can run the **ip rns** command to enter the mode of the test type. To modify the type of an RNS test, you need to first delete the RNS instance by running the **no ip rns** command in global configuration mode. Brief configuration (**ip rns** with optional parameters specified): Running **ip rns** with optional parameters specified is equivalent that **ip rns operation-number**, **ip rns schedule**, detailed test configuration (such as the ICMP echo test), **frequency**, **timeout**, and **threshold** are executed according to the logical sequence. Among these commands, the **ip rns schedule** command is executed to start a test by using the **start-time now life forever** parameter. For details about restrictions of other configuration items, see the related description in the detailed configuration. Similarly, to modify a test in brief configuration mode, you need to first delete this RNS test by running the **no ip rns** command in global configuration mode.

Configuring the Proactive Threshold Monitoring and Triggering Mechanism for the Test

Command	**ip rns reaction-configuration** *operation-number* **react** *monitored-element* [**action-type** *option*] [**threshold-type** { **average** [*number-of-measurements*] | **consecutive** [*occurrences*] | **immediate** | **never** | **xofy**[*x-value y-value*] }] [**threshold-value** *upper-threshold lower-threshold*]
Parameter Description	*operation-number*: Indicates the RNS instance ID. The value range is from 1 to 500. *monitored-element*: Specifies the monitored element. **action-type** *option*: Indicates the action taken after the test is triggered. **average** [*number-of-measurements*]: Indicates that the subsequent associated actions are triggered if the average of *number-of-measurements* of the monitored element exceeds the threshold. **consecutive** [*occurrences*]: Indicates that the test is triggered if the consecutive number of *occurrences* of the monitored element exceeds the threshold. The default value of *occurrences* is 5. The value range is from 1 to 16. **immediate**: Indicates that the test is triggered immediately after the monitored element exceeds the threshold. **never**: Indicates that the test is never triggered. **xofy** [*x-value y-value*]: Indicates that results of X tests exceed the threshold in the last Y tests. The default values of X and Y are 5. The value of X or Y ranges from 1 to 16. **threshold-value** *upper-threshold lower-threshold*: Indicate the upper and lower thresholds. ● When the value of *monitored-element* is the RTT, the threshold is the time. For default values, see "Usage Guide". The value range is from 0 to 60,000, in milliseconds. ● You do not need to configure **threshold-value** when **react** is set to **timeout**.
Command Mode	Global configuration mode
Usage Guide	You can configure multiple thresholds for one RNS test to monitor different elements. The following table provides the mapping between test types and monitored elements.

Monitored Element	icmp-echo	dns
timeout	✓	✓
rtt	✓	✓

The following table lists the default thresholds of each monitored element.

Monitored Element	Upper Threshold	Lower Threshold

	timeout	-	-
	rtt	5000 ms	0 ms

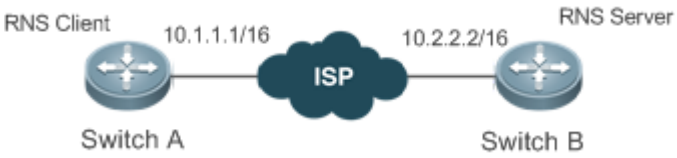
Enabling an RNS Instance to Trigger Another RNS Instance

Command	**ip rns reaction-trigger** *operation-number target-operation*
Parameter Description	*operation-number*: Indicates the number of the source RNS instance that triggers the action. The value range is from 1 to 500. *target-operation*: Indicates the number of the target RNS instance that is triggered. The value range is from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	The trigger function is typically used in network fault diagnosis scenario. In a common scenario, you do not need to configure the trigger function.

Configuring Scheduling Parameters of an RNS Instance

Command	**ip rns schedule** *operation-number* [**life** { **forever** |*seconds* } | **start-time** { *hh*:*mm* [:*ss*] [*month day* | *daymonth*] | **pending** | **now** | **after***hh*:*mm*:*ss* } | **recurring**] *
Parameter Description	*operation-number*: Indicates the number of the RNS operation. The value range is from 1 to 500. **lifeforever**: Indicates that the RNS operation life time is valid forever. **life** *seconds*: Indicates the running time of the RNS instance, in seconds. *hh:mm[:ss]*: Indicates the start time of the RNS instance, in 24-hour format. *month*: Indicates the start month of the RNS instance. The default value is the current month. *day*: Indicates the start date of the RNS instance. The default value is the current date. **pending**: Indicates that the start time of the RNS instance is not defined, which is the default. **now**: Indicates that the operation start time is now, that is, the operation starts now. **after***hh:mm:ss*: Indicates that the RNS instance starts after a delay of hh:mm:ss. **recurring**: Indicates whether the RNS instance starts at the same time every day.
Command Mode	Global configuration mode
Usage Guide	If scheduling parameters of an RNS test have been configured by running the **ip rns schedule** command, parameters cannot be modified during running. To modify the configuration, you need to run the **no ip rns schedule** command to delete the scheduling parameters. **life** { *seconds* } indicates the running time of the RNS instance. That is, the test stops after a period of time specified by *seconds*.

Restarting an RNS Test by Running the ip rns restart Command



Command	**ip rns restart** *operation-number*
Parameter Description	*operation-number*: Indicates the number of an RNS test. The value range is from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	This command restarts an RNS test for which the scheduling policy is configured and is in pending state. This command is invalid for an RNS test for which the scheduling policy is not configured.

Clearing Configurations of All the IP RNS Instances by Running the ip rns reset Command

Command	ip rns reset
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command clears configurations of all the IP RNS instances. It is used only in extreme cases, for example, when many RNS tests are configured but the configurations are found incorrect.

Configuration Example

Configuring Basic Functions of the RNS

Scenario Figure 1-2	
Configuration Steps	● Configure instance 1 on Switch A. ● Configure the scheduling method, start time, and life time of instance 1. ● Configure the proactive threshold monitoring and triggering mechanism of instance 1. ● Trigger instance 2 in pending state when the monitoring threshold of instance 1 is exceeded.

Switch A	`A# configure terminal`
	`A(config)# ip rns 1`
	`A(config-ip-rns)# icmp-echo 10.1.1.1`
	`A(config-ip-rns-icmp-echo)# exit`
	`A(config)# ip rns schedule 1 start-time now life forever`
	`A(config)# ip rns reaction-configuration 1 react timeout threshold-type immediate action-type trigger`
	`A(config)# ip rns reaction-trigger 1 2`

Verification	Run the **show ip rns configuration** command to display the instance configuration.
	`Router# show ip rns configuration 1`
	`Entry number: 1`
	`Tag: ruijie555`
	`Type of operation to perform: icmp-echo`
	`Operation timeout (milliseconds): 5000`
	`Operation frequency (milliseconds): 60000`
	`Threshold (milliseconds): 5000`
	`Recurring (Starting Everyday): FALSE`
	`Life (seconds): 3500`
	`Next Scheduled Start Time:Start Time already passed`
	`Target address/Source address: 2.2.2.3/0.0.0.0`
	`Request size (ARR data portion): 36`

1.4.2 Configuring an ICMP Echo Test

Configuration Effect

Create an ICMP echo test.

Notes

Basic functions of the RNS must be configured.

Configuration Steps

Creating an ICMP Echo Test

- Mandatory.
- Unless otherwise required, create ICMP echo test instances on each switch.

Configuring Common Optional Parameters of the Test

- Mandatory if common optional parameters of the test, for example, the repeat interval, tag, time threshold, timeout, and ToS, are required to be changed.
- Perform this configuration on every switch, unless otherwise required.

Configuring the Protocol Payload Size

- Perform this configuration if required.
- Perform this configuration on every switch, unless otherwise required.

Verification

Run the **show ip rns configuration** command to display the instance configuration.

Related Commands

Creating an ICMP Echo Test

Command	**icmp-echo** { **oob** { *destination-ip-address* | *destination-hostname* [**name-server** *ns-ip-address*] } [**source-ipaddr** *src-ip-address*] [**out-interface** *type num* [**next-hop** *nh-ip-address*]]
Parameter Description	*destination-ip-address*: Indicates the destination IP address. *destination-hostname*: Indicates the destination host name. **name-server** *ip-address*: Specifies the DNS server when the destination host name is configured. By default, the DNS server configured by using the **ipname-server** command is used for address resolution. **source-ipaddr** *ip-address*: Indicates the source IP address. **out-interface** *type num*: Specifies the outbound interface (non-MGMT interface) of test packets. **next-hop** *A.B.C.D*: Indicates the IP address of the next hop.
Command Mode	IP RNS configuration mode (config-ip-rns)
Usage Guide	After an ICMP echo test is started, the system sends an ICMP echo request packet to test whether the device is connected to the target host. After an ICMP echo test is created, the system enters the IP RNS ICMP echo mode. By default, the protocol payload size of an ICMP echo request packet is 36

	bytes. You can run the **request-data-size** command to change the packet size. You need to configure the RNS test type (for example, ICMP echo and DNS) before configuring parameters. To modify the type of an RNS instance, you need to delete the RNS instance by running the **no ip rns** command in global configuration mode.

Configuring the Protocol Payload Size of an RNS Instance

Command	**request-data-size** *bytes*
Parameter Description	*bytes*: Indicates the bytes of a test packet. The minimum and maximum bytes vary with the test type. You need to configure this parameter based on the command prompt in corresponding test mode.
Command Mode	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command is used to pad some bytes in a test packet so that large packets can be used for the test.

Configuring the Test Repeat Interval

Command	**frequency** *milliseconds*
Parameter Description	*milliseconds*: Indicates the packet sending interval, in milliseconds. The default value is 60000 ms. The value ranges from 10 to 604,800,000. The maximum value is one week.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	After an RNS instance is started, tests are conducted periodically. You can run the **frequency** command to specify the repeat interval. You need to configure the frequency based on the following formula to ensure correct test calculation: (**frequency** *milliseconds*) > (**timeout** *milliseconds*) >= (**threshold** *milliseconds*)

Configuring a Tag for an RNS Instance

Command	**tag** *text*
Parameter Description	*text*: Sets the test tag. The value is a string of up to 79 characters.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

Configuring the Time Threshold for an RNS Instance

Command	**threshold** *milliseconds*
Parameter Description	*milliseconds*: Indicates the time threshold for the test, in milliseconds. The value range is from 0 to 60,000. The default value is 5,000.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the threshold based on the following formula to ensure correct test calculation: (**frequency** *milliseconds*) > (**timeout** *milliseconds*) >= (**threshold** *milliseconds*)

Configuring the Timeout for an RNS Instance

Command	**timeout** *millisecond*

Parameter Description	*millisecond*: Indicates the test timeout, in milliseconds. The value range is from 10 to 604,800,000. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the timeout based on the following formula to ensure correct test calculation: (**frequency** *milliseconds*) > (**timeout** *milliseconds*) >= (**threshold** *milliseconds*)

Configuring the ToS Field in the IPv4 Packet Header of an IP RNS Test

Command	**tos** *number*
Parameter Description	*number*: Sets the TOS field in the IPv4 header of test packets. The value range is from 0 to 255. The default value is 0.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	The ToS field has 8 bits in the IPv4 packet header. By setting the ToS field, the device can control the priority of the test packet. For different ToS fields, processing priorities are different on intermediate routers.

Configuration Example

Figure 1-3	
Configuration	Configure RNS instance 1 and parameters on Switch A.

Switch A	`A# configure terminal`
	`A(config)# ip rns 1`
	`A(config-ip-rns)#icmp-echo 10.2.2.2`
	`A(config-ip-rns-icmp-echo)#exit`
	`A(config)#ip rns schedule 1 start-time now life forever`

Verification	● Run the **show ip rns configuration** command to display the instance configuration.

Switch A	`A#show ip rns configuration 1`
	`Entry number: 1`
	`Tag:`
	`Type of operation to perform: icmp-echo`
	`Operation timeout (milliseconds): 5000`
	`Operation frequency (milliseconds): 60000`
	`Threshold (milliseconds): 5000`
	`Recurring (Starting Everyday): FALSE`
	`Life (seconds): foerver`
	`Next Scheduled Start Time:Start Time already passed`
	`Target address/Source address: 10.2.2.2/0.0.0.0`
	`Request size (ARR data portion): 36`

1.4.3 Configuring a DNS Test

Configuration Effect

Create a DNS test.

Notes

Basic functions of the RNS must be configured.

Configuration Step

Creating a DNS Test

- Mandatory.
- Unless otherwise required, create a DNS test on each switch.

Configuring Common Optional Parameters of the Test

- Mandatory if common optional parameters of the test, for example, the repeat interval, tag, time threshold, timeout, and TOS, need to be changed.
- Perform this configuration on every switch, unless otherwise required.

Verification

Run the **show ip rns configuration** command to display the instance configuration.

Related Commands

Creating a DNS Test

Command	**dns** *destination-hostname* **name-server** *ip-address* [**out-interface** *type num* [**next-hop** *ip-address*] | **source-ipaddr** *ip-address*] *
Parameter Description	*destination-hostname*: Indicates the destination host name. **name-server** *ip-address*: Indicates the DNS IP address. **source-ipaddr** *ip-address:* Indicates the source IP address. **out-interface** *type num*: Specifies the outbound interface (non-MGMT interface) of test packets. **next-hop** *ip-address*: Indicates the IP address of the next hop when the outbound interface is specified.
Command Mode	IP RNS configuration mode (config-ip-rns)
Usage Guide	After a DNS test is started, the system sends a DNS parsing request packet to test whether the device is connected to the target host. After a DNS test instance is created, the system enters the IP RNS DNS mode. You need to configure the RNS test type before configuring parameters. To modify the type of an RNS instance, you need to delete the RNS instance by running the **no ip rns** command in global configuration mode.

Configuring the Test Repeat Interval

Command	**frequency** *milliseconds*
Parameter Description	*milliseconds*: Indicates the packet sending interval, in milliseconds. The default value is 60000 ms. The value range is from 10 to 604800000. The maximum value is one week.
Command	IP RNS DNS configuration mode (config-ip-rns-dns)

Mode	IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	After an RNS instance is started, tests are conducted periodically. You can run the **frequency** command to specify the repeat interval. You need to configure the frequency based on the following formula to ensure correct test calculation: (**frequency** *milliseconds*) > (**timeout** *milliseconds*) >= (**threshold** *milliseconds*)

Configuring a Tag for an RNS Instance

Command	**tag** *text*
Parameter Description	*text*: Sets the test tag. The value is a string of up to 79 characters.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	This command specifies a tag for a test, which is often used to indicate the function of the test.

Configuring the Time Threshold for an RNS Instance

Command	**threshold** *milliseconds*
Parameter Description	*milliseconds*: Indicates the time threshold for the test, in milliseconds. The value range is from 0 to 60000. The default value is 5000.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the threshold based on the following formula to ensure correct test calculation: (**frequency** *milliseconds*) > (**timeout** *milliseconds*) >= (**threshold** *milliseconds*)

Configuring the Time Threshold for an RNS Instance

Command	**timeout** *millisecond*
Parameter Description	*millisecond*: Indicates the test timeout, in milliseconds. The value range is from 10 to 604800,000. The default timeout varies according to the test type.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	Configure the timeout based on the following formula to ensure correct test calculation: (**frequency** *milliseconds*) > (**timeout** *milliseconds*) >= (**threshold** *milliseconds*)

Configures the ToS Field in the IPv4 Header of Test Packets

Command	**tos** *number*
Parameter Description	*number*: Sets the ToS field in the IPv4 header of test packets. The value range is from 0 to 255. The default value is 0.
Command Mode	IP RNS DNS configuration mode (config-ip-rns-dns) IP RNS ICMP echo configuration mode (config-ip-rns-icmp-echo)
Usage Guide	The ToS field has 8 bits in the IPv4 packet header. By setting the ToS field, the device can control the priority of the test packet. For different ToS fields, processing priorities are different on intermediate routers.

Configuration Example

Scenario **Figure 1-4**	
Configuration Steps	● Configure RNS instance 1 and parameters on Switch A.

Switch A	`A# configure terminal`
	`A(config)# ip rns 1`
	`A(config-ip-rns)# dns www.ruijie.com.cn name-server 10.2.2.2`
	`A(config-ip-rns-dns)#exit`
	`A(config)ip rns schedule 1 start-time now life forever`

Verification	● Run the **show ip rns configuration** command to display the instance configuration.

Switch A	`A#show ip rns configuration 1`
	`Entry number: 1`
	`Tag:`
	`Type of operation to perform: dns`
	`Operation timeout (milliseconds): 5000`
	`Operation frequency (milliseconds): 60000`
	`Threshold (milliseconds): 5000`
	`Recurring (Starting Everyday): FALSE`
	`Life (seconds): forever`
	`Next Scheduled Start Time:Start Time already passed`
	`Target host name: www.ruijie.com.cn`
	`Name Server: 10.2.2.2`

Common Errors

The DNS IP address is incorrect.

1.4.4 Configuring Track Association

Configuration Effect

- Configure the track function to track the test result of an RNS instance.
- Configure the track function to track the link status of an interface.
- Configure the track function to track the status of a track list.
- Configure the track function to track the status of an RNS list.

Notes

- To configure the track function to track the test result of an RNS instance, you need to configure an RNS instance.
- To configure the track function to track the link status of an interface, you need to configure the interface.
- To configure the track function to track the status of a track list, you need to configure members for the track list.
- To configure the track function to track the status of an RNS list, you need to configure members for the RNS list.

Configuration Step

Configuring a Track Object

- Perform this operation if required.
- The following four methods are available to create a track object:
- Create a track object for tracking the test result of an RNS instance. Perform this configuration on every switch, unless otherwise required.
- Create a track object for tracking the link status of an interface. Perform this configuration on every switch, unless otherwise required.
- Create a track object for tracking the status of a track list. Perform this configuration on every switch, unless otherwise required.
- Create a track object for tracking the status of an RNS list. Perform this configuration on every switch, unless otherwise required.

Configuring the Notification Delay of a Track Object

- Perform this configuration if notifying the status change of a track object needs to be delayed.
- The delay for notifying the status change of a track object includes the delay for notifying the status change of a track object from Up to Down and the delay for notifying the status change of a track object from Down to UP. You can configure either delay or both of them.
- Perform this configuration on every switch, unless otherwise required.

Configuring a Track Member

- Perform this configuration if a track object for tracking the status of a track list needs to be configured.
- When configuring a track member, you can set the status of a member meeting conditions to Up or Down.
- Perform this configuration on every switch, unless otherwise required.

Verification

Check the status of a track object when the status of the track object (such as test results of an RNS instance, link status of an interface, or status of a track list) changes.

- After the preset delay, run the **show track** command to check whether the track status changes.

Related Commands

Configuring a Track Object for Tracking the Link Status of an Interface

Command	**track** *object-number* **interface** *interface-type interface-number* **line-protocol**
Parameter Description	*object-number*: Indicates the number of a track object. The value range is from 1 to 700. *Interface-type interface-number*: Indicates the interface type and interface number.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the link status of an interface. When the link status of the interface is Up, the status of the corresponding track object is Up.

Configuring a Track Object for Tracking the Test Result of an RNS Test

Command	**track** *object-number* **rns** *entry-number*
Parameter Description	*object-number*: Indicates the number of a track object. The value range is from 1 to 700. *entry-number*: Indicates the number of an RNS instance. The value range is from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the result of an RNS test. If the test succeeds, the track object is in Up state.

Configuring a Track Object for Tracking the Status of a Track List

Command	**track** *object-number* **listboolean** { **and** | **or** }
Parameter Description	*object-number*: Indicates the number of a track object. The value range is from 1 to 700.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the status of a track list. The result can be the AND or OR operation result of the status of all members.

Configuring a Track Member

Command	**object** *object-number* [**not**]
Parameter Description	*object-number*: Indicates the number of a track object. The value range is from 1 to 700.
Command Mode	Track configuration mode
Usage Guide	Run this command to configure a member for a track list. The number of track list members that can be configured is restricted only by the number of track objects.

Configuring a Track Object for Tracking the Status of an RNS List

Command	**track** *object-number* **rns-list** *men-list* { **and** | **or** }
Parameter Description	*object-number*: Indicates the number of a track object. The value range is from 1 to 700. men-list: Indicates the RNS list that is tracked. The value of **mem-list** can be an RNS instance or a series of RNS instances. If the value of **mem-list** is a series of RNS instances, the format is as follows: *smallest RNS ID–largest RNS ID*, for example, 10–20. The RNS ID range is from 1 to 500.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a track object for tracking the status of an RNS list. The result can be the AND or OR operation result of the status of all members.

Configuring the Notification Delay of a Track Object

Command	**delay** { **up** *seconds* [**down** *seconds*] **|** [**up** *seconds*] **down** *seconds* }
Parameter Description	**up** *seconds*: Specifies the delay for notifying the status change of a track object from Down to Up, in seconds. The value range is from 0 to 180. The default value is 0. **down** *seconds*: Specifies the delay for notifying the status change of a track object from Up to Down, in seconds. The value ranges from 0 to 180. The default value is 0.
Command	Track configuration mode

Mode	
Usage Guide	When the status of a track object frequently changes, the status of the client that use this track object will frequently change. Using this command can delay notification of the status change of a track object. For example, if the status of a track object changes from Up to Down, and **delay down 10** is configured, the Down status of the track object is notified 10s later. If the status of the track objects changes to Up again within this period of time, no notification is sent. For the client that uses this track object, the status of the track object is always Up.

Displaying the Track Object Statistics

Command	**show track** [*object-number*]
Parameter Description	*object-number*: Indicates the number of a track object. The value range is from 1 to 700. The default value is all track objects.
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display statistics on track objects.

Configuration Example

Configuring Track Object 3 for Tracking the Link Status of FastEthernet 1/0

Configuration Steps	● Configure a track object for tracking the link status of an interface. ● Configure the delay for notifying the status change from Up to Down.

	`Hostname# configure terminal`
	`Hostname(config)# track 3 interface FastEthernet 1/0 line-protocol`
	`Hostname(config-track)# delay down 10`
	`Hostname(config-track)# exit`

Verification	Change the link status of FastEthernet 1/0 to Down. ● Immediately check the status of the track object, and verify that the status is still Up. ● Check the status of the track object 10s later, and verify that the status changes to Down.

	`Hostname# show track 3`
	`Track 3`
	`  Interface FastEthernet 1/0`
	`  The state is Up, delayed Down (5 secs remaining)`
	`    1 change, current state last: 300 secs`
	`  Delay up 0 secs, down 10 secs`

Configuring Track Object 3 (When the Status of Track Object 1 Is Up, and the Status of Track Object 2 Is Down, the Status of Track Object 3 is Up)

Configuration Steps	● Configure track object 1 and track object 2. ● Configure track object 3. Its members include track object 1 and track object 2.

	`Hostname # config terminal`
	`Hostname(config)# track 1 interface gigabitEthernet 0/0 line-protocol`
	`Hostname(config-track)# delay up 20 down 40`
	`Hostname(config-track)# exit`

	Hostname(config)# Hostname(config)# track 2 interface gigabitEthernet 0/1 line-protocol Hostname(config-track)# delay down 30 Hostname(config-track)# exit Hostname(config)# track 3 list Boolean and Hostname(config-track)# object 1 Hostname(config-track)# object 2 not Hostname(config-track)# exit
Verification	When the status of track objects 1 and 2 change, check the status of track object 3. ● When the status of track object 1 changes from Down to Up, and the status of track object 2 remains Down , verify that the status of track object 3 changes from Down to Up. ● When the status of track object 1 remains Up, and the status of track object 2 changes from Down to Up, verify that the status of track object 3 changes from Up to Down.
	Hostname# show track 3 Track 3 List boolean and Object 1 Object 2 not The state is Down 1 change,current state last:10 secs Delay up 0 secs,down 0 secs

Configuring Track Object 5 for Tracking the Test Result of RNS Instance 7

Configuration Steps	● Configure an RNS test. ● Configure a track object to track the result of the RNS test. ● Configure the delay for notifying the test result change from Up to Down, and the delay for notifying the test result change from Down to Up.
	Hostname# configure terminal Hostname(config)# ip rns 7 Hostname(config-ip-rns)# icmp-echo 2.2.2.2 Hostname(config-ip-rns-icmp-echo)# exit Hostname(config)# ip rns schedule 7 start-time now life forever Hostname(config)# track 5 rns 7 Hostname(config-track)# delay up 20 down 30 Hostname(config-track)# exit
Verification	Make the test result of RNS instance 7 change from successful to unsuccessful. ● When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still Up. ● Check the status of the track object 30s later, and verify that the status changes to Down.
	Hostname# show track 5 Track 5

	Reliable Network Service 7 The state is Down 2 change, current state last: 10 secs Delay up 20 secs, down 30 secs

Configuring Track Object 5 for Tracking the Test Results of an RNS List (Consisting of RNS Instances 1, 2–5, and 8)

Configuration Steps	● Configure and start an RNS test (see *RNS Configuration*). ● Configure a track object for tracking the test result of an RNS list. ● Configure the delay for notifying the test result change from Up to Down, and the delay for notifying the test result change from Down to Up.
	Hostname(config)# track 5 rns-list 1,2-5,8 and Hostname(config-track)# delay up 20 down 30 Hostname(config-track)# exit
Verification	Let the test result of one of the RNS instances 1, 2-5, and 8 changes from successful to unsuccessful. ● When the test result changes to unsuccessful, immediately check the status of track object 7, and verify that the status is still Up. ● Check the status of the track object 30s later, and verify that the status changes to Down.
	Hostname# show track 5 Track 5 rns-list 1,2-5,8 and The state is Down 2 change, current state last: 10 secs Delay up 20 secs, down 30 secs

Common Errors

- The track object for tracking an RNS test is configured, but the RNS test is not configured.
- The track object for tracking the link status of an interface is configured, but the corresponding interface is not configured.
- The track object for tracking the status of a track list, but no member of the RNS list is configured.
- The track object configured for tracking an RNS list, but the RNS test is not configured.

1.5 Monitoring

Displaying

Command	Description
show ip rns configuration [*operation-number*]	Displays configurations of one or more RNS instances.
show ip rns collection-statistics [*operation-number*]	Displays detailed statistics on one or more RNS instances.
show ip rns operational-state [*operation-number*]	Displays the current RNS status.

show ip rns reaction-configuration [*operation-number*]	Displays proactive threshold monitoring information about one or more RNS instances.
show ip rns reaction-trigger [*operation-number*]	Displays information about the test triggered by one or more RNS instances.
show ip rns statistics [*operation-number*]	Displays brief statistics on one or more RNS instances.
show track [*object-number*]	Displays brief statistics on one or more track objects.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug track { **all** | **proc-event** | **rdnd-event** | **client** }	Debugs the track module.
debug rns { **all** | **interface** | **lib** | **rdnd-event** | **restart** | **rns_id** [**0, 500**] }	Debugs the RNS module.

Configuring Network Management and Monitoring

1 Configuring SPAN

1.1 Overview

The Switched Port Analyzer (SPAN) is to copy packets of a specified port to another device port that is connected to a network monitoring device, so as to achieve network monitoring and troubleshooting.

All incoming and outgoing packets of a source port can be monitored through SPAN. For example, as shown in the following figure, all packets on Port 5 are mapped to Port 10, and the network analyzer connected to Port 10 receives all packets that pass through Port 5.

Figure 1-1 SPAN Configuration

The SPAN function is mainly applied in network monitoring and troubleshooting scenarios to monitor network information and rectify network faults.

1.2 Features

Basic Concepts

SPAN Session

A SPAN session is a data stream between the SPAN source port and destination port, which can be used to monitor packets of one or more ports in the inbound, outbound, or both directions. Switched ports, routed ports, and aggregate ports can be configured as source or destination ports of SPAN sessions. Normal operations on a switch are not affected when ports of the device are added to a SPAN session.

You can configure a SPAN session on a disabled port but the SPAN session is inactive. A SPAN session is in active state only after the port on which the SPAN session is configured is enabled. In addition, a SPAN session does not take effect after a device is powered on. It is active only after the destination port is in operational state. You can run the **show monitor** [**session** *session-id*] command to display the operation status of a SPAN session.

SPAN Data Streams

A SPAN session involves data streams in three directions:

- Incoming data streams: All packets received by a source port are copied to the destination port. You can monitor incoming packets of one or more source ports in a SPAN session. Some incoming packets of a source port may be discarded for some reasons (for example, considering port security). However, such packets are still mirrored to the destination port.
- Outgoing data streams: All packets transmitted by a source port are copied to the destination port. You can monitor outgoing packets of one or more source ports in a SPAN session. Packets transmitted from other ports to a source port may be discarded for some reasons and such packets will not be transmitted to the destination port. The format of outgoing packets of a source port may be changed for some reasons. For example, after routing, packets transmitted from the source port are changed in source MAC addresses, destination MAC addresses, VLAN IDs, and TTLs, and their formats are also changed after being copied to the destination port.
- Bidirectional data streams: Bidirectional data streams include incoming and outgoing data streams. In a SPAN session, you can monitor data streams of one or more source ports in inbound and outbound directions.

Source Port

A source port is called a monitored port. In a SPAN session, data streams of the source port are monitored for network analysis and troubleshooting. In a single SPAN session, you can monitor the incoming, outgoing, and bidirectional data streams, and the number of source ports is not restricted.

A source port has the following features:

- A source port can be a switched port, a routed port, or an aggregate port.
- A source port cannot be used as a destination port simultaneously.
- A source port and a destination port can belong to the same VLAN or different VLANs.

Destination Port

A SPAN session has one destination port (called a monitoring port) for receiving packets copied from a source port.

A destination port has the following features:

- A destination port can be a switched port, a routed port, or an aggregate port.
- A destination port cannot be used as a source port simultaneously.

Overview

Feature	Description
SPAN	Configures mirroring of ports on the same device.

1.2.1 SPAN

SPAN is used to monitor data streams on switches. It copies frames on one port to another switch port that is connected to a network analyzer or RMON analyzer so as to analyze communication of the port.

Working Principle

When a port transmits or receive packets, the SPAN-enabled device checks that the port is configured as a SPAN source port. Then it copies the packets transmitted and received by the port to the destination port.

Configuring a SPAN Source Port

You need to specify a SPAN session ID and source port ID to configure a SPAN source port, and set the optional SPAN direction item to determine the direction of SPAN data streams or specify an Access Control List (ACL) to mirror specific data streams.

Configuring a SPAN Destination Port

You need to specify a SPAN session ID and destination port ID to configure a SPAN destination port, and set the optional switching function item to determine whether to enable the switching function and configure the SPAN destination port to remove tags.

Related Configuration

The SPAN function is disabled by default. It is enabled only after a session is created, and the SPAN source and destination ports are configured. A SPAN session can be created when a SPAN source port or destination port is configured.

Configuring a SPAN Source Port

A SPAN session does not have a SPAN source port by default. You can run the **monitor session** *session-id* **source interface** *interface-id* [**both** | **rx** | **tx**] command to configure a SPAN source port.

session-id: Indicates the SPAN session ID. The number of supported SPAN sessions varies with products.

interface-id: Indicates the SPAN source port to be configured.

rx: Indicates that only packets received by the source port are monitored.

tx: Indicates that only packets transmitted by the source port are monitored.

both: Indicates that packets transmitted and received by the source port are copied to the destination port for monitoring. If none of **rx**, **tx**, and **both** is selected, **both** is enabled by default.

Configuring a SPAN Destination Port

A SPAN session does not have a SPAN destination port by default. You can run the **monitor session** *session-id* **destination interface** *interface-id* [**encapsulation replicate** | **switch**] command to configure a SPAN destination port.

encapsulation replicate: Forcibly removes tags (VLAN information carried in packets) from packets.

switch: Indicates that the SPAN destination port only receives packets mirrored from the SPAN source port and discards other packets if this option is disabled, and receives both packets mirrored from the SPAN source port and packets from non-source ports if this option is enabled, that is, communication between the destination port and other devices is not affected.

When the SPAN destination port is configured, the relevant function is disabled by default if **encapsulation replicate** or **switch** is not configured.

During SPAN configuration, pay attention to the following points:

- The SPAN destination port participates in STP tree calculation.
- If the VLAN configuration of the source port is changed, the configuration takes effect immediately.
- If the VLAN configuration of the destination port is changed, the configuration takes effect immediately.
- If the source port or destination port is disabled, SPAN will become ineffective.

- When VLAN (VLAN list) is used as the mirroring source, ensure that the destination port has sufficient bandwidth to receive mirroring data from the VLAN.
- Not all devices support all options of the preceding commands.

1.3 Configuration

Configuration	Description and Command	
Configuring SPAN Basic Functions	(Mandatory) It is used to create SPAN.	
	monitor session *session-id* **source interface** *interface-id* [**both | rx | tx**]	Configures a SPAN source port.
	monitor session *session-id* **destination interface** *interface-id*[**switch | encapsulation replicate**]	Configures a SPAN destination port.

1.3.1 Configuring SPAN Basic Functions

Configuration Effect

- Configure source and destination ports for a SPAN session.
- Configure a destination port to monitor any packets transmitted and received by a source port.

Notes

- If the switching function is disabled on a SPAN destination port, the destination port receives only mirrored packets and discards other packets that pass through the port. After the switching function is enabled, the destination port can receive non-mirrored packets.

Configuration Step

Configuring a SPAN Session

- Mandatory.
- Perform this configuration in global configuration mode.
- You can configure a SPAN session when configuring a SPAN source port or destination port, or when configuring a specified VLAN or some VLANs as a data source or data sources of SPAN.

Configuring a SPAN Source Port

- Mandatory.
- Perform this configuration in global configuration mode.
- You can select the SPAN direction when configuring a SPAN source port. **both** is configured by default, that is, both transmitted and received packets are monitored.

Configuring a SPAN Destination Port

- Mandatory.
- Perform this configuration in global configuration mode.

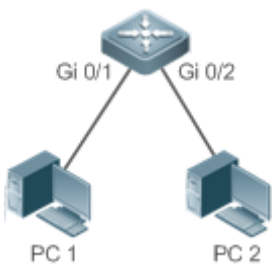
- A SPAN session is active only when a SPAN source port is configured (or a VLAN is specified as the data source of SPAN) and a SPAN destination port is configured.

Verification

- Run the **show monitor** command or the **show running** command to verify the SPAN configuration. Alternatively, analyze packet obtaining on the SPAN destination port and check whether the SPAN function takes effect based on obtained packets.

Related Commands

Configuring a SPAN Source Port



Command	**monitor session** *session-id* **source interface** *interface-id* [**both** | **rx** |**tx**]
Parameter Description	*session-id:* Indicates the ID of a SPAN session. *interface-id:* Indicates the interface ID. **both:** Indicates that packets in the inbound and outbound directions are monitored. It is configured by default. **rx:** Indicates that packets in the inbound direction are monitored. **tx:** Indicates that packets in the outbound direction are monitored.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a SPAN Destination Port

Command	**monitor session** *session-id* **destination interface** *interface-id*[**switch** | **encapsulation replicate**]
Parameter Description	*session-id:* Indicates the ID of a SPAN session. *interface-id*: Indicates the interface ID. **switch:** Indicates that the switching function is enabled on the SPAN destination port. It is disabled by default. **encapsulation replicate:** Indicates that the encapsulation function is enabled on the mirroring port. Mirrored packets are untagged forcibly if this function is enabled. It is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Local Mirroring

Scenario **Figure 1-2**	

Configuration Steps	● As shown in Figure 1-2, add ports Gi 0/1 and Gi 0/2 of Device A to VLAN 1. ● Create SVI 1 and set the address of SVI 1 to 10.10.10.10/24. ● Set IP addresses of PC 1 and PC 2 to 10.10.10.1/24 and 10.10.10.2/24 respectively. ● Configure SPAN for Device A and configure Gi 0/1 and Gi 0/2 as the source port and destination port of SPAN respectively.

A	`Hostname# configure`
	`Hostname(config)# vlan 1`
	`Hostname(config-vlan)# exit`
	`Hostname(config)# interface vlan 1`
	`Hostname(config-if-VLAN 1)# ip address 10.10.10.10 255.255.255.0`
	`Hostname(config-if-VLAN 1)# exit`
	`Hostname(config)# monitor session 1 source interface gigabitEthernet 0/1`
	`Hostname(config)# monitor session 1 destination interface gigabitEthernet 0/2`

Verification	● Run the **show monitor** command to check whether SPAN is configured correctly. After successful configuration, PC 1 sends ping packets to SVI 1 and PC 2 conducts monitoring by using the packet obtaining tool.

A	`Hostname# show monitor`
	`sess-num: 1`
	`span-type: LOCAL_SPAN`
	`src-intf:`
	`GigabitEthernet 0/1 frame-type Both`
	`dest-intf:`
	`GigabitEthernet 0/2`

Common Errors

- The session ID specified during configuration of the SPAN source port is inconsistent with that specified during configuration of the SPAN destination port.
- Packet loss may occur if packets of a port with high bandwidth are mirrored to a port with low bandwidth.

1.4 Monitoring

Displaying

Command	Description
show monitor	Displays all mirroring sessions existing in the system.
show monitor session *session-id*	Displays a specified mirroring session.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Description	Command
debug span	Debugs SPAN.

1 Configuring NTP

1.1 Overview

The Network Time Protocol (NTP) is an application-layer protocol that enables network devices to synchronize time. NTP enables network devices to synchronize time with their servers or clock sources and provides high-precision time correction (the difference from the standard time is smaller than 1 millisecond on a LAN and smaller than decades of milliseconds on a WAN). In addition, NTP can prevent attacks by using encrypted acknowledgment.

The device supports the NTP client and NTP server. That is, a Ruijie device can synchronize time with a time server, and be used as a time server to provide time synchronization for other devices. When a Ruijie device is used as a server, it supports only the unicast server mode.

Protocols and Standards

- RFC 1305: Network Time Protocol (Version 3)

1.2 Applications

Application	Description
Synchronizing Time Based on an External Reference Clock Source	A device is used as a client that synchronizes time with an external clock source. After successful synchronization, it is used as a server to provide time synchronization for other devices.
Synchronizing Time Based on the Local Reference Clock Source	A device uses a local clock as a reliable NTP reference clock source and is also used as a server to provide time synchronization for other devices.

1.2.1 Synchronizing Time Based on an External Reference Clock Source

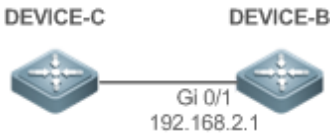
Scenario

In Figure 1-1:

- DEVICE-A is used as a reliable reference clock source to provide time synchronization for external devices.
- On DEVICE-B, DEVICE-A is used as the NTP server and synchronizes time with DEVICE-A.
- DEVICE-B provides time synchronization for DEVICE-C after successful synchronization.

Figure 1-1

Deployment



Configure DEVICE-B to work in NTP external reference clock mode.

1.2.2 Synchronizing Time Based on the Local Reference Clock Source

Scenario

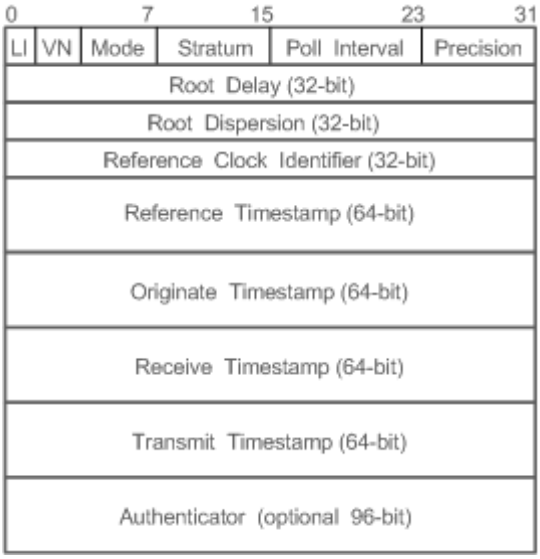
As shown in Figure 1-2, DEVICE-B uses a local clock as the NTP reference clock source and provides time synchronization for DEVICE-C.

Figure 1-2

Deployment

Configure DEVICE-B to work in NTP local reference clock mode.

1.3 Features



Basic Concepts

NTP Packet

As defined in RFC1305, NTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 1-3 shows the format of an NTP time synchronization packet.

Figure 1-3 Format of an NTP Time Synchronization Packet

- Leap Indicator(LI): indicates a 2-bit leap second indicator.

The value 00 indicates no warning information; the value 01 indicates that there are 61 seconds in the previous minute; the value 10 indicates that there are 59 seconds in the previous minute; the value 11 indicates that the clock is not synchronized.

- Version Number(VN): indicates a 3-bit NTP version number. The current version number is 3.
- Mode: indicates a 3-bit NTP working mode.

The value 0 indicates that the field is not defined; the value 1 indicates symmetric active; the value 2 indicates symmetric passive; the value 3 indicates a client; the value 4 indicates a server; the value 5 indicates broadcast; the value 6 indicates control information; the value 7 is reserved.

- Stratum: indicates the 8-bit stratum of a local clock. The value 0 indicates that the field is not defined; the value 1 indicates the master reference clock source; other values indicate slave reference clock sources.
- Poll Interval: indicates the poll interval, in seconds. The value is an 8-bit integer.
- Precision: indicates the time precision of a local clock, in seconds. The value is an 8-bit integer.
- Root Delay: indicates the round-trip time (RTT) to the master reference clock source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected last time.
- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

NTP Server

A device uses a local clock as the reference clock source to provide time synchronization for other devices on a network.

NTP Client

A device is used as an NTP client that synchronizes time with an NTP server on a network.

Stratum

In NTP, the stratum is used to describe the number of hops from a device to an authority clock source. An NTP server whose stratum is 1 has a directly connected atomic clock or radio controlled clock; an NTP server whose stratum is 2 obtains time from the server whose stratum is 1; an NTP server whose stratum is 3 obtains time from the server whose stratum is 2; and so on. Therefore, clock sources with lower stratums have higher clock precisions.

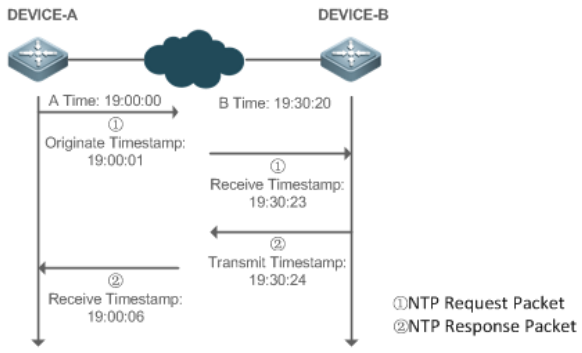
Hardware Clock

A hardware clock operates based on the frequency of the quartz crystal resonator on a device and is powered by the device battery. After the device is shut down, the hardware clock continues running. After the device is started, the device obtains time information from the hardware clock as the software time of the device.

Overview

Feature	Description
NTP Time Synchronization	Allows network devices to synchronize time with their servers or reliable clock sources to implement high-precision time correction.
NTP Authentication	Uses NTP packet encryption and authentication to protect unreliable clock sources against time synchronization interference on a device.
NTP Access Control	Filters sources of received NTP packets based on an Access Control List (ACL).

1.3.1 NTP Time Synchronization



Working Principle

NTP time synchronization is implemented by interaction of NTP packets between a client and a server:

- The client sends a time synchronization packet to all servers every 64 seconds. After receiving response packets from the servers, the client filters and selects the response packets from all servers, and synchronizes time with an optimum server.
- After receiving the time synchronization request packet, a server uses the local clock as the reference source, and fills the local time information into the response packet to be sent to the client.

Figure 1-4 shows the format of an NTP time synchronization packet.

Figure 1-4 Working Principle of NTP

DEVICE-B is used as an NTP reference clock source, DEVICE-A is used as an NTP client that synchronizes time with DEVICE-B. At a time point, the local clock of DEVICE-A is 19:00:00 and the local clock of DEVICE-B is 19:30:20.

1 DEVICE-A sends an NTP request packet. The local time (T0) when the packet leaves from DEVICE-A is 19:00:00 and is filled in Originate Timestamp.

2 After a 2-second network delay, the local time (T1) when DEVICE-B receives the request packet is 19:30:23 and is filled in Receive Timestamp.

3 DEVICE-B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from DEVICE-B is 19:30:24 and is filled in Transmit Timestamp.

4 After a 2-second network delay, DEVICE-A receives the response packet. The local time (T3) when the response packet arrives at DEVICE-A is 19:00:06.

Calculation for time synchronization is as follows:

- DEVICE-A obtains the time difference of 30 minutes and 20 seconds between DEVICE-B and DEVICE-A by using the formula ((T1-T0)+(T2-T3))/2.

- DEVICE-A obtains the packet round-trip delay of 4s between DEVICE-A and DEVICE-B by using the formula (T3-T0)-(T2-T1).

NTP Working Mode

- External clock reference mode

A device is used as both a server and a client. When receiving time synchronization requests from other clients, the device must synchronize time with the specified server first and provide time synchronization for the clients after successful synchronization.

- Local clock reference mode

A device uses the default local clock as the reliable clock source and provides time synchronization directly for other clients.

Related Configuration

Configuring an NTP Server

- The NTP function is disabled by default.
- Run the **ntp server** command to specify an NTP server (external clock reference source), that is, NTP is enabled.
- Then the device works in external clock reference mode.

Performing Real-time Synchronization

- A device performs time synchronization every 64 seconds by default.

Updating a Hardware Clock

- By default, a device does not update synchronized time to the hardware clock.
- Run the **ntp update-calendar** command to enable a device to automatically update the hardware clock after successfully synchronizing time each time.

Configuring the NTP Master Clock

- By default, a device works in external clock reference mode.
- Run the **ntp master** command to configure a device to work in local clock reference mode.

1.3.2 NTP Authentication

To prevent malicious damage on an NTP server, NTP uses the authentication mechanism to check whether time synchronization information is originated from the announced server and check the information return path to protect the device against interference.

Working Principle

An NTP client and an NTP server are configured with the same key. When sending request and response packets, a device calculates hash values of the packets by using the MD5 or HMAC-SHA256 algorithm based on the specified key and NTP packet content, and fills hash values into packet authentication information. The device receiving the packets checks whether the packets are sent by a trusted device or modified based on the authentication information.

Related Configuration

Configuring a Global Authentication Mechanism

- By default, no NTP authentication mechanism is enabled.
- Run the **ntp authenticate** command to enable the NTP authentication mechanism.

Configuring a Global Authentication Key

- By default, no global authentication key is configured.
- Run the **ntp authentication-key** command to configure an NTP global authentication key.

Configuring a Globally Trusted Key ID

- By default, no globally trusted key is configured.
- Run the **ntp trusted-key** command to configure a device as the reference clock source to provide a trusted key for time synchronization externally.

Configuring a Trusted Key ID for an External Reference Clock Source

- Run the **ntp server** command to specify an external reference source and the trusted key of this clock source.

1.3.3 NTP Access Control

Working Principle

An ACL provides the minimum security measure.

Related Configuration

Configuring Access Control Rights for NTP Services

- By default, there is no access control right for NTP.
- Run the **ntp access-group** command to configure access control rights for NTP.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of NTP	(Mandatory) It is used to enable NTP. After NTP is enabled, a device works in external clock reference mode.	
	ntp server	Configures an NTP server.
	ntp update-calendar	Automatically updates a hardware clock.
	(Optional) It is used to configure a device to work in local clock reference mode.	
	ntp master	Configures the NTP master clock.
	(Optional) It is used to configure the local clock reference mode for the device.	
	ntp interval	Configures the interval for time synchronization between the NTP client and the NTP server.

Configuration	Description and Command	
	(Optional) It is used to disable NTP.	
	no ntp	Disables all functions of NTP and clears all NTP configurations.
	ntp disable	Disables the device from receiving NTP packets from a specified interface.
	ntp service disable	Disables the NTP time synchronization service.
Configuring NTP Authentication	(Optional) It is used to protect the device gaaisnt interference by unreliable clock sources.	
	ntp authenticate	Enables an authentication mechanism.
	ntp authentication-key	Configures a global authentication key.
	ntp trusted-key	Configures a trusted key for time synchronization.
	ntp server	Configures a trusted key for an external reference clock source.
Configuring NTP Access Control	(Optional) It is used to filter sources of received NTP packets.	
	ntp access-group	Configures access control rights for NTP.

1.4.1 Configuring Basic Functions of NTP

Configuration Effect

External Clock Reference Mode

- Use a device as a client to synchronize time from an external reference clock source to the local clock.
- After time synchronization is successful, use the device as a time synchronization server to provide time synchronization.

Local Clock Reference Mode

- Use the local clock of a device as the NTP reference clock source to provide time synchronization.

Notes

- In client/server mode, a device can be used as a time synchronization server to provide time synchronization only after successfully synchronizing time with a reliable external clock source.
- Once the local clock reference mode is configured, the system will not synchronize time with a clock source with a higher stratum.
- Configuring a local clock as the master clock (especially when specifying a lower stratum) may overwrite an effective clock source. If this command is used for multiple devices on a network, the clock difference between the devices may cause unstable time synchronization of the network.

- Before a local clock is configured as the master clock, if the system does not synchronize time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference. For details about how to manually calibrate the system clock, refer to the system time configuration.

Configuration Step

Configuring an NTP Server

- Mandatory.
- At least one external reference clock source must be specified (a maximum of 20 different external reference clock sources can be configured).
- If it is necessary to configure an NTP key, you must configure NTP security authentication before configuring the NTP server.

Configuring the Interval for Time Synchronization Between the NTP Client and the NTP Server

- The default NTP time synchronization interval is 64s.

Automatically Updating a Hardware Clock

- Optional.
- By default, the system updates only the system clock, but not the hardware clock after successful time synchronization.
- After this command is configured, the system automatically updates the hardware clock after successful time synchronization.

Configuring the NTP Master Clock

- To switch a device to the local clock reference mode, run this command.

Disabling NTP

- To disable NTP and clear NTP configurations, run the **no ntp** command.
- By default, all interfaces can receive NTP packets after NTP is enabled. To disable NTP for a specified interface, run the **ntp disable** command.

Disabling the NTP Device from Providing Time Synchronization Service for Other Devices

- If an NTP device works in client/server mode, after the NTP device synchronizes time from an external reliable clock source, the device acts as the time server to provide the time synchronization service for other devices. If you want the NTP device to act as a client, configure the **ntp service disable** command to disable the NTP device from providing time synchronization service for other devices.

Verification

- Run the **show ntp status** command to display the NTP configuration.
- Run the **show clock** command to check whether time synchronization is completed.

Related Commands

Configuring an NTP Server

Command	**ntp server** { *ip-addr* | *domain* | **ip** *domain* | **ipv6** *domain* } [**version** *version* | **source** *interface* | **key** *keyid* | **prefer**] *
Parameter Description	*ip-addr*: Indicates the IPv4 or IPv6 address of the reference clock source. *domain*: Indicates the IPv4 or IPv6 domain name of the reference clock source. *version*: Indicates the NTP version number. The value is 1, 2, or 3. *interface*: Indicates the interface type, including aggregate interface, dialer GigabitEthernet interface, loopback interface, multi-link interface, null interface, tunnel interface, virtual PPP interface, virtual template interface, and VLAN interface. *keyid*: Indicates the key used for encrypted communication with the corresponding server. It is not encrypted by default. The value range is from 1 to 4294967295. **prefer**: Indicates whether the reference clock source has a high priority.
Command Mode	Global configuration mode
Usage Guide	By default, no NTP server is configured. The client supports interaction with up to 20 NTP servers. You can configure an authentication key for each server (after configuring global authentication and the key) to initiate encrypted communication with the servers. ⚠ If it is necessary to configure an authentication key, you must configure NTP authentication before configuring an NTP server. The default version of NTP for communicating with a server is NTP version 3. In addition, you can configure the source interface for transmitting NTP packets and specify that the NTP packets from a corresponding server can be received only on the transmitting interface.

Configuring the Interval for Time Synchronization Between the NTP Client and the NTP Server

Command	**ntp interval** *seconds*
Parameter Description	*seconds*: Indicates the interval for time synchronization, in seconds. The value range is from 10 to 2592000. The default value is 64.
Command Mode	Global configuration mode
Usage Guide	The default NTP time synchronization interval is 64s.

Updating a Hardware Clock

Command	**ntp update-calendar**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a Local Reference Clock Source

Command	**ntp master**[*stratum*]
Parameter Description	*stratum*: Specifies the stratum of a local clock. The value range is from 1 to 15. The default value is 8.

Command Mode	Global configuration mode
Usage Guide	N/A

Disabling NTP

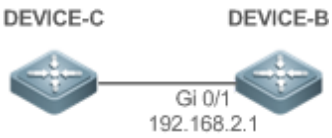
Command	**no ntp**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command can be used to rapidly disable all functions of NTP and clear all NTP configurations.

Disabling the Device from Receiving NTP Packets on an Interface

Command	**ntp disable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Disabling the NTP Device from Providing Time Synchronization for Other Devices

Command	**ntp server disable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command disables the NTP time synchronization service. After this command is configured, external devices cannot be synchronized time from the NTP device (this command is supported only in some versions).



Configuration Example

Configuring the External Clock Reference Mode of NTP

Scenario Figure 1-5	
	● DEVICE-B is configured to work in NTP external clock reference mode. ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	● Configure the local clock as the NTP reference clock source on DEVICE-A. ● Configure DEVICE-A as the reference clock source on DEVICE-B. ● Configures DEVICE-B as the reference clock source on DEVICE-C.
DEVICE-A	`A#configure terminal`

	A(config)# ntp master A(config)#exit
DEVICE-B	B#configure terminal B(config)# ntp server 192.168.1.1 B(config)# exit
DEVICE-C	C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit
Verification	● Run the **show ntp status** command on DEVICE-B to display the NTP configuration. ● DEVICE-B sends a time synchronization packet to 192.168.1.1 in order to synchronize time with DEVICE-A. ● After successfully synchronizing time with DEVICE-A, DEVICE-B can respond to the time synchronization request from DEVICE-C. ● Run the **show clock** command on DEVICE-B and DEVICE-C to check whether the time synchronization is successful.

↘ Configuring the Local Clock Reference Mode of NTP

Scenario **Figure 1-6**	
	● The local clock is used as the NTP reference clock source on DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	● Configure the local clock as the NTP reference clock source on DEVICE-B. ● Configure DEVICE-C to synchronize time with DEVICE-B.
DEVICE-B	B#configure terminal B(config)# ntp master B(config)# exit
DEVICE-C	C#configure terminal C(config)# ntp server 192.168.2.1 C(config)# exit
Verification	● Run the **show clock** command on DEVICE-C to check whether the time synchronization is successful.

1.4.2 Configuring NTP Authentication

Configuration Effect

↘ Synchronizing Time from a Trusted Reference Clock Source

Use a device as a client to synchronize time only from a trusted external reference clock source to the local clock.

↘ Providing Time Synchronization for a Trusted Device

Use the local clock of a device as the NTP reference clock source to provide time synchronization for only a trusted device.

Notes

The authentication keys of the client and server must be the same.

Configuration Step

Configuring the Global Authentication Mechanism

- Mandatory.
- By default, the security authentication mechanism is disabled.

Configuring a Global Authentication Key

- Mandatory.
- By default, a device is not configured with an authentication key.

Configuring a Globally Trusted Key ID

- Optional.
- To provide time synchronization for a trusted device, you must specify a trusted authentication key by using the key ID.
- Only one trusted key can be configured. The specified authentication key must be consistent with that of the trusted device.

Configuring an Authentication Key ID for an External Reference Clock Source

- Optional.
- To synchronize time with a trusted reference clock source, you must specify a trusted authentication key by using the key ID.
- Each trusted reference clock source is mapped to an authentication key. The authentication keys must be consistent with the keys of trusted reference clock sources.

Verification

- Run the **show run** command to verify the NTP configuration.
- Run the **show clock** command to check whether time is synchronized only with a trusted device.

Related Commands

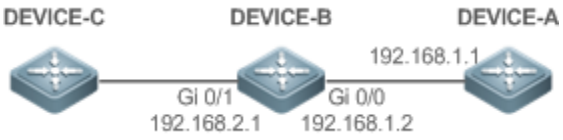
Enabling the Authentication Mechanism

Command	**ntp authenticate**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, a client does not use the global authentication mechanism. If no authentication mechanism is used, communication will not be encrypted. A global security indicator is not enough to imply that communication between the client and server is implemented in an encrypted manner. Other global keys and an encryption key for the server must be configured for initiating encrypted communication between the client and server.

Configuring a Global Authentication Key

Command	**ntp authentication-key** *key-id* { **hmac-sha256** | **md5** } *key-string* [*enc-type*]
Parameter Description	*key-id*: Indicates the ID of a global authentication key. The value range is from 1 to 4294967295. **hmac-sha256**: Specifies the HMAC-SHA256 authentication algorithm. **md5**: Specifies the MD5 authentication algorithm. *key-string*: Indicates a key string. A non-encrypted key string contains up to 31 bytes. An encrypted key string contains up to 64 bytes. *enc-type*: Indicates whether an entered key is encrypted. The value 0 indicates no encryption, and the value 7 indicates simple encryption. The default value is 0.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a Trusted Key



Command	**ntp trusted-key** *key-id*
Parameter Description	*key-id*: Indicates the ID of a trusted key. The value range is from 1 to 4294967295.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a Trusted Key for an External Reference Clock Source

Refer to Related Commands

Configuration Example

Configuring NTP Authentication

Scenario Figure 1-7	
	● DEVICE-B is configured to work in NTP client/server mode and provides NTP services requiring authentication for DEVICE-C. The authentication key is **abcd**. ● DEVICE-A is used as the reference clock source of DEVICE-B. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	● Configure DEVICE-A as the reference clock source on DEVICE-B. ● Configure DEVICE-B as the reference clock source on DEVICE-C.

DEVICE-B	`B#configure terminal`
	`B(config)# ntp authenticate`
	`B(config)# ntp authentication-key 1 md5 abcd`
	`B(config)# ntp trusted-key 1`
	`B(config)# ntp server 192.168.1.1`
	`B(config)# exit`

DEVICE-C	C#configure terminal C(config)# ntp authenticate C(config)# ntp authentication-key 1 md5 abcd C(config)# ntp trusted-key 1 C(config)# ntp server 192.168.2.1 key 1 C(config)# exit
Verification	● DEVICE-B sends a time synchronization packet that carries authentication information to 192.168.1.1 in order to synchronize time with DEVICE-A. ● Run the **show clock** command on DEVICE-B to check whether the time synchronization is successful.

1.4.3 Configuring NTP Access Control

Configuration Effect

Access control for NTP services provides the minimum security measure. A more secure method is to use an NTP authentication mechanism.

Notes

- The system does not support control query (used to control NTP servers by using network management devices, for example, setting the leap second indicator or monitoring its working status).
- If no access control rule is configured, all accesses are allowed. If any access control rule is configured, only accesses allowed by the rule can be implemented.

Configuration Step

↘ Configuring Access Control Rights for NTP

- Optional.
- Run the **ntp access-group** command to configure access control rights and a corresponding ACL for NTP.

Verification

Run the **show run** command to verify the NTP configuration.

Related Commands

↘ Configuring Access Control Rights for NTP Services

Command	**ntp access-group** { **peer** | **serve** |**serve-only** | **query-only** }*access-list-number* | *access-list-name*
Parameter Description	**peer**: Allows time request and control query for local NTP services, and allows a local device to synchronize time with a remote system (full access rights). **serve**: Allows time request and control query for local NTP services, but does not allow a local device to synchronize time with a remote system. **serve-only**: Allows only time requests for local NTP services. **query-only**: Allows only control query for local NTP services. *access-list-number*: Indicates the number of an IP ACL. The value range is from 1 to 99 and from 1300 to 1999. For details about how to create an IP ACL, see *Configuring ACL*.

	access-list-name: Indicates the name of an IP ACL. For details about how to create an IP ACL, see *Configuring ACL*.
Command Mode	Global configuration mode
Usage Guide	Configure NTP access control rights. When an access request arrives, the NTP-enabled device matches the request against rules in the sequence from the minimum access restriction to the maximum access restriction and uses the first matched rule. The matching sequence is peer, serve, serve-only, and query-only.

Configuration Example

Configuring NTP Access Control Rights

Configuration Steps	Allow only the device at 192.168.1.1 to send a time synchronization request to a local device.
	`Hostname(config)# access-list 1 permit 192.168.1.1` `Hostname(config)# ntp access-group serve-only 1`

1.5 Monitoring

Displaying

Command	Description
show ntp server	Displays NTP server information.
show ntp status	Displays NTP information.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ntp	Enables debugging.
no debug ntp	Disables debugging.

1 Configuring SNTP

1.1 Overview

The Simple Network Time Protocol (SNTP) is a simplified version of the Network Time Protocol (NTP), which is used to synchronize clocks of computers on the Internet. SNTP is applied in scenarios where it is unnecessary to use all NTP functions.

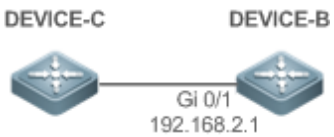
NTP uses a complex algorithm and has higher requirements for the system, whereas SNTP uses a simpler algorithm and provides higher performance. Typically, SNTP precision can reach about 1s, which meets basic requirements of most scenarios. Because SNTP packets are the same as NTP packets, the SNTP client implemented on a device is fully compatible with an NTP server.

Protocols and Standards

- RFC 2030: Simple Network Time Protocol (SNTP) Version 4 for IPv4, IPv6 and OSI

1.2 Applications

Application	Description
Synchronizing Time with an NTP Server	A device is used as a client to synchronize time with an NTP server.



1.2.1 Synchronizing Time with an NTP Server

Scenario

As shown in Figure 1-1, DEVICE-B uses a local clock as the NTP clock reference source and provides time synchronization for DEVICE-C.

DEVICE-C is used as an SNTP client to synchronize time with DEVICE-B.

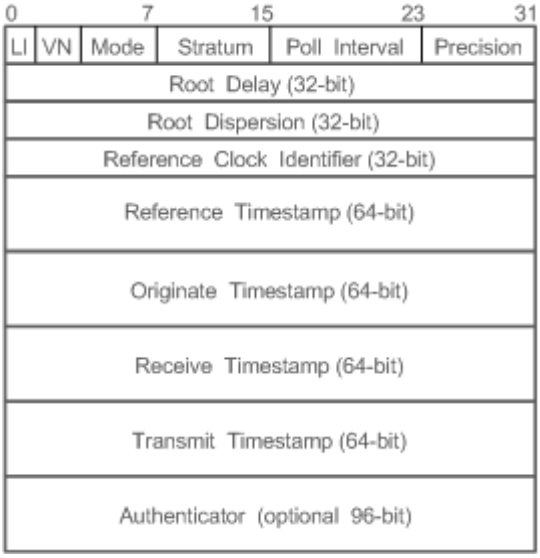
Figure 1-1

Deployment

- Specify DEVICE-B as the SNTP server of DEVICE-C.
- Enable SNTP for DEVICE-C.

1.3 Features

Basic Concepts



SNTP Packet

SNTPv4 is developed based on NTP, which is intended to simplify functions of NTP. It does not change the NTP specifications and implementation of NTP. The packet format of SNTPv4 is the same as that of NTP defined in RFC 1305, with only some data fields initialized into preset values.

As defined in RFC 1305, SNTP uses User Datagram Protocol (UDP) packets for transmission and the used UDP port ID is 123.

Figure 1-2 shows the format of an SNTP time synchronization packet.

Figure 1-2 Format of an SNTP Time Synchronization Packet

- Leap Indicator(LI): indicates a 2-bit leap second indicator.

The value 00 indicates no warning information; the value 01 indicates that there are 61 seconds in the previous minute; the value 10 indicates that there are 59 seconds in the previous minute; the value 11 indicates that the clock is not synchronized.

- Version Number(VN): indicates a 3-bit NTP/SNTP version number. The current version number is 3.
- Mode: indicates a 3-bit SNTP/NTP working mode.

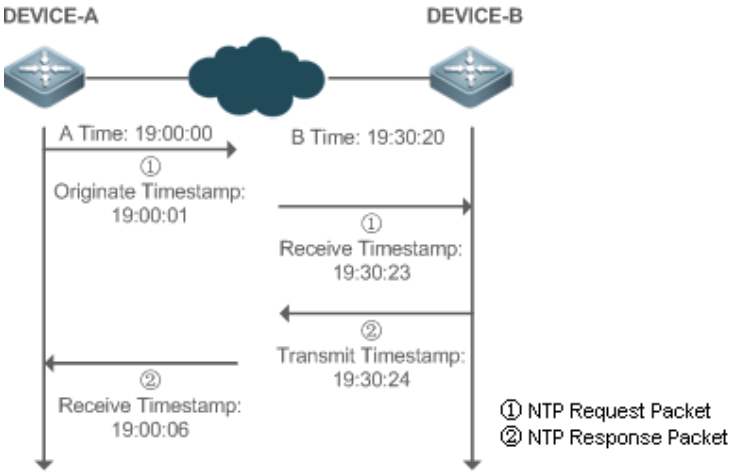
The value 0 indicates that the field is not defined; the value 1 indicates symmetric active; the value 2 indicates symmetric passive; the value 3 indicates a client; the value 4 indicates a server; the value 5 indicates broadcast; the value 6 indicates control information; the value 7 is reserved.

- Stratum: indicates the 8-bit stratum of a local clock. The value 0 indicates that the field is not defined; the value 1 indicates the master reference clock source; other values indicate slave reference clock sources.
- Poll Interval: indicates the poll interval, in seconds. The value is an 8-bit integer.
- Precision: indicates the time precision of a local clock, in seconds. The value is an 8-bit integer.
- Root Delay: indicates the round-trip time (RTT) to the master clock reference source, which is a 32-bit integer.
- Root Dispersion: indicates the largest difference from the master reference clock source, which is a 32-bit integer.
- Reference Clock Identifier: indicates the 32-bit identifier of a reference clock source.
- Reference Timestamp: indicates a 64-bit timestamp, namely, the time that is set or corrected at the last time.

- Originate Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request leaves from a client.
- Receive Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization request packet arrives at a server.
- Transmit Timestamp: indicates a 64-bit timestamp, namely, the local time when a time synchronization response packet leaves from a server.
- Authenticator (optional): indicates authentication information.

Overview

Feature	Description
SNTP Time Synchronization	Synchronizes time from an SNTP/NTP server to a local device.



1.3.1 SNTP Time Synchronization

Working Principle

SNTP time synchronization is implemented by interaction of SNTP/NTP packets between a client and a server. The client sends a time synchronization packet to the server at intervals (half an hour by default). After receiving a response packet from the server, the client synchronizes time.

Figure 1-3 shows the format of an SNTP time synchronization packet.

Figure 1-3 Working Principle of SNTP

DEVICE-B is used as an NTP reference clock source, DEVICE-A is used as an SNTP client that synchronizes time with DEVICE-B. At a time point, the local clock of DEVICE-A is 19:00:00 and the local clock of DEVICE-B is 19:30:20.

- DEVICE-A sends an SNTP/NTP request packet. The local time (T0) when the packet leaves from DEVICE-A is 19:00:00 and is filled in Originate Timestamp.
- After a 2-second network delay, the local time (T1) when DEVICE-B receives the request packet is 19:30:23 and is filled in Receive Timestamp.
- DEVICE-B processes the NTP request and sends an NTP response packet one second later. The local time (T2) when the response packet leaves from DEVICE-B is 19:30:24 and is filled in Transmit Timestamp.

- After a 2-second network delay, DEVICE-A receives the response packet. The local time (T3) when the response packet arrives at DEVICE-A is 19:00:06.

The specific calculations for time synchronization are as follows:

- DEVICE-A obtains the time difference of 30 minutes and 20 seconds between DEVICE-B and DEVICE-A by using the formula ((T1-T0)+(T2-T3))/2.
- DEVICE-A obtains the packet round-trip delay of 4s between DEVICE-A and DEVICE-B by using the formula (T3-T0)-(T2-T1).

Related Configuration

Enabling SNTP

- SNTP is disabled by default.
- Run the **sntp enable** command to enable SNTP.

Configuring an SNTP Server

- By default, no SNTP server is configured.
- Run the **sntp server** command to specify an SNTP server.

Configuring the SNTP Time Synchronization Interval

- By default, the SNTP time synchronization interval is 1,800s.
- Run the **sntp interval** command to specify the SNTP time synchronization interval.

1.4 Configuration

Configuration	Description and Command	
Configuring SNTP	(Mandatory) It is used to enable SNTP.	
	sntp enable	Enables SNTP.
	sntp server	Configures the IP address of an SNTP server.
	(Optional) It is used to configure the SNTP time synchronization interval.	
	sntp interval	Configures the SNTP time synchronization interval.

1.4.1 Configuring SNTP

Configuration Effect

An SNTP client connects to an NTP server at fixed intervals to correct the clock regularly.

Notes

All time obtained through SNTP communication is Greenwich Mean Time (GMT). To obtain precise local time, you need to set the local time zone for alignment with GMT.

Configuration Step

Enabling SNTP

- Mandatory.
- SNTP is disabled by default.

Configuring the IP Address of an SNTP Server

- Mandatory.
- No SNTP/NTP server is configured by default.

Configuring the SNTP Time Synchronization Interval

- Optional.
- By default, a device synchronizes time every half an hour.

Verification

Run the **show sntp** command to display SNTP parameters.

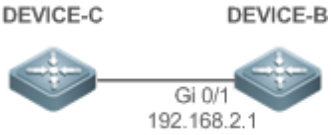
Related Commands

Enabling SNTP

Command	**sntp enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	SNTP is disabled by default. Run the **no sntp enable** command in global configuration command to disable SNTP.

Configuring the IP Address of an SNTP Server

Command	**sntp server** { *ip- address* | *domain* } [**source** *source-ip-address*]
Parameter Description	*ip-address*: Indicates the IP address of an SNTP server. No SNTP server is configured by default. *domain:* Indicates the domain name of an SNTP server. No SNTP server is configured by default. *source-ip-address*: Indicates the source IP address of an SNTP server.
Command Mode	Global configuration mode
Usage Guide	Because SNTP is fully compatible with NTP, the server can be configured as a public NTP server on the Internet. Because SNTP packets are the same as NTP packets, the SNTP client is fully compatible with the NTP server. There are many NTP servers on the Internet. You can select an NTP server with a shorter delay as the SNTP server on your device.



Configuring the SNTP Time Synchronization Interval

Command	**sntp interval** *seconds*
Parameter Description	*seconds*: Indicates the time synchronization interval, in seconds. The value range is from 60 to 65,535. The default value is 1800s.

Command Mode	Global configuration mode
Usage Guide	Run this command to set the interval for an SNTP client to synchronize time with an NTP/SNTP server. ⚠ The interval configured here does not take effect immediately. To make it take effect immediately, run the **sntp enable** command.

Configuration Example

Configuring SNTP Time Synchronization

Scenario Figure 1-4	
	● DEVICE-B is an NTP server on the Internet. ● DEVICE-C synchronizes time with DEVICE-B.
Configuration Steps	● Enable SNTP for DEVICE-C and configure DEVICE-B as an NTP server.

DEVICE-C	`C#configure terminal`
	`C(config)# sntp server 192.168.2.1`
	`C(config)# sntp enable`
	`C(config)# exit`

Verification	● Run the **show clock** command on DEVICE-C to check whether the time synchronization is successful. ● Run the **show sntp** command on DEVICE-C to display the SNTP status and check whether the server is successfully configured.

1.5 Monitoring

Displaying

Command	Description
show sntp	Displays SNTP parameters.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug sntp	Enables debugging.

1 Configuring FTP Server

1.1 Overview

The device can be configured as the File Transfer Protocol (FTP) server to connect to an FTP client. Then the FTP client can upload files to and download files from the FTP server through FTP.

You can use the FTP server function to easily obtain files such as syslog files from a device and copy files to the file system of the device through FTP.

Protocols and Standards

- RFC 959: FILE TRANSFER PROTOCOL (FTP)
- RFC 3659: Extensions to FTP
- RFC 2228: FTP Security Extensions
- RFC 2428: FTP Extensions for IPv6 and NATs
- RFC 1635: How to Use Anonymous FTP

1.2 Applications

Application	Description
Providing FTP Services on a LAN	The device provides file upload and download services for a user on a Local Area Network (LAN).

1.2.1 Providing FTP Services on a LAN

Scenario

Provide file upload and download services for a user on a LAN.

As shown in Figure 1-1, enable the FTP server only on a LAN.

- G is enabled with the FTP server function and S is enabled with Layer 2 transparent transmission.
- A user initiates a request for FTP upload and downloa services.

Figure 1-1

Remarks	S is an access device.

Deployment

- G is enabled with the FTP server.
- As a Layer 2 device, S provides Layer 2 transparent transmission.

1.3 Features

Basic Concepts

FTP

FTP is a standard protocol defined by the IETF Network Working Group. It implements file transfer based on the Transmission Control Protocol (TCP). FTP enables a user to transfer files between two networked computers and is the most important approach to transferring files on the Internet. A user can obtain abundant Internet resources for free through anonymous FTP. In addition, FTP provides functions such as login, directory query, file operation, and session control. Among the TCP/IP protocol suite, FTP is an application-layer protocol and uses TCP ports 20 and 21 for transmission. Port 20 is used to transmit data and port 21 is used to transmit control messages. Basic operations of FTP are described in RFC 959.

User Authorization

To connect an FTP client to an FTP server, you should have an account authorized by the FTP server. That is, a user can enjoy services provided by the FTP server after logging in to the FTP server with a user name and password. A maximum of 10 accounts can be configured, a maximum of two connections are allowed for each account, and a maximum of 10 connections are supported by the server.

FTP File Transmission Modes

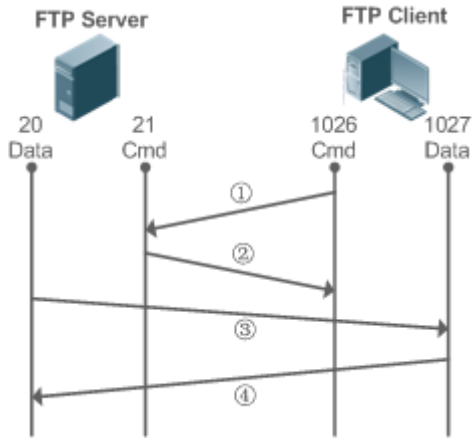
FTP provides two file transmission modes:

- Text transmission mode (ASCII mode): It is used to transfer text files (such as .txt, .bat, and .cfg files). This mode is different from the binary mode in carriage return and line feed processing. In ASCII mode, carriage return and line feed are changed to local CRC characters, for example, \n in Unix, \r\n in Windows, and \r in Mac. Assume that a file being copied contains the ASCII text. If a remote computer does not run Unix, FTP automatically converts the file format to suit the remote computer.
- Binary transmission mode: It is used to transfer program files (for example, .app, .bin and .btm files), including executable files, compressed files and image files without processing data. Therefore, the binary mode facilitates faster transfer of all files and reliable transfer of ASCII files.

FTP Working Modes

FTP provides two working modes:

Figure 1-2



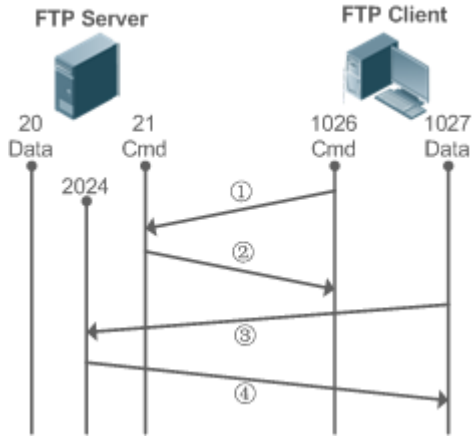


Figure 1-3

- Figure 1-2 shows the active (PORT) mode. The FTP client uses port 1026 to connect to the FTP server through port 21. The client sends commands through this channel. Before receiving data, the client sends the **PORT** command on this channel. The **PORT** command contains information on channel port 1027 of the client for receiving data. The server uses port 20 to connect to the client through port 1027 for establishing a data channel to receive and transmit data. The FTP server must establish a new connection with the client for data transmission.
- Figure 1-3 shows the passive (PASV) mode. The process for establishing a control channel is similar to that in PORT mode. However, after the connection is established, the client sends the **PASV** command but not the **PORT** command. After receiving the **PASV** command, the FTP server enables high-end port 2024at random and notifies the client that data will be transmitted on this port. The client uses port 1027 to connect the FTP server through port 2024. Then, the client and server can transmit and receive data on this channel. In this case, the FTP server does not need to establish a new connection with the client.

Supported FTP Commands

After receiving an FTP connection request, the FTP server requires the client to provide the user name and password for authentication.

If the client passes authentication, FTP client commands can be executed. The available FTP client commands are listed as follows.

ascii	delete	mdelete	mput	quit	send

bin	dir	mdir	nlist	recv	size
bye		mget		rename	system
cd	get	mkdir	passive		type
cdup		mls	put	rmdir	user
close	ls		pwd		

For details of FTP client commands, see the FTP client software document. In addition, many FTP client tools such as CuteFTP and FlashFXP provide the graphic user interface (GUI), which simplifies operations by eliminating the need for users to configure FTP commands.

Overview

Feature	Description
Enabling the FTP Server Function	Provides functions of uploading, downloading, displaying, creating, and deleting files for an FTP client.

1.3.1 Enabling the FTP Server Function

Working Principle

Devices provide FTP services after the user name, password, and top-level directory are configured.

Related Configuration

Enabling the FTP Server Function Globally

The FTP server function is disabled by default.

Run the **ftp-server enable** command to enable the FTP server function.

You must enable the FTP server function globally before using it.

Configuring the User Name, Password, and Top-Level Directory

There is no authorized user or top-level directory by default.

Run the **ftp-server username password** and **ftp-server topdir** commands to configure the authorized user and top-level directory.

The user name, password, and top-level directory must be configured; otherwise, the FTP server function cannot be enabled.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions	(Mandatory) It is used to enable an FTP server.	
	ftp-server enable	Enables the FTP server function.
	ftp-server login timeout	Configures the login timeout for an FTP session.
	ftp-server login times	Configures the valid login count.

Configuration	Description and Command	
	ftp-server topdir	Configures the top-level directory of the FTP server.
	ftp-server username password	Configures a user name and password.
	Optional.	
	ftp-server timeout	Configures the idle timeout of an FTP session.

1.4.1 Configuring Basic Functions

Configuration Effect

- Create an FTP server to provide FTP services for an FTP client.

Notes

- The user name, password, and top-level directory must be configured.
- To enable the server to close an abnormal session within a limited period, configure the idle timeout of a session.

Configuration Step

Enabling the FTP Server Function

- Mandatory.
- Unless otherwise specified, enable the FTP server function on each device.

Configuring the Top-Level Directory

- Mandatory.
- Unless otherwise specified, configure the top-level directory as the root directory on each device.

Configuring the User Name and Password for Login

- Mandatory.
- The lengths of the user name and password are restricted.

Configuring the Login Timeout for an FTP Session

- Optional.
- When a client is disconnected from the server due to an error or other causes, the FTP server may not know that the user is disconnected and continues to keep the connection. Consequently, the FTP connection is occupied for a long time and the server cannot respond to login requests of other users. This configuration can ensure that other users can connect to the FTP server within a period of time upon an error.

Verification

Connect an FTP client to the FTP server.

- Check whether the client is connected.
- Check whether operations on the client are normal.

Related Commands

Enabling the FTP Server Function

Command	**ftp-server enable**
Parameter Description	**-**
Command Mode	Global configuration mode
Usage Guide	The client cannot access the FTP server unless the top-level directory, user name, and password are configured. Therefore, it is recommended that you configure the top-level directory, user name, and password for login by referring to the subsequent chapters before enabling the FTP server function for the first time.

Configuring the Valid Login Count

Command	**ftp-server login times** *times*
Parameter Description	*times:* Indicates the valid login count. The value range is from 1 to 10.
Command Mode	Global configuration mode
Usage Guide	The valid login count refers to the number of times you can perform account verification during an FTP session. The default value is 3, which means that your session will be terminated if you enter an incorrect user name or password for three times and other users can go online.

Configuring the Login Timeout for an FTP Session

Command	**ftp-server login timeout** *time*
Parameter Description	*time*: Indicates the login timeout, in minutes. The value range is from 1 to 30.
Command Mode	Global configuration mode
Usage Guide	The login timeout refers to the maximum duration that the session lasts since the session has been established. If you do not pass password verification again during the login timeout, the session will be terminated to ensure that other users can log in.

Configuring the Top-Level Directory of the FTP Server

Command	**ftp-server topdir** *directory*
Parameter Description	*directory:* Indicates the user access path.
Command Mode	Global configuration mode
Usage Guide	If the top-level directory of the server is set to **/syslog**, the FTP client can access only the files and directories in the **/syslog** directory on the device after login. Due to restriction on the top-level directory, the client cannot return to the upper directory of **/syslog**.

Configuring the User Name and Password for Server Login

Command	**ftp-server username** *username* **password** [**0** | **7**] *password*

Parameter Description	*username*: Indicates a user name. **0**: Indicates that the password is not encrypted (cleartext) . **7**: Indicates that the password is encrypted (ciphertext). *password*: Indicates a password.
Command Mode	Global configuration mode
Usage Guide	The FTP server does not support anonymous login; therefore, a user name must be configured. A user name consists of up to 64 characters including letters, half-width digits, and symbols without spaces. A password consists of only letters or digits. Spaces at the beginning and end of the password are ignored. Spaces in the password are viewed as part of the password. A cleartext password consists of 1 to 25 characters; a ciphertext password consists of 4 to 52 characters. User names and passwords must match. A maximum of 10 users can be configured.

Configuring the Idle Timeout for an FTP Session

Command	**ftp-server timeout** *time*
Parameter Description	*time*: Indicates the idle timeout, in minutes. The value range is from 1 to 3600.
Command Mode	Global configuration mode
Usage Guide	The idle timeout of a session refers to the duration from the end of an FTP operation to the start of the next FTP operation in an FTP session. After the server responds to an FTP client command operation (for example, a file is completely transferred), the server starts to count the idle time again, and stops when the next FTP client command operation is being performed. Therefore, the idle timeout has no effect on some time-consuming file transfer operations.

Displaying the FTP Server Status

Command	**show ftp-server**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display the FTP server status.

Debugging

Command	**debug ftp-server pro/err**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to debug message or error events of the FTP server.

Configuration Example

The following configuration example is related to the FTP server only.

Creating an FTP Server on an IPv4 Network

Scenario	● A TCP connection is established from a server to a client.
Configuration Steps	● Enable the FTP server function. ● Configure the top-level directory or syslog. ● Set the user name **user** and password to **password**. ● Set the session idle timeout to 5 minutes. ● Specify an AAA method.

	`Hostname(config)#ftp-server username user`
	`Hostname(config)#ftp-server password password`
	`Hostname(config)#ftp-server timeout 5`
	`Hostname(config)#ftp-server topdir /`
	`Hostname(config)#ftp-server enable`
	`Hostname(config)# ftp-server authentication name`

Verification	● Run the **show ftp-server** command to check whether the configuration takes effect.

	`Hostname# showRuijie#sho ftp-server`
	`    ftp-server information`
	`==================================`
	`enable : Y`
	`topdir : tmp://`
	`timeout: 130min`
	`username:aaaa          config : Y`
	`password:(PLAINT)bbbb         connect num[2] config : Y`
	`    [0]trans-transfer type: BINARY (ctrl)server IP:192.168.21.100[21]`
	`                            client IP:192.168.21.26[3927]`
	`    [1]trans-type:ASCII (ctrl)server IP:192.168.21.100[21]`
	`                            client IP:192.168.21.26[3929]`
	`username:a1          password:(PLAINT)bbbb         connect num[0]`
	`username:a2          password:(PLAINT)bbbb         connect num[0]`
	`username:a3          password:(PLAINT)bbbb         connect num[0]`
	`username:a4          password:(PLAINT)bbbb         connect num[0]`
	`username:a5          password:(PLAINT)bbbb         connect num[0]`
	`username:a6          password:(PLAINT)bbbb         connect num[0]`
	`username:a7          password:(PLAINT)bbbb         connect num[0]`
	`username:a8          password:(PLAINT)bbbb         connect num[0]`
	`username:a9          password:(PLAINT)bbbb         connect num[0]control connection : N`
	`port data connection : N`
	`passive data connection : N`
	`Ruijie#`

Common Errors

- No user name is configured.

- No password is configured.
- No top-level directory is configured.

1.5 Monitoring

Displaying

Command	Description
show ftp-server	Displays the FTP server configuration.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ftp-server err	Debugs FTP server error events.
debug ftp-server pro	Debugs FTP server message events.

1 Configuring FTP Client

1.1 Overview

The File Transfer Protocol (FTP) is an application of the Transmission Control Protocol/Internet Protocol (TCP/IP). By establishing a connection-oriented and reliable TCP connection between the FTP client and server, a user can access a remote computer that runs the FTP server program.

An FTP client enables file transfer between a device and the FTP server over FTP. A user uses the client to send a command to the server. The server responds to the command and sends the execution result to the client. By means of command interaction, the user can view files in the server directory, copy files from a remote computer to a local computer, or transfer local files to a remote computer.

FTP is designed to facilitate sharing of program or data files and enable remote operations through programs. Users do not need to worry about differences in files systems across different hosts. Data is transmitted efficiently and reliably, allowing for secure remote file operations.

The device used as the FTP client is different from the standard FTP client that run interactive commands. Instead, you enter the **copy** command in the CLI to perform control-connection instructions such as **open**, **user**, and **pass**. After a control connection is established, the file transfer process starts, and then a data connection is established to upload or download files.

Original devices support TFTP. However, TFTP is used to transfer small files. FTP is used to transfer large files. Implementing FTP on a device enables the file transfer between the device and other clients or servers.

Protocols and Standards

- RFC 959: FILE TRANSFER PROTOCOL (FTP)

1.2 Applications

Application	Description
Uploading a Local File to a Remote Server	Local and remote server files need to be shared, for example, uploading a local file to a remote server.
Downloading a File from a Remote Server to a Local Device	Local and remote server files need to be shared, for example, downloading a file from a remote server to a local device.

1.2.1 Uploading a Local File to a Remote Server

Scenario

Local and remote files need to be shared, for example, uploading a local file to a remote server.

As shown in Figure 1-1, resources are shared only on the intranet.

Figure 1-1

Deployment

- Implement only communication on the intranet.
- Enable file upload on the FTP client.
- Enable file upload on the FTP server.

1.2.2 Downloading a File from a Remote Server to a Local Device

Scenario

Local and remote files need to be shared, for example, downloading a file from a remote server to a local device.

In Figure 1-2, resources are shared only on the Intranet.

Figure 1-2

Deployment

- Implement only communication on the intranet.
- Enable file download on the FTP client.
- Enable file download on the FTP server.

1.3 Features

Basic Concepts

Uploading FTP Files

Upload files from an FTP client to an FTP server.

Downloading FTP Files

Download files from an FTP server to an FTP client.

FTP Connection Mode

An FTP client and an FTP server can be connected in active or passive mode.

FTP Transmission Mode

The transmission between an FTP client and an FTP server is available in two modes, namely, ASCII and binary modes.

Specifying the Source Interface's IP Address for FTP Transmission

An FTP client is configured with a source interface's IP address for communication with an FTP server.

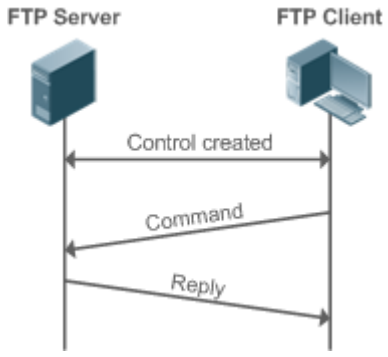
Overview

Feature	Description
Uploading FTP Files	Uploads files from an FTP client to an FTP server.
Downloading FTP Files	Downloads files from an FTP server to an FTP client.
FTP Connection Mode	Specifies the connection mode between an FTP client and an FTP server.
FTP Transmission Mode	Specifies the transmission mode between an FTP client and an FTP server.
Specifying the Source Interface's IP Address for FTP Transmission	Configures a source IP address of an FTP client for communication with an FTP server.

1.3.1 Uploading FTP Files

FTP enables file upload. Start both the FTP client and FTP server, and upload files from the FTP client to the FTP server.

1.3.2 Downloading FTP Files



FTP enables file download. Start both the FTP client and FTP server, and download files from the FTP server to the FTP client.

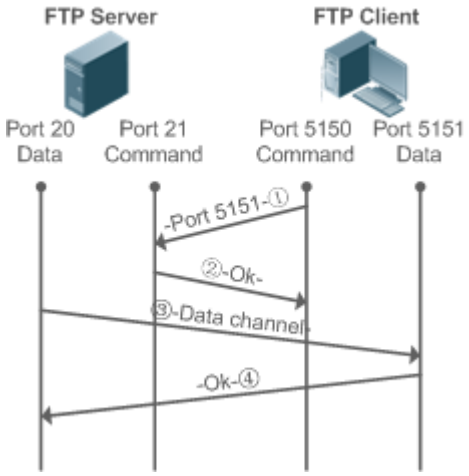
1.3.3 FTP Connection Mode

FTP needs to use two TCP connections: control link (command link) that is used to transfer commands between the FTP client and server, and data link that is used to upload or download data.

1. Control connection: Only control connections need to be established for some simple sessions. A client sends a command to a server. After receiving the command, the server sends a response. The process is shown in **Figure 1-3**.

Figure 1-3 Control Connection

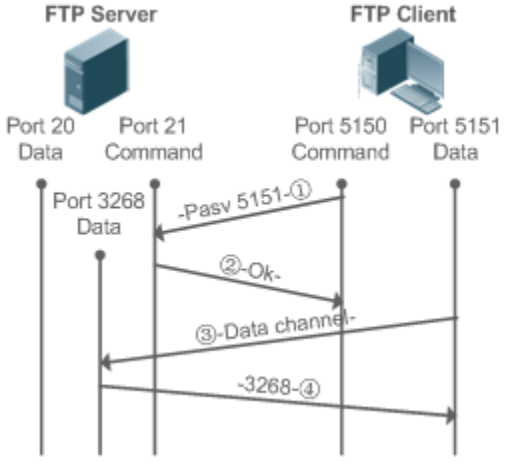
2. Control connection and data connection: When a client sends a command for uploading or downloading data, both the control connection and data connection need to be established.



FTP supports two data connection modes: active (PORT) and passive (PASC). The two modes are different in establishing a data connection.

- Active mode

In this mode, an FTP server connects to an FTP client proactively when a data connection is established. This mode involves four steps:



1. The client uses source port 5150 to communicate with the server through port 21 to send a connection request and to notify the server that the port to be used is port 5151.
2. After receiving the request, the server sends a response OK (ACK). The client and server exchanges control signaling by console ports.
3. The server enables port 20 as the source port to send data to port 5151 of the client.
4. The client sends a response.

Figure 1-4 PORT Mode

- Passive mode

Figure 1-5 PASV (Passive) Mode

This mode is often set by the **passive** command. When a data connection is established, the FTP server is connected to the FPT client passively. This mode involves four steps:

1. In passive mode, a client initializes a control signaling connection. The client uses source port 5150 to connect to the server through port 21, and runs the **passive** command to request the server to enter the PASV mode.

2. The server agrees to enter the PASV mode, selects a port number greater than 1024 at random, and notifies the client of the port number.
3. After receiving the message, the client uses port 5151 to communicate with the server through port 3268. Here, port 5151 is the source port and port 3268 is the destination port.
4. After receiving the message, the server sends data and responds an ACK (OK).

After the data connection is established, you can perform file uploading and downloading. Besides, you can perform some operations on the server file from the client.

The control connection for command and feedback transmission is always active, whereas the data connection is established as required. Only an FTP client has the right to select and set the PASV or PORT mode. The FTP client initiates a command to establish a data connection. The device used as the FTP client works in PASV mode by default.

1.3.4 FTP Transmission Mode

FTP provides two transmission modes: ASCII and binary. The device used as the FTP client support both the ASCII and binary modes and use the binary mode by default.

- ASCII mode

The difference between the ASCII and binary modes lies in carriage return and line feed processing. In ASCII mode, carriage return and line feed are changed to a local Carriage Return Character (CRC), for example, \n in Unix, \r\n in Windows, and \r in Mac.

- Binary mode

The Binary mode can be used to transfer executable files, compressed files, and image files without processing data. For example, a text file needs to be transferred from Unix to Windows. When the binary mode is used, the line breaks in Unix will not be converted from \r to \r\n. In Windows, this file has no line feeds and displays many black squares. Therefore, the binary mode facilitates faster transfer of all files and more reliable transfer of ASCII files.

1.3.5 Specifying the Source Interface's IP Address for FTP Transmission

An FTP client is configured with a source interface's IP address for communication with an FTP server. In this way, the FTP client connects to the server and shares files with the server through the specified source IP address.

1.3.6 Disabling Size Check of Files Downloaded from an FTP Server

By disabling file size check, you can download files from the FTP server that does not support file size response to FTP clients.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions	(Mandatory) It is used to configure the FTP client function.	
	copy flash	Uploads a file.
	copy ftp	Downloads a file.

Configuration	Description and Command	
Configuring Optional Functions	(Optional) It is used to configure the working mode of the FTP client.	
	ftp-client port	Sets the connection mode to active (PORT).
	ftp-client ascii	Sets the transmission mode to ASCII.
	ftp-client source	Configures the source IP address of the FTP client.
	default ftp-client	Restores the default settings, namely, connection mode set to passive (PASV), transmission mode to binary, and source IP address removed.

1.4.1 Configuring Basic Functions

Configuration Effect

- Implement file upload and download.

Notes

- Pay attention to command formats for uploading and downloading.

Configuration Step

Uploading a File

- Mandatory.
- Perform this configuration when a file needs to be uploaded.
- Configure the FTP URL as the destination address of **copy** in privileged EXEC mode.

Downloading a File

- Mandatory.
- Perform this configuration when a file needs to be downloaded.
- Configure the FTP URL as the source address of **copy** in privileged EXEC mode.

Verification

- Check whether the uploaded file exists on the FTP server.
- Check whether the downloaded file exists at the destination address.

Related Commands

Uploading a File

Command	**copy flash:**[*local-directory/*]*local-file* **ftp:** *//username:password@dest-address*[*/remote-directory*]*/remote-file*
Parameter Description	*local-directory:* Specifies a directory on the local device. If it is not specified, it indicates the current directory. *local-file:* Specifies a local file to be uploaded.

	username: Specifies a user name for accessing the FTP server. The value consists of no more than 32 bytes, excluding delimiters such as /, : and space. This parameter is mandatory. *password:* Specifies a password for accessing the FTP server. The value consists of no more than 32 bytes, excluding delimiters such as /, : and space. This parameter is mandatory. *dest-address:* Specifies an IP address for the FTP server. *remote-directory:* Specifies a directory on the server. *remote-file:* Renames the file on the server. ⚠ The directory specified by the *local-directory* field must have been created on the device. Executing this command will not automatically create a directory.
Command Mode	Global configuration mode
Usage Guide	Run this command to upload a file from the flash memory of a local device to an FTP server.

Downloading an FTP File

Command	**copy ftp:**//username:password@dest-address[/remote-directory]/remote-file **flash:**[*local-directory/*]*local-file*
Parameter Description	*username*: Specifies a user name for accessing the FTP server. The value consists of no more than 32 bytes, excluding delimiters such as /, : and space. This parameter is mandatory. *password:* Specifies a password for accessing the FTP server. The value consists of no more than 32 bytes, excluding delimiters such as /, : and space. This parameter is mandatory. *dest-address:* Specifies an IP address for the FTP server. *remote-directory:* Specifies a directory on the server. *remote-file:* Specifies a file to be downloaded. *local-directory:* Specifies a directory on the local device. If it is not specified, it indicates the current directory. *local-file:* Renames the file in the local flash. ⚠ The directory specified by the *local-directory* field must have been created on the device. Executing this command will not automatically create a directory.
Command Mode	Global configuration mode
Usage Guide	Run this command to download a file from an FTP server to the flash memory of a local device.

Configuration Example

Uploading a File

Configuration Steps	● Upload the **local-file** file in the **home** directory of a device to the **root** directory of an FTP server whose user name is **user**, password is **pass**, and IP address is **192.168.23.69**, and name the file **remote-file**.
	`Hostname# copy flash: home/local-file ftp://user:pass@192.168.23.69/root/remote-file`
Verification	● Check whether the **remote-file** file exists on the FTP server.

Downloading a File

Configuration Steps	● Download the **remote-file** file from the **root** directory of an FTP server whose user name is **user**, password is **pass**, and IP address is **192.168.23.69** to the **home** directory of a device and save the file as **local-file**.
	`Hostname# copy ftp://user:pass@192.168.23.69/root/remote-file flash:home/local-file`
Verification	● Check whether the **remote-file** file exists in the **home** directory of the flash memory.

Common Errors

- The command formats for uploading and downloading are incorrect.
- The user name or password is incorrect.

1.4.2 Configuring Optional Functions

Configuration Effect

- Configure connection and transmission modes and configure a source interface's IP address of the client for file upload and download.

Configuration Steps

Setting the Connection Mode to Active (Port)

- Optional.
- Configure the connection mode of FTP.

Setting the Transmission Mode to ASCII

- Optional.
- Configure the transmission mode of FTP.

Configuring the Source Interface's IP Address of the FTP Client

- Optional.
- Configure the source interface's IP address of the FTP client.

In global configuration mode, the **ftp client source** command is used to configure the source interface and source interface's IP address. The original **ftp client soure-address** command is abandoned and hidden. If the **ftp client soure-address** command is used, it is identified as a new configuration command and is saved.

Restoring Default Settings

- Optional.
- Restore default settings of the FTP client.

Verification

Run the **show run** command to check whether the configuration takes effect.

Related Commands

Setting the Connection Mode to Active (Port)

Command	**ftp-client port**
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to set the connection mode to active (PORT). The default connection mode is passive (PASV).

Configuring the Source Interface's IP Address of the FTP Client

Command	**ftp-client source** { *ip-address* | *ipv6-address* | *interface-type interface-number* }
Parameter Description	*ip-address:* Specifies the IPv4 address of a local interface. *ipv6-address:* Specifies the IPv6 address of a local interface. *interface-type interface-number*: Specifies a source interface of a client.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure an interface's IP address of the client for connection with the server. By default, the client is not configured with a local IP address. Instead, the IP address is selected for the client based on the route.

Setting the Transmission Mode to ASCII

Command	**ftp-client ascii**
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to set the transmission mode to ASCII. The default transmission mode is binary.

Restoring Default Settings

Command	**default ftp-client**
Parameter Description	
Command Mode	Global configuration mode
Usage Guide	Run this command to restore default settings, namely, connection mode set to passive (PASV), transmission mode to binary, and source IP address removed.

Configuration Example

Configuring Optional Functions

Configuration Steps	● Set the connection mode of FTP to PORT ● Set the transmission mode to ASCII.

	● Set the source IP address to 192.168.23.167.

	`Hostname# configure terminal`
	`Hostname(config)# ftp-client ascii`
	`Hostname(config)# ftp-client port`
	`Hostname(config)# ftp-client source 192.168.23.167`
	`Hostname(config)# end`

Verification	● Run the **show run** command on the device to check whether the configuration takes effect.
	`Hostname# show run`
	
	`!`
	`ftp-client ascii`
	`ftp-client port`
	`ftp-client vrf 123 port`
	`ftp-client vrf 123 ascii`
	`ftp-client source 192.168.23.167`
	`!`

Common Errors

- The source IP address is not a local IP address.

1.5 Monitoring

Displaying

Command	Description
show running-config	Displays the FTP client configuration.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ftp-client	Debugs the FTP client.

1 Configuring TFTP Server

1.1 Overview

You can configure the device as the Trivial File Transfer Protocol (TFTP) server. Then a TFTP client can be connected to the TFTP server to upload files to or download files from the device.

You can easily obtain files such as upgrade package files from the device or copy files to the file system of the device functioning as the TFTP server.

Protocols and Standards

- RFC 1350: The TFTP Protocol (revision 2)
- RFC 2347: TFTP Option Extension
- RFC 2348: TFTP Blocksize Option
- RFC 2349: TFTP Timeout Interval and Transfer Size Options

1.2 Applications

Application	Description
Providing the TFTP Service on a LAN	The device provides file upload and download for users on a local area network (LAN).

1.2.1 Providing the TFTP Service on a LAN

Scenario

Enable users in a LAN to upload and download files.

In Figure 1-1:

- Device G serves as a TFTP server.
- The user sends a TFTP upload or download request.

Figure 1-1

Deployment

- Enable the TFTP server on device G.
- The user uploads files to or download files from device G.

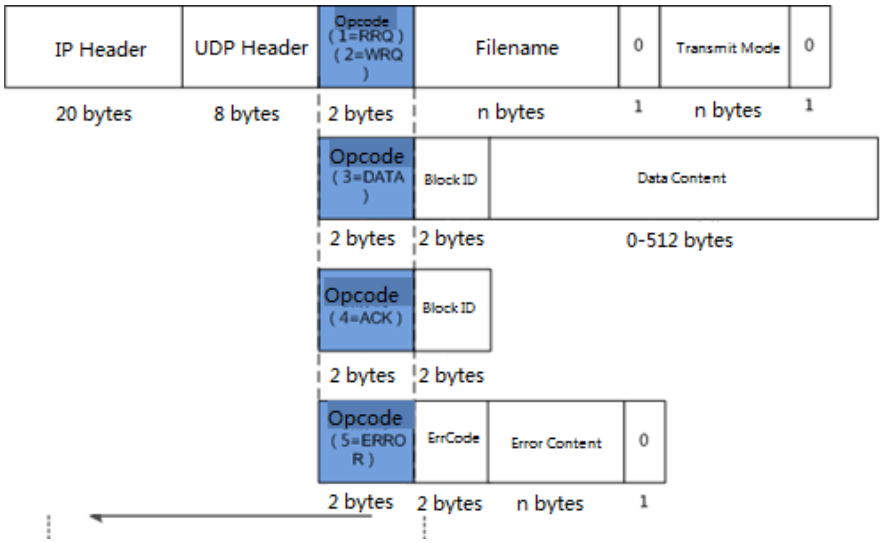
1.3 Features

Basic Concepts

TFTP

TFTP, defined by the IETF Network Working Group, works at the application layer. Based on the User Datagram Protocol (UDP), TFTP is a simple protocol to transfer files. TFTP provides only the file uploading and downloading functions instead of many common FTP functions. It does not support the directory list and the authentication function, and does not provide any security mechanism. TFTP uses the way of acknowledged retransmission upon timeout to ensure data transmission, which covers three transmission modes: netascii in the form of an 8-bit ASCII code, 8-bit octet of the source data type, and mail (which is no longer supported). TFTP uses UDP port 69. TFTP is defined in RFC 1350.

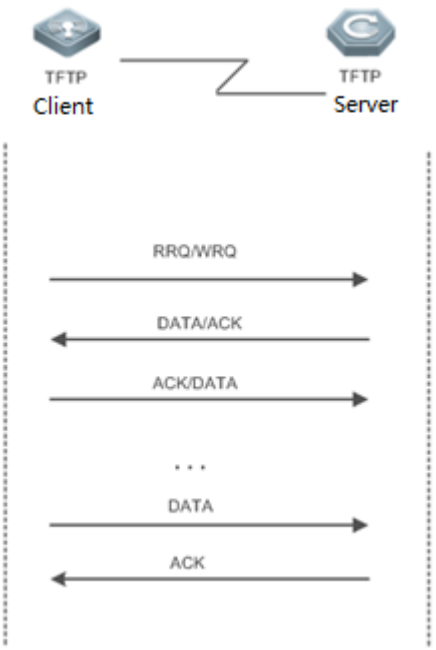
TFTP Packet



Any transfer begins with a request to read or write a file from a TFTP client. After the TFTP server grants the request, the file is sent in fixed-length blocks of 512 bytes. A data packet of less than 512 bytes indicates the termination of a transfer.

Each data packet contains a block of data, and must be acknowledged by an acknowledgement packet before the next data packet can be sent. If no acknowledgement packet is received within specified time, the last sent data packet is retransmitted.

The TFTP packet header includes an opcode field, which indicates the packet type. TFTP supports the following five types of packets:



- Read Request (RRQ)
- Write Request (WRQ)
- Data
- Acknowledgment (ACK)
- Error

Figure 1-2

Working Principle

Figure 1-3

- The TFTP client initiates an RRQ or WRQ to the TFTP server.
- Upon receipt of the RRQ, the TFTP server first determines whether the read condition is met (for example, whether the file exists or whether the client has the access permission), and returns a data packet to the TFTP client if the condition is met. Upon receipt of the WRQ, the TFTP server first determines whether the write condition is met (for example, whether there is a sufficient space or whether the client has the write permission), and returns an ACK packet to the TFTP client if the condition is met.
- The TFTP client receives the data packet in the case of file downloading, and replies with an ACK packet; or receives the ACK packet in the case of file uploading, and then sends a data packet.
- The process of transmission acknowledgement repeats till the last DATA packet is less than 512 bytes, which indicates the end of transmission.
- If errors occur during transmission, an error packet is returned.

Overview

Feature	Description
Enabling the TFTP Server Function	Provides the TFTP client with file uploading and downloading functions.

1.3.1 Enabling the TFTP Server Function

Working Principle

After the TFTP server function is enabled on the device, configure a top directory so that the TFTP service is available for users.

Related Configuration

Enabling the TFTP Server Function

- By default, the TFTP server function is disabled.
- Run the **tftp-server enable** command to enable the TFTP server function.

Configuring the Top Directory

- The default top directory is **flash:**.
- Run the **tftp-server topdir** command to configure the top directory.

1.4 Configuration

Configuration	Description and Command	
Basic Functions	(Mandatory configuration) It is used to enable the TFTP server function.	
	tftp-server enable	Enables the TFTP server function.
	tftp-server topdir	Configures the top directory of the TFTP server.

1.4.1 Basic Functions

Networking Requirements

- Enable the TFTP server function on the device to allow the connected TFTP client to upload and download files.

Notes

- The top directory needs to be configured.

Configuration Step

Enabling the TFTP Server Function

- Mandatory.
- Unless otherwise specified, enable the TFTP server function on each device.

Configuring the Top Directory

- Mandatory.
- Unless otherwise specified, configure a top directory as the root directory on each device.

Verification

Connect the TFTP server to the TFTP client.

- Check whether the client is connected to the server.
- Check whether the client can normally download files from and upload files to the server.

Related Commands

Enabling the TFTP Server Function

Command	**tftp-server enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The client cannot access the TFTP server before a top directory is correctly configured for the server. Therefore, it is recommended that you configure the top directory of the server first if it is the first time for you to enable the TFTP server. For details about how to configure the top directory, see the following configuration.

Configuring the Top Directory of the TFTP Server

Command	**tftp-server topdir** *directory*
Parameter Description	*directory*: Indicates the access path.
Command Mode	Global configuration mode
Usage Guide	For example, you can set the top directory of the server to **/dir**. Then the TFTP client can access files and folders in the **/dir** directory only on the device after logging in, and the TFTP client cannot return to the parent directory of the **/dir** directory due to restrictions of the top directory.

Enabling TFTP Server Debugging

Command	**debug tftp-server**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	You can run this command to enable TFTP server debugging, so that process or error information of the TFTP server can be output as necessary.

Displaying the Download Progress of a Client

Command	**show tftp-server updating-list**
Parameter Description	N/A
Command Mode	All modes except user mode
Usage Guide	The command is used to display the download progress of a TFTP client, excluding its completed download.

Configuration Example

Establishing the TFTP Server Function on an IPv4 Network

Scenario	• Enable the TFTP server function. • Set the top directory of the TFTP server to **/dir**.
	`Hostname(config)#tftp-server topdir /tmp`

	`Hostname(config)#tftp-server enable`

Verification	● Run the **show tftp-server** command to display the configuration.
	`Hostname#show tftp-server`
	`…`
	`tftp-server information`
	`==========`
	`enable : Y`
	`topdir : tmp:/`

Common Errors

No top directory is configured.

1.5 Monitoring

Displaying

Command	Function
show tftp-server	Displays the configuration of the TFTP server.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Function
debug tftp-server	Enables TFTP server debugging.
show tftp-server updating-list	Displays the download progress of a client.

1 Configuring TFTP Client

1.1 Overview

The Trivial File Transfer Protocol (TFTP) is an application of the Transmission Control Protocol/Internet Protocol (TCP/IP). File transfer between the TFTP client and server is implemented based on the User Datagram Protocol (UDP). Compared with TCP-based FTP, TFTP does not require authentication or have complex packets. It is suitable for a stable network environment.

TFTP is used for small file transfer, and FTP supports large file transfer.

Protocols and Standards

- RFC 783: Trivial FILE TRANSFER PROTOCOL (TFTP)

1.2 Applications

Application	Description
Uploading a File from a Local Device to the Remote TFTP Server	A local device needs to upload a file to the remote TFTP server.
Downloading a File from the Remote TFTP Server to a Local Device	A local device needs to download a file from the remote TFTP server.

1.2.1 Uploading a File from a Local Device to the Remote TFTP Server

Scenario

A local device needs to upload a file to the remote TFTP server.

As shown in Figure 1-1, resource sharing is provided only on the intranet.

Figure 1-1

Deployment

- Only communication is implemented on the Intranet.
- Enable the TFTP client file upload function on the TFTP client.

- Enable the TFTP server file upload function on the TFTP server.

1.2.2 Downloading a File from the Remote TFTP Server to a Local Device

Scenario

A local device needs to download a file from the remote TFTP server.

As shown in Figure 1-2, resource sharing is provided only on the intranet.

Figure 1-2

Deployment

- Only communication is implemented on the intranet.
- Enable the TFTP client file download function on the TFTP client.
- Enable the TFTP server file download function on the TFTP server.

1.3 Features

Basic Concepts

Uploading a File Using TFTP

Upload a file from the TFTP client to the TFTP server.

Downloading a File Using TFTP

Download a file from the TFTP server to the TFTP client.

Specifying the Source Interface's IP Address for TFTP Transmission

Specify the source IP address for the TFTP client to communicate with the TFTP server.

Specifying the Port Number for Connection with the TFTP Server

Specify the port used by the TFTP client to communicate with the TFTP server.

Overview

Feature	Description
Uploading a File Using TFTP	Uploads a file from the TFTP client to the TFTP server.
Downloading a File Using TFTP	Downloads a file from the TFTP server to the TFTP client.

Feature	Description
Specifying the Source Interface's IP Address for TFTP Transmission	Specifies the source IP address for the TFTP client to communicate with the TFTP server.
Specifying the Port Number for a Connection with the TFTP Server	Specifies the port used by the TFTP client to communicate with the TFTP server.

1.3.1 Uploading a File Using TFTP

TFTP has the file upload function. To upload a file using TFTP, enable the file upload function on both the TFTP client and TFTP server and upload a file from the TFTP client to the TFTP server.

1.3.2 Downloading a File Using TFTP

TFTP has the file download function. To download a file using TFTP, enable the file download function on both the TFTP client and TFTP server and download a file from the TFTP server to the TFTP client.

1.3.3 Specifying the Source Interface's IP Address for TFTP Transmission

You can configure the source IP address for the TFTP client to connect to and share files with the TFTP server.

1.3.4 Specifying the Port Number for a Connection with the TFTP Server

You can specify the port number for the TFTP client to connect with and share files with the TFTP server.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic TFTP Client Functions	(Mandatory) It is used to configure the TFTP client function.	
	copy flash	Uploads a file.
	copy tftp	Downloads a file.
Configuring Optional TFTP Client Functions	(Optional) It is used to configure the working mode of the TFTP client.	
	tftp-client source	Configures the source IP address of the TFTP client used for establishing a TFTP connection.
	tftp-client port	Configures the port number used by the TFTP client to connect to the TFTP server.

1.4.1 Configuring Basic TFTP Client Functions

Configuration Effect

- Implement file upload and download.

Notes

- Note the format of files to be uploaded or downloaded.

Configuration Step

Uploading a File

- Mandatory.
- Configure TFTP-related Uniform Resource Locators (URLs) for the destination address under **copy** in privileged EXEC mode.

Downloading a File

- Mandatory.
- Configure TFTP-related URLs for the source address under **copy** in privileged EXEC mode.

Verification

- Check whether the uploaded file exists in a directory of the TFTP server.
- Check whether the downloaded file exists in the destination address.

Related Commands

Uploading a File

Command	**copy flash:**[local-directory/]local-file **tftp:** // dest-address[/remote-directory]/remote-file
Parameter Description	*local-directory*: Indicates the directory on the local device. If no directory is specified, the current directory is used. *local-file*: Indicates the name of the local file to be operated. *dest-address*: Indicates the IP address of the TFTP server. *remote-directory*: Indicates the directory on the TFTP server. *remote-file*: Indicates the name of the file to be operated on the TFTP server. ⚠ The directory specified by *local-directory* must already exist on the device. Running this command does not automatically create a directory.
Command Mode	Global configuration mode
Usage Guide	This command is used to upload a file in the **flash** directory of the local device to the TFTP server.

Downloading a File

Command	**copy tftp:**// dest-address[/remote-directory]/remote-file **flash:**[local-directory/]local-file
Parameter Description	*dest-address*: Indicates the IP address of the TFTP server. *remote-directory*: Indicates the directory on the TFTP server. *remote-file*: Indicates the name of the file to be operated on the TFTP server. *local-directory*: Indicates the directory on the local device. If no directory is specified, the current directory is used. *local-file*: Indicates the name of the local file to be operated. ⚠ The directory specified by *local*-directory must already exist on the device. Running this command does not automatically create a directory.
Command	Global configuration mode

Mode	
Usage Guide	This command is used to download a file from the TFTP server to the **flash** directory of the local device.

Configuration Example

The following configuration example only describes configurations related to TFTP client upload and download.

Uploading a File

Configuration Steps	• Upload the **local-file** file in the **flash** directory on the device to the **root** directory of the TFTP server at 192.168.23.69 and rename the file **remote-file**.
	`Hostname# copy flash:local-file tftp://192.168.23.69/root/remote-file`
Verification	• Check whether the **remote-file** file exists on the TFTP server.

Downloading a File

Configuration Steps	• Download the **remote-file** file from the **root** directory of the TFTP server at 192.168.23.69 to the **flash** directory of the device and rename it **local-file**.
	`Hostname# copy tftp://192.168.23.69/root/remote-file flash:local-file`
Verification	• Check whether the **local-file** file exists in the **home** directory under the **flash** directory.

Common Errors

- The format of the uploaded or downloaded file is incorrect.
- The username or password is incorrect.

1.4.2 Configuring Optional TFTP Client Functions

Configuration Effect

- Download or upload files using the specified IP address and port number of the TFTP client.

Notes

- The remote port number ranges from 20000 to 65534.

Configuration Steps

Configuring the Source IP Address for Establishing a TFTP Connection

- Optional.
- Configure the source IP address of the TFTP client used for establishing a TFTP connection.

Configuring the Port Number Used by the TFTP Client to Connect to the TFTP Server

- Optional.
- Configure the port number used by the TFTP client to connect to the TFTP server.

Verification

Run the **show running-config** command to display the configuration.

Related Commands

Configuring the Source IP Address for Establishing a TFTP Connection

Command	**tftp-client source** { **ip** *ip-address* | **ipv6** *ipv6-address* | *interface-type interface-number* }
Parameter Description	*ipv6*-address: Indicates the IPv6 address of the local interface. *ip-address*: Indicates the IPv4 address of the local interface.
Command Mode	Global configuration mode
Usage Guide	You can use this command to bind the TFTP client to the IP address of a port so that the TFTP can use this IP address to connect to the TFTP server. By default, no source IP address is bound to the TFTP client, and an IP address is selected for the client based on the route.

Configuring the Port Number Used by the TFTP Client to Connect to the TFTP Server

Command	**tftp-client port** *port-number*
Parameter Description	*port*-number: Indicates the port number.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the port number used by the TFTP client to connect to the TFTP server.

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show running-config	Displays the TFTP client configuration.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug tftp	Debugs the TFTP client.

1 Configuring SNMP

1.1 Overview

The Simple Network Management Protocol (SNMP), established as a network management standard in August 1988 by RFC 1157, is widely supported by various vendors. It has since become a universal standard for managing networks across heterogeneous environments. SNMP enables network administrators to perform essential functions including querying network node information, configuring networks, locating faults, planning capacity, and monitoring and managing networks.

↘ SNMP Versions

The following SNMP versions are supported:

- SNMPv1: The first official version of SNMP is defined in RFC 1157.
- SNMPv2C: The community-based SNMPv2 management architecture is defined in RFC 1901.
- SNMPv3: SNMPv3 provides the following security features by identifying and encrypting data.

1 Ensures that data is tampered-resistant during transmission.

2 Ensures that data is transmitted from valid data sources.

3 Encrypts packets and ensures data confidentiality.

Protocols and Standards

- RFC 1157, Simple Network Management Protocol (SNMP)
- RFC 1901, Introduction to Community-based SNMPv2
- RFC 2578, Structure of Management Information Version 2 (SMIv2)
- RFC 2579, Textual Conventions for SMIv2
- RFC 3411, An Architecture for Describing Simple Network Management Protocol (SNMP) Management Frameworks
- RFC 3412, Message Processing and Dispatching for the Simple Network Management Protocol (SNMP)
- RFC 3413, Simple Network Management Protocol (SNMP) Applications
- RFC 3414, User-based Security Model (USM) for version 3 of the Simple Network Management Protocol (SNMPv3)
- RFC 3415, View-based Access Control Model (VACM) for the Simple Network Management Protocol (SNMP)
- RFC 3416, Version 2 of the Protocol Operations for the Simple Network Management Protocol (SNMP)
- RFC 3417, Transport Mappings for the Simple Network Management Protocol (SNMP)
- RFC 3418, Management Information Base (MIB) for the Simple Network Management Protocol (SNMP)
- RFC 3419, Textual Conventions for Transport Addresses

1.2 Applications

Application	Description
Managing Network Devices Based on SNMP	Network devices are managed and monitored based on SNMP.

1.2.1 Managing Network Devices Based on SNMP

Scenario

In Figure 1-1, network device A is managed and monitored based on SNMP network manager.

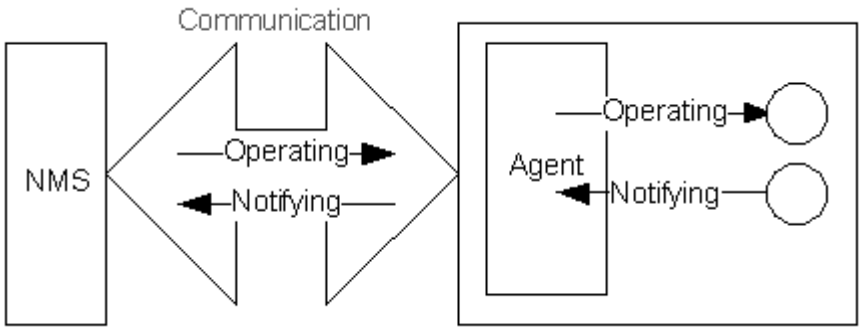
Figure 1-1

Remarks	Device A is a network device that needs to be managed. The PC is a network management station.

Deployment

The network management station is connected to managed network devices. On the network management station, users access the Management Information Base (MIB) on the network devices through the SNMP network manager and receive messages proactively sent by the network devices to manage and monitor the network devices.

1.3 Features



Basic Concepts

SNMP is an application layer protocol that works in client/server mode. It consists of three parts:

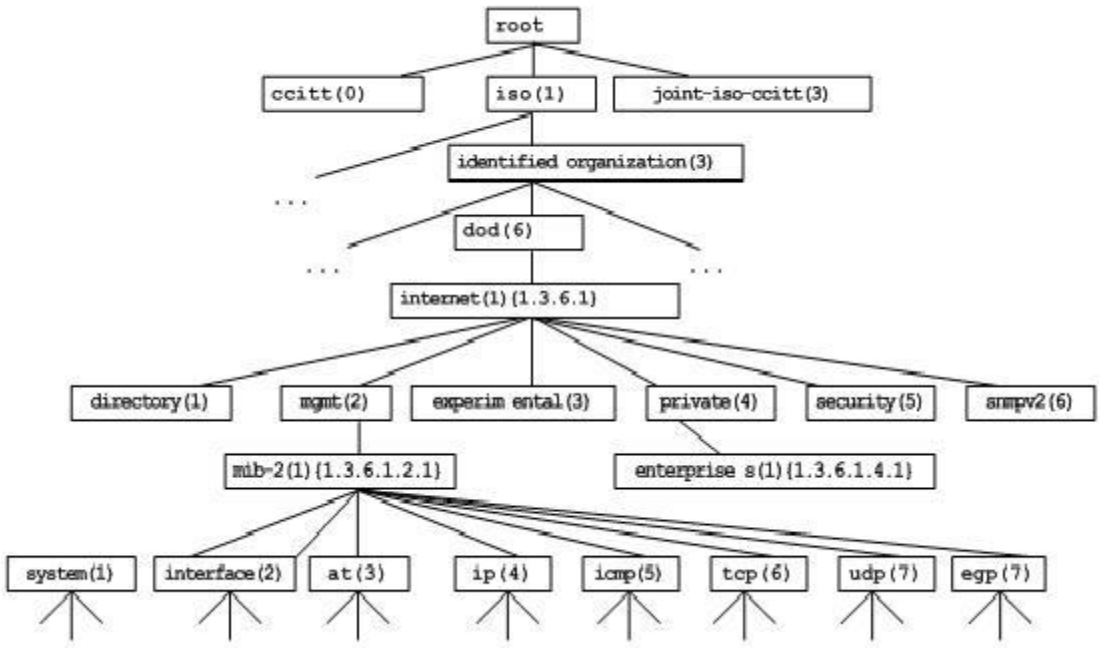
- SNMP network manager
- SNMP agent
- MIB

Figure 1-2 shows the relationship between the network management system (NMS) and the network management agent.

Figure 1-2

SNMP Network Manager

The SNMP network manager is a system that controls and monitors a network based on SNMP and is also called the NMS.



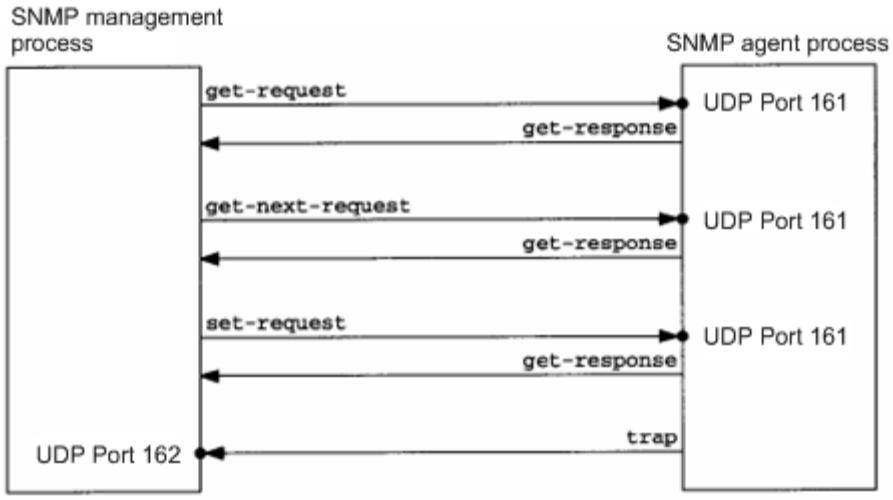
SNMP Agent

The SNMP agent (agent for short) is software running on the managed devices. It is responsible for receiving, processing, and responding to monitoring and control packets from the NMS. The agent may also proactively send messages to the NMS.

MIB

The MIB is virtual, containing extensive information within managed network devices. To uniquely identify specific management units in SNMP packets, the MIB utilizes a hierarchical tree structure. Each node in this structure denotes a distinct management unit. A sequence of digits serves as a unique identifier for each management unit system across network devices. Essentially, the MIB functions as a repository of network device unit identifiers.

Figure 1-3 Tree Hierarchical Structure



Operation Types

Six operation types are defined for information exchange between the NMS and agent based on SNMP:

- Get-request: The NMS extracts one or more parameter values from the agent.
- Get-next-request: The NMS extracts the parameter value next to one or more parameters from the agent.
- Get-bulk: The NMS extracts a batch of parameter values from the agent.
- Set-request: The NMS sets one or more parameter values of the agent.
- Get-response: The agent returns one or more parameter values, which are the operations in response to the three operations performed by the agent on the NMS.
- Trap: The agent proactively sends a message to notify the NMS of event occurrence.

The first four packets are sent by the NMS to the agent, and the last two packets are sent by the agent to the NMS. Note that SNMPv1 does not support the Get-bulk operation. Figure 1-4 illustrates the operations.

Figure 1-4 SNMP Packet Types

The three operations performed by the NMS on the agent and the response operations of the agent are based on UDP port 161. The trap operation performed by the agent is based on UDP port 162.

Overview

Feature	Description
Basic SNMP Functions	The SNMP agent is configured on network devices to implement basic functions such as information query for network nodes, network configuration, fault locating, and capacity planning.
SNMPv1 and SNMPv2C	SNMPv1 and SNMPv2C adopt the community-based security architecture, including the authentication name and access permission.
SNMPv3	SNMPv3 redefines the SNMP architecture and enhances security functions, including the security model based on users and access control model based on views. The SNMPv3 architecture includes all functions of SNMPv1 and SNMPv2C.

SNMP MIB Cache Function	The SNMP MIB cache function enables the master device to collect MIB variables on the standby/backup device in advance and cache the collected MIB variables. In this way, the NMS can directly read the cached MIB variables from the master device, avoid accessing the standby/backup device and reducing the consumed time.

1.3.1 Basic SNMP Functions

Working Principle

Working Process

SNMP involves a request-response interaction (refer to Figure 1-4 for packet exchange details). The NMS initiates requests to the agent, including Get-request, Get-next-request, Get-bulk, and Set-request. Upon receiving these requests, the agent executes necessary operations and responds with a Get-response. Occasionally, the agent sends trap and Inform messages to the NMS. While the NMS does not need to reply to trap messages, it must send back an Inform-response to the agent; otherwise, the agent will resend the Inform message.

Related Configuration

Disabling the SNMP Agent

By default, the SNMP function is enabled.

The **no snmp-server** command is used to disable the SNMP agent.

The **no enable service snmp-agent** command is used to directly disable all SNMP services.

Setting Basic SNMP Parameters

By default, the system contact mode, system location, and device Network Element (NE) information are empty. The default serial number is 60FF60, the default maximum packet length is 1572 bytes, and the default UDP port number of the SNMP service is 161.

The **snmp-server contact** command is used to configure or delete the system contact mode.

The **snmp-server location** command is used to configure or delete the system location.

The **snmp-server chassis-id** command is used to configure the system serial number or restore the default value.

The **snmp-server packetsize** command is used to configure the maximum packet length of the agent or restore the default value.

The **snmp-server net-id** command is used to configure or delete device NE information.

The **snmp-server udp-port** command is used to set the UDP port number of the SNMP service or restore the default value.

The **snmp-server source-interface** command is used to set the source interface through which packets are received from SNMP.

Configuring the SNMP Host Address

By default, no SNMP host is configured.

The **snmp-server host** command is used to configure the NMS host address to which the agent proactively sends messages or to delete the specified SNMP host address. In the messages sent to the host, the SNMP version,

receiving port, authentication name, or user can be bound. This command is used with the **snmp-server enable traps** command to proactively send trap messages to the NMS.

Setting Trap Message Parameters

By default, SNMP is not allowed to proactively send a trap message to the NMS, an interface is enabled to send a Link Trap message, the device is disabled from sending a system reboot trap message, and a trap message does not carry any private field.

By default, the IP address of the interface where SNMP packets are sent is used as the source address.

By default, the length of a trap message queue is 10 and the interval for sending a trap message is 30s.

The **snmp-server enable traps** command is used to enable the agent to proactively send a trap message to the NMS.

The **snmp trap link-status** command is used to enable an interface to send a Link Trap message.

The **snmp-server trap-source** command is used to specify the source address for sending messages.

The **snmp-server queue-length** command is used to set the length of a trap message queue.

The **snmp-server trap-timeout** command is used to set the interval for sending a trap message.

The **snmp-server trap-format private** command is used to enable the device to carry private fields in an outgoing trap message.

The **snmp-server system-shutdown** command is used to enable the device to send a system reboot trap message.

Configuring the SNMP Attack Defense and Detection Function

By default, the SNMP attack defense and detection function is disabled.

The **snmp-server authentication attempt** *times* **exceed** { **lock** | **lock-time** *minutes* | **unlock** } command is used to enable the attack defense and detection function.

Configuring Password Dictionary Check for the Community and User

Password dictionary check for community and user is disabled by default.

You can enable password dictionary check for SNMP community and user using the **snmp-server enable secret-dictionary-check** command. This command needs to be used in conjunction with the **password policy** command in global configuration mode.

Configuring the SNMP Logging Function to Record Get, Get-Next, and Set Operations Performed by the NMS on the SNMP Agent

By default, SNMP logging is enabled.

The **snmp-server logging** { **get-operation** | **set-operation** } command is used to enable the device to record Get and Set operations. **get-operation** controls Get and Get-Next operations records, and **set-operation** controls Set operation records.

Configuring the Heartbeat Trap Function and Interval

By default, the heartbeat trap function is enabled and heartbeat trap messages are sent at an interval of 5 minutes.

Run the **no snmp-server heartbeat on** command to disable the heartbeat trap function.

Run the **snmp-server heartbeat period** command to configure the interval for sending heartbeat trap messages.

1.3.2 SNMPv1 and SNMPv2C

SNMPv1 and SNMPv2C adopt the community-based security architecture. The administrator who can perform operations on the MIB of the agent is limited by defining the host address and authentication name (community string).

Working Principle

SNMPv1 and SNMPv2 determine whether the administrator has the right to use MIB objects by using the authentication name. The authentication name of the NMS must be the same as an authentication name defined on devices.

SNMPv2C introduces the Get-bulk operation mechanism, allowing for retrieval of extensive data or entire tables in fewer request-response cycles, thus optimizing efficiency. Additionally, SNMPv2C enhances error handling by providing more detailed error message types to the management workstation through expanded error codes, unlike SNMPv1 which offers only one generic error code. Given the coexistence of SNMPv1 and SNMPv2C capable management workstations on networks, SNMP agents must discern between SNMPv1 and SNMPv2C packets and respond accordingly with packets of the corresponding versions.

↘ Security

One authentication name has the following attributes:

- Read-only: Provides the read permission of all MIB variables for authorized management workstations.
- Read-write: Provide the read/write permission of all MIB variables for authorized management workstations.

Related Configuration

↘ Setting Authentication Names and Access Permissions

The default access permission of all authentication names is read-only.

The **snmp-server community** command is used to configure or delete an authentication name and access permission.

This command is pivotal for enabling the SNMP agent function because it defines community attributes and specifies the NMS scope where access to the MIB is permitted.

1.3.3 SNMPv3

SNMPv3 redefines the SNMP architecture and includes functions of SNMPv1 and SNMPv2.

Working Principle

The NMS and SNMP agent are SNMP entities. In the SNMPv3 architecture, SNMP entities consist of the SNMP engine and SNMP applications. The SNMP engine is used to send and receive messages, identify and encrypt information, and control access to managed objects. SNMP applications refer to internal applications of SNMP, which work by using services provided by the SNMP engine.

SNMPv3 determines whether a user has the right to use MIB objects by using the User-based Security Model (USM). The security level of the NMS user must be the same as that of an SNMP user defined in devices so as to manage devices.

SNMPv3 requires the NMS to obtain SNMP agent engine IDs on devices when the NMS manages devices. SNMPv3 defines the discover and report operation mechanisms. When the NMS does not learn agent engine IDs, the NMS may

first send a discover message to the agent and the agent returns a report message carrying an engine ID. Later, management operations between the NMS and the agent must carry the engine ID.

Security

- SNMPv3 determines the data security mechanism based on the security model and security level. Security models include SNMPv1, SNMPv2C, and SNMPv3. SNMPv3 includes SNMPv1 and SNMPv2C into the security model.

Table 1-1 SNMPv1 and SNMPv2C Security Models and Security Levels

Security Model	Security Level	Authentication	Encryption	Description
SNMPv1	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed based on the authentication name.
SNMPv2c	noAuthNoPriv	Authentication name	N/A	Data validity is confirmed based on the authentication name.

Table 1-2 SNMPv3 Security Model and Security Level

Security Model	Security Level	Authentication	Encryption	Description
SNMPv3	noAuthNoPriv	User name.	N/A	Data validity is confirmed based on the user name.
SNMPv3	authNoPriv	MD5/SHA /SHA256/SHA512	N/A	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA is provided.
SNMPv3	authPriv	MD5/SHA /SHA256/SHA512	DES	The data authentication mechanism based on HMAC-MD5 or HMAC-SHA and data encryption mechanism based on CBC-DES are provided.

Engine ID

An engine ID is used to uniquely identify an SNMP engine. Because each SNMP entity includes only one SNMP engine, one SNMP engine uniquely identifies an SNMP entity in a management domain. Therefore, the SNMPv3 agent as an entity must has a unique engine ID, that is, SnmpEngineID.

An engine ID is an octet string that consists of 5 to 32 bytes. RFC 3411 defines the format of an engine ID:

- The first 4 bytes indicate the private enterprise ID (allocated by IANA) of a vendor, which is expressed in hexadecimal notation.
- The fifth byte indicates remaining bytes:
- 0: Reserved.
- 1: The rightmost 4 bytes indicate an IPv4 address.
- 2: The rightmost 16 bytes indicate an IPv6 address.
- 3: The rightmost 6 bytes indicate a MAC address.
- 4: Text consisting of 27 bytes, which is defined by the vendor.

- 5: Hexadecimal value consisting of 27 bytes, which is defined by the vendor.
- 6-127: Reserved.
- 128-255: Formats specified by the vendor.

Related Configuration

Configuring a MIB View and a Group

By default, one view is configured and all MIB objects can be accessed.

By default, no user group is configured.

The **snmp-server view** command is used to configure a view and the **snmp-server group** command is used to configure a user group.

One or more instructions can be configured to specify different community names so that network devices can be managed by NMSs of different permissions.

Configuring an SNMP User

By default, no user is configured.

The **snmp-server user** command is used to configure a user.

The NMS can communicate with the agent by using only authorized users.

An SNMPv3 user can specify the security level (whether authentication and encryption are required), authentication algorithm (MD5 or SHA), authentication password, encryption password (DES), and encryption password.

1.3.4 SNMP MIB Cache Function

In the scenario where multiple devices are virtualized into one device and unified management is performed, the NMS needs to collect MIB variables on the standby/backup device through the master device. The collection process takes a long time if there are many devices.

Working Principle

The SNMP MIB cache function can be enabled to reduce the time consumed by the collection process. This function enables the master device to collect MIB variables on the standby/backup device in advance and cache the collected MIB variables. In this way, the NMS can directly read the cached MIB variables from the master device, avoid accessing the standby/backup device and reducing the consumed time.

Related Configuration

Configuring the SNMP MIB Cache Function

The SNMP MIB cache function is disabled by default.

Run the **snmp-server cache enable** command to configure the SNMP MIB cache function.

Configuring the SNMP MIB Cache Update Interval

The cache update interval is 300s by default.

Run the **snmp-server cache update-timer** *seconds* command to configure the SNMP MIB cache update interval.

Enabling the Cache Function on a Node with a Specified OID and Configuring the Cache Update Interval of This Node

The MIB cache function is disabled by default. The cache update interval of a node with a specified object identifier (OID) is consistent with the global cache update interval by default.

Run the **snmp-server cache oid** *oid-string* [**update-timer** *seconds*] command to enable the cache function on a node with a specified OID and configure the cache update interval of this node.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic SNMP Functions	(Mandatory) It is used to enable users to access the agent through the NMS.	
	enable service snmp-agent	Enables the agent function.
	snmp-server community	Sets an authentication name and access permission.
	snmp-server user	Configures an SNMP user.
	snmp-server view	Configures an SNMP view.
	snmp-server group	Configures an SNMP user group.
	snmp-server authentication	Configures the SNMP attack defense and detection function.
	snmp-server enable secret-dectionaty-check	Configures password dictionary check for communities and users.
Enabling the Trap Function	(Optional) It is used to enable the agent to proactively send a trap message to the NMS.	
	snmp-server host	Configures the NMS host address.
	snmp-server enable traps	Enables the agent to proactively send a trap message to the NMS.
	snmp trap link-status	Enables an interface to send a Link Trap message.
	snmp-server system-shutdown	Enables the device to send a system reboot trap message.
	snmp-server trap-source	Specifies the source address for sending a trap message.
	snmp-server heartbeat	Configures the heartbeat trap function and interval.
Disabling the Agent Function	(Optional) It is used to disable the agent function when the agent service is not required.	
	no snmp-server	Disables the agent function.
Setting SNMP Control Parameters	(Optional) It is used to set or change SNMP control parameters.	
	snmp-server contact	Sets the device contact mode.
	snmp-server location	Sets the device location.

Configuration	Description and Command	
	snmp-server logging	Sets the logging function.
	snmp-server chassis-id	Sets the serial number of the device.
	snmp-server net-id	Configures NE information about the device.
	snmp-server packetsize	Changes the maximum packet length.
	snmp-server udp-port	Changes the UDP port number of the SNMP service.
	snmp-server queue-length	Changes the length of a trap message queue.
	snmp-server trap-timeout	Changes the interval for sending a trap message.
Configuring SNMP MIB Cache Function	⚠ (Optional) It is used to configure or modify the SNMP MIB cache function.	
	snmp-server cache enable	Configures the global SNMP MIB cache function.
	snmp-server cache update-timer	Configures the global SNMP MIB cache update interval.
	snmp-server cache oid	Enables the cache function on a node with a specified OID and configures the cache update interval of this node.

1.4.1 Configuring Basic SNMP Functions

Configuration Effect

Enable users to access the agent through the NMS.

Notes

- By default, no authentication name is configured on network devices, and SNMPv1 or SNMPv2C cannot be used to access the MIB of network devices. When an authentication name is set, if no access permission is specified, the default access permission is read-only.

Configuration Step

↘ Configuring an SNMP View

- Optional.
- An SNMP view needs to be configured when the View-based Access Control Model (VACM) is used.

↘ Configuring an SNMP User Group

- Optional.
- An SNMP user group needs to be configured when the VACM is used.

↘ Configuring an Authentication Name and Access Permission

- Mandatory.

- An authentication name must be set on the agent when SNMPv1 and SNMPv2C are used to manage network devices.

Configuring an SNMP User

- Mandatory
- A user must be set when SNMPv3 is used to manage network devices.

Enabling the Agent Function

- Optional.
- By default, the agent function is enabled. When the agent function needs to be enabled again after it is disabled, this command must be used.

Enabling the SNMP Attack Defense and Detection Function

- Optional.
- By default, the SNMP attack protection and detection function is disabled. When malicious attacks need to be prevented, the configuration item must be used on the agent.

Setting Password Dictionary Check for Community and User

- Optional.
- Password dictionary check for the SNMP community and user is disabled by default. To avoid using the weak community or user name that is easy to crack, you can enable this function. This configuration needs to be used with the **password policy** command in global configuration mode.

Configuring the SNMP Logging Function to Record Get, Get-Next, and Set Operations Performed by the NMS on the SNMP Agent

- Optional.
- The SNMP logging function records the Get, Get-Next, and Set operations performed by the NMS on the SNMP agent. When the Get and Get-Next operations are performed, the agent records the IP address of the NMS user, operation type, and OID of the operation node. When the Set operation is performed, the agent records the IP address of the NMS user, operation type, OID of the operation node, and set value. These logs will be sent to the device's information center with the informational level, which means that they serve as general notification messages for the device.

Verification

Run the **show snmp** command to check the SNMP function on the device.

Related Commands

Configuring an SNMP View

Command	**snmp-server view** *view-name oid-tree* { **include** | **exclude** }
Parameter Description	*view-name*: Specifies the view name. *oid-tree*: Specifies the MIB objects associated with a view, which are displayed as an MIB subtree. **include:** Indicates that the MIB object subtree is included in the view.

	exclude: Indicates that the MIB object subtree is not included in the view.
Command Mode	Global configuration mode
Usage Guide	Specify a view name and use it for view-based management.

Configuring an SNMP User Group

Command	**snmp-server group** *groupname* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } } [**read** *readview*] [**write** *writeview*] [**access** { **ipv6** *ipv6-aclname* | *aclnum* | *aclname* }]
Parameter Description	**v1** | **v2c** |**v3**: Specifies the SNMP version. **auth**: Indicates that messages sent by users in the group need to be verified but data confidentiality is not required. This configuration is valid for SNMPv3 only. **noauth**: Indicates that messages sent by users in the group do not need to be verified and data confidentiality is not required. This configuration is valid for SNMPv3 only. **priv**: Indicates that messages sent by users in the group need to be verified and confidentiality of transmitted data is required. This configuration is valid for SNMPv3 only. *readview*: Associates one read-only view. *writeview*: Associates one read/write view. *aclnum*: Specifies the ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. *aclname*: Specifies the ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. *ipv6-aclname*: Specifies the IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.
Command Mode	Global configuration mode
Usage Guide	Associate users with a group and associate the group with a view. Users in a group have the same access permission. In this way, you can determine whether managed objects associated with an operation are in the allowable range of a view. Only managed objects in the range of a view can be accessed.

Configuring an Authentication Name and Access Permission

Command	**snmp-server community {** [**0** | **7**] *string* | **secret** [**0** | **8**] *string*} [**view** *view-name*] [[**ro** | **rw**] [**host** *ipaddr*]] [**ipv6** *ipv6-aclname*] [*aclnum* | *aclname*]
Parameter Description	*0*: Indicates that the input community string is a cleartext string. *7*: Indicates that the input community string is a ciphertext string. **secret**: Indicates the community name that needs to be encrypted, with the default encryption algorithm of SHA256. **0**: Indicates that the input community string is in cleartext mode, and will be encrypted using the default method. **8**: Indicates that the input community string is in ciphertext mode. *string*: Specifies the community string, which is equivalent to the communication password between the NMS and the SNMP agent. *view-name*: Specifies a view name for view-based management. **ro:** Indicates that the NMS can only read variables of the MIB.

	rw: Indicates that the NMS can read and write variables of the MIB. *aclnum*: Specifies the ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. *aclname*: Specifies the ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. *ipv6-aclname*: Specifies the ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified. *ipaddr*: Associates NMS addresses and specifies NMS addresses for accessing the MIB.
Command Mode	Global configuration mode
Usage Guide	This command is pivotal for enabling the SNMP agent function because it defines community attributes and specifies the NMS scope where access to the MIB is permitted. To disable the SNMP agent function, run the **no snmp-server** command.

Configuring an SNMP User

Command	**snmp-server user** *username groupname* { **v1** | **v2c** | **v3** [**encrypted**] [**auth** { **md5** | **sha** } *auth-password* [**priv des56** *priv-password*]] } [**access** { *aclnum* | *aclname* | **ipv6** *ipv6_aclname* }]
Parameter Description	*username*: Specifies the user name. *groupname*: Specifies the group name for a user. **v1** | **v2c** | **v3**: Specifies the SNMP version. Only SNMPv3 supports security parameters. **encrypted:** Indicates that the specified password is in ciphertext mode. Otherwise, the cleartext mode is used. If the ciphertext mode is selected, enter a key consisting of contiguous hexadecimal digits. An MD5 authentication key consists of 16 bytes and an SHA authentication key consists of 20 bytes. Two characters stand for 1 byte. Encrypted keys are valid for this engine only. **auth**: Specifies whether authentication is used. **md5**: Specifies the MD5 authentication protocol. **sha**: Specifies the SHA authentication protocol. *auth-password*: Configures a password string (not more than 32 characters) used by the authentication protocol. The system converts the password into the corresponding authentication key. **priv**: Specifies whether confidentiality is used. **des56**: Specifies the 56-bit DES encryption protocol. *priv-password*: Configures a password string (not more than 32 characters) used for encryption. The system converts the password into the corresponding encryption key. *aclnum*: Specifies the ACL number. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. *aclname*: Specifies the ACL name. The specified ACL is associated and the range of IPv4 NMS addresses from which access to the MIB is allowed is specified. *ipv6-aclname*: Specifies the IPv6 ACL name. The specified ACL is associated and the range of IPv6 NMS addresses from which access to the MIB is allowed is specified.
Command Mode	Global configuration mode
Usage Guide	Configure user information so that the NMS can communicate with the agent by using a valid user. For an SNMPv3 user, you can specify the security level, authentication algorithm (MD5, SHA,

	SHA256, or SHA512), authentication password, encryption algorithm (DES or AES128), and encryption password.

Enabling the Agent Function

Command	**enable service snmp-agent**
Parameter Description	N/A
Configuration mode	Privileged mode.
Usage Guide	This command is used to enable the SNMP agent function of a device.

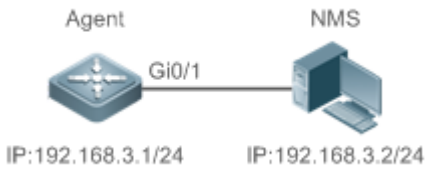
Enabling the SNMP Attack Defense and Detection Function

Command	**snmp-server authentication attempt** *times* **exceed** { **lock** | **lock-time** *minutes* | **unlock** }
Parameter Description	*times*: Specifies the number of continuous failed attempts. **lock**: Indicates that the source IP address is permanently forbidden to initiate authentication for access after continuous authentication fails. The administrator needs to manually unlock the IP address. **lock-time** *minutes*: Indicates that the source IP address is forbidden to initiate authentication for access in a period of time after continuous authentication fails. Beyond the period, the source IP address can be authenticated for access again. **unlock**: Indicates that the source IP address is allowed to access the MIB continuously after continuous authentication fails. This means that the SNMP attack defense and detection function is not configured.
Command Mode	Global configuration mode
Usage Guide	Configure the SNMP attack defense and detection function so that the corresponding measure can be taken after continuous authentication fails. The permanently forbidden source IP addresses can be authenticated for access again only after the administrator manually unlocks the IP addresses. The source IP address that are forbidden to access the MIB in a period of time can be authenticated for access again after the period expires or after the administrator manually unlocks the IP addresses.

Setting Password Dictionary Check for the Community and User

Command	**snmp-server enable secret-dictionary-check**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command must be used with the **password policy** command in global configuration mode to set checking rules, such as a minimum password length of 6. Run the **no snmp-server enable secret-dictionary-check** command to disable the check function.

Setting the SNMP Logging Function to Record Get, Get-Next, and Set Operations Performed by the NMS on the SNMP Agent



Command	**snmp-server logging** { **get-operation | set-operation** }
Parameter Description	**get-operation**: Enables logging of Get and Get-Next operations. **set-operation**: Enables logging of the Set operation.
Command Mode	Global configuration mode
Usage Guide	This command is used to record the Get, Get-Next, and Set operations performed by the NMS on the SNMP agent. When the Get and Get-Next operations are performed, the agent records the IP address of the NMS user, operation type, and OID of the operation node. When the Set operation is performed, the agent records the IP address of the NMS user, operation type, OID of the operation node, and set value. ⚠ A large number of logs will affect device performance. In normal conditions, you are advised to disable the SNMP logging function.

Displaying the SNMP Status Information

Command	**show snmp** [**mib** | **user** | **view** | **group| host | locked-ip | process-mib-time**]
Parameter Description	**mib**: Displays information about the SNMP MIB supported in the system. **user**: Displays information about an SNMP user. **view**: Displays information about an SNMP view. **group**: Displays information about an SNMP user group. **host**: Displays information about the user configuration. **locked-ip**: Specifies the source IP address that is locked after continuous authentication fails. **process-mib-time**: Displays the MIB node with the longest processing time.
Configuration mode	Privileged mode.
Usage Guide	N/A

Configuration Example

Configuring SNMPv3

Scenario **Figure 1-5**	 ● The NMS manages network devices (agents) based on the user authentication and encryption mode, for example, the NMS uses **user1** as the user name, MD5 as the authentication mode, **123** as the authentication password, DES56 as the encryption algorithm, and **321** as the encryption password. ● Network devices can control the operation permission of users to access MIB objects. For example, the user named **user1** can read MIB objects under the system node (1.3.6.1.2.1.1) and can only write MIB objects under the SysContact node (1.3.6.1.2.1.1.4.0). ● Network devices can actively send authentication and encryption messages to the NMS.
Configuration	● Configure a MIB view and a MIB group. Create a MIB view **view1**, which includes the

Steps	associated MIB object (1.3.6.1.2.1.1); then create a MIB view **view2**, which includes the associated MIB object (1.3.6.1.2.1.1.4.0). Create a group **g1**, select the version **v3**, set the security level to the authentication and encryption mode **priv**, and configure permissions to read **view1** and write **view2**. ● Configure an SNMP user. Create a user named **user1** under group **g1**, select **v3** as the version, and set the authentication mode to **md5**, authentication password to **123**, encryption mode to **DES56**, and encryption password to **321**. ● Configure the SNMP host address. Set the host address to 192.168.3.2, select **3** as the version, set the security level to the authentication and encryption mode **priv**, and associate the user name **user1**. Enable the agent to actively send a trap message to the NMS. ● Set the IP address of the agent. Set the address of Gi0/1 to 192.168.3.1/24.

Agent	`Hostname(config)#snmp-server view view1 1.3.6.1.2.1.1 include`
	`Hostname(config)#snmp-server view view2 1.3.6.1.2.1.1.4.0 include`
	`Hostname(config)#snmp-server group g1 v3 priv read view1 write view2`
	`Hostname(config)#snmp-server user user1 g1 v3 auth md5 123 priv des56 321`
	`Hostname(config)#snmp-server host 192.168.3.2 traps version 3 priv user1`
	`Hostname(config)#snmp-server enable traps`
	`Hostname(config)#interface gigabitEthernet 0/1`
	`Hostname(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0`
	`Hostname(config-if-gigabitEthernet 0/1)#exit`

Verification	1. Run the **show running-config** command to display the device configuration. 2. Run the **show snmp user** command to display the SNMP user. 3. Run the **show snmp view** command to display the SNMP view. 4. Run the **show snmp group** command to display the SNMP group. 5. Run the **show snmp host** command to display host information configured by the user. 6. Install MIB-Browser.

Agent	`Hostname# show running-config`
	`!`
	`interface gigabitEthernet 0/1`
	` no ip proxy-arp`
	` ip address 192.168.3.1 255.255.255.0`

type: trap
user: user1
security model: v3 authPriv
```

Install MIB-Browser, enter IP address 1**92.168.3.1** in **IP Address** and **user1** in **UserName**, select **AuthPriv** for **Security Level**, enter **123** in **AuthPassWord**, select **MD5** for **AuthProtocol**, and enter **321** in **PrivPassWord**. Click **Add Item** and select a management unit for which the MIB needs to be queried, for example, **System** in the following **Figure**. Click **Start**. The MIB is queried for network devices. The lowest pane in the following figure shows query results.

Common Errors

N/A

1.4.2 Enabling the Trap Function

Configuration Effect

Enable the agent to proactively send a trap message to the NMS.

Notes

N/A

Configuration Step

Configuring the SNMP Host Address

- Optional.
- Configure the host address of the NMS when the agent is required to proactively send messages.

Enabling the Agent to Proactively Send a Trap Message to the NMS

- Optional.
- Configure this item on the agent when the agent is required to proactively send a trap message to the NMS.

Enabling an Interface to Send a Link Trap Message

- Optional.
- Configure this item on the agent when a link trap message needs to be sent on an interface.

Enabling the Agent to Send a System Reboot Trap Message

- Optional
- Perform this configuration on the agent when the RGOS system is required to send a trap message to the NMS to notify system reboot before reloading or restarting the device.

Specifying the Source Address for Sending a Trap Message

- Optional
- Perform this configuration on the agent when a local IP address needs to be permanently used as the source SNMP address to facilitate management.

Enabling a Trap Message to Carry Private Fields When the Message Is Sent

- Optional
- Perform this configuration on the agent when private fields need to be carried in a trap message.

Configuring the Heartbeat Trap Function and Interval

- Optional.
- By default, the heartbeat trap function is enabled, and the heartbeat trap messages are sent at an interval of 5 minutes. Perform this configuration if the heartbeat trap function needs to be disabled or the interval for sending heartbeat trap messages needs to be changed.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display the device configuration.

Related Commands

Setting the NMS Host Address

Command	**snmp-server host** { *host-addr* | **ipv6** *ipv6-addr* } [**traps | inrorms**] [**version** { **1** | **2c** | **3** { **auth** | **noauth** | **priv** }] *community-string* [**udp-port** *port-num*] [*notification-type*]
Parameter Description	*host-addr*: Specifies the address of the SNMP host. *ipv6-addr*: Specifies the IPv6address of the SNMP host. *domain-name*: Indicates the domain name of the SNMP host. **traps | informs**: Configures the host to send a trap message or an inform message. **version**: Configures an SNMP version, which can be set to **V1**, **V2C**, or **V3**. **auth** | **noauth** | **priv**: Sets the security level of V3 users. *community-string*: Specifies the community string or user name (v3). *port-num*: Configures the port number of the SNMP host. *notification-type*: Configures the type of trap messages that are proactively sent, for example, snmp. If no trap type is specified, all trap messages are sent.
Command Mode	Global configuration mode
Usage Guide	This command is used with the **snmp-server enable traps** command to proactively send trap messages to the NMS.

Enabling the Agent to Proactively Send a Trap Message to the NMS

Command	**snmp-server enable traps** [*notification-type*]
Parameter Description	*notification-type*: Enables trap notification for the corresponding events, including the following types: authentication: Enables authentication trap message. entity: Enables entity trap message. snmp: Enables trap notification for SNMP events. bridge: Enables trap notification for bridge events. mac-notification: Enables trap notification for MAC events. nfpp: Enables NFPP Traps message. ospf: Enables trap notification for OSPF events. vrrp: Enables trap notification for VRRP events. web-auth: Enables trap notification for web-based authentication events.
Command Mode	Global configuration mode
Usage Guide	This command must be used with the **snmp-server host** command to so that trap messages can be proactively sent.

Enabling an Interface to Send a Link Trap Message

Command	**snmp trap link-status**

Parameter Description	**-**
Configuration mode	Interface configuration mode
Usage Guide	For interfaces (Ethernet interface, aggregate interface, and SVI), when this function is enabled, a Link Trap message is sent if the link status on the interfaces changes. Otherwise, such a message is not sent.

Enabling the Function of Sending a System Reboot Trap Message

Command	**snmp-server system-shutdown**
Parameter Description	-
Configuration mode	Global configuration mode
Usage Guide	When the function of notification upon SNMP system reboot is enabled, a trap message is sent to the NMS to notify system reboot before reloading or restarting the device.

Specifying the Source Address for Sending a Trap Message

Command	**snmp-server trap-source** *interface*
Parameter Description	*interface*: Specifies the interface of which the address is the SNMP source address.
Configuration mode	Global configuration mode
Usage Guide	By default, the IP address of the interface where SNMP packets are sent is used as the source address. To facilitate management and identification, run this command to specify one local IP address as the source SNMP address.

Enabling a Trap message to Carry Private Fields When the Message Is Sent

Command	**snmp-server trap-format private**
Parameter Description	N/A
Configuration mode	Global configuration mode
Usage Guide	This command can be used to enable a trap message to carry private fields when the message is sent. Supported private fields include the alarm generation time. For more information about specific data types and data ranges of the fields, see RUIJIE-TRAP-FORMAT-MIB.mib.

Configuring the Heartbeat Trap Function

Command	**snmp-server heartbeat on**
Parameter Description	N/A
Configuration Mode	Global configuration mode
Usage Guide	By default, the heartbeat trap function is enabled. You can run the **no snmp-server heartbeat**

	command to disable this function.

Configuring the Interval for Sending Heartbeat Trap Messages

Command	**snmp-server heartbeat period** *time*
Parameter Description	*time*: Indicates the interval, in seconds.
Configuration Mode	Global configuration mode
Usage Guide	This command configures the interval for sending heartbeat trap messages.

Configuration Example

Enabling the Trap Function

Scenario **Figure 1-6**	 ● The NMS manages network devices (agents) based on the community authentication mode, and network devices can proactively send messages to the NMS.
Configuration Steps	1. Perform the configuration to enable the agent to proactively send messages to the NMS. Set the SNMP host address to 192.168.3.2, the message format to Version2c, and the authentication name to **user1**. Enable the agent to proactively send trap messages. 2. Set the IP address of the agent. Set the address of Gi0/1 to 192.168.3.1/24.

Agent	`Hostname(config)#snmp-server host 192.168.3.2 traps version 2c user1`
	`Hostname(config)#snmp-server enable traps`
	`Hostname(config)#interface gigabitEthernet 0/1`
	`Hostname(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0`
	`Hostname(config-if-gigabitEthernet 0/1)#exit`

Verification	● Run the **show running-config** command to display the device configuration. ● Run the **show snmp** command to display the SNMP status.

Agent	`Hostname# show running-config`
	`ip access-list standard a1`
	`  10 permit host 192.168.3.2`
	`interface gigabitEthernet 0/1`
	`  no ip proxy-arp`

Common Errors

N/A

1.4.3 Disabling the Agent Function

Configuration Effect

Disable the agent function when the agent service is not required.

Notes

- Run the **no snmp-server** command to shield the SNMP agent function when the agent service is not required.
- Different from the shielding command, after the **no enable service snmp-agent** command is run, all SNMP services are directly disabled (that is, the SNMP agent function is disabled, no packet is received, and no response packet or trap packet is sent), but configuration information of the agent is not shielded.

Configuration Step

↘ Disabling the SNMP Agent Function for the Device

- Optional.
- To disable the configuration of all SNMP agent services, perform this configuration.

Disabling the SNMP Agent Function for the Device

- Optional.
- To directly disable all services, perform this configuration.

Verification

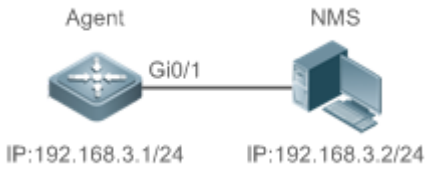
Run the **show service** command to check whether SNMP services are enabled or disabled.

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display the device configuration.

Related Commands

Disabling the SNMP Agent Function for the Device



Command	**no snmp-server**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, the SNMP agent function is disabled. When SNMP agent parameters (for example, NMS host address, authentication name, and access permission) are set, the SNMP agent service is automatically enabled. The **enable service snmp-agent** command must also be run simultaneously so that the SNMP agent service can take effect. If the SNMP agent service is disabled or the **enable service snmp-agent** command is not run, the SNMP agent service does not take effect. Run the **no snmp-server** command to disable SNMP agent services of all versions supported by the device. After this command is run, all SNMP agent service configurations are shielded (that is, after the **show running-config** command is run, no configuration is displayed. Configurations are restored after the SNMP agent service is enabled again). After the **enable service snmp-agent** command is run, the SNMP agent configurations are not shielded.

Disabling the SNMP Agent Function for the Device

Command	**no enable service snmp-agent**
Parameter Description	N/A
Configuration mode	Global configuration mode
Usage Guide	This command can be used to disable the SNMP service, but it will not shield SNMP agent parameters.

Configuration Example

Enabling the SNMP Service

Scenario **Figure 1-7**	 ● After the SNMP service is enabled and the SNMP agent server is set, the NMS can access devices based on SNMP.
Configuration Steps	1. Enable the SNMP service. 2. Set parameters for the SNMP agent server to make the SNMP service take effect.
A gent	`Hostname(config)#enable service snmp-agent`
Verification	● Run the **show service** command to check whether the SNMP service is enabled or disabled.

Agent	`Hostname#show service`
	`web-server : disabled`
	`web-server(https): disabled`
	`snmp-agent : enabled`
	`ssh-server : disabled`
	`telnet-server : enabled`

Common Errors

N/A

1.4.4 Setting SNMP Control Parameters

Configuration Effect

- Set basic parameters of the SNMP agent, including the device contact mode, device location, serial number, and parameters for sending a trap message. Based on the parameters, the NMS can obtain the contact and physical location of the device.

Notes

N/A

Configuration Step

↘ Setting the System Contact Mode

- Optional.
- When the contact mode of the system needs to be modified, perform this configuration on the agent.

↘ Setting the System Location

- Optional.
- When the system location needs to be modified, perform this configuration on the agent.

↘ Setting the System Serial Number

- Optional.

- When the system serial number needs to be modified, perform this configuration on the agent.

Setting NE Information about the Device

- Optional.
- When the NE code needs to be modified, perform this configuration on the agent.

Setting the Maximum Packet Length of the SNMP Agent

- Optional.
- When the maximum packet length of the SNMP agent needs to be modified, perform this configuration on the agent.

Setting the UDP Port Number of the SNMP Service

- Optional.
- When the UDP port number of the SNMP service needs to be modified, perform this configuration on the agent.

Setting the Queue Length of Trap Messages

- Optional.
- When the size of the message queue needs to be adjusted to control the message sending speed, perform this configuration on the agent.

Setting the Interval for Sending a Trap Message

- Optional.
- When the interval for sending a trap message needs to be modified, perform this configuration on the agent.

Configuring SNMP Flow Control

- Optional.
- If a large number of SNMP request packets result in a high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Configuring the Number of Attempts and Timeout for Sending Inform Packets

- Optional.

Verification

Run the **show snmp** command to display the SNMP status.

Run the **show running-config** command to display the device configuration.

Related Commands

Setting the System Contact Mode

Command	**snmp-server contact** *text*
Parameter Description	*text*: Indicates the string that describes the system contact mode.

Command Mode	Global configuration mode
Usage Guide	N/A

Setting the System Location

Command	**snmp-server location** *text*
Parameter Description	*text*: Indicates the string that describes system information.
Configuration mode	Global configuration mode
Usage Guide	N/A

Setting the System Serial Number

Command	**snmp-server chassis-id** *text*
Parameter Description	*text*: Indicates the text of the system serial number, which may be digits or characters.
Configuration mode	Global configuration mode
Usage Guide	Typically, the device serial number is used as the SNMP serial number for the ease of identifying the device.

Configuring NE Information About the Device

Command	**snmp-server net-id** *text*
Parameter Description	*text*: Indicates the text that is used to set the device NE code. The text is a string that consists of 1 to 255 case-sensitive characters and may include spaces.
Configuration mode	Global configuration mode
Usage Guide	Set the NE code of the device.

Setting the Maximum Packet Length of the SNMP Agent

Command	**snmp-server packetsize** *byte-count*
Parameter Description	*byte-count*: Indicates the packet size. The value range is from 484 bytes to 17876 bytes.
Configuration mode	Global configuration mode
Usage Guide	N/A

Setting the UDP Port Number of the SNMP Service

Command	**snmp-server udp-port** *port-num*
Parameter Description	*port-num*: Specifies the UDP port number of the SNMP service, that is, the number of the protocol port that receives SNMP packets.
Configuration mode	Global configuration mode

Usage Guide	Specify the protocol port number for receiving SNMP packets.

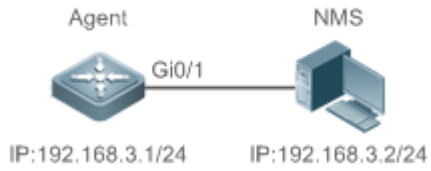
Setting the Length of a Trap Message Queue

Command	**snmp-server queue-length** *length*
Parameter Description	*length*: Specifies the queue length. The value range is from 1 to 1000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the size of the message queue to control the message sending speed.

Setting the Interval for Sending a Trap Message

Command	**snmp-server trap-timeout** *seconds*
Parameter Description	*seconds*: Specifies the interval for sending a trap message, which is expressed in the unit of 10 ms. The value range is from 1 to 1000.
Configuration mode	Global configuration mode
Usage Guide	Adjust the interval for sending a message to control the message sending speed.

Configuring SNMP Flow Control



Command	**snmp-server flow-control pps** [*count*]
Parameter Description	*count*: Specifies the number of SNMP request packets processed per second. The value range is from 50 to 65535.
Command Mode	Global configuration mode
Usage Guide	If a large number of SNMP request packets result in a high CPU usage for SNMP tasks, configure SNMP flow control to limit the number of request packets processed per second in each SNMP task, so as to control the CPU usage for SNMP tasks.

Configuring the Number of Attempts and Timeout for Sending Inform Packets

Command	**snmp-server inform** { **retries** *retry-num* | **timeout** *time* }
Parameter Description	*retry-num*: Indicates the number of attempts for sending inform packets. The value range is from 0 to 255. *time*: Indicates the timeout for sending inform packets, in seconds. The value range is from 0 to 21474836.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Setting SNMP Control Parameters

Scenario **Figure 1-8**	 ● The NMS manages network devices (agents) based on the community authentication mode and can obtain basic system information about the devices, for example, system contact mode, location, and serial number.
Configuration Steps	1. Set SNMP agent parameters, including the system location, contact mode, and serial number. 2. Set the IP address of the agent. Set the address of Gi0/1 to 192.168.3.1/24.

Agent	`Hostname(config)#snmp-server location fuzhou`
	`Hostname(config)#snmp-server contact Hostname.com.cn`
	`Hostname(config)#snmp-server chassis-id 1234567890`
	`Hostname(config)#interface gigabitEthernet 0/1`
	`Hostname(config-if-gigabitEthernet 0/1)#ip address 192.168.3.1 255.255.255.0`
	`Hostname(config-if-gigabitEthernet 0/1)#exit`

Verification	● Check the device configuration. ● Check the SNMP view and group information.

Agent	`Hostname# show running-config`
	`ip access-list standard a1`
	`  10 permit host 192.168.3.2`
	`interface gigabitEthernet 0/1`

	groupname: user1 securityModel: v2c securityLevel:noAuthNoPriv readview: v1 writeview: v1 notifyview:

Common Errors

N/A

1.4.5 Configuring SNMP MIB Cache Function

Configuration Effect

- Enable the SNMP MIB cache function to increase the speed of obtaining MIB data by the NMS. This function enables the master device to collect MIB variables on the standby/backup device in advance and cache the collected MIB variables. In this way, the NMS can directly read the cached MIB variables from the master device, avoid accessing the standby/backup device and reducing the consumed time.

Notes

- The SNMP MIB cache function applies only to MIB with specific table variables. To configure this function, only the OID of the root node of the MIB table variables needs to be configured.
- After the cache function is enabled, the cache is updated periodically, and the MIB data is not collected in real time. A short cache update interval may cause frequent cache update operations in the system, which consumes many CPU resources. On the contrary, a long cache update interval may delay MIB data updates, causing a failure to learn the system status in real time. Therefore, the cache update interval needs to be adjusted according to real-time performance of the MIB nodes and CPU resources.

Configuration Step

↘ Configuring the Global SNMP MIB Cache Function

- Optional.
- The SNMP MIB cache function is disabled by default. You can enable the MIB cache function globally.

↘ Configuring the Global SNMP MIB Cache Update Interval

- Optional.
- The global SNMP MIB cache update interval is 300s by default. You can configure the global cache update interval.

↘ Enabling Cache Function on Node with Specified OID and Configuring Cache Update Interval of This Node

- Optional.
- The cache function is disabled on all MIB nodes by default. You can enable the MIB cache function on a specified MIB node.

Verification

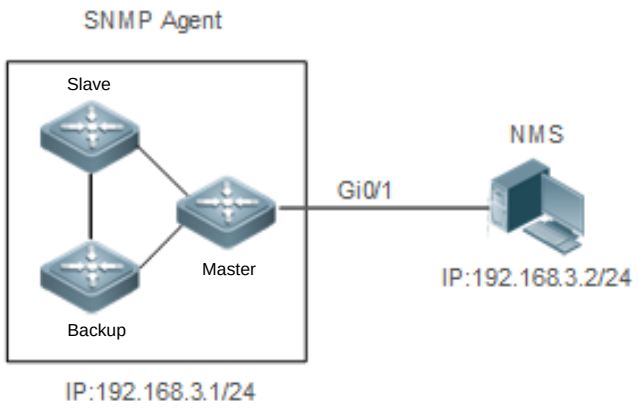
Run the **show running-config** command to display the device configuration.

Related Commands

Configuring the Global SNMP MIB Cache Function.

Command	**snmp-server cache enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	

Configuring Global SNMP MIB Cache Update Interval



Command	**snmp-server cache update-timer** *seconds*
Parameter Description	*seconds*: Specifies the global SNMP MIB cache update interval, in seconds. The value range is from 60 to 86400.
Configuration Mode	Global configuration mode
Usage Guide	

Enabling the Cache Function on a Node with a Specified OID and Configuring the Cache Update Interval of This Node

Command	**snmp-server cache oid** *oid-string* [**update-timer** *seconds*]
Parameter Description	*oid-string*: Specifies the OID of a MIB node. *seconds*: Specifies the cache update interval, in seconds. The value range is from 60 to 86400.
Configuration Mode	Global configuration mode
Usage Guide	If the cache update interval of a MIB node is not configured, the global cache update interval is used.

Configuration Example

Setting SNMP Control Parameters

Scenario **Figure 1-9**	 ● The NMS manages the SNMP agent based on the community authentication mode. The NMS

	can obtain MIB node information about the SNMP agent, such as the connection status of the AP and STA.
Configuration Steps	● 1. Configure the global SNMP MIB cache function. ● 2. Configure the global SNMP MIB cache update interval. ● 3. Enable the cache function on a node with a specified OID.

Agent	`Hostname(config)# snmp-server cache enable`
	`Hostname(config)# snmp-server cache update-timer 600`
	`Hostname(config)# snmp-server cache oid 1.3.6.1.4.1.4881.1.1.10.2.56.2.1.1.1`

Verification	● Display the device configuration.

Agent	`Hostname# show running-config | include snmp`
	`snmp-server cache enable`
	`snmp-server cache update-timer 600`
	`snmp-server cache oid 1.3.6.1.4.1.4881.1.1.10.2.56.2.1.1.1`
	`snmp-server enable traps`
	`snmp-server community public rw`

Common Errors

N/A

1.5 Monitoring

Clearing

Command	Description
clear snmp locked-ip [**ipv4** *ipv4-address* | **ipv6** *ipv6-address*]	Clears the list of source IP addresses that are locked after continuous authentication fails.

Displaying

Command	Description
show snmp [**mib** | **user** | **view** | **group| host | locked-ip | process-mib-time**]	Displays the SNMP status.

1 Configuring RMON

1.1 Overview

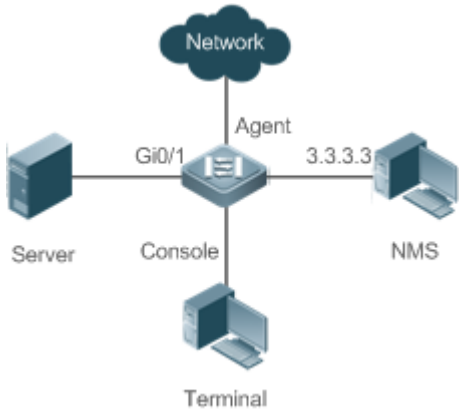
The Remote Network Monitoring (RMON) aims to address challenges of managing local area networks (LANs) and remote sites from a centralized point. In RMON, network monitoring data includes various statistics and performance indicators. These metrics are crucial for monitoring the network utilization, facilitating network planning, optimizing performance, and diagnosing network errors.

RMON is mainly used by a managing device to remotely monitor and manage managed devices.

Protocols and Standards

- STD 0059/RFC 2819: Remote Network Monitoring Management Information Base
- RFC 4502: Remote Network Monitoring Management Information Base Version 2
- RFC 3919: Remote Network Monitoring (RMON) Protocol Identifiers for IPv6 and Multi Protocol Label Switching (MPLS)
- RFC 3737: IANA Guidelines for the Registry of Remote Monitoring (RMON) MIB Modules
- RFC 3434: Remote Monitoring MIB Extensions for High Capacity Alarms
- RFC 3395: Remote Network Monitoring MIB Protocol Identifier Reference Extensions
- RFC 3287: Remote Monitoring MIB Extensions for Differentiated Services
- RFC 3273: Remote Network Monitoring Management Information Base for High Capacity Networks
- RFC 2896: Remote Network Monitoring MIB Protocol Identifier Macros
- RFC 2895: Remote Network Monitoring MIB Protocol Identifier Reference

1.2 Applications



Application	Description
Collecting Statistics on Information of a Monitored Interface	Functions of RMON are utilized to an interface to monitor network communication.

1.2.1 Collecting Statistics on Information of a Monitored Interface

Scenario

The Ethernet statistics collection function of RMON is used to monitor accumulated information about an interface, the historical statistics collection function is used to monitor the packet count of an interface within each monitoring interval, and the alarm function is used to immediately obtain packet count exceptions of an interface. **Figure 1-1** shows the networking topology.

Figure 1-1

Deployment

An interface is monitored to accumulate statistics on packet counts and to collect data on packet counts and bandwidth utilization within the monitoring interval. If there's an abnormal packet count on the interface, an alarm is sent to the network management system (NMS). The key configuration points are outlined as follows:

- Configure the RMON Ethernet statistics collection function on the interface.
- Configure the RMON historical statistics collection function on interface.
- Configure the RMON alarm table and define RMON event processing actions in configuration mode. Monitored objects of alarms are the object identifier (OID) values of specific fields in the RMON Ethernet statistical table configured for the interface.

1.3 Features

Basic Concepts

RMON defines multiple RMON groups. Devices support the statistics group, history group, alarm group, and event group, which are described as follows.

Statistics Group

A statistics group is used to monitor and collect statistics on Ethernet interface traffic information, which is accumulated from the entry creation time to the current time. Statistical items include discarded data packets, broadcast data packets, cyclic redundancy check (CRC) errors, large and small blocks, and collisions. Statistical results are stored in the Ethernet statistical table, so an administrator can easily query it.

History Group

A history group is used to periodically collect network traffic information. It records accumulated values of network traffic information and the bandwidth utilization within each interval, and saves them in the history control table. It includes two small groups:

- The HistoryControl group is used to set the sampling interval, sampling data source, and other control information.
- The EthernetHistory group provides administrators with historical data, including statistics on network segment traffic, error packets, broadcast packets, bandwidth utilization, and collision count.

Alarm Group

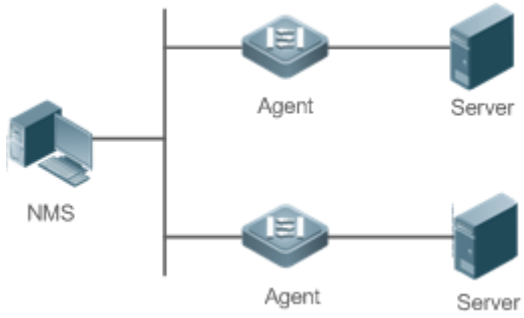
An alarm group is used to monitor a specified Management Information Base (MIB) object. When the value of a MIB object exceeds the preset upper limit or is lower than the preset lower limit, an alarm is triggered and the alarm is processed as an event.

Event Group

An event group is used to define the event processing mode. When a monitored MIB object meets alarm conditions, an event is triggered. An event can be processed in any of the following modes:

- none: No action is taken.
- log: Event-relevant information is logged so that an administrator can view it at any time.
- snmp-trap: A trap message is transmitted to the NMS to notify the NMS of event occurrence.
- log-and-trap: Event-relevant information is logged and a trap message is transmitted to the NMS.

Working Principle



RMON allows multiple monitors and provides two data collection methods:

- Method 1: A dedicated RMON probe is used to collect data, and the NMS can directly obtain all information about the RMON MIB from the RMON probe.
- Method 2: RMON agents are built into network devices (such as switches and routers), so that the network devices have the RMON probe function.

The NMS uses basic commands of the Simple Network Management Protocol (SNMP) to exchange data with RMON agents and collect network management information. This method, however, is limited by device resources and obtains information of only four groups but not all data of the RMON MIB.

Figure 1-2 shows an example of communication between the NMS and RMON agents. The NMS, through the RMON agents running on devices, can acquire information about overall traffic, error statistics, and performance statistics of the network segment where an interface of a managed network device resides, thereby implementing remote management of network devices.

Figure 1-2

Overview

Feature	Description
RMON Ethernet Statistics Collection	Accumulates statistics on the packet count, byte count, and other data of a monitored Ethernet interface.

Feature	Description
RMON Historical Statistics Collection	Records the numbers of packets and bytes, and other communication data of an Ethernet interface within the configured interval, and calculates the bandwidth utilization within the interval.
RMON Alarm	Samples values of monitored variables at intervals. The alarm table is used in combination with the event table. When the upper or lower limit is reached, an event table is triggered to perform event processing or no processing is performed.

1.3.1 RMON Ethernet Statistics Collection

Working Principle

The RMON Ethernet statistics collection function accumulatively collects statistics on network traffic information of an Ethernet interface from the entry creation time to the current time.

Related Configuration

↘ Configuring RMON Statistical Entries

- The RMON Ethernet statistics collection function is disabled by default.
- Run the **rmon collection stats** command to create Ethernet statistical entries on a specified Ethernet interface.
- After statistical entries are successfully created on a specified interface, the statistics group collects statistics on traffic information of the interface. The statistical items are variables defined in the RMON Ethernet statistical table, and recorded information is accumulated values of variables from the creation time of the RMON statistical table to the current time.

1.3.2 RMON Historical Statistics Collection

Working Principle

The RMON historical statistics collection function records accumulated statistics on traffic information about an Ethernet interface within each interval.

Related Configuration

↘ Configuring RMON Historical Control Entries

- The RMON historical statistics collection function is disabled by default.
- Run the **rmon collection history** command to create historical control entries on an Ethernet interface.
- The RMON history group collects statistics on variables defined in the RMON history table and records accumulated values of variables within each interval.

1.3.3 RMON Alarm

Working Principle

The RMON alarm function periodically monitors value changes of alarm variables. If the value of an alarm variable reaches the specified upper limit or lower limit, a corresponding event is triggered for processing. For example, a trap message is

transmitted or one logTable entry record is generated. If the lower limit or upper limit is reached multiple times consecutively, only one corresponding event is triggered and another event is triggered till a reverse limit is reached.

Related Configuration

Configuring the Event Table

- The RMON event group function is disabled by default.
- Run the **rmon event** command to configure the event table.

Configuring Alarm Entries

- The RMON alarm group function is disabled by default.
- Run the **rmon event** command to configure the event table and run the **rmon alarm** command to configure the RMON alarm table.
- The RMON alarm function is implemented by the alarm table and event table. If a trap message needs to be transmitted to a managing device in the case of an alarm event, the SNMP agent must be correctly configured first. For details on how to configure the SNMP agent, see *Configuring SNMP*.
- If a configured alarm object is a field node in the RMON statistics group or history group, the RMON Ethernet statistics collection function or RMON historical statistics collection function need to be configured on a monitored Ethernet interface first.

1.4 Configuration

Configuration	Description and Command	
Configuring RMON Ethernet Statistics Collection	⚠ (Mandatory) It is used to accumulatively collect statistics on traffic information about an Ethernet interface.	
	rmon collection stats	Configures Ethernet statistical entries.
Configuring RMON Historical Statistics Collection	⚠ (Mandatory) It is used to collect statistics on traffic information of an Ethernet interface and the bandwidth utilization within the interval.	
	rmon collection history	Configures historical control entries.
Configuring the RMON Alarm	⚠ (Mandatory) It is used to monitor whether data changes of a variable is within the valid range.	
	rmon event	Configures event entries.
	rmon alarm	Configures alarm entries.

1.4.1 Configuring RMON Ethernet Statistics Collection

Configuration Effect

Acquire accumulated statistics on traffic information of a monitored Ethernet interface from the entry creation time to the current time.

Notes

This function cannot be configured in batch interface configuration mode.

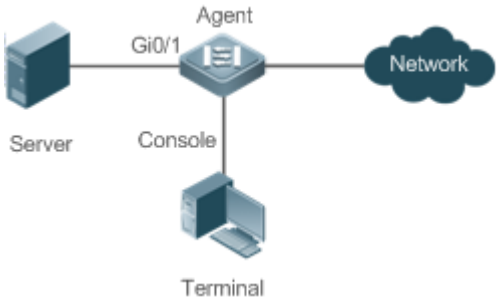
Configuration Step

Configuring RMON Statistical Entries

- Mandatory.
- If statistics and monitoring are required for a specified interface, Ethernet statistical entries must be configured on this interface.

Verification

Run the **show rmon stats** command to display Ethernet statistics.



Related Commands

Configuring RMON Statistical Entries

Command	**rmon collection stats** *index* [**owner** *ownername*]
Parameter Description	*index*: Indicates the index of a statistical entry. The value range is from 1 to 65535. **owner** *ownername*: Indicates the entry creator. The value is a string of 1 to 63 case-sensitive characters.
Command Mode	Interface configuration mode
Usage Guide	The values of statistical entry parameters cannot be changed.

Configuration Example

Configuring RMON Ethernet Statistics Collection

Scenario **Figure 1-3**	
	As shown in Figure 1-3, the RMON agent is connected to the server, and the NMS requires the RMON statistics group to conduct performance statistics on received packets of Gi0/1. An administrator can view statistics at any time to learn data about received packets of an interface and take measures in a timely manner to handle network exceptions.
Configuration Steps	● Configure a statistical table instance on GigabitEthernet 0/1 to collect statistics on traffic of the interface.

Agent	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# rmon collection stats 1 owner admin`

Verification	● Run the **show rmon stats** command to display Ethernet statistics.

Agent	`Hostname# show rmon stats`
	`ether statistic table:`
	`index = 1`
	`interface = GigabitEthernet 0/1`
	`owner = admin`
	`status = 1`
	`dropEvents = 0`
	`octets = 25696`
	`pkts = 293`
	`broadcastPkts = 3`
	`multiPkts = 0`
	`crcAlignErrors = 0`
	`underSizePkts = 0`
	`overSizePkts = 0`
	`fragments = 0`
	`jabbers = 0`
	`collisions = 0`
	`packets64Octets = 3815`
	`packets65To127Octets = 1695`
	`packets128To255Octets = 365`
	`packets256To511Octets = 2542`
	`packets512To1023Octets = 152`
	`packets1024To1518Octets = 685`

Common Errors

- Statistical table entries are reconfigured or configured statistical table entries are modified.

1.4.2 Configuring RMON Historical Statistics Collection

Configuration Effect

Acquire accumulated statistics on traffic of a monitored Ethernet interface and the bandwidth utilization within each interval.

Notes

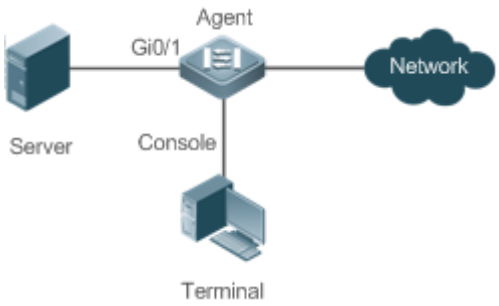
This function cannot be configured in batch interface configuration mode.

Configuration Step

- Mandatory.
- If network statistics on a specified interface need to be collected, RMON historical control entries must be configured on the interface.

Verification

Run the **show rmon history** command to display history group statistics.



Related Commands

Configuring RMON Historical Control Entries

Command	**rmon collection history** *index* [**owner** *ownername*] [**buckets** *bucket-number*] [**interval** *seconds*]
Parameter Description	*index*: Indicates the index of a history statistical entry. The value range is from 1 to 65535. **owner** *ownername*: Indicates the entry creator. The value is a string of 1 to 63 case-sensitive characters. **buckets** *bucket-number*: Sets the capacity of the history table in which a history statistical entry exists. The value range is from 1 to 65,535 and the default value is 10. **interval** *seconds*: Sets the statistics collection interval, in seconds. The value range is from 1 to 3600 and the default value is 1800.
Command Mode	Interface configuration mode
Usage Guide	The values of history statistical entry parameters cannot be changed.

Configuration Example

Configuring RMON History Statistics Collection

Scenario **Figure 1-4**	
	As shown in Figure 1-4, the RMON agent is connected to the server, and the NMS needs to collect statistics on received packets of Gi0/1 through the RMON history group at an interval of 60s, so as to monitor the network and learn emergency data.
Configuration Steps	● Configure the history control table on GigabitEthernet 0/1 to periodically collect statistics on traffic of this interface.

Agent	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# rmon collection history 1 buckets 5 interval 300 owner admin`

Verification	● Run the **show rmon history** command to display history group statistics.

Agent	`Hostname# show rmon history`
	`rmon history control table:`
	`index = 1`
	`interface = GigabitEthernet 0/1`
	`bucketsRequested = 5`
	`bucketsGranted = 5`
	`interval = 60`
	`owner = admin`
	`stats = 1`

```
rmon history table:
                    index = 1
                    sampleIndex = 786

                    overSizePkts = 0
                    fragments = 0
                    jabbers = 0
                    collisions = 0
                    utilization = 0
```

Common Errors

History control table entries are reconfigured or configured history control table entries are modified.

1.4.3 Configuring the RMON Alarm

Configuration Effect

Periodically monitor whether value changes of alarm variables are within the specified valid range.

Notes

If a trap message needs to be transmitted to a managing device when an alarm event is triggered, the SNMP agent must be correctly configured. For details on how to configure the SNMP agent, see *Configuring SNMP*.

If an alarm variable is a MIB variable defined in the RMON statistics group or history group, the RMON Ethernet statistics collection function or RMON historical statistics collection function must be configured on the monitored Ethernet interface. Otherwise, an alarm table fails to be created.

Configuration Step

Configuring Event Entries

- Mandatory.
- Perform the configuration in global configuration mode.

Configuring Alarm Entries

- Mandatory.
- Perform the configuration in global configuration mode.

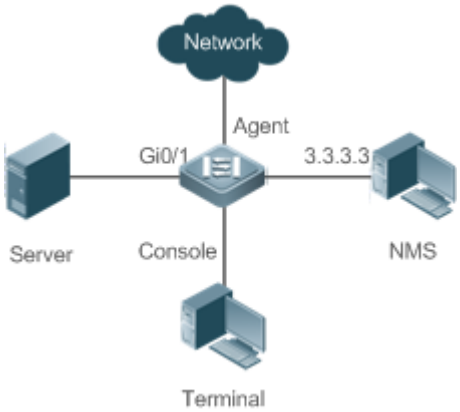
Verification

- Run the **show rmon event** command to display the event table.
- Run the **show rmon alarm** command to display the alarm table.

Related Commands

Configuring the Event Table

Command	**rmon event** *number* [**description** *description-string* | **log** | **owner** *owner-name* | **trap** *community*] *
Parameter Description	*number*: Indicates the index of an event table. The value range is from 1 to 65535. **log**: Indicates a log event. The system logs a triggered event. **trap** *community*: Indicates a trap event. When an event is triggered, the system transmits a trap message with the community name of *community*. **description** *description-string*: Sets the description of an event. The value is a string of 1 to 127 characters. **owner** *ownername*: Indicates the entry creator, which is a string of 1 to 63 case-sensitive characters.
Command Mode	Global configuration mode
Usage Guide	The values of configured event entry parameters can be changed, including the event type, trap community name, event description, and event creator.



Configuring the RMON Alarm Group

Command	**rmon alarm** *number variable interval* { **absolute | delta** } **rising-threshold** *value* [*event-number*] **falling-threshold** *value* [*event-number*] [**owner** *ownername*]
Parameter Description	*number*: Indicates the index of an alarm entry. The value range is from 1 to 65535.

	variable: Indicates an alarm variable. The value is a string of 1 to 255 characters and is represented in dotted format using the node OID (format: entry.integer.instance; example: 1.3.6.1.2.1.2.1.10.1). *Interval*: Indicates the sampling interval, in seconds. The value range is from 1 to 2147483647. **absolute**: Indicates that the sampling type is absolute value sampling, that is, variable values are directly extracted when the sampling time is reached. **delta**: Indicates that the sampling type is changing value sampling, that is, changes in the variable values within the sampling interval are extracted when the sampling time is reached. **rising-threshold** *value*: Sets the upper limit of the sampling quantity. The value range is from -2147483648 to +2147483647. *event-number:* Indicates the number of an event, which is triggered when the upper limit or lower limit is reached. **falling-threshold** *value*: Sets the lower limit of the sampling quantity. The value range is from -2147483648 to +2147483647. **owner** *ownername*: Indicates the entry creator The value is a string of 1 to 63 case-sensitive characters.
Command Mode	Global configuration mode
Usage Guide	Values of configured alarm entry parameters can be changed, including alarm variables, sampling type, entry creator, sampling interval, upper or lower limit of the sampling quantity, and trigger events.

Configuration Example

Configuring the RMON Alarm

Scenario **Figure 1-5**	
	Assume that SNMPv1 runs on the NMS, the community name is **public** with the attribute of read-write, and the IP address used by the NMS to receive trap messages is 3.3.3.3. Assume that the OID value of unknown protocol packets received by monitored interface GigabitEthernet0/3 is 1.3.6.1.2.1.2.2.1.15.3, the sampling mode is relative sampling, and the sampling interval is 60s. When the relative sampling value is larger than 100 or lower than 10, event 1 and event 2 are triggered respectively. In event 1, a trap message is transmitted and the event is logged. In event 2, the event is only logged. The configuration of the RMON agent is completed on the terminal. The RMON agent is connected to the NMS and is connected to the server through GI0/1. The RMON agent needs to monitor the count of unknown protocol packets received by GI0/1. The sampling interval is 60s. When the absolute sampling value is smaller than 10, the event is only logged. When the absolute sampling value is larger than 100, the event is logged and a trap message is transmitted to the NMS.

Configuration Steps	● Configure the host address for receiving trap messages. ● Configure an event group to process alarm triggering. ● Configure the alarm function.
Agent	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# snmp-server community public rw Hostname(config)# snmp-server host 3.3.3.3 trap public Hostname(config)# rmon event 1 description rising-threshold-event log trap public owner admin Hostname(config)# rmon event 2 description falling-threshold-event log owner admin Hostname(config)# rmon alarm 1 1.3.6.1.2.1.2.2.1.15.3 60 delta rising-threshold 100 1 falling-threshold 10 2 owner admin
Verification	● Run the **show rmon event** command to display the event table. ● Run the **show rmon alarm** command to display the alarm table.
Agent	Hostname# show rmon event rmon event table: index = 1 description = rising-threshold-event type = 4 community = public lastTimeSent = 0d:0h:0m:0s owner = admin status = 1 index = 2 description = falling-threshold-event type = 2 community = lastTimeSent = 6d:19h:21m:48s owner = admin status = 1 rmon log table: eventIndex = 2 index = 1 logTime = 6d:19h:21m:48s logDescription = falling-threshold-event Hostname# show rmon alarm rmon alarm table: index: 1, interval: 60, oid = 1.3.6.1.2.1.2.2.1.15.3 sampleType: 2,

```
alarmValue: 0,
startupAlarm: 3,
risingThreshold: 100,
fallingThreshold: 10,
risingEventIndex: 1,
fallingEventIndex: 2,
owner: admin,
stauts: 1
```

Common Errors

- The input OID of a monitored object is incorrect, the variable corresponding to the OID does not exist, or the type is not an integer or unsigned integer.
- The upper limit is smaller than or equal to the lower limit.

1.5 Monitoring

Displaying

Command	Description
show rmon	Displays all RMON configuration.
show rmon statistics	Displays the Ethernet statistical table.
show rmon history	Displays the history control table.
show rmon alarm	Displays the alarm table.
show rmon event	Displays the event table.

1 Configuring NETCONF

1.1 Overview

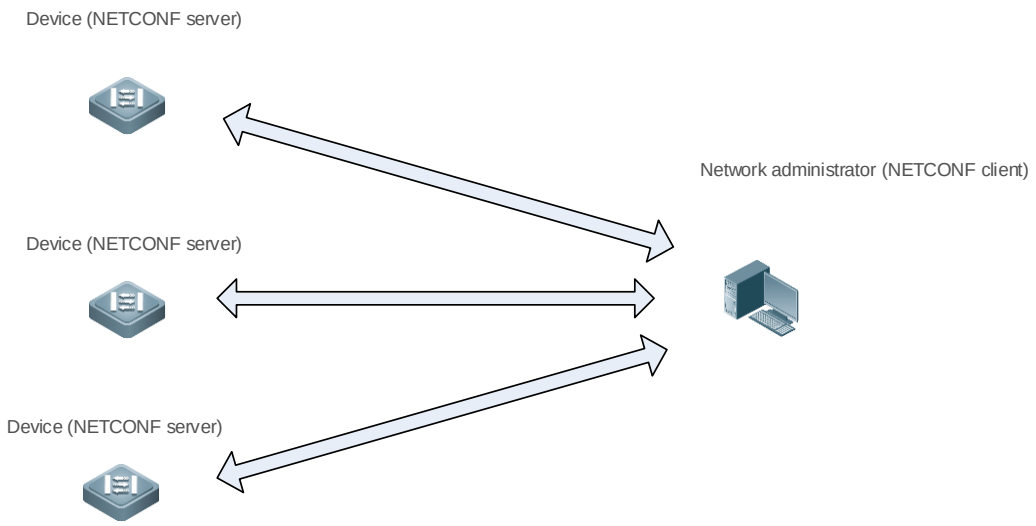
The Network Configuration Protocol (NETCONF) is a new XML-based network configuration protocol developed by the NETCONF working group in 2003. It is used to configure and retrieve device parameters and monitor and manage the device. NETCONF uses the client/server mode for communication. The server program runs on the device, and the client program runs on a user device. The NETCONF protocol packets, including all configuration data and protocol messages are in Extensible Markup Language (XML) format. The NETCONF protocol consists of four layers: content layer, operation layer, remote procedure call (RPC) layer, and transmission layer. The content layer contains managed data objects, such as configuration data of the device. The operation layer defines a set of basic primitive operations of applications at the RPC layer, such as get, get-config, edit-config, and delete-config. The RPC layer provides a simple mechanism unrelated to the transport protocol, which contains regulations for elements of some error messages. The transmission layer provides a secure transmission channel using Secure Shell (SSH), Simple Object Access Protocol (SOAP), or Blocks Extensible Exchange Protocol (BEEP). SSH is mandatory. The following sections only describe the content related to NETCONF.

Protocols and Standards

- RFC 4741: NETCONF Configuration Protocol.
- RFC 4742: Using the NETCONF Configuration Protocol over Secure Shell (SSH)
- RFC 4743: Using NETCONF over the Simple Object Access Protocol (SOAP)
- RFC 4744: Using the NETCONF Protocol over the Blocks Extensible Exchange Protocol (BEEP)
- RFC 5277: NETCONF Event Notifications
- RFC 5381: Experience of Implementing NETCONF over SOAP
- RFC 5539: NETCONF Over Transport Layer Security (TLS)
- RFC 5717: Partial Lock RPC for NETCONF
- RFC 6022: NETCONF Monitoring Schema
- RFC 6241: Network Configuration Protocol
- RFC 6242: Using the Network Configuration Protocol over Secure Shell
- RFC 6243: With-defaults capability for NETCONF
- RFC 6470: NETCONF Notification Events
- RFC 6536: NETCONF Access Control Model (NACM)
- RFC 8071: NETCONF Call Home and RESTCONF Call Home

RFC 4741 and RFC 4742 are replaced by RFC 6241 and RFC 6242, respectively.

1.2 Applications



Application	Description
Configuring NETCONF Network Device Management	A user uses the network management software (NETCONF client) to send NETCONF configuration packets (XML format) to the device to configure and manage the device.

1.2.1 Configuring NETCONF Network Device Management

Scenario

As shown in Figure 1-1, the NETCONF client is used to manage and monitor network devices.

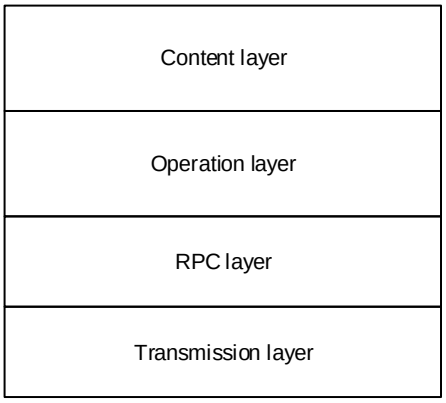
Figure 1-1

Deployment

The network management station connects to managed devices through a network, and the network management station and managed devices run SSH. On the network management station, the network administrator accesses the configuration database and status database on the network device and receives event messages proactively sent by the network devices through the NETCONF client to manage and monitor the network device.

1.3 Features

Basic Concepts



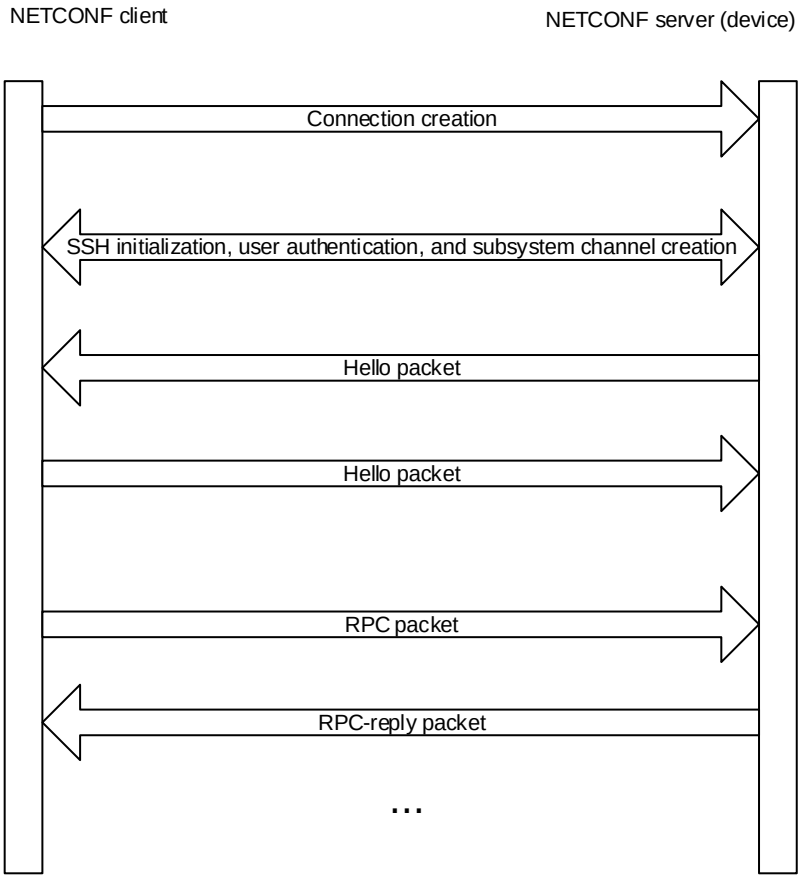
Definition of Terms

- RPC: Remote Procedure Call
- DM: data model

Network Structure of NETCONF

Figure 1-2 shows the structure of NETCONF.

Figure 1-2 Structure of NETCONF



Session Creation

- NETCONF over SSH

The server is monitored over port 830. Before using the NETCONF protocol, an SSH channel (SSH subsystem, named netconf) needs to be established. The SSH channel is established through a series of transmission algorithm negotiations (including key negotiation, compression algorithm, hash algorithm, encryption algorithm, and signature algorithm) and user authentication.

Figure 1-3 Packet Exchange in a NETCONF Session

Capability Set Exchange

After the channel is established, the server and client need to exchange capability sets. Both parties provide their implemented capability sets and ignore capabilities they do not understand or implement. However, both parties must support at least basic protocol capabilities (urn:ietf:params:netconf:base:1.1). To be compatible with earlier protocol versions, both parties need to support basic capabilities of earlier versions (urn:ietf:params:netconf:base:1.0).

Protocol Operations

The operation layer of the NETCONF protocol defines nine basic operations. get and get-config are value acquisition operations, edit-config, copy-config, and delete-config are configuration operations, lock and unlock are lock protection during concurrent operations for unique device resources (such as the configuration file), and close-session and kill-session are session termination operations.

- get: Obtains the device status and configuration data.
- get-config: Obtains configuration data based on the configuration datastore.
- edit-config: Edits configuration based on the provided data model definition and operation attributes. One important attribute is **operation**, which includes merge, replace, create, delete, and remove options. The default value of the **default-operation** parameter is **merge**.
- copy-config: Copies configuration files. For example, copy the optional configuration to the configuration file, startup configuration to running configuration, or running configuration to startup configuration. To perform this operation, ensure that the target file is writable.
- delete-config: Deletes configuration files of the device. Running files of the device cannot be deleted.
- lock: Locks configuration data files to ensure that the current client can access (or modify) the files but other clients or non-NETCONF clients (such as SNMP or CLI) cannot access (or modify) the files.
- unlock: Unlocks configuration data files.
- close-session: Closes the current session, including resource and lock release and connection disconnection. To perform this operation, ensure that the current service is handled and no new request is handled.
- kill-session: Forcibly closes a session, including resource and lock release and connection disconnection. However, the current session cannot be closed. If a service is being handled, it must be stopped. Unfinished services must be rolled back to the initial state.

Overview

Feature	Description
Exchanging Capability Sets	The NETCONF server and client send capability sets to each other. The server (device) supports NETCONF 1.0 and 1.1.
Obtaining Data	The NETCONF client obtains configuration data or status data of the device.
Obtaining the Configuration	The NETCONF client obtains configuration data of the device.
Editing the Configuration	The NETCONF client modifies configuration data of the device.
Copying the Configuration	The NETCONF client copies a configuration file on the device to another configuration file.
Deleting the Configuration	The NETCONF client deletes a configuration file on the device.
Closing the Current Session	The NETCONF client proactively closes the NETCONF session with the device.

Feature	Description
Locking the Configuration	The NETCONF client locks a configuration file on the device.
Unlocking the Configuration	The NETCONF client unlocks a configuration file on the device.

1.3.1 Exchanging Capability Sets

After a connection is established between the client and server, they exchange their capability sets immediately. Subsequent data operations can be performed only after both parties support the same NETCONF version. The format of a sent packet is as follows.

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>
      urn:ietf:params:netconf:base:1.1
    </capability>
    <capability>
      Capability set 1
    </capability>
    <capability>
      Capability set 2
    </capability>
  </capabilities>
  <session-id>Session ID</session-id>
</hello>
```

⚠ Capability exchange messages sent from the NETCONF client to the NETCONF server cannot contain the session ID node (<session-id>).

Sample capability set exchange packet on the server:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
    <capability>urn:ietf:params:netconf:base:1.1</capability>
    <capability>urn:ietf:params:netconf:capability:writable-running:1.0</capability>

  <capability>urn:ietf:params:xml:ns:yang:ietf-yang-types?module=ietf-yang-types&amp;re
  vision=2013-07-15</capability>

<capability>urn:rg:params:xml:ns:yang:rg-tacacs?module=rg-tacacs&amp;revision=2016-10-2
5</capability>

<capability>urn:rg:params:xml:ns:yang:rg-interfaces?module=rg-interfaces&amp;revision=2
016-10-25</capability>

<capability>urn:ietf:params:xml:ns:yang:ietf-inet-types?module=ietf-inet-types&amp;revi
sion=2010-09-24</capability>
```

```
<capability>urn:rg:params:xml:ns:yang:rg-openflow?module=rg-openflow&amp;revision=2016-09-26</capability>
  </capabilities>
  <session-id>28</session-id>
</hello>
```

Sample capability set exchange packet on the client:

```
<hello xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <capabilities>
    <capability>urn:ietf:params:netconf:base:1.0</capability>
  </capabilities>
</hello>
```

1.3.2 Obtaining Data

The get operation is used to obtain the device configuration or status data.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
  <filter type="subtree">
      Configuration data (or status data) filtering rule
  </filter>
  </get-config>
</rpc>
```

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
     Obtained configuration data (or status data)
  </data>
</rpc-reply>
```

If none of status data subsets on the device matches filtering rules, the device returns an empty data node.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="Message ID " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

1.3.3 Obtaining the Configuration

The get-config operation is used to obtain configuration data of the device. It obtains corresponding configuration data subsets based on various sub-tree filtering rules. However, it cannot obtain the device status data.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
 <rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <get-config>
   <source>
     <running/>
   </source>
   <filter type="subtree">
      Protocol-based filtering rule
    </filter>
  </get-config>
</rpc>
```

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
 <rpc-reply message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
      Obtained configuration data
   </data>
</rpc-reply>
```

If none of configuration data subsets on the device matches filtering rules, the device returns an empty data node.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
    <data xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"/>
</rpc-reply>
```

1.3.4 Editing the Configuration

The edit-config operation is used to edit configuration data based on the provided data model definition and operation attributes. The configuration editing packet contains five operation attributes, which are included in the operation attribute description of the configuration node in delivered XML packets. The five operation attributes are as follows:

- **merge**: Merges configuration data that contains this attribute in edit-config packets to the specified device configuration file (or database). If the configuration data does not exist, the device creates the configuration data based on the delivered content.
- **replace**: Replaces configuration data that contains this attribute in edit-config packets with the corresponding configuration data node in the specified device configuration file (or database). If the configuration data does not exist, the device creates the configuration data based on the delivered content. However, the device does not support this operation. If this attribute operation is delivered, the device performs the merge operation.
- **create**: Creates configuration data that contains this attribute in edit-config packets in the specified configuration data file (or database). If the configuration data does not exist, the device creates the configuration data based on the delivered content. If the configuration data already exists, the device returns an rpc-error packet, which carries error-tag whose content is data-exists.
- **delete**: Deletes configuration data that contains this attribute in edit-config packets from the specified configuration data file (or database). If the configuration data exists, the device directly deletes the corresponding configuration.

If the configuration data does not exist, the device returns an rpc-error packet, which carries error-tag whose content is data-missing.

- **remove**: Removes configuration data that contains this attribute in edit-config packets from the specified configuration data file (or database). If the configuration data exists, the device directly removes the corresponding configuration. If the configuration data does not exist, the device ignores this operation and returns OK.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <edit-config>
    <target> <running/> </target>
      <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
        Configuration data
      </config>
  </edit-config>
</rpc>
```

If a packet does not carry the error-option node, the node is set to **stop-on-error** by default. When the configuration of a node is incorrect, subsequent configurations in the same packet are stopped and an error is returned (rpc-error). If a packet does not carry the test-option node, the node is set to **test-then-set** by default. If a packet does not carry the default-operation node, the node is set to **merge** by default.

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="Message ID " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

When a packet carries the error-option node, the packet format is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
<edit-config>
  <target> <running/> </target>
  <error-option>Behavior option when a configuration error occurs</error-option>
  <config xmlns:xc="urn:ietf:params:xml:ns:netconf:base:1.0">
      Configuration data
  </config>
</edit-config>
</rpc>
```

The values of the error-option node are of enumerated type, including:

- **stop-on-error**: When an error occurs during an edit-config operation, the operation is stopped immediately. Data configured before this configuration packet (configuration before the error occurs) takes effect. This is the default value of the error-option node.

- **continue-on-error**: When a configuration error occurs during an edit-config operation, the error is recorded and remaining configurations are handled. However, error information is returned finally. That is, the final response packet is rpc-error in case of any configuration error.

1.3.5 Copying the Configuration

The copy-config operation is performed to synchronize the startup configuration to the running configuration.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx"  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <copy-config>
    <target>
      <startup/>
    </target>
    <source>
      <running/>
    </source>
  </copy-config>
</rpc>
```

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx"  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

1.3.6 Deleting the Configuration

The delete-config operation is used to delete the startup configuration of the device. The running configuration of the device cannot be deleted.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <delete-config>
   <target>
     <startup/>
   </target>
 </delete-config>
</rpc>
```

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

1.3.7 Closing the Current Session

The close-session operation is used to close the current session, release resources and lock, and disconnect the connection.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx" xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
   <close-session/>
</rpc>
```

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx"  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

1.3.8 Locking the Configuration

As defined in RFC 6241, the lock operation is used to lock the configuration database (configuration file) to prevent multiple sources (such as CLI, SNMP, and multiple concurrent NETCONF sessions) from modifying the device configuration file concurrently and introducing other irrelevant configuration revisions. For this operation, the device can only prevent concurrent revision (running configuration) of multiple NETCONF sessions to ensure security of configuration data revision.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc message-id="xxx " xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <lock>
   <target>
     <running/>
   </target>
 </lock>
</rpc>
```

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx "  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

1.3.9 Unlocking the Configuration

The unlock operation is used to unlock the configuration database (configuration file, running configuration here), which is opposite to the lock operation.

The format of packets sent from the client is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
```

```
<rpc message-id="xxx "  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
 <unlock>
   <target>
     <running/>
   </target>
 </unlock>
</rpc>
```

The format of packets returned by the server is as follows.

```
<?xml version="1.0" encoding="utf-8"?>
<rpc-reply message-id="xxx "  xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <ok/>
</rpc-reply>
```

1.4 Configuration

Before NETCONF is used, the SSH channel authentication-related parameters need to be configured. For details about SSH configuration, see Configuring SSH.

Configuration	Description and Command	
Configuring NETCONF Call Home	⚠ (Optional) It is used to enable the NETCONF server to send a session establishment request to the NETCONF client.	
	netconf callhome { *hostname* | *ip-address* | **ipv6** *ipv6-address* } [**port** *port*]	Configures call home.
	netconf ch-reconnect interval *seconds*	Configures the call home reconnection interval.
	netconf source [**interface**] *interface-type interface-number*	Configures the source interface of call home.
	netconf source { **ip** *ip-address* | **ipv6** *ipv6-address* }	Configures the source IP address of call home.
Configuring the Candidate Capability of NETCONF	⚠ (Optional) It is used to configure the NETCONF server to report the candidate capability to the NETCONF client during capability set exchange.	
	netconf capability candidate	Enables the candidate and confirmed-commit capabilities of NETCONF.
Configuring the Rollback Capability of NETCONF	⚠ (Optional) It is used to configure the NETCONF server to report the rollback-on-error capability to the NETCONF client during capability set exchange.	
	netconf capability rollback	Enables the rollback-on-error capability of NETCONF.

Configuration	Description and Command	
Configuring the Validate Capability of NETCONF	(Optional) It is used to configure the NETCONF server to report the validate capability to the NETCONF client during capability set exchange.	
	netconf capability validate	Enables the validate capability of NETCONF.
Enabling the NETCONF Framework	(Optional) It is used to enable the NETCONF service on the device.	
	netconf enable	Enables the NETCONF framework service.
Disabling the Feature Attribute of NETCONF	(Optional) It is used to configure the NETCONF server not to report the feature attribute to the NETCONF client during capability set exchange.	
	netconf feature-disable	Disables the feature attribute of NETCONF.
Configuring the Maximum Number of Nodes Returned During NETCONF Session Query	(Optional) It is used to configure the maximum number of nodes returned during NETCONF session query.	
	netconf filter nodes-limit	Configures the maximum number of nodes returned during NETCONF session query.
Configuring the Maximum Number of NETCONF Session Connections	(Optional) It is used to configure the maximum number of NETCONF session connections with the NETCONF server.	
	netconf max-sessions	Configures the maximum number of NETCONF session connections.
Configuring the Port Monitored by the NETCONF Server	(Optional) It is used to configure the NETCONF server to monitor the port connected by the NETCONF client.	
	netconf port	Configures the port monitored by the NETCONF server.
Configuring the NETCONF Server to Advertise All Versions of All Supported YANG Modules to the NETCONF Client	(Optional) It is used by the NETCONF server to advertise all versions of all supported YANG modules to the NETCONF client during capability set exchange.	
	netconf yang multi-revision	Configures the NETCONF server to advertise all versions of all supported YANG modules to the NETCONF client.
Configuring the NETCONF Server to Preferentially Support the OpenConfig YANG Model	(Optional) It is used to configure the NETCONF server to preferentially support the OpenConfig YANG model.	
	netconf yang suite openconfig	Configures the NETCONF server to preferentially support the OpenConfig YANG model.

1.4.1 Configuring NETCONF Call Home

Configuration Effect

The NETCONF server proactively sends a session establishment request to the NETCONF client.

Notes

N/A

Configuration Step

Configuring NETCONF Call Home

Command	**netconf callhome** { *hostname* |*ip-address*	**ipv6** *ipv6-address* } [**port** *port*]
Parameter Description	*ip-address*: Specifies the remote IPv4 address of call home. *hostname*: Specifies the remote domain name of call home. **ipv6** *ipv6-address*: Specifies the remote IPv6 address of call home. **port** *port*: Specifies the remote port of call home. The default value is 4334.
Defaults	NETCONF call home is not configured by default.
Command Mode	Global configuration mode
Usage Guide	1. The call home configuration is affected by the **netconf enable** command. When the NETCONF service is unavailable, the call home configuration does not take effect. 2. Only one call home can be configured. If a call home already exists, run the **no netconf callhome** command to delete the existing configuration.

Configuring the NETCONF Call Home Reconnection Interval

Command	**netconf ch-reconnect interval** *seconds*
Parameter Description	*Seconds*: Specifies the call home reconnection interval, in seconds. The value range is from 5 to 3600.
Defaults	The default NETCONF call home reconnection interval is 5s.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Source Interface of NETCONF Call Home

- Optional. The source IP address of NETCONF call home is the IP address of the interface that sends packets by default.
- Run the **netconf source interface** *interface-type interface-number* command to configure the source interface. If the source interface is not configured on the device or no IP address is configured for the source interface, the source IP address of call home is still the IP address of the interface that sends packets.

Command	**netconf source interface** *interface-type interface-number*
Parameter Description	*interface-type*: Specifies the type of the interface. *interface-number*: Specifies the number of the interface.
Command	Global configuration mode

Mode	
Usage Guide	By default, the source IP address for initiating call home is the IP address of the interface that sends the packets. To facilitate tracing and management, you can use this command to specify an interface's IP address as the source IP address of call home. If the source interface is not configured on the device or no IP address is configured for the source interface, the source IP address of call home is still the IP address of the interface that sends the packets.

Configuring the Source IP Address of NETCONF Call Home

- Optional. The source IP address of NETCONF call home is the IP address of the interface that initiates call home by default.
- Unless otherwise specified, configure the source IP address of NETCONF call home on the device.
- Run the **netconf source** { **ip** *ip-address* | **ipv6** *ipv6-address* } command to configure the source IP address of call home. If the IP address is not configured on the device, the source IP address of NETCONF call home is still the IP address of the interface that initiates call home.

Command	**netconf source** { **ip** *ip-address*	**ipv6** *ipv6-address* }
Parameter Description	**ip** *ip-address*: Specifies the source IPv4 address that initiates call home to the remote PC with an IPv4 address. **ipv6** *ipv6-address*: Specifies the source IPv6 address that initiates call home to the remote PC with an IPv6 address.
Command Mode	Global configuration mode
Usage Guide	By default, the source IP address of call home is the IP address of the interface that initiates call home. To facilitate tracing and management, you can use this command to specify an interface's IP address as the source IP address of call home. If the source interface is not configured on the device, the source IP address of call home is still the IP address of the interface that sends the packets.

	`Hostname(config)# netconf feature-disable`
	`Hostname(config)#`

Verification	N/A

Common Errors

N/A

1.4.7 Configuring the Maximum Number of Nodes Returned During NETCONF Session Query

Configuration Effect

When a user queries NETCONF sessions on the NETCONF client, only the number of XML nodes that does not exceed the upper limit can be returned. If the number of XML nodes returned exceeds the upper limit, an error is returned.

Notes

This configuration only affects query results with **target** set to **running**.

Configuration Step

↘ **Configuring the Maximum Number of Nodes Returned During NETCONF Session Query**

Command	**netconf filter nodes-limit** *num*
Parameter Description	*num*: Specifies the maximum number of nodes returned. The default value is 100000, and the value range is from 100 to 2147483647.
Defaults	The maximum number of nodes returned is 100000 by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

1.4.10 Configuring the NETCONF Server to Advertise All Versions of All Supported YANG Modules to the NETCONF Client

Configuration Effect

The NETCONF server advertises all versions of all supported YANG modules to the NETCONF client during capability set exchange with the NETCONF client (Hello packet and capabilities packet).

Notes

- The **netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised.
- The **no netconf yang multi-revision** command must be configured before the capability packet (Hello packet) of the NETCONF server is advertised and only the latest version of a YANG module is advertised in the capability notification packet.

Configuration Step

↘ Configuring the NETCONF Server to Advertise All Versions of All Supported YANG Modules to the NETCONF Client

- Optional.
- This configuration must be configured before the capability packet (Hello packet) of the NETCONF server is advertised.

Command	**netconf yang multi-revision**
Parameter Description	**N/A**
Defaults	The NETCONF server advertises all versions of all supported YANG modules to the NETCONF client by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

N/A

Configuration Example

↘ Configuring the NETCONF Server to Advertise All Versions of All Supported YANG Modules to the NETCONF Client

Scenario **Figure 1-13**

1.4.11 Configuring the NETCONF Server to Preferentially Support the OpenConfig YANG Model

Configuration Effect

When the NETCONF server starts, the device loads the OpenConfig YANG model.

Notes

- The **netconf yang suite openconfig** command takes effect after the device is restarted. If the command is configured, the OpenConfig YANG model is supported. Otherwise, the custom YANG model is supported.
- The **no netconf yang suite openconfig** command takes effect after the device is restarted. After the configuration takes effect, the OpenConfig YANG model is not supported.
- The **netconf yang suite openconfig** command takes effect after the device is restarted. The configuration after the CLI command is run is displayed in the **show running-config** command output.

Configuration Step

↘ **Configuring the NETCONF Server to Preferentially Support the OpenConfig YANG Model**

- Optional.
- The configuration takes effect after the device is restarted.

Command	netconf yang suite openconfig
Parameter Description	N/A
Defaults	The OpenConfig YANG model is not supported by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show netconf yang-suite** command to display the effective YANG model configuration and configured YANG model of NETCONF (restart the device if the configuration does not take effect).

Configuration Example

Configuring the NETCONF Server to Preferentially Support the OpenConfig YANG Model

Scenario **Figure 1-14**	NETCONF server NETCONF client 
Configuration Steps	● Configure the NETCONF server to advertise all versions of all supported YANG modules to the NETCONF client.

NETCONF	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#netconf yang suite openconfig`
	`This command will take effect after device restart.`
	`Hostname(config)#`

Verification	N/A

Common Errors

N/A

1.5 Monitoring

Displaying

Command	Description
show netconf yang-suite	Displays the current YANG model of NETCONF.

1 Configuring CWMP

1.1 Overview

The CPE WAN Management Protocol (CWMP) provides a general framework of unified device management, message specifications, management methods, and data models, realizing unified management and maintenance of widely distributed customer-premises equipment (CPEs), improving troubleshooting efficiency, and saving O&M costs.

CWMP provides the following functions:

- Auto configuration and dynamic service provisioning: CWMP allows an Auto-Configuration Server (ACS) to automatically provision CPEs who initially access the network after start. The ACS can also dynamically reconfigure running CPEs.
- Firmware management: CWMP manages and upgrades the firmware and its files of CPEs.
- Software module management: CWMP manages modular software according to data models implemented.
- Status and performance monitoring: CWMP enables CPEs to notify the ACE of its status and changes, achieving real-time status and performance monitoring.
- Fault diagnosis: The ACE diagnoses or resolves connectivity or service problems based on information from CPEs, and can also perform pre-defined diagnosis tests.

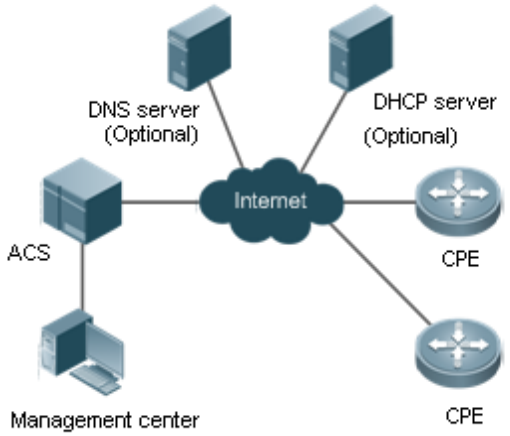
Protocols and Standards

Major CWMP protocol specifications are outlined as follows:

- TR-069_Amendment-4.pdf: CWMP standard
- TR-098_Amendment-2.pdf: Standard for Internet gateway device data model
- TR-106_Amendment-6.pdf: Standard for CPE data model
- TR-181_Issue-2_Amendment-5.pdf: Standard for CPE data model 2
- tr-098-1-4-full.xml: Definition of Internet gateway device data model
- tr-181-2-4-full.xml: Definition 2 of CPE data model 2

For details about TR069 protocol specifications, visit http://www.broadband-forum.org/technical/trlist.php.

1.2 Applications



Typical Application	Scenario
CWMP Application Scenario	Initiate a CPE-ACS connection, so as to upgrade the CPE firmware, upload configuration files, restore the configuration, and realize other features.

1.2.1 CWMP Application Scenario

Application Scenario

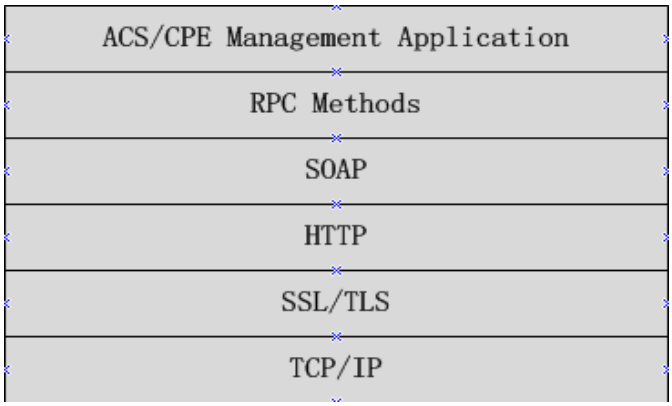
A CWMP network architecture involves CPEs, an ACS, a management center, a Dynamic Host Configuration Protocol (DHCP) server, and a Domain Name System (DNS) server. The management center manages CPEs by controlling the ACS on a web browser.

Figure 1-1

Note	
	• If the Uniform Resource Locator (URL) of the ACS is configured on CPEs, the DHCP server is optional. If not, DHCP is required to dynamically discover the URL of the ACS. • If the URLs of the ACS and CPEs contain IP addresses only, the DNS server is optional. If their URLs contain domain names, the DNS server is required to resolve the names.

Deployment

HTTP runs on both CPEs and the ACS.



1.3 Features

Basic Concepts

↘ Protocol Stack

Figure 1-2 shows the protocol stack of CWMP.

Figure 1-2 CWMP Protocol Stack

As shown in Figure 1-2, CWMP defines six layers with respective functions.

- ACS/CPE Management Application

The application layer is not a part of CWMP itself. It involves the development undertaken by various modules of the CPEs/ACS to support CWMP, similar to the Simple Network Management Protocol (SNMP), which does not cover MIB management of functional modules.

- RPC Methods

This layer provides various Remote Procedure Call (RPC) methods for interaction between the ACS and CPEs.

- SOAP

The Simple Object Access Protocol (SOAP) layer uses a XML-based syntax to encode and decode CWMP messages, so CWMP messages must comply with the XML-based syntax.

- HTTP

All CWMP messages are transmitted over the Hypertext Transfer Protocol (HTTP). Both the ACS and CPEs can behave as HTTP clients and servers. The server function is used to monitor reverse connections from the peer.

- SSL or TLS

The Secure Sockets Layer (SSL) or Transport Layer Security (TLS) layer guarantees CWMP security, including data integrity, confidentiality, and authentication.

- TCP/IP

The Transmission Control Protocol/Internet Protocol (TCP/IP) protocol stack is used.

RPC Methods

The ACS manages and monitors CPEs by calling the following main RPC methods:

- Get RPC Methods

The Get methods enable the ACS to remotely obtain the set of RPC methods, as well as names, values, and attributes of the data model (DM) parameters supported on CPEs.

- Set RPC Methods

The Set methods enable the ACS to remotely set values and attributes of DM parameters supported on CPEs.

- Inform RPC Methods

The Inform methods enable CPEs to inform the ACS of their device identifiers, parameters, and events whenever sessions are established between them.

- Download RPC Methods

The Download method enables the ACS to remotely control file download of CPEs, including firmware management, upgrade, and web package upgrade.

- Upload RPC Methods

The Upload method enables the ACS to remotely control file upload of CPEs, including upload of firmware and logs.

- Reboot RPC Methods

The Reboot method enables the ACS to remotely reboot CPEs.

Session Management

CWMP works based on CWMP sessions or interactions. All CWMP interactions between the ACS and CPEs rely on these session exchanges. The ACS exchanges with CPEs to manages and monitors CPEs through session transmission, management, and maintenance. A typical session between ACS and CPE involves establishing a TCP connection, which starts from the Inform negotiation to TCP disconnection. Sessions are categorized into two types based on the initiator: those initiated by the CPE and those requested by the ACS.

↘ DM Management

CWMP operates based on the CWMP DM. CWMP manages all functional modules by a set of operations performed on DM. Each functional module registers and implements a respective data model, similar to MIBs implemented by various functional modules of SNMP.

A CWMP data model is represented in the form of a character string. For a clear hierarchy of the data model, a dot (.) is used as a delimiter to distinguish an upper-level data model node from a lower-level data model node. For instance, in the data model **InternetGatewayDevice.LANDevice**, **InternetGatewayDevice** is the parent data model node of **LANDevice**, and **LANDevice** is the child data model node of **InternetGatewayDevice**.

DM nodes are classified into two types: object and parameter nodes. The parameter nodes are also known as leaf nodes. An object node is a node under which there are child nodes, and a parameter node is a leaf node under which there is no any child node. Object nodes are further classified into single-instance and multi-instance object nodes. A single-instance object node indicates that there is only one instance for this object node, whereas a multi-instance object node indicates that there are multiple instances for this object node.

DM nodes can be also classified into read and read-and-write nodes. A read node is a node whose parameter values can be read but cannot be modified, and a read-and-write node is a node whose parameter values can be both read and modified.

A data model node has two attributes. One attribute relates to a notification function, that is, whether to inform the ACS of changes (not changes caused by CWMP) to parameter values of the data model. The other attribute is an identifier indicating that the parameters of the data model node can be written using other management modes (not the ACS), that is, whether the values of the parameters can be modified using other management modes such as Telnet. The ACS can modify attributes of the data models using RPC methods.

CWMP manages data models using corresponding RPC methods.

↘ Event Management

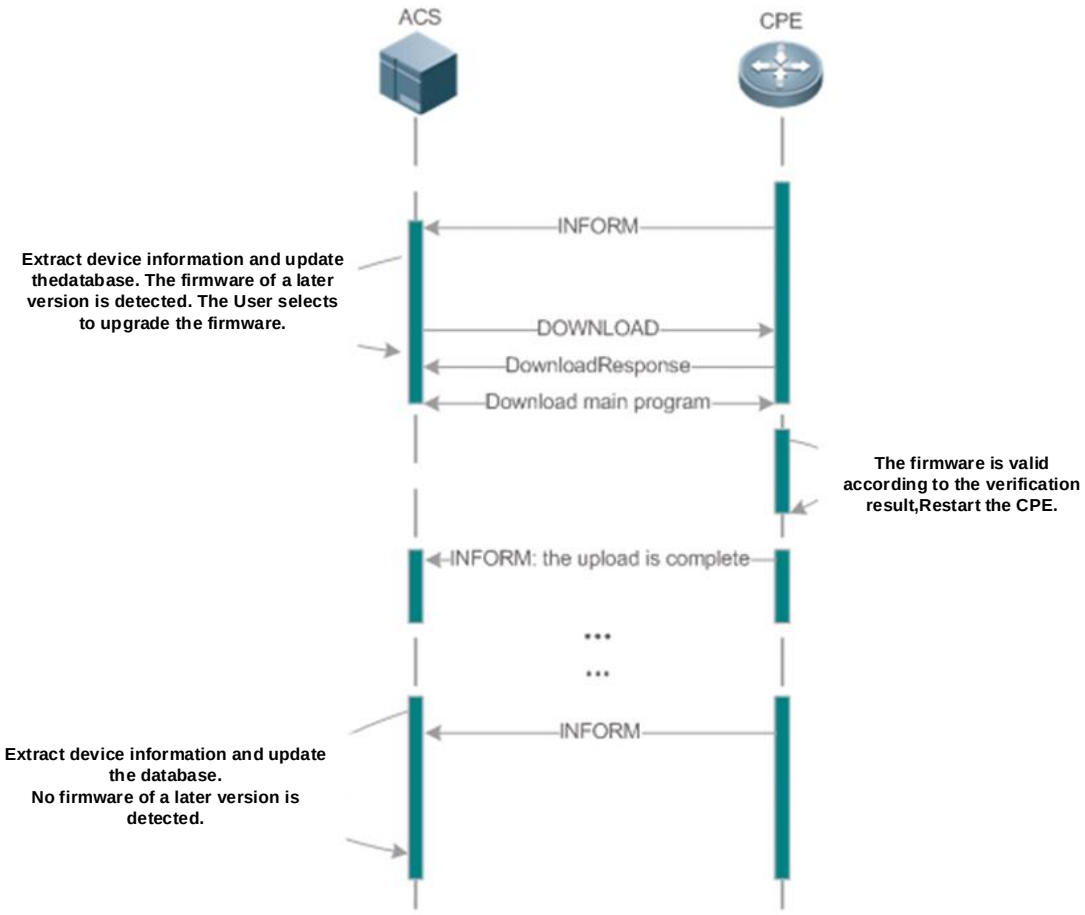
When some events concerned by the ACS occur on the CPE, the CPE will inform the ACS of these events. The ACS monitors these events to monitor the working status of the CPE. The CWMP events are similar to trap messages of SNMP or device logs. Using RPC methods, the ACS filters out unconcerned types of events. CWMP events are classified into two types: single (non-cumulative) events and cumulative events. A single event means that there is no quantitative change to the same event upon re-occurrence of the event, with old events discarded and the newest event kept. A cumulative event means that old events are not discarded and the newest event is kept as a complete event when an event re-occurs for multiple times later; that is, the number of this event is incremented by 1.

All events that occur on the CPE are notified to the ACS using the Inform method.

Features

Feature	Description
Upgrading the Firmware	The ACS controls the upgrade of the firmware of a CPE using the Download method.

Upgrading Configuration Files	The ACS controls the upgrade of the configuration files of a CPE using the Download method.
Uploading Configuration Files	The ACS controls the upload of the configuration files of a CPE using the Upload method.
Backing Up and Restoring a CPE	When a CPE fails to be managed by the management center, this feature can be used to remotely restore the CPE to the previous status.



1.3.1 Upgrading the Firmware

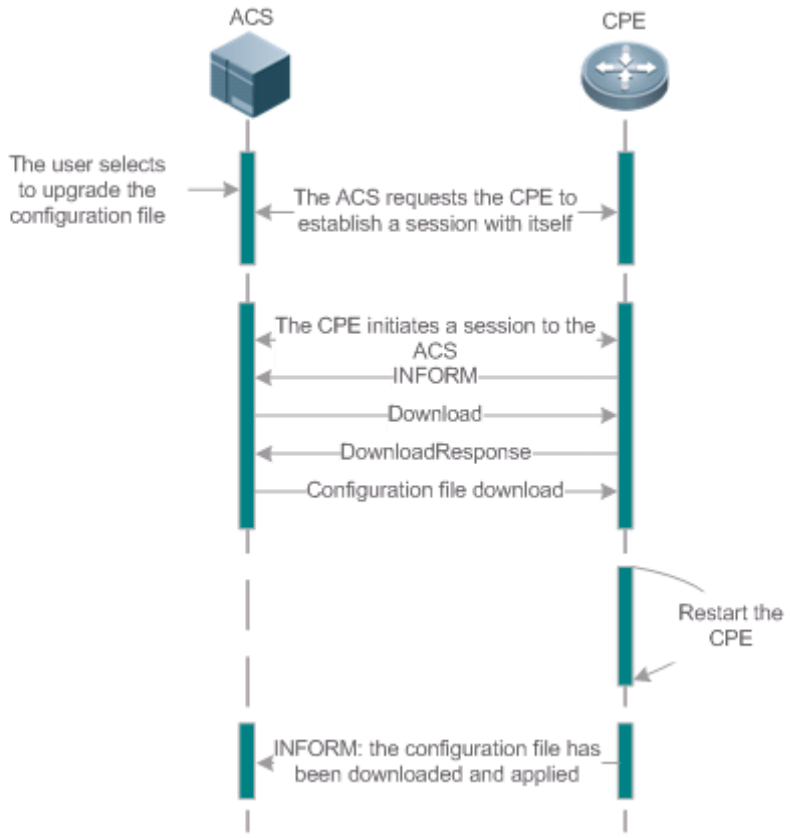
The firmware of a network element (NE) can be upgraded, so as to implement device version upgrade or replacement.

Working Principle

Sequence Diagram of Upgrading the Firmware

Figure 1-3

You can specify a CPE for the ACS to deliver the Download method for upgrading the firmware. The CPE receives the request and starts to download the latest firmware from the destination file server, upgrade the firmware, and then reboot. Then the CPE will notify the ACS of upgraded completed.



The file server can be the ACS or separately deployed.

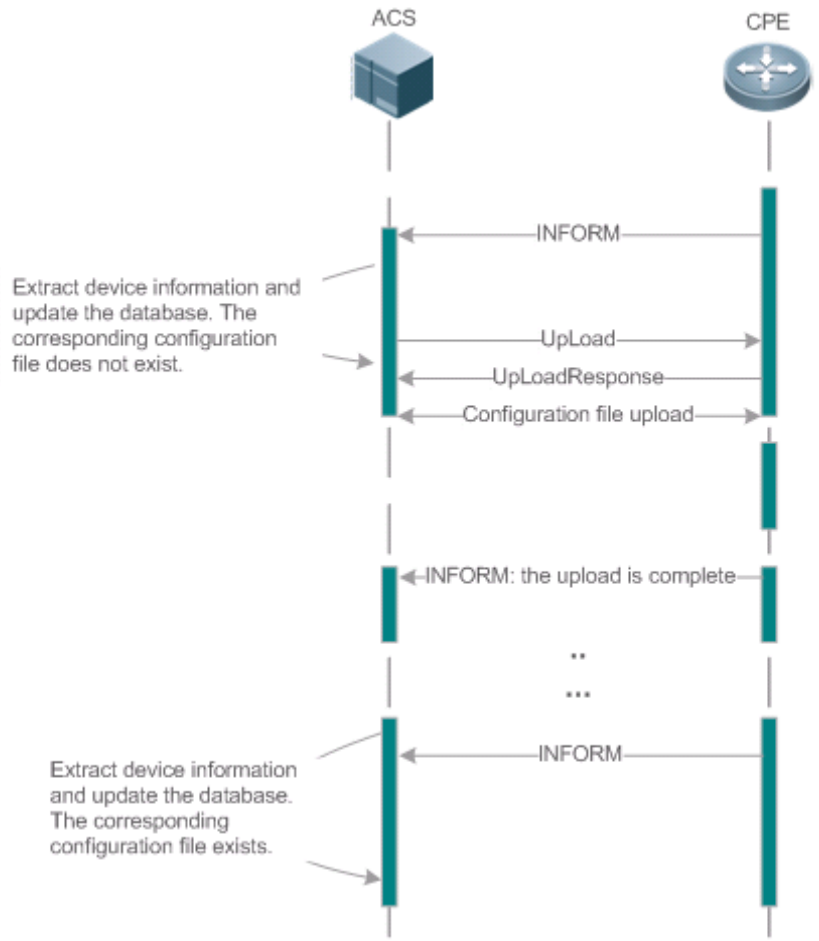
1.3.2 Upgrading Configuration Files

Configuration files of a CPE can be replaced with specified configuration files, so that the new configuration files are used on the CPE after reset.

Working Principle

Figure 1-4

You can specify a CPE for the ACS to deliver the Download method for upgrading its configuration files. The CPE downloads the configuration files from the specified file server, upgrade configuration files, and then reboot. Then the CPE will notify the ACS of upgraded completed.



The file server can be the ACS or separately deployed.

1.3.3 Uploading Configuration Files

The ACS controls configuration files of CPEs by using the Upload method.

Working Principle

Figure 1-5

When a CPE initially connects to the ACS, the ACS attempts to learn the configuration files of the CPE in the following sequence:

- When the ACS initially receives an Inform message from the CPE, it locates corresponding database information according to device information carried in the message.
- If the database does not contain the configuration files of the CPE, the ACS delivers the Upload method to the CPE for uploading the configuration files.
- The CPE uploads its current configuration files to the ACS.
- The CPE notifies the ACS that the configuration files are uploaded.

1.3.4 Configuring Pre-registration

The unconfigured CPE automatically connects to the Ruijie Cloud server and automatically goes online based on the CWMP configuration delivered by Ruijie Cloud.

1.3.5 Backing Up and Restoring a CPE

When a remote CPE fails to be managed by the management center due to exceptions, the CPE backup and restoration feature helps restore the CPE to the previous status, so that the management center can remotely manage the CPE and take corresponding actions.

Working Principle

You can configure the restoration function on a CPE, so that the CPE can restore itself upon exceptions of its firmware or configuration files. When the CPE fails to connect to the ACS and fails to be managed by the management center after its firmware or configuration files are upgraded, the previous firmware or configuration files of the CPE can be restored in a timely manner for the ACS to manage the CPE. Such an exception occurs due to delivery of an incorrect version or configuration file.

Before the CPE receives a new firmware or configuration files for the upgrade, the CPE will back up its current version and configuration files. In addition, there is a mechanism for determining whether the problem described in the preceding scenario has occurred. If the problem has occurred, the CPE is restored to the previous manageable status.

1.4 Configuration

Configuration	Description and Command	
Establishing a Basic CWMP Connection	⚠ (Mandatory) It is used to configure the ACS or CPE username and password to be authenticated for a CWMP connection.	
	cwmp	Enables CWMP and enters the CWMP configuration mode.
	acs username	Configures the ACS username for establishing a CWMP connection.
	acs password	Configures the ACS password for establishing a CWMP connection.
	cpe username	Configures the CPE username for establishing a CWMP connection.
	cpe password	Configures the CPE password for establishing a CWMP connection.
	⚠ (Optional) It is used to configure URLs of the CPE and ACS.	
	acs url	Configures the URL of the ACS.
	cpe url	Configures the URL of the CPE.
Configuring CWMP-Related Attributes	⚠ (Optional) It is used to configure basic functions of the CPE, such as upload, backup, and restoration of the firmware, configuration files, or logs.	
	cpe inform	Configures the periodic notification function of the CPE.
	disable download	Disables the device from sending or downloading the firmware and configuration files from the ACS.
	disable upload	Disables the device from uploading configuration and log files to the ACS.
	cpe back-up	Configures the backup and restoration of the firmware and configuration file of the CPE.
	stun max-period	Configures the maximum STUN keepalive interval.

Configuration	Description and Command	
	stun min-period	Configures the minimum STUN keepalive interval.
	stun port	Configures the STUN server port.
	timer cpe- timeout	Configures the ACS response timeout on CPEs.
	register device	Enables pre-registration.

1.4.1 Establishing a Basic CWMP Connection

Configuration Effect

- A connection is established between the ACS and the CPE.

Notes

- N/A

Configuration Step

Enabling CWMP

- Mandatory.
- The CWMP function is enabled by default.
- Perform this configuration on the CPE.

Command	**cwmp**
Parameter Description	N/A
Command Mode	Global configuration guide
Usage Guide	N/A

Configuring the ACS Username for Establishing a CWMP Connection

- Mandatory.
- Perform this configuration on the ACS.
- Only one username can be configured for the ACS. If multiple usernames are configured, the latest username is used.

Command	**acs username** *username*
Parameter Description	**username** *username*: Indicates the ACS username for establishing a CWMP connection.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the ACS Password for Establishing a CWMP Connection

- Mandatory.
- Perform this configuration on the ACS.

- The password of the ACS can be in cleartext or ciphertext mode. Only one password can be configured for the ACS. If multiple passwords are configured, the latest password is used.

Command	**acs password** {*password* | *encryption-type encrypted-password*}
Parameter Description	*password*: Indicates the ACS password. *encryption-type*: Indicates the encryption mode. The value 0 indicates non-encryption and the value 7 indicates simple encryption. *encrypted-password:* Indicates the password text.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the CPE Username for Establishing a CWMP Connection

- Mandatory.
- Perform this configuration on the CPE.
- Only one username can be configured for the CPE. If multiple usernames are configured, the latest username is used.

Command	**cpe username** *username*
Parameter Description	*username*: Indicates the CPE username.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the CPE Password for Establishing a CWMP Connection

- Mandatory.
- Perform this configuration on the CPE.
- The password of the CPE can be in cleartext or ciphertext mode. Only one password can be configured for the CPE. If multiple passwords are configured, the latest password is used.

Command	**cpe password** {*password* | *encryption-type encrypted-password*}
Parameter Description	*password*: Indicates the CPE password. *encryption-type*: Indicates the encryption mode. The value 0 indicates non-encryption and the value 7 indicates simple encryption. *encrypted-password:* Indicates the password text.
Command Mode	CWMP configuration mode
Usage Guide	Use this command to configure the CPE user password to be authenticated for the ACS to connect to the CPE. Typically, the encryption mode does not need to be specified. The encryption mode needs to be specified only when the encrypted password of this command is copied or pasted. A valid password should meet the following requirements: - It must contain 1 to 26 characters including letters and numerals. - The leading spaces will be ignored, while the trailing and middle spaces are valid.

Configuring the URL of the ACS for Establishing a CMWP Connection

- Optional.
- Perform this configuration on the CPE.
- Only one URL of the ACS can be configured. If multiple URLs are configured, the latest URL is used. The URL must be in HTTP format.

Command	**acs url** *url*
Parameter Description	*url*: Indicates the URL of the ACS.
Command Mode	CWMP configuration mode
Usage Guide	If the URL of the ACS is not configured but obtained through DHCP, CPEs will use this dynamic URL to initiate a connection to the ACS. The ACS URL must be in the format of http://ip [: port]/path and contains up to 255 characters.

Configuring the URL of the CPE for Establishing a CMWP Connection

- Optional.
- Perform this configuration on the CPE.
- Only one URL of the CPE can be configured. If multiple URLs are configured, the latest URL is used. The CPE URL must be in HTTP format but not the domain name format.

Command	**cpe url** *url*
Parameter Description	*url:* Indicates the URL of the CPE.
Command Mode	CWMP configuration mode
Usage Guide	If the URL of the CPE is not configured, it is obtained through DHCP. The the URL of the CPE must be in the format of http://ip [: port]/path and contains up to 255 characters.

Verification

- Run the **show cwmp configuration** command.

Command	**show cwmp configuration**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Examples	The following example displays the CWMP configuration.
	`Hostname(config-cwmp)# show cwmp configuration`
	`CWMP Status : enable`
	`ACS URL : http://www.ruijie.com.cn/acs`
	`ACS username : admin`
	`ACS password : ******`

```
CPE URL                          : http://10.10.10.2:7547/
CPE username                     : ruijie
CPE password                     : ******
CPE inform status                : disable
CPE inform interval              : 60s
CPE inform start time            : 0:0:0 0 0 0
CPE wait timeout                 : 50s
CPE download status              : enable
CPE upload status                : enable
CPE back up status               : enable
CPE back up delay time           : 60s
```

Configuration Examples

The following configuration examples describe CWMP-related configuration only.

Configuring Usernames and Passwords on the CPE

Network Environment Figure 1-6	
Configuration Method	● Enable CWMP. ● On the CPE, configure the ACS username and password to be authenticated for the CPE to connect to the ACS. ● On the CPE, configure the CPE username and password to be authenticated for the ACS to connect to the CPE.

CPE	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# cwmp`
	`Hostname(config-cwmp)# acs username USERB`
	`Hostname(config-cwmp)# acs password PASSWORDB`
	`Hostname(config-cwmp)# cpe username USERB`
	`Hostname(config-cwmp)# cpe password PASSWORDB`

Verification	● Run the **show** command on the CPE to check whether commands have been successfully executed.

CPE	`Hostname# show cwmp configuration`
	`CWMP Status                    : enable`
	`ACS URL                         : http://10.10.10.1:7547/acs`
	`ACS username                    : USERA`
	`ACS password                    : ******`
	`CPE URL                         : http://10.10.10.2:7547/`
	`CPE username                    : USERB`
	`CPE password                    : ******`

Configuring the URLs of the ACS and the CPE

Network Environment	See Figure 1-6.
Configuration Method	● Configure the URL of the ACS. ● Configure the URL of the CPE.

CPE	`Hostname# configure terminal`
	`Hostname(config)# cwmp`
	`Hostname(config-cwmp)# acs url http://10.10.10.1:7547/acs`
	`Hostname(config-cwmp)# cpe url http://10.10.10.1:7547/`

Verification	● Run the **show** command on the CPE to check whether commands have been successfully executed.

CPE	`Hostname# show cwmp configuration`
	`CWMP Status : enable`
	`ACS URL : http://10.10.10.1:7547/acs`
	`ACS username : USERA`
	`ACS password : ******`
	`CPE URL : http://10.10.10.1:7547/`

Common Errors

- The input encrypted password is shorter than two characters or longer than 254 characters, or the length of the password is not an even number.
- The input cleartext password is longer than 126 characters.
- The input cleartext password contains invalid characters.
- The URL of the ACS is set to **NULL**.
- The URL of the CPE is set to **NULL**.

1.4.2 Configuring CWMP-Related Attributes

Configuration Effect

- You can configure common functions of the CPE, such as the backup and restoration of its firmware or configuration file, whether to enable the CPE to download firmware and configuration files from the ACS, and whether to enable the CPE to upload its configuration and log files to the ACS.

Configuration Step

↘ Configuring the Periodic Notification Function of the CPE

- Optional.
- The value range is from 30 to 3600, in seconds. The default value is 600s.
- Perform this configuration to reset the periodical notification interval of the CPE.
- Perform this configuration on the CPE.

Command	**cpe inform** [**interval** *seconds*] [**starttime** *time*]
Parameter Description	*seconds*: Specifies the periodical notification interval of the CPE. The value range is from 30 to 3600, in seconds.

	time: Specifies the date and time for starting periodical notification in *yyyy-mm-ddThh:mm:ss* format.
Command Mode	CWMP configuration mode
Defaults	The default value is 600 seconds.
Usage Guide	Use this command to configure the periodic notification function of the CPE. ● If the time for starting periodical notification is not specified, periodical notification starts after the periodical notification function is enabled. The notification is performed once within every notification interval. ● If the time for starting periodical notification is specified, periodical notification starts at the specified start time. For instance, if the periodical notification interval is set to 60s and the start time is 12:00 am next day, periodical notification will start at 12:00 am next day and once every 60s.

Disabling the Device from Downloading Firmware and Configuration Files from the ACS

- Optional.
- The CPE can download firmware and configuration files from the ACS by default.
- Perform this configuration if the CPE does not need to download firmware and configuration files from the ACS.
- Perform this configuration on the CPE.

Command	**disable download**
Parameter Description	N/A
Defaults	The CPE can download firmware and configuration files from the ACS by default.
Command Mode	CWMP configuration mode
Usage Guide	Use this command to disable the device from downloading the main program and configuration files from the ACS. ● This command is invalid for configuration script files. The configuration scripts can still be executed even if this function is disabled.

Disabling the Device from Uploading Configuration and Log Files to the ACS

- Optional.
- The CPE can upload configuration and log files to the ACS by default.
- Perform this configuration if the CPE does not need to upload configuration and log files to the ACS.
- Perform this configuration on the CPE.

Command	**disable upload**
Parameter Description	N/A
Defaults	The CPE can upload configuration and log files to the ACS by default.
Command Mode	CWMP configuration mode
Usage Guide	Use this command to disable the function of uploading configuration and log files to the ACS.

Configuring the Backup and Restoration of the Firmware and Configuration Files of the CPE

- Optional.
- The backup and restoration of the firmware and configuration files of the CPE is enabled by default. The value range is from 30 to 10000, in seconds. The default value is 60s.
- Perform this configuration to change the time for backup and restoration of the firmware and configuration files of the CPE.
- Perform this configuration on the CPE.

Command	**cpe back-up** [**delay-time** *seconds*]
Parameter Description	*seconds*: Specifies the delay for backup and restoration of the firmware and configuration file of the CPE.
Defaults	The default value is 60s.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the Maximum STUN Keepalive Interval

- Optional.
- Configure the maximum STUN keepalive interval in the range of 0s to 3600s. The default value is 60s.

Command	**stun max-period** *seconds*
Parameter Description	*seconds*: Configures the maximum STUN keepalive interval, in seconds.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the Minimum STUN Keepalive Interval

- Optional.
- Configure the minimum STUN keeaplive interval in the range of 0s to 3600s. The default value is 20s.

Command	**stun min-period** *interval*
Parameter Description	*seconds*: Configures the minimum STUN keepalive interval, in seconds.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the STUN Server Port

- Optional.
- The STUN server port range is from 0 to 65535.

Command	**stun port** *port-number*
Parameter	*port-number*: Configures the STUN server port.

Description	
Command Mode	CWMP configuration mode
Usage Guide	N/A

Configuring the ACS Response Timeout Interval

- Optional.
- The value range is from 10 to 600, in seconds. The default value is 30s.
- Perform this configuration to change the ACS response timeout interval on the CPE.
- Perform this configuration on the CPE.

Command	**timer cpe- timeout** *seconds*
Parameter Description	*seconds*: Specifies the timeout interval, in seconds. The value range is from 10 to 600.
Defaults	The default value is 30s.
Command Mode	CWMP configuration mode
Usage Guide	N/A

Enabling the Pre-registration Function

- The function is enabled by default.
- Run the **no register device** command to disable the pre-registration function in global configuration mode.

Command	**register device**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command takes effect only on devices where the pre-registration macro is enabled. In scenarios where Ruijie Cloud is not required or there are high requirements on information security, you can use this command to disable the pre-registration function.

Verification

- Run the **show cwmp configuration** command.

Command	**show cwmp configuration**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Examples	The following example displays the CWMP configuration.
	`Hostname(config-cwmp)#show cwmp configuration`
	`CWMP Status : enable`
	`ACS URL : http://www.ruijie.com.cn/acs`

	ACS username : admin ACS password : ****** CPE URL : http://10.10.10.2:7547/ CPE username : ruijie CPE password : ****** CPE inform status : disable CPE inform interval : 60s CPE inform start time : 0:0:0 0 0 0 CPE wait timeout : 50s CPE download status : enable CPE upload status : enable CPE back up status : enable CPE back up delay time : 60s

Configuration Examples

Configuring the Periodical Notification Interval of the CPE

Scenario	See Figure 1-6.
Configuration Steps	● Enable the CWMP function and enter the CWMP configuration mode. ● Set the periodical notification interval of the CPE to 60s.
CPE	Hostname# config Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# cwmp Hostname(config-cwmp)# cpe inform interval 60
Verification	● Run the **show** command on the CPE to check whether commands have been successfully configured.
CPE	Hostname# show cwmp configuration CWMP Status : enable …… CPE inform interval : 60s

Disabling the Device from Sending or Downloading Firmware and Configuration Files from the ACS

Scenario	See Figure 1-6.
Steps	● Enable the CWMP function and enter the CWMP configuration mode. ● Disable the device from sending or downloading the firmware and configuration files from the ACS.
CPE	Hostname# config Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# cwmp Hostname(config-cwmp)# disable download
Verification	● Run the **show** command on the CPE to check whether commands have been successfully configured.
CPE	Hostname#show cwmp configuration CWMP Status : enable

	…… CPE download status : disable

Disabling the Device from Uploading Configuration and Log Files to the ACS

Scenario	See Figure 1-6.
Configuration Steps	● Enable the CWMP function and enter the CWMP configuration mode. ● Disable the device from uploading configuration and log files to the ACS.
CPE	Hostname# config Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# cwmp Hostname(config-cwmp)# disable upload
Verification	● Run the **show** command on the CPE to check whether commands have been successfully configured.
CPE	Hostname# show cwmp configuration CWMP Status : enable …… CPE upload status : disable

Configuring the Delay for Backup and Restoration

Network Environment	See Figure 1-6.
Configuration Steps	● Enable the CWMP function and enter the CWMP configuration mode. ● Set the delay for backup and restoration to 100s.
CPE	Hostname# config Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# cwmp Hostname(config-cwmp)# cpe back-up Seconds 30
Verification	● Run the **show** command on the CPE to check whether commands have been successfully configured.
CPE	Hostname# show cwmp configuration CWMP Status : enable …… CPE back up delay time : 30s

Configuring the ACS Response Timeout of the CPE

Scenario	See Figure 1-6.
Configuration Steps	● Enable the CWMP function and enter the CWMP configuration mode. ● Set the response timeout of the CPE to 100s.
CPE	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# cwmp Hostname(config-cwmp)# timer cpe-timeout 100
Verification	● Run the **show** command on the CPE to check whether commands have been successfully configured.

CPE	Hostname# show cwmp configuration CWMP Status : enable …… CPE wait timeout : 100s

Common Errors

N/A

1.5 Monitoring

Displaying

Command	Function
show cwmp configuration	Displays the CWMP configuration.
show cwmp status	Displays the CWMP running status.

1 Configuring gRPC

1.1 Overview

Google Remote Procedure Calls (gRPC) is a Google-developed RPC protocol. It is widely used in server program design. When Local Procedure Call (LPC) is used, a code snippet needs to be executed on the local host for performing an operation. When RPC is used, the service user and provider can be located on different computers. The client notifies the server by sending a request to the server over the network. The server returns the result to the client after the request is executed.

gRPC uses the protocol buffer for data serialization and deserialization and uses HTTP 2 as the data transmission protocol, ensuring better performance.

Protocols and Standards

- https://github.com/grpc/grpc

1.2 Applications

Application	Description
One-to-One Topology	One device reports gRPC information to one server.
One-to-Multi Topology	One device reports gRPC information to multiple servers.

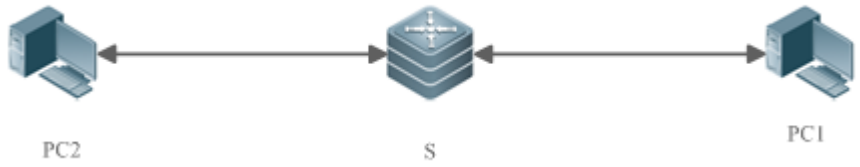
1.2.1 One-to-One Topology

Scenario

A tested device (device S) is connected to a server and reports gRPC data to the server, as shown in Figure 1-1.

Figure 1-1 One-to-One Topology

Deployment



- Ensure that the network between device S and PC1 is reachable.
- Enable the gRPC function on device S.
- Configure events that need to be reported to the server on device S.

1.2.2 One-to-Multi Topology

Scenario

A tested device (device S) is connected to multiple servers and reports gRPC data to servers simultaneously, as shown in Figure 1-2.

Figure 1-2 One-to-Multi Topology

Deployment

- Ensure that the network between device S and PC1 and between device S and PC2 is reachable.
- Configure different IP addresses for PC1 and PC2.
- Enable the gRPC function on device S.
- Configure events that need to be reported to the server on device S.

1.3 Features

Basic Concepts

gRPC

gRPC is a cross-platform open-source high-performance RPC framework that was initially created by Google. It is based on HTTP2 and Protobuf 3.x.

Channel

A channel is established between the device and a server.

Stub

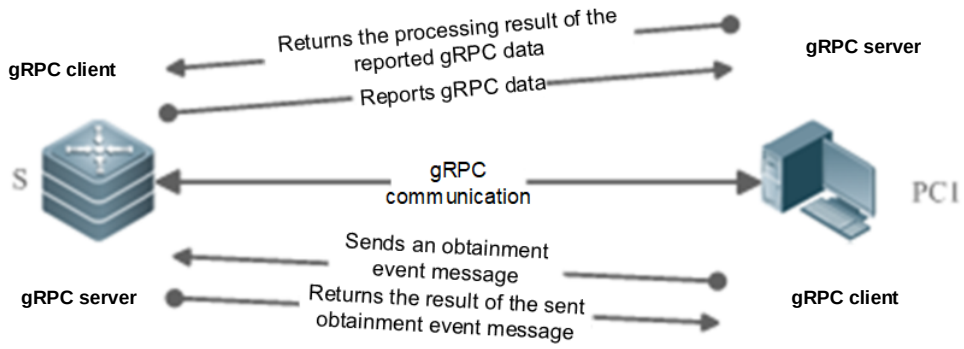
The stub is used to execute RPC.

For details about gRPC terms, see https://github.com/grpc/grpc.

Overview

Feature	Description
Enabling gRPC	Enables gRPC on the device. The device can serve as the gRPC server to receive authentication requests and obtain messages. It can also serve as the client to report gRPC data.
Supporting Login and Logout Operations	Supports login and logout operations initiated by a server.
Configuring Event Types Supported by gRPC	Configures event types supported by gRPC. Events include real-time, periodic, and obtainment events.
Specifying the Source Interface for Sending gRPC Data	Specifies the source interface for sending gRPC data.
Pre-configuring the Subscribing Server and Events to Be Subscribed to	Pre-configures the subscribing server and events to be subscribed to.

Feature	Description
Pre-configuring Server Login User Information	Pre-configures server login user information.
Configuring YANG Model Data Subscription (Defined in openconfig-telemetry.yang)	Configures YANG model data subscription.
Supporting RPC Methods Defined by a Third Party	Supports RPC methods defined by a third party.



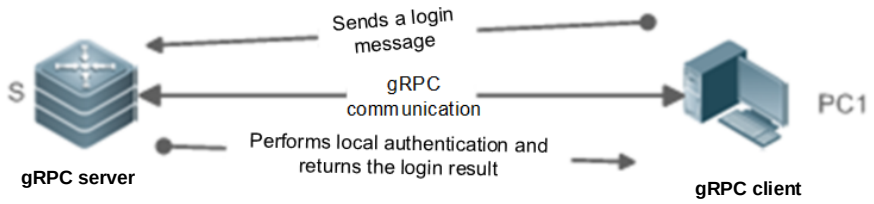
1.3.1 Enabling gRPC

Enable gRPC on the device. The device can serve as the gRPC server to receive authentication requests and obtain messages. It can also serve as the client to report gRPC data.

Working Principle

gRPC communication is implemented over the HTTP2 protocol. After a gRPC client initiates a request and a server returns a response, one data interaction is completed. Only the client can initiate a request, and then the server sends a response. Figure 1-3 shows the process.

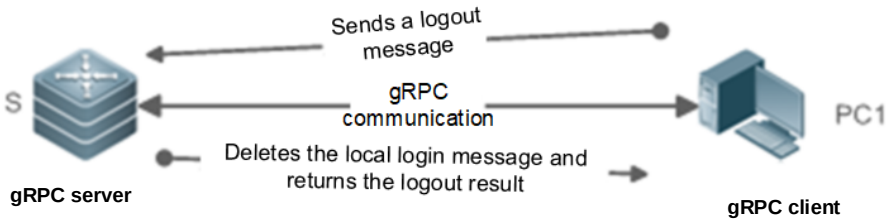
Figure 1-3 gRPC communication



- After gRPC is configured on device S, the gRPC client and server are enabled on device S.
- The gRPC server of device S receives an obtainment event message from the server and returns a response to the obtainment event to the server.
- The gRPC client of device S reports gRPC data to the gRPC server based on the events subscribed to and waits for a response.

1.3.2 Supporting Login and Logout Operations

gRPC supports login and logout operations initiated by a server.



Working Principle

Figure 1-4 gRPC Login

- gRPC is configured on device S, and the gRPC server service is enabled.
- After device S receives a login request from the server, it authenticates the server locally and returns a login result to the server.
- The gRPC server of device S only receives the obtainment events initiated by the server that has logged in.

Figure 1-5 Logout Flow

- gRPC is configured on device S, and the gRPC server is enabled.
- After device S receives a logout request from the server, it deletes local matched login information and returns a logout result to the server.
- The gRPC server of device S no longer receives the obtainment events initiated by the server that has logged out.

1.3.3 Configuring Event Types Supported by gRPC

gRPC supports real-time , periodic, and obtainment events.

Working Principle

Real-time event: Is triggered when a specified threshold is met, irrespective of time. When the threshold is met, the device collects information once and reports it to the server.

Periodic events: Is reported regularly. When the time is reached, the device collects information once and reports it to the server.

Obtainment events: Is initiated by the server to query data. After the device receives a query request, the device collects information and reports it to the server.

1.3.4 Specifying the Source Interface for Sending gRPC Data

Working Principle

After gRPC is configured on the device and a channel with the server is created, the device creates a socket and attempts to send some ping packets to check whether the path is reachable. If the path is reachable, the device sends gRPC packets. By default, the created socket is bound randomly to the source address of a device port to send ping packets. If the server receives only packets from the specified source address, the default behavior of the device with gRPC enabled does not make the path reachable. As a result, gRPC packets cannot be uploaded.

If the specified source address is bound when a socket is created, the reachable path can ensure that gRPC packets are correctly uploaded.

1.3.5 Pre-configuring the Subscribing Server and Events to Be Subscribed to

Working Principle

The device can use a configuration command, NETCONF, or other methods to pre-create a server to be subscribed to and an event of concern.

The device can use a configuration command, NETCONF, or other methods to configure a standby server. When the active server malfunctions, the device automatically sends data to the standby server.

The device can use a configuration command to delete a server and an event that have been subscribed to and simulate the controller to notify the server of server and event unsubscription through NETCONF.

1.3.6 Pre-configuring Server Login User Information

Working Principle

By running a configuration command, the device can pre-create login user information about the server that passes authentication, simulate the server to initiate a login request, pass authentication, and save user information.

By running a configuration command, the device can delete login user information about the server that passes authentication, simulate the server to initiate a logout request, and delete login user information.

1.3.7 Configuring YANG Model Data Subscription (Defined in openconfig-telemetry.yang)

Working Principle

The device can use a configuration command, NETCONF, or other methods to deliver the configuration defined in **openconfig-telemetry.yang** to collect YANG model data of the device.

The device can use a configuration command, NETCONF, or other methods to delete the configuration defined in **openconfig-telemetry.yang**.

1.3.8 Supporting RPC Methods Defined by a Third Party

Working Principle

The device can use configuration commands to enable relevant functions defined in **gnmi.proto**. It can also collect device data by using RPC methods defined in **gnmi.proto**, such as Get, Set, and Subscribe.

The device can use configuration commands to disable relevant functions defined in **gnmi.proto**.

1.4 Configuration

Configuration	Description and Command	
Enabling gRPC	(Mandatory) It is used to enable the gRPC function. The device supports data subscription and reporting only after the gRPC function is enabled.	
	grpc	Creates the gRPC mode and enables the gRPC function.
Configuring Authentication Modes and AAA Server Authentication Attributes for gRPC Login and Logout	(Optional) It is used to configure server login authentication as required.	
	authen login { **local | authentication** *mlist* }	Configures the authentication mode of server login.
	authen aaa-config { **retry** *times* **| timeout** *second* }	Configures the number of retries and timeout interval during AAA server authentication.
Configuring Event Types Supported by gRPC	(Mandatory) It is used to configure events subscribed to.	
	subscr realtime enable	Enables the device to focus on all subscribed-to real-time events.
	subscr sample enable	Enables the device to focus on all subscribed-to periodic events.
	subscr-sample-interval *interval* [**millisecond** *millisecond*]	Changes the timer value of periodic events, which can be set to milliseconds.
	subscr-realtime-interval {all *interval* **| realtime** *json-event interval***}**	Configures the suppression time of real-time events.
Specifying the Source Interface for Sending gRPC Data	**subscr-source-interface**	Configures the source interface for sending real-time data and periodic data.
Configuring the Response Timeout Interval for gRPC Data	**reply-timeout**	Configures the response timeout interval for Get/Set data.
Pre-configuring the Subscribing Server and Events to Be Subscribed to	**user-server** *ip-address port-id*	Pre-configures the subscribing server.
	standby-server *ip-address port-*	Pre-configures the standby server of the subscribing server.
	type *json-event* **value** *value* [**value-extend** *value-extend*]	Pre-configures the subscribed-to event of the specified server.
Pre-configuring the Server Login User Information	**user-client** *id user-name ip-address*	Pre-configures server login user information.
Configuring a gRPC YANG Model Path and Its Group	**sensor-group** *group-id*	Configures a YANG model path.
	sensor-path *path*	
Configuring the gRPC Destination Server	**destination-group** *group-id*	Configures the destination server address.
	ip *ip-address* **port** *port-id*	
	protocol grpc {**tls | no-tls**}	Configures the protocol used by the destination server.

Configuration	Description and Command	
Configuring a gRPC Subscription Association	**sensor-group** *group-id* **sample-interval** *interval*	Configures the subscription association relationship.
	destination-group *group-id*	
Supporting RPC Methods Defined by a Third Party	**rpc gnmi enable**	Configures RPC methods defined in **gnmi.proto**.

1.4.1 Enabling gRPC

Configuration Effect

- Enable the gRPC client and gRPC server.

Notes

- The device and server must be reachable to each other.
- The port number of the local gRPC server is 50051.

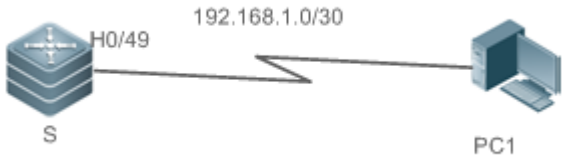
Configuration Step

Enabling gRPC

- Mandatory.
- Unless otherwise specified, enable gRPC in the global configuration mode of each device.

Command	**grpc**
Parameter Description	N/A
Defaults	gRPC is disabled by default.
Command Mode	Global configuration mode
Usage Guide	This command is used to create a gRPC instance, enable the gRPC function, and enter the gRPC process configuration mode. When the gRPC function is enabled, the gRPC client and gRPC server are created. The gRPC client uploads data to the server, and the gRPC server parses authentication messages and obtainment messages sent from the server.

Verification



- Run the **show grpc status** command to display the running time after the gRPC function is enabled.

Configuration Example

Only gRPC-related configuration is described.

Enabling gRPC

Scenario	The network communication between device S and PC1 is normal.

Figure 1-6 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Configure a WAN port.

S	`S(config)# grpc`
	`S(config-grpc)# exit`
	`S(config)# interface HundredGigabitEthernet 0/49`
	`S(config-if-HundredGigabitEthernet 0/49)# ip address 192.168.1.1 255.255.255.252`

Verification	● Ping the server address to check whether the address is reachable. ● Check whether the gRPC function is enabled.
S	`S# show grpc status`

Common Errors

N/A

1.4.2 Configuring Authentication Modes and AAA Server Authentication Attributes for gRPC Login and Logout

Configuration Effect

- The authentication mode of the gRPC login and logout function is configured as non-authentication, AAA local authentication, or AAA server authentication (timeout interval and retry count).

Notes

- If AAA server authentication is configured, the new-model mode must be enabled.
- You are not advised to configure the non-authentication mode.
- You are not advised to modify the timeout interval or retry count.

Configuration Step

↘ Configuring the Authentication Mode for gRPC Login and Logout

- Optional.
- Perform this configuration as needed.
- Unless otherwise specified, configure authentication login in gRPC process configuration mode of the device where this configuration needs to be performed.

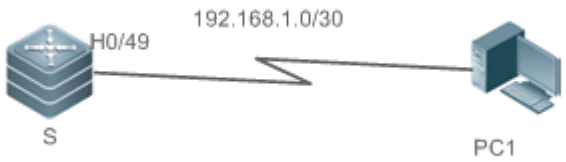
Command	**authen login** { **local** | **authentication** *mlist* }
Parameter Description	**local**: Enables authentication based on the local username database. It is the default configuration. **authentication**: Uses the specified AAA server list for authentication. *mlist*: Specifies the name of the AAA list.

Defaults	Local login is used by default, that is, **authen login local**.
Command Mode	gRPC process configuration mode
Usage Guide	Upon receiving a login request from the server, the device selects AAA local authentication, AAA server authentication, or non-authentication based on the configured authentication mode. After the server passes authentication, login user information, namely, the IP address and username of the server, is recorded. The device only returns responses to the obtainment event requests from the server that passes authentication.

Configuring AAA Server Authentication Attributes for gRPC Login and Logout

- Optional. The configuration relies on AAA configuration and takes effect only after the AAA configuration (**aaa new-model**) is completed.
- Perform this configuration as needed.
- Unless otherwise specified, do not change the device configuration.

Command	**authen aaa-config** { **retry** *times* **| timeout** *second* }
Parameter Description	**retry**: Configures the retry count during AAA server authentication. *times*: Specifies the retry count. The value range is from 1 to 100. The default retry count is 1. **timeout**: Configures the timeout interval of AAA server authentication. *second:* Specifies the timeout interval, in seconds. The value range is from 0 to 300. The value 0 indicates that waiting for the AAA server times out. The default timeout interval is 4s.
Command Mode	gRPC process configuration mode
Usage Guide	This command is used to configure the retry count and timeout interval of AAA server authentication during server login. You are not advised to modify the retry count or timeout interval. If the retry count exceeds a limit or an improper timeout time is configured, AAA users may be locked for 15 minutes. The lock time can be canceled by running the **clear aaa local user lockout all** command.



Verification

- Run the **show running** command to check whether the configuration is correct.

Configuration Example

Only gRPC-related configuration is described.

Configuring the Authentication Mode for gRPC Login and Logout

Scenario	The network communication between device S and PC1 is normal.
Figure 1-7 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Configure the new-model and mlist test.

S	S(config)# grpc S(config-grpc)# authen login authentication test
Verification	● Check whether the configuration is saved correctly. ● Check whether the PC client can ping the device. ● Check whether the PC client can be authenticated and record the authentication information.
S	S# show running S# show grpc client

Common Errors

N/A

1.4.3 Configuring Event Types Supported by gRPC

Configuration Effect

- Enable the device to focus on all subscribed-to real-time events on the device.
- Enable the device to focus on all subscribed-to periodic events on the device.
- Change the timer value of periodic events.

Notes

- An event that the server subscribes to takes effect only when the event is configured on the device.

Configuration Steps

↘ Enabling the Device to Focus on Subscribed-to Events on the Device

- Mandatory.
- Run the **subscr realtime enable** command to enable the device to focus on all subscribed-to real-time events on the device.
- Run the **subscr sample enable** command to enable the device to focus on all subscribed-to periodic events on the device.
- Run the **show grpc channel [counter]** command to display information about real-time or periodic events that the server registers and subscribes to or various statistics.

Command	**subscr** [**realtime** | **sample**] **enable**
Parameter Description	**realtime**: Specifies the subscribed-to real-time events that need to be concerned. The function of concerning subscribed-to real-time or periodic events is disabled by default. **sample**: Specifies the subscribed-to periodic events that need to be concerned.
Command Mode	gRPC process configuration mode
Usage Guide	After the gRPC process configures the function of concerning subscribed-to events, the gRPC process waits for the NETCONF manager to send the subscribed-to events. When the received subscription message matches the locally subscribed-to event, the gRPC process enables the corresponding event and reports gRPC data to the server. When the NETCONF manager sends an event unsubscription message to the gRPC process and the received unsubscription message matches the locally subscribed-to event, the gRPC process disables the event and reports gRPC

	data to the server. If the function of concerning subscribed-to events is not configured on the gRPC process, the gRPC process ignores the event subscription and unsubscription messages sent by the NETCONF manager.

Configuring the Timer Value of Periodic Events

- Optional.
- Perform this configuration as needed.
- Unless otherwise specified, run the **subscr-sample-interval** command in gRPC process configuration mode of the device that requires this configuration to change the timer value of periodic events.

Command	**subscr-sample-interval** *interval* [**millisecond** *millisecond*]
Parameter Description	*interval*: Indicates the second part in the locally configured interval for reporting periodic events. The value range is from 0 to 65535. The default value is 10s. The default timer value for periodic events is used by default. *millisecond*: Indicates the millisecond part in the locally configured interval for reporting periodic events. The value range is from 0 to 999, and the default value is 0. This value plus *interval* is the actual reporting interval, which should not be smaller than 100 milliseconds.
Command Mode	gRPC process configuration mode
Usage Guide	When the function of concerning subscribed-to periodic events is enabled on the device and the NETCONF manager sends a subscribed-to periodic event, the periodic event timer starts and gRPC data is sent to the subscribing server. If the periodic event sent by the NETCONF manager does not carry the timer value, the timer value is determined by the **subscr-sample-interval** command. If the periodic event sent by the NETCONF manager carries the timer value, the timer value sent by the NETCONF manager is used.

Configuring the Suppression Time of Real-Time Events

- Optional.
- Perform this configuration as needed.
- Unless otherwise specified, run the **subscr-realtime-interval** command in gRPC process configuration mode of the device that requires this configuration to change the suppression time of real-time events.

Command	**subscr-realtime-interval {all** *interval* **| realtime** *json-event interval***}**
Parameter Description	**all**: Configures the suppression time for all real-time events. realtime: Configures the suppression time for real-time events. Real-time events are not suppressed by default. *json-event:* Indicates the type of the configured real-time event. *interval:* Indicates the suppression interval for real-time event reporting, in milliseconds. The value range is from 1 to 1000000. No suppression interval is configured by default.
Command Mode	gRPC process configuration mode
Usage Guide	When the device subscribes to a real-time event and the threshold of the real-time event is reached, real-time packets are generated and sent to the subscribing server. If the threshold of the real-time

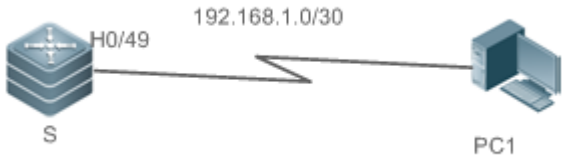
	event is triggered frequently, many packets are generated within a short time and sent to the subscribing server. These packets may be the same, and processing these packets will increase the overhead of the device and the server. To address this issue, run the **subscr-realtime-interval** command.

Verification

- Run the **show grpc subscr realtime** command to display registered real-time events.
- Run the **show grpc subscr sample** command to display registered periodic events.
- Run the **show grpc channel** [**counter**] command to display the server IP address, port number, and registered events or various statistics.

Configuration Example

Enabling the Function of Concerning Subscribed-to Real-Time Events on the Device

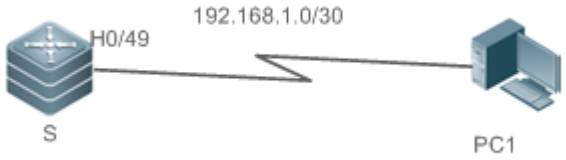


Scenario	The network communication between device S and PC1 is normal.
Figure 1-8 One-to-One Topology	
Configuration Steps	• Enable the gRPC function. • Configure the device to concern the subscribed-to CLI configuration modification real-time events. • Configure the NETCONF manager to subscribe to the CLI configuration modification real-time events.
S	`S(config)# grpc` `S(config-grpc)# subscr realtime enable`
Verification	• Run the **show grpc subscr realtime** command to display the status and statistics of the CLI configuration modification real-time event. • Run the **show grpc channel** [**counter**] command to display the server IP address, port number, and registered events or various statistics.
S	`S# show grpc subscr realtime` `S# show grpc channel counter`

Common Errors

N/A

Enabling the Function of Concerning Subscribed-to Periodic Events on the Device



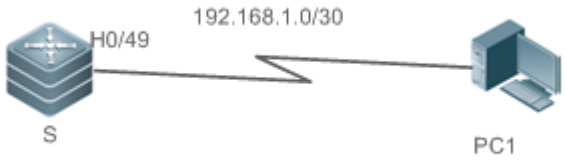
Scenario	The network communication between device S and PC1 is normal.

Figure 1-9 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Configure the device to concern subscribed-to DCB and PFC periodic events. ● Configure the NETCONF manager to subscribe to the DCB and PFC periodic events.
S	`S(config)# grpc` `S(config-grpc)# subscr sample enable`
Verification	● Run the **show grpc subscr sample** command to display the status and statistics of DCB and PFC periodic events. ● Run the **show grpc channel** [**counter**] command to display the server IP address, port number, and registered events or various statistics.
S	`S# show grpc subscr sample` `S# show grpc channel counter`

Common Errors

N/A

Configuring the Timer Value of Periodic Events



Scenario	The network communication between device S and PC1 is normal.
Figure 1-10 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Set the timer value for obtaining subscribed-to periodic events that need to be concerned to 10 seconds.
S	`S(config)# grpc` `S(config-grpc)# subscr-sample-interval 10`
Verification	● Run the **show grpc subscr sample** command to display the expiration time of all subscribed-to periodic events.
S	`S# show grpc subscr sample`

Common Errors

N/A

Configuring the Suppression Time of Real-Time Events

Scenario	The network communication between device S and PC1 is normal.

Figure 1-11 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Set the suppression time of all subscribed-to real-time events that need to be concerned to 500 milliseconds.
S	`S(config)# grpc` `S(config-grpc)# subscr-realtime-interval all 500`
Verification	● Run the **show grpc subscr realtime** command to display the suppression time of all subscribed-to real-time events.
S	`S# show grpc subscr realtime`

Common Errors

N/A

1.4.4 Specifying the Source Interface for Sending gRPC Data

Configuration Effect

- Use the IP address of the specified interface to send gRPC packets.

Notes

- The bound interface must be Up and be configured with an IP address.

Configuration Step

↘ Configuring the Source Interface for Sending Real-Time Data and Periodic Data

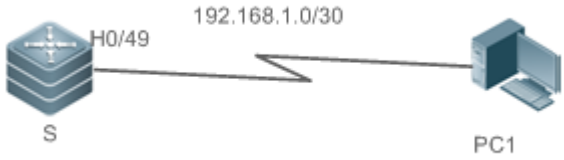
- Optional.
- Perform this configuration as needed.
- Unless otherwise specified, run the **subscr-source-interface** command in gRPC process configuration mode of the device that requires this configuration.

Verification

- Run the **show running** command to check whether the configuration is correct.

Related Commands

↘ Configuring the Source Interface for Sending Real-Time Data and Periodic Data



Command	**subscr-source-interface** *interface-type interface-number*
Parameter Description	*interface-type interface-number*: Specifies the type and number of a specified interface. The source interface for sending real-time data and periodic data is selected at random by default.
Command	gRPC process configuration mode

Mode	
Usage Guide	A source interface is bound at random to send real-time data and periodic data. If a server receives only packets from a specified source address, this command can be used to configure the specified source interface.

Configuration Example

Only gRPC-related configuration is described.

Binding a Specified Interface for Sending gRPC Packets

Scenario	The network communication between device S and PC1 is normal.
Figure 1-12 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Configure a WAN port.

S	`S(config)# interface HundredGigabitEthernet 0/49`
	`S(config-if-HundredGigabitEthernet 0/49)# ip address 192.168.1.1 255.255.255.252`
	`S(config-if-HundredGigabitEthernet 0/49)# exit`
	`S(config)# grpc`
	`S(config-grpc)# subscr-source-interface HundredGigabitEthernet 0/49`

Verification	● Check whether the configuration is saved correctly. ● Ping the server address to check whether the address is reachable. ● Check whether the communication between the device and server is normal.
S	`S# show running` `S# show grpc channel`

Common Errors

N/A

1.4.5 Configuring the Response Timeout Interval for gRPC Data

Configuration Effect

- Configure the data response timeout interval for the device serving as the gRPC server.

Notes

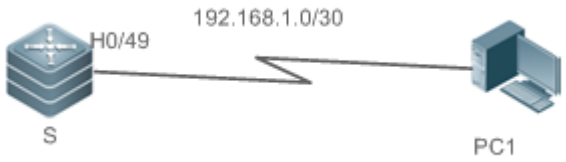
- The value can be set as needed. A smaller value may result in a timeout error when the GET operation involves time-consuming data.

Related Commands

Configuring the Response Timeout Time for gRPC Data

- Mandatory.

Command	**reply-timeout** *interval*
Parameter Description	*interval:* Specifies the data response timeout interval of the device serving as the gRPC server, in seconds. The value ranges from 1 to 300 and the default value is 10.
Command Mode	gRPC process configuration mode
Usage Guide	After a timeout interval is configured for the gRPC process and the collector initiates a GET/SET operation, the device returns a timeout error to the collector if it fails to obtain data within the timeout interval.



Verification

- Run the **show running** command to check whether the configuration is correct.

Configuration Example

Only gRPC-related configuration is described.

Configuring the Response Timeout Interval for gRPC Data

Scenario	The network communication between device S and PC1 is normal.
Figure 1-13 One-to-One Topology	
Configuration Steps	• Enable the gRPC function. • Configure the response timeout interval for gRPC data.
S	`S(config)# grpc` `S(config-grpc)# reply-timeout 30`
Verification	• Check whether the configuration is saved correctly. • Check whether the displayed timeout interval is the same as the configured value.
S	`S# show running`

Common Errors

N/A

1.4.6 Pre-configuring the Subscribing Server and Events to Be Subscribed to

Configuration Effect

- After the subscribing server and subscribed-to events are pre-configured, gRPC packets of corresponding events can be reported to the server.

- After the standby server is pre-configured for the subscribing server, the standby server becomes the new active server when the active server malfunctions and packets are automatically sent to the new active server.

Notes

- The IP address and port number of the subscribing server must be valid.
- The subscribed-to events and parameters must be correct and valid.

Configuration Step

Pre-configuring the Subscribing Server

- Mandatory.

Command	**user-server** *ip-address port-id*
Parameter Description	*ip-address:* Specifies the IPv4 address of the subscribing server. *port-id*: Specifies the port number of the server.
Command Mode	gRPC process configuration mode
Usage Guide	This configuration relies on the configuration described in 1.4.3 Configuring Event Types Supported by gRPC. The configuration takes effect only after the supported real-time events or periodic events are enabled. This command is used to pre-create a channel for a specified server and enter the gRPC subscribing server mode. The subscription events of this channel can be configured in this mode. By running a configuration command, the device can pre-create the subscribing server and events concerned. The device can use a configuration command to delete a server and an event that have been subscribed to, and to simulate the controller to notify the server of server and event unsubscription through NETCONF.

Pre-configuring Events to Be Subscribed to

- Mandatory.

Command	**type** *json-event* **value** *value* [**value-extend** *value-extend*]
Parameter Description	*json-event:* Specifies the type of the configured event. For details, see the **show grpc subscr | include json** command. *value:* Specifies the parameter value, that is, the threshold of real-time events and the period time of periodic events. *value-extend*: Specifies the extension field of *value*. This parameter is used to set the millisecond part in the interval for reporting periodic events. The value range is from 0 to 999. This value plus *value* should not be smaller than 100 milliseconds.
Command Mode	gRPC subscription server mode
Usage Guide	This command is used to configure subscription events and parameters of this channel and ensure that the configuration is consistent with the NETCONF configuration.

Configuring the Heartbeat Detection Mechanism

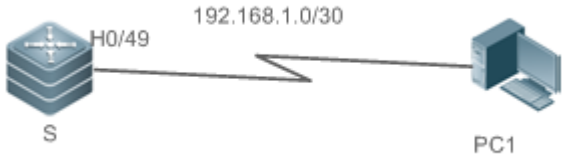
- Optional.

Command	**heartbeat inform** [**interval** *interval*] [**keepalive-times** *times*]
Parameter Description	**inform:** Enables the heartbeat detection mechanism. *interval:* Specifies the heartbeat detection interval, in seconds. The value range is from 1 to 3600. *times:* Specifies the number of heartbeat keepalive times. If the number of keepalive failures exceeds this value, it is determined that the server malfunctions. The value range is from 1 to 300. When the active server malfunctions and the standby server operates properly, data will be sent to the standby server.
Command Mode	gRPC process configuration mode
Usage Guide	This command is used to enable the heartbeat detection mechanism, and configure the heartbeat detection interval and number of heartbeat keepalive times. After the number of keepalive failures exceeds the configured value, it is determined that the server malfunctions.

Pre-configuring the Standby Server of the Subscribing Server

- Optional.

Command	**standby-server** *ip-address port-id*
Parameter Description	*ip-address*: Specifies the IPv4 address of the server. *port-id*: Specifies the port number of the server.
Command Mode	gRPC subscription server mode
Usage Guide	This command is used to configure a standby server. You need to enable the heartbeat detection mechanism first so that the device can automatically send data to the standby server when the active server malfunctions.



Verification

- Run the **show running** command to check whether the configuration is correct.
- Run the **show grpc channel** command to check whether the subscribing server and subscribed-to events are correct.

Configuration Example

Only gRPC-related configuration is described.

Pre-configuring the Subscribing Server and Events to Be Subscribed to

Scenario	The network communication between device S and PC1 is normal.
Figure 1-14 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Enable the heartbeat detection mechanism, and configure the heartbeat detection interval

	and the number of keepalive times. ● Configure the specified channel. ● Configure the specified subscription type. ● Configure the standby server.

S	`S(config)# grpc`
	`S(config-grpc)# heartbeat inform interval 1 keepalive-times 1`
	`S(config-grpc)# user-server 192.168.0.1 12345`
	`S(config-grpc-us)# type 0x10000000 value 10`
	`S(config-grpc-us)# standby-server 192.168.0.2 12345`

Verification	● Check whether the configuration is saved correctly. ● Ping the server address to check whether the address is reachable. ● Check whether the communication between the device and server is normal. ● Check whether the heartbeat link is normal, and whether data is automatically sent to the standby server when the active server malfunctions.
S	`S# show running` `S# show grpc channel`

Common Errors

The threshold range of real-time events is from –1 to +100. The period range of periodic events is from –1 to +65535. The selected event type must be available. Otherwise, the configuration is invalid and not reserved.

1.4.7 Pre-configuring the Server Login User Information

Configuration Effect

- After login user information is pre-configured for a server, the server can obtain correct information for sent obtainment event requests.

Notes

- The IP address of the server must be valid.
- The sequence number of the login user must be unique.

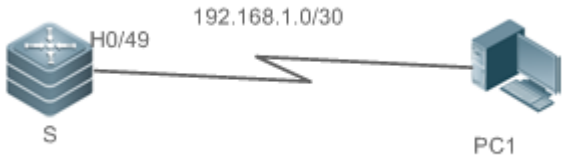
Related Commands

↘ Pre-configuring Server Login User Information

- Mandatory.

Command	**user-client** *id user-name ip-address*
Parameter Description	*id:* Sequence number of the login user. *user-name:* Specifies the username (which may not exist in the AAA library). *ip-address:* Specifies the allowed address.
Command Mode	gRPC process configuration mode
Usage Guide	By running a configuration command, the device can pre-create the login user information of the server that passes authentication, simulate the server to initiate a login request, pass the authentication, and save the user information.

	By running a configuration command, the device can delete login user information of the server that passes authentication, simulate the server to initiate a logout request, and delete login user information.



Verification

- Run the **show running** command to check whether the configuration is correct.
- Run the **show grpc client** command to display login user information.

Configuration Example

Only gRPC-related configuration is described.

Pre-configuring Server Login User Information

Scenario	The network communication between device S and PC1 is normal.
Figure 1-15 One-to-One Topology	
Configuration Steps	• Enable the gRPC function. • Configure login user information of the specified server.
S	`S(config)# grpc` `S(config-grpc)# user-client 12345 test-user 192.168.0.1`
Verification	• Check whether the configuration is saved correctly. • Ping the server address to check whether the address is reachable. • Check whether the server can obtain correct information for sent obtainment event requests.
S	`S# show running` `S# show grpc client`

Common Errors

N/A

1.4.8 Configuring a gRPC YANG Model Path and Its Group

Configuration Effect

- Configure a YANG model path (data collection source) for data collection. Then the device sends relevant data to the server configured in a subscription association.

Notes

- The YANG model path must be valid and data exists in this path.

Configuration Steps

Configuring a YANG Model Path Group

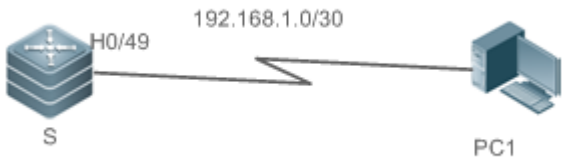
- Mandatory.

Command	**sensor-group** *group-id*
Parameter Description	*group-id*: Specifies the ID of a group.
Command Mode	gRPC process configuration mode
Usage Guide	This command is used to create a gRPC YANG model path group and switch to the gRPC YANG model group configuration mode. In this mode, you can configure multiple YANG model paths in this group.

Configuring a gRPC YANG Model Path and Its Group

- Mandatory.

Command	**sensor-path** *path*
Parameter Description	*path*: Specifies the YANG model path.
Defaults Command Mode	N/A gRPC YANG model group configuration mode
Usage Guide	This command is used to configure a YANG model path in a YANG model path group. For details on how to compile a path, refer to the output of the **show grpc yang tree/node-path** command.



Verification

- Run the **show running** command to check whether the configuration is correct.

Configuration Example

Only gRPC-related configuration is described.

Configuring a gRPC YANG Model Path and Its Group

Scenario	The network communication between device S and PC1 is normal.
Figure 1-16 One-to-One Topology	
Configuration Steps	• Enable the gRPC function. • Configure a YANG model path group. • Configure a YANG model path.

S	`S(config)# grpc`
	`S(config-grpc)# sensor-group 1`
	`S(config-grpc-us)# sensor-path /rg-bridge:bridge/vlan/entry[id='1']/swport-list`

Verification	• Check whether the configuration is saved correctly.

S	S# show running

Common Errors

The configured YANG model path is invalid. You must check the YANG file and compile the path based on the output of the **show grpc yang tree/node-path** command.

1.4.9 Configuring the gRPC Destination Server

Configuration Effect

- Configure the address of the destination server so that the destination server subscribes to a YANG model path based on the subscription association.

Notes

- The server address and port number must be valid.

Configuration Step

Configuring a gRPC Destination Group

- Mandatory.

Command	**destination-group** *group-id*
Parameter Description	*group-id*: Specifies the ID of a group.
Command Mode	gRPC process configuration mode
Usage Guide	This command is used to create a gRPC destination group and switch to the gRPC destination group configuration mode. In this mode, you can configure multiple destination addresses in this group.

Configuring a gRPC IPv4 Destination Address

- Mandatory.

Command	**ip** *ip-address* **port** *port-id*
Parameter Description	*ip-address*: Specifies the IPv4 address of the server. *port-id*: Specifies the port number of the server.
Command Mode	gRPC destination group configuration mode
Usage Guide	This command is used to configure the IP address of the gRPC server.

Verification

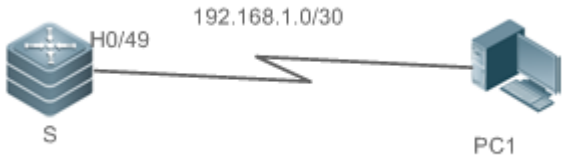
- Run the **show running** command to check whether the configuration is correct.

Configuring the Protocol Used by the Destination Server

- Mandatory.

Command	**protocol grpc** {**tls** | **no-tls**}

Parameter Description	**tls**: Configures TLS encryption for gRPC. The gRPC protocol that uses TLS encrypted transmission is enabled by default. **no-tls**: Configures cleartext transmission for gRPC.
Command Mode	gRPC destination group configuration mode
Usage Guide	This command is used to configure the protocol used by the destination server.



Verification

- Run the **show running** command to check whether the configuration is correct.

Configuration Example

Only the gRPC-related configuration is described.

Configuring the gRPC Destination Server and Its Group

Scenario	The network communication between device S and PC1 is normal.
Figure 1-17 One-to-One Topology	
Configuration Steps	• Enable the gRPC function. • Configure a destination group. • Configure the destination address and port number. • Configure cleartext transmission for gRPC.

S	`S(config)# grpc`
	`S(config-grpc)# destination-group 1`
	`S(config-grpc-destination)# ip 192.168.0.1 port 12345`
	`S(config-grpc-destination)# protocol grpc no-tls`

Verification	• Check whether the configuration is saved correctly. • Ping the server address to check whether the address is reachable. • Check whether the communication between the device and server is normal.
S	`S# show running`

Common Errors

N/A

1.4.10 Configuring a gRPC Subscription Association

Configuration Effect

- Configure a subscription association to enable the device to collect data of the associated YANG model path group and send the data to a destination server in the associated destination group.

Notes

- A YANG model path group must have been configured.
- A destination group must have been configured.

Configuration Step

Configuring a Subscription Association

- Mandatory.

Command	**subscription** *subscription_id*
Parameter Description	*subscription_id*: Specifies the ID of a group.
Command Mode	gRPC process configuration mode
Usage Guide	This command is used to create a gRPC subscription association and switch to the gRPC subscription association mode. In this mode, you can configure subscription associations between multiple YANG model path groups and multiple destination groups.

Configuring an Associated YANG Model Path Group and Its Data Collection Interval

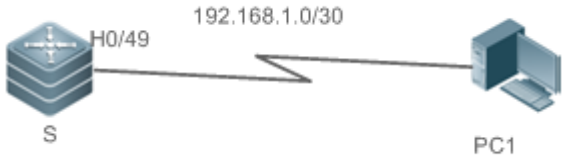
- Mandatory.

Command	**sensor-group** *group_id* [**sample-interval** *interval*]
Parameter Description	*group_id*: Specifies the ID of a YANG model path group. *interval*: Specifies the interval for periodic data collection. It is not required for collection of triggered data.
Command Mode	gRPC subscription association configuration mode
Usage Guide	This command is used to configure the data source of a subscription association. If ***sample-interval*** is configured, data needs to be collected periodically. If it is not configured, triggered data needs to be collected.

Configuring an Associated Destination Group

- Mandatory.

Command	**destination-group** *group_id*
Parameter Description	*group_id*: Specifies the ID of a group.
Command Mode	gRPC subscription association configuration mode
Usage Guide	This command is used to configure the destination group of a subscription association.



Verification

- Run the **show running** command to check whether the configuration is correct.
- Run the **show grpc openconfig subscription** command to check whether the configuration is correct.

Configuration Example

Only gRPC-related configuration is described.

Pre-configuring the Subscribing Server and Events to Be Subscribed to

Scenario	The network communication between device S and PC1 is normal.
Figure 1-18 One-to-One Topology	
Configuration Steps	● Enable the gRPC function. ● Configure a subscription association. ● Configure an associated YANG model path group and data collection interval. ● Configure an associated destination group.

S	`S(config)# grpc`
	`S(config-grpc)# subscription 1`
	`S(config-grpc-us)# sensor-group 1 sample-interval 1000`
	`S(config-grpc-us)# destination-group 1`

Verification	● Check whether the configuration is saved correctly. ● Ping the server address to check whether the address is reachable. ● Check whether the communication between the device and server is normal.
S	`S# show running` `S# show grpc openconfig subscription`

Common Errors

The YANG model path is invalid and no data exists in this path.

1.4.11 Supporting RPC Methods Defined by a Third Party

Configuration Effect

- Support RPC methods defined in **gnmi.proto**. Defined RPC methods such as Get, Set, and Subscribe can be used to collect device data.

Notes

- The device and server must be reachable to each other.

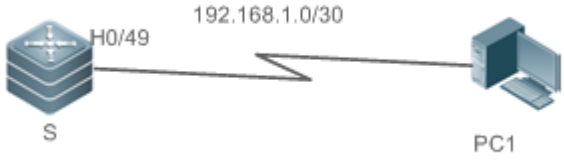
Configuration Step

Supporting RPC Methods Defined by a Third Party

- Mandatory.

Command	**rpc gnmi enable**
Parameter Description	N/A RPC methods defined by a third party are not supported by default.
Command	gRPC process configuration mode

Mode	
Usage Guide	This command is used to use RPC methods defined in **gnmi.proto**.



Verification

- Run the **show running** command to check whether the configuration is correct.

Configuration Example

Only gRPC-related configuration is described.

Pre-configuring the Subscribing Server and Events to Be Subscribed to

Scenario	The network communication between device S and PC1 is normal.
Figure 1-19 One-to-One Topology	
Configuration Steps	• Enable the gRPC function. • Enable the gNMI function.
S	`S(config)# grpc` `S(config-grpc)# rpc gnmi enable`
Verification	• Check whether the configuration is saved correctly.
S	`S# show running`

Common Errors

N/A

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear grpc channel [*ip-address port-id*] [**counter**]	Clears statistics about the server which gRPC subscribes to.
clear grpc subscr [**sample**] [**counter**]	Clears data about periodic events and real-time events of gRPC.

Displaying

Command	Description
show grpc channel [**counter**]	Displays the server IP address, port number, and subscribed-to events or various statistics.
show grpc client	Displays gRPC server login information.
show grpc status	Displays gRPC running status information.

show grpc subscr [**realtime | sample**]	Displays status and statistics of events which are subscribed to.
show grpc openconfig subscription	Displays information about static subscription associations of the device (defined in **openconfig-telemetry.proto**).
show grpc gnmi subscription	Displays information about subscription associations generated through RPC methods defined in **gnmi.proto** on the client.
show grpc yang node-path [*module_name*]	Displays the path of a YANG node.
show grpc yang tree [*module_name*]	Displays the YANG model tree defined in the RG-gRPC YANG file.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug grpc { all | **event }**	Debugs gRPC information.

1 Configuring INC

1.1 Overview

In the Simplified Optical Ethernet (SOE) Solution, the Intent-Business Network Commander (INC) function enables the device to monitor network devices in real time and manage basic services. After this function is enabled, the Google Remote Procedure Calls (gRPC) transmission protocol and YANG model data structure can make information collection and transmission between the device and the INC more efficient and convenient.

Protocols and Standards

N/A

1.2 Features

Basic Concepts

↘ INC

INC is the next-generation integrated network management platform for perception-free replacement, optical link O&M, real-time monitoring, and information collection of network devices.

↘ gRPC

gRPC uses coding in protocol buffer format and HTTP/2 as the transport layer protocol, ensuring efficient, real-time, and accurate information transmission.

Overview

Feature	Description
Enabling INC	Enables the INC function and configures gRPC-related configuration.

1.2.1 Enabling INC

Enable the INC function on the device. The device serves as the gRPC client, and the INC serves as the gRPC server. After a subscription relationship is established through gRPC, the device and INC can exchange network data.

Working Principle

After the INC function is enabled on the device, the device sends a request to the gRPC server to establish a subscription relationship. To simplify the configuration process of network administrators, the device automatically executes key configurations before exchanging data with the gRPC server. The key configurations include:

- IP address and port number of the gRPC server

  The device sends a request to this server address to try to establish a subscription relationship.
- Data sources in the YANG data model

The data source is reported by the device (gRPC client) to the INC (gRPC server).

- Association between the gRPC server and YANG model

  After the association between the gRPC server and YANG model is configured, data in the YANG model is reported only to the associated gRPC server. The device presets different sending periods for different gRPC data sent to the gRPC server. These sending periods prevent network congestion caused by simultaneous reporting of a large amount of data.

Based on the preceding pre-configured key information, the device periodically collects data based on the data paths in the YANG model and sends gRPC data requests to the INC, ensuring real-time device monitoring by the INC.

1.3 Configuration

Configuration	Description and Command	
Enabling INC	(Optional) It is used to enable INC.	
	inc-config grpc-config	Configures the gRPC server address and the subscription relationship for reporting data.

1.3.1 Enabling INC

Configuration Effect

- Configure the gRPC server address and the subscription relationship for reporting data.

Notes

N/A

Configuration Step

- Optional.
- Configure the IPv4 address of the gRPC server and the subscription relationship for reporting data in the global configuration mode of the access controller (AC).

Command	**inc-config grpc-config** *ipv4-address port*
Parameter Description	*ipv4-address*: Indicates the IPv4 address of the gRPC server. *port*: Indicates the port number of the gRPC server. The value range is from 1024 to 65535, and the default value is 30001.
Defaults	N/A
Command Mode	Global configuration mode

Usage Guide	This command is used to establish a subscription relationship between the AC and the INC and complete key configurations for message transmission between the AC and INC. The key configurations are as follows:
	1. IP address and port number of the gRPC server
	`destination-group 1`
	`  ip 1.1.1.1 port 1024`

2. Data sources in the YANG data model

```
sensor-group 1
  sensor-path /rg-interfaces:interfaces-state
  sensor-path /rg-interfaces:interfaces
  exit-sensor-group
 sensor-group 2
  sensor-path /rg-inc-wlan-dev-info:devinfo/wlan-dev-info
  exit-sensor-group
 sensor-group 3
  sensor-path /rg-inc-wlan-ap-list:aplist/wlan-ap-list
  exit-sensor-group
 sensor-group 4
  sensor-path /rg-inc-wlan-am-list:amlist/wlan-am-list
  exit-sensor-group
 sensor-group 5
  sensor-path /rg-inc-wlan-sta-list:stalist/wlan-sta-list
  exit-sensor-group
 sensor-group 6
  sensor-path
/rg-inc-wlan-statistics-info:dev-total-count/wlan-statistics-info
  exit-sensor-group
 sensor-group 7
  sensor-path /rg-inc-wlan-ap-list:netconf-ap-event/wlan-ap-list
  sensor-path /rg-inc-wlan-am-list:netconf-am-event/wlan-am-list
  sensor-path /rg-inc-wlan-sta-list:netconf-sta-event/wlan-sta-list
  exit-sensor-group
```

In the preceding pre-configuration, the device collects specified data from different data paths in the YANG model.

YANG Data Model Group	Data Path	Description
1	interfaces-state/interfaces	Interface status and information of the AC
2	wlan-dev-info	Host information of the AC
3	wlan-ap-list	List of online access points (APs)
4	wlan-am-list	List of online all-optical i-Share hosts
5	wlan-sta-list	List of online STAs
6	wlan-statistics-info	Device statistics, including the number of online APs, number of offline APs, number of all-optical i-Share hosts, and number of online STAs

3. Association between the gRPC server and YANG model and default period for reporting messages, in milliseconds

```
subscription 1
  sensor-group 1 sample-interval 300000
```

	sensor-group 2 sample-interval 300000 sensor-group 3 sample-interval 120000 sensor-group 4 sample-interval 1800000 sensor-group 5 sample-interval 60000 sensor-group 6 sample-interval 1800000 sensor-group 7 destination-group 1 ● Use the **no** form of this command on the AC to delete the configuration of a single server or all servers. After all server configurations are deleted, the gRPC function is disabled.

Verification

- Run the **show running-config** command on the AC to display the configuration.

Configuration Example

↘ Enabling INC on the AC

Configuration Steps	● Enable the Network Configuration Protocol (NETCONF) on the AC. Because gRPC relies on NETCONF, NETCONF must be enabled first.
AC	Hostname # configure terminal Hostname(config)#crypto key generate dsa Hostname(config)#enable service ssh-server Hostname(config)#username admin privilege 15 password Hostname123 Hostname(config)#line vty 0 35 Hostname(config-line)#login local Hostname(config-line)#exit Hostname(config)#netconf enable Hostname(config)#netconf max-sessions 32
	● Configure the IP address and port number of the gRPC server and enable the INC function.
AC	Hostname(config)#inc-config grpc-config 172.29.4.102 30001
	● Delete the configuration of a gRPC server.
AC	Hostname(config)#no inc-config grpc-config 172.29.4.102 30001
	● Delete the configuration of all gRPC servers.
AC	Hostname(config)#no inc-config grpc-config all
Verification	● Run the **show running-config** command to display the AC configuration.
AC	Hostname#show running-config ! inc-config grpc-config 172.29.4.102 30001 ! grpc no authen login rpc gnmi enable sensor-group 1 sensor-path /rg-interfaces:interfaces-state sensor-path /rg-interfaces:interfaces

```
 exit-sensor-group
 sensor-group 2
  sensor-path /rg-inc-wlan-dev-info:devinfo/wlan-dev-info
  exit-sensor-group
 sensor-group 3
  sensor-path /rg-inc-wlan-ap-list:aplist/wlan-ap-list
  exit-sensor-group
 sensor-group 4
  sensor-path /rg-inc-wlan-am-list:amlist/wlan-am-list
  exit-sensor-group
 sensor-group 5
  sensor-path /rg-inc-wlan-sta-list:stalist/wlan-sta-list
  exit-sensor-group
 sensor-group 6
  sensor-path
/rg-inc-wlan-statistics-info:dev-total-count/wlan-statistics-info
  exit-sensor-group
 sensor-group 7
  sensor-path /rg-inc-wlan-ap-list:netconf-ap-event/wlan-ap-list
  sensor-path /rg-inc-wlan-am-list:netconf-am-event/wlan-am-list
  sensor-path /rg-inc-wlan-sta-list:netconf-sta-event/wlan-sta-list
  exit-sensor-group
 destination-group 1
  ip 172.29.4.102 port 30001
  exit-destination-group
 subscription 1
  sensor-group 1 sample-interval 300000
  sensor-group 2 sample-interval 300000
  sensor-group 3 sample-interval 120000
  sensor-group 4 sample-interval 1800000
  sensor-group 5 sample-interval 60000
  sensor-group 6 sample-interval 1800000
  sensor-group 7

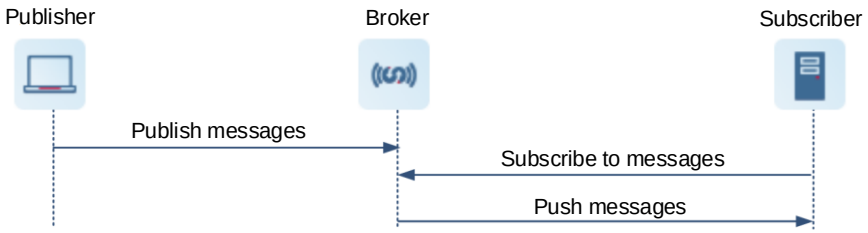
1 Configuring MQTT

1.1 Overview

Message Queuing Telemetry Transport (MQTT) is a transmission protocol of the International Organization for Standardization (ISO) standard (ISO/IEC PRF 20922). MQTT messages occupy low bandwidth and apply to low-bandwidth and low-power devices. Based on machine-to-machine (M2M) communication, MQTT is a lightweight messaging protocol in binary format. Based on the MQTT publish/subscribe messaging system, most operations are performed on the intermediate broker. MQTT has low requirements for performance of remote devices. Therefore, it is applied to the Internet of Things (IoT), M2M, Instance Messaging (IM), and Hypertext Transfer Protocol (HTTP).

Protocols and Standards

N/A



1.2 Features

Basic Concepts

↘ MQTT

Figure1-1 shows the network architecture of MQTT.

Figure 1-1 Architecture of MQTT

The MQTT protocol requires three roles: publisher, broker, and subscriber. The MQTT clients include the publisher and subscriber who publishes and subscribes to messages respectively. The server serves as a message broker. The subscriber can also publish messages as the publisher.

Messages transmitted by MQTT include the topic and payload:

- Topic: Indicates the message type. After a subscriber subscribes to a topic, the subscriber will receive the payload of this topic.
- Payload: Indicates the message content, that is, the detailed content used by a subscriber.

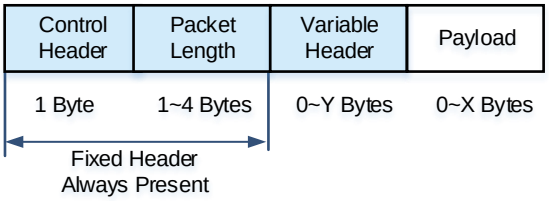
MQTT Client

An application or a device needs to establish a network connection with the server when using MQTT. You can perform the following operations on an MQTT client:

- Publish messages that other clients may subscribe to.
- Subscribe to messages published by other clients.
- Unsubscribe to or delete application messages.
- Disconnect from the server.

MQTT Server

The MQTT server is the broker, which can be an application or a device between the message publisher and subscriber. The MQTT server can take the following actions:



- Accept network connection requests from clients.
- Receive application information published by clients.
- Process subscription and unsubscription requests from clients.
- Forward application messages to subscribers.

MQTT Control Packets

Name	Value	Packet Flow	Description
Reserved	0	Disabled	Packet reserved
CONNECT	1	Client ---> Server	Client connecting to the server
CONNACK	2	Server ---> Client	Connection request acknowledged
PUBLISH	3	Client <--> Server	Publishing messages
PUBACK	4	Client <--> Server	Publishing request acknowledged
PUBREC	5	Client <--> Server	Message received (QoS 2 phase 1)
PUBREL	6	Client <--> Server	Message released (QoS 2 phase 2)
PUBCOMP	7	Client <--> Server	Publishing ends (QoS 2 phase 3)
SUBSCRIBE	8	Client ---> Server	The client sends a subscription request to the server.
SUBACK	9	Server ---> Client	The server confirms the subscription request.
UNSUBACRIBE	10	Client ---> Server	The client sends an unsubscription request to the server.
UNSUBACK	11	Server ---> Client	The server confirms the unsubscription request.
PINGREQ	12	Client ---> Server	Heartbeat message sent by the client

Name	Value	Packet Flow	Description
PINGRESP	13	Server ---> Client	Heartbeat response from the server
DISCONNECT	14	Client ---> Server	Disconnection request sent by the server
Reserved	15	Disabled	Packet reserved

Figure 1-2 Format of MQTT Messages

Overview

Feature	Description
MQTT Connection	Establishes a basic MQTT connection.

1.2.1 MQTT Connection

MQTT enables communication between remote sensors and control devices in a low-bandwidth and unstable network environment.

Working Principle

MQTT provides the following functions:

1 Uses the publish/subscribe messaging mode to broadcast messages to multiple clients.

Compared with a similar messaging mode, Extensible Messaging and Presence Protocol (XMPP), MQTT eliminates information redundancy and transmits data more efficiently.

2 Transmits messages with the payload content blocked.

3 Provides network connections based on TCP/IP.

Typically, MQTT is based on a TCP connection. Some MQTT versions are based on User Datagram Protocol (UDP), such as MQTT-SN. Different connection modes have their advantages and disadvantages.

4 Supports three message publishing modes to flexibly control the service quality.

- At most once

Message push completely relies on the underlying TCP/IP network. Messages may be lost, and repeated messages may occur. This mode can be used for ambient sensor data because the lost data will soon be transmitted for the second time. In this mode, messages are usually pushed through common apps. If a client is disconnected from the network when a message is pushed, the message will be lost and the client will not receive the message after reconnecting to the network.

- At least once

This mode ensures that messages can reach the destination. However, repeated messages may occur.

- Only once

This mode ensures that messages can reach the destination only once. If messages are repeated or lost, the result may be incorrect in some systems, such as the billing system. The message publishing service of the highest quality applies to these systems with strict requirements. This mode can also be used to push messages of IM apps.

5 Minimize protocol exchange to reduce network traffic.

In IoT and other environments, the computing capability of clients is poor and the network bandwidth is low, making it difficult to ensure normal network transmission. The transmission overhead of MQTT is small, and the header has a fixed length of only 2 bytes, which ensure transmission in a low-power and low-bandwidth environment.

6 Inform clients when the connection is interrupted.

Use the Last Will and Testament mechanisms to notify other devices subscribing to the same topic that the device sending the last will is disconnected.

1.3 Configuration

Configuration	Description and Command	
Establishing a Basic MQTT Connection	**mqtt-server enable**	Enables the MQTT broker service.
	mqtt-server authen login { **default-user** | **local** }	Configures the authentication mode for MQTT server login.
	mqtt-server authen aaa-config	Configures the number of attempts and timeout interval for AAA server authentication.
	mqtt-server port	Configures the port number used by MQTT.
	mqtt-server tls-port	Configures the TLS port number used by MQTT.
	mqtt-client broker username	Configures the username for the MQTT broker.
	mqtt-client broker password	Configures the password for the MQTT broker.
	mqtt-client use-tls	Configures TLS encryption for the MQTT client.

1.3.1 Establishing a Basic MQTT Connection

Configuration Effect

The server configured with MQTT enables an ordered, reliable, and bidirectional transmission connection with clients to realize topic subscription and message push.

Notes

N/A

Configuration Step

Enabling the MQTT Broker Service

- Enable the MQTT broker service on the server in global configuration mode.

Command	**mqtt-server enable**
Parameter Description	N/A
Defaults	The MQTT broker service is disabled.
Command Mode	Global configuration mode
Usage Guide	After the MQTT broker service is enabled, MQTT clients can connect to the broker to subscribe to topics and publish messages.

Configuring an Authentication Mode for MQTT Server Login

- Configure an authentication mode for MQTT server login on the broker in global configuration mode.

Command	**mqtt-server authen login** { **default-user** | **local** }
Parameter Description	N/A
Defaults	Local login is employed.
Command Mode	Global configuration mode
Usage Guide	Upon receiving a login request from the broker, the device selects AAA local authentication, AAA server authentication, or authentication exemption based on the configured authentication mode.

Configuring the Number of Attempts and Timeout Interval for AAA Server Authentication

- Configure the number of attempts and timeout interval for AAA server authentication on the broker in global configuration mode.

Command	**mqtt-server authen aaa-config** { **retry** *times* | **timeout** *second* }
Parameter Description	*times*: Indicates the number of attempts for AAA server authentication. The value range is from 1 to 100. *second:* Indicates the timeout interval, in seconds. The value range is from 0 to 300. The value 0 indicates waiting for the AAA server to time out.
Defaults	The number of attempts is 1 and the timeout interval is 4s.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the number of attempts and timeout interval for AAA server authentication during server login. You are advised not to change the number of attempts and timeout interval. If the number of attempts exceeds a limit or an improper timeout interval is configured, AAA authentication may be locked for 15 minutes. The lock can be canceled by running the **clear aaa local user lockout all** command.

Configuring the Port Number Used by MQTT

- Configure the port number used by MQTT on the server in global configuration mode.

Command	**mqtt-server port** *port*
Parameter Description	*port*: Indicates the port number. The value range is from 1025 to 65535.
Defaults	The port number is 1883.
Command Mode	Global configuration mode
Usage Guide	The default port number is 1883. The port number can be reconfigured.

Configuring the TLS Port Number Used by MQTT

- Configure the TLS port number used by MQTT on the server in global configuration mode.

Command	**mqtt-server tls-port** *port*
Parameter Description	*port*: Indicates the port number. The value range is from 1025 to 65535.
Defaults	The TLS port number is 8883.
Command Mode	Global configuration mode
Usage Guide	The default TLS port number is 8883. The port number can be reconfigured.

Configuring the Username for the MQTT Broker

- Configure the username for the MQTT broker on the client in global configuration mode.

Command	**mqtt-client broker username** *username*
Parameter Description	*username*: Indicates the username of the MQTT broker.
Defaults	The username is **ruijie**.
Command Mode	Global configuration mode
Usage Guide	The username and password are required for MQTT broker authentication. Configure the username before connecting to the server.

Configuring the Password for the MQTT Broker

- Configure the password for the MQTT broker on the client in global configuration mode.

Command	**mqtt-client broker password** *password*
Parameter Description	*password*: Indicates the password of the MQTT broker.
Defaults	The password is **Ruijie_mosquitto_pwd**.
Command Mode	Global configuration mode
Usage Guide	The username and password are required for MQTT broker authentication. Configure the password

	before connecting to the server.

Configuring TLS Encryption for the MQTT Client

- Configure TLS encryption for the MQTT client in global configuration mode.

Command	**mqtt-server enable**
Parameter Description	N/A
Defaults	TLS encryption is configured.
Command Mode	Global configuration mode
Usage Guide	TLS encryption is employed for the MQTT client by default. To disable TLS encryption, run the **no** form of the command.

Verification

N/A

Configuration Examples

Enabling the MQTT Broker

Configuration Steps	• Use this command to enable the MQTT broker.

Server	`Hostname> enable`
	`Hostname# configure terminal`
	`Hostname(config)# mqtt-server enable`

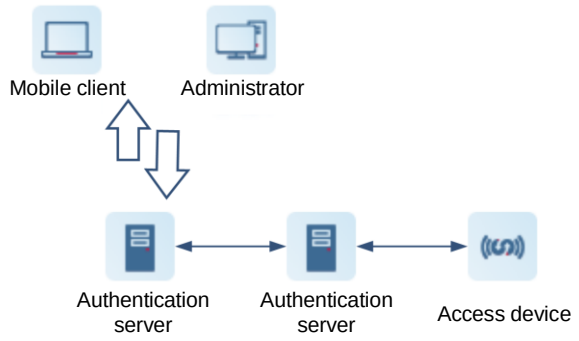
1.5 Configuration Examples



1.5.1 Configuring Basic MQTT Functions

1.5.1.1 Requirements

Enable the MQTT function and establish an MQTT message channel.

1.5.1.2 Topology

Figure 1-3 Topology for Basic MQTT Functions

1.5.1.3 Notes

- The link between the MQTT server and device is reachable.
- The MQTT broker service is enabled on the MQTT server.

1.5.1.4 Procedure

Enable the MQTT broker.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# mqtt-server enable
```

Configure AAA local authentication with the username and password for the MQTT broker.

```
DeviceA> enable
DeviceA# configure terminal
DeviceA(config)# mqtt-server login local
DeviceA(config)# username mqtt_user password Mqtt_password
```

Configure the username and password for the client.

```
DeviceA> enable
DeviceA# configure terminal
```

```
DeviceA(config)# mqtt-client broker username mqtt_user
DeviceA(config)# mqtt-client broker password Mqtt_password
```

1.5.1.5 Verification

Run the **show mqtt clients** command on the MQTT client to display MQTT client information.

```
DeviceA#show mqtt clients
count: 2

id: ac-001a.2c18.82af
    sock: 580
    username: DeviceA
    address: 127.0.0.1
    sub_count: 5
    last_msg_in: 408672
    next_msg_out: 408687

id: am/c0b8.e64e.e374/2
    sock: 1415
    username: DeviceA
    address: 16.30.49.1
    sub_count: 4
    last_msg_in: 408672
    next_msg_out: 408687
```

1 Configuring RPCAP

Whether this function is supported depends on the product version.

1.1 Overview

Remote Packet Capture Protocol (RPCAP) is a protocol used for remote wireless sniffing. Remote packet capture enables users to collect wireless fault information conveniently and promptly, troubleshoot wireless client faults in time, and improve wireless network quality.

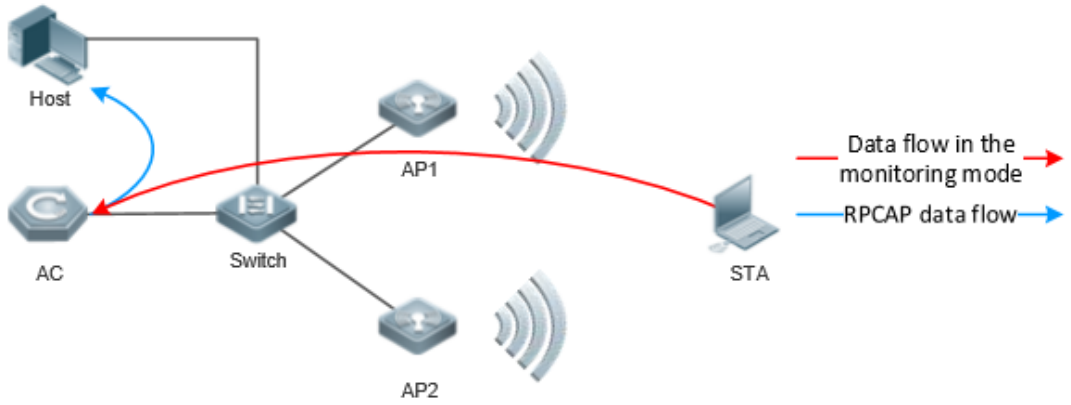
The remote packet capture function captures wireless packets sent and received on the radio port of an access point (AP) by accessing and controlling the AP through a remote host. This function, making full use of the AP deployed in the wireless network, can realize wireless data capture on the entire network and remotely analyze the captured wireless data in real time.

Remote packet capture works in a listening mode, dedicated to sniff wireless packets within its signal coverage scope. When packets are being captured in the listening mode, connection status and packet interaction of users associated with the corresponding RF port cannot be guaranteed.

Protocols and Standards

N/A

1.2 Applications



Application	Description
Remote Packet Capture in Fit AP Mode	In fit AP mode, enable the wireless sniffing service on the access controller (AC). The remote host sniffs packets on the radio port of the fit AP through packet sniffing tools.

1.2.1 Remote Packet Capture in Fit AP Mode

Scenario

In fit AP mode, the remote host enables the monitoring mode on the radio 1 port of the AP 1 through packet sniffing tools that support RPCAP and captures wireless packets (including packets between the STA and the radio 1 port of the AP 2 which shares the same channel with the radio 1 port of the AP 1).

Figure 1-1 RPCAP Remote Packet Capture in Fit AP Mode

Note: Switch: Indicates a switch.
AC: Indicates a wireless controller.
Host: Indicates a remote host.

Deployment

- Enable the remote packet capture service on the AC.
- Configure the radio 1 port of the AP 1 as the port for packet capture in the AP 1 configuration mode on the AC.
- Use Wireshark on the remote host to sniff packets.

1.3 Features

Basic Concepts

STA, AP and AC

STA: Indicates wireless station with wireless network interface cards (NICs), for example, a laptop or a mobile phone.

AP: Indicates the wireless access point that provides wireless signals for STAs to access the network.

AC: Indicates the wireless controller that provides wireless connection and related services.

Control Channel and Data Channel

RPCAP uses the control channel and data channel to communicate with the packet sniffing tool.

Control channel: Transmits signaling based on reliable TCP connection.

Data channel: Transmits captured data based on TCP or UDP.

CAPWAP Tunnel

On the fit AP network, the AC manages all APs through a Control and Provisioning of Wireless Access Points (CAPWAP) tunnel. Control policies sent to the APs do not need to be independently configured on the APs. The CAPWAP protocol establishes the control channel and data channel between the APs and the AC. The control channel is used by the AC to configure the APs and used by the APs to send event advertisements to the AC. The data channel is used to send data packets between the APs and the AC.

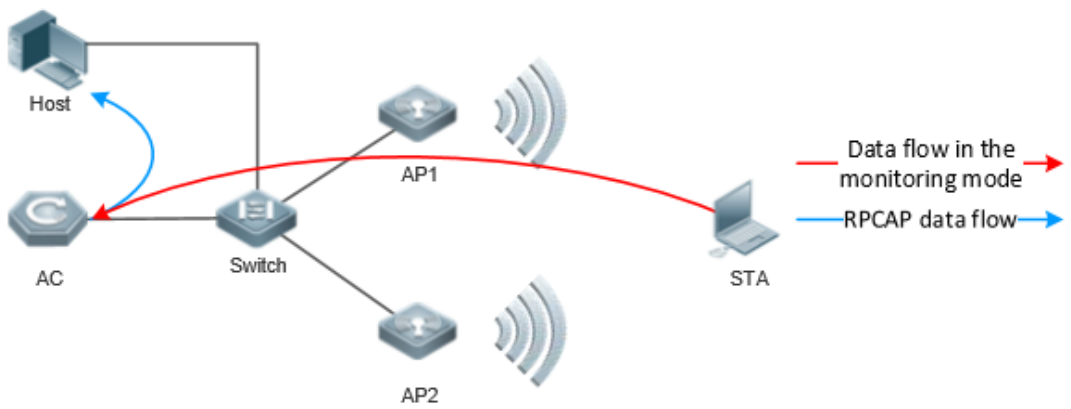
Features

Feature	Description
Remote packet capture function	Indicates that a remote host accesses an AP and captures packets sent and received on the radio port of the AP.

1.3.1 Remote Packet Capture Function

The remote packet capture function allows a remote host to access an AP and capture packets sent and received on the radio port of the AP. This function realizes wireless data sniffing on the entire network and remotely analyzes the sniffed wireless data in real time.

Working Principle



The remote packet capture function is based on the RPCAP protocol. RPCAP uses the control channel and data channel to communicate with the packet sniffing tool. The control channel is used to transmit signaling based on reliable TCP connection. The data channel is used to transmit captured data based on TCP or UDP. The RPCAP protocol defines a total of 18 control message types, including authentication, interface retrieval, sampling rate, filter rules, statistics handling, and control for initiating, stopping, and terminating sniffing operations. Additionally, it defines a data message type dedicated for identifying sniffed data packets.

The working principle of remote packet capture involves implementing the RPCAP protocol on Ruijie ACs. This enables remote hosts to control the wireless sniffing process on the radio port of APs which are managed by ACs and analyze the wireless data in real time using RPCAP-supporting sniffing tools. The following figure shows the data flow and working process of remote packet capture:

The remote host accesses, controls, and enables the wireless sniffing function on the radio port of the AP.

1. The radio port of the AP begins wireless sniffing.
2. The AP adds antenna information to the captured wireless packets and sends them to the AC through the CAPWAP tunnel.
3. The AC encapsulates the wireless packets with the RPCAP protocol header and sends them to the remote host.
4. The remote host uses a tool that supports RPCAP (such as Wireshark) to analyze and process the packets.

Figure 1-2 Remote Packet Capture Data Flow

Note: Switch: Indicates a switch.
AC: Indicates a wireless controller.
Host: Indicates a remote host.

1.4 Configuration

Configuration	Description and Command	
Configuring the Wireless Sniffing Function	(Mandatory) It is used to configure the wireless sniffing function on a specified AP radio port.	
	wlan-cap enable	Configures the wireless sniffing function on a radio port.
Configuring RPCAP Remote Access Information	(Optional) It is used to configure the listening TCP port accessed remotely by RPCAP and login information for remote host access.	
	rpcap port	Configures the listening TCP port number.
	rpcap login	Configures login information for remote host access.
	wlan-cap	Creates or enters the sniffing configuration mode.
Configuring the Packet Sniffing Policy	(Optional) It is used to configure the channel for packet capture and the forwarding mode for sniffed packets.	
	forward	Configures the forwarding mode for sniffed packets.
Enabling Wireless Sniffing	(Mandatory) It is used to enable or disable the wireless sniffing service.	
	wlan-cap	Enters the wireless sniffing mode.
	service enable	Enables/Disables the wireless sniffing service.

1.4.1 Configuring the Wireless Sniffing Function

Configuration Effect

Enable the wireless sniffing function on the specified RF port of the fit AP.

Notes

N/A

Configuration Steps

Configuring the Wireless Sniffing Function

- Mandatory.
- To implement remote wireless sniffing on a specified port, add the port into the sniffing port list on the AP.
- Use the **wlan-cap enable radio** *radio-id* command to enable the wireless sniffing function on this port.

- When the radio port of the AP is added into the wireless sniffing port list, the wireless sniffing function will be enabled on this port.

Command	**wlan-cap enable** { **radio** *radio-id* | **eth** *eth-id* }
Parameter Description	*radio-id*: Indicates the RF port ID. *eth-id*: Indicates the Ethernet port ID.
Defaults	The wireless sniffing function is disabled by default.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	The wireless sniffing function can be enabled only on the RF port of the online AP that supports wireless sniffing.

Verification

Run the **show wlan-cap interface** command to check whether the wireless sniffing function is enabled.

Configuration Example

Enabling Wireless Sniffing on the Specified RF Port of the AP in Fit AP Mode

Configuration Steps	Use this command to enable the wireless sniffing function on radio 1 of online AP 1. The wireless sniffing function on radio 1 of offline AP 2 fails to be enabled.
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# ap-config AP1 Hostname(config-ap)# wlan-cap enable radio 1 Hostname(config-ap)# exit Hostname(config)# ap-config AP2 Hostname(config-ap)# wlan-cap enable radio 1 The ap is not online.
Verification	Run the following command to display wireless sniffing configuration on a specified port.
AC	Hostname# show wlan-cap interface Wlan capture interface info: Total Interface : 2 Total capturing Interface : 0 Total Idle Interface : 2 AP Name MAC Address Type Index Channel Status Users ----- --------- -------------- ----- ----- ------- ------- ----- AP1 00d0.f822.33d0 radio 1 11 Idle 0

Common Error

N/A

1.4.2 Configuring RPCAP Remote Access Information

Configuration Effect

- Configuring RPCAP remote access information includes configuring the listening TCP port for RPCAP remote access and login information for remote host access
- The listening TCP port for RPCAP remote access is port 2002 by default.

Notes

- The wireless sniffing configuration mode must be entered first.
- The listening port can be configured only when wireless sniffing is disabled. The configured TCP port must be a currently idle port. (Use the **show tcp port** command to check the status of TCP ports.) Otherwise, a port binding failure may occur when wireless sniffing is enabled (the console will display related information).
- Login information can be configured only when wireless sniffing is disabled. The maximum length of both the username and the password is 64 characters.
- When RPCAP packets are being captured in listening mode, connection status and packet interaction of users associated with the corresponding RF port cannot be guaranteed.

Configuration Steps

Entering the Wireless Sniffing Configuration Mode

- Optional.
- The listening port and login information can be configured only on the AC.

Command	**wlan-cap**
Parameter Description	N/A
Defaults	The wireless sniffing configuration mode is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Listening Port

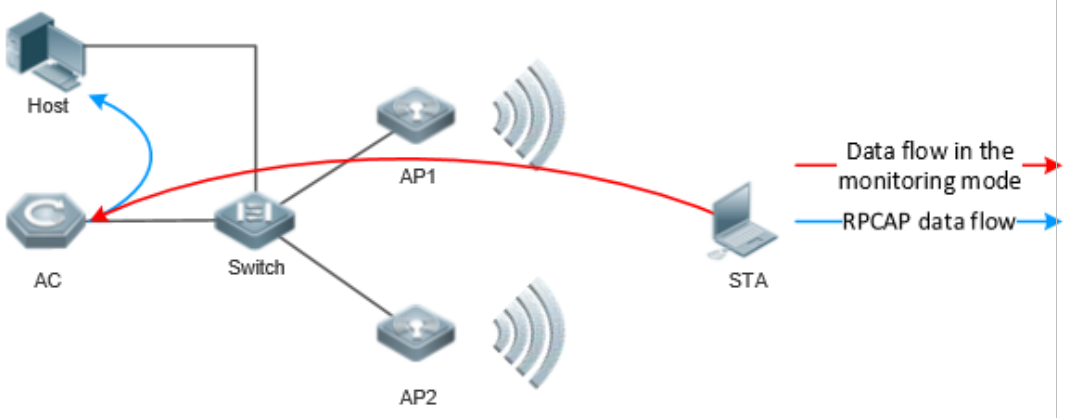
- Optional.
- The listening port can be configured only on the AC.

Command	**rpcap port** *port-value*
Parameter Description	**port-value**: Indicates the listening port number. The value ranges from 1 to 65535.
Defaults	The default value is 2002.
Command Mode	Wireless sniffing configuration mode
Usage Guide	N/A

Configuring Login Information

- Optional.
- Login information for remote host access can be configured only on the AC.

- Configuring RPCAP remote access information includes configuring the port to be accessed and the username and password used for remote host login.



Command	**rpcap login** *username password*
Parameter Description	*username*: Indicates the username used for login. *password*: Indicates the password used for login.
Defaults	No username and password are configured by default.
Command Mode	Wireless sniffing configuration mode
Usage Guide	N/A

Verification

Run the **show wlan-cap config** command to display wireless sniffing configuration.

Configuration Example

Setting the Listening Port Number of the AC to 65535 in the Fit AP Mode

Scenario **Figure** 1-2	
Configuration Steps	● Use this command to enter the wireless sniffing configuration mode and set the listening port to 65535 for RPCAP remote access.
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#wlan-cap Hostname(wlan-cap)#rpcap port 65535
Verification	Run the following command to display wireless sniffing configuration.
AC	Hostname#show wlan-cap config ========================== Wlan-cap-config ====================== Listen port: 65535 Login info: Anonymous Forward: Central Service enable: No

Configuring Login Information for the AC

Configuration Steps	● Use this command to enter the wireless sniffing configuration mode and set the username and password for RPCAP remote access to **wlan-capture**.
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# wlan-cap Hostname(wlan-cap)# rpcap login wlan-capture wlan-capture
Verification	Run the following command to display wireless sniffing configuration.
AC	Hostname# show wlan-cap config ========== Wlan-cap-config ========== Listen port: 2002 Login info: wlan-capture : wlan-capture Forward: Central Service enable: No

Common Error

N/A

1.4.3 Configuring the Packet Sniffing Policy

Configuration Effect

- A packet sniffing policy can be configured to obtain packets from the channel of the current AP radio and to specify whether the packets obtained by the AP are forwarded to the remote host directly by the AP or forwarded by the AC.

Notes

- N/A

Configuration Steps

↘ Configuring the Forwarding Mode

- Optional.
- The forwarding mode can be configured only when wireless sniffing is disabled. It is configured on the AC.
- Configure a packet sniffing policy for the remote host to specify the AP channel for sniffing and determine whether the packets captured by the AP are forwarded to the host by the AC or directly by the AP.

Command	**forward** { **central** | **local** }
Parameter Description	**central**: Indicates centralized forwarding. Packets captured by the AP are forwarded to the remote host by the AC. **local**: Indicates local forwarding. Packets captured by the AP are directly forwarded to the remote host.
Defaults	The forwarding mode is centralized forwarding by default.
Command Mode	Wireless sniffing configuration mode
Usage Guide	N/A

Verification

- Display wireless sniffing configuration to check the configured packet sniffing policy.

Configuration Example

Configuring the Forwarding Mode

Configuration Steps	• Use this command to enter the wireless sniffing configuration mode • and set the forwarding mode to local forwarding on the AC.
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# wlan-cap Hostname(wlan-cap)# forward local
Verification	Run the following command to display wireless sniffing configuration on the AC.
AC	Hostname#show wlan-cap config ========== Wlan-cap-config ========== Listen port: 2002 Login info: Anonymous Forward: Local Service enable: No

Common Error

N/A

1.4.4 Enabling Wireless Sniffing

Configuration Effect

The wireless sniffing service can be used normally only after the wireless sniffing function is enabled.

Notes

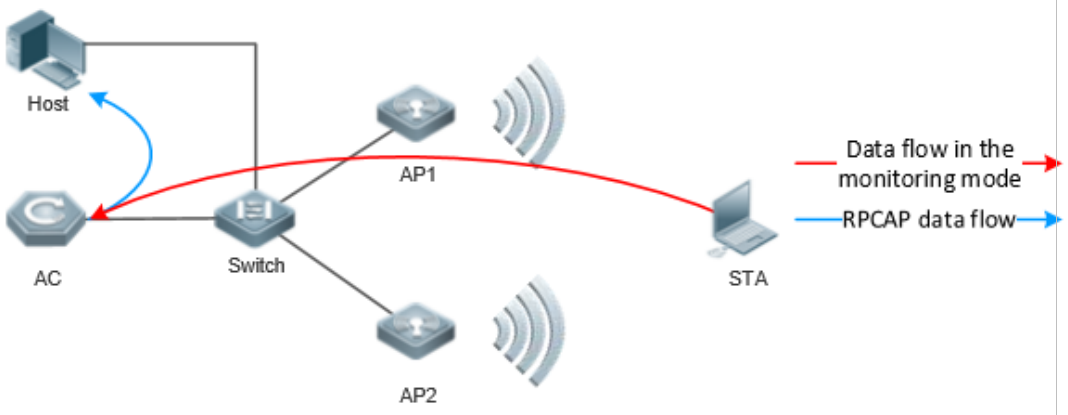
After wireless sniffing is enabled, only the sniffed channel can be modified, and the other configurations cannot be modified in this configuration mode.

Configuration Steps

Configuring Wireless Sniffing

- Mandatory.
- To use the wireless sniffing function on the AC, you must enable this service first.
- Use the **service enable** command to enable wireless sniffing.

Command	**service enable**
Parameter Description	N/A
Defaults	Wireless sniffing is disabled by default.
Command	Wireless sniffing configuration mode



Mode	
Usage Guide	After wireless sniffing is enabled, only the sniffed channel can be modified, and the other configurations cannot be modified in this configuration mode.

Verification

Run the **show wlan-cap config** command to check whether wireless sniffing is enabled.

Configuration Example

Configuring Wireless Sniffing on the AC

Scenario **Figure** 1-3	
Configuration Steps	● Use this command to enter the wireless sniffing configuration mode and enable wireless sniffing on the AC.
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# wlan-cap Hostname(wlan-cap)# service enable
Verification	Run the following command to display wireless sniffing configuration on the AC.
AC	Hostname#show wlan-cap config ========== Wlan-cap-config ========== Listen port: 2002 Login info: Anonymous Forward: Central Service enable: Yes

Common Error

N/A

1.5 Monitoring

Clearing

N/A

Displaying

Configuring Gateway

1. Configuring Application Identification
2. Configuring AEM
3. Configuring QoS-based Key Service Assurance
4. Configuring DNS-CACHE
5. Configuring RNFP

1 Configuring Application Identification

1.1 Overview

Application identification refers to classification and identification of a network data flow based on application characteristics. Application identification analyzes packet payload and flow characteristics to obtain the application protocol type of the data flow. It detects and identifies content at layers 4 to 7 of a packet and some protocols (such as HTTP, TCP, and RTP). The application identification technology classifies and identifies specific applications by matching feature codes in data packets.

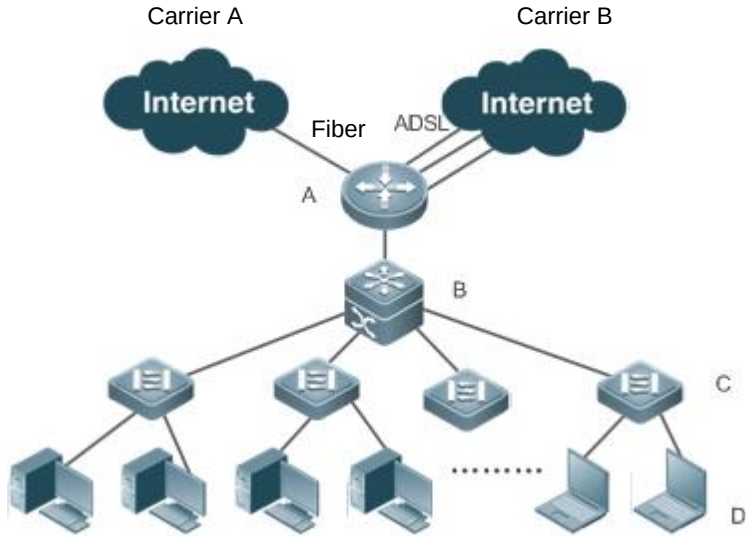
Application identification provides application class information for other functional modules, such as key service assurance, flow control, and traffic audit. The service module can be used for application quality analysis and application assurance policy control based on the service flow identification result.

At present, APP-ROUTE distributes application traffic depending on the initial packet identification technology. For the TCP flow, due to a lack of payload in the handshake packet, initial packet identification cannot be implemented based on the Deep Packet Inspection (DPI) rule.

1.2 Applications

Application	Description
Egress Gateway Deployment	Deploys application identification on the egress gateway.

1.2.1 Egress Gateway Deployment



Scenario

An egress gateway can connect to lines of different operators, for example, one fiber line of China Telecom and one Asymmetric Digital Subscriber Line (ADSL) of China Unicom, or one fiber line of China Telecom and multiple ADSLs of China Unicom.

Functions that rely on application identification include:

- Flow control
- Flow audit
- Application routing
- Content audit

Figure 1-1 Typical Application Scenario of Egress Gateway

Remarks	A indicates an egress gateway. B indicates a core switch. C indicates an access switch. D indicates an intranet PC.

Deployment

Basic NAT: Implement basic network address translation (NAT) to ensure that clients access the Internet normally.

Application identification: Indentify the application with traffic forwarding, and cooperate with the flow control module to implement application-based flow control.

Application routing: Enable traffic of heavy-traffic applications or key applications to be transmitted via specified egress ports based on application identification.

Multi-link load balancing: Distribute traffic of data flows to multiple links to ensure proper utilization of bandwidth.

Flow control: Implement rate limitation on P2P download traffic and realize functions such as traffic guarantee of key applications in combination with application identification.

Flow audit: Provide application-based traffic reports in combination with application identification, so that users can learn whether the egress bandwidth is sufficient and whether capacity expansion is needed.

1.3 Features

Basic Concepts

Data Flow

A data flow is a flow of packets with the same 5-tuple. According to protocols, data flows fall into three types: TCP flow, UDP flow, and IP flow (specific for non-TCP/UDP applications). The following table describes the 5-tuple of different data flows:

Flow Type	5-tuple Identifier

TCP flow	Source IP address|destination IP address|IP|TCP source port|TCP destination port
UDP flow	Source IP address|destination IP address|IP|UDP source port|UDP destination port
IP flow	Source IP address|destination IP address

Application Routing

To ensure effective utilization of network resources, it is proposed that enterprises or Internet cafes rent two (or multiple) WAN links and use one high-quality line for transmitting data of key applications that are sensitive to transmission delay and jitter and use the other low-quality line for transmitting data of P2P and other download applications. To realize the method, the egress gateway should be able to route packets based on applications. Different from the conventional IP routing technology that is based on the destination IP address of a packet, application-based routing (also referred to as application routing for short) is a routing and forwarding technology that is based on application types of data flows. With the application routing technology, traffic of data flows of different application types can be distributed to different egress ports, to separate data flows of key services from data flows of rate-limited services and to minimize impact. The major problem of application routing is how to identify the initial packet of data flows. For details about application routing, refer to relevant descriptions.

Initial Packet Identification

The capability of identifying the first packet of each flow is initial packet identification. This function ensures the application routing effect. If packet identification starts from the midway of a data flow, the flow will be transmitted along at least two lines, which will cause flow interruption. For the TCP flow, the initial packet is a handshake packet, and the first payload packet is a request packet.

Overview

Feature	Description
Signatures Database Upgrade	Upgrades the signature database of the gateway.
Application Protocol Object Management	Manages application protocol objects.
Application	Identifies the application with traffic forwarding, and cooperates with the flow control module to implement application-based flow control.
Application Identification of the AP with the Assistance of the AC	The AC assists the AP in performing application identification.
URL Identification	Enables URL identification.

1.3.1 Signatures Database Upgrade

As software is upgraded, packet characteristics of the software may change. With signature database upgrade, packet characteristics are updated to ensure accurate and effective application identification without software upgrade.

Working Principle

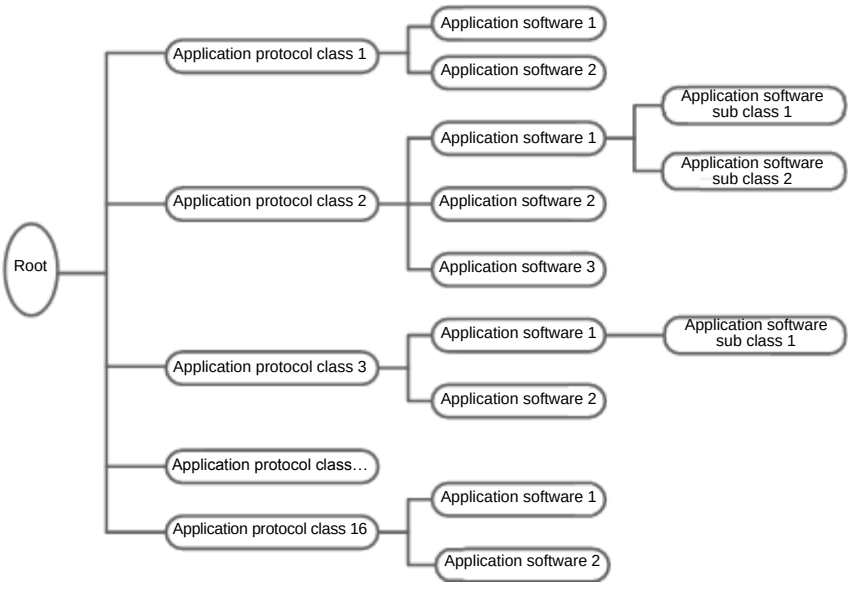
The professional signature database analysis team of Ruijie Networks formulates a mature characteristics analysis procedure. According to the procedure, the team analyzes packet characteristics of different applications and constantly update the characteristics to the signature database.

Users can download the signature database from the provided URL or obtain the signature database from the customer service center and then upgrade the local signature database on a Web portal. Alternatively, the signature database can be automatically updated to the latest version via Web settings from the Ruijie signature database server, which is convenient and ensures automatic and timely update.

Signatures database upgrade is a procedure of analyzing and processing the compressed signature database package (app_signature.upd) to form matching rules relevant to application identification.

After the signature database is upgraded successfully, application identification will store the signature database to the flash memory. After the gateway restarts, the signature database in the flash memory is automatically upgraded.

1.3.2 Application Protocol Object Management



By grouping application protocol objects, application protocol object management is simplified. By defining applications, users can define application protocol objects according to the 5-tuple information and add the user-defined application protocol objects into groups for management.

Working Principle

Protocol Objects of Signatures Database

By parsing the signature database, class objects are generated and a protocol tree is formed. Figure 1-2 shows the organization form.

Figure 1-2 Protocol tree

Applications are organized at three levels (application protocol class, application software, and application software sub class) to form a protocol tree in the system.

User-defined Application

Packets compliant with specific 5-tuple attributes are defined as one type of user-defined application.

Matching of user-defined applications is dedicated for TCP, UDP, and IP packets. Users extract the source and destination IP addresses, source and destination ports, and protocol ID from packets and query the data structures of the user-defined applications to determine whether there is a matched user-defined application.

User-defined applications are added to the same tree as other applications. The entire system has only one protocol tree, which contains all applications, including user-defined applications.

Application Grouping

Applications can be grouped by the default classes of the system, preset groups of the system, or user requirements.

According to the default classes of the system, applications are classified into the following types: instant messaging, VoIP, network game, video streaming, P2P, stock, Internet file transfer, email, database, network management protocol, routing protocol, security protocol, tunnel application, remote access protocol, network application update, online banking, network hard disk, software update, mobile Internet downloader, mobile Internet video/audio, mobile Internet web disk, mobile Internet software update, mobile Internet instant messaging, mobile Internet game, mobile Internet social network, mobile Internet web browsing, mobile Internet stock, and RFC. The classification is based on the actual signature database.

According to the preset groups of the system, applications are classified into the following groups: key application group, rate-limited application group, blocked application group, Other application group, Web_Group, Online_Video_Group, P2p_Video_Group, Download_Group, P2p_Group, Update_Group, Upload_Group, High_Group, Middle_Group, and Low_Group. The names of these application groups cannot be modified, but users can add the default classes of the system or an application of a class into the groups. Some system applications (with the index of x-0-0-0) belong to the other application group by default.

Applications can be grouped according to user requirements as well. Users can add the default classes of the system or an application of a class into the user-defined group.

1.3.3 Application Identification

Application identification identifies application attributes of data flows so that other modules execute policy actions according to the application attributes.

Working Principle

Application identification identifies the application attributes of data flows using technologies such as predictive identification, DPI, detective identification, Deep/Dynamic Flow Inspection (DFI), and length sequence identification.

Predictive Identification

Some application protocols have distinct flow characteristics. For example, a flow may contain information such as an IP address and a port for subsequent sessions. With an analysis on the flow information, flow characteristics are extracted and recorded. Subsequent flows that comply with the characteristics can be identified as flows of the application. The predicted characteristics will age after a period of time. Users can configure the aging time.

Detective Identification

Some application protocols may generate unknown encrypted data flows. The Ruijie gateway can identify the application type corresponding to this type of encrypted data flows using detection mechanisms.

DPI

DPI is specific for payloads of packets. By parsing the packet payloads based on the protocol layer, the DPI identifies the protocol type and port of the packets, encodes the payloads, and then matches the payload content with the strings in the signature database. Multiple models are used to match and identify the payload characteristics. If different match

results are obtained, the DPI selects a final result based on priorities. If the protocol type of an application has to be determined by identifying payloads of multiple packets, the status tracking module will trace the status.

QUIC Identification

Quick UDP Internet Connections (QUIC) identification is a part of DPI identification used to identify QUIC packets. After decoding QUIC packets, the system matches the decoding content with the feature string in the feature library to obtain the corresponding identification result.

DFI

DFI is a technology that identifies applications based on flow characteristics. Generally, session connections or data flow statuses vary with the specific application type, for example, the P2P download flow and voice flow. DFI identifies the characteristics of the data flows, builds flow classifiers, and then classifies the data flows using the classifiers, thereby implementing smart identification of application types.

QUIC Identification

When application identification is enabled, QUIC identification is enabled by default.

Run the **identify-application quic enable** command to disable QUIC identification.

After QUIC identification is disabled, applications that use QUIC packets cannot be identified. Typically, you are advised to enable QUIC identification.

Length Sequence Identification

Packet payloads generated by some applications, though encrypted, feature a fixed length. Based on this characteristic, encrypted P2P download flows can be identified. A typical example is the eDonkey encrypted download flow.

1.3.4 Application Identification of the AP with the Assistance of the AC

The AP performs application identification with the assistance of the AC.

Working Principle

In local forwarding mode, the AP mirrors some initial packets of a data flow to the AC (the number of mirrored packets vary with different protocols). The AC identifies the application based on the packets and sends the identification result to the AP to assist the AP in performing application identification.

1.3.5 URL Identification

Identify data stream attributes of users' Uniform Resource Locator (URL) access requests, so other modules can enforce corresponding policies based on the attributes.

Working Principle

HTTP identifies URL attributes corresponding to a data flow based on URL information in GET, POST, PUT, and HEAD request packets.

HTTPS identifies URL attributes corresponding to a data flow based on host information in client and server Hello packets.

Related Configuration

Enabling URL Identification

Run the **identify-url enable** command to enable URL identification globally.

Adding an HTTP port

Run the **identify-url http-port** *port-num* command to add the HTTP port used by a website whose URL is not identified by default port 80 or 8080 to the port identification list so that the website URL can be identified.

Adding an HTTPS port

Run the **identify-url https-port** *port-num* command to add the HTTPS port used by a website whose URL is not identified by default port 443 or 8080 to the port identification list so that the website URL can be identified.

Adding a URL Group

Run the **identify-url url-group** *group-id* [**name** *group-name*] command to add a custom URL group for a control policy, such as the ACL function.

Adding a URL Object

Run the **identify-url url-name** *url-name* **regexp** *regexp* command to add a custom URL object.

Adding the URL Object to the Custom URL Group

Run the **url** *url-name* command in URL group configuration mode to add the URL object to the custom URL group.

1.4 Configuration

Configuration	Description and Command	
Upgrading Signatures Database	(Mandatory) It is used to build a protocol tree and rules of the signature database.	
	Identify-application signature update	Triggers signature database upgrade.
Defining Applications	(Optional) It is used to define application rules.	
	identify-application custom name	Defines application rules.
Grouping Applications	(Optional) It is used to manage application protocol objects.	
	identify-application clear key-inhibitive-block-other group	Clears all the applications in the key application group, rate-limited application group, and blocked application group.
	identify-application custom-group	Defines a group.
	app-add	Adds applications to the user-defined group.
	app-del	Deletes applications from the user-defined group.

	identify-application block	Blocks applications from the user-defined group.
	identify-application key	Adds an application to the key application group.
	identify-application inhibitive	Adds an application to the rate-limited application group.
	identify-application other	Adds an application to the Other application group.
	identify-application web-group	Adds an application to Web_Group.
	identify-application online-video-group	Adds an application to Online_Video_Group.
	identify-application p2p-video-group	Adds an application to P2p_Video_Group.
	identify-application download-group	Adds an application to Download_Group.
	identify-application p2p-group	Adds an application to P2p_Group.
	identify-application update-group	Adds an application to Update_Group.
	identify-application upload-group	Adds an application to Upload_Group.
	identify-application high-group	Adds an application to High_Group.
	identify-application middle-group	Adds an application to Middle_Group.
	identify-application low-group	Adds an application to Low_Group.
Configuring A	(Mandatory) It is used to enable application identification.	
	identify-application enable	Enables application identification.
	identify-application proto-detect enable	Enables detective identification.
	identify-application proto-expect enable	Enables predictive identification.
	identify-application proto-expect timeout	Sets aging time of protocol information.
	identify-application dpi enable	Enables DPI.
	identify-application quic enable	Enables QUIC identification.
	identify-application dfi enable	Enables DFI.
	identify-application len-seq enable	Enables length sequence identification.
	identify-application app-db enable	Enables the application collection function.
Configuring the L2 Application Identification Feature of the AC	(Optional) It is used to enable the L2 application identification feature on the AC.	
	identify-application ac-enable compatible	Enables the L2 application identification feature on the AC.
Configuring Application Identification of the AP with the Assistance of the AC	**identify-application ap-enable**	Enables application identification of the AP with the assistance of the AC.
	identify-application ap-db	Configures information about application groups that can be identified by the AP.
Configuring URL Identification	(Mandatory) It is used to enable URL identification.	
	identify-url enable	Enables URL Identification
	identify-url http-port	Adds an HTTP port for URL identification.
	identify-url https-port	Adds an HTTPS port for URL identification.
	identify-url url-group	Adds a custom URL group.

	identify-url url-name	Configures a custom URL object.
	url	Adds a URL object to a custom URL group.
Configuring the Language in Which Application Identification Information Is Displayed	**identify-application signature language**	Configures the language in which application identification information is displayed.

1.4.1 Upgrading Signatures Database

Configuration Effect

Build a protocol tree of the signature database.

Create or update the signature database rules.

Notes

If the current database version of the gateway is consistent with the target database version, the upgrade fails.

Configuration Step

Upgrading Signatures Database

Mandatory.

Upgrade the signature database on the egress gateway. Obtain the signature database from the official website to the local PC, download the compression package of the signature database to the gateway, and then upgrade the local signature database on the web portal. Alternatively, the signature database can be updated in HTTP mode.

⚠ For details about HTTP upgrade, refer to relevant documents. This document mainly describes the configuration method of local upgrade. If the upgrade is implemented via a web portal or automatic update, users do not need to run relevant commands to trigger signature database parsing.

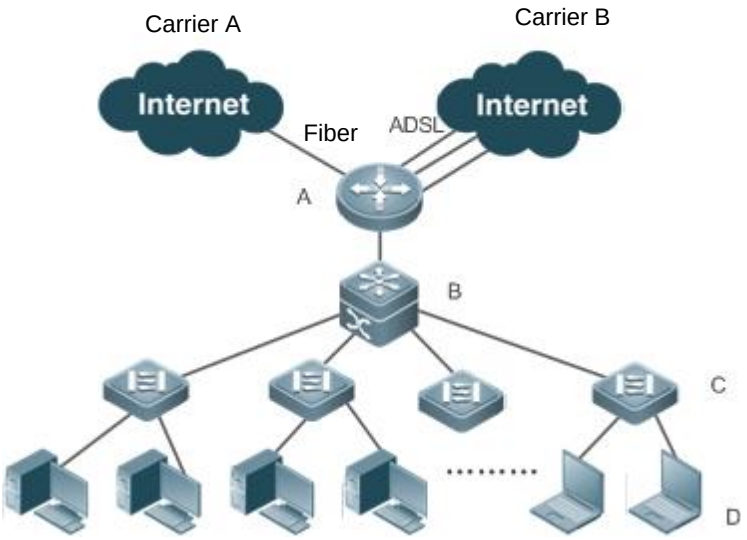
Verification

Check the version number of the signature database to determine whether the signature database is upgraded successfully.

Related Commands

Upgrading Signatures Database

Command	**Identify-application signature update**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Download the compression package of the signature database to the gateway and run this command to trigger signature database upgrade.



Displaying Version Number of Signatures Database

Command	**show identify-application version**

Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	N/A

Configuration Example

Upgrading Signatures Database

Scenario Figure 1-3	
Configuration Steps	1. Choose **Advanced** > **System Upgrade** > **Signatures Database Download** > **Download Application Database** to download the signature database package to the gateway. 2. Decompress the package, choose **Advanced** > **System Upgrade** > **Local Upgrade** to select the **app_signature.upd** file in the package directory, and click **Start** to upgrade the signature database. The system will prompt upgrade success after the upgrade.
A	`Hostname#*Apr 25 14:08:55: %DPI-5-LOCAL_UPDATE: Local signature database upgrading.` `Hostname#*Apr 25 14:10:14: %DPI-5-SIGNATURE_UPDATE: Signature database is upgraded successfully!`
Verification	3. Run the **show identify-application version** command to display the version number of the signature database.
A	`Hostname#show identify-application version` `Version:2013.05.22.13.05.22(V2.0)`

Common Errors

The current database version of the gateway is consistent with the target database version.

1.4.2 Defining Applications

Configuration Effect

Define applications and identify application traffic based on the 5-tuple information.

⚠ If the gateway does not have a signature database, user-defined applications cannot be identified.

Notes

User-defined applications fall into the following types:

Protocol type and source and destination ports

Protocol type, source IP address, and source port

Protocol type and source and destination IP addresses

Protocol type, destination IP address, and destination port

Pay attention to the following limits during configuration:

For the first type of applications, the source and destination ports cannot be set to **any** at the same time.

For the second type of applications, neither the source IP address nor the source port can be set to **any**.

For the third type of applications, the source and destination IP addresses cannot be set to **any** at the same time.

For the fourth type of applications, neither the destination IP address nor the destination port can be set to **any**.

A single IP address or an IP address segment can be configured. In the IP address segment, the number of IP addresses cannot be greater than 32 and the IP addresses must be consecutive.

Users can add characteristics to an existing application or application class. The original characteristics of the existing application or application class are not affected but are less prioritized than the user-defined application characteristics.

The name of a user-defined class contains no more than 31 characters, and the name of a user-defined application contains no more than 27 characters.

If user-defined applications share a source or destination IP address, a maximum of 16 port configurations can be configured for the applications. For example, for the combination of destination IP address + destination port, the possible configurations are IP:1.1.1.1 + port:80, IP:1.1.1.1 + port:100, and IP:1.1.1.1 + port:200.

Both the source IP address and the destination IP address cannot be 0.

Configuration Step

Run relevant commands in global configuration mode to create applications.

Verification

Check whether the user-defined applications are created successfully.

Related Commands

Defining Rules

Command	**identify-application custom name** *software-name* **class** *class-name* { **ip sip** { **any any** | *sip-low sip-high* } **dip** { **any any** | *dip-low dip-high* } **|** { **tcp** | **udp** } { **sport** { **any any** | *sport-low sport-high* } **dport** { **any any** | *dport-low dport-high* } | **sip** { **any any** | *sip-low sip-high* } { **sport** { **any any** | *sport-low sport-high* } | **dip** { **any any** | *dip-low dip-high* } } | **dip** { **any any** | *dip-low dip-high* } **dport** { **any any** | *dport-low dport-high* } } }
Parameter Description	*software-name*: Indicates an application name. *class-name*: Indicates an application class name. *sport-low*: Indicates the start source port. The value ranges from 0 to 65,535 or is **any**.

	sport-high: Indicates the end source port. The value ranges from 0 to 65,535 or is **any**. *dport-low*: Indicates the start destination port. The value ranges from 0 to 65,535 or is **any**. *dport-high*: Indicates the end destination port. The value ranges from 0 to 65,535 or is **any**. *sip-low*: Indicates the start source IP address (IPv4). *sip-high*: Indicates the end source IP address (IPv4). *dip-low*: Indicates the start destination IP address (IPv4). *dip-high*: Indicates the end destination IP address (IPv4).
Command Mode	Global configuration mode
Usage Guide	N/A

Displaying Defined Rules

Command	**show identify-application custom- rule**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Defining Rules

Configuration Steps	Define a rule.
	Hostname# configure terminal Hostname(config)#identify-application custom name XLgame class Custom Game tcp sport 1 10 dport 1 100
Verification	Display the defined rule on the gateway.
	Hostname#show identify-application custom-rule TYPE NAME CLASS SPL SPH DPL DPH SIPL SIPH DIPL DIPH ---- ---------- ---------- ----- ----- ----- ----- ---------- ---------- ---------- ---------- TCP XLgame Custom Game 1 10 1 100 any any any any

Common Errors

The specified limit conditions are not met. For details about the limit conditions, refer to the preceding Notes.

1.4.3 Grouping Applications

Configuration Effect

- Group applications so that the flow control and application routing modules can associate policies with the application groups.

Notes

An application cannot be added to two system groups at the same time, but the application and corresponding class can be added to different system groups. For example, for Tencent QQ (a type of instant messaging software) and the class of instant messaging software, the class of instant messaging software can be added to the key application group while Tencent QQ is added to the rate-limited application group. Without manual intervention, Tencent QQ will be added to the same system group (that is, the key application group) as the class of instant messaging software by default.

Application identification protocols fall into user-defined protocols and signature database protocols. The user-defined protocols prevail over the signature database protocols. If a protocol is self-defined by users and also exists in the signature database, the system prefers the user-defined protocol.

A maximum of 100 classes of application groups can be defined.

Configuration Step

Decide a grouping mode.

Create groups.

Add applications or application classes to the groups.

Verification

Check the current application grouping mode.

Display groups and confirm that the groups are created successfully.

Display the applications or application classes in the groups.

Related Commands

Configuring Grouping Mode

Command	**identify-application clear key-inhibitive-block-other group**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to delete applications from system groups.

Creating Groups

Command	**identify-application custom-group** *group-name*
Parameter Description	group-name: Indicates a group name.
Command Mode	Global configuration mode
Usage Guide	Use this command to add user-defined groups. A maximum of 100 classes of application groups can be defined. After the command is run, enter the group-group mode.

Adding Applications to Groups

Command	**app-add** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	application group configuration mode
Usage Guide	Use this command to add applications (including applications and application classes) to the groups.

Deleting Applications from Groups

Command	**app-del** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	application group configuration mode
Usage Guide	Use this command to delete applications from the groups.

Configuring Blocked Application Group

Command	**identify-application block** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring P2p_Group

Command	**identify-application p2p-group** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Update_Group

Command	**identify-application update-group** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Upload_Group

Command	**identify-application upload-group** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring High_Group

Command	**identify-application high-group** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Middle_Group

Command	**identify-application middle-group** *app-name*
Parameter Description	app-name: Indicates an application name.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Low_Group

Command	**identify-application low-group** *app-name*
Parameter Description	app-name: Indicates an application name.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Displaying Protocol Tree

Command	**show identify-application**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Application Classes

Command	**show identify-application class [class-name]**
Parameter Description	**class-name**: Indicates a class name.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Current Application Grouping Mode

Command	**show identify-application group-state**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Groups and Applications or Application Classes in Groups

Command	**show identify-application custom-group**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Blocked Application Group

Command	**show identify-application block**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Key Application Group

Command	**show identify-application key**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Rate-limited Application Group

Command	**show identify-application inhibitive**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Other Application Group

Command	**show identify-application other**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Web_Group

Command	**show identify-application web-group**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Online_Video_Group

Command	**show identify-application online-video-group**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying P2p_Video_Group

Command	**show identify-application p2p-video-group**
Parameter Description	N/A
Command	Privileged EXEC mode

Mode	
Usage Guide	N/A

Displaying Download_Group

Command	**show identify-application download-group**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying P2p_Group

Command	**show identify-application p2p-group**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Update_Group

Command	**show identify-application update-group**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Upload_Group

Command	**show identify-application upload-group**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Creating Groups and Adding Applications to Groups

Configuration Steps	1. Create a group. 2. In application group configuration mode, add applications to the group.

	Hostname# configure terminal Hostname(config)#identify-application custom-group mygroup Hostname(config-custom-group)#app-add BQQ Hostname(config-custom-group)#app-add MSN Hostname(config-custom-group)#exit
Verification	Display the groups and applications in the groups.
	Hostname#show identify-application custom-group system-group: Key_Group system-group: Unkey_Group system-group: Block_Group application: HTTP-single thread system-group: Other_Group custom-group: mygroup application: BQQ application: MSN (group)

Configuring System Groups

Configuration Steps	Add applications or application classes to the key application group.
	Hostname# configure terminal Hostname(config)#identify-application key BQQ
Verification	Display the groups and applications in the groups.
	Hostname#show identify-application key BQQ Hostname#

Common Errors

- The specified limit conditions are not met. For details about the limit conditions, refer to the preceding Notes.

1.4.4 Configuring Application Identification

Configuration Effect

- After application identification is configured, application types of different data flows can be identified and application information can be collected.

Notes

- If application identification is disabled, all application identification functions are invalid.
- The application identification functions rely on the signature database. If the gateway does not have a signature database, application identification is invalid.
- The application identification functions are enabled by default provided that application identification is enabled.
- If application identification is enabled during application use, applications may not be accurately identified. To ensure accurate identification, enable application identification first.

Configuration Steps

In global configuration mode, run relevant commands to enable application identification and application identification functions.

Verification

- Check the module status and statuses of different application identification functions.

Related Commands

Enabling Application Identification

Command	**identify-application enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling Detective Identification

Command	**identify-application proto-detect enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling Predictive Identification

Command	**identify-application proto-expect enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Setting Aging Time of Protocol Information

Command	**identify-application proto-expect timeout** *time-seconds*
Parameter	time-seconds: Indicates the aging time, in seconds. The value range is from 0 to 65535.

Description	
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling DPI

Command	**identify-application dpi enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling DFI

Command	**identify-application dfi enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling QUIC Identification

Command	**identify-application quic enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	QUIC identification is enabled by default.

Enabling Length Sequence Identification

Command	**identify-application len-seq enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling Application Collection

Command	**identify-application app-db enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Displaying Application Identification

Command	**show identify-application enable**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Predictive Identification Function

Command	**show identify-application proto-expect enable**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the prediction status and default aging time.

Displaying DFI Function

Command	**show identify-application dfi enable**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to display the prediction status and default aging time.

Configuration Example

Enabling Application Identification

Configuration Steps	1. Enable application identification. 2. Disable DFI.
	Hostname# configure terminal Hostname(config)#no identify-application dfi enable
Verification	Display application identification and the DFI function.
	Hostname#show identify-application enable on Hostname#show identify-application dfi enable dfi unable!

Enabling Predictive Identification

Configuration Steps	1. Enable the predictive identification function. 2. Enable the application collection function.
	Hostname# configure terminal Hostname(config)#identify-application proto-expect enable Hostname(config)#identify-application app-db enable

Verification	Display the predictive identification function.
	Hostname#show identify-application proto-expect enable Proto-expect is enable Proto-expect app_db is enable Proto-expect timeout is not set[0s]

Common Errors

- Application identification is disabled, causing enabling failure of an application identification function.

1.4.5 Configuring the Feature of Assistance with AP Application Identification on the AC

Configuration Effect

After application identification of the AP with the assistance of the AC is configured, the AP can identify an application category based on a data flow and implement policy-based control including key application guarantee on this basis.

Notes

This feature takes effect only for APs in local forwarding mode. The application identification feature on the AC needs to be enabled simultaneously.

An application signature database must have been created on the AC. Otherwise, this feature does not take effect.

Configuration Step

In global configuration mode, use commands to enable application identification of the AP with the assistance of the AC and add or delete information about application groups that can be identified by the AP.

Verification

Run the **show identify-application ap-db** command to check whether the application identification feature is enabled and display information about application groups that can be identified.

Related Commands

Enabling Assistance with AP Application Identification on the AC

Command	**identify-application ap-enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	1. This feature is supported only for APs in local forwarding mode. 2. After enabling application identification of the AP with the assistance of the AC, use the **identify-application ap-db** command to add information about application groups that can be identified by the AP to make the feature of application identification take effect on the AC. 3. After this feature is disabled, application group information added through the **identify-application ap-db** command will not be deleted.

Configuring an Application Group That Can be Identified by the AP

Command	**identify-application ap-db** { *group-name* | **any** }
Parameter Description	*group-name*: Name of a custom application group.
Command Mode	Global configuration mode
Usage Guide	1. Use this command to configure a custom or system application group that needs to be identified. Applications in the configured application group will be identified by the AP. 2. If all applications need to be identified by the AP, run the **identify-application ap-db any** command. 3. The **no identify-application ap-db any** command is used to cancel the preceding configuration only. Information about custom or system application groups added through the **identify-application ap-db** command will not be deleted.

Configuration Example

Enabling the Feature of Assistance with AP Application Identification on the AC

Configuration Steps	1. Enable application identification of the AP with the assistance of the AC. 2. Configure information about an application group to be identified as required.

	`Hostname# configure terminal`
	`Hostname(config)# identify-application ap-enable`
	`Hostname(config)# identify-application ap-db Key_Group`

Verification	The following example displays information about application groups that can be identified by the AP.

	`Hostname# show identify-application ap-db`
	`ap-identify-application:on`
	`application list:`
	`  Key_Group`

Common Errors

After enabling this feature on the AC in centralized forwarding mode, the AP still does not support the application identification feature.

1.4.6 Configuring the L2 Application Identification Feature on the AC

Configuration Effect

The AC can identify applications for L2 packets after this feature is enabled.

Notes

This feature can be enabled after the feature of assistance with AP application identification on the AC is disabled.

Configuration Steps

Run the corresponding command in global mode to enable this feature.

Verification

Run the **show running-config** command to check whether the L2 application identification feature is enabled.

Related Commands

1. Enabling the L2 Application Identification Feature on the AC

Command	**identify-application ac-enable compatible**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	1. This feature conflicts with the feature of assistance with AP application identification on the AC, so it can only be enabled after the feature of assistance with AP application identification on the AC is disabled. 2. After this feature is enabled, the AC can identify L2 service applications. This feature is compatible with the identification features of 11.9(6)W4B1 and earlier versions. 3. The VAC scenario is not supported.

Configuration Example

1. Enabling the L2 Application Identification Feature on the AC

Configuration Steps The following example enables the L2 application identification feature on the AC.

```
Hostname#configure terminal
Hostname(config)#identify-application ac-enable compatible
```

Verification Run the **show running-config** command to display the configuration.

```
Hostname# show running-config | inc identify-application ac-enable compatible
identify-application ac-enable compatible
```

Common Errors

Disable the feature of assistance with AP application identification on the AC before enabling the L2 application identification feature on the AC.

1.4.7 Configuring URL Identification

Configuration Effect

- Configure a custom URL object to identify HTTP or HTTPS data traffic based on URL matching information.
- Configure URL groups so that different ACLs can be applied to them.
- URL identification enables the device to identify URL information in data flows, and to apply different policies to different URLs.

Notes

- You can configure a maximum of 200 custom URL objects.

- You can add a maximum of 100 custom URL groups.
- If HTTP and HTTPS match characteristics of application identification and URL identification, and different policies are configured for application identification and URL identification, the blocking policy has the highest priority and takes effect first among all policies. For example, if rate limiting is configured in a WQoS profile and URL filtering is configured in an ACL for the same HTTP characteristics, URL filtering takes effect first and the packets are blocked, and rate limiting cannot be performed on the packets.
- Security channel has a higher priority than access control (policy control based on user role authentication). Free URL is a policy of security channel, while URL filtering based on user role is an access control policy. Therefore, if both free URL and URL filtering policies are configured, the free URL policy takes effect preferentially.
- A URL policy based on user role takes precedence over a global URL policy. If they are configured simultaneously, the URL policy based on user role takes effect preferentially.
- If a web page resource or sub-link no longer contains the URL of the parent page, it cannot be identified unless the URL of the subpage is also within the configured URL limit.
- If a browser uses the proxy function, URL identification becomes ineffective.
- In some scenarios, browsers use QUIC for data transmission, which causes URL filtering to take ineffective. The solution is to configure a QUIC application blocking policy, where UDP port 443 is used by default.
- Application identification includes the custom application identification protocol and application identification protocol of the signature database. In the system, custom protocol characteristics take precedence over protocol characteristics in the signature database. If an application protocol has both custom protocol characteristics and protocol characteristics of the signature database, the system matches custom protocol characteristics.
- IPv6 is not supported.
- Traffic identification on an AC's wired interface is not supported.

Configuration Step

Enabling URL Identification

Command	**identify-url enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the HTTP Port for URL Identification

Command	**identify-url http-port** *port-num*
Parameter Description	*port-num*: Indicates the port number. The value range is from 1 to 65535. Ports 80 and 8080 are supported by the system by default and cannot be configured or deleted.
Command Mode	Global configuration mode
Usage Guide	Run this command to add the HTTP port used by a website whose URL is not identified by default port 80 or 8080 to the port identification list so that the website URL can be identified.

Configuring the HTTPS Port for URL Identification

Command	**identify-url https-port** *port-num*
Parameter Description	*port-num*: Indicates the port number. The value range is from 1 to 65535. Ports 443 and 8080 are supported by the system by default and cannot be configured or deleted.
Command Mode	Global configuration mode
Usage Guide	If a website uses a non-default port (not port 443) as its HTTPS port to identify the website URL, you can run this command to add the HTTPS port number to the port identification list so that the interface can identify the website URL.

Creating a URL Group

Command	**identify-url url-group** *group-id* [**name** *group-name*]
Parameter Description	*group-id*: Indicates the ID of a URL group. The value range is from 1 to 511. *group-name*: Indicates the name of a URL group.
Command Mode	Global configuration mode
Usage Guide	1. This command is used to add a custom URL group or enter the URL group configuration mode if the URL group already exists. 2. A maximum of 100 custom URL groups can be added.

Creating a URL Object

Command	**identify-url url-name** *url-name* **regexp** *regexp*
Parameter Description	url-name: Indicates the name of a URL object. The value is a string of up to 63 characters. regexp: Indicates URL character matching information, which can contain a maximum of 99 characters. Only numerals, letters, and symbols are supported. The prefix http:// or https:// is not supported. Multi-level directories are not supported, that is, the directory symbol / is not supported.
Command Mode	Global configuration mode
Usage Guide	1. Fuzzy URL matching supports only domain name matching and does not support matching of lower-level directories. 2. URL character matching applies to both HTTP and HTTPS packets. 3. A maximum of 200 URL objects can be added.

Adding a URL Object to a URL Group

Command	**url** *url-name*
Parameter Description	url-name: Indicates the name of a URL object.
Command Mode	URL group configuration mode
Usage Guide	This command is used to add URL objects to a custom URL group.

Configuration Example

Configuring URL Identification

Configuration Steps

1. Enable URL identification.
2. Add HTTP port 60000 for URL identification.
3. Add HTTPS port 4430 for URL identification.
4. Create a URL object named **test** and configure the device to encapsulate the key character string baidu.com into protocol packets.
5. Create a URL group and set the group ID and group name to 5 and Web, respectively.
6. Add the created URL object **test** to the web group.

```
Hostname#config
Hostname(config)# identify-url enable
Hostname(config)# identify-url http-port 60000
Hostname(config)# identify-url https-port 4430
Hostname(config)# identify-url url-name test regexp *baidu.com*
Hostname(config)# identify-url url-group 5 name Web
Hostname(config-url-group)# url test
```

Verification

1. Run the **show identify-url enable** command to check whether URL identification is enabled.
2. Run the **show identify-url http-port** command to display HTTP ports for URL identification.
3. Run the **show identify-url https-port** command to display HTTPS ports for URL identification.
4. Run the **show identify-url url-name** command to display URL objects and packet matching information configured for each URL object.
5. Run the **show identify-url url-group** command to display URL groups and URL objects in each group.

Common Errors

More than 200 customized URL objects are added.

More than 100 custom URL groups are added.

1.4.8 Configuring the Language in Which Application Identification Information Is Displayed

Configuration Effect

The device displays identified application information based on the configured language.

Notes

Running this command triggers the signature database to be reloaded.

After the language is switched, the **identify-application custom name** and **identify-application custom-group** commands will be cleared. You need to reconfigure them.

After the language is switched, the **identify-application key** and **identify-application block** commands will be cleared. You need to reconfigure them.

Configuration Step

Run a command in global configuration mode to configure the language in which application identification information is displayed.

Verification

Run the **show running-config** command to display the configuration status of application language switching.

Run the **show identify-application class** command to display the language in which application identification information is displayed.

Related Commands

Configuring the Language in Which Application Identification Information Is Displayed

Command	**identify-application signature language** { **zh** | **en** }
Parameter Description	**zh**: Indicates that the application name and category are displayed in Chinese. **en**: Indicates that the application name and category are displayed in English.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Application Identification Information Displayed in English

Configuration Steps Configure application identification information displayed in English.

```
Hostname# configure terminal
Hostname(config)# identify-application signature language en
```

Verification Display the language in which application identification information is displayed.

```
Hostname#show identify-application class
HTTP 1-0-0-0
VOIP 2-0-0-0
```

Common Errors

N/A

1.5 Monitoring

Clearing

Command	Description
clear identify-url statistics	Clears URL identification packet statistics.

Displaying

Command	Description
show identify-application	Displays the application protocol tree information.
show identify-application block	Displays the applications or application classes that are added to the blocked application group.

show identify-application class	Displays the application class information.
show identify-application custom-group	Displays the application group information.
show identify-application custom- rule	Displays the user-defined application rules.
show identify-application download-group	Displays the applications or application classes that are added to Download_Group.
show identify-application enable	Displays application identification.
show identify-application group-state	Displays the grouping mode.
show identify-application high-group	Displays the applications or application classes that are added to High_Group.
show identify-application inhibitive	Displays the applications or application classes that are added to the rate-limited application group.
show identify-application key	Displays the applications or application classes that are added to the key application group.
show identify-application low-group	Displays the applications or application classes that are added to Low_Group.
show identify-application middle-group	Displays the applications or application classes that are added to Middle_Group.
show identify-application other	Displays the applications or application classes that are added to the Other application group.
show identify-application proto-expect enable	Displays the predictive protocol information.
show identify-application proto-detect enable	Displays the detective protocol information.
show identify-application version	Displays the version number of the signature database.
show identify-application ap-db	Displays information about application groups that can be identified by the AP and whether a feature is enabled or disabled.
show identify-url enable	Displays the application identification status.
show identify-url http-port	Displays the HTTP port information available for URL identification.
show identify-url https-port	Displays the HTTPS port information used for URL identification.
show identify-url statistics	Displays URL statistics.
show identify-url url-group [*group-id*]	Displays URL group information.
show identify-url url-name [*url-name*]	Displays custom URL information.

1 Configuring AEM

1.1 Overview

Application Experience Measurement (AEM) is used to measure the network performance between wireless users and application service nodes. Administrators can create an application group, add applications of interest to be measured to this group, and then configure this group as an application group of interest. AEM collects metrics between clients and servers that provide services for applications to measure the network performance of the applications of interest.

AEM can measure the following 32 metrics between wireless users and service nodes of applications in an application group of interest.

No.	Metric
1	Uplink traffic increment (byte)
2	Downlink traffic increment (byte)
3	Uplink packet number increment
4	Downlink packet number increment
5	Average server latency in TCP handshake (ms)
6	Average client latency in TCP handshake (ms)
7	Average air interface latency in TCP handshake (ms)
8	Client response latency (ms)
9	Server response latency or application latency (ms)
10	Number increment of TCP uplink retransmitted packets
11	Number increment of TCP downlink retransmitted packets
12	Number increment of TCP uplink out-of-order packets
13	Number increment of TCP downlink out-of-order packets
14	Average downlink air interface latency of application packets (ms)
15	Number increment of downlink application packets retransmitted over the air interface
16	Number increment of downlink application packets lost on the air interface
17	Number of active TCP flows of applications
18	Number of active UDP flows of applications
19	Number of new packet flows
20	Downlink packet sending times of the air interface
21	Average uplink TCP jitter (ms)
22	Average downlink TCP jitter (ms)
23	Average downlink jitter on the air interface (ms)
24	Number of TCP handshake failures
25	Number increment of uplink RTP packets
26	Number increment of downlink RTP packets
27	Number increment of lost uplink RTP packets

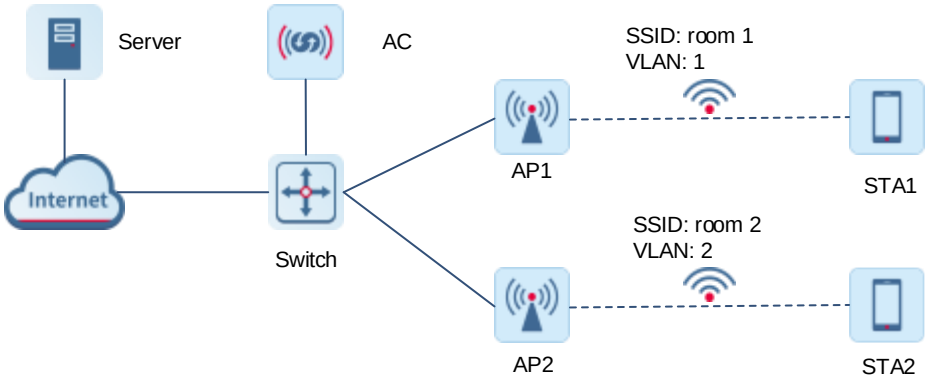
No.	Metric
28	Number increment of lost downlink RTP packets
29	Number increment of uplink RTP out-of-order packets
30	Number increment of downlink RTP out-of-order packets
31	Average uplink RTP jitter (ms)
32	Average downlink RTP jitter (ms)

The following sections describe the AEM function only.

Protocols and Standards

N/A

1.2 Applications



Application	Description
Measuring Application Experience of STAs in Fit AP Networking	Measures the network performance between STAs and the servers of the applications in an application group of interest in a fit AP scenario.

1.2.1 Measuring Application Experience of STAs in Fit AP Networking

Scenario

In a fit AP scenario, configure an application group of interest on the AC and deliver the application group of interest to APs. Then, measurement on applications of interest is automatically enabled on the APs. The APs collect metrics between STAs and the application server, including the packet transmission latency and the packet loss rate, and periodically report the information to the AC, as shown in the following figure.

Figure 1-1 AEM for STAs in Fit AP Networking

Remarks	Server: third-party application server on the remote end Switch: switch device AC: wireless access controller AP1 and AP2: wireless access points STA1 and STA2: client devices

Deployment

1. Enable application identification of the AC.
2. On the AC, enable application identification for APs.
3. Create an application group of interest.

1.3 Features

Basic Concepts

Application

An application (app) refers to the software program installed and run on a STA. Applications can be installed on smartphones, tablets, smart watches, or other devices to provide users with various network services, such as browsing web pages, sending emails, playing games, and holding video conferences.

Application of Interest

In various service scenarios, users have different requirements for applications. Therefore, network administrators need to have a comprehensive understanding of the user experience of specified applications. This helps them configure proper network management policies, thereby improving the user experience. Applications that administrators pay special attention to are known as applications of interest.

Application Group of Interest

To measure and manage the network experience of different applications, administrators can add the applications of interest to an application group and manage the application group to achieve unified management of the applications. Such an application group is called an application group of interest. The applications in an application group of interest are applications of interest.

RTP

Real-Time Transport Protocol (RTP) typically uses User Datagram Protocol (UDP) as the transport layer protocol. RTP is typically used to transmit real-time audio and video data over the Internet.

Overview

Features	Description
Measurement on Applications of Interest	Measures the packets of the applications in an application group of interest on STAs.

Features	Description
Collection Scale Limit	Adjusts the scale of measurement data collection on APs.

1.3.1 Measurement on Applications of Interest

On an AP, if an application identified by the application identification function belongs to an application group of interest, the AP collects statistics on packet flows of the application, and proactively reports them to the AC. Then, the AC measures the network performance of the application.

Working Principle

Measurement on applications of interest depends on application identification results. Upon receiving a packet, an AP performs application identification on the packet. If the application type is identified, the AP determines whether the application is a specified application of interest based on the application index. For applications of interest, the AP collects specific parameter information in packet flows based on the protocol characteristics of packets. The AP collects and summarizes information about applications of interest, and then proactively uploads the information to the AC.

1.3.2 Collection Scale Limit

Reporting information about applications of interest to the AC consumes a portion of network performance resources. Therefore, configure a proper policy for collecting information on applications of interest on the AC based on actual services. After the AC delivers the policy to APs, the APs report information about specified applications to the AC based on the policy.

Working Principle

When an AP summarizes the collected information about applications of interest, it limits the data specifications uploaded to the AC in three dimensions:

- Number of STAs for which application information is collected by each AP
- Number of applications of interest on each STA
- Number of data flows of each application of interest

1.4 Configuration

Configuration	Description and Command	
Configuring Measurement on Applications of Interest	⚠ (Mandatory)	
	app-experience app-group	Adds an application group of interest.
	⚠ (Optional) It is used to adjust the collection interval.	
	app-experience app-interval	Configures a collection interval for applications of interest.

Configuration	Description and Command	
Configuring an Application Information Collection Scale	(Optional) It is used to limit the number of STAs for which application information is collected by each AP to limit the data collection scale.	
	app-experience maximum-sta	Configures the maximum number of STAs for which application information is collected by each AP.
	(Optional) It is used to limit the number of applications of interest to be collected on each STA.	
	app-experience maximum-app	Configures the maximum number of applications of interest to be collected on each STA.
	(Optional) It is used to limit the number of packet flows to be collected for each application of interest.	
	app-experience maximum-flow	Configures the maximum number of packet flows to be collected for each application of interest.

1.4.1 Configuring Measurement on Applications of Interest

Configuration Effect

After an application group is configured as an application group of interest on the AC and is delivered to APs, measurement on applications of interest is automatically enabled on the APs. The APs periodically collect information on applications of interest and report the information to the AC.

Notes

- Before applying measurement on applications of interest, enable application identification of the AC and application identification for APs.
- Before applying measurement on applications of interest, ensure that application identification has been enabled for the system application group **any** on the APs.

Configuration Steps

Adding Application Group of Interest

- Mandatory.
- When an application group of interest is added, measurement on applications of interest is automatically enabled.

Command	**app-experience app-group** *custom-group-name*
Parameter Description	*custom-group-name*: Indicates the name of the application group. The value range is from 1 to 63 characters.

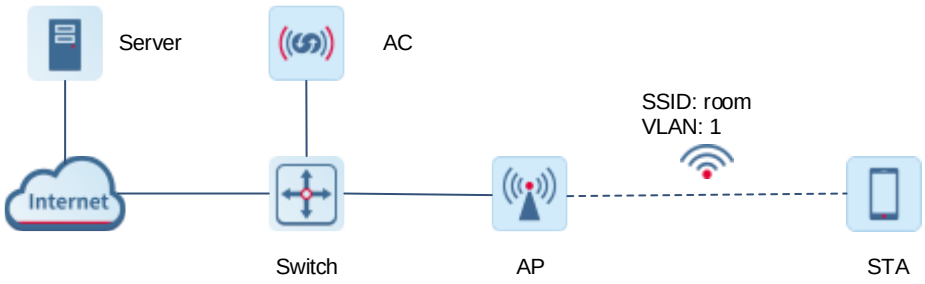
Defaults	No application group of interest is configured.
Command Mode	Global configuration mode
Usage Guide	1. Measurement on applications of interest depends on application identification results. Therefore, before applying measurement on applications of interest, enable application identification of the AC and application identification for APs. If application identification of the AC or application identification for APs is disabled, information on applications in the application group of interest cannot be collected. 2. Run the custom application group creation command of the application identification function to create an application group. Then, run this command to configure the created application group as an application group of interest. If an application group does not exist, the configuration fails. 3. Before applying measurement on applications of interest, ensure that application identification has been enabled for the system application group **any** on the APs. That is, verify that the **identify-application ap-db any** command has been executed. Application identification is enabled for the system application group **any** by default. If it is disabled, you need to manually enable it before applying measurement on applications of interest. After an application group is configured as an application group of interest, the applications in this application group become applications of interest.

Configuring an Application Information Reporting Interval for an Application Group of Interest

- Optional.

Command	**app-experience app-interval** *interval-time*
Parameter Description	*interval-time*: Indicates the interval for reporting collected information to the AC, in seconds. The value range is from 30 to 300.
Defaults	60s
Command Mode	Global configuration mode
Usage Guide	-

Verification



You are advised to perform the following two steps to verify the configuration and check whether the function takes effect.

- Run the **show running-config** command to display configuration.
- After a user uses an application of interest (such as opening the homepage of the application), run the **show app-experience table** command on the AC to display the collected application data.

For details about the **show** command output, see the command reference of the corresponding function.

Configuration Example

Adding Application Group of Interest

Scenario **Figure 1-2**	
Configuration Steps	1. Enable application identification of the AC. 2. Enable application identification for APs. 3. Create custom application group Download-Group and add application HTTP-DOWNLOAD to this application group. 4. Configure Download-Group as an application group of interest.

AC	`Hostname# configure terminal`
	`Hostname(config)# identify-application enable`
	`Hostname(config)# identify-application ap-enable`
	`Hostname(config)# identify-application custom-group Download-Group`
	`Hostname(config-custom-group)# app-add HTTP-DOWNLOAD`
	`Hostname(config-custom-group)# exit`
	`Hostname(config)# app-experience app-group Download-Group`

Verification	After STAs access applications in the application group of interest, run the **show app-experience table** command to display the collected data about the applications of interest.

AC	`Hostname# show app-experience table`
	`sta ip time appidx upbytes dnbytes uppkts dnpkts tssd tscd tsad tur tdr tudp tddp tump tdmp dad dadp dalp tfc ufc tsfc dap turj tdrj dadj tsft`
	
	`rtp_uppkts rtp_dnpkts rtp_uplost rtp_dnlost rtp_upser rtp_dnser rtp_upjt rtp_dnjt`
	`92B2.5FE5.51A8 192.168.30.61 2024-08-06 10:08:01 1-26-2-0 8802 326586 163 220 0 0 0 0 3 0 0 0 0 0 0 0 2 0 2 0 0 269 0 0`
	`92B2.5FE5.51A8 192.168.30.61 2024-08-06 10:07:56 1-26-2-0 9504 1122395 176 751 0 0 0 0 15 0 0 0 0 0 0 0 4 0 4 0 0 12 0 0`

Common Errors

- Application identification of the AC or application identification for APs is disabled.
- A non-existing application group is configured as an application group of interest.
- Application identification is disabled for the system application group **any** on the APs. That is, the **no identify-application ap-db any** command has been executed.

1.4.2 Configuring an Application Information Collection Scale

Configuration Effect

An AP reports the collected information to the AC based on the configured collection limit, including the collection range and number.

Notes

N/A

Configuration Steps

Configuring the Maximum Number of STAs for Application Information Collection per AP

- Optional.

Command	**app-experience maximum-sta** *max-number*
Parameter Description	*max-number*: Indicates the maximum number of STAs for which application information is collected by each AP. The value range is from 1 to 100.
Defaults	The number of STAs for which application information is collected by each AP is not limited.
Command Mode	Global configuration mode
Usage Guide	Run this command to limit the number of STAs for which application information is collected by each AP, thereby limiting the collection scale.

Configuring the Maximum Number of Applications to Be Collected on Each STA

- Optional.

Command	**app-experience maximum-app** *max-number*
Parameter Description	*max-number*: Indicates the maximum number of applications to be collected on each STA. The value range is from 1 to 10.
Defaults	5
Command Mode	Global configuration mode
Usage Guide	-

Configuring the Maximum Number of Packet Flows to Be Collected for Each Application

- Optional.

Command	**app-experience maximum-flow** *max-number*
Parameter Description	*max-number*: Indicates the maximum number of packet flows to be collected for each application. The value range is from 1 to 5.
Defaults	Packet flow statistics are not collected based on applications.
Command Mode	Global configuration mode
Usage Guide	-

Verification

Run the **show running-config** command to display the application information collection limit.

Configuration Example

N/A

1.5 Monitoring

Clearing

1 QoS-based Key Service Assurance

1.1 Overview

QoS-based key service assurance refers to policy services provided by Quality of Service (QoS) to guarantee the experience of key services. The policy services provided by QoS include modifying the Differentiated Services Code Point (DSCP) values of packets and configuring execution policies (such as rate limiting and blocking). QoS-based key service assurance includes key application assurance and key area assurance.

1.1.1 Key Application Assurance

For key application assurance, QoS policies are configured for applications based on application identification results. Application identification indicates that the access controller (AC) identifies the application (such as WeChat, QQ, Youku, and Fantasy Westward Journey) to which a packet belongs based on the packet features. On the AC, you can configure an application policy profile and define rules (such as configuring the DSCP value, packet discarding, and rate limiting for an application group) in the profile. An access point (AP) converts the DSCP value into an 802.11e priority and schedules and forwards packets based on the 802.11e priority, ensuring application-based QoS. Currently, a DSCP value can be configured only for downlink traffic.

If the priority configured for downlink traffic is higher than that of uplink traffic, the uplink traffic will be suppressed because the total channel bandwidth is fixed. If different priorities are set for traffic from different STAs, traffic with a higher priority can be accelerated theoretically. However, its bandwidth may not be improved because the air interface competition capabilities of STAs are determined by their drive and hardware.

This document only provides guidance on configuring key application assurance. For details about the guidance for application identification, see documents related to application identification.

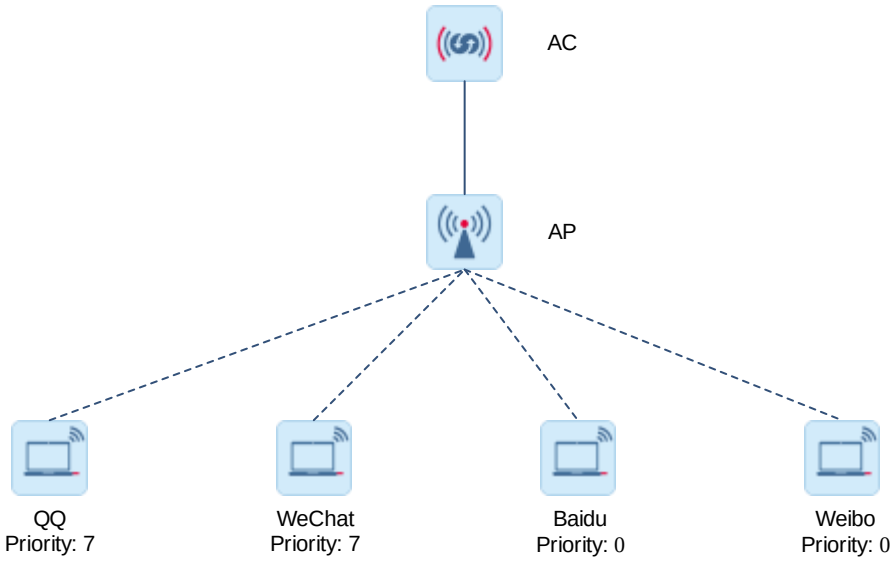
1.1.2 Key Area Assurance

In finance and enterprise campus network scenarios, when an important activity is held in a conference room or an area, network experience in the area needs to be preferentially guaranteed. For example, preferentially guarantee network services at the conference site during an annual meeting. Essentially, key area assurance preferentially guarantees the traffic of VIP users or key applications within a small scope to ensure preferred forwarding of key traffic.

Protocols and Standards

- IEEE 802.11e-2005: Amendment 8: Medium Access Control (MAC) QualityofServiceEnhancements, IEEE Computer Society
- Wi-Fi: WMM Specification version 1.1

1.2 Applications



Application	Description
Configuring QoS Policies for Key Application Assurance in Fit AP Networking	Fit AP networking is adopted, including at least one AC and one AP.

1.2.1 Configuring QoS Policies for Key Application Assurance in Fit AP Networking

Scenario

On a wireless local area network (WLAN), an AC is deployed and application-based priority control is configured for the WLAN on the AC to guarantee traffic for key applications such as Tencent-related applications.

Figure 1-1

Remarks	AC: wireless access controller AP: wireless access point

Deployment

- Configure an application profile on the AC.
- Associate the WLAN with the application profile.

1.3 Features

Basic Concepts

DSCP

DSCP is a QoS classification standard of Differentiated service (Diff-Serv) released by IETF in December 1998. In the type of service (ToS) field in the IP header of each packet, the used 6 bits and unused 2 bits are used to distinguish the priority. DSCP uses 6 bits, and the DSCP value ranges from 0 to 63.

802.11e priority indicates the priority of wireless packets, which is divided into eight levels (0–7).

The following table describes the default mapping between DSCP values and 802.11e priorities.

802.11e Priority	DSCP Value: Binary (Decimal)
0	BE:000000(0)
1	CS2:010000(16), AF21:010010(18), AF22:010100(20), AF23:010110(22)
2	CS3:011000(24), AF31:011010(26), AF32:011100(28), AF33:011110(30
3	CS1:001000(08), AF11:001010(10), AF12:001100(12), AF13:001110(14)
4	CS4:100000(32), AF41:100010(34), AF42:100100(36), AF43:100110(38)
5	CS5:101000(40), EF:101110(46)
6	CS6:110000(48)
7	CS7:111000(56)

Overview

Feature	Description
QoS Policies for Key Application Assurance	Configures DSCP priorities, packet discarding, and rate limiting based on applications.
QoS Policies for Key Area Assurance	Configures DSCP priorities based on key areas.
Configuring Application Traffic Statistics Collection	Collects traffic statistics of different applications and uploads the statistics to the cloud.

1.3.1 QoS Policies for Key Application Assurance

Working Principle

Based on traffic characteristics, the application identification component on the AC can identify applications and control the uplink and downlink DSCP priorities of different applications in the following ways:

Different DSCP values can be set for different applications in the downlink direction. When a packet is sent to an AP, the Wi-Fi Multimedia (WMM) function on the AP converts the DSCP value of the packet to an 802.11e priority. Then, the AP schedules the packet based on the priority, ensuring priority control of different applications.

Different DSCP values can be set for different applications in the uplink direction. When an uplink application packet is sent to an AP through the air interface, the packet is marked with the corresponding DSCP value. The upstream wired network device converts the DSCP value of the packet into the corresponding priority for scheduling.

The DSCP priorities of uplink and downlink packets can be flexibly controlled in different application scenarios, improving network performance and QoS. In addition, Packet discarding can be configured for specified applications to block unauthorized application traffic. Different rate limits can be configured for different applications, such as configuring a traffic rate limit for download applications to avoid excessive bandwidth consumption.

1.3.2 QoS Policies for Key Area Assurance

Working Principle

For key area assurance, specific APs are added to key areas. Clients that access in the key areas are considered as key clients. When common clients access key applications, the DSCP priorities of packets are re-marked by QoS to ensure preferred traffic forwarding.

The APs in key areas re-mark the key traffic with higher DSCP priorities so that the key traffic in the key area is preferentially processed. Key traffic includes traffic of VIP users, traffic of key applications, and traffic of VIP users and key applications. For example, when common users access common applications in key areas, packets are not preferentially forwarded. When common users access key applications in key areas, packets are preferentially forwarded based on configured DSCP values.

1.3.3 Configuring Application Traffic Statistics Collection

Working Principle

The application identification module on the AC can identify an application based on the packet flow feature of the application. The AP stores packet size information based on flow space and sends the information to the AC. Run different commands to check statistics from different dimensions.

1.4 Configuration

Configuration	Description and Command	
Configuring QoS Policies for Key Application Assurance	⚠ (Mandatory) It is used to configure an application profile.	
	app-profile	Adds or modifies an application profile.
	app-rule	Configures a QoS policy for an application group.
	⚠ (Mandatory) It is used to configure an application profile for a WLAN.	
	app-profile	Associates a WLAN with the specified application profile.
Configuring QoS Policies for Key Area Assurance	⚠ (Mandatory) It is used to configure a key area profile.	
	dscp { **up-streams** | **down-streams** }	Configures the DSCP priorities of uplink or downlink traffic for a key area group.
	⚠ (Mandatory) It is used to associate an AP with a specified key area group profile.	
	area-group	Associates an AP with a specified key area group profile.
Configuring Application Traffic Statistics Collection	**app-traffic**	Configures application traffic statistics collection.
	app-traffic report enable	Configures the feature of reporting application traffic statistics to the cloud.

Configuration	Description and Command	
	app-traffic report interval	Configures the interval for reporting application traffic statistics to the cloud.

1.4.1 Configuring QoS Policies for Key Application Assurance

Configuration Effect

- Preferentially guarantee traffic of specific applications such as Tencent-related applications, including WeChat and QQ on WLAN 1. According to captured wireless packets, it is found that the 802.11e priority of WeChat, QQ, and Qzone is 7 and the 802.11e priority of other applications is 0.
- Preferentially guarantee wireless services of specific applications. In this case, the packets of the specified applications are forwarded preferentially. For example, if the DSCP value of uplink packets of Tencent-related applications is set to 56, when the uplink packets are sent to the AP through the air interface, the upstream wired network device captures the packets and finds that the packets are marked with DSCP 56, indicating that the forwarding priority of the packets is 56.
- Configure network access rules for different time ranges on the network. For example, block the access to stock software from 9:00 to 18:00 on Monday to Friday.
- Configure rate limiting for specific applications. For example, set the downlink rate limit to 10 Mbps for HTTP download applications.

Notes

- Application identification is implemented on the AC.
- Application identification QoS only supports the centralized forwarding mode. Before associating a WLAN with a profile, check the forwarding mode. If the forwarding mode is not centralized forwarding, set it to centralized forwarding.
- Before configuring key application assurance, enable application identification.

Configuration Steps

↘ Configuring an Application Profile

- Mandatory.
- Run the **app-profile** command in global configuration mode on the AC.

Command	**app-profile** *profile-name*
Parameter Description	*profile-name*: Name of an application profile.
Defaults	No application profile is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Configuring Uplink and Downlink DSCP Policies for an Application Group

Command	**app-rule** *group-name* **dscp** [**up-streams** | **down-streams**] *value* [**time-range** *time-rang-name*]

Parameter Description	*group-name*: Name of an application group. **up-streams**: DSCP value of uplink packets of a specific application group. **down-streams**: DSCP value of uplink packets of a specific application group. *value*: DSCP value, ranging from 0 to 63. *time-rang-name*: Effective time of the DSCP policy. You can associate the DSCP policy with a configured time policy name. For details about the time policy, see *Configuring Time Range*.
Defaults	No application profile is configured by default.
Command Mode	app-profile mode
Usage Guide	N/A

Configuring a Block Policy for an Application Group

Command	**app-rule** *group-name* **deny** [**time-range** *time-rang-name*]
Parameter Description	*group-name*: Name of an application group. *time-rang-name*: Effective time of the block policy. You can associate the block policy with a configured time policy name. For details about the time policy, see *Configuring Time Range*.
Defaults	No block policy is configured.
Command Mode	app-profile mode
Usage Guide	N/A

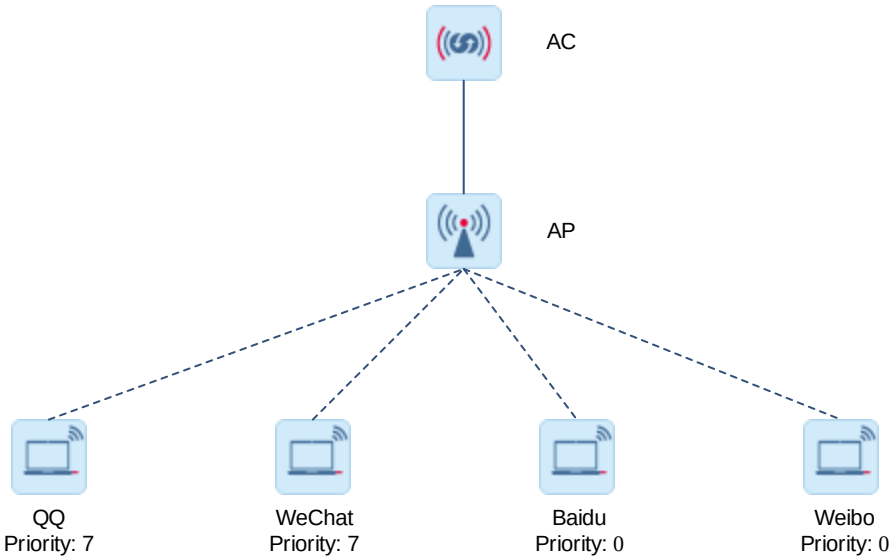
Configuring a Rate Limit Policy for an Application Group

Command	**app-rule** *group-name* **per-user-limit** { **down-streams** | **up-streams** } **average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate* [**time-range** *time-rang-name*]
Parameter Description	*group-name*: Name of an application group. **down-streams**: Downlink traffic rate limit for an application group. **up-streams**: Uplink traffic rate limit for an application group. *average-data-rate*: Average rate limit, in 8 kbps. The value ranges from 8 to 261,120. *burst-data-rate*: Burst limit, in 8 kbps. The value ranges from 8 to 261,120. *time-rang-name*: Effective time of the block policy. You can associate the block policy with a configured time policy name. For details about the time policy, see *Configuring Time Range*.
Defaults	No rate limit policy is configured.
Command Mode	app-profile mode
Usage Guide	The rate limit policy for an application group takes effect for the application group of each user on a WLAN.

Associating a WLAN with an Application Profile

- Mandatory.
- Run the **app-profile** command in WLAN configuration mode on the AC.

Command	**app-profile** *profile-name*
Parameter Description	*name*: Name of an application profile.



Defaults	A WLAN is not associated with an application profile by default.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the profile information and WLAN association information.

Configuration Example

Configuring Application-based Traffic Priority Control

Scenario **Figure 1-2**	
Configuration Steps	Create a custom application group Tencent and add WeChat, QQ, and QZone to this group.

AC	`Hostname(config)# identify-application custom-group Tencent`
	`Hostname(config-custom-group)# app-add QZone`
	`Hostname(config-custom-group)# app-add WeChat`
	`Hostname(config-custom-group)# app-add QQ`

	Add an application profile.
	`Hostname(config)# app-profile P-Tencent` `Hostname(config-app-profile)#`
	According to the DSCP table in the Basic Concepts section, DSCP 56 maps wireless priority 7. Therefore, set the DSCP value of application group Tencent to 56.
	`Hostname(config-app-profile)# app-rule Tencent dscp down-streams 56`
	Set the uplink DSCP value of app group tencent to 56.
	`Hostname(config-app-profile)#app-rule Tencent dscp up-streams 56`
	Block access to stock software for a network.
	`Hostname(config-app-profile)# app-rule Stock-Group deny`
	Block access to stock software from 9:00 to 18:00 on Monday to Friday.
	`Hostname(config)#time-range app_rule_tl` `Hostname(config-time-range)# periodic Weekdays 9:00 to 18:00`

	Hostname(config)#app-profile P-Office Hostname(config-app-profile)#app-rule Stock-Group deny time-range app_rule_tl
	Set the downlink traffic rate limit for applications used for HTTP download to 10 Mbps.
	Hostname(config-app-profile)# app-rule Download-Group down-streams average-data-rate 10000 burst-data-rate 12000
	Associate the WLAN with the application profile.
	Hostname(config)# wlan-config 1 Hostname(config-wlan)# app-profile P-Tencent
Verification	Run the **show running-config** command to display the configurations.
AC	Hostname# show running-config | begin app-profile app-profile P-Tencent app-rule Tencent dscp 56

Common Errors

- N/A

1.4.2 Configuring QoS Policies for Key Area Assurance

Configuration Effect

Uplink and downlink packets of VIP users and key applications in key areas are preferentially forwarded.

Notes

You can specify the DSCP priorities for uplink and downlink packets based on VIP users, key applications, and key area groups separately. The combination rules are as follows:

- VIP user: If a wireless application profile is associated in user role configuration mode, client users of this role that access the applications in the profile are subject to the policy of the application group (for example, modifying the DSCP value of uplink packets to 46).
- Key application: If a wireless application profile is associated in WLAN configuration mode, client users on the WLAN that access the applications in the profile are subject to the policy of the application group (for example, modifying the DSCP value of uplink packets to 48).

  If two wireless application profiles are separately associated in user role configuration mode and WLAN configuration mode and both the role and WLAN attributes of a client user match the two profiles, the profile associated in user role configuration mode prevails. (In this example, the policy rule of modifying the DSCP value of uplink packets to 46 prevails.)
- Key area: In AP configuration mode, specify the DSCP priority of uplink or downlink packets (for example, modifying the DSCP value of uplink packets to 56). If policy rules are also configured for VIP users and key applications, the policy rule with the largest DSCP value prevails. (That is, if a VIP user connects to the AP in a key area and accesses the applications in the application profile, the DSCP value of the uplink packets of the user is modified to 56.)

Configuration Steps

Configuring a Key Area Group

- Mandatory.

- Run the **area-group** command in global configuration mode on the AC. If no key area group exists, run this command to create a group and enter the area group configuration mode. If a key area group exists, run this command to enter the area group configuration mode.

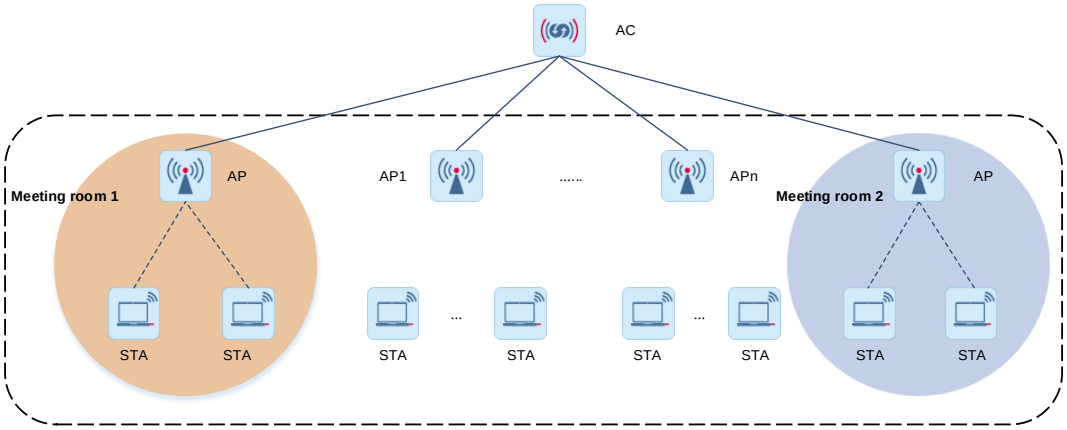
Command	**area-group** *group-name*
Parameter Description	*group-name*: Indicates the name of a key area group. The value is a string of 1 to 63 characters.
Defaults	No key area group is configured.
Command Mode	Global configuration mode
Usage Guide	A maximum of 128 key area groups can be added. You can run the **no area-group** *group-name* command to delete an existing area group.

Configuring Policy Rules for the DSCP Value of Uplink or Downlink Traffic in a Key Area Group

Command	**dscp** { **up-streams** | **down-streams** } *dscp-value*
Parameter Description	**up-streams**: Configures the DSCP value for a key area group in the uplink direction. **down-streams**: Configures the DSCP value for a key area group in the downlink direction. *dscp-value*: Indicates the DSCP value. The value range is from 0 to 63. A larger value indicates a higher priority.
Defaults	No policy rule is configured.
Command Mode	Area group configuration mode
Usage Guide	If DSCP value policies are configured for a key area group and a VIP user or key application simultaneously, the configuration with the largest DSCP value prevails.

Associating an AP with a Key Area Group

- Mandatory.
- Run the **area-group** command in AP configuration mode on the AC.



Command	**area-group** *group-name*
Parameter Description	*group-name*: Indicates the name of a key area group. The value is a string of 1 to 63 characters.
Defaults	An AP is not associated with a key area group.
Command Mode	AP configuration mode
Usage Guide	1. An AP can be associated with only one key area group and a key area group can be associated with up to 50 APs. 2. A key area group cannot be associated in all-AP configuration mode.

Verification

- Run the **show running-config** command to display key area and AP association information.

Configuration Example

QoS Policies based on the Key Area Group

Scenario **Figure 1-3**	
Configuration Steps	Add key area group **Meeting room 1**, set the DSCP values of both uplink and downlink traffic to 56, and associate the area group with AP1.
AC	Hostname(config)# area-group Meeting room 1 Hostname(config-area-group)# dscp up-streams 56 Hostname(config-area-group)# dscp down-streams 56 Hostname(config-area-group)# exit Hostname(config)# ap-config AP1 Hostname(config-ap)# area-group Meeting room 1
	Add key area group **Meeting room 2**, set the DSCP values of both uplink and downlink traffic to 46, and associate the area group with AP2.
	Hostname(config)# area-group Meeting room 2 Hostname(config-area-group)# dscp up-streams 46 Hostname(config-area-group)# dscp down-streams 46 Hostname(config-area-group)# exit Hostname(config)# ap-config AP2 Hostname(config-ap)# area-group Meeting room 2
Verification	Run the **show running-config** command to display the configuration.

Common Errors

N/A

1.4.3 Configuring Application Traffic Statistics Collection

Configuration Effect

- Enable or disable application traffic statistics collection to control whether the AC periodically collects application traffic statistics.
- Enable or disable the feature of reporting statistics to the cloud to control whether application traffic statistics are uploaded to the cloud.
- Configure the interval for reporting statistics to the cloud to control the frequency of synchronizing application traffic statistics from a device to the cloud.

Notes

Before configuring application traffic statistics collection, enable the application identification feature first.

Configuration Steps

Configuring Application Traffic Statistics Collection

- Mandatory.
- Use the **app-traffic enable-statistics** command to configure this feature in global configuration mode on the AC.

Command	**app-traffic** { **enable-statistics** | **disable-statistics** | **reset-statistics** }
Parameter Description	**enable-statistics**: Enables application traffic statistics collection. **disable-statistics**: Disables application traffic statistics collection. **reset-statistics**: Clear application traffic statistics.
Defaults	The feature is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Feature of Reporting Application Traffic Statistics to the Cloud

- (Optional) This feature is used to decide whether application traffic statistics are uploaded to and displayed on the cloud
- Use the **app-traffic report enable** command to configure this feature in global configuration mode on the AC.

Command	**app-traffic report enable**
Parameter Description	N/A
Defaults	The feature is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Interval for Reporting Application Traffic Statistics to the Cloud

Use the **app-traffic report interval** *value* command to configure this feature in global configuration mode on the AC.

Command	**app-traffic report interval** *value*
Parameter Description	*value*: Interval for reporting application traffic statistics to the cloud, in seconds. The value ranges from 30 to 3,600.
Defaults	300s
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running** command to check the configuration.

Configuration Example

Configuring the Feature of Collecting Application Traffic Statistics and Reporting the Statistics to the Cloud

Configuration Steps	1. Enable the feature of collecting application traffic statistics. 2. Enable the feature of reporting application traffic statistics to the cloud. 3. Set the interval for reporting statistics to 60 seconds.

AC	`Hostname# config`
	`Hostname(config)# app-traffic enable-statistics`
	`Hostname(config)# app-traffic report enable`
	`Hostname(config)# app-traffic report interval 60`

Verification	● Run the **show running** command to display the configuration.

AC	`Hostname# show running | include app-traffic`
	`app-traffic enable-statistics`
	`app-traffic report enable`
	`app-traffic report interval 60`

Common Errors

N/A

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show app-profile	Displays details of an application profile.
show area-group [*group-name*]	Displays details about a key area group.
show app-traffic top-apps *N* **scope** { **app** | **group** }	Displays the traffic of the top *N* apps/application groups on the AC.
show app-traffic per-station *mac-address* **top** *N* **scope** { **app | group** }	Displays the traffic of the top *N* applications/application groups of a MAC address on the AC.
show app-traffic per-app *app-name* **top** *N* **scope** { **app** | **group** }	Displays the top *N* STAs of an application/application group on the AC.

1 Configuring DNS-CACHE

1.1 Overview

DNS-CACHE can cache the results of domain name resolutions. When a client requests for access to a domain name for the first time, the domain name is resolved and the resolution result is cached. When the client requests to access the same domain name next time, the device directly returns the cached result, instead of obtaining the IP address from an external domain name server (DNS).

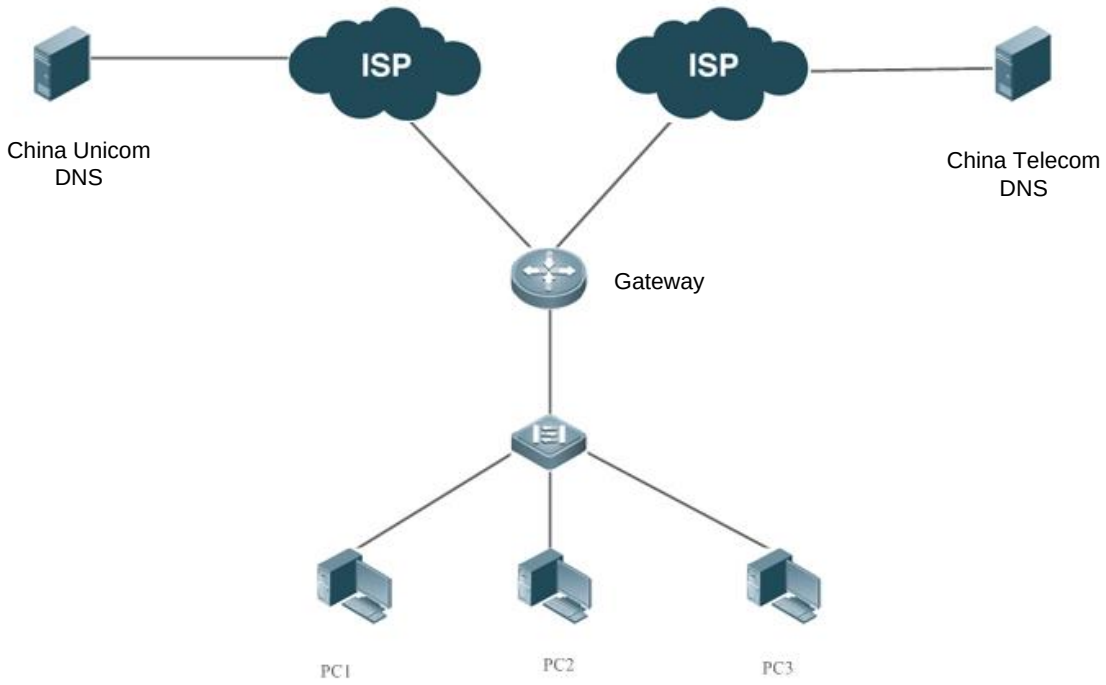
Protocols and Standards

RFC1034: Domain Names - Concepts and Facilities

1.2 Applications

Application	Description
Deploying Egress Gateway of Cybercafé	Deploys DNS-CACHE in the egress gateway of a cybercafé.

1.2.1 Deploying Egress Gateway of Cybercafé



Scenario

Scenario restrictions related to DNS-CACHE are as follows:

1. The DNS is deployed in the internal network.
2. The virtual private network (VPN) supports Point-to-Point Tunneling Protocol (PPTP) and Layer 2 Tunneling Protocol (L2TP) clients only.

Figure 1-1 shows the typical application scenario of cybercafé clients.

Figure 1-1 Typical Application Scenario of Cybercafé clients

Remarks	In the cybercafé scenario, the DNS is generally located in an external network. A large number of network applications connect to the Internet via the egress gateway to browse Web pages, play online games, and so on.

Deployment

- Basic NAT: Implement basic network address translation (NAT) to ensure that clients access the Internet normally.
- Application identification: Indentify the application with traffic forwarding.
- Flow control: Implement functions such as traffic guarantee of key applications in combination with APP-IDENTIFY.
- Flow control: Control the application traffic in the network.
- DNS-CACHE: Cache the results of domain name resolutions to avoid network performance from being affected by an unstable external DNS server, thereby improving user experience.

1.3 Features

Basic Concepts

Domain Name

A domain name is an easy-to-remember server address that facilitates communication. During network access, one or more domain names are resolved into a corresponding IP address.

Static Cache

Static cache is a user-defined rule that specifies a resolution correspondence between a domain name and a fixed IP address.

Overview

Feature	Description
DNS-CACHE	Caches the results of domain name resolutions.

1.3.1 DNS-CACHE

DNS-CACHE can cache the results of domain name resolutions. When a client requests for access to a domain name for the first time, the domain name is resolved and the resolution result is cached. When the client requests access to the same domain name next time, the device directly returns the cached result, instead of obtaining the IP address from an external DNS.

Working Principle

Cache matching is performed on a DNS request packet. If the DNS request packet hits the cache, a DNS response packet is constructed and returned, and the DNS request packet is discarded. The matching criteria include the domain name, DNS IP address, and egress gateway. If the DNS request packet misses the cache, the DNS request is forwarded and the DNS response packet is cached.

Related Configuration

Enabling DNS-CACHE

DNS-CACHE is enabled by default.

Run the **dns-cache enable** command in global configuration mode to enable DNS-CACHE.

Run the **no dns-cache enable** command in global configuration mode to disable DNS-CACHE.

Configuring Cache Time

The cache time of a DNS node is 300 seconds by default.

Run the **dns-cache old time** *time* command to adjust the cache time in the range 1–600 seconds.

Run the **no dns-cache old-time** command in global configuration mode to delete related configurations. After the deletion, the cache time is restored to the default value.

Configuring Static Cache Policy

The dynamic cache is matched by default.

Run the **dns-cache static domain** *domain* **ip"***ip1 ip2 …***"** command to configure the static cache policy. You can configure a maximum of eight IP addresses in one policy.

Run the **no dns-cache static domain** *domain* command in configuration mode to delete related configurations.

1.4 Configuration

Configuration	Description and Command	
Enabling/Disabling DNS-CACHE	(Mandatory) It is used to enable traffic monitoring and audit.	
	dns-cache enable	Enables DNS-CACHE.
Configuring Cache Time	(Optional) It is used to configure the cache time of a node.	
	dns-cache old-time *time*	Configures the cache time in seconds. The value ranges from 1 to 600 seconds.
Configuring User-defined Static Cache	(Optional) It is used to configure the user-defined static cache.	
	dns-cache static domain *domain* **ip"***ip1 ip2 …***"**	Configures the user-defined static cache. You can configure a maximum of 100 static cache policies, and one domain name corresponds to a maximum of eight IP addresses.

1.4.1 Enabling/Disabling DNS-CACHE

Configuration Effect

- Enable DNS-CACHE to cache results of domain name resolutions. In this way, the gateway can directly return response packets for requests with the same domain name, instead of applying for the IP address from an external server.

Notes

- If DNS-CACHE is disabled, the DNS cache function is invalid.
- The DNS cache time is limited. The DNS cache time is 300 seconds by default and can be set to 600 seconds at maximum.
- If DNS-CACHE is disabled, cached data is deleted.

Configuration Steps

- Run the **dns-cache enable** command in global configuration mode to enable DNS cache audit.

Verification

- Run the ***show dns-cache enable*** command to check whether DNS-CACHE is enabled.

Related Commands

Enabling Traffic Monitoring and Audit

Command	**dns-cache enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Run this command to enable DNS-CACHE

Configuration Example

Enabling Traffic Monitoring and Audit

Configuration Steps	Configure this function on the egress gateway.
	`Hostname# configure terminal` `Hostname(config)#dns-cache enable`
Verification	● Check whether DNS-CACHE is enabled.

	`Hostname#show dns-cache enable`
	`dns-cache is on`
	`Hostname#`

1.4.2 Configuring Cache Time

Configuration Effect

- Configure the cache time for storing the cached results. The cache time is 300 seconds by default and ranges from 1–600 seconds.

Notes

- Optional
- If DNS-CACHE is disabled, the DNS cache function is invalid and cached data is deleted.
- The cache time is 300 seconds by default and ranges from 1–600 seconds.
- After the configuration is deleted, the cache time is restored to the default value.

Configuration Steps

- Run the **dns-cache old-time** *time* command in global configuration mode to configure the DNS cache time.

Verification

- Check the cache time of each node.

Related Commands

Configuring Cache Time

Command	**dns-cache old-time** *time*
Parameter Description	*time*: Indicates the cache time. The range is 1–600 seconds.
Command Mode	Global configuration mode
Usage Guide	Run this command to change the cache time of each node.

Configuration Example

Setting the Cache Time to 600 Seconds

Configuration Steps	Set the cache time to 600 seconds on the egress gateway.

	`Hostname# configure terminal`
	`Enter configuration commands, one per line. End with CNTL/Z.`
	`Hostname(config)# dns-cache old-time 600`

Verification	● Check the configuration information.
	`Hostname(config)#show run | in dns-cache` `dns-cache old-time 600`

1.4.3 Configuring User-defined Static Cache

Configuration Effect

- Configure the user-defined static cache, so that a domain name is directly resolved into a fixed IP address without involving the DNS server.

Notes

- If DNS-CACHE is disabled, the DNS cache function is invalid.
- You can configure a maximum of 100 policies.
- One domain name corresponds to a maximum of eight IP addresses.

Configuration Steps

- Run a command in global configuration mode to configure static cache.

Verification

- Check whether the designated domain name is directly resolved into the fixed IP address without involving the DNS server.

Related Commands

Configuring the Pre-generation Time of Reports

Command	**dns-cache static domain domain** { **interface** *interface-type interface-number* **| ip "***ip1 ip2 …***"** }
Parameter Description	*domain*: Indicates the domain name, which contains no more than 64 bytes. **interface** *interface-type interface-number*: Indicates the interface type and number. The specified

	domain name will be resolved into the IP address of this interface. *ip*: Indicates the IP address obtained by resolving the domain name.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Mapping Domain Name www.baidu.com to IP Address 1.2.3.4 5.6.7.8 9.1.3.5

Configuration Steps	Map the domain name www.baidu.com to the IP address 1.2.3.4 5.6.7.8 9.1.3.5 on the egress gateway.
	Hostname#config Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#dns-cache static domain www.baidu.com ip "1.2.3.4 5.6.7.8 9.1.3.5"
Verification	● Check the static cache.
	Hostname(config)#show run | in dns-cache dns-cache static domain www.baidu.com ip 1.2.3.4 5.6.7.8 9.1.3.5 Hostname(config)#

1.5 Monitoring

Displaying

Description	Command
Displays the operation status of DNS-CACHE.	**show dns-cache state**

Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging switch immediately after use.

Description	Command
Debugs data configured in the CLI.	**debug dns-cache cli**

1 Configuring RNFP

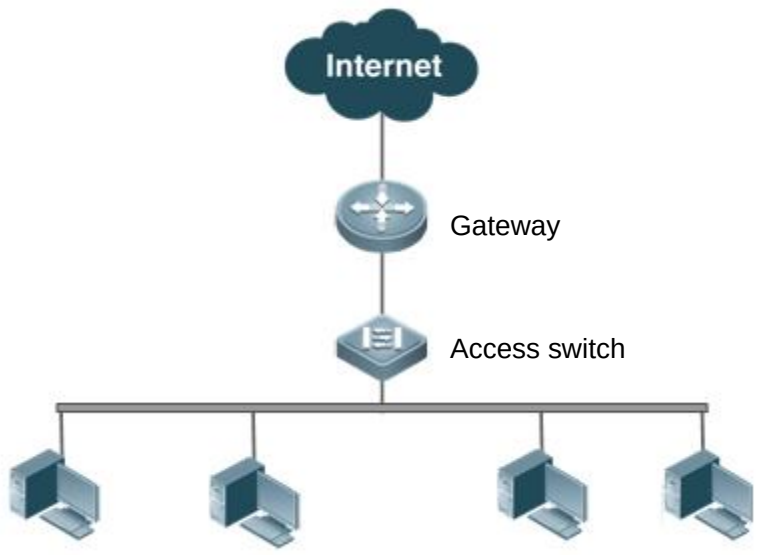
1.1 Overview

Ruijie Network Foundation Protection (RNFP) is a collection of means for defending devices against attacks.

When encountering network attacks or high loads, RNFP is capable of protecting key resources on the control and management plane of routers, to prevent device breakdown and improve device availability.

1.2 Applications

Application	Description
There Are a Large Amount of Traffic that Attacks Devices on the Network	A large amount of abnormal traffic on the network will cause very high CPU utilization of devices, slow or suspended response of the Command Line Interface (CLI), loss of link or network control protocol packets, and finally link or network jitter. The processing bandwidth is occupied by illegitimate packets, which results in the failure to process important protocol packets.



1.2.1 There Are a Large Amount of Traffic that Attacks Devices on the Network

Scenario

In the network-attacked environment, RNFP reduces the CPU utilization in case of attacks and safeguards key protocol packets so that administrators can access the devices normally.

- Restricts attack traffic.
- Safeguards non-attack traffic.

Figure 1-1

Deployment

- Configure the local anti-attack rate-limit policy on the device.
- Add the IP address of the administrator to the whitelist to safeguard the traffic for the administrator to manage devices.

1.3 Features

Basic Concepts

Classify

RNFP identifies and classifies data traffic transmitted to the control plane. It classifies traffic into the protocol traffic, manage traffic, and data traffic, which facilitates submodules to limit the rate and filter traffic in a differentiated manner.

Sub-interface

All traffic transmitted to the control plane is classified by Classify into three types, which are separately processed by the three sub-interfaces below:

- Protocol sub-interface: Processes all protocol control traffic transmitted to the local device, including link-layer protocol packets and routing protocol packets.
- Manage sub-interface: Processes all management protocol traffic transmitted to the local device, such as FTP, Telnet, SNMP, and ARP protocol packets.
- Data sub-interface: Processes all data traffic that cannot be processed by the fast forwarding plane.

SCPP

Segregate Control Plane Protection (SCPP), according to user-defined policies, match traffic of the three sub-interfaces to different ACLs according to user-defined policies, to implement finer-granularity rate limit and protection.

Glean-CAR

Glean-CAR limits the rate of the traffic that is matched by the fast forwarding plane to the REF Glean adjacency (the traffic is matched to the direct route but the host route that matches the destination IP address is not found, and therefore the traffic needs to be transmitted to the control plane for destination IP address resolution).

ARP-CAR

The fast forwarding plane cannot process ARP packets and need to transmit them to the control plane for processing. ARP-CAR can limit the rate of ARP packets for each neighbor.

Port-Filter

Port-Filter checks whether ports are enabled on local applications for TCP and UDP packets transmitted to the local device, and filters out the traffic transmitted to the local device, for which the network service is not enabled on the local device, before the traffic reaches the control plane.

MPP

Management Plane Protection (MPP) allows administrators to specify one or multiple interfaces as the inband management interfaces (supporting receiving of management packets and forwarding of normal services). After MPP is enabled, only a specified inband management interface is allowed to receive management packets of a specified protocol. Service packets, protocol packets, and ARP packets are not affected.

ACPP

Aggregate Control Plane Protection (ACPP) uses the default or user-defined rate to limit the rate of the traffic on the protocol sub-interface, manage sub-interface, and data sub-interface based on classification results of Classify, to ensure that the traffic does not exceed the processing capacity of the control plane, thereby protecting the control plane.

Local Anti-attack Whitelist

When accessing an attacked device, users will feel stuck or fail to access the device. The local anti-attack whitelist can be configured to free whitelisted users from all anti-attack policies, their device access packets are not discarded due to rate limit, thereby preventing stuck access or access failures.

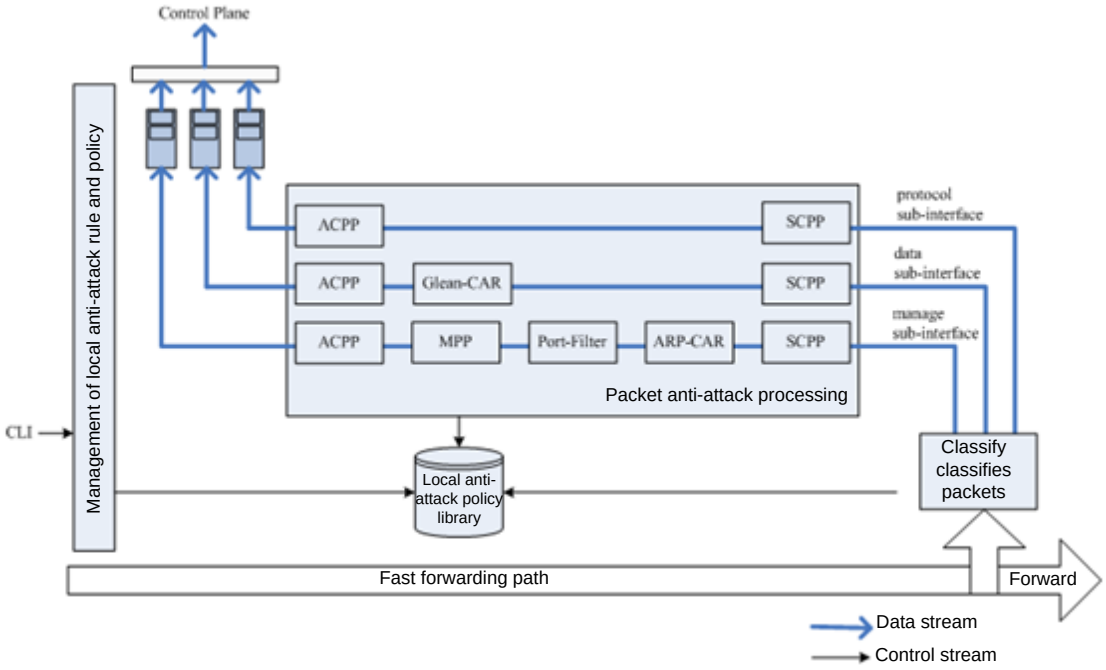
User Management Device Restriction

User management device restriction forbids intranet/extranet users to ping the device, access the Web page of the device, telnet to the device or log in to the device in Secure Shell (SSH) mode, and manage the device over the Simple Network Management Protocol (SNMP), with no need to associate Access Control Lists (ACLs).

ARP Attack Detection

In a Layer-2 environment, the Address Resolution Protocol (ARP) attacks in the intranet may affect the normal Internet access of intranet users. ARP attack detection aims at detecting possible ARP attacks on the network and listing suspicious hosts of ARP attacks for administrators to locate and rectify faults.

- Sub-interfaces involved in the device anti-attack are different from traditional sub-interfaces of devices. A device anti-attack interface indicates an internal channel for transmitting a certain type of traffic to the control plane. Such interfaces can be used to conveniently conduct anti-attack configuration and processing on traffic.
- Anti-attack sub-functions of devices (SCPP, Glean-CAR, ARP-CAR, Port-Filter, MPP, and ACPP) are independent of each other in the configuration. Users can combine or configure anti-attack sub-functions according to requirements and policies. Note that some sub-interfaces have restrictions on the application sub-interfaces.



Overview

Feature	Description
Local Anti-attack	Distributes packets transmitted to the control plane to different sub-interfaces for rate limit based on the packet type.
Attack Detection	Detects attack behaviors on the network.
Local Anti-attack Whitelist	Ensures management traffic by not limiting the rate of traffic from whitelisted users.
User Management Device Restriction	Forbids intranet/extranet users to ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and manage the device over SNMP.

1.3.1 Local Anti-attack

Classify and filter data packets to be processed by the control plane, and limit their rates, so as to protect key resources of the control plane.

Working Principle

As shown in the figure above, packet classification and rate limit are implemented by multiple submodules. Packets to be processed by the control plane are classified and then rate limit is conducted on them according to policies configured for different sub-interfaces.

protocol sub-interface

The protocol sub-interface conducts rate limit and filtering on all protocol control traffic transmitted to the local device. It covers two submodules: SCPP and ACPP. Packets are processed by in SCPP > ACPP order.

data sub-interface

The data sub-interface conducts rate limit and filtering on all traffic that cannot be processed by the fast forwarding plane. It covers three submodules: SCPP, Glean-CAR, and ACPP. Packets are processed by in SCPP > Glean-CAR > ACPP order.

manage sub-interface

The manage sub-interface conducts rate limit and filtering on all management protocol traffic transmitted to the local device. It covers five submodules: SCPP ARP-CAR, Port-Filter, MPP, and ACPP. Packets are processed by in SCPP > ARP-CAR > Port-Filter > MPP >ACPP order.

ACPP directly forwards the packets allowed by SCPP, ARP packets, and Glean packets without rate limit.

Related Configuration

Configuring Local Anti-attack

By default, all rate limit functions are disabled.

Run the **control-plane** [**protocol** | **manage** | **data**] command to access different sub-interfaces and configure different function policies for the sub-interfaces.

Run the **ef-rnfp enable** command to globally enable packet classification and rate limit.

Run the **scpp list** *acl_no* { [**bw-rate** *rate* **bw-burst-rate** *brust-rate*] [**conn-create-rate** *create-rate* **conn-create-burst-rate** *create-burst-rate*] [**conn-total** *num*] } [**log**] command to configure SCPP to limit the rate of ACL-matched packets and adjust the rate limit values of SCPP.

Run the **acpp bw-rate** *rate* **bw-burst-rate** *burst-rate* [**log**] command to configure the ACPP rate limit.

Run the **glean-car** *packet_rate_per_group* [**log**] command to configure Glean-CAR and limit the rate of packets that matches the Glean-CAR.

Run the **port-filter** [**log**] command to configure port-filter to reject packets received by locally disabled ports.

Run the **management-interface** *interface* **allow** { **ftp** | **http** | **ssh** | **snmp** | **telnet** | **tftp** } [**log**] command to configure the management interface and configure the management interface to receive packets of the specified management protocols. Non-configured interfaces cannot receive packets of these protocols.

Run the **arp-car** *packet_rate_per_group* [**log**] command to configure ARP-CAR to limit the rate of ARP packets.

1.3.2 Attack Detection

Detect and record attack behaviors on the network.

Working Principle

When the total packets discarded by submodules of sub-interfaces reach a threshold, the device considers that traffic attack occurs on the network. It collects statistics on the type of attack packets, IP addresses, packet count, and packet size.

When the device receives abnormal ARP packets from a host, it records the host as the suspicious host of ARP attacks. The device considers that ARP spoofing occurs and adds the hosts to the ARP spoofing suspect list in the event of the following cases: A host conducts ARP scanning on the entire network (by default, more than 200 ARP requests are transmitted within 10s); the MAC address of a host maps to multiple IP addresses; the MAC address attempted to be updated based on an ARP request is different from the existing MAC address.

Related Configuration

↘ Configuring Traffic Attack Detection

By default, attack detection is disabled. When the **ef-rnfp enable** command is executed to globally enable packet classification and rate limit, traffic attack detection is enabled by default.

Run the **attack threshold** *drop-num* command to set the attack judgment threshold. The default value is 500.

Run the **show attack** { **current** | **history** } command to display attack information.

↘ Configuring ARP Attack Detection

By default, attack detection is disabled.

Run the **anti-arp-spoof** command to enable ARP attack detection.

Run the **anti-arp-spoof** [**scan** *arp-num*] command to set the ARP scanning threshold. The default value is 20.

Run the **show arp-suspect** command to display the ARP spoofing suspect list.

1.3.3 Local Anti-attack Whitelist

Add the IP address of the administrator to the whitelist so that the administrator can normally manage devices even if the network is attacked.

Working Principle

The local anti-attack module does not limit the rate of traffic from whitelisted IP addresses but allows the traffic to directly pass.

Related Configuration

Configuring the Local Anti-attack Whitelist

By default, there is no IP address in the whitelist.

Run the **security web permit** *low-ip-address* [*high-ip-address*] command to configure the whitelist range. A maximum of 32 IP addresses or IP address segments are supported.

1.3.4 User Management Device Restriction

For common Ping, Web, Telnet, SSH, and SNMP attack behaviors on the network, user management device restriction forbids intranet/extranet users to ping the device or access the Web page of the device, with no need to use ACLs, delivering great flexibility and convenience.

Working Principle

User management device restriction intercepts ping packets, Web packets for device access, Telnet packets or SSH login packets, and SNMP packets, in an effort to forbid the ping, Web access, Telnet and SSH login, and SNMP management behaviors.

Related Configuration

Configuring User Management Device Restriction

By default, the function is disabled.

Run the **security deny** command to configure the user management device restriction function.

1.4 Configuration

Configuration	Description and Command	
Configuring Local Anti-attack	⚠ (Optional) It is used to configure rate limit rules.	
	control-plane	Enters the control-plane configuration mode.
	scpp	Configures SCPP.
	glean-car	Configures Glean rate limit.
	arp-car	Configures ARP rate limit.

	port-filter	Configures port filtering.
	mpp	Configures MPP.
	acpp	Configures ACPP.
	ef-rnfp	Enables local anti-attack.
	rnfp-ping-reply { **enable** | **threshold** }	Configures rnfp-ping response acceleration.
Configuring Attack Detection	(Optional) It is used to configure attack detection rules.	
	attack threshold	Configures the attack confirmation threshold.
	anti-arp-spoof	Configures ARP attack detection.
Configuring the Local Anti-attack Whitelist	(Optional) It is used to configure local anti-attack whitelisted users.	
	security web permit	Configures whitelisted IP addresses.
Configuring User Management Device Restriction	(Optional) It is used to forbid intranet/extranet users to ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and manage the device over SNMP.	
	security deny	Forbids intranet/extranet users to ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and manage the device over SNMP.

1.4.1 Configuring Local Anti-attack

Configuration Effect

- Reduce the CPU utilization of the device even if the network is attacked.
- Improve the CLI response speed even if the network is attacked.
- Safeguard important packets such as link or network control protocol packets when the network is attacked.

Notes

- If the Telnet operation and Web access slow down after the function is configured, you can add the IP address used in the Telnet operation and Web access to the local anti-attack whitelist to ensure the traffic of the IP address.

Configuration Steps

↘ Entering the control-plane Configuration Mode

- Mandatory.
- Enter different sub-interfaces.

↘ Configuring Rate Limit

- Mandatory.
- Configure different functions to implement rate limit.

Verification

- Check the CPU utilization.
- Check the CLI response speed.
- Check whether important protocol packets are safeguarded.

Related Commands

Entering the control-plane Configuration Mode

Command	**control-plane** [**protocol** | **manage** | **data**]
Parameter Description	**protocol**: Enters the protocol sub-interface. **manage**: Enters the manage sub-interface. **data**: Enters the data sub-interface. Non-sub-interface functions are configured if no parameter is set.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring SCPP

Command	**scpp list** *acl_no* { [**bw-rate** *rate* **bw-burst-rate** *burst-rate*] [**conn-create-rate** *create-rate* **conn-create-burst-rate** *create-burst-rate*] [**conn-total** *num*] } [**log**]
Parameter Description	**list** *acl_no*: Indicates ACL rules, which are used to search out the traffic to be processed by SCPP. **bw-rate** *rate*: Indicates the rate limit. The unit is pps. **bw-burst-rate** *burst-rate*: Indicates the burst rate limit. The unit is pps. **conn-create-rate** *create-rate*: Indicates the rate limit for connection creation per second. **conn-create-burst-rate** *create-burst-rate*: Indicates the rate limit for burst connection creation per second. **conn-total** *num*: Indicates the limit on the total number of connections. **log**: Indicates whether to output logs.
Command Mode	control-plane mode
Usage Guide	The three sub-interfaces can conduct SCPP processing on traffic on the sub-interfaces. By default, SCPP is disabled. It is enabled only after users explicitly configure SCPP rules.

Configuring Glean Rate Limit

Command	**glean-car** *packet_rate_per_group*
Parameter Description	*packet_rate_per_group*: Configures the rate limit value for the traffic that is initiated by users (sources), who are in the same group according to the hash algorithm, and is matched to the Glean adjacency. The unit is pps.
Command Mode	control-plane mode
Usage Guide	The Glean-CAR function can be configured only on the data sub-interface. Currently, the hash algorithm extracts lower *N* bits from the source address (the value of *N* varies with products).

	Note that Glean-CAR can limit the rate of the traffic that is initiated by users, who are in the same group according to the hash algorithm, and is matched to the Glean adjacency. For example, User A (with IP address of 192.168.52.57) and User B (with IP address of 192.168.60.57) (share the same hash result) send traffic to directly connected Destination Host C (with IP address of 172.16.0.5). Before 172.16.0.5 is successfully resolved by ARP, if Glean-CAR 5 is configured, a maximum of five packets out of the traffic initiated by User A and User B can be transmitted to the control plane every second, requesting the control plane to conduct ARP resolution on the destination IP address. By default, Glean-CAR is disabled. It is enabled only after users explicitly configure Glean-CAR rules.

Configuring ARP Rate Limit

Command	**arp-car** *packet_rate_per_group*
Parameter Description	*packet_rate_per_group*: Configures the rate limit value for ARP traffic that is initiated by users, who are in the same group according to the hash algorithm. The unit is pps.
Command Mode	control-plane mode
Usage Guide	The ARP-CAR function can be configured only on the manage sub-interface. Currently, the hash algorithm extracts lower *N* bits from the source address (the value of *N* varies with products). Note that ARP-CAR can limit the rate of the ARP traffic initiated by users who are in the same group according to the hash algorithm. For example, User A (with IP address of 192.168.52.57) and User B (with IP address of 192.168.60.57) (share the same hash result) send the ARP request for 192.168.52.1 to the device. If ARP-CAR 5 is configured, a maximum of five packets out of the traffic initiated by User A and User B can be transmitted to the control plane every second, requesting the control plane to give ARP response. By default, ARP-CAR is disabled. It is enabled only after users explicitly configure ARP-CAR rules.

Configuring Port Filtering

Command	**port-filter**
Parameter Description	**N/A**
Command Mode	control-plane mode
Usage Guide	Configure Port-Filter to filter out received transport-layer packets, for which services are not enabled. The Port-Filter function can be configured only on the manage sub-interface. By default, Port-Filter is disabled. It is enabled only after users explicitly configure Port-Filter.

Configuring MPP

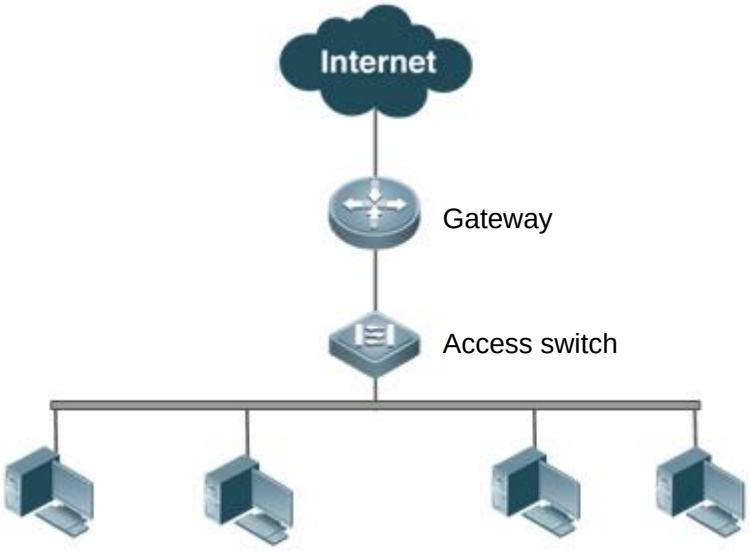
Command	**management-interface** *interface* **allow** { **ftp** | **http** | **ssh** | **snmp** | **telnet** | **tftp** }
Parameter Description	*interface*: Specifies an inband management interface. **allow** { **ftp** | **http** | **ssh** | **snmp** | **telnet** | **tftp** }: Configures the allowed management protocol.
Command Mode	control-plane mode
Usage Guide	Configure MPP to specify an inband management interface and management protocol packets allowed by the interface.

	The MPP sub-function can be configured only on the manage sub-interface. A maximum of 16 inband management interfaces can be configured, and each interface can receive packets of multiple or all management protocols. After MPP is enabled, non-inband management interfaces are not allowed to receive management packets, and inband management interfaces are allowed to receive packets of only specified management protocols. By default, MPP is disabled. It is enabled only after users explicitly configure MPP rules.

Configuring ACPP

Command	**acpp bw-rate** *rate* **bw-burst-rate** *burst-rate*
Parameter Description	*rate*: Indicates rate limit. The unit is pps. *burst-rate*: Indicates burst rate limit. The unit is pps.
Command Mode	control-plane mode
Usage Guide	Configure ACPP for classified traffic that is transmitted to the control plane. The three sub-interfaces can conduct ACPP processing on the traffic on the sub-interfaces. By default, ACPP is disabled. It is enabled only after users explicitly configure ACPP rules.

Enabling Local Anti-attack



Command	**ef-rnfp** { **enable** | **disable** }
Parameter Description	**enable**: Enables local anti-attack. **disable**: Disables local anti-attack.
Command Mode	control-plane mode
Usage Guide	When no local anti-attack policy is configured, if local anti-attack is enabled, the default policy (ACPP on each sub-interface, port-filter on the manage sub-interface, and Glean-CAR on the data sub-interface) is enabled. The default anti-attack rules and policy are set based on different products and platforms. After local anti-attack is disabled, rate limit functions are all unavailable.

Configuring Ping Response Acceleration

Command	**rnfp-ping-reply** { **enable** | **threshold** }
Parameter Description	**enable**: Accelerates the response to external ping requests. **threshold**: Indicates the threshold for the number of ping packets responded per second. The value ranges from 0 to 65,535, in packets per second (pps).
Command Mode	Global configuration mode
Usage Guide	When ping response acceleration is enabled, the forwarding plane directly responds to external ping requests. This reduces response latency. When ping response acceleration is disabled, ping requests will be responded through the standard protocol stack. The ping response acceleration function is disabled by default.

Configuration Example

Configuring Local Anti-attack on the Gateway

Scenario Figure 1-2	
Configuration Steps	● Configure the local anti-attack rate-limit policy on the gateway. ● Configure ACPP on the protocol sub-interface, and set the rate limit to 500 pps for the traffic on the protocol sub-interface and allowable burst peak to 600 pps. ● Configure ACPP on the data sub-interface, and set the rate limit to 500 pps for the traffic on the data sub-interface and allowable burst peak to 600 pps. ● Configure Glean-CAR to allow 10 packets from each source to be matched to the Glean adjacency every second. ● Configure ACPP on the manage sub-interface, and set the rate limit to 500 pps for the traffic on the manage sub-interface and allowable burst peak to 600 pps. ● Configure ARP-CAR to allow 10 ARP packets from each source to pass every second. ● Configure Port-Filter. ● Configure MPP rules, in which Port Gi0/0 is specified as the inband management interface, and the interface is allowed to receive packets of only the Telnet and SNMP protocols. ● Enable local anti-attack globally.

A	`Hostname # configure terminal`
	`Hostname(config)# control-plane protocol`
	`Hostname(config-cp)# acpp bw-rate 500 bw-burst-rate 600`
	`Hostname(config)# control-plane data`

  dropped 0 management protocol packet from non management interface
```

Common Errors

- If only an interface is configured as the inband management interface, other interfaces may not be managed normally.

1.4.2 Configuring Attack Detection

Configuration Effect

- The device can detect and record attacks occurring on the network.

Notes

- The local anti-attack must be enabled.

Configuration Steps

Entering the Global control-plane Mode

- Mandatory.

Configuring the Traffic Attack Detection Threshold

- Mandatory.
- Configure the traffic attack detection threshold.

Configuring ARP Attack Detection

- Mandatory.
- Configure the ARP attack detection policy.

Verification

- The device can detect traffic attacks on the network.
- The device can detect ARP attacks on the network.

Related Commands

Configuring the Attack Confirmation Threshold

Command	**attack threshold** *drop-num*
Parameter Description	*drop-num*: Indicates the rate threshold of packets discarded by the local anti-attack module for determining whether network attacks exist. The unit is pps.
Command Mode	control-plane mode
Usage Guide	N/A

Configuring ARP Attack detection

Command	**anti-arp-spoof** [**scan** *arp-num*]
Parameter Description	*arp-num*: Indicates the quantity threshold of ARP packets received from an IP address per second within 10 seconds for determining whether the IP address is used to conduct ARP scanning. ARP attack detection is enabled if no parameter is set.
Command Mode	control-plane mode
Usage Guide	Enable ARP anti-attack. If this command is run, the device is capable of identifying ARP spoofing. It considers that ARP spoofing occurs and adds the hosts to the ARP spoofing suspect list in the event of

	the following cases: A host conducts ARP scanning on the entire network (more than 200 ARP requests are transmitted within 10s); the MAC address of a host maps to multiple IP addresses; the MAC address attempted to be updated based on an ARP request is different from the existing MAC address.

Configuration Example

↘ Configuring Attack Detection

Configuration Steps	● Enable the local anti-attack function globally. ● Set the traffic attack threshold. ● Configure ARP attack detection.
	Hostname# configure terminal Hostname(config)# control-plane Hostname(config-cp)# ef-rnfp enable Hostname(config-cp)# attack threshold 500 Hostname(config-cp)# anti-arp-spoof scan 10 Hostname(config-cp)# anti-arp-spoof
Verification	● Display traffic attack information. ● Display ARP attack information.
	Hostname# show ip pim sparse-mode mroute Hostname# show attack-info current System currently not in attack! Hostname# show attack-info history System attack record at 1970-1-2 15:53:18, System in attack 8s ALL: 6958 packets, 584680 bytes PROTOCOL packets bytes ARP 1733 103980 UDP 5225 480700 TOP5 IP attack: IP packets bytes interface 172.18.3.84 2797 257324 Gi0/5 172.18.3.52 2428 223376 Gi0/5 172.18.3.80 1635 98100 Gi0/5 192.168.205.196 92 5520 Gi0/5 3.3.3.6 6 360 Gi0/5 Hostname#show arp-suspect IP address MAC address

	192. 168. 1. 1 00d0. f800. 0002

1.4.3 Configuring the Local Anti-attack Whitelist

Configuration Effect

- When the device is attacked, whitelisted users can manage the device in Telnet or Web mode.

Notes

- Only add the IP address of the administrator to the whitelist.

Configuration Steps

↘ **Entering Global control-plane Mode**

- Mandatory.

↘ **Configuring Whitelisted Users**

- Optional.

Verification

Simulate network attacks to initiate device attacks, enable the local anti-attack, and configure whitelisted users.

- Non-whitelisted users feel stuck when telnetting to or accessing the Web page of the device, or fail to access the Web page of the device.
- Whitelisted users can telnet to and access the Web page of the device smoothly.

Related Commands

↘ **Configuring Anti-attack Whitelisted Users**

Command	**security web permit** *low-ip-address* [*high-ip-address*]
Parameter Description	*low-ip-address*: Indicates the allowable IP address or the start IP address of the allowable IP address range. *group-or-source-address*: Indicates the end IP address of the allowable IP address range.
Command Mode	control-plane mode
Usage Guide	If a user configures security deny to deny Web access but needs to allow some specified IP addresses to access the Web page of the device, the user can run this command to add allowable IP addresses to the web permit IP whitelist. This command specifies the IP addresses that are allowed to access the Web page of the device (regardless of the local anti-attack rate limit and deny command).

Configuration Example

↘ **Configuring the Local Anti-attack Whitelist (Whitelisted IP Address Range: 192.168.1.2—192.168.1.10)**

Configuration Steps	● Configure whitelisted users.

	Hostname# configure terminal Hostname(config)# control-plane Hostname(config-cp)# security web permit 192.168.1.2 192.168.1.10
Verification	Simulate network attacks and configure local anti-attack whitelisted users. ● Users not included in the local anti-attack whitelist cannot smoothly telnet to the device or access the Web page of the device. ● Users included in the local anti-attack whitelist can smoothly telnet to the device and access the Web page of the device.
	N/A

Common Errors

- All intranet users are added to the whitelist. As a result, the CPU utilization will be abnormal in the case of attacks from intranet users.

1.4.4 Configuring User Management Device Restriction

Configuration Effect

- After the ping operation is forbidden, non-whitelisted users cannot ping the device.
- After the Web access is forbidden, non-whitelisted users cannot access the Web page of the device.
- After Telnet and SSH login are forbidden, non-whitelisted users cannot telnet to the device or log in to the device in SSH mode.
- After SNMP management is forbidden, non-whitelisted users cannot manage the device over SNMP.

Notes

- This function can be used with the local anti-attack whitelist.

Configuration Steps

↘ **Entering Global control-plane Mode**

- Mandatory.

↘ **Forbidding Intranet/Extranet Users to Ping the Device**

- Optional.

↘ **Forbidding Intranet/Extranet Users to Access the Web Page of the Device**

- Optional.

↘ **Forbidding Intranet/Extranet Users to Telnet to the Device or Log In to the Device in SSH Mode**

- Optional.

↘ **Forbidding Intranet/Extranet Users to Manage the Device over SNMP**

- Optional.

Verification

Enable the function of forbidding intranet/extranet users to ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and manage the device over SNMP.

- Non-whitelisted users fail to ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and mange the device over SNMP.
- Whitelisted users can ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and mange the device SNMP.

Related Commands

Configuring User Management Device Restriction

Command	**security deny** { **lan** { **tcp** | **udp** } **port** *port-number* | **lan-ping** | **lan-snmp** | **lan-ssh** | **lan-telnet** | **lan-web** | **vpn-telnet-ssh-web** | **wan** { **tcp** | **udp** } **port** *port-number* | **wan-ping** | **wan-snmp** | **wan-ssh** | **wan-telnet** | **wan-web** }
Parameter Description	**lan**: Forbids users to access specified TCP or UDP ports of the device from a LAN port. **tcp**: Indicates TCP ports. **udp**: Indicates UDP ports. **port** *port-number*: Indicates the TCP or UDP port number. **lan-ping**: Forbids users to ping the device from a LAN port. **lan-snmp**: Forbids users to manage the device over SNMP from a LAN port. **lan-ssh**: Forbids users to login to the device in SSH mode from a LAN port. **lan-telnet**: Forbids users to telnet to the device from a LAN port. **lan-web**: Forbids users to access the Web page of the device from a LAN port. **vpn-telnet-ssh-web**: Forbids VPN users to telnet to the device, login to the device in SSH mode or access the Web page of the device. **wan**: Forbids users to access specified TCP or UDP ports of the device from a WAN port. **wan-ping**: Forbids users to ping the device from a WAN port. **wan-snmp**: Forbids users to manage the device over SNMP from a WAN port. **wan-ssh**: Forbids users to login to the device in SSH mode from a WAN port. **wan-telnet**: Forbids users to telnet to the device from a WAN port. **wan-web**: Forbids users to access the Web page of the device from a WAN port.
Command Mode	control-plane mode
Usage Guide	If the functions are enabled but no whitelist is configured, you need to edit configurations through the console or Telnet.

Configuration Example

Configuring the Local Anti-attack Whitelist (Whitelisted IP Address Range: 192.168.1.2—192.168.1.10)

Configuration Steps	● Configure whitelisted users. ● Configure the functions of forbidding Intranet/Extranet users to ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and manage the device over SNMP.
	Hostname# configure terminal Hostname(config)# control-plane Hostname(config-cp)# security web permit 192.168.1.2 192.168.1.10 Hostname(config-cp)# security deny wan-ping Hostname(config-cp)# security deny wan-web Hostname(config-cp)# security deny lan-ping Hostname(config-cp)# security deny lan-web Hostname(config-cp)# security deny lan-snmp Hostname(config-cp)# security deny wan-snmp Hostname(config-cp)# security deny lan-ssh Hostname(config-cp)# security deny lan-telnet Hostname(config-cp)# security deny wan-ssh Hostname(config-cp)# security deny wan-telnet Hostname(config-cp)#
Verification	● Non-whitelisted users cannot ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and or mange the device over SNMP. ● Whitelisted users can ping the device, access the Web page of the device, telnet to the device or log in to the device in SSH mode, and mange the device over SNMP.

Common Errors

- After the ping operation and Web access are forbidden, but no user is added to the whitelist, users cannot log in to the Web page of the device.

1.5 Monitoring

Clearing

Description	Command
Clears historical attack information.	**clear attack-info history**

Displaying

Description	Command

Displays device anti-attack configurations and statistics.	**show ef-rnfp** {**acpp** { **data** | **manage** | **protocol** } | **scpp** { **data** | **manage** | **protocol** } | **glean-car** | **arp-car** | **port-filter** | **mpp** | **all** | **web-permit-ip** | **anti-arp-spoof** }
Displays current attack traffic.	**show attack-info current**
Displays historical attack traffic.	**show attack-info history**
Displays the ARP spoofing suspect list.	**show arp-suspect**

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs local anti-attack.	**debug** { **acpp** | **scpp** | **glean-car** | **arp-car** | **port-filter** | **mpp** | **all** }
Records debugging data into the buffer.	**show ef-rnfp debug-buf clear**
Outputs debugging data.	**show ef-rnfp debug-buf echo**
