Personal Data Statement

During the operation or troubleshooting of the products, services, or features you have purchased, certain personal data of users may be collected or used. Therefore, it is essential for you to establish and implement appropriate privacy policies, in compliance with the relevant laws and regulations of the applicable countries or regions, to ensure the complete protection of users' personal data.

If Ruijie Networks is involved in this process, we will strictly adhere to the relevant laws and regulations of the applicable countries or regions and take all necessary actions to safeguard users' personal data.

When discarding, reclaiming, or reusing a device, please ensure to back up or clear any stored data to avoid data leakage. For assistance, please contact our after-sales technical support.

Preface

Intended Audience

This document is intended for:

- Network engineers
- Technical support and servicing engineers
- Network administrators

Technical Support

Conventions

1. Conventions

Convention	Description
Boldface	The keywords of a command line are in **boldface**.
Italic	Command arguments are in *italics*.
[ ]	Items in square brackets are optional.
[x | y]	Optional items are grouped in braces and separated by vertical bars. One item or no item is selected.
{ x | y }	Optional items are grouped in brackets and separated by vertical bars. One item is selected.
[x | y | ...] *	Optional items are grouped in braces and separated by vertical bars. Several items or no item can be selected.
{ x | y | ... } *	Optional items are grouped in brackets and separated by vertical bars. A minimum of one item or a maximum of all items can be selected.
&<1-n>	The parameter before the & sign can be repeated for consecutive 1-n times.

Convention	Description
//	A line starting with double slashes is comments.

2. Signs

The signs used in this document are described as follows:

Warning

An alert that calls attention to important rules and information that if not understood or followed can result in data loss or equipment damage.

Caution

An alert that calls attention to essential information that if not understood or followed can result in function failure or performance degradation.

Note

An alert that contains additional or supplementary information that if not understood or followed will not lead to serious consequences.

Specification

An alert that contains a description of product or version support.

3. Notes

The manual provides configuration information, including models, port types, and command line interfaces, for reference purposes only. In the event of any discrepancy or inconsistency between the manual and the actual version, the actual version shall take precedence.

Configuring Basic Configuration

1. Configuring CLI
2. Configuring Basic Management
3. Configuring Lines
4. Configuring HTTP Service
5. Configuring Syslog
6. Configuring Software Authorization Management
7. Configuring USB
8. Configuring Package Management
9. Configuring Time Range

1 Configuring CLI

1.1 Overview

The command line interface (CLI) is a window used for text command interaction between users and network devices. You can enter commands in the CLI window to configure and manage network devices.

Protocols and Standards

N/A

1.2 Applications

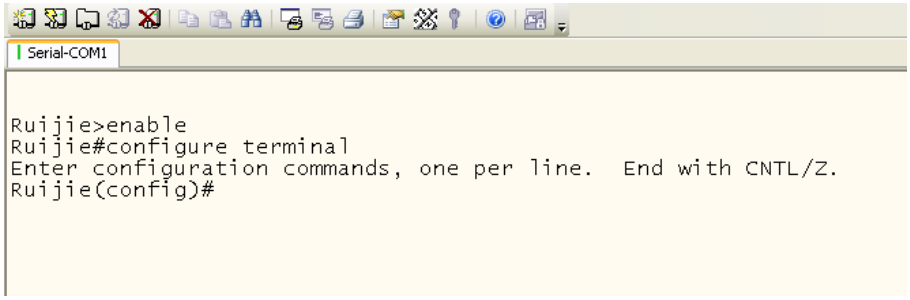
Application	Description
Configuring and Managing Network Devices Through the CLI	You can enter commands in the CLI window to configure and manage network devices

1.2.1 Configuring and Managing Network Devices Through the CLI

Scenario

As shown in Figure 1-1, a user accesses network device A using a PC, and enter commands in the CLI window to configure and manage the network device.

Figure 1-1



Remarks	A is the network device to be managed. PC is a terminal.

Deployment

As shown in Figure 1-2, the user uses the Secure CRT installed on a PC to set up a connection with network device A, and opens the CLI window to enter configuration commands.

Figure 1-2

1.3 Features

Overview

Feature	Description
Accessing the CLI	You can log in to a network device for configuration and management.
Command Modes	The CLI provides several command modes. Commands that can be used vary according to command modes.
System Help	You can obtain help information of the system during CLI configuration.
Abbreviated Commands	If the input string can be used to identify a unique command, you do not need to enter the full string of the command.
No and Default Forms of Commands	You can use the **no** form of a command to disable a function or perform the operation opposite to the command, or use the **default** form of the command to restore default settings.
Prompts Indicating Incorrect Commands	An error message will be displayed if an incorrect command is entered.
Historical Commands	You can use shortcut keys to display or call history commands.
Featured Editing	The system provides shortcut keys for editing commands.
Searching and Filtering of the Show Command Output	You can run the **show** command to search for or filter specified commands.
Command Alias	You can configure the alias of a command to replace the command.

1.3.1 Accessing the CLI

Before using the CLI, you need to connect a terminal or PC to a network device. You can use the CLI after starting the network device and finishing hardware and software initialization. When being used for the first time, the network device can be connected only through the console port, which is called out-of-band management. After performing the configuration, you can connect and manage the network device through Telnet.

1.3.2 Command Modes

A device provides many commands. The commands are classified by function to facilitate the use of commands. The CLI provides several command modes, and all commands are registered in one or more command modes. You must first enter the command mode of a command before using this command. Different command modes are interconnected yet distinct from one another.

As soon as a new session is set up with the network device management interface, you enter the user EXEC mode. In this mode, you can use only a small number of commands and command functions are limited, such as **show** commands. Execution results of commands in user EXEC mode are not saved.

To use more commands, you must first enter the privileged EXEC mode. Typically, you must enter a password to enter the privileged EXEC mode. In privileged EXEC mode, you can use all commands registered in this command mode, and further enter the global configuration mode.

Using commands in a specified configuration mode such as the global or interface configuration mode will affect the configuration in use. If you save the configuration, these commands will be saved and executed next time the system is restarted. You must enter the global configuration mode before entering another configuration mode, such as the interface configuration mode.

The following table summarizes the command modes by assuming that the name of the network device is **Hostname**.

Command Mode	Access Method	Prompt	Exit or Entering Another Mode	About
User EXEC mode	Enter the user EXEC mode by default when accessing a network device.	Hostname>	Run the **exit** command to exit the user EXEC mode. Run the **enable** command to enter the privileged EXEC mode.	Use this command mode to conduct basic tests or display system information.
Privileged EXEC mode	In User EXEC mode, run the **enable** command to enter Privileged EXEC mode.	Hostname#	Run the **disable** command to return to the user EXEC mode. Run the **configure** command to enter the global configuration mode.	Use this command mode to check whether the configuration takes effect. This mode is password protected.
Global configuration mode	In Privileged EXEC mode, run the **configure** command to enter global configuration mode.	Hostname(config)#	Run the **exit** or **end** command, or press **Ctrl+C** to return to the privileged EXEC mode. Run the **interface** command to enter the interface configuration mode. When using the **interface** command, you must specify the interface. Run the **vlan** *vlan_id* command to enter the VLAN configuration mode.	Using commands in this mode will affect global parameters of the network device.

Command Mode	Access Method	Prompt	Exit or Entering Another Mode	About
Interface configuration mode	In global configuration mode, run the **interface** command to enter interface configuration mode.	Hostname(config-if)#	Run the **end** command, or press **Ctrl+C** to return to Privileged EXEC mode. Run the **exit** command to return to global configuration mode. When using the **interface** command, you must specify the interface.	Use this configuration mode to configure various interfaces of the network device.
VLAN configuration mode	In global configuration mode, run the **vlan** *vlan_id* command to enter VLAN configuration mode.	Hostname(config-vlan)#	Run the **end** command, or press **Ctrl+C** to return to the privileged EXEC mode. Run the **exit** command to return to the global configuration mode.	Use this configuration mode to configure VLAN parameters.

1.3.3 System Help

When entering commands in the CLI window, you can obtain help information using the following methods:

1. At the command prompt in any mode, enter a question mark (?) to list the commands supported by the current command mode and related command description.

Example:

```
Hostname>?
Exec commands:
  <1-99>      Session number to resume
  disable     Turn off privileged commands
  disconnect  Disconnect an existing network connection
  enable      Turn on privileged commands
  exit        Exit from the EXEC
  help        Description of the interactive help system
  lock        Lock the terminal
  ping        Send echo messages
  show        Show running system information
  telnet      Open a telnet connection
  traceroute  Trace route to destination
```

2. Enter a space and a question mark (?) following a keyword of a command to list the next keyword or variable associated with the keyword.

Example:

```
Hostname(config)#interface ?
  Aggregateport     Aggregate port interface
  Dialer            Dialer interface
  GigabitEthernet   Gigabit Ethernet interface
  Loopback          Loopback interface
  Multilink         Multilink-group  interface
  Null              Null interface
  Tunnel            Tunnel interface
  Virtual-ppp       Virtual PPP interface
  Virtual-template  Virtual Template interface
  Vlan              Vlan interface
  range             Interface range command
```

If the keyword is followed by a parameter value, the value range and description of this parameter are displayed as follows.

```
Hostname(config)#interface vlan ?
  <1-4094>  Vlan port number
```

3. Enter a question mark (?) following an incomplete string of a command keyword to list all command keywords starting with the string.

For example

```
Hostname#d?
debug  delete  diagnostic  dir  disable  disconnect
```

4. After an incomplete command keyword is entered, if the suffix of this keyword is unique, press the **Tab** key to display the complete keyword.

Example:

```
Hostname# show conf<Tab>
Hostname# show configuration
```

5. In any command mode, run the **help** command to obtain brief description about the help system.

Example:

```
Hostname(config)#help
Help may be requested at any point in a command by entering
a question mark '?'.  If nothing matches, the help list will
be empty and you must backup until entering a '?' shows the
available options.
Two styles of help are provided:
```

```
1. Full help is available when you are ready to enter a
   command argument (e.g. 'show ?') and describes each possible
   argument.
2. Partial help is provided when an abbreviated argument is entered
   and you want to know what arguments match the input
   (e.g. 'show pr?'.)
```

1.3.4 Abbreviated Commands

If a command is long, you can enter a sufficient portion of it to identify the command keyword.

For example, to run the **interface** *gigabitEthernet 0/1* command in the configuration mode of GigabitEthernet 0/1, enter the following abbreviated command.

```
Hostname(config)#int g0/1
Hostname(config-if-GigabitEthernet 0/1)#
```

1.3.5 No and Default Forms of Commands

Most commands have the **no** form. Typically, the **no** form of a command is used to disable a feature or function, or perform the operation opposite to the command. For example, run the **no shutdown** command to perform the operation opposite to the **shutdown** command, that is, enabling the interface. The keyword without the **no** form is used to enable a disabled feature or a feature that is disabled by default.

Most configuration commands have the **default** form. The **default** form of a command is used to restore default settings of the command. Default values of most commands are used to disable related functions. Therefore, the function of the **default** form is the same as that of the **no** form in most cases. For some commands, however, the default values are used to enable related functions. In this case, the function of the **default** form is opposite to that of the **no** form. At this time, the **default** form is used to enable the related function and set variables to default values.

For specific function of the **no** or **default** form of each command, see the command reference.

1.3.6 Prompts Indicating Incorrect Commands

When you enter an incorrect command, an error message is displayed.

The following table lists common CLI error messages.

Error Message	Description	How to Obtain Help
% Ambiguous command: "show c"	The input characters are insufficient for identifying a unique command.	Re-enter the command, and enter a question mark (?) following the word that is ambiguous. All the possible keywords will be displayed.
% Incomplete command.	The mandatory keyword or variable is not entered in the command.	Re-enter the command, and enter a space and a question mark (?). All the possible keywords or variables will be displayed.
% Invalid input detected at '^' marker.	An incorrect command is entered. The sign (^) indicates the position of the word that causes the error.	At the current command mode prompt, enter a question mark (?). All the command keywords allowed in this command mode will be displayed.

1.3.7 Historical Commands

The system automatically saves commands that are entered recently. You can use shortcut keys to display or call historical commands.

Operation	Result
Ctrl+P or up arrow key	Display the previous command in the historical command list. Starting from the latest record, you can repeatedly perform this operation to query earlier records.
Ctrl+N or down arrow key	After pressing **Ctrl+N** or the down arrow key, you can return to a command that is recently executed in the historical command list. You can repeatedly perform this operation to query recently executed commands.

The standard terminals such as VT100 series support arrow keys.

1.3.8 Featured Editing

When editing a command line, you can use the keys or shortcut keys listed in the following table.

Function	Key or Shortcut Key	Description
Move the cursor on the editing line.	Left arrow key or **Ctrl+B**	Move the cursor to the previous character.
	Right arrow key or **Ctrl+F**	Move the cursor to the next character.
	Ctrl+A	Move the cursor to the head of the command line.
	Ctrl+E	Move the cursor to the end of the command line.
Delete an entered character.	Backspace key	Delete one character to the left of the cursor.
	Delete key	Delete one character to the right of the cursor.
Move the output by one line or one page.	Return key	When displaying contents, press the return key to move the output one line upward and display the next line. This operation is performed when the output does not end.
	Space key	When displaying contents, press the space key to page down and display the next page. This operation is performed when the output does not end.

When the editing cursor is close to the right boundary, the command line shifts left by 20 characters, with the hidden part at the front replaced by the symbol ($). You can use specific keys or shortcuts to move the cursor to preceding characters or return to the beginning of the command line.

For example, the **access-list** command may exceed the width of one screen. As the cursor approaches the end of the line for the first time, the command line shifts left by 20 characters, with the hidden part at the front replaced by the symbol ($). This shift by 20 characters occurs each time the boundary is approached.

```
access-list 199 permit ip host 192.168.180.220 host

$ost 192.168.180.220 host 202.101.99.12

$0.220 host 202.101.99.12 time-range tr
```

Press **Ctrl+A** to return to the beginning of the command line. At this point, the hidden part at the end of the command line will be replaced by the symbol ($).

```
access-list 199 permit ip host 192.168.180.220 host 202.101.99.$
```

The default screen width is 80 characters.

1.3.9 Searching and Filtering of the Show Command Output

To search specified contents from the output of the **show** command, run the following command.

Command	Description
show *any-command* | **begin** *regular-expression*	Searches specified contents from the output of the **show** command. The first line containing the contents and all information that follows this line will be output.

The **show** command can be executed in any mode.

Searched contents are case-sensitive.

To filter specified contents from the output of the **show** command, run the following commands.

Command	Description
show *any-command* | **exclude** *regular-expression*	Filters the output of the **show** command. Except those containing the specified contents, all lines will be output.
show *any-command* | **include** *regular-expression*	Filters the output of the **show** command. Only the lines containing the specified contents will be output.

To search or filter the output of the **show** command, you must enter a vertical line (|). Up to 32 filtering conditions can be defined in the command. You can select the searching or filtering rules and contents (character or string) following the vertical line (|). Searched and filtered contents are case-sensitive.

```
Hostname#show running-config | include interface
interface GigabitEthernet 0/0
interface GigabitEthernet 0/1
interface GigabitEthernet 0/2
interface GigabitEthernet 0/3
interface GigabitEthernet 0/4
interface GigabitEthernet 0/5
interface GigabitEthernet 0/6
interface GigabitEthernet 0/7
interface Mgmt 0
```

1.3.10 Command Alias

You can configure any word as the alias of a command to simplify the command input.

Configuration Effect

1. Replace a command with a word.

For example, configure **mygateway** as the alias of the **ip route** *0.0.0.0 0.0.0.0192.1.1.1* command. To run this command, you only need to enter **mygateway**.

2. Replace the front part of a command with a word, and enter the later part.

For example, configure **ia** as the alias of the **ip address** command. To run this command, you need to enter **ia** and then the specified IP address and subnet mask.

Configuration Step

Displaying Default Alias

In user EXEC or privileged EXEC mode, the default aliases are available for some commands. You can run the **show aliases** command to display the default aliases.

```
Hostname(config)#show aliases
Exec mode alias:
  h                    help
  p                    ping
  s                    show
  u                    undebug
  un                   undebug
```

The default aliases cannot be deleted.

Configuring a Command Alias

Command	**alias** *mode command-alias original-command*
Parameter Description	*mode*: Indicates the command mode of the command represented by the alias. *command-alias*: Indicates the command alias. *original-command*: Indicates the command represented by the alias.
Command Mode	Global configuration mode
Usage Guide	In global configuration mode, run the **alias** ? command to list all command modes that can be configured with aliases.

Displaying Settings of Command Aliases

Run the **show aliases** command to display alias settings in the system.

Notes

- The command replaced by an alias must start from the first character of the command line.
- The command replaced by an alias must be complete.
- The entire alias must be entered when the alias is used; otherwise, the alias cannot be identified.

Configuration Example

Defining an Alias to Replace the Entire Command

Configuration Steps	In global configuration mode, configure the alias **ir** to represent the default route configuration command **ip route** *0.0.0.0 0.0.0.0 192.168.1.1.*

	Hostname#configure terminal Hostname(config)#alias config ir ip route 0.0.0.0 0.0.0.0 192.168.1.1
Verification	● Run the **show alias** command to check whether the alias is configured successfully. Hostname(config)#show alias Exec mode alias: h help p ping s show u undebug un undebug Global configuration mode alias: ir ip route 0.0.0.0 0.0.0.0 192.168.1.1
	● Use the configured alias to run the command, and run the **show running-config** command to check whether the alias is configured successfully.
	Hostname(config)#ir Hostname(config)#show running-config Building configuration... ! alias config ir ip route 0.0.0.0 0.0.0.0 192.168.1.1 //Configuring an alias ... ip route 0.0.0.0 0.0.0.0 192.168.1.1 //Configuration result after the alias "ir" is entered !

Defining an Alias to Replace the Front Part of a Command

Configuration Steps	In global configuration mode, configure the alias **ir** to represent the front part **ip route** of the default route configuration command.
	Hostname#configure terminal Hostname(config)#alias config ir ip route
Verification	● Run the **show alias** command to check whether the alias is configured successfully. Hostname(config)#show alias Exec mode alias: h help p ping

	s show u undebug un undebug Global configuration mode alias: ir ip route
	● Enter the alias **ir** and then the later part of the command **0.0.0.0 0.0.0.0 192.168.1.1**. ● Run the **show ir ap-config running** command to check whether the configuration is successful.
	Hostname(config)#ir 0.0.0.0 0.0.0.0 192.168.1.1 Hostname(config)#show running Building configuration... ! alias config ir ip route //Configuring an alias ! ip route 0.0.0.0 0.0.0.0 192.168.1.1 //Configuration result after the alias "ir" and the later part of the command are entered !

System Help

1. The system provides help information for command alias. An asterisk (*) will be displayed in front of an alias.

```
*command-alias=original-command
```

For example, in privileged EXEC mode, the default command alias **s** represents the **show** keyword. If you enter **s?**, the keywords starting by **s** and alias information are displayed.

```
Hostname#s?
*s=show  show  start-chat  start-terminal-service
```

2. If the command represented by an alias contains more than one word, the command is displayed in a pair of quotation marks.

For example, in privileged EXEC mode, configure the alias **sv** to replace the **show version** command. If you enter **s?**, the keywords starting by **s** and alias information are displayed.

```
Hostname#s?
*s=show  *sv="show version" show  start-chat
start-terminal-service
```

3. You can use the alias to obtain help information about the command represented by the alias.

For example, configure the alias **ia** to represent the **ip address** command in interface configuration mode. If you enter **ia?** in interface configuration mode, the help information on **ip address?** is displayed, and the alias is replaced by the command.

```
Hostname(config-if)#ia ?

  A.B.C.D  IP address

  dhcp     IP Address via DHCP

Hostname(config-if)#ip address
```

If you enter a space in front of a command, the command represented by this alias will not be displayed.

1 Configuring Basic Management

1.1 Overview

This document is a getting started guide for network device management. It describes how to manage, monitor, and maintain network devices.

1.2 Applications

Application	Description
Network Device Management	A user logs in to a network device from a terminal and runs commands on a command line interface (CLI) to manage device configurations.

1.2.1 Network Device Management

Scenario

Network device management described in this document is performed through the CLI. A user logs in to network device A from a terminal and runs commands on the CLI to manage device configurations.

Figure 1-1

1.3 Features

Basic Concepts

TFTP

The Trivial File Transfer Protocol (TFTP) is a TCP/IP protocol which allows a client to transfer a file to a server or obtain a file from a server.

AAA

AAA is short for authentication, authorization and accounting.

Authentication refers to verification of user identities and network services.

Authorization refers to granting of network services to users according to authentication results.

Accounting refers to tracking of network services consumed by users. A billing system charges users based on consumption records.

RADIUS

The Remote Authentication Dial In User Service (RADIUS) is the most widely used AAA protocol.

Telnet

Telnet is a terminal emulation protocol in the TCP/IP protocol suite that provides access to a remote host through a virtual terminal connection. It is a standard protocol located at Layer 7 (application layer) of the Open System Interconnection (OSI) model and used on the Internet for remote login. A Telnet connection is established between the local PC and a remote host.

System Information

System information includes the system description, power-on time, hardware and software versions, and control-layer and boot-layer software versions.

Hardware Information

Hardware information includes physical device information as well as slot and module information. The device information includes the device description and slot quantity. The slot information includes the slot ID, module description (which is empty if a slot does not have a module), and actual and maximum numbers of physical ports.

Overview

Feature	Description
User Access Control	Controls terminals' access to network devices on the Internet based on passwords and privilege levels.
Login Authentication Control	Performs username-password authentication to grant access to network devices when AAA is enabled. (Authentication is performed by a dedicated server.)
Basic System Parameters	Configures system parameters including the clock, banner, and console baud rate.
Displaying Configurations	Displays system configurations, including the configurations that the system is running and device configurations stored in the nonvolatile random access memory (NVRAM).
Telnet	Provides the standard governing remote login and virtual terminal communication on the Internet.
Restart	Introduces system restart. Telnet is an application-layer protocol in the TCP/IP protocol suite.
Running Batch File Commands	Runs commands stored in the batch file.
Character Set Encoding	After an STA enters a command in the CLI, the command is automatically converted into a command in the unified character set encoding format before delivery.
Configuring Active Backup of the Running Configuration File to a Remote Server	Configures the device to automatically backs up the running configuration file to the remote server when the device running configuration changes.

1.3.1 User Access Control

User access control refers to control of terminals' access to network devices on the Internet based on passwords and privileges.

Working Principle

Privilege Level

Sixteen privilege levels are defined ranging from 0 to 15 for the CLI on network devices to grant users access to different commands. Level 0 is the lowest level granting access to just a few commands, whereas level 15 is the highest level granting access to all commands. Levels 0 and 1 are common user levels without the device configuration permission (users are not allowed to enter the global configuration mode by default). Levels 2–15 are privileged user levels with the device configuration permission.

Password Classification

Passwords are classified into two types: password and security. The first type refers to simple encrypted passwords at level 15; the second type refers to secure encrypted passwords at levels 0–15. If a level is configured with both simple and secure encrypted passwords, the simple encrypted password will not take effect. If you configure a non-15 level simple encrypted password, a warning is displayed and the password is automatically converted into a secure encrypted password. If you configure the same simple encrypted password and secure encrypted password at level 15, a warning is displayed.

Password Protection

Each privilege level on a network device has a password. An increase in the privilege level requires the input of the password of the target level, whereas a decrease in the privilege level does not require password input.

By default, only two privilege levels are password-protected, namely, level 1 (common user level) and level 15 (privileged user level). Sixteen privilege levels with password protection can be assigned to the commands in each mode to grant access to different commands.

If no password is configured for a privileged user level, access to this level does not require password input. It is recommended that a password be configured to ensure security.

Command Authorization

Each command has its lowest execution level. A user with a privilege level lower than this level is not allowed to run the command. After the command is assigned a privilege level, users at this level and higher have access to the command.

Related Configuration

Configuring a Simple Encrypted Password

Run the **enable password** command.

Configuring a Secure Encrypted Password

- Run the **enable secret** command.
- A secure encrypted password is used to control switching between user levels. It has the same function as a simple encrypted password but uses an enhanced password encryption algorithm. Therefore, secure encrypted passwords are recommended to ensure security.

Configuring Command Privilege Levels

- Run the **privilege** command to assign a privilege level to a command.
- A command at a lower level is accessible by more users than a command at a higher level.

Raising or Lowering a User Privilege Level

- Run the **enable** command or the **disable** command to raise or lower a user privilege level respectively.
- After logging in to a network device, the user can change the level to obtain access to commands at different privilege levels.
- Run the **login privilege log** command to enable the log information prompt for raised user privilege level.

Enabling Line Password Protection

- Line password protection is required for remote login such as login through Telnet.
- Run the **password** [**0** [*line*] | **7** *line*] *line* command to configure a line password, and then run the **login** command to enable password protection.
- By default, terminals do not support the **lock** command.

1.3.2 Login Authentication Control

In login authentication with AAA disabled, the input password is checked against the configured line password. If they are consistent, a user can access the network device. In local authentication mode, the username and password entered by a user are checked against those stored in the local user database. If they are matched, the user can access the network device with proper management permissions.

In AAA, the username and password entered by a user are authenticated by a server. If authentication is successful, the user can access the network device and enjoy certain management permissions.

For example, a RADIUS server can be used to authenticate usernames and passwords and control users' management permissions on network devices. Network devices no longer store users' passwords, but send encrypted user information to the RADIUS server, including usernames, passwords, shared passwords, and access policies. This provides a convenient way to manage and control user access and improve user information security.

Working Principle

Line Password

If AAA is disabled, you can configure a line password used to verify user identities during login. After AAA is enabled, line password verification does not take effect.

Local Authentication

If AAA is disabled, you can configure local authentication to verify user identities and control management permissions by using the local user database. After AAA is enabled, local authentication does not take effect.

AAA

AAA provides three independent security functions, namely, authentication, authorization and accounting. A server (or the local user database) is used to perform authentication based on the configured login authentication method list and control users' management permissions. For details about AAA, see *Configuring AAA*.

Related Configuration

Configuring Local User Information

Run the **username** command to configure the account used for local identity authentication and authorization, including usernames, passwords, and optional authorization information.

Configuring Local Authentication for Line-based Login

- Run the **login local** command when AAA is disabled.
- Perform this configuration on each device.

Configuring AAA Authentication for Line-based Login

- The default authentication method is used after AAA is enabled.
- Run the **login authentication** command to configure a login authentication method list for a line.
- Perform this configuration when the local AAA authentication is required.

Configuring Non-AAA Authentication for Line-based Login After AAA Is Enabled

- After AAA is enabled, run the **login access non-aaa** command in global configuration mode to configure non-AAA authentication for line-based login.
- Perform this configuration on each device.

Configuring the Connection Timeout Time

- The default connection timeout time is 10 minutes.
- Run the **exec-timeout** command to change the default connection timeout time. An established connection will be terminated if no output is detected during the timeout time.
- Perform this configuration when you need to increase or reduce the connection timeout time.

Configuring the Session Timeout Time

- The default session timeout time is 0 minutes, indicating no timeout.
- Run the **session-timeout** command to change the default session timeout time.
- The session established with a remote host through a line will be disconnected if no output is detected during the timeout time. Then the remote host is restored to idle. Perform this configuration when you need to increase or reduce the session timeout time.

Locking a Session

- By default, terminals do not support the **lock** command.
- Run the **lockable** command to lock the terminals connected to the current line.
- To lock a session, first enable terminal lock in line configuration mode, and then run the **lock** command in terminal EXEC mode to lock the terminal.

1.3.3 Basic System Parameters

System Time

The network device system clock records the time of events on the device. For example, the time shown in system logs is obtained from the system clock. The ime is recorded in the format of *year-month-day, hour*:*minute*:*second*, *day of the week*.

When you use a network device for the first time, set its system clock to the current date and time manually.

Configuring a System Name and Command Prompt

You can configure a system name to identify a network device. The default system name is **Ruijie**. A name with more than 32 characters will be truncated to keep only the first 32 characters. The command prompt keeps consistent with the system name.

Banner

A banner is used to display login prompt information. There are two types of banner: daily notification and login banner.

- Daily notification is displayed on all terminals connected to network devices upon login. Urgent messages (such as immediate system shutdown) can be delivered to users through daily notification.
- A login banner appears after daily notification to display login information.

Configuring the Console Baud Rate

You can manage a network device through a console port. When a network device is used for the first time, the configuration must be performed through the console port. The serial port's baud rate can be changed as needed. Note that the management terminal must have consistent baud rate setting with the device console.

Configuring the Connection Timeout Time

The connection timeout time is used to control device connections (including established connections and sessions established with remote hosts). A connection will be ended when no input is detected during the timeout time.

Related Configuration

Configuring the System Date and Clock

Run the **clock set** command to configure the system time of a network device manually. The device clock starts from the configured time and keeps running even when the device is powered off.

Updating the Hardware Clock

If the hardware clock and software clock are not synchronized, run the **clock update-calendar** command to copy the date and time of the software clock to the hardware clock.

Configuring a System Name

- Run the **hostname** command to change the default system name.
- The default host name is **Ruijie**.

Configuring a Command Prompt

Run the **prompt** command.

Configuring Daily Notification

- By default, no daily notification is configured.

- Run the **banner motd** command to configure daily notification.
- Daily notification is displayed on all terminals connected to network devices upon login. Urgent messages (such as immediate system shutdown) can be delivered to users through daily notification.

Configuring a Login Banner

- By default, no login banner is configured.
- Run the **banner login** command to configure a login banner to display login information.

Configuring the Console Baud Rate

- Run the **speed** command.
- The default baud rate is 9600 bps.

1.3.4 Displaying Configurations

System configurations include the configurations that the system is running and device configurations stored in the NVRAM.

Working Principle

Running Configurations

Running configurations, namely, running-config, are the configurations that individual component modules run in real time. A request can be made to all running components to collect configurations, which will be orchestrated before being displayed to users. Only running components may provide real-time configurations, whereas unloaded components do not display configurations. When the system is started, a component process is restarted, and a hot patch is executed, the configurations collected during this period may be inaccurate due to the component's unstable status. For example, the configurations of a component may be missing initially but can be displayed later.

Startup Configurations

The configurations stored in the NVRAM, namely, startup-config, are the configurations executed during device startup. When the system is restarted, startup-config is loaded to become new running-config. To display permanent configurations, the system needs to read the **startup-config** file in the NVRAM.

⚠ The startup-config file copied to the device from an external environment only supports UTF-8 (without BOM) encoding.

Related Configuration

Displaying Running Configurations

Run the **show running-config** [**interface** *interface*] command to display the configurations that the system is running or the configurations on an interface or all interfaces.

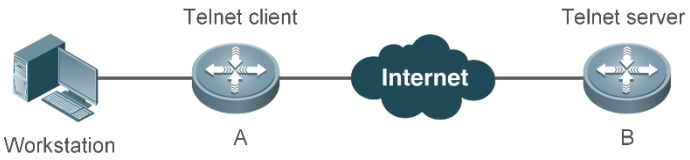
Displaying Startup Configurations

Run the **show startup-config** command to display configurations executed during device startup.

Storing Startup Configurations

Run the **write** or **copy running-config startup-config** command to store the current running configurations as new startup configurations.

1.3.5 Telnet



Working Principle

Telnet is an application-layer protocol in the TCP/IP protocol suite. It provides the standard governing remote login and virtual terminal communication on the Internet.

The Telnet client service allows a local or remote user who has logged in to a network device to use its Telnet client program to access other remote system resources on the Internet. In Figure 1-2, a user's PC connects to network device A by using the terminal emulation or Telnet program and then logs in to network device B by using the **telnet** command to perform configuration management.

Telnet program supports the use of IPv4 and IPv6 addresses. A Telnet server accepts Telnet connection requests that carry IPv4 and IPv6 addresses. A Telnet client can send connection requests to hosts identified by IPv4 and IPv6 addresses.

Figure 1-2

Related Configuration

Enabling the Telnet Client Service

Run the **telnet** command to log in to a remote device.

Enabling the Do Telnet Client Service

Run the **do telnet** command to log in to a remote device through Telnet.

Restoring a Telnet Client Session

Run the **<1-99>** command.

Disconnecting a Suspended Telnet Client Session

Run the **disconnect** *session-id* command.

Enabling the Telnet Server

- Run the **enable service telnet-server** command.
- Perform this configuration when you need to enable Telnet login.

1.3.6 Restart

The scheduled restart feature makes user operation easier in some scenarios (such as tests).

- If you configure a time interval, the system will restart after the interval. The interval is in the format of *mmm* or *hhh:mm*, in minutes. You can specify the interval name to represent the restart purpose.
- If you define a future time, the system will restart when the time is reached.

⚠ The clock feature must be supported by the system if you want to use the **at** option. It is recommended that you configure the system clock in advance. A new restart plan will overwrite the existing one. A restart plan will become invalid if the system is restarted before the plan takes effect.

⚠ The span between the restart time and current time cannnot exceed 31 days, and the restart time must be later than the current system time. After you configure a restart plan, do not change the system clock; otherwise, the plan may fail (for example, the system time is changed to a time after the restart time.)

Related Configuration

Configuring Restart

- Run the **reload** command to configure a restart policy.
- Perform this configuration when you need to restart a device at a specific time.

1.3.7 Running Batch File Commands

It may take a long time to enter many commands on the CLI for system function management. This process is prone to errors and omissions. The commands can be placed in a batch file according to configuration steps. Executing the file will complete all configurations.

ℹ You can specify the name and content of the batch file on your PC and transfer the file to the flash memory of the device through TFTP. The content of the batch file simulates user input. Therefore, the content must be edited according to the configuration sequence of the CLI commands. For some interactive commands, the responses must be written in the batch file to ensure normal running of the commands.

⚠ The batch file cannot exceed 128 KB in size; otherwise, it will fail to be executed. You can divide a large batch file into multiple files, each smaller than 128 KB in size.

Related Configuration

Running Batch File Commands

- Run the **execute** command to execute commands in a batch file.
- Use this command to configure multiple commands in batch for a function, simplifying user operations.

1.3.8 Character Set Encoding

The character set encoding function enables the device to specify a unified character set encoding format. After a client enters a command in the CLI, the command is automatically converted into a command in the unified character set encoding format before delivery.

ℹ When current running configurations in different formats exist on a device, you can set a unified character set encoding format only after manually delete running configurations that are not in the unified character set encoding format.

Related Configuration

Setting the Character Set Encoding Format

Run the **language character-set** { **UTF-8** | **GBK** | **default** } command to set the character set encoding format.

The value **default** indicates that mixed codes are supported.

Displaying the Character Set Encoding Format

Run the **show language character-set** command to display the current character set encoding format.

1.3.9 Configuring Active Backup of the Running Configuration File to a Remote Server

After active backup of running configurations to a remote server is configured, the device automatically backs up the running configuration file to the remote server when the device running configuration changes.

When the running configuration file is backed up to the remote server, NETCONF sends real-time configuration update notifications. Only the HTTPS protocol is supported. A remote HTTPS file server needs to be set up in advance. Only one file server can be configured. To replace the existing file server, delete the existing file server and then configure a new one.

Related Configuration

Enabling Active Backup of the Running Configuration File

Run the **auto-backup running-config** command to enable active backup of the running configuration file and enter the backup configuration mode.

Configuring Active Backup of the Running Configuration File to a Remote Server

Run the **server** *ipv4-address* **port** *port-number* **transport https** [**username** *username* **password** { [**0**] *password* | **7** *encrypted-password* }] [**remote-path** *path*] command to configure a remote server.

1.4 Configuration

Configuring Passwords and Privileges	(Optional) It is used to configure passwords and command privilege levels.	
	enable password	Configures a simple encrypted password.
	enable secret	Configures a secure encrypted password.
	enable	Raises a user privilege level.
	login privilege log	Outputs logs after the user privilege level is raised.
	disable	Lowers a user privilege level.
	privilege	Configures command privilege levels.
	password	Specifies a line password.
	login	Enables line password protection.

Configuring Login and Authentication	(Optional) It is used to configure different login modes and authentication modes.	
	username	Configures local user account information and optional authorization information.
	login local	Configures local authentication for line-based login.
	login access non-aaa	Configures non-AAA authentication for line-based login after AAA is enabled.
	login authentication	Configures AAA authentication for line-based login.
	telnet	Enables the Telnet client.
	do telnet	Enables the Do Telnet client.
	enable service telnet-server	Enables the Telnet server.
	exec-timeout	Configures the connection timeout time.
	session-timeout	Configures the session timeout time.
	lockable	Enables line-based terminal lock.
	lock	Locks a terminal connected to a line.
	ip telnet source-interface *interface-name*	Specifies the IP address of the interface as the source IP address of a Telnet session.
Configuring Basic System Parameters	(Optional) It is used to configure basic system parameters.	
	clock set	Configures the system date and clock.
	clock update-calendar	Updates the hardware clock.
	hostname	Configures a system name.
	prompt	Configures a command prompt.
	banner exec *c message c*	Customizes a welcome prompt indicating that a user has entered the user EXEC mode of a line.
	banner incoming *c message c*	Configures a prompt indicating the establishment of a reverse Telnet session.
	banner motd	Configures daily notification.
	Bannerlogin *c message c*	Configures a login banner.
	banner prompt-timeout *c message c*	Configures the timeout message to notify timeout.
	banner slip-ppp *c message c*	Configures the SLIP/PPP message for the SLIP/PPP session.
	exec-banner	Configures display of an EXEC banner for a specific line.
	motd-banner	Configures display of a MOTD banner

		for a specific line.
	speed	Configures the console baud rate.
	write [**memory** | **terminal**]	Saves system configurations (running-config) to a specific directory.
	username import *filename*	Imports user information from a file.
	username export *filename*	Exports user information to a file.
Enabling and Disabling a Specific Service	⚠ (Optional) It is used to enable and disable a specific service.	
	enable service	Enables a service.
Configuring a Restart Policy	⚠ (Optional) It is used to configure a system restart policy.	
	reload	Restarts a device.
Running Batch File Commands	⚠ Optional. It is used to run batch file commands.	
	execute { [**flash:**] *filename* }	Runs batch file commands.
Configuring the Character Set Encoding Format	⚠ (Optional) It is used to configure the language character set.	
	language character-set { **UTF-8** | **GBK** | **default** }	Configures the language character set.
Configuring Active Backup of the Running Configuration File to a Remote Server	**auto-backup running-config**	Enables active backup of the running configuration file.
	server	Configures active backup of the running configuration file to a remote server.

1.4.1 Configuring Passwords and Privileges

Configuration Effect

- Configure passwords to control users' access to network devices.
- Assign a privilege level to a command to grant the command access to only the users at or higher than the level.
- Lower the command privilege level to grant more users' access to the command.
- Raise the command privilege level to limit the command access to a few users.

Notes

- You can use the password configuration command with the **level** option to configure a password for a specific privilege level. After you specify the level and password, the password works for the users who need to access this level.
- By default, no password is configured for any level. The default level is 15.
- If you configure a simple encrypted password with a non-15 level, a warning is displayed and the password is automatically converted into a secure encrypted password.
- The system chooses the secure encrypted password if both simple and secure encrypted passwords are configured.

Configuration Step

Configuring a Simple Encrypted Password

- Optional. Perform this configuration when you need to establish simple encrypted password verification during user switching between different privilege levels.
- Run the **enable password** command to configure a simple encrypted password.

Configuring a Secure Encrypted Password

- Optional. Perform this configuration when you need to establish secure encrypted password verification during user switching between different privilege levels.
- Run the enable secret command to configure a secure encrypted password.
- A secure encrypted password has the same function as a simple encrypted password but uses an enhanced password encryption algorithm. Therefore, secure encrypted passwords are recommended to ensure security.

Configuring Command Privilege Levels

- Optional.
- A command at a lower level is accessible by more users than a command at a higher level.

Raising or Lowering a User Privilege Level

- After logging in to a network device, a user can change the level to obtain access to commands at different privilege levels.
- Run the **enable** or **disable** command to raise or lower a user privilege level respectively.
- Run the **login privilege log** command to enable the log information prompt for raised user privilege level.

Enabling Line Password Protection

- Optional. Line password protection is required for remote login such as login through Telnet.
- Run the **password** [**0** [*line*] | **7** *line*] command to configure a line password, and then run the **login** command to enable login authentication.

⚠ If a line password is configured but login authentication is not configured, the system does not display password prompt.

Verification

- Run the **show privilege** command to display the current user level.
- Run the **show running-config** command to display the configuration.

Related Commands

Configuring a Simple Encrypted Password

Command	**nable password** [**level** *level*] [{ *password* | { **0** [*password*] | **7** *encrypted-password* } }]
Parameter Description	*level*: Indicates a specific user level. *password:* Indicates the password used to enter the privileged EXEC mode. **0***:* Indicates that the password is entered in cleartext.

	7*:* Indicates that the password is entered in ciphertext. *encrypted-password:* Indicates the password text, which must contain case-sensitive English letters and digits. Leading spaces are allowed, but will be ignored. However, intermediate and trailing spaces are recognized.
Command Mode	Global configuration mode
Usage Guide	Simple encrypted passwords can be configured with only level 15 and take effect only when no secure encrypted password is configured. If you configure a simple encrypted password with a non-15 level, a warning is displayed and the password is automatically converted into a secure encrypted password. If level-15 simple encrypted password and secure encrypted password are the same, a warning is displayed. If you specify an encryption type and enter a password in plaintext, you cannot re-enter the privileged EXEC mode. An encrypted password cannot be retrieved once being lost. You have to configure a new password.

Configuring a Secure Encrypted Password

Command	**enable secret** [**level** *level*] { *secret* | { [**0** | **5**] *encrypted-secret* } }
Parameter Description	*level*: Indicates a specific user level. *secret:* Indicates the cleartext password used to enter the privileged EXEC mode. **0** | **5**: Indicates the encryption type for a password. **0** indicates no encryption while **5** indicates that a password is encrypted using the MD5 encryption algorithm. *encrypted-password:* Indicates the password text.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure passwords for different privilege levels.

Raising a User Privilege Level

Command	**enable** [*privilege-level*]
Parameter Description	*privilege-level*: Indicates a specific privilege level.
Command Mode	Privileged EXEC mode
Usage Guide	An increase in the privilege level requires input of the target-level password.

Lowering a User Privilege Level

Command	**disable** [*privilege-level*]
Parameter Description	*privilege-level*: Indicates a specific privilege level.
Command Mode	Privileged EXEC mode
Usage Guide	A decrease in the privilege level does not require password input.

	Use this command to exit the privileged EXEC mode and return to the user EXEC mode. If *privilege-level* is specified, the current privilege level is reduced to the specified level. *privilege-level* must be lower than the current level.

Enabling Log Information Prompt for Raised User Privilege Level

Command	**login privilege log**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to enable the monitoring of an increase in user privilege level. This function applies to all terminals.

Configuring Command Privilege Levels

Command	**privilege** *mode* [**all**] { **level** *level* | **reset** } *command-string*
Parameter Description	*mode*: Indicates the CLI mode of the command. For example, **config** indicates the global configuration mode, **EXEC** indicates the privileged command mode, and **interface** indicates the interface configuration mode. **all**: Changes the subcommand privilege levels of a specific command to the same level. **level** *level*: Indicates a privilege level. The value range is from 0 to 15. **reset**: Restores the command privilege level to the default level. *command-string*: Indicates the command to be assigned a privilege level.
Command Mode	Global configuration mode
Usage Guide	To restore a command privilege level, run the **no privilege** *mode* [**all**] { **level** *level* | **reset** } *command-string* command in global configuration mode.

Specifying a Line Password

Command	**password** [{ [**0**] [*password*] | **7** *encrypted-password* }]
Parameter Description	**0**: Configures a password in cleartext. *password*: Indicates the cleartext password for remote line-based login. The password is a string of 1 to 25 characters. **7** *encrypted-password*: Indicates the password is a string of ciphertext characters.
Command Mode	Line configuration mode
Usage Guide	N/A

Enabling Line Password Protection

Command	**login**
Parameter Description	N/A
Command Mode	Line configuration mode

Usage Guide	N/A

Configuration Example

Configuring Command Authorization

Scenario	Assign privilege level 1 to the **reload** command and its subcommands and configure level 1 as the valid level (by configuring the **test** password).
Configuration Steps	● Assign privilege level 1 to the **reload** command and its subcommands.

	`Hostname# configure terminal`
	`Hostname(config)# privilege exec all level 1 reload`
	`Hostname(config)# enable secret level 1 0 test`
	`Hostname(config)# end`

Verification	● Check whether the **reload** command and its subcommands are accessible at level 1.

	`Hostname# disable 1`
	`Hostname> reload ?`
	`at  reload at`

1.4.2 Configuring Login and Authentication

Configuration Effect

- Establish line-based login identity authentication.
- Run the **telnet** command on a network device to log in to a remote device.
- End an established connection if no output is detected during the timeout time.
- Disconnect an established session connecting to a remote host and restore the host to idle if no output is detected during the timeout time.
- Lock a terminal to deny access. When a user enters any character on the locked terminal, the password prompt is displayed. The terminal will be automatically unlocked if the input password is correct.

Configuration Step

Configuring Local User Information

- Mandatory.
- Run the **username** command to configure the account used for local identity authentication and authorization, including usernames, passwords, and optional authorization information.
- Perform this configuration on each device.

Configuring Local Authentication for Line-Based Login

- Mandatory.
- Configure local authentication for line-based login when AAA is disabled.
- Perform this configuration on each device.

Configuring AAA Authentication for Line-based Login

- Optional. Perform this configuration to configure AAA authentication for line-based login.
- Configure AAA authentication for line-based login when AAA is enabled.
- Perform this configuration on each device.

Configuring non-AAA Authentication for Line-based Login When AAA Is Enabled

- Optional.
- After AAA is enabled, run the **login access non-aaa** command in global configuration mode to configure non-AAA authentication for line-based login.
- Perform this configuration on each device.

Enabling the Telnet Client Service

Run the **telnet** command to log in to a remote device.

Enabling the Do Telnet Client Service

Run the **do telnet** command to log in to a remote device.

Restoring a Telnet Client Connection

Optional. Perform this configuration to restore the connection on a Telnet client.

Closing a Suspended Telnet Client Connection

Optional. Perform this configuration to close the suspended connection on a Telnet client.

Enabling the Telnet Server

- Optional.
- Enable the Telnet server when you need to enable Telnet login.

Configuring the Connection Timeout Time

- Optional.
- An established connection will be terminated if no output is detected during the timeout time.
- Perform this configuration when you need to increase or reduce the connection timeout time.

Configuring the Session Timeout Time

- Optional.
- The session connected to a remote host will be disconnected and the host be restored to idle if no output is detected during the timeout time.
- Perform this configuration when you need to increase or reduce the session timeout time.

Locking a Session

- Optional. Perform this configuration when you need to temporarily exit a session on a device.

- To lock a session, first enable terminal lock in line configuration mode, and then run the **lock** command to lock the terminal.

Verification

- Run the **show running-config** command to display the configuration.
- When AAA is disabled, and local user information and line-based local authentication are configured, check whether a user is asked to enter the username and password for access to the CLI.
- When AAA is enabled, and local user information and local AAA authentication are configured, check whether a user is asked to enter the username and password input for access to the CLI.
- Run the **show user** command to display information about the users who have logged in to the CLI.
- Telnet clients can connect to devices enabled with the Telnet server.
- When a user presses **enter** on a locked CLI, the user is prompted for password input. The session is unlocked only when the input password is the same as the configured one.
- Run the **show sessions** command to display each established Telnet client instance.

Related Commands

Configuring Local User Information

Command	**username** *name* [**login mode** { **aux** | **console** | **ssh** | **telnet** }] [**online amount** *number*] [**permission** *oper-mode path*] [**privilege** *privilege-level*] [**reject remote-login**] [**web-auth**] [**pwd-modify**] [**nopassword** | [**password** { [**0** | **7**] *text-string* }] | [**secret** { [**0** | **5**] *text-string* }]]
Parameter Description	*name*: Indicates a user name. **aux**: Sets the login mode to AUX. **login mode**: Indicates the login mode. **console**: Sets the login mode to console. **ssh**: Sets the login mode to SSH. **telnet**: Sets the login mode to Telnet. **online amount** *number*: Indicates the maximum number of online accounts. **permission** *oper-mode path*: Configures the file operation permission. *op-mode* indicates the operation mode, and *path* indicates the directory or path of a specific file. **privilege** *privilege-level*: Indicates the account privilege level. The value range is from 0 to 15. **reject remote-login**: Rejects remote login by using the account. **web-auth**: Allows only web-based authentication for the account. **pwd-modify**: Allows the account owner to change the password. The parameter is available only when **web-auth** is configured. **nopassword**: Indicates that no password is configured for the account. **Password** { [**0** | **7**] *text-string* }: Indicates the password configured for the account. The value 0 indicates that the password is input in cleartext, and the value 7 indicates that the password is input in ciphertext. The default is plaintext. **secret** { [**0** | **5**] *text-string* }: Configures the password for the account. The password configured in this command is encrypted in irreversible mode and saved in ciphertext. The value 0 indicates that the password is input in cleartext, and the value 7 indicates that the password is input in ciphertext. The default is cleartext.

Command Mode	Global configuration mode
Usage Guide	Use this command to create a local user database to be used by authentication. If the value 7 is selected for the encryption type, the entered ciphertext string must consist of an even number of characters. This setting is applicable to the scenario where encrypted passwords may be copied and pasted. In other cases, the value 7 is not selected.

Configuring Local Authentication for Line-based Login

Command	**login local**
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	Use this command to configure local authentication for line-based login when AAA is disabled. Local user information is configured by using the **username** command.

Configuring AAA Authentication for Line-based Login

Command	**login authentication** { **default** | *list-name* }
Parameter Description	**default:** Indicates the default authentication method list name. *list-name*: Indicates the optional method list name.
Command Mode	Line configuration mode
Usage Guide	Use this command to configure AAA authentication for line-based login when AAA is enabled. The AAA authentication modes, including RADIUS authentication, local authentication, and non-authentication, are used during authentication.

Configuring Non-AAA Authentication for Line-based Login After AAA Is Enabled

Command	**login access non-aaatelnet** *host* [*port*] [**/source** { **ip** *A.B.C.D* | **ipv6** *X:X:X:X::X* | **interface** *interface-name* }]
Parameter Description	N/A
Command Mode	Global configuration mode
User Guide Parameter Description	To perform non-AAA authentication for a line when AAA is enabled, run this command. The configuration is valid for all clients. *host*: Indicates the IPv4 address, IPv6 address, or host name of the Telnet server. *port*: Indicates the TCP port number of the Telnet server. The default value is 23. **/source**: Specifies the source IP address or source interface used by the Telnet client. **ip** *A.B.C.D*: Specifies the source IPv4 address used by the Telnet client. **ipv6** *X:X:X:X::X*: Specifies the source IPv6 address used by the Telnet client. **interface** *interface-name*: Specifies the source interface used by the Telnet client.

Enabling the Telnet Client Service

Command	**telnet** *host* [*port*] [**/source** { **ip** *A.B.C.D* | **IPv6** *X:X:X:X::X* | **interface** *interface-name* }]
Parameter Description	*host*: Indicates the IPv4 address, IPv6 address, or host name of the Telnet server. *port*: Indicates the TCP port number of the Telnet server. The default value is 23. **/source:** Indicates the source IP address or source port used by a Telnet client. **ip** *A.B.C.D:* Indicates the source IPv4 address used by the Telnet client. **IPv6** *X:X:X:X::X:* Indicates the source IPv6 address used by the Telnet client. **interface** *interface-name*: Indicates the source port used by the Telnet client.
Command Mode	Privileged EXEC mode
Usage Guide	You can log in to a remote device identified by an IPv4 host name, IPv6 host name, IPv4 address, or IPv6 address in Telnet mode.

Enabling the Do Telnet Client Service

Command	**do telnet** *host* [*port*] [**/source** { **ip** *A.B.C.D* | **ipv6** *X:X:X:X::X* | **interface** *interface-name* }]
Parameter Description	*host*: Indicates the IPv4 address, IPv6 address, or host name of the Telnet server. *port*: Indicates the TCP port number of the Telnet server. The default value is 23. **/source**: Specifies the source IP address or source interface used by the Telnet client. **ip** *A.B.C.D*: Specifies the source IPv4 address used by the Telnet client. **ipv6** *X:X:X:X::X*: Specifies the source IPv6 address used by the Telnet client. **interface** *interface-name*: Specifies the source interface used by the Telnet client.
Command Mode	Privileged EXEC mode, user EXEC mode, or interface configuration mode
Usage Guide	Through the Do Telnet service, a user can log in to a remote device identified by an IPv4 host name, IPv6 host name, IPv4 address, or IPv6 address. The configuration varies with different models.

Restoring a Telnet Client Session

Command	<1-99>
Parameter Description	N/A
Command Mode	User EXEC mode
Usage Guide	Use this command to restore a Telnet client session. A user can press the shortcut key **Ctrl**+**Shift**+**6** **X** to temporarily exit the Telnet client session that is established using the **telnet** command, run the **<1-99>** command to restore the session, and run the **show sessions** command to display session information.

Closing a Suspended Telnet Client Connection

Command	**disconnect** *session-id*
Parameter Description	*session-id*: Indicates the suspended Telnet client session ID.
Command Mode	User EXEC mode
Usage Guide	Use this command to close a specific Telnet client session by entering the session ID.

Enabling the Telnet Server

Command	**enable service telnet-server**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to enable the Telnet server. The IPv4 and IPv6 services are also enabled after the command is executed.

Configuring the Connection Timeout Time

Command	**exec-timeout** *minutes* [*seconds*]
Parameter Description	*minutes*: Indicates the connection timeout time, in minutes. *seconds*: Indicates the connection timeout time, in seconds.
Command Mode	Line configuration mode
Usage Guide	Use this command to configure the timeout time for the established connections on a line. A connection will be closed when no input is detected during the timeout time. To remove the connection timeout configuration, run the **no exec-timeout** command in line configuration mode.

Configuring the Session Timeout Time

Command	**session-timeout** *minutes* [**output**]
Parameter Description	*minutes*: Indicates the session timeout time, in minutes. **output**: Indicates whether to use data output for determining the timeout.
Command Mode	Line configuration mode
Usage Guide	Use this command to configure the timeout time for remote host sessions on a line. A session will be disconnected when no input is detected during the timeout time. To cancel the session timeout time, run the **no session-timeout** command in line configuration mode.

Enabling Line-based Terminal Lock

Command	**lockable**
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	N/A

Locking a Terminal Connected to a Line

Command	**lock**
Parameter Description	N/A
Command Mode	Line configuration mode

Usage Guide	N/A

Specifies the IP address of the Interface as the Source IP Address of the Telnet Session.

Command	**ip telnet source-interface** *interface-name*
Parameter Description	*Interface-name*: Specifies the IP address configured on the interface as the source address for the Telnet session. The interface type can be the aggregate interface, gigabit interface, loopback interface, null interface, tunnel interface, or VLAN interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Establishing a Telnet Session with a Remote Network Device

Configuration Steps	● Establish a Telnet session with a remote network device at 192.168.65.119. ● Establish a Telnet session with a remote network device at 2AAA:BBBB::CCCC. ● Run the **telnet** command in privileged EXEC mode, or run the **do telnet** command in privileged EXEC mode, user EXEC mode, or interface configuration mode.

	`Hostname# telnet 192.168.65.119`
	`Trying 192.168.65.119 ... Open`
	`User Access Verification`
	`Password:`

	`Hostname# telnet 2AAA:BBBB::CCCC`
	`Trying 2AAA:BBBB::CCCC ... Open`
	`User Access Verification`
	`Password:`

	`Hostname(config)# do telnet 2AAA:BBBB::CCCC`
	`Trying 2AAA:BBBB::CCCC ... Open`
	`User Access Verification`
	`Password:`

Verification	Check whether Telnet sessions are established with the remote network devices.

Configuring the Connection Timeout Time

Configuration Steps	Set the connection timeout time to 20 minutes.

	`Hostname# configure terminal//Enter the global configuration mode.`
	`Hostname# line vty 0 //Enter the line configuration mode.`
	`Hostname(config-line)#exec-timeout 20 //Set the connection timeout time to 20 minutes.`

Verification	Check whether the connection between a terminal and the local device is closed when no input is detected during the timeout time.

1.4.3 Configuring Basic System Parameters

Configuration Effect

Configure basic system parameters.

Configuration Step

Configuring the System Date and Clock

- Mandatory.
- Configure the system time of a network device manually. The device clock starts from the configured time and keeps running even when the device is powered off.

⚠ The time configuration is applied only to the software clock if the network device does not provide a hardware clock. The configuration will be invalid when the device is powered off.

Updating the Hardware Clock

- Optional.
- Perform this configuration when you need to copy the date and time of the software clock to the hardware clock so that the hardware clock is synchronized with the software clock.

Configuring a System Name

- Optional.
- Perform this configuration to change the default system name.

Configuring a Command Prompt

- Optional.
- Perform this configuration to change the default command prompt.

Configuring Daily Notification

- Optional.
- Perform this configuration when you need to display important prompts or warnings to users.
- You can configure notification in one or more lines, which will be displayed to users after login.

Configuring a Login Banner

- Optional.
- Perform this configuration when you need to display important messages to users upon login or logout.

Configuring the Console Baud Rate

- Optional.
- Perform this configuration to change the default console baud rate.

Verification

- Run the **show clock** command to display the system time.

- Check whether a login banner is displayed after login.
- Run the **show version** command to display the system information and version.

Related Commands

Configuring the System Date and Clock

Command	**clock set** *hh:mm:ss month day year*
Parameter Description	*hh:mm:ss*: Indicates the current time, in the format of *hour* (24-hour format):*minute*:*second*. *day*: Indicates a day (1–31) of the month. *month*: Indicates a month (from January to December) of the year. *year*: Indicates a year. The value range is from 1993 to 2035. The abbreviation is not supported.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to configure the system time. If the device does not provide a hardware clock, the time configuration will be invalid when the device is powered off.

Updating the Hardware Clock

Command	**clock update-calendar**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	After this command is configured, the time of the software clock will overwrite that of the hardware clock.

Configuring the System Name

Command	**hostname** *name*
Parameter Description	*name*: Indicates the system name, which must consist of printable characters and cannot exceed 63 bytes.
Command Mode	Global configuration mode
Usage Guide	To restore the default system name, run the **no hostname** command in global configuration mode.

Configuring a Command Prompt

Command	**prompt** *string*
Parameter Description	*string*: Indicates the command prompt name. A name with more than 32 characters will be truncated to keep only the first 32 characters.
Command Mode	Privileged EXEC mode
Usage Guide	To restore the command prompt to the default settings, run the **no prompt** command in global configuration mode.

Customizing a Welcome Prompt Before Users Enter the User EXEC Mode of a Line

Command	**banner exec** *c message c*
Parameter Description	*c*: Indicates a delimiter. Spaces are not allowed in the welcome prompt. *Message:* Configures the welcome prompt.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a Prompt Indicating Establishment of a Reverse Telnet Session

Command	**banner incoming** *c message c*
Parameter Description	*c*: Indicates a delimiter. Spaces are not allowed in the prompt. *message*: Configures a prompt for establishment of a reverse Telnet session.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Daily Notification

Command	**banner motd** *c message c*
Parameter Description	*c*: Indicates a delimiter, which can be any character, such as &.
Command Mode	Global configuration mode
Usage Guide	After entering the delimiter and pressing **enter**, you can start entering the text. To conclude text input, you need to type the delimiter again followed by pressing **enter**. Note that any characters entered after the concluding delimiter will be discarded by the system. The delimiter letters should not appear in the text of the notification, and the text length cannot exceed 2047 bytes.

Configuring a Login Banner

Command	**banner login** *c message c*
Parameter Description	*c*: Indicates a delimiter, which can be any character, such as &.
Command Mode	Global configuration mode
Usage Guide	After entering the delimiter and pressing **enter**, you can start entering the text. To conclude text input, you need to type the delimiter again followed by pressing **enter**. Note that any characters entered after the concluding delimiter will be discarded by the system. The delimiter letters should not appear in the text of the banner, and the text length cannot exceed 2047 bytes. To remove the login banner configuration, run the **no banner login** command in global configuration mode.

Configuring the Timeout Message to Notify Timeout

Command	**banner prompt-timeout** *c message c*
Parameter Description	*c*: Indicates the separator of the message. Delimiters are not allowed in the message. *message*: Indicates the content of the message.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Configuring the SLIP/PPP Message for the SLIP/PPP Session

Command	**banner slip-ppp** *c message c*
Parameter Description	*c*: Indicates the separator of the message. Delimiters are not allowed in the message. *message*: Indicates the content of the message.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Display of EXEC Banner for a Specific Line

Command	**exec-banner**
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	If the **banner exec** and **banner motd** commands are configured on the device, EXEC and MOTD banners are displayed for all lines by default. To disable EXEC and MOTD banners displayed for a specific line, run the **no** form of these two commands.

Configuring Display of MOTD Banner for a Specific Line

Command	**motd-banner**
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	If the **banner exec** and **banner motd** commands are configured on the device, EXEC and MOTD banners are displayed for all lines by default. To disable EXEC and MOTD banners displayed for a specific line, run the **no** form of these two commands.

Configuring the Console Baud Rate

Command	**speed** *speed*
Parameter Description	*speed*: Indicates the console baud rate, in bps. The serial port baud rate can be set to 9600 bps, 19200 bps, 38400 bps, 57600 bps, or 115200 bps. The default is 9600 bps.
Command Mode	Line configuration mode
Usage Guide	You can configure the asynchronous line baud rate as needed. The **speed** command is used to configure receive and transmit rates for the asynchronous line.

Saving System Configurations to a Specific Directory

Command	**write** [**memory** | **terminal**]
Parameter	**memory**: Writes system configurations to the NVRAM. It has the same effect as running the **copy**

Description	**running-config startup-config** command. **terminal**: Displays system configurations. It has the same effect as running the **show running-config** command.
Command Mode	Privileged EXEC mode
Usage Guide	There are alternatives to this command, but this command is widely used. If the device where the file is stored exists, the system automatically creates a file and writes the system configurations to the file. If the device does not exist, for example, the startup configuration file is specified to be in a portable storage device such as a USB flash drive or SD card, but the device is not mounted during execution of the **write** [memory] command, the system asks you whether to save the current configurations to the default startup configuration file **config.text** and performs corresponding operations.

Importing User Information from a File

Command	**username import** *filename*
Parameter Description	*filename*: Indicates the name of a file.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Exporting User Information to a File

Command	**username export** *filename*
Parameter Description	*filename*: Indicates the name of a file.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuration Example

Configuring the System Time

Configuration Steps	Change the system time to 2003-6-20, 10:10:12.
	`Hostname# clock set 10:10:12 6 20 2003 //Configure the system time and date.`
Verification	Run the **show clock** command in privileged EXEC mode to display the system time.
	`Hostname# show clock //Confirm that the changed system time takes effect.` `clock: 2003-6-20 10:10:54`

Configuring Daily Notification

Configuration Steps	Configure the daily notification message "Notice: system will shutdown on July 6th." with the pound key (#) as the delimiter.

	Hostname(config)# banner motd #//Starting delimiter Enter TEXT message. End with the character '#'. Notice: system will shutdown on July 6th.# //Ending delimiter Hostname(config)#
Verification	● Run the **show running-config** command to display the configuration. ● Connect to the local device through the console, Telnet, or SSH, and check whether daily notification is displayed before the CLI appears.
	C:\>telnet 192.168.65.236 Notice: system will shutdown on July 6th. Access for authorized users only. Please enter your password. User Access Verification Password:

Configuring a Login Banner

Configuration Steps	Configure the login banner message "Access for authorized users only. Please enter your password." with the pound key (#) as the delimiter.
	Hostname(config)# banner login #//Starting delimiter Enter TEXT message. End with the character '#'. Access for authorized users only. Please enter your password. # //Ending delimiter Hostname(config)#
Verification	● Run the **show running-config** command to display the configuration. ● Connect to the local device through the console, Telnet, or SSH, and check whether the login banner is displayed before the CLI appears.
	C:\>telnet 192.168.65.236 Notice: system will shutdown on July 6th. Access for authorized users only. Please enter your password. User Access Verification Password:

Configuring the Serial Port Baud Rate

Configuration Steps	Set the serial port baud rate to 57,600 bps.

	Hostname# configure terminal //Enter global configuration mode.
	Hostname(config)# line console 0 //Enter console line configuration mode.
	Hostname(config-line)# speed 57600 //Set the console baud rate to 57,600 bps.
	Hostname(config-line)# end //Returns to privileged mode.

Verification	Run the **show** command to display the configuration.
	Hostname# show line console 0 //Displays the console configuration. CON Type speed Overruns * 0 CON 57600 0

```
Line 0, Location: "", Type: "vt100"
Length: 25 lines, Width: 80 columns
Special Chars: Escape  Disconnect  Activation
            ^^x    none       ^M
Timeouts:     Idle EXEC    Idle Session
            never       never
History is enabled, history size is 10.
Total input: 22 bytes
Total output:  115 bytes
Data overflow:  0 bytes
stop rx interrupt:  0 times
Modem: READY
```

1.4.4 Enabling and Disabling a Specific Service

Configuration Effect

Dynamically adjust system services when the system is running, and enable and disable specific services (SNMP agent, SSH server, and Telnet server).

Configuration Step

↘ Enabling the SNMP Agent, SSH Server, and Telnet Server

- Optional.
- Perform this configuration when you need to use these services.

Verification

- Run the **show running-config** command to display the configuration.
- Run the **show service** command to display the service status.

Related Commands

↘ Enabling the SSH Server, Telnet Server, and SNMP Agent Services

Command	**enable service** { **ssh-server** | **telnet-server** | **snmp-agent** }
Parameter Description	**ssh-server:** Enables or disables the SSH server. IPv4 and IPv6 services are also enabled with this service. **telnet-server:** Enables or disables the Telnet server. IPv4 and IPv6 services are also enabled with this service. **snmp-agent:** Enables or disables the SNMP agent. IPv4 and IPv6 services are also enabled with this service.
Command Mode	Global configuration mode
Usage Guide	Use this command to enable and disable specific services.

Configuration Example

Enabling the SSH Server

Configuration Steps	Enable the SSH server.
	`Hostname# configure terminal //Enter the global configuration mode.` `Hostname(config)#enable service ssh-server //Enable the SSH server.`
Verification	• Run the **show running-config** command to display the configuration. • Run the **show ip ssh** command to display the configuration and running state of the SSH server.

1.4.5 Configuring a Restart Policy

Configuration Effect

Configure a restart policy to restart a device as scheduled.

Configuration Step

Configuring Direct Restart

Run the **reload** command in privileged EXEC mode to restart the system immediately.

Configuring Scheduled Restart

```
reload at hh:mm:ss month day year
```

If you configure a specific time, the system will restart at the time. The time must be a time in the future. The **month day year** parameter is optional. If it is not specified, the system clock time is used by default.

The clock feature must be supported by the system if you want to use the **at** option. It is recommended that you configure the system clock in advance. A new restart plan will overwrite the existing one. A restart plan will be invalid if the system is restarted before the plan takes effect.

The restart time must be later than the current system time. After you configure a restart plan, do not change the system clock; otherwise, the plan may fail (for example, the system time is changed to a time after the restart time.)

Related Commands

Restarting a Device

Command	**reload** [**at** { *hh* [:*mm* [:*ss*]] } [*month* [*day* [*year*]]]]
Parameter Description	**at** *hh:mm:ss*: Indicates the time when the system will restart. *month*: Indicates a month of the year. The value range is from 1 to 12. *day*: Indicates a date. The value range is from 1 to 31. *year*: Indicates a year. The value range is from 1993 to 2035. The abbreviation is not supported.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to enable a device to restart at a specific time.

1.4.6 Running Batch File Commands

Configuration Effect

Run commands in a batch file.

Configuration Step

Running the execute Command

In the **execute** command, specify the path of the batch files to be executed.

You can specify the name and content of the batch file on your PC and transfer the file to the flash memory of the device through TFTP. The content of the batch file simulates user input. Therefore, you must edit the content according to the configuration sequence of the CLI commands. For some interactive commands, the responses must be written in the batch file to ensure normal running of the commands.

The batch file cannot exceed 128 KB in size; otherwise, it will fail to be executed. You can divide a large batch file into multiple files, each smaller than 128 KB in size.

Related Commands

Restarting a Device

Command	**execute** { [**flash:**] *filename* }
Parameter Description	*filename*: Indicates the path of a batch file.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command to execute multiple commands in batch for a function, simplifying user operations.

1.4.7 Configuring the Character Set Encoding Format

Configuration Effect

A unified character set encoding format is used on a device.

Notes

None

Configuration Step

Setting a Character Set Encoding Format

Run the **language character-set** command to set a character set encoding format.

When current running configurations in different formats exist on a device, you can set a unified character set encoding format only after manually delete running configurations that are not in the unified character set encoding format.

Verification

Run the **show language character-set** command to display the specified character set encoding format.

Related Commands

Command	**language character-set** { **UTF-8** | **GBK** | **default** }
Parameter Description	**UTF-8**: Sets the character set encoding format to UTF-8. **GBK**: Sets the character set encoding format to GBK. **default**: Sets the character set encoding format to the default format (mixed codes supported).
Command Mode	Global configuration mode
Usage Guide	Run this command to use a unified character set encoding format on a device.

Common Errors

None

1.4.8 Configuring Active Backup of the Running Configuration File to a Remote Server

Configuration Effect

After active backup of the running configuration file to a remote server is configured, the device automatically backs up the running configuration file to a remote server when the device running configuration changes.

Notes

- This command is used to configure active backup of the running configuration file. When the running configuration is changed, the device checks the change in the running configuration file one minute later. If the running configuration file is changed, the device backs up the current running configuration file to the remote server. If the configuration is consecutively changed at an interval of one minute, the device backs up the running configuration one minute after the last change or five minutes after the first change.
- When the device restarts, it backs up the running configurations to the remote server once.
- When the running configuration file is backed up to the remote server, NETCONF sends real-time configuration update notifications.
- Only the HTTPS protocol is supported. A remote HTTPS file server needs to be set up in advance.
- Only one file server can be configured. To replace the existing file server, delete the existing file server and configure a new one.

Configuration Steps

(1) Enter the privilege EXEC mode.
enable

(2) Enter the global configuration mode.
configure terminal

(3) Enable active backup of the running configuration file and enter the backup configuration mode.
auto-backup running-config
By default, this function is disabled.

(4) Configure active backup of the running configuration file to a remote server.
server ipv4-address port *port-number* **transport https** [**username** *username* **password** { [0] *password* | 7 *encrypted-password* }] [remote-path path]
By default, this function is disabled.

Verification

N/A

1.5 Monitoring

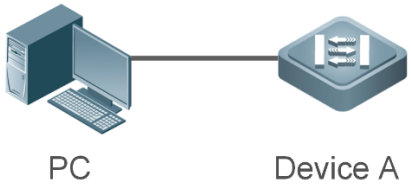
Displaying

Command	Description
show clock	Displays the current system time.
show line { **console** *line-num* | **vty** *line-num* **|** *line-num* }	Displays line configurations.
show running-config [**interface** *interface*]	Displays the current running configurations of the device or the configurations on an interface.
show version [**devices | module | slots**]	Displays the system information.
show sessions	Displays the information about the established Telnet client instances.
execute diagnose-cmd { **help** | *shell-command* }	Displays the information of the supported diagnostic commands and the device.
show reload	Displays system restart settings.
show startup-config	Displays the device configurations stored in the NVRAM.
show hostname	Displays the host name of the device.
show language character-set	Displays the line configurations.
show service	Displays the service enabled or disabled.

1 Configuring Lines

1.1 Overview

There are various types of terminal lines on network devices. You can manage terminal lines in groups based on their types. Configurations on these terminal lines are called line configurations. On network devices, terminal lines are classified into multiple types such as the console terminal line (CTY), teletype terminal line (TTY), auxiliary line (AUX), and virtual terminal line (VTY).



1.2 Applications

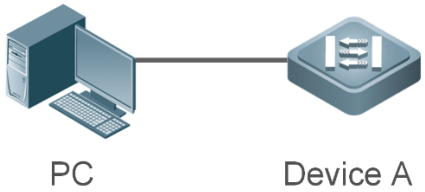
Application	Description
Accessing a Device Through the Console	Enter the command line interface (CLI) of a network device through the console.
Accessing a Device Through the VTY	Enter the CLI of a network device through Telnet or the Secure Shell (SSH).

1.2.1 Accessing a Device Through the Console

Scenario

Figure 1-1

Remarks	A is a network device to be managed. PC is a network management station.



Deployment

The network management station connects to the console port of a network device through a serial cable. Using the console software (HyperTerminal or other terminal simulation software) on the network management station, you can access the console of the network device and enter the CLI to configure and manage the network device.

1.2.2 Accessing a Device Through the VTY

Scenario

Figure 1-2

Remarks	Device A is to be managed. The PC is a network management station.

Deployment

The network management station connects to a network device through the network. Using a VTY client (such as PUTTY) on the network management station, you can access the network device through Telnet or SSH and enter the CLI to configure and manage the network device.

1.3 Features

Basic Concepts

CTY

The CTY refers to the line connected to the console port. Most network devices have a console port. You can access the local system through the console port.

VTY

The VTY is a virtual terminal line that does not correspond to any hardware. It is used for a Telnet or SSH connection.

Overview

Feature	Description
Basic Features	Configures a terminal, and displays and clears terminal connection information.

1.3.1 Basic Features

Related Configuration

Configuring Terminal Lines

Run the **line** command in global configuration mode to enter a specified terminal configuration mode.

Various terminal attributes can be configured.

Clearing Terminal Connections

When a terminal connects to a network device, the corresponding terminal line is occupied. You can run the **show user** command to display the connection status of these terminal lines. To disconnect the terminal from the network device, run the **clear line** command to clear the terminal line. After the terminal line is cleared, corresponding connection (such as Telnet and SSH) is terminated, the CLI exits, and the terminal lines restore to the unoccupied status. You can reestablish connections.

Specifying the Number of VTY Terminals

Run the **line vty** command to enter the VTY line configuration mode and specify the number of VTY terminals.

By default, there are five VTY terminals, numbered from 0 to 4. You can increase the number of VTY terminals to 36, with new ones numbered from 5 to 35. Only new terminals can be removed.

1.4 Configuration

Configuration	Description and Command	
Entering the Line Configuration Mode	(Mandatory) It is used to enter the line configuration mode.	
	line [**console** | **tty** | **vty**] *first-line* [*last-line*]	Enters the specified line configuration mode.
	line vty *line-number*	Increases or reduces the number of available VTY lines.
Configuring Line Attributes	**access-class** { *access-list-number* | *access-list-name* } { **in** | **out** }	Configures login to the terminal through an IPv4 ACL.
	accounting commands *level* { **default** | *list-name* }	Enables command accounting for a line.
	accounting exec { **default** | *list-name* }	Enables user access accounting for a line.
	authorization commands *level* { **default** | *list-name* }	Enables command authorization for a line.
	accounting exec { **default** | *list-name* }	Enables EXEC authorization for a line.
	disconnect-character *ascii-value*	Configures the hot key for terminal service disconnection.
	escape-character *escape-value*	Configures the character for exiting a line.
	exec	Configures access to the CLI through a line.
	history [**size** *size*]	Enables command history for the line or configures the number of commands in the command history.
	ipv6 access-class *access-list-name* { **in** | **out** }	Configures login to the terminal through an IPv6 ACL.
	length *screen-length*	Configures the maximum number of lines that are displayed on a single screen for a specific line terminal.
	location *location*	Configures the location description for a specified line.
	monitor	Enables logging on terminals.
	privilege level	Configures a privilege level for line-based login.
	refuse-message [*c message c*]	Configures the prompt for refusing line-based login.
	speed *baudrate*	Configures the baud rate for a specified terminal.

	terminal escape-character *escape-value*	Configures the character for exiting current terminal.
	terminal history [**size** *size*]	Enables command history or configures the number of commands in the command history for the line connected to the current terminal.
	terminal length *screen-length*	Configures the maximum number of lines that are displayed on a single screen on the current terminal.
	terminal location *location*	Configures the location description for the current terminal.
	terminal speed *baudrate*	Configures the baud rate for the current terminal.
	terminal width *screen-width*	Configures the maximum number of columns that are displayed in a single line on the current terminal, that is, the line width.
	timeout login response *seconds*	Configures the authentication timeout for line-based login.
	transport input { **all** | **ssh** | **telnet** | **none** }	Specifies communication protocols supported in a line.
	vacant-message [*c message c*]	Configures the prompt for line-based logout.
	width *screen-width*	Configures the maximum number of columns that are displayed in a single line on a specified terminal, that is, the line width.

1.4.1 Entering the Line Configuration Mode

Configuration Effect

Enter the line configuration mode to configure other functions.

Configuration Step

Entering the Line Configuration Mode

- Mandatory.
- Unless otherwise specified, enter the line configuration mode on each device to configure line attributes.

Command	**line** [**console** | **vty**] *first-line* [*last-line*]
Parameter Description	**console**: Indicates the console port. **vty**: Indicates a virtual terminal line, which supports Telnet or SSH. *first-line*: Indicates the number of the first line. *last-line*: Indicates the number of the last line.

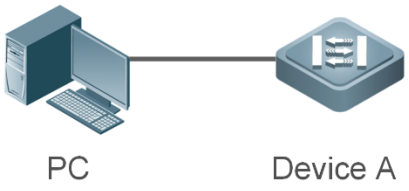
Command Mode	Global configuration mode
Usage Guide	N/A

Increasing or Reducing the Number of VTY Lines

- Optional.
- Run the [**no**] **line vty** *line-number* command to increase or reduce the number of VTY lines.

Command	**line vty** *line-number*
Parameter Description	*line-number*: Indicates the number of VTY lines. The value range is from 0 to 35.
Command Mode	Global configuration mode
Usage Guide	Run the **no line vty** *line-number* command to reduce the number of available VTY lines.

Displaying Line Configuration



Command	**show line** { **console** *line-num* | **vty** *line-num* **|** *line-num* }
Parameter Description	**console**: Indicates the console port. **vty**: Indicates a virtual terminal line, which supports Telnet or SSH. *line-num*: Indicates the line to be displayed.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Verification

Run the **show line** command to display the line configuration.

Configuration Example

Configuring the Number of VTY Terminals

Scenario Figure 1-3	
Configuration Steps	• Connect the PC to Device A through the console line and enter the CLI on the PC. • Run the **show user** command to display the connection status of the terminal line. • Run the **show line console 0** command to display the status of the console line. • Enter the global configuration mode and run the **line vty** command to increase the number of VTY terminals to 36.
Device A	`Hostname#show user` `Line User Host(s) Idle Location`

	``
	--------------- ----------- ------------------- ---------- -----------
	------- 	
	* 0 con 0 --- idle 00:00:00 ---
	
	Hostname#show line console 0
	
	CON Type speed Overruns
	* 0 CON 9600 0
	Line 0, Location: "", Type: "vt100"
	Length: 24 lines, Width: 79 columns
	Special Chars: Escape Disconnect Activation
	               ^^x ^D ^M
	Timeouts: Idle EXEC Idle Session
	               00:10:00 never
	History is enabled, history size is 10.
	Total input: 490 bytes
	Total output: 59366 bytes
	Data overflow: 0 bytes
	stop rx interrupt: 0 times
	
	Hostname#show line vty ?
	  <0-5> Line number
	
	Hostname#configure terminal
	Enter configuration commands, one per line. End with CNTL/Z.
	Hostname(config)#line vty 35
	Hostname(config-line)#
	*Oct 31 18:56:43: %SYS-5-CONFIG_I: Configured from console by console
	``

Verification	● After running the **show line** command, you can find that the number of terminals increases. ● Run the **show running-config** command to display the configuration.
Device A	``` Hostname#show line vty ? <0-35> Line number Hostname#show running-config Building configuration... Current configuration : 761 bytes version 11.0(1C2B1)(10/16/13 04:23:54 CST -ngcf78) ip tcp not-send-rst vlan 1 ! interface GigabitEthernet 0/0 ! ```

1.4.2 Configuring Line Attributes

Configuration Effect

Configure line attributes in line configuration mode.

Configuration Step

↘ Configuring Login into the Terminal Through an IPv4 ACL

Command	**access-class** { *access-list-number* | *access-list-name* } { **in** | **out** }
Parameter Description	*access-list-number*: Specifies the ACL number. A standard IP ACL number is from 1 to 99 and from 1300 to 1999. An extended IP ACL number is from 100 to 199 and from 2000 to 2699. *access-list-name*: Specifies the ACL name. **in**: Filters incoming connections. **out**: Filters outgoing connections.
Command Mode	Line configuration mode
Usage Guide	N/A

↘ Enabling User Access Accounting for a Line

Command	**accounting exec** { **default** | *list-name* }

Parameter Description	*level*: Indicates the level of commands that need accounting. The value range is from 0 to 15. Information needs to be recorded for execution of commands of a specified level. **default**: Specifies the name of the default authentication method list. *list*-name: Indicates the name of the optional method list.
Command Mode	Line configuration mode
Usage Guide	N/A

Enabling Command Authorization for a Line

Command	**authorization commands** *level* { **default** | *list-name* }
Parameter Description	*level*: Indicates the level of commands that need authorization. The value range is from 0 to 15. Only authorized commands can be executed. **default**: Specifies the name of the default authentication method list. *list*-name: Indicates the name of the optional method list.
Command Mode	Line configuration mode
Usage Guide	N/A

Enabling EXEC Authorization for a Line

Command	**accounting exec** { **default** | *list-name* }
Parameter Description	**default**: Specifies the name of the default authentication method list. *list*-name: Indicates the name of the optional method list.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Hot Key for Terminal Service Disconnection

Command	**disconnect-character** *ascii-value*
Parameter Description	*ascii*-value: Indicates the ASCII decimal value of the hot key that disconnects terminal service connections. The value range is from 0 to 255.
Command Mode	Line configuration mode
Usage Guide	This command is used to configure the hot key for disconnecting terminal connections as needed. The hot key for disconnecting terminal connections cannot be common ASCII values (such as a–z, A–Z, and 0–9). Otherwise, the terminal service may be abnormal.

Configuring the Character for Exiting a Line

Command	**escape-character** *escape-value*
Parameter Description	*escape-value*: Indicates the ASCII value in decimal notation of the user-defined character for exiting the current terminal. The value range is from 0 to 255.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Access to the CLI Through a Line

Command	**exec**
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	N/A

Enabling Command History for the Line or Configuring the Number of Commands in the Command History

Command	**history** [**size** *size*]
Parameter Description	***size*** *size*: Configures number of commands. The value range is from 0 to 256.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring Login into the Terminal Through an IPv6 ACL

Command	**ipv6 access-class** *access-list-name* { **in** | **out** }
Parameter Description	*access-list-name*: Specifies the ACL name. **in**: Filters incoming connections. **out**: Filters outgoing connections.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Maximum Number of Lines on a Single Screen for a Specified Line Terminal

Command	**length** *screen-length*
Parameter Description	*screen-length*: Indicates the line height. The value range is from 0 to 512.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Location Description for a Specified Line

Command	**location** *location*
Parameter Description	*location*: Indicates the location description of a line.
Command Mode	Line configuration mode
Usage Guide	N/A

Enabling Logging on Terminals

Command	**monitor**

Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring a Privilege Level for Line-based Login

Command	**privilege level**
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Prompt for Refusing Line-based Login

Command	**refuse-message** [*c message c*]
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Baud Rate for a Specified Line Terminal

Command	**speed** *baudrate*
Parameter Description	*baudrate*: Indicates the baud rate. The value range is from 9600 to 115200.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Character for Exiting the Current Terminal

Command	**terminal escape-character** *escape-value*
Parameter Description	*escape*-value: Indicates the ASCII value in decimal notation of the user-defined character for exiting the current terminal. The value range is from 0 to 255.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Enabling Command History for the Line Connected to the Current Terminal or Configuring the Number of Commands in the Command History

Command	**terminal history** [**size** *size*]
Parameter Description	***size*** *size*: Configures number of commands. The value range is from 0 to 256.

Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuring the Maximum Number of Lines Displayed on a Single Screen on the Current Terminal

Command	**terminal length** *screen-length*
Parameter Description	*screen-engath*: Indicates the line height. The value range is from 0 to 512.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuring the Location Description for a Terminal

Command	**terminal location** *location*
Parameter Description	*location*: Indicates the location description of the current line.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuring the Baud Rate for the Current Terminal

Command	**terminal speed** *baudrate*
Parameter Description	*baudrate*: Indicates the baud rate. The value range is from 9600 to 115200.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuring the Line Width on the Current Terminal

Command	**terminal width** *screen-width*
Parameter Description	*screen*-width: Indicates the maximum number of columns displayed in a single line, that is, the line width. The value range is from 0 to 256.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Configuring the Authentication Timeout for Line-based Login

Command	**timeout login response** *seconds*
Parameter Description	**response**: Indicates the time period during which a line waits for a user to enter any message. *seconds*: Indicates the authentication timeout duration for line-based login, in seconds. The value range is from 1 to 300.
Command Mode	Line configuration mode

Usage Guide	N/A

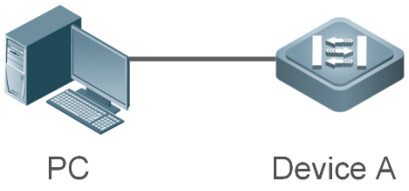
Specifying Communication Protocols Supported in a Line

Command	**transport input** { **all** | **ssh** | **telnet** | **none** }
Parameter Description	***all***: Indicates that all protocols are supported by default. ***ssh***: Indicates that SSH protocol is supported. ***telenet***: Indicates that Telnet protocol is supported. ***none***: Indicates that no protocol is supported for communication in a line.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Prompt for Line-based Logout

Command	**vacant-message** [*c message c*]
Parameter Description	*c*: Indicates the delimiter of the prompt for line-based logout, which is not allowed within the message message: Indicates a prompt for line-based logout.
Command Mode	Line configuration mode
Usage Guide	N/A

Configuring the Line Width on a Specified terminal



Command	**width** *screen-width*
Parameter Description	*screen*-width: Indicates the maximum number of columns displayed in a single line, that is, the line width. The value range is from 0 to 256.
Command Mode	Line configuration mode
Usage Guide	N/A

Verification

- Run the **show line** command to display the line configuration.

Configuration Example

Configuring the Baud Rate for a Line

Scenario Figure 1-4	
Configuration Steps	● Connect the PC to the console port of AP1 with an Ethernet cable and enter the CLI. ● Enter global configuration mode and configure the baud rate for a line. ● Run the **show line console 0** command to check the console line status.
AP1	`Hostname#configure terminal` `Enter configuration commands, one per line.  End with CNTL/Z.`

```
Hostname(config)#line console 0
Hostname(config-line)#speed 115200
Hostname#show line console 0

CON     Type    speed   Overruns
* 0     CON     115200  0
Line 0, Location: "", Type: "vt100"
Length: 24 lines, Width: 79 columns
Special Chars: Escape  Disconnect  Activation
               ^^x     none
Timeouts:      Idle EXEC    Idle Session
               00:10:00     never
History is enabled, history size is 10.
Total input: 636 bytes
Total output:  30498 bytes
Data overflow:  0 bytes
stop rx interrupt:  0 times
```

Verification

- Run the **show running-config** command to check the configuration.

AP1

```
Hostname#show line vty ?
  <0-35>  Line number

Hostname#show running-config

Building configuration...
Current configuration : 761 bytes

version 11.0(1C2B1)(10/16/13 04:23:54 CST -ngcf78)
ip tcp not-send-rst

end
```

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear line { **console** *line-num* | **vty** *line-num* | *line-num* }	Clears the line connection status.

Displaying

Command	Description
show line { **console** *line-num* | **vty** *line-num* | *line-num* }	Displays the line configuration.
show history	Displays historical records of a line.
show privilege	Displays the privilege level of a line.
show users [**all**]	Displays users on a line.

1 Configuring HTTP Service

1.1 Overview

The Hypertext Transfer Protocol (HTTP) is used to transmit web page information on the Internet. It is at the application layer of the TCP/IP protocol suite. The transport layer uses connection-oriented Transmission Control Protocol (TCP).

The Hypertext Transfer Protocol Secure (HTTPS) is an HTTP supporting the Secure Sockets Layer (SSL) protocol. HTTPS is mainly used to create a secure channel on an insecure network, ensure that information can hardly be intercepted, and protects the device against main-in-the-middle attacks. HTTPS is widely used for secure and sensitive communication on the Internet, for example, electronic transactions.

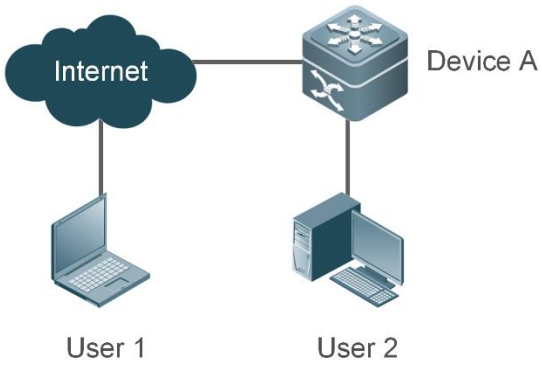
Protocols and Standards

- RFC1945: Hypertext Transfer Protocol -- HTTP/1.0
- RFC2616: Hypertext Transfer Protocol -- HTTP/1.1
- RFC2818: Hypertext Transfer Protocol Over TLS -- HTTPS

1.2 Applications

Application	Description
HTTP Application Service	Devices are managed based on web.
HTTP Remote Upgrade Service	HTTP remote upgrade is used to upgrade files.

1.2.1 HTTP Application Service



Scenario

After the HTTP service is enabled, you can access the web management page after passing authentication by only entering **http://IP address of a device** in the browser of a PC. On the web page, you can monitor the device status, configure devices, upload and download files.

The following figure is used here to describe web management.

- You can remotely access devices on the Internet or configure and manage devices on the Local Area Network (LAN) by logging in to the web server.
- You can choose to enable the HTTPS or HTTP service independently or enable both of them.
- You can also access the HTTP service of devices by setting and using HTTP/1.0 or HTTP/1.1 in the browser.

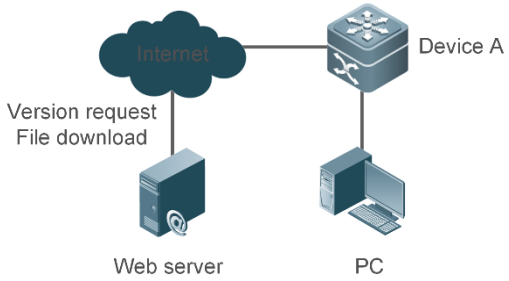
Figure 1-1

Remarks	Device A is a switch. User 1 accesses the device through the Internet. User 2 accesses the device through a LAN.

Deployment

- When a device runs HTTP, you can access the device by entering **http://IP address of the device** in the browser of a PC.
- When a device runs HTTPS, you can access the device by entering **https://IP address of the device** in the browser of a PC.

1.2.2 HTTP Remote Upgrade Service



Scenario

The HTTP remote upgrade service allows a device to connect to a remote HTTP server as a client and upgrade the local files by obtaining files from the server.

As shown in the following figure, you use the HTTP remote upgrade service to upgrade files.

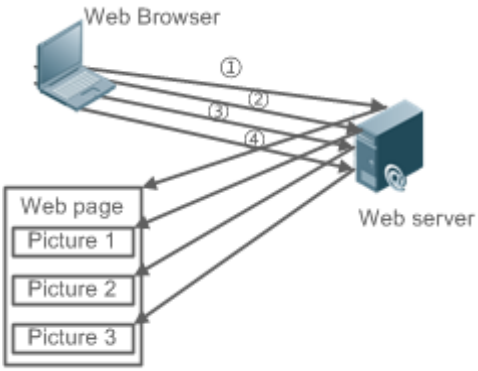
- The device remotely accesses the upgradeable files from the server at a scheduled time every day.
- The latest files are downloaded from the server and the upgrade device is updated.

Figure 1-1

Deployment

When the device runs HTTP, you can send commands directly to the device through a browser to obtain the latest upgradeable files from the web server.

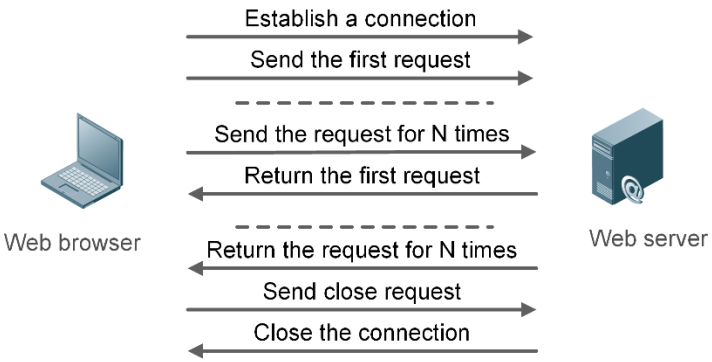
1.3 Features



Basic Concepts

HTTP Service

The HTTP service refers to transmission of web page information on the Internet by using HTTP. HTTP/1.0 is the most widely used. Because one web server may receive thousands or even millions of access requests, HTTP/1.0 adopts the short connection mode to facilitate connection management. One TCP connection is established for each request. After a request is completed, the TCP connection is released. The server does not need to record or trace previous requests. Although HTTP/1.0 simplifies connection management, HTTP/1.0 introduces performance defects.



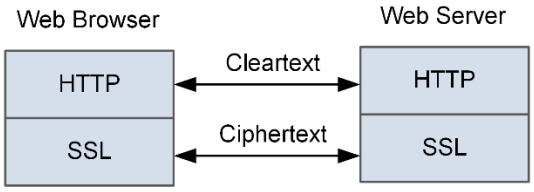
For example, a web page may require many pictures. However, the web page contains not real picture contents but URLs of the pictures. In this case, the browser sends multiple requests during access. Each request requires establishment of an independent connection and each connection is completely isolated. Establishing and releasing connections is troublesome, which severely affects the performance of the client and server, as shown in the following figure.

Figure 1-2

HTTP/1.1 overcomes the defect. It supports persistent connection, that is, one connection can be used to transmit multiple requests and response messages. In this way, a client can send a second request without waiting for completion of the previous request. This reduces network delay and improves performance.

Figure 1-3

The device supports both HTTP/1.0 and HTTP/1.1.



The HTTP version that can be used by a device is decided by the web browser.

HTTPS Service

The HTTPS service adds SSL based on the HTTP service. To run HTTPS properly, a server must have a Public Key Infrastructure (PKI) certificate while a client may not necessarily need one. The SSL protocol provides the following services:

- Authenticating users and servers and ensuring that data is sent to the correct client and server
- Encrypting data to prevent data from being intercepted
- Maintaining data integrity and ensuring that data is not changed during transmission

Figure 1-4

HTTP Upgrade Service

HTTP upgrade includes local and remote HTTP upgrade:

- During local upgrade, a device serves as an HTTP server. You can log in to the device through a web browser and upload upgrade files to the device to realize file upgrade on the device.
- During remote upgrade, a device is connected to a remote HTTP server as a client and realizes local file upgrade by obtaining files from the server.

Features

Feature	Description
HTTP Service	You log in to devices through web pages to configure and manage devices.
HTTP Redirection to HTTPS	When a user accesses the web page through HTTP, HTTP is automatically redirected to HTTPS.
HTTPS Service Certificate	A new self-signed HTTPS service certificate is generated or a third-party certificate is installed.
HTTP Remote Upgrade Service	The device is connected to a remote HTTP server as a client and upgrades local files by obtaining files from the server.
HTTP Local Upgrade Service	The files to be upgraded are uploaded to the device, achieving the upgrade of files on the device.

1.3.1 HTTP Service

HTTP is a service provided for web management. You can log in to devices through web pages to configure and manage devices.

Working Principle

Web management covers web clients and servers. Similarly, the HTTP service also adopts the client/server mode. The HTTP client is embedded in the web browser of the web management client. It can send HTTP packets and receive

HTTP response packets. The web server (namely HTTP server) is embedded in devices. Information exchange between the client and server is as follows:

- A TCP connection is established between the client and server. The default port IDs of the HTTP service and HTTPS service are 80 and 443, respectively.
- The client sends a request message to the server.
- The server resolves the request message sent by the client. The request includes obtaining a web page, executing a CLI command, and uploading a file.
- After executing the request, the server sends a response message to the client.

Related Configuration

Enabling the HTTP Service

By default, the HTTP service is disabled.

The **enable service web-server** command can be used to enable HTTP service functions, including the HTTP service and HTTPS service.

The HTTP service must be enabled so that users can log in to devices through web pages to configure and manage devices.

Configuring HTTP Authentication Information

By default, the system creates the **admin** and the **guest** account. The accounts cannot be deleted and only the password of the account can be changed. The administrator account is the **admin** account, which corresponds to the level 0 permission. The **admin** account owns all permissions on the Web client and can edit other management accounts and authorize the accounts to access pages. The **guest** account corresponds to the level 2 permission. The **guest** account can only view the homepage. The new accounts that are added correspond to the level 1 permission.

The **webmaster level** command can be used to configure an authenticated user name and a password.

After this command is run, you need to enter the configured user name and password to log in to the Web page.

Configuring an HTTP Service Port

By default, the HTTP service port ID is 80.

The **http port** command can be used to configure an HTTP service port ID. The value range of the port ID is 80 and 1025 to 65535.

By configuring an HTTP service port ID, you can reduce the number of attacks initiated by illegal users on the HTTP service.

Configuring an HTTPS Service Port

By default, the HTTPS service port ID is 443.

The **http secure-port** command can be used to configure an HTTPS service port ID. The value range of the port ID is 443 and 1025 to 65535.

By configuring an HTTPS service port ID, you can reduce the number of attacks initiated by illegal users on the HTTPS service.

1.3.2 HTTP Redirection to HTTPS

The device redirects the browser access request to HTTPS when a user accesses the web management service through the HTTP.

Working Principle

- A user enters the URL of HTTP in the address bar of the browser, for example, http://192.168.1.1. The browser sends an HTTP access request to the device.
- The device returns an HTTP access response packet containing a redirection URL, for example, https://192.168.1.1.
- The browser sends an HTTPS access request to the device to access the web management page.

1.3.3 HTTPS Service Certificate

An HTTPS service certificate is used to authenticate a server and encrypt data transmission. You can enable the device to generate a new self-signed certificate or install a trust certificate issued by the certificate authority. If the HTTPS service certificate is not trusted by the browser, the browser displays a security prompt, asking for user's confirmation before the user accesses the web management system of the device through HTTPS.

Working Principle

- The device generates a self-signed certificate as the HTTPS service certificate upon its first startup. You can enable the device to generate a new self-signed certificate again or install a trust certificate issued by the certificate authority.
- The server delivers the certificate to the browser after the browser connects to the server through HTTPS.
- The browser checks the certificate delivered by the server to determine whether the certificate user matches the address accessed, whether the certificate is in the validity period, and whether the certificate issuer is trusted by the browser. If not, the browser displays a security prompt, asking for user's confirmation before the user accesses the server.

1.3.4 HTTP Remote Upgrade Service

The device is connected to a remote HTTP server as a client and upgrades local files by obtaining files from the server.

Working Principle

- When the device attempts to connect to the server, the device first attempts to connect to the server address configured by the user. If it fails to connect, it attempts to connect to the server address in the local upgrade record file.
- The device sends version numbers of its various service modules to the server.
- The server analyzes information and provides a list of downloadable files.
- The device connects to the file server according to the list and downloads the files that need to be upgraded. You can connect to different servers to download different files.
- The device upgrades the files.

1.3.5 HTTP Local Upgrade Service

The device serves as the HTTP server. Users log in to the device through a Web browser and upload the files to be upgraded (including the component package and web package) to the device or directly upload files to the device through the Trivial File Transfer Protocol (TFTP).

Working Principle

- A component package or web package is uploaded through the local upgrade function in the web management system.
- After receiving the file package, the device checks the version for validity.
- After the file check is successful, if the file is a web package, the device performs the upgrade directly; if the file is a component package, a user determines whether to perform the upgrade in the browser by restarting the device.

1.4 Configuration

Configuration	Description and Command	
Configuring the HTTP Service	(Mandatory) It is used to enable the HTTP service.	
	enable service web-server	Enables the HTTP service.
	webmaster level	Configures HTTP authentication information.
	http port	Configures an HTTP service port.
	http secure-port	Configures an HTTPS service port.
Configuring HTTP Redirection to HTTPS	(Optional) It is used to enable automatic HTTP redirection to HTTPS.	
	web-server http redirect-to-https	Configures HTTP redirection to HTTPS.
Configuring the Maximum Number of Concurrent Logins Using the Same Account	(Optional) It is used to configure the maximum number of concurrent login using the same account from different clients.	
	http limit	Configures the maximum number of concurrent logins using the same account from different clients.
Configuring an HTTPS Service Certificate	(Optional) It is used to replace a HTTPS service certificate.	
	web-server https generate self-signed-certificate	Generates a new self-signed HTTPS service certificate again.
	web-server https certificate	Installs an HTTPS service certificate.
Configuring HTTP Remote Upgrade	(Mandatory) It is used to realize HTTP remote upgrade.	
	http update server	Configures the HTTP upgrade server.
	http update mode	Configures the HTTP upgrade mode.
	http update time	Configures the HTTP automatic detection time.

Configuration	Description and Command	
	http check-version	Checks upgradeable file information from the HTTP server.
	http update	Upgrades files manually.
Configuring HTTP Local Upgrade	(Mandatory) It is used to implement HTTP local upgrade.	
	upgrade download	Automatically downloads the web package from the server and automatically upgrades the web package.
Allowing AAA Users to Log In to the Web Page	(Mandatory) It is used to allow AAA users to log in to the web page.	
	http authen login local	Allows AAA users to log in to the web page.

1.4.1 Configuring the HTTP Service

Configuration Effect

After the HTTP service is enabled on a device, you can log in to the web management page after passing authentication and monitor the device status, configure devices, and upload and download files.

Configuration Step

Enabling the HTTP Service

- The HTTP service is disabled by default.
- Run the **enable service web-server** command to enable HTTP service functions including HTTP service and HTTPS service.
- You can log in to devices through web pages to configure and manage the devices only after HTTP service is enabled.

Command	**enable service web-server** [**http** | **https** | **all**]
Parameter Description	**http** | **https** | **all**: Enables the corresponding service. **http** indicates enabling the HTTP service, **https** indicates enabling the HTTPS service, and **all** indicates enabling both HTTP and HTTPS services. By default, both HTTP and HTTPS services are enabled.
Command Mode	Global configuration mode.
Usage Guide	If no keyword or **all** is placed at the end of the command when the command is run, both HTTP and HTTPS services are enabled. If **http** is placed at the end of the command, only the HTTP service is enabled; if **https** is placed at the end of the command, only the HTTPS service is enabled. The **no enable service web-server** or **default enable service web-server** command is used to disable the corresponding HTTP service. If no keyword is placed at the end of the **no enable service web-server** or **default enable service web-server** command, HTTP and HTTPS services are disabled.

Configuring HTTP Authentication Information

- Unless otherwise specified, you can log in to the web page by using the default username and directly update authentication information through the web browser.
- By default, the level, username, and password are set to 0, **admin**, and **admin** respectively.
- Run the **webmaster level** command to configure a username and a password for authentication.
- If this command is configured, you need to enter the configured username and password for authentication before logging in to the web page.

Command	**webmaster level** *privilege-level* **username** *name* **password** { *password* | [**0** | **7**] *encrypted-password* }
Parameter Description	*privilege-level*: Indicates the permission level bound to a user. *name*: Indicates the user name. *password*: Indicates the user password. **0** | **7**: Indicates the password encryption type. The value 0 indicates no encryption and the value 7 indicates simple encryption. The default value is 0. *encrypted-password*: Indicates the password text.
Command Mode	Global configuration mode.
Usage Guide	When the HTTP server is used, you need to be authenticated before logging in to the web page. The **webmaster level** command is used to configure a user name and a password for logging in to the web page. Run the **no webmaster level** *privilege-level* command to delete all user names and passwords of the specified permission level. Run the **no webmaster level** *privilege-level* **username** *name* command to delete the specified user name and password. User names and passwords involve three permission levels. Up to 10 user names and passwords can be configured for each permission level. By default, the system creates the **admin** account. The account cannot be deleted and only the password of the account can be changed. The administrator account is the **admin** account, which corresponds to level-0 permission. The administrator account owns all permissions on the web client and can edit other management accounts and authorize the accounts to access pages. The new accounts that are added correspond to level-1 permission.

Configuring an HTTP Service Port

- If an HTTP service port needs to be changed, the HTTP service port must be configured.
- Unless otherwise specified, the default HTTP service port 80 can be used for access.
- Run the **http port** command to configure an HTTP service port number. The value is 80 and ranges from 1025 to 65535.
- Configure an HTTP service port number to reduce attacks initiated by unauthorized users on the HTTP service.

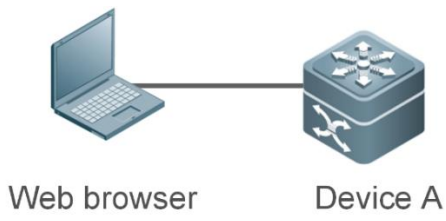
Command	**http port** *port-number*
Parameter Description	*port-number*: Configures an HTTP service port. The value is 80 and ranges from 1025 to 65535.

Command Mode	Global configuration mode.
Usage Guide	Run the command to configure an HTTP service port.

Configuring an HTTPS Service Port

- If an HTTPS service port needs to be changed, the HTTPS service port must be configured.
- Unless otherwise specified, the default HTTPS service port 443 can be used for access.
- Run the **http secure-port** command to configure an HTTPS service port number. The value is 443 and ranges from 1025 to 65535.
- Configure an HTTPS service port number to reduce attacks initiated by unauthorized users on the HTTPS service.

Command	**http secure-port** *port-number*
Parameter Description	*port-number*: Configures an HTTPS service port. The value is 443 and ranges from 1025 to 65535.
Command Mode	Global configuration mode.
Usage Guide	Run the command to configure an HTTPS service port.



Verification

- Enter **http://IP address of the device: service port** to check whether you can redirect to the authentication page.
- Enter **https://IP address of the device: service port** to check whether you can redirect to the authentication page.

Configuration Example

Managing One Device by Using the Web and Logging In to the Device Through a Web Browser to Configure Related Functions

- Log in to the device by using the **admin** account configured by default.
- To improve security, the web browser is required to support both HTTP and HTTPS for access.
- The user is required to configure an HTTP service port to reduce the number of attacks initiated by unauthorized users on HTTP.

Scenario **Figure 1-5**	
Configuration Steps	• Enable both HTTP and HTTPS services. • Set the HTTP service port ID to 8080 and the HTTPS service port ID to 4430.

Device A	`Hostname#configure terminal`
	`Hostname(config)# enable service web-server`
	`Hostname(config)# http port 8080`

	Hostname(config)# http secure-port 4430
Verification	Check the HTTP configuration.
Device A	Hostname# show web-server status http server status: enabled http server port: 8080 https server status:enabled https server port: 4430

Common Errors

If the HTTP service port is not the default port 80 or 443, you must enter a specific configured service port in the browser. Otherwise, you cannot access devices on the web client.

1.4.2 Configuring HTTP Redirection to HTTPS

Configuration Effect

After HTTP and HTTPS are enabled on the device, HTTP can be automatically redirected to HTTPS to improve security when users access the web management page of the device through HTTP.

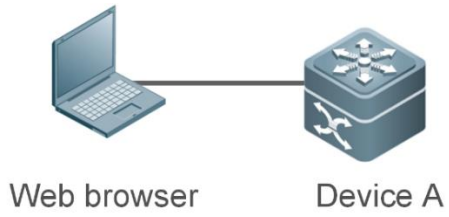
Configuration Step

Configuring HTTP Redirection to HTTPS

- Automatic HTTP redirection to HTTPS is disabled by default.
- Run the **web-server http redirect-to-https** command to enable automatic HTTP redirection to HTTPS.
- After automatic HTTP redirection to HTTPS is enabled, HTTP service requests can be redirected to the HTTPS service to improve security and reduce information leakage risk.

Command	**web-server http redirect-to-https**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When a user uses a browser to access the web management system through HTTP after automatic HTTP redirection to HTTPS is configured, the web server address is automatically redirected to HTTPS. Run the **no web-server http redirect-to-https** or **default web-server http redirect-to-https** command to disable automatic HTTP redirection to HTTPS. The HTTP service is automatically redirected to the HTTPS service only when the HTTP and HTTPS services are enabled. Whether this command is supported is subject to devices. If an IP address to be accessed is a Network Address and Port Translation (NAPT) address, the redirection function may become ineffective. To access the device through HTTP, disable NAPT.

	To access the device through HTTPS, use HTTPS directly.



Verification

- Enter **http://IP address of the device: service port** in the address bar of a browser to check whether the browser is redirected to **https://IP address of the device: service port**.
- Run the **show web-server status** command to check whether automatic HTTP redirection to HTTPS is enabled.

Configuration Example

Logging In to the Web Management System of a Device Through a Browser

- To improve security, HTTP is automatically redirected to HTTPS when a user accesses the page through HTTP,

Scenario **Figure 1-6**	
Configuration Steps	● Enable both HTTP and HTTPS services. ● Configure HTTP redirection to HTTPS.

Device A	`Hostname#configure terminal`
	`Hostname(config)# enable service web-server`
	`Hostname(config)# web-server http redirect-to-https`

Verification	● Check the web service status. ● Enter **http://*IP address of the device*** in the address bar of a browser to check whether the browser is redirected to **https://*IP address of the device***.

Device A	`Hostname#show web-server status`
	`http server status: enabled`
	`http server port: 80`
	`https server status:enabled`
	`https server port: 443`
	`http redirect to https: true`

1.4.3 Configuring the Maximum Number of Concurrent Logins Using the Same Account

Configuration Effect

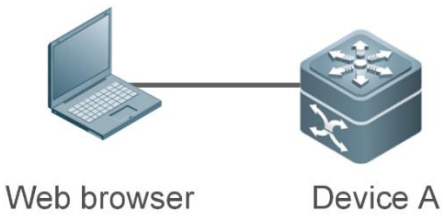
The number of concurrent logins using the same account from different clients (with different IP addresses) is limited. For example, if the maximum number of concurrent logins is set to 2, the account can be logged in from two different clients simultaneously.

Configuration Steps

Configuring the Maximum Number of Concurrent Logins Using the Same Account

- The maximum number of concurrent logins using the same account is 10 by default.
- You can configure the concurrent logins using the same account to restrict the logins from different IP addresses. This enhances access security and reduces the risk of information leakage and malicious attacks.

Command	**http limit** *limit-number*
Parameter Description	*limit-number*: Indicates the maximum number of concurrent logins using the same account. The value range is from 1 to 256.
Command Mode	Global configuration mode
Usage Guide	1. The login count is calculated based on the IP addresses of the devices where the same account is logged in. If the account is logged in on multiple pages from the same device, the login count is considered as 1 because the IP address is the same. If the account is logged in from two different devices at the same time, the login count is considered as 2, and so on. The login limit is the configured maximum number of concurrent logins. 2. When the login count reaches the upper limit, a login failure message will be displayed when a new client attempts to log in to the account.



Verification

- When the maximum number of concurrent logins is set to 1, a user has logged in to the web system using an account on PC1 and attempts to log in using the same account on PC2, a login failure occurs.
- After the account is logged out on PC1, it can be logged in on PC2.
- After the login times out on PC1, the account can be logged in on PC2. (If you directly close the web page, you can only wait for the login timeout or manually log out from PC1. Otherwise, the login restriction cannot be removed.)
- Run the **http limit** command to set the maximum number of concurrent logins to 2, the same account can be logged in on PC2, but a login failure will occur on PC3.
- Run the **show web-server status** command to display the maximum number of concurrent logins. The configuration is not displayed when the default value is used.

Configuration Examples

↘ Logging In to the Web Management System of a Device by Browser

To enhance security, the maximum number of concurrent logins using the same account is set to 1.

Scenario Figure1-2	
Configuration Steps	Set the maximum number of concurrent logins using the same account to 1.
Device A	`Hostname#configure terminal` `Hostname(config)#http limit 1`
Verification	● Run the **show web-server status** command to display the web server configuration. ● After logging in to a web account on a device, you cannot log in to the web management system

	using the same account on another device. The system prompts that the number of concurrent logins has reached the upper limit.

Device A	`Hostname#show web-server status`
	`http server status: enabled`
	`http server port: 80`
	`https server status:enabled`
	`https server port: 443`
	`http redirect to https: true`
	`User login is limited to (1)`

1.4.4 Configuring an HTTPS Service Certificate

Configuration Effect

The devices use an automatically generated self-signed certificate as the HTTPS service certificate by default. After an HTTPS service certificate is configured, the device generates a self-signed certificate again or uses the certificate assigned by the certificate authority.

Configuration Step

Regenerating a Self-Signed HTTPS Service Certificate

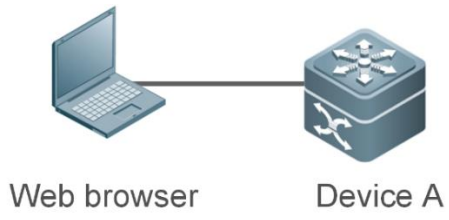
- The HTTPS service uses the self-signed certificate by default.
- Run the **web-server https generate self-signed-certificate** command to generate a self-signed HTTPS service certificate.

Command	**web-server https generate self-signed-certificate**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command is an interactive command. After running this command, enter information to generate a self-signed certificate as prompted, or press **Ctrl+C** to cancel the operation. If the device is installed with a third-party HTTPS service certificate, it uses the HTTPS certificate preferentially. The re-generated self-signed certificate does not replace the current HTTPS service certificate. This command is not displayed in the configuration (running-config). After the HTTPS service certificate is generated again, the browser may require you to add the trust certificate again before you continue to access the web management page of the device. You are advised to open the web management page again after closing the browser.

Installing the HTTPS Certificate

- The HTTPS service uses the self-signed certificate by default.
- Run the **web-server https certificate** command to install the HTTPS service certificate issued by the certificate authority.

- An HTTPS certificate issued by a trusted certificate authority can be installed on the device to eliminate the warning that the browser's certificate is untrusted when you access the device through HTTPS.



Command	**web-server https certificate** { **pem** *cert-filename* **private-key** *key-filename* } | { **pfx** *cert-filename* } [**password** *password-text*]
Parameter Description	**pem**: Imports the certificate file and private key file in pem. format. **pfx**: Imports the certificate file in pfx. format from which a private key is exported. *cert-filename*: Indicates the file name in the **flash:** partition. *key-filename*: Indicates the private key file name in the **flash:** partition. **password** *password-text*: Indicates the decryption password of the private key file or decryption password of the private key exported from the pfx certificate.
Command Mode	Global configuration mode
Usage Guide	Run the **copy** command to copy the certificate or private key file to the **flash:** partition before running the command to install the third-party HTTPS service certificate. Then you can delete the certificate or private key file from the **flash:** partition. Run the **no web-server https certificate** command to remove the installed HTTPS service certificate. Then the HTTPS service will use the self-signed certificate. This command is not displayed in the configuration (running-config). The supported configuration may vary depending on devices. After the HTTPS service certificate is installed, the browser may require you to add the trust certificate again before you continue access to the wWeb management page of the device. You are advised to open the web management page again after closing the browser.

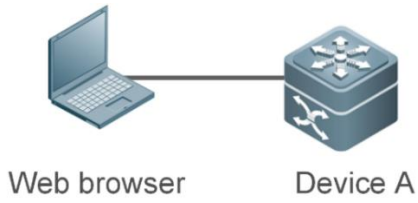
Verification

Run the **show web-server https certificate information** command to display information about the HTTPS service certificate.

Configuration Example

Regenerating a Self-Signed Certificate

Scenario Figure 1-6	
Configuration Steps	Configure the device to generate a self-signed certificate again.



Device A	`Hostname#configure terminal`
	`Hostname(config)# web-server https generate self-signed-certificate`
	`RSA key modulus bits (1024~4096) [2048]:`
	`Common Name (e.g. server IP) [Self-Signed-600B16C2]:`
	`% Generate self-signed certificate successfully`

Verification	● Run the **show web-server https certificate information** command to display information about the certificate.

Device A	`Hostname#show web-server https certificate information`
	`Source: Default`
	`Certificate:`
	`  Data:`
	`  Version: 3 (0x2)`
	`  Serial Number: 1 (0x1)`
	`  Signature Algorithm: sha256WithRSAEncryption`
	`  Issuer: CN=Self-Signed-600B16C2`
	`  Validity`
	`  Not Before: Feb 28 05:49:39 2019 GMT`
	`  Not After : Feb 25 05:49:39 2029 GMT`
	`  Subject: CN=Self-Signed-600B16C2`
	`  Subject Public Key Info:`
	`  Public Key Algorithm: rsaEncryption`
	`  Public-Key: (2048 bit)`
	`  Modulus:`
	……

Installing the Third-Party HTTPS Service Certificate

The name of the certificate file is **usercert.pfx**, and the password of the private key file is **123456.** The TFTP server is enabled on the PC and the certificate file is in the directory of the TFTP server.

Scenario **Figure 1-6**	
Configuration Steps	● Run the **copy** command to copy the certificate or private key file to the **flash:** partition. ● Run the **web-server https certificate** command to install the HTTPS service certificate.

Device A	`Hostname# copy tftp://192.168.1.1/usercert.pfx flash:usercert.pfx`
	`Press Ctrl+C to quit`
	`!`
	`Copy success.`
	`Hostname#configure terminal`
	`Hostname(config)# web-server https certificate pfx usercert.pfx password 123456`
	`*Feb 28 14:38:37: %HTTPD-4-CERT_CHANGE: HTTPS certificate changed.`
	`% The certificate was successfully installed.`

Verification	● Run the **show web-server https certificate information** command to display information about the certificate.
Device A	`Hostname#show web-server https certificate information`

```
Source: Installed
Certificate:
    Data:
        Version: 3 (0x2)
        Serial Number: 4 (0x4)
    Signature Algorithm: sha1WithRSAEncryption
        Issuer: C=CN, CN=mytestCA
        Validity
            Not Before: Jan 23 08:36:21 2019 GMT
            Not After : Jan 23 08:36:21 2020 GMT
        Subject: C=CN, CN=test-cert-2
        Subject Public Key Info:
            Public Key Algorithm: rsaEncryption
                Public-Key: (2048 bit)
                Modulus:
……
```

1.4.5 Configuring HTTP Remote Upgrade

Configuration Effect

The device is connected to a remote HTTP server as a client and upgrades local files by obtaining files from the server.

Notes

- Before configuring the HTTP upgrade server domain name, users are required to enable the device's DNS function and configure the DNS server address.

Configuration Step

↘ Configuring the HTTP Upgrade Server

- Mandatory if you want to change the server address and port number for HTTP remote upgrade.
- Unless otherwise specified, there is no need to configure the HTTP upgrade server on each device.
- By default, the server address for HTTP remote upgrade is 0.0.0.0 and the port number is 80.
- Use the **http update server** command to configure the address and port number for the HTTP remote upgrade server.
- During HTTP upgrade, the device will try to connect to the server address configured with this command first. If the connection fails, it will try to connect to the locally recorded server addresses one by one. If all servers cannot be connected, the upgrade cannot proceed.

Command	**http update server** { *host-name* | *ip-address* } [**port** *port-number*]
Parameter Description	*host-name*: Indicates the server domain name. *ip-address*: Indicates the IP address of the server. **port** *port-number*: Indicates the server port number. The value range is from 1 to 65535 and the default value is 80.

Command Mode	Global configuration mode
Usage Guide	This command is used to configure the address and port number for the HTTP upgrade server. During HTTP upgrade, the device will try to connect to the server address configured with this command first. If the connection fails, it will try to connect to the locally recorded server addresses one by one. If all servers cannot be connected, the upgrade cannot proceed. The system records one or more upgrade server addresses, which cannot be modified. Whether this configuration is supported depends on the actual product version. The server address can be left unconfigured because the local upgrade record file records possible upgrade server addresses. By default, DNS needs to be enabled and the DNS server address needs to be configured. The IPv6 server address is not supported.

Configuring the HTTP Upgrade Mode

- Mandatory if the manual HTTP upgrade mode is required.
- Unless otherwise specified, the default HTTP upgrade mode is automatic.
- By default, HTTP uses automatic upgrade mode.
- Use the **http update mode** command to configure the HTTP upgrade mode as manual.

Command	**http update mode manual**
Parameter Description	**manual**: Indicates the manual upgrade mode.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the HTTP upgrade mode. This command is used to configure a manual upgrade mode. Run the **no** form of this command to set the HTTP upgrade mode to automatic mode. When the automatic upgrade time arrives, the device will automatically detect the upgradable file information on the server by default and download the files for upgrade. Whether this configuration is supported depends on the actual product version.

Configuring the HTTP Automatic Upgrade Time

- Mandatory if you want to change the HTTP automatic upgrade time.
- If there are no special requirements, the HTTP automatic upgrade time is random by default.
- By default, the HTTP remote automatic upgrade time is a random time within the range of 00:00–23:59.
- The **http update time** command can be used to change the automatic upgrade time, which can only be configured to a specific time each day, accurate to minutes.
- By configuring this command, if the upgrade mode is automatic, the device will check the file version on the server and upgrade the files on the device at a specified time every day.

Command	**http update time daily** *hh*:*mm*

Parameter Description	*hh*:*mm*: Indicates the specific upgrade time, in the format of hour(24-hour clock):minute.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the HTTP automatic upgrade time. The device automatically connects to the web server at the specified time each day to check whether there is any upgradeable file information. The file information obtained can be viewed through the web interface. If the **no** form of the command is executed, the device upgrade time will be a random time within the range of 00:00–23:59. Whether this configuration is supported depends on the actual product version.

Checking Upgradeable File Information from the HTTP Server

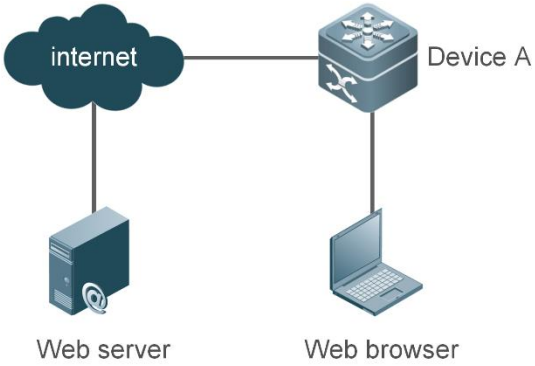
- Mandatory if you want to check upgradeable file information on the HTTP server.
- Unless otherwise specified, you do not need to perform this task because automatic upgrade is enabled by default.
- By default, the device is disabled from detecting upgradeable HTTP files.
- The **http check-version** command can be used to detect upgradeable files on the server.
- By configuring this command, you can detect files on the server that are more up-to-date than local files.

Command	**http check-version**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	This command is used to detect the file types to be upgraded. The detected files are those that are more up-to-date on the server than on the local device. Whether this configuration is supported depends on the actual product version.

Upgrading Files Manually

- Mandatory.
- Unless otherwise specified, configure manual file upgrade on each device.
- The **http update** command can be used to manually upgrade files.

Command	**http update** { **all** | *string* **}**
Parameter Description	**all**: Indicates that all service modules are upgraded. *string*: Indicates the name of the service module to be upgraded.
Command Mode	Privileged EXEC mode
Usage Guide	This command is used to manually upgrade a specified service module or all service modules. Whether this configuration is supported depends on the actual product version.



Verification

- Run the **ping** command to verify that the device can establish a connection with the server.
- Run the **http check-version** command to obtain version information about relevant files on the device.

Configuration Example

Upgrading the Files Using HTTP Remote Upgrade

- The device can automatically obtain upgradeable file information from the server and download the files for upgrading at 2:00 a.m. every day.
- Check the currently upgradeable file information.
- The latest files are downloaded from the server and the upgrade device is updated.

Scenario **Figure** 1-3	
Configuration Steps	● Configure DNS information. ● Set the device's scheduled remote monitoring time to 2:00 a.m. ● Obtain upgradeable file information from the remote server. ● Download the files from the server and update them.

Device A	`Hostname#configure terminal`
	`Hostname(config)#ip domain-lookup`
	`Hostname(config)#ip name-server 192.168.58.110`
	`Hostname(config)#http update time daily 02:00`
	`Hostname(config)#http check-version`
	`Hostname(config)#end`
	`Hostname# http update all`

Common Errors

The DNS services are disabled, resulting in the device being unable to establish a connection with the server.

1.4.6 Configuring HTTP Local Upgrade

Configuration Effect

This section describes how to perform an HTTP upgrade through the browser or the **upgrade download** command.

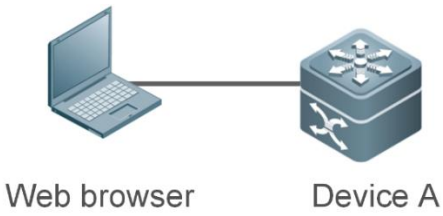
Notes

- If a web package is uploaded by browser and passes the version check, the device directly upgrades the web package to the latest one.
- Run the **upgrade download** command to automatically download the file from the TFTP server and perform automatic upgrade.

Configuration Steps

Downloading a Web Package from the TFTP Server

- Run the **upgrade download** command to download a web package from the TFTP server.
- After the configuration, the device downloads a web package from the TFTP server and performs validity check. If the web package is valid, the device directly upgrades the web package, eliminating the need for a device restart.



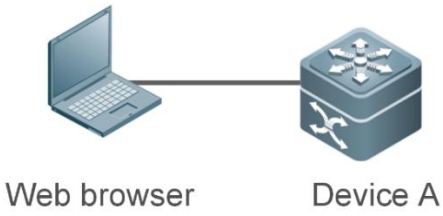
Command	**upgrade download tftp:***path*
Parameter Description	**tftp**: Indicates that the web package is downloaded through the common data port connected to the TFTP server. *path*: Indicates the path of the web package on the TFTP server.
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to download a web package from the TFTP server and automatically upgrade the device the web package.

Verification

You can directly access the web system by browser to view the latest web pages.

Configuration Example

Configuring the Device to Run the Latest Web Package After It Is Obtained from the Official Website



Scenario **Figure1-4**	
Configuration Steps	● Connect the device to a local PC, whose IP address is 10.10.10.13. Configure an IP address 10.10.10.131 in the same network segment for the device. ● Log in to the device through the web system and upload the latest web package to the device.

Device A	`Hostname#configure terminal`
	`Hostname(config)# vlan 1`
	`Hostname(config-vlan)# exit`
	`Hostname(config)# interface vlan 1`
	`Hostname(config-VLAN 1)# ip address 10.10.10.131 255.255.255.0`
	`Hostname(config-VLAN 1)# exit`
	`Hostname(config)# enable service web-server`

	On the PC, use the local upgrade function on the web page to upload the web package for upgrade.
Verification	On the PC, perform web-based authentication again for login and check whether the latest web page

	is displayed.

Running the upgrade download Command to Upgrade a Web Package

Scenario **Figure1-9**	
Configuration Steps	● Connect the device to a local PC, whose IP address is 10.10.10.13. Configure an IP address 10.10.10.131 in the same network segment for the device. ● Enable the TFTP server.

Device A	`Hostname#configure terminal`
	`Hostname(config)# vlan 1`
	`Hostname(config-vlan)# exit`
	`Hostname(config)# interface vlan 1`
	`Hostname(config-VLAN 1)# ip address 10.10.10.131 255.255.255.0`
	`Hostname(config-VLAN 1)# end`
	`Hostname#upgrade download tftp:// 10.10.10.13/web.upd`
	`Press Ctrl+C to quit`
	`!!!!!!!!`
	`download 3896704 bytes`
	`Begin to upgrade the web package...`
	`Web package upgrade successfully.`

Verification	On the PC, perform web-based authentication again for login and check whether the latest web page is displayed.

Common Errors

If the new web package is not updated after you access the web system by browser, the local browser may have a cache. Clear the browser cache and access the web system again.

1.4.7 Allowing AAA Users to Log In to the Web Page

Configuration Effect

- Users can successfully log in to the web page by using usernames and passwords in the local AAA database or remote AAA server, and they have the admin permission after login.

Notes

N/A

Configuration Steps

Allowing AAA Users to Log In to the Web Page

- Optional.
- Configure this function when AAA users need to be authorized to log in to the web page.

Command	http authen login local
Parameter Description	**local**: Allows users in the local AAA database to log in to the web page.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running-config** command to check whether AAA users can log in to the web page.
- An AAA user can log in to the web page successfully and has the admin permission.

Configuration Example

Allowing AAA Users to Log In to the Web Page

Configuration Steps	Allows users in the local AAA database to log in to the web page.
	`Hostname(config)# http authen login local`
Verification	Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`…`
	`http authen login local`
	`…`

1.5 Monitoring

Displaying

Command	Description
show web-server status	Displays the configuration and status of the web service.
show web-server https certificate information	Displays the HTTPS certificate of the web server.

1 Configuring Syslog

1.1 Overview

During device running, status changes (such as link Up and Down) or abnormal events (such as abnormal packets or processing exceptions) may occur. Devices provide the syslog mechanism to automatically generate messages (log packets) in fixed format upon status changes or occurrence of events. These messages are displayed on the related windows such as the console or monitoring terminal, recorded in the media such as the memory buffer or log files, or sent to a group of log servers on a network so that the administrator can analyze network performance and identify faults based on the log packets. Log packets can be added with the timestamps and sequence numbers and classified by severity so that the administrator can easily read and manage log packets.

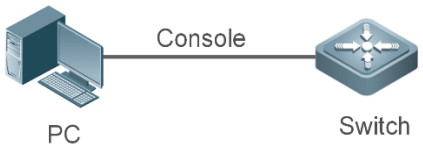
Protocols and Standards

- RFC 3164: The BSD syslog Protocol
- RFC 5424: The_Syslog_Protocol

1.2 Applications

Application	Description
Sending Syslogs to the Console	Monitor syslogs through the console.
Configuring the Device to Send Syslogs to the Log Server	Monitor syslogs through the server.

1.2.1 Sending Syslogs to the Console



Scenario

Syslogs can be sent to the console, so an administrator can monitor the performance of the system. The requirements are as follows:

1. Send logs of severity 6 or higher to the console.
2. Send logs of only the ARP and IP modules to the console.

Figure 1-1 shows the network topology.

Figure 1-1 Network topology

Deployment

Perform the following configurations:

1. Set the severity of logs that can be sent to the console to informational (severity 6).
2. Set the filtering direction of logs to terminal.
3. Set the log filtering mode of logs to contains-only.
4. Set the filtering rule of logs to single-match. The module name contains only ARP or IP.

1.2.2 Configuring the Device to Send Syslogs to the Log Server

Scenario

When the device is configured to send syslogs to the log server, an administrator can easily monitor logs of devices on the server. The requirements are as follows:

1. Send syslogs to the log server at 10.1.1.1.
2. Send syslogs from the source interface Loopback 0 to the log server.
3. Configure the logs that cannot be received. Send the logs of IP address assignment by DHCP to the log server.
4. Configure warning (severity 4) logs that can be sent to the log server.

Figure 1-2 shows the network topology.

Figure 1-2 Network topology

Deployment

Perform the following configurations:

1. Set the IPv4 address of the server to 10.1.1.1.
2. Set the source interface of logs sent to the log server to Loopback 0.
3. Set the sending mode of logs sent to the log server to audit.
4. Configure the log filtering rules in audit mode to allow the device to send logs of IP address assignment by DHCP and warning (severity 4) logs to the log server.

1.3 Features

Basic Concepts

↘ Classification of Syslogs

Syslogs can be classified into two types:

- Log type
- Debug type

Severities of Syslogs

Eight severities of syslogs are defined in descending order, including emergency, alert, critical, error, warning, notification, informational, and debugging. These severities correspond to eight numerals in the range of 0 to 7. A smaller value indicates a higher severity.

Only logs with a severity that is the same as or higher than the specified severity can be output. For example, if the severity of logs is set to informational (severity 6), logs of severity 6 or higher will be output.

The following table describes the log severities.

Severity	Numerical Value	Description
emergencies	0	Indicates that the system cannot run normally.
alerts	1	Indicates that measures must be taken immediately.
critical	2	Indicates a critical condition.
errors	3	Indicates an error.
warnings	4	Indicates a warning.
notifications	5	Indicates a notification message that requires attention.
informational	6	Indicates an informational message.
debugging	7	Indicates a debugging message.

Output Direction of Syslogs

Syslogs can be output to the console, monitor, server, buffer, and file. The default severity and type of logs vary with the output direction. You can customize filtering rules for different output directions.

The following table describes output directions of syslogs.

Output Direction	Description	Default Output Severity	Description
Console	Console	Debugging (severity 7)	Logs and debugging information are output.
Monitor	Monitoring terminal	Debugging (severity 7)	Logs and debugging information are output.
Server	Log server	Informational (severity 6)	Logs and debugging information are output.
Buffer	Log buffer	Debugging (severity 7)	Logs and debugging information are output. The log buffer is used to store syslogs.
File	Log file	Informational (severity 6)	Logs and debugging information are output. Logs in the log buffer are periodically written into files.

RFC 3164 Log Format

Formats of syslogs may vary with the syslog output direction.

- If syslogs can be output to the console, monitor, buffer, or file, the syslog format is as follows:

```
seq no: *timestamp: sysname %module-level-mnemonic: content
```

For example, if you exit configuration mode, the following log is displayed on the Console:

```
001233: *May 22 09:44:36: Hostname %SYS-5-CONFIG_I: Configured from console by console
```

- If syslogs can be output to the log server, the syslog format is as follows:

```
<priority>seq no: *timestamp: sysname %module-level-mnemonic: content
```

For example, if you exit the configuration mode, the following log is displayed on the log server:

```
<189>001233: *May 22 09:44:36: Hostname %SYS-5-CONFIG_I: Configured from console by console
```

Each field in the log is described as follows.

1. Priority

This field is valid only when logs are sent to the log server.

The priority is calculated using the following formula:

Priority = Facility x 8 + Severity

The severity indicates the numerical code of the log severity and the facility indicates the numerical code of the facility. The default facility value is local7 (23). The following table lists the value range of the facility.

Numerical Code	Facility Keyword	Facility Description
0	kern	kernel messages
1	user	user-level messages
2	mail	mail system
3	daemon	system daemons
4	auth1	security/authorization messages
5	syslog	messages generated internally by syslogs
6	lpr	line printer subsystem
7	news	network news subsystem
8	uucp	UUCP subsystem
9	clock1	clock daemon
10	auth2	security/authorization messages
11	ftp	FTP daemon
12	ntp	NTP subsystem
13	logaudit	log audit
14	logalert	log alert
15	clock2	clock daemon
16	local0	local use 0 (local0)
17	local1	local use 1 (local1)
18	local2	local use 2 (local2)
19	local3	local use 3 (local3)
20	local4	local use 4 (local4)
21	local5	local use 5 (local5)
22	local6	local use 6 (local6)
23	local7	local use 7 (local7)

2. Sequence number

The sequence number of a syslog is a 6-digit integer, and increases sequentially. By default, the sequence number is not displayed. You can run a command to display or hide this field.

3. Timestamp

The timestamp records the time when a syslog is generated so that you can display and check the system event easily. Devices support two syslog timestamp formats: datetime and uptime.

If the device does not have the real time clock (RTC) that is used to record the system absolute time, the device uses its startup time (uptime) as the syslog timestamp by default. If the device has the RTC, the device uses its absolute time (datetime) as the syslog timestamp by default.

The two timestamp formats are described as follows:

- Datetime format

The datetime format is as follows.

```
Mmm dd yyyy hh:mm:ss.msec
```

The following table describes each parameter of the datetime.

Timestamp Parameter	Parameter Name	Description
Mmm	Month	Mmm refers to abbreviation of the current month. The 12 months in a year are written as Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, and Dec.
dd	Day	dd indicates the current date.
yyyy	Year	yyyy indicates the current year, and is not displayed by default.
hh	Hour	hh indicates the current hour.
mm	Minute	mm indicates the current minute.
ss	Second	ss indicates the current second.
msec	Millisecond	msec indicates the current millisecond.

By default, the datetime timestamp displayed in the syslog does not contain the year and millisecond. You can run a command to display or hide the year and millisecond of the datetime timestamp.

- Uptime format

The uptime format is as follows.

```
dd:hh:mm:ss
```

The timestamp string indicates the accumulated days, hours, minutes, and seconds since the system has started.

4. Sysname

This field indicates the name of the device that generates the log so that the log server can identify the host that sends the log. By default, this field is not displayed. You can run a command to display or hide this field.

5. Module

This field indicates the name of the module that generates the log. The module name is a string of 2 to 20 upper-case characters, which contain upper-case letters, digits, or underscores. The module field is mandatory in log information, and optional in debugging information.

6. Severity

Eight syslog severities from 0 to 7 are defined. The severityl of syslogs generated by each module is fixed and cannot be modified.

7. Mnemonic

This field indicates brief information about the log. The mnemonic is a string of 4 to 32 upper-case characters, which contains upper-case letters, digits, or underscores. The mnemonic field is mandatory in log information, and optional in debugging information.

8. Content

This field indicates the detailed content of the syslog.

RFC 5424 Log Format

The syslog format in the output direction is as follows.

```
<priority>version timestamp sysname MODULE LEVEL MNEMONIC [structured-data] description
```

For example, if you exit configuration mode, the following log is displayed on the Console:

```
<133>1 2013-07-24T12:19:33.130290Z Hostname SYS 5 CONFIG - Configured from console by console
```

Each field in the log is described as follows

1. Priority

   The priority is calculated using the following formula:

   Priority = Facility x 8 + Severity

   The severity indicates the numerical code of the log severity and the facility indicates the numerical code of the facility. When the RFC 5424 format is enabled, the default value of the facility field is local0 (16).

2. Version

According to RFC 5424, the version has a fixed value of 1.

3. Timestamp

The timestamp records the time when a syslog is generated so that you can display and check the system event conveniently. Devices use the following uniformed timestamp format when the RFC 5424 logging function is enabled:

```
YYYY-MM-DDTHH:MM:SS.SECFRACZ
```

The following table describes each parameter of the timestamp.

Timestamp Parameter	Description	Remark
YYYY	Year	YYYY indicates the current year.
MM	Month	MM indicates the current month.
DD	Day	DD indicates the current date.
T	Separator	The date must end with T.
HH	Hour	HH indicates the current hour.
MM	Minute	MM indicates the current minute.
SS	Second	SS indicates the current second.
SECFRAC	Millisecond	SECFRAC indicates the current millisecond (1–6 digits).
Z	End mark	The time must end with Z.

4. Sysname

This field indicates the name of the device that generates the log so that the log server can identify the host that sends the log.

5. Module

This field indicates the name of the module that generates the log. The module name is a string of 2 to 20 upper-case characters, which contain upper-case letters, digits, or underscores. The module field is mandatory in log information, and optional in debugging information.

6. Severity

Eight syslog severities from 0 to 7 are defined. The severityl of syslogs generated by each module is fixed and cannot be modified.

7. Mnemonic

This field indicates brief information about the log. The mnemonic is a string of 4 to 32 upper-case characters, which contains upper-case letters, digits, or underscores. The mnemonic field is mandatory in log information, and optional in debugging information.

8. Structured-Data

Structured-data introduced in RFC 5424 is parsed as a string containing parameter information. Each log may contain no parameter or multiple parameters. If there is no parameter, use the placeholder (-). The format of this field is as follows.

```
[SD_ID@enterpriseID PARAM-NAME=PARAM-VALUE]
```

The following table describes each parameter of the structured-data field.

Parameter in structured-data	Description	Remarks
SD_ID	Parameter information name	The parameter information name is capitalized, and must be unique in a log.
@	Separator	"@enterpriseID" is added only to the customized parameter information, not to the parameter information defined in RFC 5424.
enterpriseID	Enterprise ID	The enterprise ID is maintained by the Internet Assigned Numbers Authority (IANA). The enterprise ID of devices has a fixed value of 4881. You can query the enterprise ID at the official website of IANA. `http://www.iana.org/assignments/enterprise-numbers`
PARAM-NAME	Parameter name	The parameter name is capitalized, and must be unique in the structured-data of a log.
PARAM-VALUE	Parameter value	The parameter value must be enclosed in double quotation marks. Values of the IP address or MAC address must be capitalized, and other types of values are capitalized as required.

9. description

This field indicates the content of the syslog.

Overview

Feature	Description
Logging	Enable or disable system logging functions.
Syslog Format	Configure the syslog format.
Logging Direction	Configure the parameters in syslogs sent in different directions.
Syslog Filtering	Configure parameters of the syslog filtering function.
Featured Logging	Configure parameters of the featured logging function.

Syslog Monitoring	Configure parameters of the syslog monitoring function.

1.3.1 Logging

Enable or disable logging, redirection logging, and log statistics collection functions.

Related Configuration

Enabling Logging

By default, logging is enabled.

Run the **logging on** command to enable logging in global configuration mode. After logging is enabled, logs generated by the system are sent in various directions for the administrator to monitor the system performance.

Enabling Log Statistics

By default, log statistics collection is disabled.

Run the **logging count** command to enable log statistics collection in global configuration mode. After log statistics collection is enabled, the system records the number of times a log is generated and the last time when the log was generated.

1.3.2 Syslog Format

Configure the syslog format, including the RFC 5424 log format, timestamp format, sysname, and sequence number.

Related Configuration

Enabling the RFC 5424 Log Format

By default, the RFC 5424 log format is disabled.

After the new format (RFC 5424 log format) is enabled, **service sequence-numbers**, **service sysname**, **service timestamps**, **service private-syslog**, and **service standard-syslog** that are applicable only to the old format (RFC 3164 log format) take ineffective and are hidden.

After the old format (RFC 3164 log format) is enabled, **logging delay-send**, **logging policy**, and **logging statistic** that are applicable only to the RFC 5424 log format take ineffective and are hidden.

After log format switchover, the outputs of the **show logging** and **show logging config** commands change accordingly.

Configuring the Timestamp Format

By default, the syslog uses the datetime timestamp format, and the timestamp does not contain the year or millisecond.

Run the **service timestamps** command in global configuration mode to use the datetime timestamp format that contains the year and millisecond in the syslog, or change the datetime format to the uptime format.

Adding Sysname to the Syslog

By default, the syslog does not contain sysname.

Run the **service sysname** command in global configuration mode to add sysname to the syslog.

Adding the Sequence Number to the Syslog

By default, the syslog does not contain the sequence number.

Run the **service sequence-numbers** command in global configuration mode to add the sequence number to the syslog.

Enabling the Standard Log Format

By default, logs are displayed in the following format.

```
*timestamp: %module-level-mnemonic: content
```

Run the **service standard-syslog** command in global configuration mode to enable the standard log format. Logs are displayed in the following format.

```
timestamp %module-level-mnemonic: content
```

Compared with the default log format, an asterisk (*) is missing in front of the timestamp, and a colon (:) is missing at the end of the timestamp in the standard log format.

Enabling the Private Log Format

By default, logs are displayed in the following format.

```
*timestamp: %module-level-mnemonic: content
```

Run the **service private-syslog** command in global configuration mode to enable the private log format. Logs are displayed in the following format.

```
timestamp module-level-mnemonic: content
```

Compared with the default log format, an asterisk (*) is missing in front of the timestamp, a colon (:) is missing at the end of the timestamp, and a percent sign (%) is missing at the end of the module name in the private log format.

1.3.3 Logging Direction

Configure parameters for sending syslogs in different directions, including the console, monitor, buffer, log server, and log files.

Related Configuration

Configuring Synchronization of User Input and Log Output

Synchronization of user input and log output is disabled by default.

Run the **logging synchronous** command to enable synchronization of user input and log output in line configuration mode to prevent interruption of user input.

Configuring the Rate Limit for Logging

By default, logging is not rate-limited.

Run the **logging rate-limit** { *number* | **all** *number* | **console** {*number* | **all** *number* } } [**except** [*severity*]] command in global configuration mode to configure the rate limit for logging.

Configuring the Severity of Logs Sent to the Console

By default, the severity of logs sent to the console is debugging (severity 7).

Run the **logging console** [*level*] command in global configuration mode to configure the severity of logs that can be sent to the console.

Sending Logs to the Monitor Terminal

By default, sending logs to the monitor terminal is not allowed.

Run the **terminal monitor** command in privileged EXEC mode to send logs to the monitor terminal.

Configuring the Severity of Logs Sent to the Monitor Terminal

By default, the severity of logs sent to the monitor terminal is debugging (severity 7).

Run the **logging monitor** [*level*] command in global configuration mode to configure the severity of logs that can be sent to the monitor terminal.

Writing Logs into the Memory Buffer

By default, logs are written into the memory buffer, and the default severity of logs is debugging (severity 7).

Run the **logging buffered** [*buffer-size*] [*level*] command in global configuration mode to configure parameters for writing logs into the memory buffer, including the buffer size and log severity.

Sending Logs to the Log Server

By default, logs are not sent to the log server.

Run the **logging server** { *ip-address* | **ipv6** *ipv6-address* } [**udp-port** *port*] command in global configuration mode to send logs to a specified log server.

Configuring the Severity of Logs Sent to the Log Server

By default, the severity of logs sent to the log server is informational (severity 6).

Run the **logging trap** [*level*] command in global configuration mode to configure the severity of logs that can be sent to the log server.

Configuring the Facility Value of Logs Sent to the Log Server

If the RFC 5424 log format is disabled, the facility value of logs sent to the log server is local7 (23) by default. If the RFC 5424 log format is enabled, the facility value of logs sent to the log server is local0 (16) by default.

Run the **logging facility** *facility-type* command in global configuration mode to configure the facility value of logs sent to the log server.

Configuring the Source Address of Logs Sent to the Log Server

By default, the source address of logs sent to the log server is the IP address of the interface sending logs.

Run the **logging source interface** *interface-type interface-number* command to configure the source interface of logs. If this source interface is not configured or the IP address is not configured for this source interface, the source address of logs is the IP address of the interface sending logs.

Run the **logging source** { **ip** *ip-address* | **ipv6** *ipv6-address* } command to configure the source IP address of logs. If this IP address is not configured on the device, the source address of logs is the IP address of the interface sending logs.

Writing Logs into Log Files

By default, logs are not written into log files. After the device is enabled to write logs into log files, the severity of logs written into log files is informational (severity 6) by default.

Run the **logging file** { **sata0:***filename* | **flash:***filename* | **usb0**:*filename* | **usb1**:*filename* | **sd0**:*filename* } [*max-file-size*] [level] command in global configuration mode to configure parameters for writing logs into log files, including the type of device where the file is stored, file name, file size, and log severity.

Configuring the Number of Log Files

By default, the number of log files is 16.

Run the **logging file** numbers *numbers* command in global configuration mode to set the number of log files.

Configuring the Interval at Which Logs Are Written into Log Files

By default, logs are written into log files at the interval of 3600s (one hour).

Run the **logging flash interval** *seconds* command in global configuration mode to configure the interval at which logs are written into log files.

Configuring the Storage Time of Log Files

By default, the storage time is not configured.

Run the **logging life-time level** *level days* command in global configuration mode to configure the storage time of logs. The administrator can specify different storage days for logs of different severities.

Immediately Writing Logs in the Buffer into Log Files

By default, syslogs are stored in the syslog buffer, and then written into log files periodically when the buffer is full or the timer expires.

Run the **logging flash flush** command in global configuration mode to immediately write logs in the buffer into log files so that the administrator can collect logs conveniently.

1.3.4 Syslog Filtering

By default, logs generated by the system are sent in all directions. To view some specified syslogs, use syslog filtering.

Working Principle

Filtering Direction

Five log filtering directions are defined:

- **buffer**: Filters out logs sent to the log buffer, that is, logs displayed by the **show logging** command.
- **file**: Filters out logs written into log files.
- **server**: Filters out logs sent to the log server.
- **terminal**: Filters out logs sent to the console and monitor terminal (including Telnet and SSH).

The four filtering directions can be used in combinations to filter out logs sent in various directions, or used separately to filter out logs sent in a single direction.

Filtering Mode

Two filtering modes are available:

- **contains-only**: Indicates that only logs that contain keywords specified in filtering rules are output. You may focus on only a specified type of logs. In this case, you can apply the contains-only mode on the device to display only logs that match filtering rules on the terminal, helping you check whether any event occurs.
- **filter-only**: Indicates that logs that contain keywords specified in the filtering rules are filtered out and will not be output. If a module generates many logs, information is flooded on the terminal interface. If you do not care about this type of logs, you can apply the filter-only mode and configure filtering rules to filter out logs.

The two filtering modes cannot be configured simultaneously.

Filtering Rule

Two filtering rules are available:

- **exact-match**: If **exact-match** is selected, you must select all the three filtering options (module, severity, and mnemonic). To filter out a specified log, use the exact-match filtering rule.
- **single-match**: If **single-match** is selected, you only need to select one of the three filtering options (module, severity, and mnemonic). To filter out a specified type of logs, use the single-match filtering rule.

If the same module, severity, or mnemonic is configured for both the single-match and exact-match rules, the single-match rule takes effect.

Related Configuration

Configuring the Log Filtering Direction

By default, the log filtering direction is all, that is, logs sent in all directions are filtered.

Run the **logging filter direction** { **all** | **buffer** | **file** | **server** | **terminal** } command in global configuration mode to configure the log filtering direction to filter out logs in the specified directions.

Configuring the Log Filtering Mode

By default, the log filtering mode is filter-only.

Run the **logging filter type** { **contains-only** | **filter-only** } command in global configuration mode to configure the log filtering mode.

Configuring the Log Filtering Rule

By default, no log filtering rule is configured on a device, that is, logs are not filtered out.

Run the **logging filter rule exact-match module** *module-name* **mnemonic** *mnemonic-name* **level** *level* command in global configuration mode to configure the exact-match rule.

Run the **logging filter rule single-match** { **level** *level* | **mnemonic** *mnemonic-name* | **module** *module-name* } command in global configuration mode to configure the single-match rule.

1.3.5 Featured Logging

The featured logging functions include severity-based logging, delayed logging, and periodical logging. If the RFC 5424 log format is enabled, logs can be sent in all directions, delayed logging is enabled, and periodical logging is disabled by

default. If the RFC 5424 log format is disabled, severity-based logging, delayed logging, and periodical logging are disabled.

Working Principle

Severity-based Logging

You can use the severity-based logging function to send syslogs to different destinations based on different module and severity. For example, you can configure commands to send WLAN module logs of severity 4 or lower to the log server, and WLAN module logs of severity 5 or higher to local log files.

Delayed Logging

After logs are generated, they are not directly sent to the log server. Instead, they are buffered in the log file. The device sends the log file to the syslog server through FTP at a specified interval. This function is called delayed logging.

If the device generates many logs, sending all logs to the server in real time may deteriorate the performance of the device and the syslog server, and increase the burden of the network. In this case, the delayed logging function can be used to reduce packet interaction.

By default, the log file sent to the remote server is named ***file size_device IP address_index*.txt**. If the prefix of the log file name is modified, the log file sent to the remote server is named ***configured file name prefix_file size_device IP address_index*.txt**. The file stored in the local flash memory of the device is named ***configured file name prefix_index*.txt**. By default, the file name prefix is **syslog_ftp_server**, the delayed logging interval is 3600s (one hour), and the log file size is 128 KB.

The maximum value of the delayed logging interval is 65535s, that is, 18 hours. If you set the delayed logging interval to the maximum value, the amount of logs generated in this period may exceed the file size (128 KB). To prevent loss of logs, logs will be written into a new log file and the index increases by 1. When the timer expires, all log files buffered in this period will be sent to the FTP or TFTP server at a time.

The flash memory in the device that is used to buffer local log files is limited in size. A maximum of eight log files can be buffered on the device. If the number of local log files exceeds eight before the timer expires, all log files that are generated earlier will be sent to the FTP or TFTP server at a time.

Periodical Logging

Logs about performance statistics are periodically sent. All periodical logging timers are managed by the syslog module. When the timer expires, the syslog module calls the log processing function registered with each module to output performance statistic logs and send logs to the remote syslog server in real time. The server analyzes these logs to evaluate the device performance.

By default, the periodical logging interval is 15 minutes. To enable the server to collect all performance statistic logs at a time, you need to set the log periodical logging intervals of different statistic objects to a common multiple of them. The interval can be set to 0, 15, 30, 60, or 120. The value 0 indicates that periodical logging is disabled.

Related Configuration

Configuring the Severity-based Logging Policy

By default, device logs are sent in all directions.

Run the **logging policy module** *module-name* [**not-lesser-than**] *level* **direction** { **all** | **server** | **file** | **console** | **monitor** | **buffer** } command in global configuration mode to configure the level-based logging policy.

Enabling Delayed Display of Logs on the Console and Remote Terminal

By default, delayed display of logs on the Console and remote terminal is disabled.

Run the **logging delay-send terminal** command in global configuration mode to enable delayed display of logs on the console and remote terminal.

Configuring the Name of the File for Delayed Logging

By default, the log file sent to the remote server is named ***file size_device IP address_index*.txt**. If the prefix of the log file name is modified, the log file sent to the remote server is named ***configured file name prefix_file size_device IP address_index*.txt**. The file stored on the local flash memory of the device is named ***configured file name prefix_index*.txt**. The default file name prefix is **syslog_ftp_server**.

Run the **logging delay-send file flash:***filename* command in global configuration mode to configure the name of the log file that is buffered on the local device.

Configuring the Delayed Logging Interval

By default, the delayed logging interval is 3600s (one hour).

Run the **logging delay-send interval** *seconds* command in global configuration mode to configure the delayed logging interval.

Configuring the Server Address and Delayed Logging Mode

By default, logs are not sent to any FTP or TFTP server.

Run the **logging delay-send server** { *ip-address* | **ipv6** *ipv6-address* } **mode** { **ftp user** *username* **password** [**0** | **7**] *password* | **tftp** } command in global configuration mode to configure the server address and delayed logging mode.

Enabling Periodical Logging

By default, periodical logging is disabled.

Run the **logging statistic enable** command in global configuration mode to enable periodical uploading of logs. After this function is enabled, the system outputs a series of performance statistics at a certain interval so that the log server can monitor the system performance.

Enabling Periodical Display of Logs on the Console and Remote Terminal

By default, periodical display of logs on the console and remote terminal is disabled.

Run the **logging statistic terminal** command in global configuration mode to enable periodical display of logs on the console and remote terminal.

Configuring the Periodical Logging Interval

By default, the periodical logging interval is 15 minutes.

Run the **logging statistic mnemonic** *mnemonic* **interval** *minutes* command in global configuration mode to configure the periodical logging interval.

1.3.6 Syslog Monitoring

After syslog monitoring is enabled, the system monitors access attempts of users and generates logs.

Working Principle

After logging of login or logout attempts is enabled, the system records access attempts of users. The log contains the user name and source address.

After logging of operations is enabled, the system records changes in device configurations. The log contains the user name, source address, and operation.

Related Configuration

Enabling Logging of Login or Logout Attempts

By default, a device generates logs when users log in or log out of the device.

Run the **logging userinfo** command in global configuration mode to enable logging of login or logout attempts. After this function is enabled, the device displays logs when users access the devices through Telnet, SSH, or HTTP so that the administrator can monitor device connections.

Enabling Logging of Operations

By default, a device generates logs when users modify device configurations.

Run the **logging userinfo command-log** command in global configuration mode to enable logging of operations. After this function is enabled, the system displays logs to notify the administrator of configuration changes.

1.4 Configuration

Configuration	Description and Command	
Configuring the Syslog Format	(Optional) It is used to configure the syslog format.	
	service timestamps [*message-type* [**uptime**| **datetime** [**msec**] [**year**]]]	Configures the timestamp format of syslogs.
	service sysname	Adds the sysname to the syslog.
	service sequence-numbers	Adds the sequence number to the syslog.
	service standard-syslog	Enables the standard syslog format.
	service private-syslog	Enables the private syslog format.
	service log-format rfc5424	Enables the RFC 5424 syslog format.
Sending Syslogs to the Console	(Optional) It is used to configure parameters for sending syslogs to the console.	
	logging on	Enables logging.
	logging count	Enables log statistics collection.
	logging console [*level*]	Configures the severity of logs displayed on the console.
	logging rate-limit { *number* | **all** *number* | **console** {*number* | **all** *number* } } [**except** [*severity*]]	Configures the rate limit for logging.
Sending Syslogs to the Monitor Terminal	(Optional) It is used to configure parameters for sending syslogs to the monitor terminal.	

Configuration	Description and Command	
	terminal monitor	Enables the monitor terminal to display logs.
	logging monitor [*level*]	Configures the severity of logs displayed on the monitor terminal.
Writing Syslogs into the Memory Buffer	⚠ (Optional) It is used to configure parameters for writing syslogs into the memory buffer.	
	logging buffered [*buffer-size*] [*level*]	Configures parameters for writing syslogs into the memory buffer, including the buffer size and log severity.
Sending Syslogs to the Log Server	⚠ (Optional) It is used to configure parameters for sending syslogs to the log server.	
	logging server { *ip-address* | **ipv6** *ipv6-address* } [**udp-port** *port*]	Sends logs to a specified log server.
	logging [**server**] { *ip-address* | **ipv6** *ipv6-address* } [**via** *mgmt-name*] [**tcp-transport** [**tcp-port** *tcp_port*] [**tls**]]	Configures TCP connection and TLS encryption for the specified port of the log server.
	logging trap [*level*]	Configures the severity of logs sent to the log server.
	logging facility *facility-type*	Configures the facility value of logs sent to the log server.
	logging source interface *interface-type interface-number*	Configures the source interface of logs sent to the log server.
	logging source { **ip** *ip-address* | **ipv6** *ipv6-address* }	Configures the source address of logs sent to the log server.
	logging trap [*level*]	Configures the severity of logs that can be sent to the log server.
	logging facility *facility-type*	Configures the facility value of logs sent to the log server.
Writing Syslogs into Log Files	⚠ (Optional) It is used to configure parameters for writing syslogs into a file.	
	logging file { **sata0:***filename* | **flash:***filename* | **usb0**:*filename* | **usb1**:*filename* | **sd0**:*filename* } [*max-file-size*] [level]	Configures parameters for writing syslogs into a file, including the file storage type, file name, file size, and log severity.
	logging file numbers *numbers*	Sets the number of log files. The value is 16 by default.
	logging flash interval *seconds*	Configures the interval at which logs are written into log files. The default value is 3600.
	logging life-time level *level days*	Configures the storage time of log files.
Configuring Syslog	⚠ (Optional) It is used to enable the syslog filtering function.	

Configuration	Description and Command	
Filtering	**logging filter direction** { **all** | **buffer** | **file** | **server** | **terminal** }	Configures the log filtering direction.
	logging filter type { **contains-only** | **filter-only** }	Configures the log filtering mode.
	logging filter rule exact-match module *module-name* **mnemonic** *mnemonic-name* **level** *level*	Configures the exact-match filtering rule.
	logging filter rule single-match { **level** *level* | **mnemonic** *mnemonic-name* | **module** *module-name* }	Configures the single-match filtering rule.
Configuring Severity-based Logging	⚠ (Optional) It is used to configure logging policies for the device to send syslogs based on module and severity.	
	logging policy module *module-name* [**not-lesser-than**] *level* **direction** { **all** | **server** | **file** | **console** | **monitor** | **buffer** }	Sends logs to different destinations by module and severity.
Configuring Delayed Logging	⚠ (Optional) It is used to enable the delayed logging function.	
	logging delay-send terminal	Enables delayed display of logs on the console and remote terminal.
	logging delay-send file flash:*filename*	Configures the name of the file on the local device where logs are buffered.
	logging delay-send interval *seconds*	Configures the interval at which logs are sent to the log server.
	logging delay-send server { *ip-address* | **ipv6** *ipv6-address* } **mode** { **ftp user** *username* **password** [**0** | **7**] *password* | **tftp** }	Configures the server address and delayed logging mode.
Configuring Periodical Logging	⚠ (Optional) It is used to enable the periodical logging function.	
	logging statistic enable	Enables the periodical logging function.
	logging statistic terminal	Enables periodical display of logs on the console and remote terminal.
	logging statistic mnemonic *mnemonic* **interval** *minutes*	Configures the interval at which logs of a performance statistic object are sent to the server.
Configuring Syslog Monitoring	⚠ (Optional) It is used to configure parameters of the syslog monitoring function.	
	logging userinfo	Enables logging of login or logout attempts.
	logging userinfo command-log	Enables logging of operations.
Synchronizing User Input	⚠ (Optional) It is used to configure synchronization of user input and log output.	

Configuration	Description and Command	
with Log Output	**logging synchronous**	Configures synchronization of user input and log output.

1.4.1 Configuring the Syslog Format

Configuration Effect

Configure the format of syslogs.

Notes

RFC 3164 Log Format

- If the device does not have the real time clock (RTC), which is used to record the system absolute time, the device uses its startup time (uptime) as the syslog timestamp by default. If the device has the RTC, the device uses its absolute time (datetime) as the syslog timestamp by default.
- The log sequence number is a 6-digit integer. Each time a log is generated, the sequence number increases by one. Each time the sequence number increases from 000000 to 1,000,000, or reaches 2^32, the sequence number starts from 000000 again.

RFC 5424 Log Format

- After the RFC 5424 log format is enabled, the timestamp is uniform.
- In the RFC 5424 log format, the timestamp may contain the time zone or not. The device supports only the timestamp without the time zone.

Configuration Step

Configuring the Timestamp Format of Syslogs

- Optional.
- By default, the datetime timestamp format is used.
- Unless otherwise specified, perform this configuration on the device to configure the timestamp format.

Adding the Sysname to the Syslog

- Optional.
- By default, the syslog does not contain the sysname.
- Unless otherwise specified, perform this configuration on the device to add the sysname to the syslog.

Adding the Sequence Number to the Syslog

- Optional.
- By default, the syslog does not contain the sequence number.
- Unless otherwise specified, perform this configuration on the device to add the sequence number to the syslog.

Enabling the Standard Log Format

- Optional.

- By default, the default log format is used.
- Unless otherwise specified, perform this configuration on the device to enable the standard log format.

Enabling the Private Log Format

- Optional.
- By default, the default log format is used.
- Unless otherwise specified, perform this configuration on the device to enable the private log format.

Enabling the RFC 5424 Log Format

- Optional.
- By default, the RFC 5424 log format is disabled.
- Unless otherwise specified, perform this configuration on the device to enable the RFC 5424 log format.

Adding a Space Next to the <pri> Option in the Log Format

- Optional.
- By default, no space is added next to the <pri> option in the log format.
- Unless otherwise specified, you should perform this configuration on the device that needs a space next to the <pri> option in the log format.

Verification

Generate a syslog and check the log format.

Related Commands

Configuring the Timestamp Format of Syslogs

Command	**service timestamps** [*message-type* [**uptime** | **datetime** [**msec**] [**year**]]]
Parameter Description	*message-type*: Indicates the log type. There are two log types: log and debug. **uptime**: Indicates the device startup time in the format of dd:hh:mm:ss, for example, 07:00:10:41. **datetime**: Indicates the current device time in the format of MM DD hh:mm:ss, for example, Jul 27 16:53:07. **msec**: Indicates that the current device time contains millisecond. **year**: Indicates that the current device time contains year.
Command Mode	Global configuration mode
Usage Guide	Two syslog timestamp formats are available: uptime and datetime. You can select a timestamp format as required.

Adding the Sysname to the Syslog

Command	**service sysname**
Parameter Description	N/A
Command	Global configuration mode

Mode	
Usage Guide	This command is used to add the sysname to the log to enable you to learn about the device that sends syslogs to the server.

Adding the Sequence Number to the Syslog

Command	service sequence-numbers
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command is used to add the sequence number to the log. The sequence number starts from 1. After the sequence number is added, you can learn clearly whether any log is lost and the generation sequence of logs.

Enabling the Standard Syslog Format

Command	service standard-syslog
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	By default, logs are displayed in the following format (default format):
	`*timestamp: %module-level-mnemonic: content`
	If the standard syslog format is enabled, logs are displayed in the following format:
	`timestamp %module-level-mnemonic: content`
	Compared with the default format, an asterisk (*) is missing in front of the timestamp, and a colon (:) is missing at the end of the timestamp in the standard log format.

Enabling the Private Syslog Format

Command	service private-syslog
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	By default, logs are displayed in the following format (default format.
	`*timestamp: %module-level-mnemonic: content`
	If the private syslog format is enabled, logs are displayed in the following format.
	`timestamp module-level-mnemonic: content`
	Compared with the default format, an asterisk (*) is missing in front of the timestamp, a colon (:) is missing at the end of the timestamp, and a percent sign (%) is missing in front of the module name in the private log format.

Enabling the RFC 5424 Syslog Format

Command	**service log-format rfc5424**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After the new format (RFC 5424 log format) is enabled, the **service sequence-numbers**, **service sysname**, **service timestamps**, **service private-syslog**, and **service standard-syslog** commands that are applicable only to the old format (RFC 3164 log format) become ineffective and are hidden. After the old format (RFC 3164 log format) is enabled, the **logging delay-send**, **logging policy**, and **logging statistic** commands that are applicable only to the RFC 5424 log format become ineffective and are hidden. After log format switchover, the outputs of the **show logging** and **show logging config** commands change accordingly.

Configuration Example

Enabling the RFC 3164 Log Format

Scenario	The timestamp format needs to be configured as follows: 1. Enable the RFC 3164 format. 2. Change the timestamp format to datetime and add the millisecond and year to the timestamp. 3. Add the sysname to the log. 4. Add the sequence number to the log.
Configuration Steps	● Configure the syslog format.

	`Hostname# configure terminal`
	`Hostname(config)# no service log-format rfc5424`
	`Hostname(config)# service timestamps log datetime year msec`
	`Hostname(config)# service timestamps debug datetime year msec`
	`Hostname(config)# service sysname`
	`Hostname(config)# service sequence-numbers`

Verification	After the timestamp format is configured, verify that new syslogs are displayed in RFC 3164 format. ● Run the **show logging config** command to display the configuration. ● Enter or exit the global configuration mode to generate a new log, and check the format of the timestamp in the new log.

	`Hostname(config)#exit`
	`001302: *Jun 14 2013 19:01:40.293: Hostname %SYS-5-CONFIG_I: Configured from console by admin on console`
	`Hostname#show logging config`
	`Syslog logging: enabled`
	`  Console logging: level informational, 1306 messages logged`
	`  Monitor logging: level informational, 0 messages logged`
	`  Buffer logging: level informational, 1306 messages logged`
	`  File logging: level informational, 121 messages logged`

	File name:syslog_test.txt, size 128 Kbytes, have written 5 files Standard format:false Timestamp debug messages: datetime Timestamp log messages: datetime Sequence-number log messages: enable Sysname log messages: enable Count log messages: enable Trap logging: level informational, 121 message lines logged,0 fail

Enabling the RFC 5424 Log Format

Scenario	The RFC 5424 format needs to be enabled.
Configuration Steps	Configure the syslog format.
	Hostname# configure terminal Hostname(config)# service log-format rfc5424
Verification	Verify that new syslogs are displayed in RFC 5424 format. ● Run the **show logging config** command to display the configuration. ● Enter or exit the global configuration mode to generate a new log, and check the format of the new log.
	Hostname(config)#exit <133>1 2013-07-24T12:19:33.130290Z Hostname SYS 5 CONFIG - Configured from console by console Hostname#show logging config Syslog logging: enabled Console logging: level debugging, 4740 messages logged Monitor logging: level debugging, 0 messages logged Buffer logging: level debugging, 4745 messages logged Statistic log messages: disable Statistic log messages to terminal: disable Delay-send file name:syslog_ftp_server, Current write index:3, Current send index:3, Cycle:10 seconds Count log messages: enable Trap logging: level informational, 2641 message lines logged,4155 fail logging to 192.168.23.89 logging to 2000::1 Delay-send logging: 2641 message lines logged logging to 192.168.23.89 by tftp

1.4.2 Sending Syslogs to the Console

Configuration Effect

- Send syslogs to the console to facilitate the administrator to monitor the system performance.

Notes

If many syslogs are generated, you can limit the log generation rate to reduce the number of logs displayed on the console.

Configuration Step

Enabling Logging

- Optional.
- By default, the logging function is enabled.

Enabling Log Statistics Collection

- Optional.
- By default, log statistics collection is disabled.
- Unless otherwise specified, perform this configuration on the device to enable log statistics collection.

Configuring the Severity of Logs Displayed on the Console

- Optional.
- By default, the severity of logs displayed on the console is debugging (severity 7).
- Unless otherwise specified, perform this configuration on the device to configure the severity of logs displayed on the console.

Configuring the Rate Limit for Logging

- Optional.
- By default, no rate limit is configured.
- Unless otherwise specified, perform this configuration on the device to limit the log generation rate.

Verification

Run the **show logging config** command to display the severity of logs displayed on the console.

Related Commands

Enabling Logging

Command	**logging on**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, logging is enabled. Do not disable logging. If many syslogs are generated, you can configure log severities to reduce the number of logs.

Enabling Log Statistics Collection

Command	**logging count**

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, log statistics collection is disabled. If log statistics collection is enabled, syslogs will be classified and counted. The system records the number of times a log is generated and the last time when the log was generated.

Configuring the Severity of Logs Displayed on the Console

Command	**logging console** [*level*]
Parameter Description	*level*: Indicates the log severity.
Command Mode	Global configuration mode
Usage Guide	By default, the severity of logs displayed on the console is debugging (severity 7). You can run the **show logging config** command in privileged EXEC mode to display the severity of logs displayed on the console.

Configuring the Rate Limit for Logging

Command	**logging rate-limit** { *number* | **all** *number* | **console** { *number* | **all** *number* } } [**except** [*severity*]]
Parameter Description	*number*: Indicates the maximum number of logs processed per second. The value range is from 1 to 10,000. **all**: Indicates that the rate limit is applied to all logs ranging from severity 0 to severity 7. **console**: Indicates the number of logs displayed on the console per second. **except** *severity*: The rate limit is not applied to logs with a specified severity or lower. By default, the severity is error (severity 3), that is, rate limit is not applied to logs of severity 3 or lower.
Command Mode	Global configuration mode
Usage Guide	By default, no rate limit is configured.

Configuration Example

Sending Syslogs to the Console

Scenario	Syslogs need to be displayed on the console: 1. Enable log statistics collection. 2. Set the severity of logs that can be displayed on the console to informational (severity 6). 3. Set the rate limit to 50.
Configuration Steps	Configure parameters for displaying syslogs on the console.

	`Hostname# configure terminal`
	`Hostname(config)# logging count`
	`Hostname(config)# logging console informational`
	`Hostname(config)# logging rate-limit console 50`

Verification	Run the **show logging config** command to display the configuration.

	Hostname(config)#show logging config Syslog logging: enabled Console logging: level informational, 1303 messages logged Monitor logging: level debugging, 0 messages logged Buffer logging: level debugging, 1303 messages logged File logging: level informational, 118 messages logged File name:syslog_test.txt, size 128 Kbytes, have written 5 files Standard format:false Timestamp debug messages: datetime Timestamp log messages: datetime Sequence-number log messages: enable Sysname log messages: enable Count log messages: enable Trap logging: level informational, 118 message lines logged,0 fail

1.4.3 Sending Syslogs to the Monitor Terminal

Configuration Effect

Send syslogs to a remote monitor terminal to facilitate the administrator to monitor the system performance.

Notes

- If many syslogs are generated, you can limit the log rate to reduce the number of logs displayed on the monitor terminal.
- By default, the current monitor terminal is not allowed to display logs after you access the device remotely. You need to manually run the **terminal monitor** command to allow the current monitor terminal to display logs.

Configuration Step

↘ Allowing the Monitor Terminal to Display Logs

- Mandatory.
- By default, the monitor terminal is not allowed to display logs.
- Unless otherwise specified, perform this operation on each monitor terminal connected to the device.

↘ Configuring the Severity of Logs Displayed on the Monitor Terminal

- Optional.
- By default, the severity of logs displayed on the monitor terminal is debugging (severity 7).
- Unless otherwise specified, perform this configuration on the device to configure the severity of logs displayed on the monitor terminal.

Verification

Run the **show logging config** command to display the severity of logs displayed on the monitor terminal.

Related Commands

Allowing the Monitor Terminal to Display Logs

Command	**terminal monitor**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	By default, the current monitor terminal is not allowed to display logs after you access the device remotely. You need to manually run the **terminal monitor** command to allow the current monitor terminal to display logs.

Configuring the Severity of Logs Displayed on the Monitor Terminal

Command	**logging monitor** [*level*]
Parameter Description	*level*: Indicates the log severity.
Command Mode	Global configuration mode
Usage Guide	By default, the severity of logs displayed on the monitor terminal is debugging (severity 7). You can run the **show logging config** command in privileged EXEC mode to display the severity of logs displayed on the monitor terminal.

Configuration Example

Sending Syslogs to the Monitor Terminal

Scenario	Syslogs need to be displayed on the monitor terminal: 1. Display logs on the monitor terminal. 2. Set the severity of logs that can be displayed on the monitor terminal to informational (severity 6).
Configuration Steps	Configure parameters for displaying syslogs on the monitor terminal.

	`Hostname# configure terminal`
	`Hostname(config)# logging monitor informational`
	`Hostname(config)# line vty 0 4`
	`Hostname(config-line)# monitor`

Verification	Run the **show logging config** command to display the configuration.

	`Hostname#show logging config`
	`Syslog logging: enabled`
	`  Console logging: level informational, 1304 messages logged`
	`  Monitor logging: level informational, 0 messages logged`
	`  Buffer logging: level debugging, 1304 messages logged`
	`  File logging: level informational, 119 messages logged`
	`  File name:syslog_test.txt, size 128 Kbytes, have written 5 files`
	`  Standard format:false`
	`  Timestamp debug messages: datetime`
	`  Timestamp log messages: datetime`

	Sequence-number log messages: enable Sysname log messages: enable Count log messages: enable Trap logging: level informational, 119 message lines logged,0 fail

Common Errors

To disable this function, run the **terminal no monitor** command but not the **no terminal monitor** command.

1.4.4 Writing Syslogs into the Memory Buffer

Configuration Effect

Write syslogs into the memory buffer so that the administrator can view recent syslogs by running the **show logging** command.

Notes

If the buffer is full, old logs will be overwritten by new logs that are written into the memory buffer.

Configuration Step

↘ Writing Logs into the Memory Buffer

- Optional.
- By default, the system writes logs into the memory buffer, and the default severity of logs is debugging (severity 7).
- Unless otherwise specified, perform this configuration on the device to write logs into the memory buffer.

Verification

- Run the **show logging config** command to display the severity of logs written into the memory buffer.
- Run the **show logging** command to display the severity of logs written into the memory buffer.

Related Commands

↘ Writing Logs into the Memory Buffer

Command	**logging buffered** [*buffer-size*] [*level*]
Parameter Description	*buffer-size*: Indicates the size of the memory buffer. *level*: Indicates the severity of logs that can be written into the memory buffer.
Command Mode	Global configuration mode
Usage Guide	By default, the severity of logs written into the memory buffer is debugging (severity 7). Run the **show logging** command in privileged EXEC mode to display the severity of logs written into the memory buffer and the buffer size.

Configuration Example

↘ Writing Syslogs into the Memory Buffer

Scenario	Syslogs need to be written into the memory buffer: 1. Set the log buffer size to 128 KB (131,072 bytes). 2. Set the information severity of logs that can be written into the memory buffer to informational (severity 6).
Configuration Steps	● Configure parameters for writing syslogs into the memory buffer.
	`Hostname# configure terminal` `Hostname(config)# logging buffered 131072 informational`
Verification	● Run the **show logging config** command to display the configuration and recent syslogs.

	`Hostname#show logging`
	`Syslog logging: enabled`
	`  Console logging: level informational, 1306 messages logged`
	`  Monitor logging: level informational, 0 messages logged`
	`  Buffer logging: level informational, 1306 messages logged`
	`  File logging: level informational, 121 messages logged`
	`  File name:syslog_test.txt, size 128 Kbytes, have written 5 files`
	`  Standard format:false`
	`  Timestamp debug messages: datetime`
	`  Timestamp log messages: datetime`
	`  Sequence-number log messages: enable`
	`  Sysname log messages: enable`
	`  Count log messages: enable`
	`  Trap logging: level informational, 121 message lines logged,0 fail`
	`Log Buffer (Total 131072 Bytes): have written 4200`
	`001301: *Jun 14 2013 19:01:09.488: Hostname %SYS-5-CONFIG_I: Configured from console by admin on console`
	`001302: *Jun 14 2013 19:01:40.293: Hostname %SYS-5-CONFIG_I: Configured from console by admin on console`
	//Logs displayed are subject to the actual output of the **show logging** command.

1.4.5 Sending Syslogs to the Log Server

Configuration Effect

Send syslogs to the log server to facilitate the administrator to monitor logs on the server.

Notes

To send logs to the log server, you must add the timestamp and sequence number to logs. Otherwise, logs are not sent to the log server.

Configuration Step

↘ Sending Logs to a Specified Log Server

- Mandatory.
- By default, syslogs are not sent to any log server.

- Unless otherwise specified, perform this configuration on each device.

Configuring the Severity of Logs Sent to the Log Server

- Optional.
- By default, the severity of logs sent to the log server is informational (severity 6).
- Unless otherwise specified, perform this configuration on the device to configure the severity of logs sent to the log server.

Configuring the Facility Value of Logs Sent to the Log Server

- Optional.
- If the RFC 5424 format is disabled, the facility value of logs sent to the log server is local7 (23) by default. If the RFC 5424 format is enabled, the facility value of logs sent to the log server is local0 (16) by default.
- Unless otherwise specified, perform this configuration on the device to configure the facility value of logs sent to the log server.

Configuring the Source Interface of Logs Sent to the Log Server

- Optional.
- By default, the source interface of logs sent to the log server is the interface sending logs.
- Unless otherwise specified, perform this configuration on the device to configure the source interface of logs sent to the log server.

Configuring the Source Address of Logs Sent to the Log Server

- Optional.
- By default, the source address of logs sent to the log server is the IP address of the interface sending logs.
- Unless otherwise specified, perform this configuration on the device to configure the source address of logs sent to the log server.

Verification

Run the **show logging config** command to display the configuration related to the log server.

Related Commands

Sending Logs to a Specified Log Server

Command	**logging** { *ip-address* | **ipv6** *ipv6-address* } [**udp-port** *port*]
Parameter Description	*ip-address*: Specifies the IPv4 address of the host that receives logs. **ipv6** *ipv6-address*: Specifies the IPv6 address of the host that receives logs. **udp-port** *port*: Specifies the port ID of the log server. The default port ID is 514.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify the address of the log server that receives logs. You can specify multiple log servers, and logs will be sent to all these log servers simultaneously.

	Up to five log servers can be configured on the device. Whether this parameter is supported and the value range of this parameter depend on the actual product version.

Configuring TCP Connection and TLS Encryption for the Specified Port of the Log Server

Command	**logging** [**server**] { *ip-address* | **ipv6** *ipv6-address* } [**tcp-transport** [**tcp-port** *tcp_port*] [**tls**]]
Parameter Description	*ip-address*: Specifies the IP address of the server that receives logs. **ipv6** *ipv6-address*: Specifies the IPv6 address of the server that receives logs. **tcp-transport**: Indicates TCP flags. **tcp-port** *tcp_por*: Specifies the port number of the log server (the default TCP port number is 601). **tls**: Indicates whether TLS encryption is enabled.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify the IP address of the server that receives logs based on TCP. You can specify multiple log servers. The logs will be sent to all configured log servers. The **tls** parameter can be configured only when the **tcp-transport** parameter is configured in this command. Up to five log servers are configured for a Ruijie product.

Configuring the Severity of Logs Sent to the Log Server

Command	**logging trap** [*level*]
Parameter Description	*level*: Indicates the log severity.
Command Mode	Global configuration mode
Usage Guide	By default, the severity of logs sent to the log server is informational (severity 6). You can run the **show logging config** command in privileged EXEC mode to display the severity of logs sent to the log server.

Configuring the Facility Value of Logs Sent to the Log Server

Command	**logging facility** *facility-type*
Parameter Description	*facility-type*: Indicates the facility value of logs.
Command Mode	Global configuration mode
Usage Guide	If the RFC 5424 format is disabled, the facility value of logs sent to the server is local7 (23) by default. If the RFC 5424 format is enabled, the facility value of logs sent to the server is local0 (16) by default.

Configuring the Source Interface of Logs Sent to the Log Server

Command	**logging source interface** *interface-type interface-number*
Parameter Description	*interface-type*: Indicates the interface type. *interface-number*: Indicates the interface number.

Command Mode	Global configuration mode
Usage Guide	By default, the source interface of logs sent to the log server is the interface sending logs. To facilitate management, you can use this command to configure the source interface of all logs so that the administrator can identify the device that sends logs based on the unique address.

Configuring the Source Address of Logs Sent to the Log Server

Command	**logging source** { **ip** *ip-address* | **ipv6** *ipv6-address* }
Parameter Description	**ip** *ip-address*: Specifies the source IPv4 address of logs sent to the IPv4 log server. **ipv6** *ipv6-address*: Specifies the source IPv6 address of logs sent to the IPv6 log server.
Command Mode	Global configuration mode
Usage Guide	By default, the source IP address of logs sent to the log server is the IP address of the interface sending the logs. To facilitate management, you can use this command to configure the source IP address of all logs so that the administrator can identify the device that sends logs based on the unique address..

Configuration Example

Sending Syslogs to the Log Server

Scenario	Syslogs need to be sent to the log server: 1. Set the IPv4 address of the log server to 10.1.1.100. 2. Set the source interface to Loopback 0. 3. Set the logs that cannot be received. Send the logs of IP address assignment by DHCP to the log server. 4. Set the warning (severity 4) logs that can be sent to the log server.
Configuration Steps	Configure parameters for sending syslogs to the log server.

	`Hostname# configure terminal`
	`Hostname(config)# logging server 10.1.1.100`
	`Hostname(config)# logging source interface Loopback 0`

Verification	● Run the **show run | inc logging server** command to display the parameter configuration. ● Run the **show logging config** command to display the configuration.

	`Hostname#show run | inc logging server`
	`logging server 10.1.1.100`
	`Hostname#show logging config`
	`Syslog logging: enabled`
	`  Console logging: level informational, 1307 messages logged`
	`  Monitor logging: level informational, 0 messages logged`
	`  Buffer logging: level informational, 1307 messages logged`
	`  File logging: level informational, 122 messages logged`
	`  File name:syslog_test.txt, size 128 Kbytes, have written 5 files`
	`  Standard format:false`
	`  Timestamp debug messages: datetime`

Scenario	Syslogs need to be sent to the log server: 1. Set the IPv4 address of the log server to 10.1.1.100. 2. Set the source interface to Loopback 0. 3. Set the logs that cannot be received. Send the logs of IP address assignment by DHCP to the log server. 4. Set the warning (severity 4) logs that can be sent to the log server.
Configuration Steps	Configure parameters for sending syslogs to the log server.

	`Hostname# configure terminal`
	`Hostname(config)# logging server 10.1.1.100`
	`Hostname(config)# logging source interface Loopback 0`

Verification	● Run the **show run | inc logging server** command to display the parameter configuration. ● Run the **show logging config** command to display the configuration.

	`Timestamp log messages: datetime`
	`Sequence-number log messages: enable`
	`Sysname log messages: enable`
	`Count log messages: enable`
	`Trap logging: level debugging, 122 message lines logged,0 fail logging to 10.1.1.100`

1.4.6 Writing Syslogs into Log Files

Configuration Effect

Write syslogs into log files at the specified interval so that the administrator can view historical logs anytime on the local device.

Notes

Sylsogs are not immediately written into log files. They are first buffered in the memory buffer, and then written into log files periodically (at the interval of one hour by default) or when the buffer is full.

Configuration Step

↘ Writing Logs into Log Files

- Mandatory.
- By default, syslogs are not written to any log file.
- Unless otherwise specified, perform this configuration on each device.

↘ Configuring the Number of Log Files

- Optional.
- By default, syslogs are written to 16 log files.
- Unless otherwise specified, perform this configuration on the device to configure the number of files which logs are written into.

↘ Configuring the Interval at Which Logs Are Written into Log Files

- Optional.
- By default, syslogs are written to log files every hour.
- Unless otherwise specified, perform this configuration on the device to configure the interval at which logs are written into log files.

Configuring the Storage Time of Log Files

- Optional.
- By default, no storage time is configured.
- Unless otherwise specified, perform this configuration on the device to configure the storage time of log files.

Immediately Writing Logs in the Buffer into Log Files

- Optional.
- By default, syslogs are stored in the buffer and then written into log files periodically or when the buffer is full.
- Unless otherwise specified, perform this configuration to write logs in the buffer into log files immediately. This command takes effect only once after being configured.

Verification

Run the **show logging config** command to display the configuration related to the log server.

Related Commands

Writing Logs into Log Files

Command	**logging file** { **sata0:***filename* | **flash:***filename* | **flash2:***filename* | **usb0**:*filename* | **usb1**:*filename* | **sd0**:*filename* } [*max-file-size*] [*level*]
Parameter Description	**sata0**: Indicates that log files are stored on the hard disk drive. **flash**: Indicates that log files will be stored in the extended flash. **flash2**: Indicates that log files are stored in the extended FLASH2. **usb0**: Indicates that log files will be stored in USB 0. This parameter is available only when the device has one USB port and a USB flash drive is inserted into the USB port. **usb1**: Indicates that log files will be stored in USB 1. This parameter is available only when the device has two USB ports and USB flash drives are inserted into the USB ports. **sd0**: Indicates that log files will be stored in the SD card. This parameter is available only when the device has an SD port and an SD card is inserted into the SD port. *filename*: Indicates the log file name, which does not contain a file name extension. The file name extension is always txt. *max-file-size*: Indicates the maximum size of a log file. The value range is from 128 KB to 6 MB. The default value is 128 KB. *level*: Indicates the severity of logs that can be written into a log file.
Command Mode	Global configuration mode
Usage Guide	This command is used to create a log file with the specified file name on the specified file storage device. The file size increases with the amount of logs, but cannot exceed the configured maximum size. If the file size is not specified, the maximum size of a log file is 128 KB by default.

	After this command is configured, the system saves logs to log files. A log file name does not contain any file name extension. The file name extension is always txt, which cannot be changed. After this command is configured, logs will be written into log files every hour. If you run the **logging flie flash:syslog** command, a total of 16 log files will be created, namely, **syslog.txt**, **syslog_1.txt**, **syslog_2.txt**, …, **syslog_14.txt**, and **syslog_15.txt**. Logs are written into the 16 log files in sequence. For example, the system writes logs into **syslog_1.txt** after **syslog.txt** is full. When **syslog_15.txt** is full, logs are written into **syslog.txt** again, If no extended flash space is available, the **logging file flash** command is automatically hidden and cannot be configured. If no FLASH2 is available, the **logging file flash2** command is hidden automatically and cannot be configured. Otherwise, the logs are stored in FLASH2 after the **logging file flash** command is configured.

Configuring the Number of Log Files

Command	**logging file numbers** *numbers*
Parameter Description	*numbers*: Indicates the number of log files. The value range is from 2 to 32.
Command Mode	Global configuration mode
Usage Guide	This command can be used to set the number of log files for writing log information. Modifying the number of log files will not delete the log files already generated. To save the extended flash space, you need to manually delete the log files already generated (you can transfer the log files to an external server through TFTP before deletion). For example, after the device is enabled to write logs, 16 log files will be written by default. Assuming that the device has already generated 16 log files, if you want to change the number of log files to 2, the newly generated log information will be continuously overwritten and rewritten in the log files with index values of 0 and 1. However, the log files with index values of 2 to 16 that have been previously generated will still be retained, and the system will not delete them. You can manually delete these log files as needed.

Configuring the Interval at Which Logs Are Written into Log Files

Command	**logging flash interval** *seconds*
Parameter Description	*seconds*: Indicates the interval at which logs are written into log files. The value range is from 1s to 51840s.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the interval at which logs are written into log files. The countdown starts after the command is configured.

Configuring the Storage Time of Log Files

Command	**logging life-time level** *level days*
Parameter Description	*level*: Indicates the log severity. *days*: Indicates the storage time of log files, in days. The storage time is not less than seven days.
Command Mode	Global configuration mode
Usage Guide	After the log storage time is configured, the system writes logs of the same severity that are

	generated in the same day into the same log file. The log file is named **yyyy-mm-dd_filename_level.txt**, where **yyyy-mm-dd** is the absolute time of the day when the logs are generated, **filename** is the log file configured by the **logging file flash** command, and **level** is the log severity. After you specify the storage time for logs of a severity, the system deletes the logs after the storage time expires. The storage time ranges from 7 days to 365 days. If the log storage time is not configured, logs are stored based on the file size to ensure compatibility with old configuration commands.

Immediately Writing Logs in the Buffer into Log Files

Command	**logging flash flush**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is configured, syslogs are stored in the buffer and then written into log files periodically or when the buffer is full. You can run this command to immediately write logs into log files. ⚠ The **logging flash flush** command takes effect once after being configured. That is, after this command is configured, logs in the buffer are immediately written into log files.

Configuration Example

Writing Syslogs into Log Files

Scenario	Syslogs need to be written into log files: 1. Set the log file name to syslog. 2. Set the severity of logs sent to the console to debugging (severity 7). 3. Set the interval at which device logs are written into files to 10 minutes (600s).
Configuration Steps	Configure parameters for writing syslogs into log files.

	`Hostname# configure terminal`
	`Hostname(config)# logging file flash:syslog debugging`
	`Hostname(config)# logging flash interval 600`

Verification	Run the **show logging config** command to display the configuration.

	`Hostname(config)#show logging config`
	`Syslog logging: enabled`
	`  Console logging: level informational, 1307 messages logged`
	`  Monitor logging: level informational, 0 messages logged`
	`  Buffer logging: level informational, 1307 messages logged`
	`  File logging: level debugging, 122 messages logged`
	`  File name:syslog.txt, size 128 Kbytes, have written 1 files`
	`  Standard format:false`
	`  Timestamp debug messages: datetime`

Scenario	Syslogs need to be written into log files: 1. Set the log file name to syslog. 2. Set the severity of logs sent to the console to debugging (severity 7). 3. Set the interval at which device logs are written into files to 10 minutes (600s).
Configuration Steps	Configure parameters for writing syslogs into log files.

	`Hostname# configure terminal`
	`Hostname(config)# logging file flash:syslog debugging`
	`Hostname(config)# logging flash interval 600`

Verification	Run the **show logging config** command to display the configuration.

	`Timestamp log messages: datetime`
	`Sequence-number log messages: enable`
	`Sysname log messages: enable`
	`Count log messages: enable`
	`Trap logging: level debugging, 122 message lines logged,0 fail`
	`logging to 10.1.1.100`

1.4.7 Configuring Syslog Filtering

Configuration Effect

- Filter out a specified type of syslogs if the administrator does not want to display these syslogs.
- By default, logs generated by all modules are displayed on the console or other terminals. You can configure log filtering rules to display only required logs.

Notes

- Two filtering modes are available: contains-only and filter-only. You can configure only one filtering mode at a time.
- If the same module, severity, or mnemonic is configured in both the single-match and exact-match rules, the single-match rule takes effect.

Configuration Step

↘ Configuring the Log Filtering Direction

- Optional.
- By default, the filtering direction is all, that is, all logs are filtered out.
- Unless otherwise specified, perform this configuration on the device to configure the log filtering direction.

↘ Configuring the Log Filtering Mode

- Optional.
- By default, the log filtering mode is filter-only.
- Unless otherwise specified, perform this configuration on the device to configure the log filtering mode.

↘ Configuring the Log Filtering Rule

- Mandatory.
- By default, no filtering rule is configured.
- Unless otherwise specified, perform this configuration on the device to configure the log filtering rule.

Verification

Run the **show running-config** command to display the configuration.

Related Commands

Configuring the Log Filtering Direction

Command	**logging filter direction** { **all** | **buffer** | **file** | **server** | **terminal** }
Parameter Description	**all**: Filters out all logs. **buffer**: Filters out logs sent to the log buffer, that is, logs displayed by the **show logging** command. **file**: Filters out logs written into log files. **server**: Filters out logs sent to the log server. **terminal**: Filters out logs sent to the console and VTY terminal (including Telnet and SSH).
Command Mode	Global configuration mode
Usage Guide	The default filtering direction is **all**, that is, all logs are filtered out. Run the **default logging filter direction** command to restore the default filtering direction.

Configuring the Log Filtering Mode

Command	**logging filter type** { **contains-only** | **filter-only** }
Parameter Description	**contains-only**: Indicates that only logs that contain keywords specified in the filtering rules are displayed. **filter-only**: Indicates that logs that contain keywords specified in the filtering rules are filtered out and will not be displayed.
Command Mode	Global configuration mode
Usage Guide	Log filtering modes include contains-only and filter-only. The default filtering mode is filter-only.

Configuring the Log Filtering Rule

Command	**logging filter rule** { **exact-match module** *module-name* **mnemonic** *mnemonic-name* **level** *level* | **single-match** { **level** *level* | **mnemonic** *mnemonic-name* | **module** *module-name* } }
Parameter Description	**exact-match**: If exact-match is selected, you must specify all three filtering options. **single-match**: If single-match is selected, you may specify only one of the three filtering options. **module** *module-name*: Indicates the module name. Logs of this module will be filtered out. **mnemonic** *mnemonic-name*: Indicates the mnemonic. Logs with this mnemonic will be filtered out. **level** *level*: Indicates the log severity. Logs of this severity will be filtered out.
Command Mode	Global configuration mode
Usage Guide	Log filtering rules include exact-match and single-match. The **no logging filter rule exact-match** [**module** *module-name* **mnemonic** *mnemonic-name* **level** *level*] command is used to delete the exact-match filtering rules. You can delete all exact-match

	filtering rules at a time or one by one. The **no logging filter rule single-match** [**level** *level* | **mnemonic** *mnemonic-name* | **module** *module-name*] command is used to delete the single-match filtering rules. You can delete all single-match filtering rules at a time or one by one.

Configuration Example

↘ Configuring Syslog Filtering

Scenario	Syslog filtering function needs to be configured: 1. Set the filtering directions of logs to **terminal** and **server.** 2. Set the log filtering mode to filter-only. 3. Set the log filtering rule to single-match to filter out logs that contain the module name **SYS**.
Configuration Steps	Configure the syslog filtering function.

	`Hostname# configure terminal`
	`Hostname(config)# logging filter direction server`
	`Hostname(config)# logging filter direction terminal`
	`Hostname(config)# logging filter type filter-only`
	`Hostname(config)# logging filter rule single-match module SYS`

Verification	● Run the **show running-config | include logging** command to display the configuration. ● Enter and exit the global configuration mode, and verify that the system displays logs accordingly.

	`Hostname#configure`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#exit`
	`Hostname#`
	`Hostname#show running-config | include logging`
	`Hostname#configure`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#exit`
	`Hostname#`
	`Hostname#show running-config | include logging`
	`logging filter direction server`
	`logging filter direction terminal`
	`logging filter rule single-match module SYS`

1.4.8 Configuring Severity-based Logging

Configuration Effect

You can use the severity-based logging function to send syslogs to different destinations based on different module and severityl. For example, you can configure a command to send WLAN module logs of severity 4 or lower to the log server, and WLAN module logs of severity 5 or higher to local log files.

Notes

Severity-based logging takes effect only when the RFC 5424 format is enabled.

Configuration Step

Configuring Severity-based Logging

- Optional.
- By default, logs are sent in all directions.
- Unless otherwise specified, perform this configuration on the device to configure logging polices to send syslogs to different destinations based on the module and severity.

Verification

Run the **show running** command to display the configuration.

Related Commands

Configuring Severity-based Logging

Command	**logging policy module** *module-name* [**not-lesser-than**] *level* **direction** { **all** | **server** | **file** | **console** | **monitor** | **buffer** }
Parameter Description	*module-name*: Indicates the name of the module to which the logging policy is applied. **not-lesser-than**: If this parameter is specified, logs of the specified severity or higher will be sent to the specified destination, and other logs will be filtered out. If this parameter is not specified, logs of the specified severity or lower will be sent to the specified destination, and other logs will be filtered out. *level*: Indicates the severity of logs for which the logging policy is configured. **all**: Indicates that the logging policy is applied to all logs. **server**: Indicates that the logging policy is applied only to logs sent to the log server. **file**: Indicates that the logging policy is applied only to logs written into log files. **console**: Indicates that the logging policy is applied only to logs sent to the console. **monitor**: Indicates that the logging policy is applied only to logs sent to a remote terminal. **buffer**: Indicates that the logging policy is applied only to logs stored in the buffer.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure logging polices to send syslogs to different destinations based on module and severity.

Configuration Example

Configuring Severity-based Logging

Scenario	Logging policies need to be configured: 1. Send logs of severity 5 or higher that are generated by the system to the console. 2. Send logs of severity 3 or lower that are generated by the system to the buffer.
Configuration Steps	Configure the logging policies.

	Hostname# configure terminal Hostname(config)# logging policy module SYS not-lesser-than 5 direction console Hostname(config)# logging policy module SYS 3 direction buffer
Verification	● Run the **show running-config | include logging policy** command to display the configuration. ● Exit and enter global configuration mode to generate a log containing module name **SYS**. Verify that the log is sent to the destination as configured.
	Hostname#show running-config | include logging policy logging policy module SYS not-lesser-than 5 direction console logging policy module SYS 3 direction buffer

1.4.9 Configuring Delayed Logging

Configuration Effect

- By default, delayed logging is enabled by default at the interval of 3600s (one hour). The name of the log file sent to the remote server is ***file size_device IP address_index*.txt**. Logs are not sent to the console or remote terminal.
- You can configure the interval based on the frequency that the device generates logs for delayed uploading. This can reduce the burden on the device, syslog server, and network. In addition, you can configure the name of the log file as required.

Notes

- This function takes effect only when the RFC 5424 format is enabled.
- You are advised to disable the delayed display of logs on the console and remote terminal. Otherwise, a large amount of logs will be displayed, increasing the burden on the device.
- The file name cannot contain any dot (.) because the system automatically adds the index and the file name extension (.txt) to the file name when generating a locally buffered file. The index increases each time a new file is generated. In addition, the file name cannot contain characters prohibited by your file system, such as \, /, :, *, ", <, >, and |. For example, the file name is **log_server**, the current file index is 5, the file size is 1000 bytes, and the source IP address is 10.2.3.5. The name of the log file sent to the remote server is **log_server_1000_10.2.3.5_5.txt**, while the name of the log file stored on the device is **log_server_5.txt**. If the source IP address is an IPv6 address, the colon (:) in the IPv6 address must be replaced by the hyphen (-) because the colon (:) is prohibited by the file system. For example, the file name is **log_server**, the current file index is 6, the file size is 1000 bytes, and the source IPv6 address is 2001::1. The name of the log file sent to the remote server is **log_server_1000_2001-1_6.txt**, while the name of the log file stored on the device is **log_server_6.txt**.
- If few logs are generated, you can set a large interval so that many logs can be sent to the remote server at a time.

Configuration Step

↘ Enabling Delayed Display of Logs on the Console and Remote Terminal

- Optional.
- By default, delayed display of logs on the console and remote terminal is disabled.

- Unless otherwise specified, perform this configuration on the device to enable delayed display of logs on the console and remote terminal.

Configuring the Name of the File for Delayed Logging

- Optional.
- By default, the name of the file for delayed logging is ***file size_device IP address_index*.txt**.
- Unless otherwise specified, perform this configuration on the device to configure the name of the file for delayed logging.

Configuring the Delayed Logging Interval

- Optional.
- By default, the delayed logging interval is 3600s (one hour).
- Unless otherwise specified, perform this configuration on the device to configure the delayed logging interval.

Configuring the Server Address and Delayed Logging Mode

- Optional.
- By default, log files are not sent to any remote server.
- Unless otherwise specified, perform this configuration on the device to configure the server address and delayed logging mode

Verification

Run the **show running** command to display the configuration.

Related Commands

Enabling Delayed Display of Logs on the Console and Remote Terminal

Command	**logging delay-send terminal**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A.

Configuring the Name of the File for Delayed Logging

Command	**logging delay-send file flash:***filename*
Parameter Description	**flash:***filename*: Indicates the name of the file on the local device where logs are buffered.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the name of the file on the local device where logs are buffered. The file name cannot contain any dot (.) because the system automatically adds the index and the file name extension (.txt) to the file name when generating a locally buffered file. The index increases

	each time a new file is generated. In addition, the file name cannot contain characters prohibited by your file system, such as \, /, :, *, ", <, >, and |. For example, the configured file name is **log_server**, the current file index is 5, the file size is 1000 bytes, and the source IP address is 10.2.3.5. The name of the log file sent to the remote server is **log_server_1000_10.2.3.5_5.txt**, while the name of the log file stored on the device is **log_server_5.txt**. If the source IP address is an IPv6 address, the colon (:) in the IPv6 address must be replaced by the hyphen (-) because the colon (:) is prohibited by the file system. For example, the file name is **log_server**, the current file index is 6, the file size is 1000 bytes, and the source IPv6 address is 2001::1. The name of the log file sent to the remote server is **log_server_1000_2001-1_6.txt**, while the name of the log file stored on the device is **log_server_6.txt**.

Configuring the Delayed Logging Interval

Command	**logging delay-send interval** *seconds*
Parameter Description	*seconds*: Indicates the delayed logging interval, in seconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the delayed logging interval. The value range is from 600 to 65535.

Configuring the Server Address and Delayed Logging Mode

Command	**logging delay-send server** { *ip-address* | **ipv6** *ipv6-address* } **mode** { **ftp user** *username* **password** [**0** | **7**] *password* | **tftp** }
Parameter Description	*ip-address*: Indicates the IPv4 address of the server that receives logs. **ipv6** *ipv6-address*: Indicates the IPv6 address of the server that receives logs. *username*: Specifies the user name of the FTP server. *password*: Specifies the password of the FTP server. **0**: Indicates that the password is in cleartext, which is optional. **7**: Indicates that the following password is encrypted.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify an FTP or a TFTP server for receiving device logs. You can configure a total of five FTP or TFTP servers, but a server cannot be both an FTP and TFTP server. Logs will be simultaneously sent to all FTP or TFTP servers.

Configuration Example

Configuring Delayed Logging

Scenario	Delayed logging needs to be configured: 1. Enable the delayed display of logs on the console and remote terminal. 2. Set the delayed logging interval to 7200s (two hours). 3. Set the name of the file for delayed logging to **syslog_Hostname**. 4. Set the IP address of the server to 192.168.23.12, user name to **admin**, password to **admin**, and logging mode to FTP.
Configuration Steps	● Configure the delayed logging function.

	`Hostname# configure terminal`
	`Hostname(config)# logging delay-send terminal`
	`Hostname(config)# logging delay-send interval 7200`
	`Hostname(config)# logging delay-send file flash:syslog_Hostname`
	`Hostname(config)# logging delay-send server 192.168.23.12 mode ftp user admin password admin`

Verification	● Run the **show running-config | include logging delay-send** command to display the configuration. ● Verify that logs are sent to the remote FTP server after the timer expires.

	`Hostname#show running-config | include logging delay-send`
	`logging delay-send terminal`
	`logging delay-send interval 7200`
	`logging delay-send file flash:syslog_Hostname`
	`logging delay-send server 192.168.23.12 mode ftp user admin password admin`

1.4.10 Configuring Periodical Logging

Configuration Effect

- By default, periodical logging is disabled. The periodical logging interval is 15 minutes. Periodical display of logs on the console and remote terminal are disabled.
- You can modify the periodical logging interval. The server will collect all performance statistic logs at the time point that is the least common multiple of intervals of all statistic objects.

Notes

- Periodical logging takes effect only when the RFC 5424 format is enabled.
- The settings of the periodical logging interval and the function of displaying logs on the console and remote terminal take effect only when the periodical logging function is enabled.
- You are advised to disable periodical display of logs on the console and remote terminal. Otherwise, a large amount of performance statistic logs will be displayed, increasing the burden on the device.
- The timer will be restarted when you modify the periodical logging interval of a statistic object, so the server can collect all performance statistic logs at the same time point

Configuration Step

↘ **Enabling Periodical Logging**

- Optional.
- By default, periodical logging is disabled.
- Unless otherwise specified, perform this configuration on the device to enable periodical logging.

Enabling Periodical Display of Logs on the Console and Remote Terminal

- Optional.
- By default, periodical display of logs on the console and remote terminal is disabled.
- Unless otherwise specified, perform this configuration on the device to enable periodical display of logs on the console and remote terminal.

Configuring the Periodical Logging Interval

- Optional.
- By default, the periodical logging interval is 15 minutes.
- Unless otherwise specified, perform this configuration on the device to configure the interval at which logs of statistic objects are sent to the server.

Verification

Run the **show running-config** command to display the configuration.

Related Commands

Enabling Periodical Logging

Command	**logging statistic enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This command is used to enable periodical logging. After this function is enabled, the system outputs a series of performance statistics at a specified interval so that the log server can monitor the system performance.

Enabling Periodical Display of Logs on the Console and Remote Terminal

Command	**logging statistic terminal**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Periodical Logging Interval

Command	**logging statistic mnemonic** *mnemonic* **interval** *minutes*
Parameter	*mnemonic*: Identifies a performance statistic object.

Description	*minutes*: Indicates the periodical logging interval, in minutes.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the periodical logging interval for a specified performance statistic object. The interval can be set to 0, 15, 30, 60, or 120 minutes. The value 0 indicates that periodical logging is disabled.

Configuration Example

Configuring Periodical Logging

Scenario	Periodical logging needs to be configured: 1. Enable the periodical logging function. 2. Enable periodical display of logs on the console and remote terminal. 3. Set the periodical logging interval of the statistic object TUNNEL_STAT to 30 minutes.
Configuration Steps	Configure the periodical logging function.

	`Hostname# configure terminal`
	`Hostname(config)# logging statistic enable`
	`Hostname(config)# logging statistic terminal`
	`Hostname(config)# logging statistic mnemonic TUNNEL_STAT interval 30`

Verification	● Run the **show running-config | include logging statistic** command to display the configuration. ● After the periodical logging timer expires, verify that logs of all performance statistic objects are generated at the time point that is the least common multiple of the intervals of all statistic objects.

	`Hostname#show running-config | include logging statistic`
	`logging statistic enable`
	`logging statistic terminal`
	`logging statistic mnemonic TUNNEL_STAT interval 30`

1.4.11 Configuring Syslog Monitoring

Configuration Effect

- Record login or logout attempts. After logging of login or logout attempts is enabled, logs are displayed on the device when users access the device through Telnet or SSH. This helps the administrator to monitor device connections.
- Record modification of device configurations. After logging of operations is enabled, corresponding logs are displayed on the device when users modify device configurations. This helps the administrator to monitor changes in device configurations.

Notes

If both the **logging userinfo** command and the **logging userinfo command-log** command are configured on the device, only the configuration result of the **logging userinfo command-log** command is displayed when you run the **show running-config** command.

Configuration Step

Enabling Logging of Login or Logout Attempts

- Optional.
- By default, logging of login or logout attempts is disabled.
- Unless otherwise specified, perform this configuration on each line of the device to enable logging of login or logout attempts.

Enabling Logging of Operations

- Optional.
- By default, logging of operations is disabled.
- Unless otherwise specified, perform this configuration on each line of the device to enable logging of operations.

Verification

Run the **show running-config** command to display the configuration.

Related Commands

Enabling Logging of Login or Logout Attempts

Command	**logging userinfo**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, a device generates related logs when users log in to or out of the device.

Enabling Logging of Operations

Command	**logging userinfo command-log**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The system generates related logs when users run configuration commands. By default, a device does not generate logs when users modify device configurations.

Configuration Example

Configuring Syslog Monitoring

Scenario	Syslog monitoring needs to be configured: 1. Enable logging of login or logout attempts. 2. Enable logging of operations.
Configuration Steps	Configure the syslog monitoring function.

	Hostname# configure terminal Hostname(config)# logging userinfo Hostname(config)# logging userinfo command-log
Verification	● Run the **show running-config | include logging** command to display the configuration. ● Run a command in global configuration mode, and verify that the system generates a log.
	Hostname#configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#interface gigabitEthernet 0/0 *Jun 16 15:03:43: %CLI-5-EXEC_CMD: Configured from console by admin command: interface GigabitEthernet 0/0 Hostname#show running-config | include logging logging userinfo command-log

1.4.12 Synchronizing User Input with Log Output

Configuration Effect

By default, user input is not synchronized with log output. After this function is enabled, the content input during log output is displayed after log output is completed, ensuring integrity and continuity of the input.

Notes

This command is executed in line configuration mode. You need to configure this command on each line as required.

Configuration Step

↘ Synchronizing User Input with Log Output

- Optional.
- By default, the synchronization function is disabled.
- Unless otherwise specified, perform this configuration on each line to synchronize user input with log output.

Verification

Run the **show running-config** command to display the configuration.

Related Commands

↘ Synchronizing User Input with Log Output

Command	**logging synchronous**
Parameter Description	N/A
Command Mode	Line configuration mode
Usage Guide	This command is used to synchronize user input with log output to prevent user input from being interrupted.

Configuration Example

Synchronizing User Input with Log Output

Scenario	User input needs to be synchronized with log output: 1. Enable the synchronization function.
Configuration Steps	● Configure the synchronization function.

	`Hostname# configure terminal`
	`Hostname(config)# line console 0`
	`Hostname(config-line)# logging synchronous`

Verification	● Run the **show running-config | begin line** command to display the configuration.

	`Hostname#show running-config | begin line`
	`line con 0`
	` logging synchronous`
	` login local`
	As shown in the following output, when a user types in **vlan**, the state of interface 0/1 changes and the related log is output. After log output is completed, the log module automatically displays the user input **vlan** so that the user can continue typing.
	`Hostname(config)#vlan`
	`*Aug 20 10:05:19: %LINK-5-CHANGED: Interface GigabitEthernet 0/1, changed state to up`
	`*Aug 20 10:05:19: %LINEPROTO-5-UPDOWN: Line protocol on Interface GigabitEthernet 0/1, changed state to up`
	`Hostname(config)#vlan`

1.5 Monitoring

Clearing

⚠ During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear logging	Clears logs in the memory buffer.

Displaying

Command	Description
show logging	Displays log statistics and logs in the memory buffer based on the timestamp from oldest to latest.
show logging reverse	Displays log statistics and logs in the memory buffer based on the timestamp from latest to oldest.
show logging config	Displays syslog configurations and statistics.
show logging count	Displays log statistics of each module in the system.

1 Configuring Software Authorization Management

1.1 Overview

Software authorization is an intermediary process that enables users to access certain extended features on their devices. Users need to install the correct license file before utilizing the corresponding extended functionalities. The extension functions provided by Ruijie Operating System (RGOS) include the Virtual Switch Device (VSD), Transparent Interconnection of Lots of Links (TRILL), Fibre Channel over Ethernet (FCoE), number of users supported by an access point (AP), and number of concurrent users supported by Secure Shell (SSL) Virtual Private Network (VPN). A user can use basic functions and extended functions of the RGOS after being authorized.

- Typically, all features of the RGOS are installed for the device before device delivery. However, users cannot use some features of the RGOS before they obtain a corresponding license file.
- Whether a feature requires authorization and the authorization type are specified in the configuration guide of the feature. Unless otherwise specified, basic functions of the system can be used without authorization.

1.2 Applications

1.2.1 VSD

Scenario

VSD, a network system virtualization technology, is used to virtualize one physical device into multiple logical devices. In addition, VSD maximizes use of existing resources, reducing the network operation cost.

Before being authorized, a user can only use VSD0 (that is, common CLI). After being authorized, the user can create other VSDs.

Deployment

The authorization module only functions on VSD0. License files cannot be installed on other VSDs.

1.2.2 FCoE

Scenario

FCoE technology can map a fiber channel to the Ethernet and insert fiber channel information into Ethernet packets, so requests and data over a fiber channel between a server and the SAN device can be transmitted over the Ethernet. This eliminates the need of specified fiber channels.

Before the FCoE license file is installed on the device, FCoE is unavailable. After the FCoE license file is installed, users can use FCoE.

Deployment

N/A

1.3 Features

Basic Concepts

License File for a Feature

A license for a certain special feature obtained by means of license file, hardware entity, or legal contract. This license stipulates the maximum number of users allowed to use it, the maximum number of instances allowed to be used, and validity period.

Authorized Software

Software function that can be used after being authorized.

Host ID

Unique serial number for identifying each device.

⚠ In a VSU, a license can adopt the host ID of any chassis. When the chassis exits the VSU, the feature corresponding to the license becomes invalid.

Authorization by Product

One license file is applied to only one device, which matches the host number. License file migration is not supported.

Purchase Voucher

The purchase voucher contains the product activation key (PAK) and the website for downloading the license file.

Product Activation Key (PAK)

The legal owner of the purchase voucher logs in to the website (listed on the purchase voucher) for downloading the license file and uses the PAK for registration. Then a corresponding license file is provided on the webpage for downloading or directly sent to the registered mailbox.

License File

After a license file is installed on a device, users can use corresponding functions. Each license file contains a digital signature to avoid manipulation. A license file is used for authorization based on products.

License Stacking

Different license files can be used on one device. For example, if a device provides both FCoE and TRILL functions, users can purchase the license files of the two functions and use them on the same device.

Temporary License File

A temporary license file becomes invalid after a period of time.

Evaluation License File

The evaluation license file is temporary. Typically, an evaluation license file is installed on a device before delivery, and it is mainly used to provide users with the function of using a trial feature. This type of license file is independent of the host number.

Permanent License File

A permanent license file is permanently valid.

Single-instance License File

Only one license file can be installed for a feature at a time.

The license file for the feature such as the number of concurrent users supported by VSD, TRILL, FCoE, and SSL VPN is a single-instance license file.

Multi-instance License File

Multiple license files can be installed for the same feature on a device.

Only the license file for the number of users supported by an AP is a multi-instance license file.

Periodic Warning

A periodic warning is advertised through a log or trap message several days before the license file expires. It is set to prevent a license file with a validity period from stopping working suddenly when the validity period expires, ensuring network performance.

Functions and Features

Function and Feature	Description
Obtaining and Using a License File	Obtain and use a license file.
Backing Up, Updating, and Removing a License File	Back up, update, and remove a license file.

1.3.1 Obtaining and Using a License File

Using a License File

A license file must be purchased from the website or marketing channel of formal authorization. Authorization is based on each device. To obtain a license file, visit the website on the purchase voucher and provide the PAK and host ID. The license file can be directly downloaded by a user or sent to a user by email. After obtaining the license file, users need to install the license file. After installing the license file, users can use the features corresponding to the license file.

The license files of the RGOS include permanent and temporary license files (evaluation license file is a type of temporary license file). Once a user starts using a temporary license for a certain feature, timekeeping is started for this license file, and this feature is disabled after the validity period of the license file expires. To continue using this feature, the user can purchase another license file (permanent or temporary license file) from the website or marketing channel.

In a VSU, multiple devices form one virtual device. In this scenario, as long as one device obtains the license file for a certain feature, the VSU obtains the license file for this feature. However, when these devices are used separately again, authorization is still based on each device.

The VSD function provided by RGOS virtualized one RGOS device into multiple virtual devices. For users, each virtual device behaves as an independent device. License files are managed in global configuration mode. That is, when the license file for a certain feature is obtained, the license files for this feature in all VSD domains are obtained. In addition, license files are installed and managed in the default VSD exclusively.

Check of the License File

After a device starts to run, the license file for each authorized feature needs to be checked. If the corresponding license file is properly installed, this feature is ready. Otherwise, this feature becomes invalid and cannot be used.

Checking the license files for various features occurs at different time points. That is, the license files for some features are checked during startup, and the license files for some features are checked in real time.

Loss of the License File

License files are stored in the **data** directory of a device and will not be lost after software upgrade.

If the memory or file system is damaged with the license file backed up, you can install the backup license file again after system recovery. If the license file is not backed up, you can visit the authorization website and obtain the license file again. The process of regaining the license file is the same as the process of obtaining a new license file (you do not need to purchase the license file again).

Authorization is based on each device. After a license file is provided for a specified device, authorization through this license file can be conducted on this device exclusively. The host ID may change during device maintenance or replacement. In case of host ID change, the license file obtained before can no longer be identified. In this case, contact after-sales engineers.

1.3.2 Backing Up, Updating, and Removing a License File

Backing Up a License File

When a fault such as file system storage media damage occurs on a device, the license file on the device may be lost after you rectify this fault. Therefore, you need to back up the license file for reinstallation in case of a fault.

Updating a License File

If the existing license file in the system cannot meet users' requirements for a feature, users can visit the website to purchase a license file and then update the license file locally.

Removing a License File

If a feature is not required, the user can remove the license file for this feature to improve the utilization rate of various resources such as the memory. If the user want to use this feature again after removing its license file, reinstall the license file. It is recommended that license files be kept properly.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of Software Authorization	(Mandatory) It is used to install a license file.	
	show license hostid	Obtains the host ID of the device.
	license install	Installs a license file manually.
	license auto-install	Installs a license file by automatic matching.
	(Optional) It is used to back up a license file.	

Backing Up the License File	**license copy**	Backs up a license file.
Configuring the Periodic Warning	(Optional) It is used to set the time of issuing a warning before the validity period of a license file expires.	
	license grace-peroid	Sets a friendly period warning.
Updating the License File	(Optional) It is used to update an existing license file on the device.	
	license update	Updates a license file.
Removing the License File	(Optional) It is used to remove an existing license file on the device.	
	license uninstall	Removes a license file manually.
	license auto-uninstall	Removes a license file by auto-match.
Unbinding a **License**	(Optional) It is used to unbind the license on the device.	
	license unbind	Unbinds the license.

1.4.1 Configuring Basic Functions of Software Authorization

Configuration Effect

Install a license file to enable the corresponding function.

Notes

- After downloading a license file from a specified website, upload this license file to the device (or store it in a USB flash drive) for installation. You do not need to connect the device to the Internet during installation.
- Different devices cannot share the same license file.
- After a license file is installed on a device, this license file is automatically backed up in the **data** directory of the system (the name of a license file ends with **.lic**). When you remove a license file, the backup file of this license file is also removed.

Configuration Step

↘ Obtaining the Host ID of the Device

- Mandatory.
- **hostid** indicates the host ID.
- If you want to apply a feature requiring authorization without installing the license file, the CLI displays a prompt indicating that the unauthorized feature is unavailable and provides the website for downloading the license file.

Command	**show license hostid**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	The name of a license file cannot be modified.

	This command does not require license.

Obtaining the PAK

- Mandatory.
- A PAK is provided in a paper purchase voucher by a vendor after a user purchases a license file.

Obtaining the License File of the Product from a Website

- Mandatory.
- After logging in to the authorization website, you can obtain the license file as prompted.

Copying the License File to the File System of the Device

- Mandatory.
- Use conventional file system operation commands to perform this operation. For example, download the license file through the TFTP protocol or copy the license file to a USB flash drive.

Installing the License File

- Optional.
- You can use the **license-install** or **license auto-install** command to install a license file. If you use the **license install** command in a VSU, only the device configured with the command is installed with the license file.
- If you use the **license auto-install** command in a VSU, all devices are installed with the license file through automatic matching. The two commands have the same effect in the non-VSU environment.

If you use the **license install** command in a VSU, the VSU is configured with the feature corresponding to the license file as long as one device obtains that feature. Once the devices are separated, the license takes effect on only the device configured with the command.

In a VSU, if the license install command is executed, licenses can only be installed locally. If the license auto-install command is run, licenses can be automatically matched and installed on all devices in the VSU.

The **license auto-install** command enables the automatic matching function only in the VSU. In the non-VSU environment, it has the same effect as the **license install** command.

In the VSD, license files are managed in global configuration mode. That is, when the license file for a certain feature is obtained, the license files for this feature in all VSD domains are obtained. In addition, license files are installed and managed in the default VSD exclusively.

Command	**license install** { **flash: | usb0:** } *filename*
Parameter Description	**flash**: Indicates that the license file is installed in the internal flash file system. **usb0**: Indicates that the license file is installed in the USB file system. *filename*: Specifies the name of the license file.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Command	**license auto-install** { **flash:	usb0:** } *filename*
Parameter Description	**flash**: Indicates that the license file is installed in the internal flash file system. **usb0**: Indicates that the license file is installed in the USB file system. *filename*: Specifies the name of the license file.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Verification

- You can run the **show license all_license** command to check the license name in a non-VSU. If the license name is displayed, the corresponding license file is installed.
- You can run the **show license dev_license** command to check the license name in a VSU. If the license name is displayed, the corresponding license file is installed.

Command	**show license** { **all_license	file** [*license*] }
Parameter Description	**all_license**: Displays all license files installed on the device. *license*: Displays a specified license file.
Command Mode	Privileged EXEC mode
Usage Guide	You can check whether a license file is installed by checking the feature name.

Verification	`Hostname#show license all-license`
	`Searching license in the system...`
	`1. Service name: LIC-FCoE`
	`Attribute: Permanent, Single_instance, Releasable`
	`Licensed serial number: LIC-FCOE00000012268889`
	`2. Service name: LIC-VSD`
	`Attribute: Temporary, Single_instance, Releasable`
	`Left days: 362`
	`Licensed serial number: LIC-VSD00000012268888`

Command	**show license dev-license**
Parameter Description	**dev-license**: Displays all license files in all environments.
Command Mode	Privileged EXEC mode
Usage Guide	You can check whether a license file is installed by checking the feature name.

Verification	`Hostname#show license dev-license`
	`Searching license in the system...`
	`Dev 1`
	`1. Service name: LIC-FCoE`
	`Attribute: Permanent, Single_instance, Releasable`

	Licensed serial number: LIC-FCOE00000012268889 2. Service name: LIC-VSD Attribute: Temporary, Releasable Left days: 362 Licensed serial number: LIC-VSD00000012268888 Dev 2 1. Service name: LIC-AP-64 Attribute: Multiple_instance, Releasable [Permanent licenses] [Licensed serial number] 19880966.lic LIC-AP-6400000012264966 19880988.lic LIC-AP-6400000012264988 [Temporary license] [Licensed serial number] 19880900.lic LIC-AP-6400000012264900 (63 days left)

Configuration Examples

Installing a VSD License File in Non-VSU Environment

Network Environment	The VSD function needs to be enabled.
Configuration Steps	● Run the **show license hostid** command to obtain the host ID of the device. ● Register at the authorization website, and perform operation as prompted to obtain the license file **vsd.lic** for the VSD feature (the host ID of the device and PAK are required). The detailed operation is omitted in this example. ● Store the **vsd.lic** file in a USB flash drive, and connect the USB flash drive to the device. ● Install the **vsd.lic** file.
	Hostname#show license hostid 8708EH5F00042 Hostname#license install usb0:vsd.lic License file install success, service name: LIC-VSD.
Verification	Run the **show license all_license** command to check the license name. If the license name is displayed, the corresponding license file is installed.
	Hostname(config)#show license all-license Searching license in the system... 1.Service name: LIC-VSD Attribute: Temporary, Single instance, Releasable Left days: 362 Licensed serial number: LIC-VSD00000012268888

Installing an FC License File in the VSU Environment

Network Environment	The FC function needs to be enabled.

Configuration Steps	● Run the **show license** *dev-hostid* command to obtain the host ID of device 2. ● Register at the authorization website, and perform operation as prompted to obtain the license file **fc.lic** for the FC feature (the host ID of the device and PAK are required). ● Store the **fc.lic** file in a USB flash drive, and connect the USB flash drive to the device. ● Install the **fc.lic** file.

	`Hostname#show license dev-hostid`
	`Dev 1: 8708EH5F00042`
	`Dev 2: GH3002893D300`
	`Hostname#license auto-install usb0:fc.lic`
	`License file install success, dev 2 installed it, service name: LIC-FC-BLADE-S.`

Verification	Run the **show license dev-license** command to check the license name. If the license name is displayed, the corresponding license file is installed.

	`Hostname#show license dev-license`
	`Searching license in the system...`
	`Dev 1`
	`1.Service name: LIC-VSD`
	`Attribute: Temporary, Single_instance, Releasable`
	`Left days: 362`
	`Licensed serial number: LIC-VSD00000012268888`
	`Dev 2`
	`1. Service name: LIC-FC-BLADE-S`
	`Attribute: Permanent, Single_instance, Releasable`
	`Licensed serial number: LIC-FC-BLADE-S00000012265522`

Common Errors

- A license file that does not belong to the device is installed.
- No matching device is available.
- A license file has been installed.
- A license file with its later version has been installed in the system.

1.4.2 Backing Up the License File

Configuration Effect

The license files of one or all features in the system are backed up.

Notes

- The license file of the evaluation version cannot be backed up.
- License files can be backed up only when the device has sufficient storage space.

One license file occupies a space of 4 KB to 10 KB.

Configuration Step

Backing Up a License File of the System

- The backup license file is a regular file.
- When you back up all license files in the system, a tar file is generated.

Command	**license** { **copy-all** | **copy-file** *filename* } { **flash: | usb0:** } [*target-filename*]
Parameter Description	**copy-all**: Copies all permanent license files in the system. **copy-file** *filename*: Copies the *filename* license file in the system. ***filename*** can be the name of a license file installed in the system or the name of a feature. When ***filename*** is a feature name, all license files installed for this feature are backed up. **flash**: Indicates that the license file is installed in the internal flash file system. **usb0**: Indicates that the license file is installed in the USB file system. *target-filename*: Specifies the name of the license file.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Uploading a License File to Another System for Storage

You can use a file system management command to further save a license file to other storage devices, such as a USB flash drive.

Verification

You can run the **dir** command to check whether the license file backup is generated. In addition, you can check whether the backup is correct by comparing the output of the **dir** command with the license file name in the **installed license** field of the feature with permanent authorization displayed by running the **show license all-license** command.

Command	**dir** [*filesystem*:] [*file-url*]
Parameter Description	*filesystem*: Indicates the URL of the file system, which is followed by a colon. The file systems include **flash:**, **sata:**, **usb:**, **sd:**, and **tmp:**. *file-url*: Indicates the path name. The path starting with the slash (/) indicates an absolute path. Otherwise, it is a relative path.
Command Mode	Privileged EXEC mode
Usage Guide	This command does not require a license.

Verification	`Hostname#dir usb0:rg-license-lics`
	`Directory of usb0:/rg-license-lics`
	`1 drwx 4096 Fri Jun 20 12:29:32 2014 .`
	`2 drwx 4096 Fri Jun 20 12:28:37 2014 ..`
	`3 -rwx 8704 Fri Jun 20 12:29:12 2014 lics.tar`
	`1 file, 2 directories`
	`536870912 bytes total (740,687,872 bytes free)`

Command	**show license** { **all-license | file** [*license*] }

Parameter Description	**all-license**: Displays all license files installed on the device. *license*: Displays a specified license file.
Command Mode	Privileged EXEC mode
Usage Guide	You can check whether a license file is installed by checking the feature name. ⚠ Only a multi-instance license file has the **installed license** field. The multi-instance license file backup is named the ID of the multi-instance license file. At most one single-instance license file exists in the system at a time; therefore, the single-instance license file backup is named the feature.

Verification	`Hostname#show license all-license`
	`Searching license in the system...`
	`1. Service name: LIC-FCoE`
	`Attribute: Permanent, Single_instance, Releasable`
	`Licensed serial number: LIC-FCOE00000012268889`
	`2. Service name: LIC-VSD`
	`Attribute: Temporary, Single_instance, Releasable`
	`Left days: 362`
	`Licensed serial number: LIC-VSD00000012268888`
	`3. Service name: LIC-AP-64`
	`Attribute: Permanent, Multiple_instance, Releasable`
	`[Installed licenses] [Licensed serial number]`
	`19881021.lic LIC-AP-6400000012264966`
	`19881023.lic LIC-AP-6400000012264988`

Configuration Examples

↘ Backing Up All License Files of the System

Network Environment	Back up all license files in the system and name the backup **lics.tar**.
Configuration Steps	● Connect a USB flash drive to the device. ● Back up all permanent license files in the USB flash drive and name the backup lics.tar.
	`Hostname#lic copy-all usb0:rg-license-lics/lics.tar` `Success to copy all permanent license.`
Verification	You can run the **dir** command to check whether the license file package is generated. After decompressing the package, you can check whether the backup is correct by comparing the files in the package with the license file name displayed in the **installed license** field of the feature with permanent authorization displayed by running the **show license all-license** command. ⚠ Only a multi-instance license file has the **installed license** field. The multi-instance license file backup is named the ID of the multi-instance license file. At most one single-instance license file exists in the system at a time; therefore, the internal single-instance license file backup is named the feature.

	⚠ In this example, the IDs **19881021.lic** and **19881023.lic** are embedded in the license file. License files are stored in different folders based on the features during the packing; therefore, you can still identify the mapping between license files and features.
	Hostname#dir usb0:rg-license-lics Directory of usb0:/rg-license-lics 1 drwx 4096 Fri Jun 20 12:29:32 2014 . 2 drwx 4096 Fri Jun 20 12:28:37 2014 .. 3 -rwx 8704 Fri Jun 20 12:29:12 2014 lics.tar 1 file, 2 directories 536870912 bytes total (740,687,872 bytes free) Hostname#show license all-license Searching license in the system... 1. 1. Service name: LIC-FCoE Attribute: Permanent, Single_instance, Releasable Licensed serial number: LIC-FCOE00000012268889 2. Service name: LIC-VSD Attribute: Temporary, Single_instance, Releasable Left days: 362 Licensed serial number: LIC-VSD00000012268888 3. Service name: LIC-AP-64 Attribute: Permanent, Multiple_instance, Releasable [Installed licenses] [Licensed serial number] 19881021.lic LIC-AP-6400000012264966 19881023.lic LIC-AP-6400000012264988

Common Errors

- A license file or a file does not exist in the system.
- A temporary license file is used for backup (a temporary license file cannot be backed up).

1.4.3 Configuring the Periodic Warning

Configuration Effect

Before the validity period of an evaluation license file expires, a warning is issued in a log, notifying an administrator of taking measures immediately.

Notes

- Each authorized feature should be set separately.
- This setting may be affected by time adjustment on the device.
- A permanent license file does not need to be configured with the periodic warning.

Configuration Step

↘ **Configuring a Periodic Warning for an Authorized Feature**

Command	**license grace-peroid** *filename days*
Parameter Description	*filename*: Indiates the name of the license file for a feature. *days*: Indiates the period from the expiry time to the warning time.
Defaults	The default value is the smaller one between 120 and half of the evaluation license file's validity period.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Verification

- Method 1: Set the expiry time of a license file to be earlier than the warning time and check whether the warning is displayed at intervals.
- Method 2: Run the **show license** command to check whether the time of the **Alarm starting point** filed is consistent with the setting.

Command	**show license** { **all-license | file** [*license*] }
Parameter Description	**all-license**: Displays all license files installed on the device. *license*: Displays a specified license file.
Command Mode	Privileged EXEC mode
Usage Guide	This command does not require a license.

Verification	`Hostname#show license file LIC-VSD`
	`Service name: LIC-VSD`
	`Attribute: Temporary, Single instance, Releasable`
	`Left days: 362`
	`Licensed serial number: LIC-VSD00000012268888`

Configuration Examples

Changing the Periodic Warning Time

Network Environment	The temporary license file has already been installed on the device, and the periodic warning time is set to 100 days.
Configuration Steps	Set the periodic warning time to 100 days.
	`Hostname#lic grace-period LIC-VSD 100` `RG_LICENSE: success to set alarm starting point of license LIC-VSD.`
Verification	When the validity period of the license file is shorter than 100 days, the periodic warning is displayed at intervals.
	`Hostname#*Jun 18 10:06:36: %RG_LICENSE-4-LICENSE_DEADLINE_INFO: Service LIC-VSD will be disabled 80 days behind. In order to avoid the inconvenience to you, please log on website http://192.168.5.227:8080/login.jsf to get a new license.`

Common Errors

- The periodic warning is configured for a permanent license file.
- No license file is installed in the preset feature system.

1.4.4 Updating the License File

Configuration Effect

- The license file for a feature of the system is updated. This configuration is performed to update an evaluation license file into a temporary license file.

Notes

- A formal permanent license file does not need to be updated.
- A license file cannot be updated to the earlier version.

A license file has a time filed. The value of this field is subject to the time when the license file is generated from the website. The later the time, the later the version.

Configuration Step

Updating a License File

- You can run the **license update** command to update the license file for a feature.
- Update the license file without connecting the device to the Internet.

Command	**license update** { **flash: | usb0:** } *filename*
Parameter Description	**flash**: Indicates that the license file is installed in the internal flash file system. **usb0**: Indicates that the license file is installed in the USB file system. *filename*: Specifies the name of the license file.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Verification

You can run the **show license** command and check the **Attribute** field. If the field is displayed as **Permanent**, the corresponding attribute is updated.

Command	**show license** { **all-license | file** [*license*] }
Parameter Description	**all-license**: Displays all license files installed on the device. *license*: Displays a specified license file.
Command Mode	Privileged EXEC mode
Usage Guide	This command does not require a license.

Verification	`Hostname#show  license all-license`
	`Searching license in the system...`
	`  1. Service name: LIC-FCoE`
	`    Attribute: Permanent, Single_instance, Releasable`

	Licensed serial number: LIC-FCOE00000012268889 2. Service name: LIC-VSD Attribute: Temporary, Single_instance, Releasable Left days: 362 Licensed serial number: LIC-VSD00000012268888

Configuration Examples

Updating the VSD License File

Network Environment	Update the temporary license file for the VSD in the system to a permanent license file.
Configuration Steps	● Purchase the permanent license file **vsd_perm.lic** for the VSD, store the **vsd_perm.lic** file in a USB flash drive, and connect the USB flash drive to the device. ● Update the license file for the VSD.
	Hostname#license update usb0:vsd_perm.lic License file update success, temporary license LIC-VSD changes into permanent.
Verification	You can run the **show license** command and check the **Attribute** field. If the field is displayed as **Permanent**, the corresponding attribute is updated.
	Hostname(config)#show license all-license Searching license in the system... 1. Service name: LIC-FCoE Attribute: Permanent, Single_instance, Releasable Licensed serial number: LIC-FCOE00000012268889 2. Service name: LIC-VSD Attribute: Permanent, Single_instance, Releasable Licensed serial number: LIC-VSD00000012266666

Common Errors

- A license file that does not belong to the device is installed.
- The license file of the new version is replaced with that of the old version.
- A license file is re-installed.
- The permanent license file is replaced with the temporary license file.
- The corresponding feature is not installed for the system before the update.

1.4.5 Removing the License File

Configuration Effect

- Remove the license files for one or all features in the system.

If a feature is not required, you can remove the license file for this feature to improve the utilization rate of various resources such as the memory. After being removed, this feature becomes unavailable.

Notes

- If you remove the license file in use, the removal operation takes effect next time when the feature is enabled or restarted.
- To reinstall a license file after removing it, you need to obtain the license file. It is recommended that you back up the license file before removing it.

Configuration Step

Removing a License File from the System

- Run the **license uninstall** command to remove a license file from the system.

Command	**license uninstall** *license* [*filename*]
Parameter Description	*license*: Indicates the name of the license file to be removed. *filename*: Indicates the name of the file to be removed.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	After you remove the license file for a feature that is running, the license file cannot be removed. A license file that is removed cannot be restored. It is recommended that you back up the license file before removing it. This command does not require a license.

Verification

You can run the **show license all-license** command to display the **Service name** filed. If the name of a feature corresponding to a license file removed is not displayed, the license file is removed successfully.

Command	**show license** { **all-license | file** [*license*] }
Parameter Description	**all-license**: Displays all license files installed on the device. *license*: Displays a specified license file.
Command Mode	Privileged EXEC mode
Usage Guide	This command does not require a license.

Verification	`Hostname#show license all-license`
	`Searching license in the system...`
	`1. Service name: LIC-FCoE`
	`Attribute: Permanent, Single_instance, Releasable`
	`Licensed serial number: LIC-FCOE00000012268889`

Removing a License File in the VSU Environment

- Run the **license auto-uninstall** command to remove a license file in the VSU environment.

Command	**license auto-uninstall** *devid license* [*filename*]
Parameter Description	*devid*: Indicates the ID of the device where the file is stored. *license*: Indicates the name of the license to be removed. *filename*: Indicates the name of the file to be removed..

Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	After you remove the license file for a feature that is running, the license file cannot be removed. A license file that is removed cannot be restored. It is recommended that you back up the license file before removing it. This command does not require a license.

Verification

Run the **show license dev-license** command to display the **Service name** field. If the name of a feature corresponding to a license file removed is not displayed, the license file is removed successfully.

Command	**show license dev-license**
Parameter Description	**dev-license:** Displays all license files in all environments.
Command Mode	Privileged EXEC mode
Usage Guide	This command does not require a license.

Verification	`Hostname#show  license dev-license`
	`Searching license in the system...`
	`Dev 1`
	`1. Service name: LIC-FCoE`
	`Attribute: Permanent, Single_instance, Releasable`
	`Licensed serial number: LIC-FCOE00000012268889`
	`2. Service name: LIC-VSD`
	`Attribute: Temporary, Single_instance, Releasable`
	`Left days: 362`
	`Licensed serial number: LIC-VSD00000012268888`
	`Dev 2`
	`There’s no license installed in this device.`

Configuration Examples

↘ Removing the VSD License File

Network Environment	Remove the license file for the VSD in the system.
Configuration Steps	Remove the license file for the VSD.
	`Hostname(config)#license uninstall LIC-VSD` `License file uninstall LIC-VSD success.`
Verification	● Run the **show license all-license** command to view the **Service name** filed. If the name of a feature corresponding to a license file already removed is not displayed, the license file is removed successfully.
	`Hostname(config)#show  license all-license`

	Searching license in the system... 1. Service name: LIC-FCoE Attribute: Permanent, Single instance, Releasable Licensed serial number: LIC-FCOE00000012268889
Configuration Steps	Remove the license file for the FC on device 2.
	Hostname#license auto-uninstall 2 LIC-FC-BLADE-S License file uninstall LIC-FC-BLADE-S of device 2 success.
Verification	Run the **show license dev-license** command to display the **Service name** field. If the name of a feature corresponding to a license file already removed is not displayed, the license file is removed successfully.
	Hostname#show license dev-license Searching license in the system... Dev 1 1. Service name: LIC-FCoE Attribute: Permanent, Single_instance, Releasable Licensed serial number: LIC-FCOE00000012268889 2. Service name: LIC-VSD Attribute: Temporary, Single_instance, Releasable Left days: 362 Licensed serial number: LIC-VSD00000012268888 Dev 2 There'heresed serial number: LIC-VSD000000122

Common Errors

- The license file has not been installed on the device.
- A specified license file does not exist on the device.

1.4.6 Unbinding a License

Configuration Effect

Unbind and uninstall a license file.

If you want to unbind a license file from the device, you should unbind the license code from the device first.

Notes

- After the license file is unbound from the device, you will obtain a verification code, which will be used for the unbinding operation at the authorization website.
- After the license code is unbound, the corresponding license file cannot be installed again.

Configuration Step

Unbinding a License File

Run the **license unbind** command to unbind a license file.

Command	**license unbind** *pak*
Parameter Description	*pak*: Indicates the license code.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Run the **show license all-license** command to display the installed license code. This command does not require a license.

Verification

Run the **show license all-license** command to display the **licensed serial number** field. If the license code is not displayed, the license is unbound.

Command	**show license** { **all-license** | **file** [*license*] }
Parameter Description	**all-license**: Displays all license files installed on the device. *license*: Displays a specified license file.
Command Mode	Privileged EXEC mode
Usage Guide	This command does not require a license.

Configuration Example

↘ Unbinding License Code LIC-VSD00000012268888

Network Environment	The license corresponding to license code LIC-VSD00000012268888 is installed.
Configuration Steps	Unbind license code LIC-VSD00000012268888.

	`Hostname#license unbind LIC-VSD00000012268888`
	`Success to unbind license LIC-VSD00000012268888.`
	`The verification string is:`
	`775719468737BA269825589557F558657575B5D5D5D5D785782598859765A8355855`

Verification	Run the **show license all-license** command to display the **licensed serial number** field. If the license code is not displayed, the license is unbound.

	`Before Binding`
	`Hostname#show license all-license`
	`Searching license in the system...`
	`1. Service name: LIC-AP-64`
	`Attribute: Releasable`
	`[Permanent licenses] [Licensed serial number]`
	`19880966.lic LIC-AP-6400000012264966`
	`19880988.lic LIC-AP-6400000012264988`
	
	`[Temporary license] [Licensed serial number]`
	`19880900.lic LIC-AP-6400000012264900`

```
   (63 days left)

 2. Service name: LIC-VSD
   Attribute: Permanent, Releasable
   Licensed serial number: LIC-VSD00000012268888

After Binding
Hostname#show  license all-license
Searching license in the system...
 1. Service name: LIC-AP-64
   Attribute: Releasable
   [Permanent licenses]    [Licensed serial number]
   19880966.lic           LIC-AP-6400000012264966
   19880988.lic           LIC-AP-6400000012264988

   [Temporary license]     [Licensed serial number]
   19880900.lic           LIC-AP-6400000012264900
   (63 days left)
```

Common Errors

No matching license code exists in the system.

1.5 Monitoring

Displaying

Command	Function
show license { **all_license | file** [*license*] }	Displays license configuration.
show license dev-license	Displays the license configuration of all devices.
show license usage	Displays the license in use.
show license hostid	Displays the serial number of the device where the license is installed.
show license dev-hostid	Displays the host ID for the license (all devices).
show license unbind-code	Displays the unbound license code on the current device.
show license dev-unbind-code	Displays the unbound license code on all devices in the system.

1 Configuring USB

1.1 Overview

The universal serial bus (USB) is an external bus standard. In this document, USB refers to a USB-compliant peripheral device, for example, a USB flash drive.

The USB is a hot swappable device. You can use it to copy files (such as configuration and log files) from a communication device, or copy external data (such as system upgrade files) to the flash of the communication device.

For more information about application scenarios of the USB, see configuration guides of related functions. This document describes only how to identify, use, and remove the USB, and view information about the USB.

The device does not support USB viewing, using, or uninstallation.

1.2 Applications

Application	Description
Using a USB Flash Drive to Upgrade a Device	Upgrade files are stored in a USB flash drive. After a device is powered on, the device detects the USB flash drive and runs the upgrade command to load the upgrade files. After loading is completed, the device is reset and runs the upgraded version.

1.2.1 Using a USB Flash Drive to Upgrade a Device

Scenario

Upgrade files are stored in a USB flash drive. After a device is powered on, the device detects the USB flash drive and runs the upgrade command to load the upgrade files. After loading is completed, the device is reset and runs the upgraded version. An example of the upgrade command is as follows:

upgrade usb0:/s12k-ppc_11.0(1B2)_20131025_main_install.bin

If the file is valid and execution of this command succeeds, the device will be automatically reset and run the upgraded version.

Deployment

- Use the prefix "usb0:/" to access USB 0. Run the **show usb** command to display information about the USB with the ID of 0.
- Run the **upgrade** command to perform upgrade.

1.3 Features

Using the USB

Insert a USB into the USB slot. The system automatically searches for the USB. After the USB is located, the driver module automatically initializes the USB. After initialization, the system automatically loads the file system in the USB. Then the system can read or write the USB.

- If the system finds a USB and successfully loads the USB, the following information will be displayed:

```
*Jan  1 00:09:42: %USB-5-USB_DISK_FOUND: USB Disk <Mass Storage> has been inserted to USB port 0!
*Jan  1 00:09:42: %USB-5-USB_DISK_PARTITION_MOUNT: Mount usb0(type:FAT32),size : 1050673152B(1002MB)
```

Mass Storage indicates the name of the searched device, and **usb0:** indicates the first USB. **Size** indicates the size of the partition. For example, according to the preceding information displayed, the USB flash drive has a space of 1002 MB.

Removing the USB

Use a command line interface (CLI) command to remove the USB first; otherwise, an error may occur if the system is currently using the USB.

- If the USB is successfully removed, the following information will be displayed:

```
OK, now you can pull out the device 0.
```

You can remove the USB only after the preceding information is displayed.

1.4 Configuration

Configuration	Description and Command	
Using a USB	Mandatory.	
	N/A	
Removing a USB	(Mandatory) It is used to remove a USB.	
	usb remove	Removes a USB.

1.4.1 Using a USB

Configuration Effect

After a USB is loaded, you can run the file system commands (such as **dir**, **copy**, and **del**) to perform operations on the USB.

Notes

- The Ruijie General Operating System (RGOS) is applicable only to devices (generally common USB flash drives) that support standard Small Computer System Interface (SCSI) commands. Other devices, such as the USB flash drive embedded in the USB network interface card (NIC) and USB flash drive with the virtual CD-ROM drive, cannot be used in the RGOS. Some devices are configured with the function of converting a USB port to the serial port.

- The USB supports only the FAT file system. Other file systems in the USB must be formatted to the FAT file system on a PC before the USB can be used on a device.
- The RGOS supports the hub. When a USB flash drive is inserted to a port on a hub, the access path becomes different. If the USB flash drive is inserted to a USB port on a device, the access path is **usbX:/**, where **X** indicates the device ID. You can run the **show usb** command to display this path. If the USB flash drive is inserted to a USB port through a hub, the access path is **usbX-Y:/**, where **X** indicates the device ID, and **Y** indicates the hub port ID. For example, **usb0-3:/** indicates port 3 on the hub that is connected to USB port 0 on the device.

Configuration Step

Identifying a USB

A USB can be directly inserted to the USB slot without a CLI operation.

Using a USB

Perform the following operations to copy files from a USB to the flash memory:

- Run the **cd** command to enter the partition of the USB.
- Run the **copy** command to copy files in the USB to the flash memory on the device.
- Run the **dir** command to check whether the files are copied to the device.

If the USB has multiple partitions, you can access only the first FAT partition on the device.

The path of the USB does not contain any upper-level directory. After running the **cd usbX:** command to access a USB, you can run the **cd flash:** command to return to the flash file system.

Verification

Run the **show usb** command to display information about the USB inserted to the device.

Configuration Example

Using a USB Flash Drive

Scenario	Standalone environment
Configuration Steps	● Insert the USB flash drive into the USB slot of the device. ● Run the **show usb** command on the device console. ● Copy the **config.txt** file from the USB flash drive to the flash memory on the device.
	Hostname#show usb Device: Mass Storage ID: 0 URL prefix: usb0 Disk Partitions: usb0(type:vfat) Size:15789711360B(15789.7MB) Available size:15789686784B(15789.6MB) Hostname# Hostname#

```
Hostname#dir usb0:/
Directory of usb0:/
  1 -rwx           4  Tue Jan  1 00:00:00 1980  fac_test
  2 -rwx           1  Mon Sep 30 13:15:48 2013  config.txt
2 files, 0 directories
15,789,711,360 bytes total (15,789,686,784 bytes free)
Hostname#
Hostname#
Hostname#copy usb0:/config.txt flash:/
Copying: !
Accessing usb0:/config.txt finished, 1 bytes prepared
Flushing data to flash:/config.txt...
Flush data done
Hostname#
Hostname#
```

Verification

- Check whether the **config.txt** file exists in the flash memory.

```
Hostname#
Hostname#dir flash:/
Directory of flash:/

```

	9 files, 15 directories 5,095,424 bytes total (4,960,256 bytes free) Hostname#

Common Errors

- Insert a USB flash drive that supports non-SCSI commands to the device.
- The USB does not use the FAT file system, and cannot be identified by the system.

1.4.2 Removing a USB

Configuration Effect

Remove the USB and ensure that the USB and the device are intact.

Notes

- Run the **usb remove** command before removing the USB; otherwise, a system error occurs.

Configuration Steps

Running the Remove Command

- Mandatory.
- Run the **usb remove** command before removing the USB.

Removing the USB

After the **remove** command is executed, remove the USB.

Verification

Run the **show usb** command to display information about the USB inserted to the device.

Related Commands

Removing a USB

Command	**usb remove** *device-id*
Parameter Description	*device-id*: Indicates the ID of the USB port on the device. You can run the **show usb** command to display this ID.
Command Mode	Privileged EXEC mode
Usage Guide	Before removing a USB, run the **usb remove** command; otherwise, an error occurs if the USB is in use. If the command is executed, related information will be displayed, and you can remove the USB. If the command execution fails, the USB is in use. In this case, do not remove the USB until it is not in use.

Configuration Example

Removing a USB

Scenario	Standalone environment
Configuration Steps	● Run the **show usb** command to display the ID of the USB. ● Run the **usb remove** command to remove the USB.
	Hostname#show usb Device: Mass Storage ID: 0 URL prefix: usb0 Disk Partitions: usb0(type:vfat) Size:15789711360B(15789.7MB) Available size:15789686784B(15789.6MB) Hostname# Hostname# Hostname#usb remove 0 OK, now you can pull out the device 0.
Verification	● Run the **show usb** command again to check whether the USB is removed. If the device with ID 0 is not displayed in output of the **show usb** command, the USB is removed.
	Hostname#show usb Hostname#

1.5 Monitoring

Displaying

Command	Description
show usb	Displays information about the inserted USB.

1 Configuring Package Management

1.1 Overview

Package management refers to the package management and upgrade module. This module is responsible for installing, upgrading/degrading, querying, and maintaining components of the device, among which upgrade is the main function. Through upgrade, you can install new version of software that is more stable or powerful. Adopting the modular architecture, the system supports overall upgrade and subsystem upgrade, and supports separate upgrade of a feature package. In addition, the system supports upgrade through hot patches.

Component upgrade described in this document applies to both the fixed device and rack-type device. In addition, this document is for only version 11.0 and later.

Protocols and Standards

N/A

1.2 Applications

Application	Scenario
Upgrading or Degrading the Subsystem	Upgrade subsystem firmware such as boot, kernel, and rootfs on the box-type device.
Upgrading or Degrading a Single Feature Package	Upgrade a single feature package on the fixed device.
Installing a Hot Patch Package	Install a hot patch, and repair a part of the feature component.

1.2.1 Upgrading or Degrading the Subsystem

Scenario

After the upgrade of a subsystem firmware is complete, all system software on the device is updated, and the overall software is enhanced. Typically, the subsystem firmware of the fixed device is called main package.

The main features of this upgrade mode are as follows: All software on the device is updated after the upgrade is completed; all known software bugs are fixed. It takes a long time to finish upgrade.

Deployment

You can store the main package in the root directory of the TFTP server, download the package to the device, and then run an upgrade command to upgrade the package locally. You can also store the main package in a USB flash drive or SD card, connect the USB flash drive to the device, and then run an upgrade command to upgrade the package.

1.2.2 Upgrading Subsystem Components with One Click

Scenario

It is typically used in VSU dual-device systems, and is also used for upgrading and degrading subsystem components. In privileged EXEC mode, run the **upgrade auto** command to perform automatic upgrade. This upgrade process requires no user intervention and does not interrupt services. For a single device in VSU or standalone mode, executing the **upgrade auto** command is equivalent to executing the **upgrade** command followed by an automatic restart of the entire system, but this upgrade process interrupts services.

Deployment

Upgrade or degrade subsystem components.

1.2.3 Upgrading or Degrading a Single Feature Package

Scenario

Device software consists of several components, and each component is an independent feature module. After an independent feature package is upgraded, only the feature bug corresponding to this package is fixed. Besides, this feature is enhanced, while the other features remain unchanged.

Typically, a feature package is small in size and the upgrade speed is high. After the upgrade is completed, only the corresponding functional module is improved, and other functional modules remain unchanged.

Deployment

You can store this package in the root directory of the TFTP server, download the package to the local device, and then complete the upgrade. You can also store the package in a USB flash drive, connect the USB flash drive or SD card to the device, and then complete the upgrade.

1.2.4 Installing a Hot Patch Package

Scenario

To fix software bugs without restarting the device, you can install hot patch packages. Hot patch packages are only applicable to fixing a specific software version. In most situations, hot patch packages are released to fix the software of a certain version only when the device cannot be started.

The most significant feature of hot patch upgrade is that all bugs can be fixed without device restart after the upgrade is completed.

Deployment

You can store this package in the root directory of the TFTP server, download the package to the local device, and then complete the upgrade. You can also store the package in a USB flash drive, connect the USB or SD card flash drive to the device, and then complete the upgrade.

1.3 Features

Basic Concepts

↘ Subsystem

A subsystem exists on a device in the form of images:

- boot: After being powered on, the device loads and runs the boot subsystem first. This subsystem is responsible for initializing the device, and loading and running system images.
- kernel: The kernel is the OS core of the system. The subsystem shields hardware composition of the system and provides applications with abstract running environment.
- rootfs: rootfs is the collection of applications in the system.

Main Package

The main package is often used to upgrade or degrade a subsystem of the fixed device. The main package is a combination package of the boot, kernel, and rootfs subsystems. The main package can be used for overall system upgrade or degrade.

Rack Package

The rack package is used for upgrading the subsystem component of the rack-type device, which includes the main installation package of the supervisor module and all line cards. This package can upgrade all cards on the rack-type device at one time.

Feature Package

The feature package refers to a collection which enables a certain feature. When the device is delivered, all supported functions are contained in the rootfs subsystem. You can upgrade only a specific feature by upgrading a single feature package.

Hot Patch Package

A hot patch package contains hot patches of several features. You can upgrade a hot patch package to install patches for various features. New features are provided immediately without device restart after the upgrade.

⚠ The firmware in this document refers to an installation file that contains a subsystem or feature module.

Overview

Feature	Description
Upgrading or Degrading and Managing Subsystem Components	Upgrades or degrades a subsystem and checks available subsystem components.
Upgrading or Degrading and Managing Functional Components	Upgrades or degrades a functional component, checks available subsystem components, and activates the specified subsystem component.
Upgrading or Degrading and Managing Hot Patch Packages	Installs a hot patch package.

1.3.1 Upgrading or Degrading and Managing Subsystem Components

Subsystem upgrade or degrade aims to upgrade the software by replacing subsystem components of the device with subsystem components in the firmware. The subsystem component contains redundancy design. Subsystems of the device are not directly replaced with the subsystems in the package during upgrade or degrade in most cases. Instead, subsystems are added to the device and then activated during upgrade or degrade.

Working Principle

Upgrade or Degrade

Various subsystems exist in the device in different forms. Therefore, upgrade or degrade varies with different subsystems.

- boot: Typically, this subsystem exists on the norflash device in the form of images. Therefore, upgrading or degrading this subsystem is to write the image into the norflash device.
- kernel: This subsystem exists in a specific partition in the form of files. Therefore, upgrading or degrading this subsystem is to write the file.
- rootfs: In most cases, this subsystem exists on the nandflash device in the form of images. Therefore, upgrading or degrading this subsystem is to write the image into the nandflash device.

Management

Query the subsystem components that are available currently and then load subsystem components as required.

Each subsystem component uses the redundancy design. During the upgrade or degrade:

- boot: The boot subsystem always contains an active boot subsystem and a standby boot subsystem. Only the active boot subsystem is involved in the upgrade, and the standby boot subsystem serves as the redundancy backup all along.
- kernel: The kernel subsystem contains at least one redundancy backup. More redundancy is allowed if there is enough space.
- rootfs: The rootfs subsystem always contains one redundancy.

The boot component is not included in the scope of subsystem management due to its particularity. During upgrade of the kernel or rootfs subsystem component, the upgrade or degrade module always records the subsystem component in use, redundant subsystem component, and management information about various versions.

Relevant Configuration

Upgrade

Store the upgrade file on the local device, and then run the **upgrade** command for upgrade.

1.3.2 Upgrading or Degrading and Managing Functional Components

Working Principle

Upgrading a feature is replacing feature files on the device with feature files in the package.

Managing feature components and hot patches is aimed at recording information about feature components and hot patches by using a database. Installing components, displaying component information, and uninstalling components are results of database addition, querying, and deletion.

Relevant Configuration

Upgrade

- Store the upgrade file on the local device, and then run the **upgrade** command for upgrade.

1.3.3 Upgrading or Degrading and Managing Hot Patch Packages

Working Principle

Upgrading a feature component is replacing feature files on the device with feature files in the package.

Upgrading hot patch packages is similar to upgrading features. The difference is that only files to be revised are replaced during hot patch package upgrade. In addition, after the files are replaced, the new files take effect automatically.

After package upgrade, component upgrade cannot be performed.

Management

Similar to feature component management, hot patch management also includes query, installation, and uninstallation operations, which are results of adding, querying and deleting data.

Hot patches and feature components are managed based on the same technology. The difference is that the hot patches involve three different states, that is, non-installed, installed, and activated.

The hot patch in installed state only indicates that this hot patch exists on the device, but does not take effect.

Only the hot patch in activated state is valid.

Relevant Configuration

Upgrade

- Store the upgrade file in the local file system, and then run the **upgrade** command for upgrade.
- Run the **upgrade autoload** command to install and activate hot patches with one click. The patches that have been installed with the **autoload** command do not need to be repeatedly activated with the **patch active** and **patch running** commands.

Activating a Hot Patch

- You can run the **patch active** command to activate a patch temporarily. The patch becomes invalid after device restart. To use this patch after device restart, you need to activate it again.
- You can also run the **patch running** command to activate a patch permanently. The patch is still valid after device restart.
- The patch that is not activated will never become valid.

Deactivating a Hot Patch

To deactivate an activated patch, run the **patch deactive** command.

Uninstalling a Hot Patch

You can run the **patch delete** command to uninstall a hot patch.

1.4 Configuration

Configuration	Description and Command
Upgrading or Degrading a Firmware	(Mandatory) It is used to install and upgrade or degrade a subsystem firmware, feature package, and hot patch package. This command is valid on both the fixed device and rack-type device.

	upgrade [**peer** *ip-address*] **flash:/***/path* [**force**]	Upgrades the firmware stored on the device. *path* is a local path where the firmware is stored.
	upgrade [**peer** *ip-address*] **download tftp:/***/path* [**force | vrf**]	Downloads a firmware from the server and upgrade the package automatically. *path* is the path of the firmware on the server.
	patch active	Temporarily activates installed patches.
	patch running	Permanently activates installed patches.
Deactivating and Uninstalling a Hot Patch	⚠ (Optional) It is used to invalidate activated hot patches or uninstalls hot patches.	
	patch deactive	Invalidates the activated patches.
	patch delete	Uninstalls hot patches.

1.4.1 Upgrading or Degrading a Firmware

Configuration Effect

Available installation packages include the following types:

- After the upgrade of the main package is complete, all system software on the line card is updated, and the overall software is enhanced.
- After an independent feature package is upgraded, only the feature bug corresponding to this package is fixed. Besides, this feature is enhanced, with other features remain unchanged.

✅ The main package is typically released to upgrade a fixed device.

Notes

N/A

Configuration Step

↘ Upgrading the Main Package for the Device

- Optional.
- Perform the configuration when all system software on the device needs to be upgraded.
- Download the firmware to the local device and run the **upgrade** or **upgrade patch** command.

✅ The main package is typically released to upgrade a fixed device.

↘ Upgrading Each Feature Package

- Optional.
- Perform the configuration to fix bugs of a certain feature and enhance the function of this feature.
- Download the firmware to the local device and run the **upgrade** command.

↘ Upgrading a Hot Patch Package

- Optional.
- Perform the configuration to fix software bugs without restarting the device.

- Download the firmware to the local device and run the **upgrade** command.
- After the upgrade, to use the hot patch, first activate it. The configuration in this step is mandatory. You can run the **patch active** command to activate a patch temporarily, or run the **patch running** command to activate a patch permanently.

⚠ The **patch running** command must be used to activate a patch permanently in user scenarios. The **patch active** command can be used to activate a patch only when a user intends to verify the patch.

Upgrading the Server

- Optional. This function is enabled by default. You can perform the configuration to disable the server.
- After the server is disabled, automatic upgrade cannot be performed if no line card with the main program is installed. If an upgrade package of a line card is being downloaded from the server, the server cannot be disabled.

Verification

- After upgrading a subsystem component, run the **show upgrade history** command to check whether the upgrade is successful.
- After upgrading a feature component, run the **show component** command to check whether the upgrade is successful.
- After upgrading a hot patch package, run the **show patch** command to check whether the upgrade is successful.

Commands

Upgrade

Command	**upgrade** [**peer** *ip-address*] **flash://***path* [**force**]
Parameter Description	**peer**: Indicates the peer device. *ip-address*: Specifies the IP address of a device. *path*: Indicates the local path where an installation package is stored. **force**: Indicates forcible device upgrade.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Command	**upgrade** [**peer** *ip-address*] **download tftp://***path* [**force** | **vrf**]
Parameter Description	**peer**: Indicates the peer device. **all**: Indicates all devices. *ip-address*: Specifies the IP address of a device. *path*: Indicates the path of the upgrade package on the TFTP server. The command enables the device to automatically download the upgrade package from the TFTP server and perform upgrade. **force**: Indicates forcible upgrade. **vrf**: VRF name for upgrade.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying the Firmware Stored on the Device

Command	**show upgrade file** *url*
Parameter Description	*url*: Indicates the path of the firmware in the device file system.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Display the Upgrade Status of Each Card on the Rack-type Device

Command	**show upgrade status**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Upgrade History

Command	**show upgrade history**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying Installed Feature Components

Command	**show component** [*component _name*]
Parameter Description	*component _name*: Indicates the component name. When this parameter value is empty, the command is used to display all components installed on the device and basic information about these components. When this parameter value is not empty, the command is used to display detailed information about the corresponding component, check whether the component is intact, and check whether this component works properly. All parameters apply to rack-type devices only.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Displaying the Upgrade Status

Command	**show upgrade peer** { **all** | *ip-address* } **status**
Parameter Description	**peer**: Indicates the peer device. **all**: Indicates all devices. *ip-address*: Specifies the IP address of a device.

Command Mode	Privileged EXEC mode
Usage Guide	All parameters apply to graded devices only.

Displaying Installed Patch Packages

Command	**show patch**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	All parameters apply to rack-type devices only.

Activating Patches Temporarily

Command	**patch active**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	This operation can be performed only on the device that has a patch installed. This command can be used to activate a patch temporarily, and the activated patch becomes invalid after device restart. All parameters apply to rack-type devices only.

Activating the Patches Permanently

Command	**patch running**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	This operation can be performed only on the device that has a patch installed. This command can be used to activate a patch permanently. All parameters apply to rack-type devices only.

Configuration Example

Upgrading a Subsystem Firmware on the Fixed Device

Network Environment	Before the upgrade, you must copy the firmware to the device. The upgrade module provides the following solutions. ● Run some file system commands such as **copy tftp** and **copy xmodem** to copy the firmware on the server to the device file system, and then run the **upgrade *url*** command to upgrade the firmware in the local file system. ● Run the **upgrade download tftp://***path* command directly to upgrade the firmware file stored on the TFTP server.

	● Copy the firmware to a USB flash drive or SD card, insert the USB flash drive or SD card to the device, and then run the **upgrade** *url* command to upgrade the firmware in the USB flash drive or SD card.
Configuration Steps	● Run the **upgrade** command. ● After upgrading the subsystem, restart the device.
	Hostname# upgrade download tftp://192.168.201.98/eg1000m_main_1.0.0.0f328e91.bin Accessing tftp://192.168.201.98/eg1000m_main_1.0.0.0f328e91.bin... !!! !!! !!! !!! !!!!!!!!!!!!!!!! Transmission finished, file length 21525888 bytes. Upgrade processing is 10% Upgrade processing is 60% Upgrade processing is 90% Upgrade info [OK] Kernel version[2.6.32.91f9d21->2.6.32.9f8b56f] Rootfs version[1.0.0.2ad02537->1.0.0.1bcc12e8] Upgrade processing is 100% Reload system to take effect! Reload system?(Y/N)y Restarting system.
Verification	● Check the system version on the device. If version information changes, the upgrade is successful.
	Hostname#show version detail upgrade history System description : EG1000m System start time : 2013-10-19 02:25:28 System uptime : 0:00:00:50 System hardware version : 1.00 System software version : RGOS11.0(1C2) Release(20131022) System boot version : 1.0.0.e7a1451 System core version : 2.6.32.9f8b56f System main version : 1.0.0.1bcc12e8 System boot build : unknown System core build : 2013/10/22 04:54:03 System main build : 2013/10/22 05:33:38

Upgrading a Feature Package on the Fixed Device

Network Environment	Before the upgrade, you must copy the firmware to the device. The upgrade module provides the following solutions.

	● Run some file system commands such as **copy tftp** and **copy xmodem** to copy the firmware on the server to the device file system, and then run the **upgrade *url*** command to upgrade the firmware in the local file system. ● Run the **upgrade download tftp://*path*** command directly to upgrade the firmware file stored on the TFTP server. ● Copy the firmware to a USB flash drive or SD card, connect the USB flash drive or SD card to the device, and then run the **upgrade** *url* command to upgrade the firmware in the USB flash drive or SD card.
Configuration Steps	● Run the **upgrade** command. ● Check whether the device needs to be restarted based on the prompt displayed after the upgrade.

	`Hostname#upgrade sata0://bridge_eg1000m_2.3.1.1252ea-1.mips.rpm`

Verification	● Check the hot patches installed on the device.
	:patch package patch_install installed in the system, version:pa1 Package : patch_bridge Status: running

	Version: pa1 Build time: Mon May 13 09:03:07 2013 Size: 277 Install time: Tue May 21 03:07:17 2013 Description: a patch for bridge Required packages: None

Common Errors

If an error occurs during the upgrade, the upgrade module displays an error message. The following provides an example:

```
Upgrade info [ERR]
       Reason:creat config file err(217)
```

Common error messages are as follows:

- Invalid firmware: The cause is that the firmware may be damaged or incorrect. You are advised to obtain the firmware again and perform the upgrade.
- Firmware not supported by the device: You may incorrectly use the firmware of other devices. You are advised to obtain the firmware again, verify the package, and perform the upgrade.
- Insufficient device space: Typically, this error occurs on a rack-type device. You are advised to check whether the device is equipped with a USB flash drive or SD card. The device often has a USB flash drive.

1.4.2 Deactivating and Uninstalling a Hot Patch

Configuration Effect

An activated hot patch is deactivated or uninstalled.

Notes

A hot patch that is not activated does not take effect; therefore, you cannot deactivate it.

Configuration Steps

↘ Deactivating an Activated Patch

- Optional.
- To deactivate an activated patch, run the **patch deactive** command.

↘ Uninstalling a Hot Patch

- Optional.
- To uninstall a hot patch that is installed, run the **patch delete** command.

Verification

You can run the **show patch** command to check whether a patch is activated or uninstalled.

Commands

↘ Deactivating an Activated Patch

Command	**patch deactive**

Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	You can perform this operation on only an activated patch. All parameters are applicable to only the rack-type device.

Deleting a Hot Patch

Command	**patch delete**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	This command is used to remove the hot patch package from the device. All parameters are applicable to only the rack-type device.

Configuration Example

Deactivating and Uninstalling a Patch on the Fixed Device

Configuration Steps	● Run the **patch deactivate** command. ● Run the **patch delete** command.

	`Hostname#patch deactive`
	`Deactive the patch package success`
	`Hostname# patch delete`
	`Clear the patch patch_bridge success`
	`Clear the patch success`
	`You use reset patch command have risky, Are you sure? Continue [Y/n]y`
	`Patch operate finish!`

Verification	● Display the patch status.
	`Hostname#show patch` `No patch package installed in the system`

Invalidating and Uninstalling the Patch on the Rack-type Device

Configuration Steps	● Run the **patch deactive** command. ● Run the **patch delete** command.
	Hostname#patch deactive slot M1 [Slot M1]: Deactive the patch package success Hostname# patch delete slot M1 [Slot M1]: Clear the patch patch_bridge success Clear the patch success
Verification	Display the patch status.
	Hostname#show patch slot M1 [Slot M1]: No patch package installed in the system

Common Errors

Run the **patch deactive** command when the patch is not activated. You are advised to check the patch status. You can run the **patch deactive** command only when the patch is in **status:running** state.

1.5 Monitoring

Clearing

Command	Function
patch delete	Deletes a hot patch package that is installed.
clear storage [*url*]	Removes an installation package on the local device.

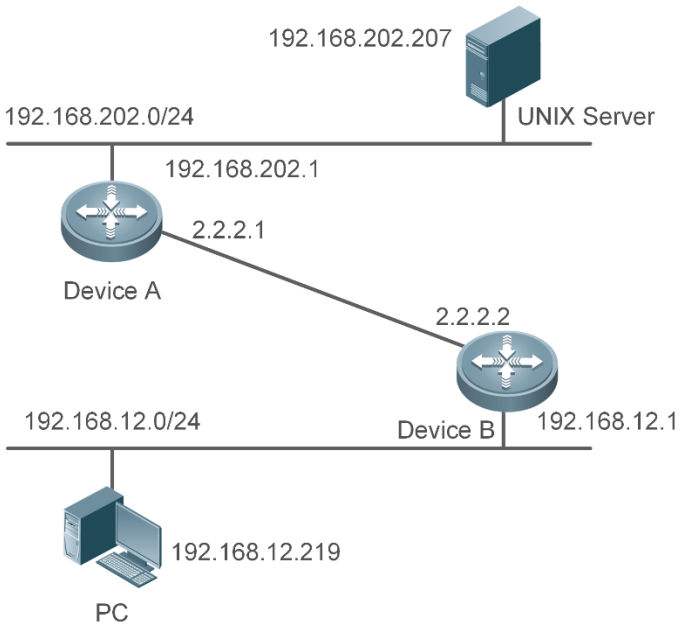
Displaying

Command	Function
show component [*component _name*]	Displays all components installed on the device and their information.
show patch [*patch _name*]	Displays information about hot patch packages installed on the device.
show upgrade status	Display the upgrade status of each card on the rack-type device.
show upgrade history	Displays the upgrade history.

1 Configuring Time Range

1.1 Overview

The time range is a time-based control service that provides some applications with time control. For example, you can configure a time range and associate it with an access control list (ACL) so that the ACL takes effect within certain time periods of a week.



1.2 Applications

Typical Application	Scenario
Applying a Time Range to an ACL	Apply a time range to an ACL module so that the time-based ACL takes effect

1.2.1 Applying a Time Range to an ACL

Scenario

An organization allows users to access the Telnet service on a remote Unix host during working hours only, as shown in Figure 1-1

Note	Configure an ACL on Device B to implement the following security function: Hosts on network segment 192.168.12.0/24 can access the Telnet service on a remote Unix host during working hours only.

Deployment

On Device B, apply an ACL to control Telnet service access of users on network segment 192.168.12.0/24. Associate the ACL with a time range, so that the users' access to the Unix host is allowed only during working hours.

1.3 Features

Basic Concepts

Absolute Time Range

The absolute time range is a time period between a start time and an end time. For example, [12:00 January 1 2000, 12:00 January 1 2001] is a typical absolute time range. When an application based on a time range is associated with the time range, a specified function takes effective within this time range.

Periodic Time

The periodic time refers to a periodical interval in the time range. For example, "from 8:00 every Monday to 17:00 every Friday" is a typical periodic time interval. When a time-based application is associated with the time range, a specified function takes effective periodically from every Monday to Friday.

Overview

Feature	Function
Using the Absolute Time Range	Sets an absolute time range for a time-based application, so that a specified function takes effect within the absolute time range.
Using the Periodic Time	Sets the periodic time or a time-based application, so that a specified function takes effect within the periodic time.

1.3.1 Using the Absolute Time Range

Working Principle

When a function is enabled for a time-based application, the application determines whether the current time is within the absolute time range. If so, the function becomes effective or ineffective at the current time depending on specific configuration.

1.3.2 Using the Periodic Time

Working Principle

When a function is enabled for a time-based application, the application determines whether the current time is within the period time. If so, the function becomes effective or ineffective at the current time depending on specific configuration.

1.4 Configuration

Configuration	Description and Command
Configuring the Time	(Mandatory) It is used to configure the time range.

Range	**time-range** *time-range-name*	Configures a time range.
	(Optional) It is used to configure parameters of a time range.	
	absolute { [**start** *time date*] [**end** *time date*] }	Configures an absolute time range.
	periodic *day-of-the-week time* **to** [*day-of-the-week*] *time*	Configures the periodic time.

1.4.1 Configuring the Time Range

Configuration Effect

Configure a time range, which may be an absolute time range or a periodic time, so that a time-range-based application can enable a certain function within the time range.

Configuration Step

Configuring a Time Range

- Mandatory.
- Perform the configuration on a device to which a time range applies.

Command Syntax	**time-range** *time-range-name*
Parameter Description	*time-range-name*: Indicates the name of the time range to be created.
Defaults	No time range is configured.
Command Mode	Global configuration mode
Usage Guide	Some applications (such as ACL) may run based on the time. For example, an ACL can be effective within certain time ranges of a week. You must configure a time range, and then you can configure time control in time range configuration mode.

Configuring the Absolute Time Range

Optional.

Command Syntax	**absolute** { [**start** *time date*] | [**end** *time date*] }
Parameter Description	**start** *time date*: Indicates the start time of the time range. **end** *time date*: Indicates the end time of the time range. The maximum time range is from 00:00 January 1, 0000 to 23:59 December 31, 9999.
Defaults	No absolute time range is configured. The maximum time range is used by default.
Command Mode	Time range configuration mode
Usage Guide	Use the **absolute** command to configure an absolute time range between a start time and an end time to allow a certain function to take effect within the absolute time range.

Configuring the Periodic Time

Optional.

Command Syntax	**periodic** *day-of-the-week time* **to** [*day-of-the-week*] *time*
Parameter Description	*day-of-the-week*: Indicates the week day when the periodic time starts or ends. *time*: Indicates the exact time when the periodic time starts or ends.
Defaults	No periodic time is configured.
Command Mode	Time range configuration mode
Usage Guide	Use the **periodic** command to configure a periodic time to allow a specified function to take effect within the periodic time. If no periodic time is configured, a certain function takes effect within the periodic time. Before changing the periodic time of a service, disassociate the time range from the service, and then re-associate the time range with the service after the change.

Verification

Use the **show time-range** [*time-range-name*] command to check the time range configuration.

Command Syntax	**show time-range** [*time-range-name*]
Parameter Description	*time-range-name*: Specifies a time range to be displayed.
Command Mode	Privileged EXEC mode
Usage Guide	Use the **show time-range** [*time-range-name*] command to check the time range configuration.

Verification	1: Display the time range configuration:
	`Hostname# show time-range`
	`time-range entry: test (inactive)`
	`  absolute end 01:02 02 February 2012`

1.5 Monitoring

Displaying

Command	Function
show time-range [*time-range-name*]	Displays time range configuration.

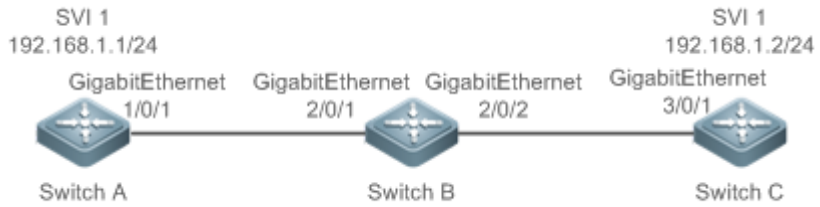
Configuring Interface

1. Configuring Interfaces
2. Configuring Aggregate Interface

1 Configuring Interfaces

1.1 Overview

Interfaces are used for data exchange on network devices. Network devices support physical and logical interfaces. A physical interface is a hardware interface on a device, such as the 100M and 1000M Ethernet interfaces. A logical interface is not a hardware interface on the device. A logical interface, such as the loopback interface and tunnel interface, can be associated with a physical interface or independent of any physical interface. For network protocols, physical and logical interfaces serve the same function.



1.2 Applications

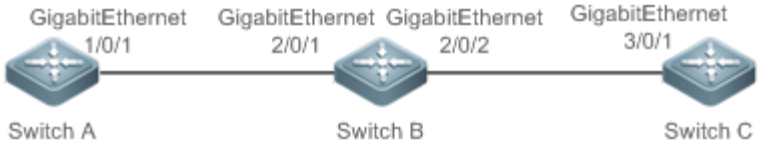
Application	Description
Layer 2 Data Switching Through a Physical Ethernet Interface	Implement Layer 2 data communication of network devices through the physical Layer 2 Ethernet interface.
Layer 3 Routing Through a Physical Ethernet Interface	Implement Layer 3 data communication of network devices through the physical Layer 3 Ethernet interface.

1.2.1 Layer 2 Data Switching Through a Physical Ethernet Interface

Scenario

Figure 1-1

As shown in Figure 1-1, Switch A, Switch B, and Switch C form a simple Layer 2 data switching network.



Deployment

- Connect Switch A to Switch B through GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1.
- Connect Switch B to Switch C through GigabitEthernet 2/0/2 and GigabitEthernet 3/0/1.
- Configure GigabitEthernet 1/0/1, GigabitEthernet 2/0/1, GigabitEthernet 2/0/2, and GigabitEthernet3/0/1 as trunk interfaces.
- Create a switch virtual interface (SVI), SVI 1, on Switch A and Switch C respectively, and configure IP addresses from the same network segment for the two SVIs. The IP address of SVI 1 on Switch A is 192.168.1.1/24, and the IP address of SVI 1 on Switch C is 192.168.1.2/24.
- Run the **ping 192.168.1.2** command on Switch A and the **ping 192.168.1.1** command on Switch C to implement data switching through Switch B.

1.2.2 Layer 3 Routing Through a Physical Ethernet Interface

Scenario

Figure 1-2

As shown in Figure 1-2, Switch A, Switch B, and Switch C form a simple Layer 3 data communication network.

Deployment

- Connect Switch A to Switch B through GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1.
- Connect Switch B to Switch C through GigabitEthernet 2/0/2 and GigabitEthernet 3/0/1.
- Configure GigabitEthernet 1/0/1, GigabitEthernet 2/0/1, GigabitEthernet 2/0/2, and GigabitEthernet3/0/1 as Layer 3 routed interfaces.
- Configure IP addresses from the same network segment for GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1. The IP addresses of GigabitEthernet 1/0/1 and GigabitEthernet 2/0/1 are 192.168.1.1/24 and 192.168.1.2/24, respectively.
- Configure IP addresses from the same network segment for GigabitEthernet 2/0/2 and GigabitEthernet 3/0/1. The IP addresses of GigabitEthernet 2/0/2 and GigabitEthernet 3/0/1 are 192.168.2.1/24 and 192.168.2.2/24, respectively.
- Configure a static route entry on Switch C so that Switch C can directly access the network segment 192.168.1.0/24.
- Run the **ping 192.168.2.2** command on Switch A and the **ping 192.168.1.1** command on Switch C to implement Layer 3 routing through Switch B.

1.3 Features

Basic Concepts

Interface Classification

Interfaces on devices fall into three categories:

- Layer 2 interface (supported by switches or network bridges)
- Layer 3 interface (supported by Layer 3 devices)

1. Common Layer 2 interfaces are classified into the following types:

- Switch interface
- Layer 2 aggregate interface

2. Common Layer 3 interfaces are classified into the following types:

- Routed interface
- Layer 3 aggregate interface
- SVI
- Loopback interface
- Tunnel interface

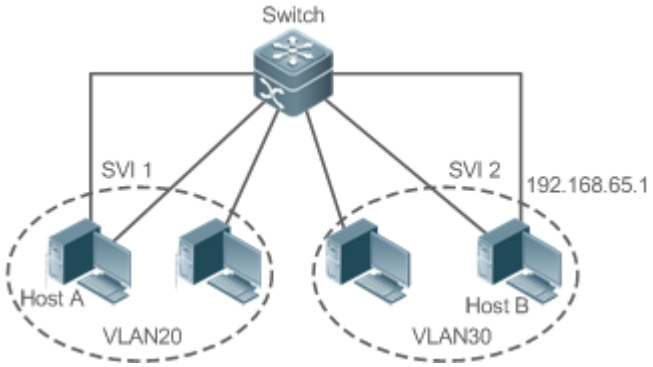
Switch Interface

A switch interface is an individual physical interface on the device, and implements only the Layer 2 switching function. The switch interface is used to manage physical interfaces and Layer 2 protocols related to physical interfaces.

Layer 2 Aggregate Interface

An aggregate interface is formed by aggregating multiple physical interfaces. Multiple physical links can be bound together to form a simple logical link. This logical link is called an aggregate interface.

For Layer 2 switching, an aggregate interface is equivalent to a switch interface that combines bandwidth values of multiple interfaces, increasing the link bandwidth. Frames sent over the Layer 2 aggregate interface are load balanced among the member interfaces. If one member link fails, the Layer 2 aggregate interface automatically transfers the traffic on the faulty link to other member links, improving reliability.



SVI

An SVI can be used as the management interface of the local device, through which an administrator can manage the device. You can also create an SVI as a gateway interface, which is mapped to the virtual interface of each VLAN to implement routing across VLANs among Layer 3 devices. You can run the

interface vlan command to create an SVI and assign an IP address to this interface to implement routing between VLANs.

As shown in Figure 1-3, hosts in VLAN 20 can communicate with each other without participation of Layer 3 devices. If Host A in VLAN 20 wants to communicate with Host B in VLAN 30, SVI 1 of VLAN 20 and SVI 2 of VLAN 30 must be used.

Figure 1-3

Routed Interface

A physical interface on a Layer 3 device can be configured as a routed interface, which functions as the gateway interface for Layer 3 switching. A routed interface is irrelevant to a specific VLAN. Instead, it is just an access interface. The routed interface cannot be used for Layer 2 switching. You can run the **no switchport** command to change a switch interface to a routed interface and assign an IP address to this interface for routing. Running the **no switchport** command will delete all Layer 2 features of the interface.

If an interface is a member interface of the Layer 2 aggregate interface or an interface where 802.1X authentication fails, you cannot run the **switchport** or **no switchport** command to switch the interface.

Layer 3 Aggregate Interface

Similar to a Layer 2 aggregate interface, a Layer 3 aggregate interface is a logical interface that aggregates multiple physical member interfaces. The member interfaces must be the Layer 3 interfaces of the same type. The aggregate interface functions as a gateway interface for Layer 3 switching. Multiple physical links are combined into one logical link, increasing link bandwidth. Frames sent over the Layer 3 aggregate interface are load balanced among member interfaces. If one member link fails, the Layer 3 aggregate interface automatically transfers the traffic on the faulty link to other member links, improving reliability.

A Layer 3 aggregate interface cannot be used for Layer 2 switching. You can run the **no switchport** command to change a Layer 2 aggregate interface that does not contain any member interface into a Layer 3 aggregate interface, add multiple routed interfaces to the Layer 3 aggregate interface, and then assign an IP address to this Layer 3 aggregate interface for routing.

Loopback Interface

A loopback interface is a local Layer 3 logical interface simulated by the software that is always Up. Packets sent to the loopback interface are processed on the device locally, including routing information. The IP address of the loopback interface can be used as the device ID of the Open Shortest Path First (OSPF) or for Telnet access. The procedure for configuring a loopback interface is similar to that for configuring an Ethernet interface (the loopback interface can be considered as a virtual Ethernet interface).

Tunnel Interface

A tunnel interface implements tunneling. Transmission protocols such as IP can be used to transmit packets of any protocol over a tunnel interface. Like other logical interfaces, the tunnel interface is also a virtual interface of the system. The tunnel interface provides a standard point-to-point (P2P) transmission mode, without specifying any transmission protocol or load protocol. Therefore, a tunnel interface must be configured for each individual link.

Overview

Feature	Description

Feature	Description
Interface Configuration Commands	Configures interface attributes in interface configuration mode. If you enter the interface configuration mode of a nonexistent logical interface, the interface will be created.
Interface Description and Administrative Status	Configures the description for an interface, which helps you identify the interface and remember functions of the interface. You can also configure the administrative status of the interface.
MTU	Configures the maximum transmission unit (MTU) of an interface to limit the length of a frame that can be received or sent over this interface.
Bandwidth	Configures the bandwidth of an interface.
Load Interval	Specifies the interval for load calculation of an interface.
Carrier Delay	Configures the carrier delay of an interface to adjust the delay after which the status of an interface changes from Down to Up or from Up to Down.
Link Trap Policy	Enables or disables the link trap function on an interface.
Interface Index Persistence	Enables the interface index persistence function so that the interface index remains unchanged after the device is restarted.
Routed	You can configure a physical interface on a Layer 3 device as a routed interface, which functions as the gateway interface for Layer 3 switching.
Layer 3	You can configure an aggregate interface on a Layer 3 device as a Layer 3 aggregate interface, which functions as the gateway interface for Layer 3 switching.
Interface Speed, Duplex Mode, Flow Control Mode, and Auto-negotiation Factor	You can configure the speed, duplex mode, flow control mode, and auto negotiation of an interface.
Interface Errdisable Recovery	After an interface is shut down due to a violation, you can run the **errdisable recovery** command in global configuration mode to recover all the interfaces in errdisable state and enable these interfaces.
Interface Flapping Protection	You can configure the interface flapping protection function. The system can automatically shut down the interface when flapping occurs on the interface.

1.3.1 Interface Configuration Commands

Run the **interface** command in global configuration mode to enter the interface configuration mode. You can configure interface attributes in interface configuration mode.

Working Principle

Run the **interface** command in global configuration mode to enter the interface configuration mode. If you enter the interface configuration mode of a nonexistent logical interface, the interface will be created. You can also run the **interface range** or **interface range macro** command in global configuration mode to configure the range (IDs) of interfaces. Interfaces defined in the same range must be of the same type and have the same attributes.

You can run the **no interface** command in global configuration mode to delete a specified logical interface.

↘ Interface Numbering Rules

In standalone mode, the ID of a physical interface consists of two parts: slot ID and interface ID on the slot. For example, if the slot ID of the interface is 2, and interface ID on the slot is 3, the interface ID is 2/3. In VSU or stack mode, the ID of a physical interface consists of three parts: device ID, slot ID, and interface number on the slot. For example, if the device ID is 1, slot ID of the interface is 2, and interface number of the slot is 3, the interface ID is 1/2/3.

The device ID ranges from 1 to the maximum number of supported member devices.

The slot number rules are as follows: The static slot ID is 0, whereas the ID of a dynamic slot (pluggable module or line card) ranges from 1 to the number of slots. Facing the device panel, dynamic slot are numbered from 1 sequentially from front to rear, from left to right, and from top to bottom.

The ID of an interface on the slot ranges from 1 to the number of interfaces on the slot, and is numbered sequentially from left to right.

You can select fiber or copper as the medium of a combo interface. Regardless of the medium selected, the combo interface uses the same interface ID.

The ID of an aggregate interface ranges from 1 to the number of aggregate interfaces supported by the device.

The ID of an SVI is the VID of the VLAN corresponding to this SVI.

Configuring Interfaces Within a Range

You can run the **interface range** command in global configuration mode to configure multiple interfaces at a time. Attributes configured in interface configuration mode apply to all the interfaces.

The **interface range** command can be used to specify several interface ranges.

The **macro** parameter is used to configure the macro corresponding to a range. For details, see *Configuring Macros of Interface Ranges*.

Ranges can be separated by commas (,).

Types of interfaces within all ranges specified in a command must be the same.

Pay attention to the format of the **range** parameter when you run the **interface range** command.

The following interface range formats are valid:

- **FastEthernet** device/slot/{first interface} - {last interface}
- **GigabitEthernet** device/slot/{first interface} - {last interface}
- **TenGigabitEthernet** device/slot/{first interface} - {last interface}
- **FortyGigabitEthernet** device/slot/{first interface} - {last interface}
- **AggregatePort** *Aggregate-port ID* (The aggregate interface ID ranges from 1 to the maximum number of aggregate interfaces supported by the device.)
- **vlan** vlan-ID-vlan-ID (The VLAN ID ranges from 1 to 4094.)
- **Loopback** loopback-ID (The loopback interface ID ranges from 1 to 2147483647.)
- **Tunnel** tunnel-ID (The tunnel interface ID ranges from 0 to the maximum number of tunnel interfaces supported by the device minus 1.)

Interfaces in an interface range must be of the same type, namely, FastEthernet or GigabitEthernet.

Configuring Macros of Interface Ranges

You can define macros to replace the interface ranges. Before using the **macro** parameter in the **interface range** command, first run the **define interface-range** command in global configuration mode to define these macros.

Run the **no define interface-range macro_name** command in global configuration mode to delete the configured macros.

1.3.2 Interface Description and Administrative Status

You can configure the description for an interface to identify the interface, which helps you remember functions of the interface.

You can enter interface configuration mode to enable or disable an interface.

Working Principle

Interface Description

You can configure the description of an interface based on the purpose of the interface. For example, if you want to assign GigabitEthernet 0/1 for user A exclusively, you can configure the description of the interface as "Port for User A."

Interface Administrative Status

You can configure the administrative status of an interface to disable the interface as required. If the interface is disabled, no frame will be received or sent on this interface. You can enable a disabled interface by configuring the administrative status of the interface. Two types of interface administrative status are defined: Up and Down. The administrative status of an interface is Down when the interface is disabled, and Up when the interface is enabled.

1.3.3 MTU

You can configure the MTU of an interface to limit the length of a frame that can be received or sent over this interface.

On some devices, the MTU cannot be configured on an interface but can be configured globally.

Working Principle

When a large amount of data is exchanged over a interface, frames whose length is greater than that of standard Ethernet frames may exist. This type of frame is called jumbo frame. The MTU is the length of a valid data segment in a frame. It does not include the Ethernet encapsulation overhead.

If an interface receives or sends a frame with a length greater than its MTU, the frame will be discarded.

1.3.4 Bandwidth

Working Principle

The **bandwidth** command is mainly used by a routing protocol (for example, OSPF) to calculate the route metric and the Resource Reservation Protocol (RSVP) to calculate the reserved bandwidth. Changing the interface bandwidth will not affect the data transmission rate of the physical interface.

1.3.5 Load Interval

Working Principle

You can run the **load-interval** command to specify the interval for load calculation of an interface. Typically, the interval is 10s.

1.3.6 Carrier Delay

Working Principle

The carrier delay refers to the delay after which the data carrier detect (DCD) signal changes from Down to Up or from Up to Down. If the DCD status changes during the delay, the system will ignore this change to avoid negotiation at the upper data link layer. If a large carrier delay is used, nearly every DCD change is not detected. On the contrary, if the carrier delay is set to 0, every DCD signal change will be detected, resulting in poor stability.

If the DCD carrier is interrupted for a long time, a small carrier delay should be used to accelerate convergence of the topology or route. On the contrary, if the DCD carrier interruption time is shorter than the topology or route convergence time, a large carrier delay should be used to avoid topology or route flapping.

1.3.7 Link Trap Policy

You can enable or disable the link trap function on an interface.

Working Principle

When the link trap function on an interface is enabled, the Simple Network Management Protocol (SNMP) sends link traps when the link status changes on the interface.

1.3.8 Interface Index Persistence

Similar to an interface description, the interface index also identifies an interface. When an interface is created, the system automatically assigns a unique index to the interface. The index of an interface may change after the device is restarted. You can enable the interface index persistence function so that the interface index remains unchanged after the device is restarted.

Working Principle

On the device enabled with interface index persistence, the interface index remains unchanged after the device is restarted.

1.3.9 Routed Interface

Working Principle

A physical interface on a Layer 3 device can be configured as a routed interface, which functions as the gateway interface for Layer 3 switching. The routed interface cannot be used for Layer 2 switching. You can run the **no switchport** command to change a switch interface to a routed interface and assign an IP address to this interface for routing. Running the **no switchport** command will delete all Layer 2 features of the interface.

1.3.10 Layer 3 Aggregate Interface

Working Principle

Similar to a Layer 3 routed interface, you can run the **no switchport** command to change a Layer 2 aggregate interface into a Layer 3 aggregate interface on a Layer 3 device, and then assign an IP address to this aggregate interface for routing. Running the **no switchport** command will delete all Layer 2 features of the aggregate interface.

A Layer 2 aggregate interface with one or more member interfaces cannot be configured as a Layer 3 aggregate interface. Similarly, a Layer 3 aggregate interface with one or more member interfaces cannot be changed to a Layer 2 aggregate interface.

1.3.11 Interface Speed, Duplex Mode, Flow Control Mode, and Auto-negotiation Factor

You can configure the interface speed, duplex mode, flow control mode, and auto-negotiation factor of an Ethernet physical interface or aggregate interface**.**

Working Principle

Speed

Typically, the speed of an Ethernet physical interface is determined through negotiation with the peer device. The negotiated speed can be any speed within the interface capability. You can also configure any speed within the interface capability for the Ethernet physical interface.

When you configure the speed of an aggregate interface, the configuration takes effect on all of its member interfaces. (All these member interfaces are Ethernet physical interfaces.)

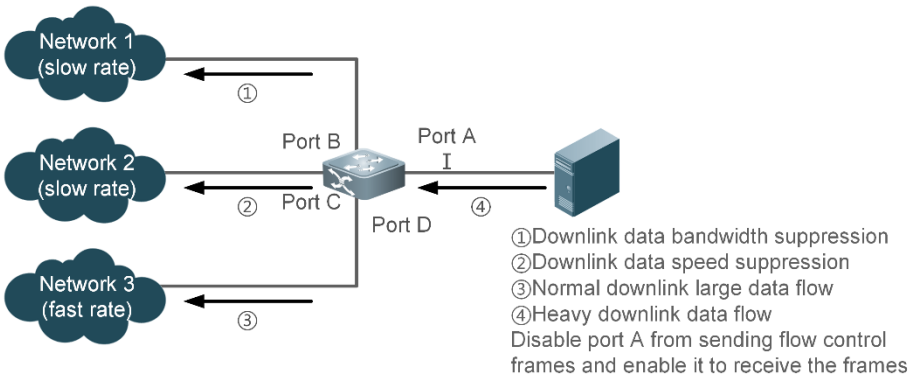
Duplex Mode

The duplex mode of an Ethernet physical interface or aggregate interface can be configured as follows:

- Set the duplex mode of the interface to full-duplex so that the interface can receive packets while sending packets.
- Set the duplex mode of the interface to half-duplex so that the interface can receive or send packets at a time.
- Set the duplex mode of the interface to auto-negotiation so that the duplex mode of the interface is determined through auto negotiation between the local interface and peer interface.

When you configure the duplex mode of an aggregate interface, the configuration takes effect on all of its member interfaces. (All these member interfaces are Ethernet physical interfaces.)

Flow Control



Flow control on an interface is performed in asymmetric or symmetrical mode:

- Symmetric mode: After flow control is enabled on an interface, the interface processes the received flow control frames, and sends flow control frames when the interface is congested. The incoming and outgoing flow control frames are processed in the same way.
- Asymmetric mode: In some cases, an interface on a device is expected to process the received flow control frames without packet loss due to congestion, and expected not to send flow control frames to avoid network speed decrease. In this case, you need to configure the asymmetric mode in which incoming and outgoing flow control frames are processed separately.

When you configure the flow control mode of an aggregate interface, the configuration takes effect on all of its member interfaces. (All these member interfaces are Ethernet physical interfaces.)

As shown in Figure 1-4, port A of the device is an uplink interface, ports B, C, and D are downlink interfaces, and port B and port C are connected to different networks. Assume that port A is enabled to send and receive flow control frames. If heavy data flow is sent on port B and port C, port B and port C will be congested, and consequently congestion occurs in the inbound direction of port A. Therefore, port A sends flow control frames. When the uplink device responds to the flow control frames, it reduces the data flow sent to port A, which causes the network speed to decrease on port D. In this case, you can disable the port A from sending flow control frames to ensure the bandwidth utilization of the entire network.

Figure 1-4

Auto-negotiation Mode

The auto-negotiation mode of an interface can be **on** or **off**. The auto-negotiation status of the interface is different from the auto-negotiation mode. The auto-negotiation status of the interface depends on the interface rate, duplex mode, flow control mode, and auto-negotiation mode.

Typically, if one of the interface rate, duplex mode, and flow control mode is set to **auto**, or the auto-negotiation mode of the interface is **on**, the auto-negotiation status of the interface is **on**, that is, the auto-negotiation function of the interface is enabled. If none of the interface rate, duplex mode, and flow control mode is set to **auto**, and the auto-negotiation mode of the interface is **off**, the auto-negotiation function of the interface is disabled.

1.3.12 Interface Errdisable Recovery

Some protocols support the interface errdisable recovery function to ensure security and stability of the network. For example, when you enable port security and configure the maximum number of security addresses on the interface, an interface violation event is generated if the number of addresses learned on this interface exceeds the maximum number of security addresses. For other protocols, such as the Spanning Tree Protocol (STP), 802.1X, Rapid Ethernet Uplink Protection Protocol (REUP), and frequent interface flapping, and an interface where a violation event occurs will be automatically shut down to ensure security.

Working Principle

When a interface is disabled due to setting violation of the REUP link state tracking group, the interface can be recovered by setting scheduled REUP recovery or by running the REUP errdisable recovery command in global configuration mode. In other cases, you can run the **errdisable recovery** command in global configuration mode to recovery all the interfaces in errdisable state and enable these interfaces. You can manually recover a interface, or automatically recover a interface at a scheduled time. For some products, you can run the **shutdown** and **no shutdown** commands in interface configuration mode to recover all the interfaces in errdisable state and enable the interfaces.

1.3.13 Interface Flapping Protection

An interface flapping causes a lot of hardware interruptions, consuming many CPU resources. Moreover, frequent interface flapping damages the interface. You can configure the interface flapping protection function to protect interfaces.

Principles

By default, the interface flapping protection function is enabled. You can disable this function as required. When an interface flapping occurs, the interface detects flapping every 2s or 10s. If the interface detect

six flappings in 2s, the device displays a prompt. If the device display 10 prompts continuously, that is, the interface detects flapping continuously within 20s, the interface is shut down (the violation cause is displayed as **Link Dither**). If the interface detects 10 flaps within 10s on an interface, the device displays a prompt without shutting down the interface.

1.3.14 Interface Syslog

You can enable or disable the syslog function to determine whether to view information about interface status changes or exceptions.

Principles

You can enable or disable the syslog function as required. By default, this function is enabled. When an exception occurs on an interface, for example, the interface status changes, or the interface receives error frames, or flapping occurs, the system displays prompts to notify users.

1.4 Configuration

Configuration	Description and Command	
Performing Basic Configurations	(Optional) It is used to manage interface configurations, for example, creating or deleting an interface, or configuring the interface description.	
	interface	Creates an interface and enters the configuration mode of the created interface or a specified interface.
	interface range	Enters an interface range, creates these interfaces (if not created), and enters the interface configuration mode.
	define interface-range	Creates a macro to specify an interface range.
	snmp-server if-index persist	Enables the interface index persistence function so that the interface index remains unchanged after the device is restarted.
	description	Configures the interface description of up to 80 characters in interface configuration mode.
	snmp trap link-status	Configures whether to send link traps of the interface.
	shutdown	Shuts down an interface in interface configuration mode.
	physical-port dither protect	Configures the interface flapping protection function in global configuration mode.
	logging [**link-updown** | **error-frame** | **link-dither**]	Configures the syslog function on an interface in global configuration mode.
Configuring Interface Attributes	(Optional) It is used to configure interface attributes.	
	bandwidth	Configures the bandwidth of an interface in interface configuration mode.
	carrier-delay	Configures the carrier delay of an interface in interface configuration mode.
	load-interval	Configures the interval for load calculation of an interface.
	duplex	Configures the duplex mode of an interface.
	flowcontrol	Enables or disables flow control on an interface.
	mtu	Configures the MTU of an interface.
	speed	Configures the speed of an interface.
	switchport	Configures an interface as a Layer 2 interface in interface configuration mode. (Run the **no switchport** command to configure an interface as a Layer 3 interface.)
	errdisable recovery	Recovers an interface in errdisable state in global configuration mode or privileged EXEC mode (errdisable recovery).

1.4.1 Performing Basic Configurations

Configuration Effect

- Create a specified logical interface and enter the configuration mode of this interface, or enter the configuration mode of an existing physical or logical interface.
- Create multiple specified logical interfaces and enter the interface configuration mode, or enter the configuration mode of multiple existing physical or logical interfaces.
- The interface indexes remain unchanged after the device is restarted.
- Configure the interface description, which helps to learn information about the interface.
- Enable or disable the link trap function of an interface.
- Enable or disable an interface.

Notes

- The **no** form of the command can be used to delete a specified logical interface or logical interfaces in a specified range, but cannot be used to delete a physical interface or physical interfaces in a specified range.
- The **default** form of the command can be used in interface configuration mode to restore default settings of a specified physical or logical interface, or interfaces in a specified range.

Configuration Step

↘ Configuring a Specified Interface

- Optional.
- Run this command to create a logical interface or enter the configuration mode of a physical interface or an existing logical interface.

Command	**interface** *interface-type interface-number*
Parameter Description	*interface-type interface-number*: Indicates the type and number of the interface. The interface can be an Ethernet physical interface, aggregate interface, SVI, or loopback interface.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	● If a logical interface is not created, run this command to create this interface and enter the configuration mode of this interface. ● For a physical interface or an existing logical interface, run this command to enter the configuration mode of this interface. ● Use the **no** form of the command to delete a specified logical interface. ● Use the **default** form of the command to restore default settings of the interface in interface configuration mode.

↘ Configuring Interfaces Within a Range

- Optional.
- Run this command to create multiple logical interfaces or enter the configuration mode of multiple physical interface or existing logical interfaces.

Command	**interface range** { *port-range* | **macro** *macro_name* }
Parameter Description	*port-range*: Indicates the type and ID range of interfaces. These interfaces can be Ethernet physical interfaces, aggregate interfaces, SVIs, or loopback interfaces. *macro_name*: Indicates the name of the interface range macro.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	● If logical interfaces are not created yet, run this command to create these interfaces and enter the interface configuration mode. ● For multiple physical interfaces or existing logical interfaces, run this command to enter the interface configuration mode. ● Use the **default** form of the command to restore default settings of these

	interfaces in interface configuration mode. ● Before using a macro, run the **define interface-range** command to define the interface range as a macro name in global configuration mode, and then run the **interface range macro** *macro_name* command to apply the macro.

Configuring Interface Index Persistence

- Optional.
- Run this command when the interface indexes must remain unchanged after the device is restarted.

Command	**snmp-server if-index persist**
Parameter Description	N/A
Defaults	By default, interface index persistence is disabled.
Command Mode	Global configuration mode
Usage Guide	After this command is executed, current indexes of all interfaces will be saved, and the indexes remain unchanged after the device is restarted. You can use the **no** or **default** form of the command to disable the interface index persistence function.

Configuring the Description of an Interface

- Optional.
- Run this command to configure the description of an interface.

Command	**description** *string*
Parameter Description	*string:* Indicates a string of up to 80 characters.
Defaults	By default, no description is configured.
Command Mode	Interface configuration mode
Usage Guide	This command is used to configure the description of an interface. You can use the **no** or **default** form of the command to delete the description of an interface.

Configuring the Link Trap Function of an Interface

- Optional.
- Run this command to obtain link traps through SNMP.

Command	**snmp trap link-status**
Parameter Description	N/A
Defaults	By default, the link trap function is enabled.
Command Mode	Interface configuration mode
Usage Guide	This command is used to configure the link trap function on an interface. When this function is enabled, the SNMP-enabled device sends link traps when the link status changes on the interface. You can use the **no** or **default** form of the command to disable the link trap function.

Configuring the Administrative Status of an Interface

- Optional.
- Run this command to enable or disable an interface.
- An interface that is disabled cannot send or receive packets.

Command	**Shutdown**
Parameter Description	N/A
Defaults	By default, the administrative status of an interface is Up.
Command Mode	Interface configuration mode
Usage Guide	You can run the **shutdown** command to disable an interface, or the **no shutdown** command to enable an interface. You can use the **no** or **default** form of the command to enable the interface. The following cases may occur for different devices: ● You cannot run the **no shutdown** command on the interface in errdisable state. ● You can run the **shutdown** and **no shutdown** commands to recover the interfaces in errdisable state.

Configuring Interface Flapping Protection

- Optional.
- Run this command to protect the interface where flapping occurs.

Command	physical-port dither protect
Parameter Description	N/A
Defaults	By default, interface flapping protection is enabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Syslog Function

- Optional.
- Run this command to enable or disable the syslog function on an interface.

Command	[no] logging [link-updown | error-frame | link-dither]
Parameter Description	**link-updown**: Logs status change information. **error-frame**: Logs error frame information. **link-dither**: Logs interface flapping information.
Defaults	By default, the syslog function is enabled on an interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Configuring a Specified Interface

- Run the **interface** command. If you can enter the interface configuration mode, the configuration is successful.
- For a logical interface, after the **no interface** command is executed, run the **show running** or **show interfaces** command to check whether the logical interface exists. If not, the logical interface is deleted.
- After the **default interface** command is executed, run the **show running** command to check whether the default settings of the corresponding interface are restored. If so, the operation is successful.

Configuring Interfaces Within a Range

- Run the **interface range** command. If you can enter the interface configuration mode, the configuration is successful.
- After the **default interface range** command is executed, run the **show running** command to check whether the default settings of the corresponding interfaces are restored. If so, the operation is successful.

Configuring Interface Index Persistence

- After the **snmp-server if-index persist** command is executed, run the **write** command to save the configuration, restart the device, and run the **show interface** command to check the interface index. If the index of an interface remains the same after the restart, interface index persistence is enabled.

Configuring the Link Trap Function of an Interface

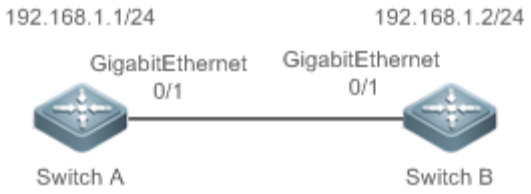
- Remove and then install the network cable on a physical interface, and enable the SNMP server. If the SNMP server receives link traps, the link trap function is enabled.
- Run the **no** form of the **snmp trap link-status** command. Remove and then install the network cable on a physical interface. If the SNMP server does not receive link traps, the link trap function is disabled.

Configuring the Administrative Status of an Interface

- Insert the network cable on a physical interface, enable the interface, and run the **shutdown** command on this interface. If the syslog is displayed on the console indicating that the interface goes Down, and the LED on the interface is off, the interface is disabled. Run the **show interfaces** command, and verify that the interface status changes to Administratively Down. Then run the **no**

shutdown command to enable the interface. If the syslog is displayed on the console indicating that the interface goes Up, and the LED on the interface is on, the interface is enabled.

Configuring Interface Flapping Protection



- Run the **physical-port dither protect** command in global configuration mode. Frequently remove and install the network cable on a physical interface to simulate interface flapping. Verify that a syslog indicating interface flapping is displayed on the console. After such a syslog is displayed for several times, the system displays a message indicating that the interface will be shut down. Run the **physical-port dither period** command in global configuration mode to configure parameters of flapping detection, such as the detection period, threshold for triggering flappings, and the number of consecutive periods for triggering violations.

Configuring the Syslog Function

- Run the **logging link-updown** command in global configuration mode to display interface status information. Remove and then install the network cable on a physical interface. The interface status will change twice. Verify that information is displayed on the console, indicating that the interface state changes from Up to Down, and then from Down to Up. Run the **no logging link-updown** command. Remove and then install the network cable. Verify that related information is no longer displayed on the console. This indicates that the syslog function is normal.

Configuration Example

Configuring Basic Attributes of Interfaces

Scenario Figure 1-1	
Configuration Steps	● Connect two devices through the switch interfaces. ● Configure an SVI on two devices respectively, and assign IP addresses from the same network segment to the two SVIs. ● Enable interface index persistence on the two devices. ● Enable the link trap function on the two devices. ● Configure the interface administrative status on the two devices.

A	`A# configure terminal`
	`A(config)# snmp-server if-index persist`
	`A(config)# interface vlan 1`
	`A(config-if-VLAN 1)# ip address 192.168.1.1 255.255.255.0`
	`A(config-if-VLAN 1)# exit`
	`A(config)# interface gigabitethernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# snmp trap link-status`
	`A(config-if-GigabitEthernet 0/1)# shutdown`
	`A(config-if-GigabitEthernet 0/1)# end`
	`A# write`

B	`B# configure terminal`
	`B(config)# snmp-server if-index persist`
	`B(config)# interface vlan 1`
	`B(config-if-VLAN 1)# ip address 192.168.1.2 255.255.255.0`
	`B(config-if-VLAN 1)# exit`
	`B(config)# interface gigabitethernet 0/1`
	`B(config-if-GigabitEthernet 0/1)# snmp trap link-status`

	B(config-if-GigabitEthernet 0/1)# shutdown B(config-if-GigabitEthernet 0/1)# end B# write
Verification	Perform verification on Switch A and Switch B as follows: ● Run the **shutdown** command on GigabitEthernet 0/1, and check whether GigabitEthernet 0/1 and SVI 1 are Down. ● Run the **shutdown** command on GigabitEthernet 0/1, and check whether a trap indicating that this interface is Down is sent. ● Restart the device, and check whether the index of GigabitEthernet 0/1 is the same as that before the restart.

1.4.2 Configuring Interface Attributes

Configuration Effect

- Enable the device to connect and communicate with other devices through the switch interface or routed interface.
- Adjust interface attributes on the device.

Configuration Step

↘ Configuring a Routed Interface

- Optional.
- Run this command to configure an interface as a Layer 3 routed interface.

- After an interface is configured as a Layer 3 routed interface, Layer 2 protocols running on the interface do not take effect.
- This command is applicable to a Layer 2 switch interface.

Command	**no switchport**
Parameter Description	N/A
Defaults	By default, an Ethernet physical interface is a Layer 2 switch interface.
Command Mode	Interface configuration mode
Usage Guide	On a Layer 3 device, you can run this command to configure a Layer 2 switch interface as a Layer 3 routed interface. You can run the **switchport** command to change a Layer 3 routed interface into a Layer 2 switch interface.

Configuring a Layer 3 Aggregate Interface

- Optional.
- Run the **no switchport** command in interface configuration mode to configure a Layer 2 aggregate interface as a Layer 3 aggregate interface. Run the **switchport** command to configure a Layer 3 aggregate interface as a Layer 2 aggregate interface.
- After an interface is configured as a Layer 3 routed interface, Layer 2 protocols running on the interface do not take effect.
- This command is applicable to a Layer 2 aggregate interface.

Command	**no switchport**
Parameter Description	N/A
Defaults	By default, an aggregate interface is a Layer 2 aggregate interface.
Command Mode	Interface configuration mode
Usage Guide	After entering the configuration mode of a Layer 2 aggregate interface on a Layer 3 device, you can run this command to configure a Layer 2 aggregate interface as a Layer 3 aggregate interface. After entering the configuration mode of a Layer 3 aggregate interface, you can run the **switchport** command to change a Layer 3 aggregate interface into a Layer 2 aggregate interface.

Configuring the Speed of an Interface

- Optional.
- Interface flappings may occur if the configured speed of an interface changes.
- This command is applicable to an Ethernet physical interface or aggregate interface.
- The same speed mode must be configured on four consecutive 25 Gbps interfaces.

Command	**speed** [**10** | **100** | **1000** | **2500** | **5000** | **10G** | **auto**]
Parameter Description	**10**: Indicates that the speed of the interface is 10 Mbps. **100**: Indicates that the speed of the interface is 100 Mbps. **1000**: Indicates that the speed of the interface is 1000 Mbps. **2500**: Indicates that the speed of the interface is 2500 Mbps. **5000**: Indicates that the speed of the interface is 5000 Mbps. **10G**: Indicates that the speed of the interface is 10 Gbps. **auto**: Indicates that the speed of the interface is self-adaptative.
Defaults	By default, the speed of an interface is auto.
Command Mode	Interface configuration mode
Usage Guide	If an interface is a member interface of an aggregate interface, the speed of this interface is determined by the speed of the aggregate interface. When the interface is removed from the aggregate interface, it uses its own speed configuration. You can run **show interfaces** to display the speed configuration. The speed options available to an interface vary with the type of the interface. For example, you cannot set the speed of an SFP interface to 10 Mbps.

Configuring the Duplex Mode of an Interface

- Optional.
- Interface flappings may occur if the configured duplex mode of an interface changes.
- This command is applicable to an Ethernet physical interface or aggregate interface.

Command	**duplex** { **auto** | **full** | **half** }
Parameter Description	**auto**: Indicates automatic switching between full duplex and half duplex. **full**: Indicates full duplex. **half**: Indicates half duplex.
Defaults	By default, the duplex mode of an interface is auto.
Command Mode	Interface configuration mode
Usage Guide	The duplex mode of an interface is related to the interface type. You can run **show interfaces** to display the configuration of the duplex mode.

Configuring the Flow Control Mode of an Interface

- Optional.
- Typically, the default flow control mode of an interface is **off** by default. However, the default flow control mode is **on** for some devices.
- After the flow control mode is enabled on an interface, flow control frames will be received or sent to adjust the network data traffic in case of congestion on the interface.
- Interface flappings may occur if the configured duplex mode of an interface changes.
- This command is applicable to an Ethernet physical interface or aggregate interface.

Command	**flowcontrol** { **auto** | **off** | **on** }
Parameter Description	**auto**: Indicates auto-negotiation. **off**: Disables flow control. **on**: Enables flow control.
Defaults	By default, the flow control mode of an interface is **off**.
Command Mode	Interface configuration mode
Usage Guide	You can run the **show interfaces** command to display the flow control configuration and actual flow control information on interfaces.

Configuring the MTU of an Interface

- Optional.
- You can configure the MTU of an interface to limit the length of a frame that can be received or sent over this interface.
- This command is applicable to an Ethernet physical interface or SVI.

Command	**mtu** *num*
Parameter Description	*num*: Indicates the MTU. The value range is from 64 to 2604.
Defaults	By default, the MTU of an interface is 1500 bytes.
Command Mode	Interface configuration mode
Usage Guide	This command is used to configure the interface's MTU, that is, the maximum length of a data frame at the link layer. You can configure the MTU for only a physical interface or an aggregate interface that contains one or more member interfaces.

Configuring the Bandwidth of an Interface

- Optional.
- Typically, the bandwidth of an interface is the same as the speed of the interface.

Command	**bandwidth** *kilobits*
Parameter Description	*kilobits*: Indicates the bandwidth unit, in kilo bits. The value range is from 1 to 2147483647.
Defaults	Typically, the bandwidth of an interface matches the type of the interface. For example, the default bandwidth of a 1000M Ethernet physical interface is 1000000, and that of a 10GE Ethernet physical interface is 10000000.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Carrier Delay of an Interface

- Optional.

- If the configured carrier delay is long, it takes a long time to change the protocol status when the physical status of an interface changes. If the carrier delay is set to 0, the protocol status changes immediately after the physical status of an interface changes.

Command	**carrier-delay** *num*
Parameter Description	*num*: Indicates the carrier delay, in seconds. The value range is from 0 to 60.
Defaults	By default, the carrier delay of an interface is 2s.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Load Interval of an Interface

- Optional.
- The configured load interval affects computation of the average packet rate on an interface. If the configured load interval is short, the average packet rate can accurately reflect the changes of real-time traffic.

Command	**load-interval** *seconds*
Parameter Description	*seconds*: Indicates the load interval, in seconds. The value range is from 5 to 600.
Defaults	By default, the load interval of an interface is 10s.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring Interface Errdisable Recovery

- Optional.
- By default, an interface will be disabled and will not be recovered after a violation occurs. After interface errdisable recovery is configured, an interface in errdisable state will be recovered and enabled.

Command	**errdisable recovery** [**interval** *time*]
Parameter Description	*time*: Indicates the automatic recovery time, in seconds. The value range is from 30 to 86400.
Defaults	By default, interface errdisable recovery is disabled.
Command Mode	Global configuration mode or privileged EXEC mode (errdisable recovery)
Usage Guide	By default, an interface in errdisable state is not recovered. You can recover the interface manually or run this command to automatically recover the interface.

Verification

- Run the **show interfaces** command to display the attribute configuration of interfaces.

Command	**show interfaces** [*interface-type interface-number*] [**description | switchport | trunk**]
Parameter Description	*interface-type interface-number*: Indicates the type and number of an interface. **description**: Indicates the interface description, including the link status. **switchport**: Indicates Layer 2 interface information. This parameter is valid only for a Layer 2 interface. **trunk**: Indicates trunk interface information. This parameter is valid for a physical interface or an aggregate interface.
Command Mode	Privileged EXEC mode
Usage Guide	Use this command without any parameter specified to display basic interface information.

	`SwitchA#show interfaces GigabitEthernet 0/1`
	`Index(dec):1 (hex):1`
	`GigabitEthernet 0/1 is DOWN, line protocol is DOWN`
	`  Hardware is Broadcom 5464 GigabitEthernet, address is 00d0.f865.de9b (bia 00d0.f865.de9b)`
	`  Interface address is: no ip address`

```
  Interface IPv6 address is:
    No IPv6 address
  MTU 1500 bytes, BW 1000000 Kbit
  Encapsulation protocol is Ethernet-II, loopback not set
  Keepalive interval is 10 sec, set
  Carrier delay is 2 sec
  Ethernet attributes:
    Last link state change time: 2012-12-22 14:00:48
    Time duration since last link state change: 3 days, 2 hours, 50
minutes, 50 seconds
    Priority is 0
    Medium-type is Copper
    Admin duplex mode is AUTO, oper duplex is Unknown
    Admin speed is AUTO, oper speed is Unknown
    Flow receive control admin status is OFF,flow send control admin
status is OFF
    Flow receive control oper status is Unknown,flow send control oper
status is Unknown
    Storm Control: Broadcast is OFF, Multicast is OFF, Unicast is OFF
  Bridge attributes:
    Port-type: trunk
    Native vlan:1
    Allowed vlan lists:1-4094  //Allowed VLAN list of the Trunk port
    Active vlan lists:1, 3-4  //Active VLAN list (indicating that only
VLAN 1, VLAN 3, and VLAN 4 are created on the device)
  Rxload is 1/255,Txload is 1/255
  5 minutes input rate 0 bits/sec, 0 packets/sec
  5 minutes output rate 0 bits/sec, 0 packets/sec
    0 packets input, 0 bytes, 0 no buffer, 0 dropped
    Received 0 broadcasts, 0 runts, 0 giants
    0 input errors, 0 CRC, 0 frame, 0 overrun, 0 abort
    0 packets output, 0 bytes, 0 underruns, 0 dropped
    0 output errors, 0 collisions, 0 interface resets
```

- Run the **show interfaces counters rate** command to display transmission rates of interfaces.

Command	**show interfaces counters rate** [**up** | **down**]
Parameter Description	**up**: Displays transmission rates of interfaces in Up state. **down**: Displays transmission rates of interfaces in Down state.
Command Mode	Privileged EXEC mode
Usage Guide	If the interface is not specified, the transmission rates of all physical interfaces and aggregate interfaces are displayed.

Command Presentation	`Hostname#show interfaces counters rate up`
	`Interface  Sampling Time  Input Rate  Input Rate  Output Rate  Output Rate`
	`(bits/sec)  (packets/sec)  (bits/sec)  (packets/sec)`
	`---------- ---------- ---------- ---------- ---------- ----------`
	`Te1/21  5 seconds  0  0  762  0`
	`Te1/22  5 seconds  0  0  212  0`
	`Te1/23  5 seconds  511546  999  762  0`
	`Te1/24  5 seconds  0  0  762  0`
	`Te8/1  5 seconds  0  0  546946  1004`
	`Ag4  5 seconds  0  0  834  0`

Sampling Time	Sampling time.
Input Rate	Receiving rate
Output Rate	Sending Rate

- Run the **show interfaces brief** command to display Ethernet information about interfaces.

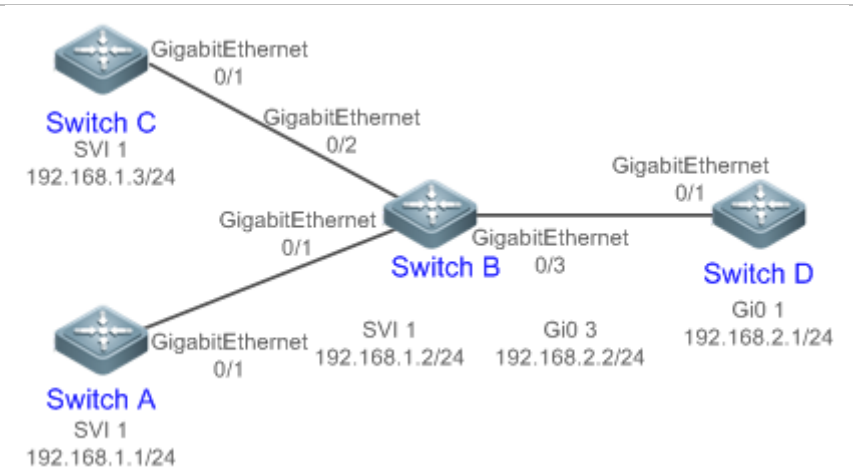
Command	**show interfaces** [*interface-type interface-number*] **ethernet brief** [**up** | **down**]
Parameter Description	*interface-type interface-number*: Displays Ethernet information about the specified interface. **up**: Displays Ethernet information of interfaces in Up state. The parameter is available only when no interface is specified. **down**: Displays Ethernet information of interfaces in Down state. The parameter is available only when no interface is specified.
Command Mode	Privileged EXEC mode
Usage Guide	Run this command to display brief information about all physical and aggregate interfaces, including the link status, VLANs, auto-negotiation mode, duplex mode, interface rates and bandwidth usage, and description (alias).

1. Display brief information about GigabitEthernet 0/1.

```
Hostname#show interfaces GigabitEthernet 0/1 brief
down: link down
*down: administratively down
disabled: err-disabled(Please reference to command [show interface status
err-disabled] for detail.)
Interface  Link Stat  Vlan  Auto-Neg  Duplex   Speed    Input Usage  Output
Usage   Description
---------  ---------  ----  --------  -------  -------  -----------
-------------  -----------
Gi0/1      down      1     OFF       Unknown  Unknown  0.00%        0.00%
10G port
```

Link Stat	Link status
Vlan	VLAN
Auto-Neg	Auto-negotiation mode
Duplex	Duplex mode
Speed	Interface rate
InputUsage	Input bandwidth usage
OutputUsage	Output bandwidth usage
Description	Description (alias)

2. Display brief information about all connected interfaces.



```
Hostname#show interfaces ethernet brief up
down: link down
*down: administratively down
disabled: err-disabled(Please reference to command [show interface status
err-disabled] for detail.)
Interface  Link Stat  Vlan  Auto-Neg  Duplex   Speed    Input Usage  Output
Usage   Description

Configuration Example

Configuring Interface Attributes

Scenario Figure 1-5	
Configuration Steps	● On Switch A, configure GigabitEthernet 0/1 as an access interface, and use default VLAN 1. Assign an IP address to SVI 1 and create a route to Switch D. ● On Switch B, configure GigabitEthernet 0/1 and GigabitEthernet 0/2 as trunk interfaces, and use default VLAN 1. Assign an IP address to SVI 1. Configure GigabitEthernet 0/3 as a routed interface, and assign an IP address from another network segment to this interface. ● On Switch C, configure GigabitEthernet 0/1 as an access interface, and use default VLAN 1. Assign an IP address to SVI 1. ● On Switch D, configure GigabitEthernet 0/1 as a routed interface, assign an IP address to this interface, and create a route to Switch A.

A	`A# configure terminal`
	`A(config)# interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# switchport mode access`
	`A(config-if-GigabitEthernet 0/1)# switchport access vlan 1`
	`A(config-if-GigabitEthernet 0/1)# exit`
	`A(config)# interface vlan 1`
	`A(config-if-VLAN 1)# ip address 192.168.1.1 255.255.255.0`
	`A(config-if-VLAN 1)# exit`
	`A(config)# ip route 192.168.2.0 255.255.255.0 VLAN 1 192.168.1.2`

B	`B# configure terminal`
	`B(config)# interface GigabitEthernet 0/1`
	`B(config-if-GigabitEthernet 0/1)# switchport mode trunk`
	`B(config-if-GigabitEthernet 0/1)# exit`

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear counters [*interface-type interface-number*]	Clears the counters of a specified interface.
clear interface *interface-type interface-number*	Resets the interface hardware.

Displaying

Displaying the Interface Configuration and Status

Command	Description
show interfaces [*interface-type interface-number*]	Displays all the status and configuration of a specified interface.
show interfaces [*interface-type interface-number*] **status**	Displays the interface status.
show interfaces [*interface-type interface-number*] **status err-disable**	Displays the interface errdisable status.
show interfaces [*interface-type interface-number*] **link-state-change statistics**	Displays the link status change time and count of a specified interface.
show interfaces [*interface-type interface-number*] **switchport**	Displays the administrative and operational states of switch interfaces (non-routed interfaces).
show interfaces [*interface-type interface-number*] **description** [**up** | **down**]	Displays the description and status of a specified interface.
show interfaces [*interface-type interface-number*] **counters** [**up | down**]	Displays the counters of a specified interface, among which the displayed speed may have an error of ±0.5%.
show interfaces [*interface-type interface-number*] **counters increment** [**up** | **down**]	Displays the number of packets increased in a load interval.
show interfaces [*interface-type interface-number*] **counters error** [**up** | **down**] [**nozero**]	Displays statistics about error packets.
show interfaces [*interface-type interface-number*] **counters rate** [**up | down**] **nozero**]	Displays the packet sending or receiving rate of an interface.

Command	Description
show interfaces [*interface-type interface-number*] **counters summary** [**up** | **down**] [**nozero**]	Displays a summary of interface information.
show interfaces [*interface-type interface-number*] **counters drops** [**up** | **down**]	Displays statistics on discarded packets on an interface.
show interfaces [*interface-type interface-number*] **usage** [**up** | **down**]	Displays the bandwidth usage of an interface.
show interfaces [*interface-type interface-number*] **brief** [**up** | **down**]	Displays brief information about an interface, including the interface status, transmit bandwidth usage, receive bandwidth usage, and numbers of transmitted and received error packets.
show interfaces [*interface-type interface-number*] **ethernet brief** [**up** | **down**] **usage**	Displays brief Ethernet information of an interface, including the link status, VLAN, auto-negotiation mode, duplex mode, interface rates and bandwidth usage, and description (alias). Displays the bandwidth usage of an interface.

1 Configuring Aggregate Interface

1.1 Overview

An aggregate interface is used to bundle multiple physical links into one logical link to increase the link bandwidth and improve connection reliability.

An aggregate interface supports load balancing, namely, distributes load evenly among member links. Besides, an aggregate interface realizes link backup. When a member link of the aggregate interface is disconnected, the load carried by the link is automatically allocated to other functional member links. A member link does not forward broadcast or multicast packets to other member links.

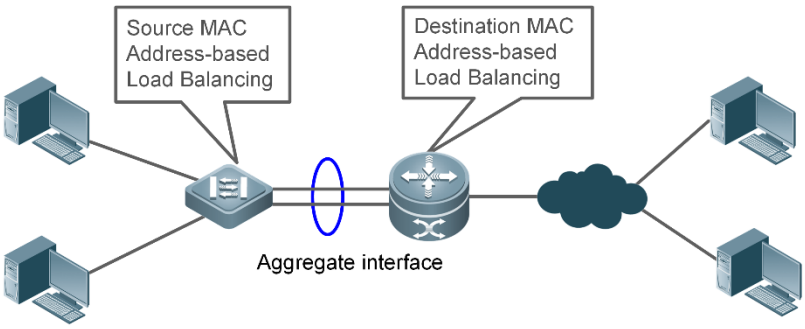
For example, the link between two devices supports a maximum bandwidth of 1000 Mbps. When service traffic carried by the link exceeds 1000 Mbps, excess traffic will be discarded. Interface aggregation can be used to solve the problem. For example, you can connect the two devices with network cables and combine multiple links to form a logical link with the bandwidth of *N* multiplied by 1000 Mbps, where *N* refers to the number of links.

For example, there are two devices connected by a network cable. When the link between the two interfaces of the devices is disconnected, services carried by the link will be interrupted. After the connected interfaces are aggregated, the services will not be affected as long as one link remains connected.

Protocols and Standards

IEEE 802.3ad

1.2 Applications



Applications	Description
Link Aggregation and Load Balancing	A large number of packets are transmitted between an aggregation device and a core device, which requires higher bandwidth. To meet this requirement, you can bundle the physical links between the devices into one logical link to increase the link bandwidth, and configure a proper load balancing algorithm to distribute the work load evenly to each physical link, thus improving bandwidth utilization.

1.2.1 Link Aggregation and Load Balancing of the Aggregate Interface

Scenario

In Figure 1-1, the switch communicates with the router through an aggregate interface. All the devices on the intranet (such as the two PCs on the left) use the router as a gateway. All the devices on the extranet (such as the two PCs on the right) send packets to the internet devices through the router, with the gateway's MAC address as its source MAC address. To distribute the load between the router and other hosts to other links, configure destination MAC address-based load balancing. On the switch, configure source MAC address-based load balancing.

Figure 1-1 Link Aggregation and Load Balancing of the Aggregate Interface

Deployment

- Configure the directly connected interfaces between the switch and router to form an aggregate interface in static or Link Aggregation Control Protocol (LACP) mode.
- On the switch, configure a source MAC address-based load balancing algorithm.
- On the router, configure a destination MAC address-based load balancing algorithm.

1.3 Features

Basic Concepts

Static Aggregate Interface

In static mode, physical interfaces are directly added to an aggregate interface through manual configuration and can forward packets when their link status and protocol status are Up.

An aggregate interface in static mode is called a static aggregate interface, and its member interfaces are called static member interfaces.

LACP

LACP enables the local device to exchange information with the connected device through LACP data units (LACPDUs).

An aggregate interface in LACP mode is called an LACP aggregate interface, and its member interfaces are called LACP member interfaces.

AP Member Port Mode

There are three aggregation modes available, namely, active, passive, and static.

AP member interfaces in active mode initiate LACP negotiation. AP member interfaces in passive mode only respond to received LACPDUs. AP member interfaces in static mode do not send LACPDUs for negotiation. The following table lists the requirements for peer interface mode.

Local Interface Mode	Remote Interface Mode
Active mode	Active or passive mode
Passive mode	Active mode
Static mode	Static mode

Member Interface Status

A static member interface has the following states:

- When a member interface is Down, the interface cannot forward packets. The Down state is displayed.
- When a member interface is Up and the link protocol is ready, the interface can forward packets. The Up state is displayed.

An LACP member interface has the following states:

- When the link of an interface is Down, the interface cannot forward packets. The Down state is displayed.
- When the link of an interface is Up and the interface is added to an aggregation group, the bndl state is displayed.
- When the link of an interface is Up but the interface is suspended because the peer end is not enabled with LACP or the attributes of the interface are inconsistent with those of the active interface, the susp state is displayed. (The interface in susp state does not forward packets.)

Only full-duplex interfaces support LACP aggregation.

LACP aggregation can be implemented only when the rates, flow control status, medium types, and Layer 2 or Layer 3 attributes of member interfaces are consistent.

If you change the preceding attributes of a member interface in the aggregation group, LACP aggregation will fail.

The interfaces which are prohibited from joining or exiting an aggregate interface cannot be added to or removed from a static aggregate interface or an LACP aggregate interface.

LACP System ID

One device can be configured with only one LACP aggregation system. The system is identified by a system ID and each system has a priority, which is a configurable value. The system ID consists of the LACP system priority and MAC address of the device. A lower system priority indicates a higher priority of the system ID. If the system priorities are the same, a smaller MAC address of the device indicates a higher priority of the system ID. The system with the system ID of a higher priority determines the interface status. The interface status of a system with an ID of a lower priority keeps consistent with that of a higher priority.

LACP Interface ID

Each interface has an independent LACP interface priority, which is a configurable value. The interface ID consists of the LACP interface priority and interface number. A smaller interface priority indicates a higher priority of the interface ID. If the interface priorities are the same, a smaller interface number indicates a higher priority of the interface ID.

LACP Active Interface

When dynamic member interfaces are Up, LACP selects one of those interfaces to be the active interface based on the rates and duplex modes, ID priorities of the interfaces in the aggregation group, and bundling status of the member interfaces in Up state. Only the interfaces that have the same attributes as the active interface are in bundle state and participate in data forwarding. When the attributes of interfaces are changed, LACP reselects an active interface.

Overview

Overview	Description

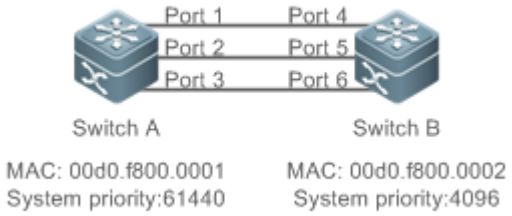
Link Aggregation	Aggregates physical links statically or dynamically to increase link bandwidth and achieves link backup.
Load Balancing	Balances the load within an aggregation group flexibly by using different load balancing methods.

1.3.1 Link Aggregation

Working Principle

There are two link aggregation modes: static and LACP modes.

- Static Mode



The static aggregate interface configuration is simple. You only need to add the specified physical interface to the aggregate interface through a command. After joining the aggregation group, a member interface can receive and transmit data and participate in load balancing.

- LACP Mode

An LACP-enabled interface sends LACPDUs to advertise its system priority, system MAC address, interface priority, interface number, and operation key. When receiving the LACPDU from the peer end, the device compares the system priorities of both ends based on the system ID in the LACPDU. The end with a higher system ID priority sets the interfaces in the aggregation group to bundle state based on the interface ID priorities in descending order, and sends an updated LACPDU. When receiving the LACPDU, the peer end sets corresponding interfaces to bundle state so that both ends maintain consistency when an interface is removed from or added to the aggregation group. The physical link can forward packets only after the interfaces at both ends are bundled dynamically.

After link aggregation, LACP member interfaces periodically exchange LACPDUs. When an interface does not receive an LACPDU in a given period of time, timeout occurs and the links are unbundled. In this case, the member interfaces cannot forward packets. There are two timeout modes: long and short timeout. In long timeout mode, an interface sends an LACPDU every 30s. If it does not receive an LACPDU from the peer end in 90s, timeout occurs. In short timeout mode, an interface sends an LACPDU every 1s. If it does not receive an LACPDU from the peer end in 3s, timeout occurs.

Figure 1-2 LACP Negotiation

In Figure 1-2, Switch A is connected to Switch B through three interfaces. System priorities of Switch A and Switch B are set to 61440 and 4096 respectively. LACP is enabled on ports 1–6, the aggregation mode of the three interfaces are set to the active mode, and the interface priority is set to the default value 32768.

When receiving an LACPDU from Switch A, Switch B finds that it has a higher system ID priority than Switch A (the system priority of Switch B is higher than that of Switch A). Switch B sets Port 4, Port 5, and Port 6 to bundle state based on the order of interface ID priorities (or in ascending order of interface numbers if the interface priorities are the

same). When receiving an updated LACPDU from Switch B, Switch A finds that Switch B has a higher system ID priority and has set Port 4, Port 5, and Port 6 to bundle state. Then Switch A also sets Port 1, Port 2, and Port 3 to bundle state.

1.3.2 Load Balancing

Working Principle

An aggregate interface identifies packet flows by using load balancing algorithms based on packet characteristics, such as the source and destination MAC addresses, source and destination IP addresses, and Layer 4 source and destination interface numbers. The same packet flow is transmitted by one member link, and different packet flows are evenly distributed to member links. For example, in source MAC address-based load balancing, packets are distributed to member links based on source MAC addresses of the packets. Packets with different source MAC addresses are evenly distributed to member links. Packets with the identical source MAC address are forwarded by one member link.

The device supports the following load balancing modes:

- Source or destination MAC address
- Source and destination MAC addresses
- Source or destination IP address
- Source and destination IP addresses
- Layer 4 source or destination interface number
- Layer 4 source and destination interface numbers
- Source IP address + Layer 4 source interface number
- Source IP address + Layer 4 destination interface number
- Destination IP address + Layer 4 source interface number
- Destination IP address + Layer 4 destination interface number
- Source IP address + Layer 4 source interface number + Layer 4 destination interface number
- Destination IP address + Layer 4 source interface number + Layer 4 destination interface number
- Source IP address + destination IP address + Layer 4 source interface number
- Source IP address + destination IP address + Layer 4 destination interface number
- Source IP address + destination IP address + Layer 4 source interface number + Layer 4 destination interface number

Load balancing based on IP addresses or interface numbers is applicable only to Layer 3 packets. When a device enabled with this load balancing mode receives Layer 2 packets, it automatically switches to the default load balancing method.

All the load balancing methods use a load algorithm (hash algorithm) to calculate the member links based on the input parameters of the modes. The input parameters include the source MAC address, destination MAC address, source and destination MAC addresses, source IP address, destination IP address, source and destination IP addresses, source and destination IP addresses + Layer 4 interface number, and so on. The algorithm ensures that packets with different input parameters are evenly distributed to member links. It does not indicate that these packets are always distributed to different member links. For example, in IP address-based load balancing, two

packets with different source and destination IP addresses may be distributed to the same member link through calculation.

1.4 Configuration

Configuration	Description and Command	
Configuring a Static Aggregate Interface	(Mandatory) It is used to configure link aggregation manually.	
	interface aggregateport	Creates an Ethernet aggregate interface.
	port-group	Configures static member interfaces.
Configuring an LACP Aggregate Interface	(Mandatory) It is used to configure link aggregation dynamically.	
	port-group mode	Configures LACP member interfaces.
	lacp system-priority	Configures the LACP system priority.
	lacp port-priority	Configures the interface priority.
	lacp short-timeout	Configures the short timeout mode on an interface.
Enabling LinkTrap	(Optional) It is used to enable LinkTrap.	
	snmp trap link-status	Enables LinkTrap advertisement for an aggregate interface.
	aggregateport member linktrap	Enables LinkTrap t for member interfaces.
Configuring a Load Balancing Mode	(Optional) It is used to configure a load balancing mode for an aggregated link.	
	aggregateport load-balance	Configures a load balancing algorithm for an aggregate interface or its member interfaces.
Configuring Aggregate Interface Configuration Delivery from the AC	**ap-interface wire** *portnumber* **-group** *apnumber*	Configures aggregate interface configuration delivery from the AC.

1.4.1 Configuring a Static Aggregate Interface

Configuration Effect

- Manually configure multiple physical interfaces as member interfaces of an aggregate interface to realize link aggregation.
- The bandwidth of the aggregated link is equal to the sum of bandwidth of member links.
- When a member link of the aggregate interface is disconnected, the load carried by the link is automatically allocated to other functional member links.

Notes

- Only physical interfaces can be added to an aggregate interface.
- The interfaces of different media types or interface modes cannot be added to the same aggregate interface.

- Layer 2 interfaces can be added to only a Layer 2 aggregate interface, and Layer 3 interfaces can be added to only a Layer 3 aggregate interface. The Layer 2 or Layer 3 attributes of an aggregate interface that contains member interfaces cannot be modified.
- After an interface is added to an aggregate interface, attributes of the interface are replaced by those of the aggregate interface.
- After an interface is removed from an aggregate interface, attributes of the interface are restored.

After an interface is added to an aggregate interface, attributes of the interface are consistent with those of the aggregate interface. Therefore, do not perform configuration on the member interfaces or apply configuration to a specific member interface. However, some configurations (the **shutdown** and **no shutdown** commands) can be configured on member interfaces. When you use member interfaces, check whether the function that you want to configure can take effect on a specific member interface, and perform this configuration properly.

Static aggregation has no error detection. Member interfaces are bound if links are connected, so you must ensure topology accuracy and consistency among member interfaces' negotiation attributes.

Configuration Step

Creating an Ethernet Aggregate Interface

- Mandatory.
- Perform this configuration on a device that supports the aggregate interface.

Command	**interface aggregateport** *ap-number*
Parameter Description	*ap-number*: Indicates the number of an aggregate interface. The value range is from 1 to 4.
Defaults	By default, no aggregate interface is created.
Command Mode	Global configuration mode
Usage Guide	To create an Ethernet aggregate interface, run **interfaces aggregate** in global configuration mode. To delete the specified Ethernet aggregate interface, run **no interfaces aggregateport** *ap-number* in global configuration mode.

Run **port-group** to add a physical interface to a static aggregate interface in interface configuration mode. If the aggregate interface does not exist, it will be created automatically.

Run **port-group mode** to add a physical interface to an LACP aggregate interface in interface configuration mode. If the aggregate interface does not exist, it will be created automatically.

The aggregate interface must be configured on the devices at both ends of a link and the aggregate interface mode must be the same (static or LACP mode).

Configuring Static AP Member Ports

- Mandatory.
- Perform this configuration on AP-enabled devices.

Command	**port-group** *ap-number*
Parameter	**port-group** *ap-number*: Indicates the number of an aggregate interface. The value range is from 1

Description	to 4.
Defaults	By default, no interfaces are added to any static aggregate interface.
Command Mode	Interface configuration mode of the specified Ethernet interface
Usage Guide	To add member interfaces to an aggregate interface, run **port-group** in interface configuration mode. To remove member interfaces from an aggregate interface, run **no port-group** in interface configuration mode.

The static member interfaces configured on the devices at both ends of a link must be consistent.

After a member interface is removed from the aggregate interface, the default settings of member interface are restored. The original configuration of member interfaces may be processed by different functional modules differently, so check the interface settings after a member interface is removed from an aggregate interface.

After a member interface is removed from an aggregate interface, the interface is disabled by using the **shutdown** command to avoid loops. After you confirm that the topology is normal, run **no shutdown** in interface configuration mode to enable the interface again.

Converting a Layer 2 Aggregate Interface to a Layer 3 Aggregate Interface

- Optional.
- To enable Layer 3 routing on an aggregate interface, for example, configure IP addresses or static routing entries, convert the Layer 2 aggregate interface to a Layer-3 aggregate interface and enable routing on the Layer 3 aggregate interface.
- Perform this configuration on the device that supports Layer 2 and Layer 3 features, and the aggregate interface, such as Layer 3 switches or access controllers (ACs).

Command	**no switchport**
Parameter Description	N/A
Defaults	By default, aggregate interfaces are Layer 2 aggregate interfaces.
Command Mode	Aggregate interface configuration mode
Usage Guide	The Layer 3 aggregate interface is supported by only Layer 3 devices.

The aggregate interface created on a Layer 3 device that does not support Layer 2 features is a Layer 3 aggregate interface. Otherwise, the aggregate interface is a Layer 2 aggregate interface.

Verification

- Run **show running-config** to display the configuration.
- Run **show aggregateport summary** to display the aggregate interface configuration.

Command	**show aggregateport** *aggregate-port-number* [**load-balance** | **summary**]
Parameter Description	*aggregate-port-number*: Indicates the number of an aggregate interface. **load-balance**: Displays the load balancing algorithm. **summary**: Displays the summary of each link.
Command Mode	Any mode

Usage Guide	Information about all aggregate interfaces is displayed if you do not specify the aggregate interface number.

	`Hostname# show aggregateport 1 summary`
	`AggregatePort MaxPorts SwitchPort Mode Ports`
	`------------ -------- ---------- ------`
	`-----------------------------------`
	`Ag1` `32 Enabled TRUNK` **`Gi0/1 ,Gi0/2`**

Configuration Example

Configuring a Static Aggregate Interface

Scenario **Figure 1-3**	
Configuration Steps	● Add GigabitEthernet 0/1 and GigabitEthernet 0/2 on Switch A to static aggregate interface 1. ● Add GigabitEthernet 0/1 and GigabitEthernet 0/2 on Switch B to static aggregate interface 1.

Switch A	`SwitchA# configure terminal`
	`SwitchA(config)# interface range GigabitEthernet 0/1-2`
	`SwitchA(config-if-range)# port-group 1`

Switch B	`SwitchB# configure terminal`
	`SwitchB(config)# interface range GigabitEthernet 0/1-2`
	`SwitchB(config-if-range)# port-group 1`

Verification	● Run **show aggregateport summary** to check whether aggregate interface 3 contains member interfaces GigabitEthernet 1/1 and GigabitEthernet 1/2.

Switch A	`SwitchA# show aggregateport summary`
	`AggregatePort MaxPorts SwitchPort Mode Ports`
	`------------ -------- ---------- ------ -----------------------------------`
	`Ag1` `32 Enabled ACCESS` **`Gi0/1,Gi0/2`**

Switch B	`SwitchB# show aggregateport summary`
	`AggregatePort MaxPorts SwitchPort Mode Ports`
	`------------ -------- ---------- ------ -----------------------------------`
	`Ag1` `32 Enabled ACCESS` **`Gi0/1,Gi0/2`**

1.4.2 Configuring an LACP Aggregate Interface

Configuration Effect

- Connected devices realize dynamic link aggregation through LACP auto-negotiation.

- The bandwidth of the aggregated link is equal to the sum of bandwidth of member links.
- When a member link of the aggregate interface is disconnected, the load carried by the link is automatically allocated to other functional member links.
- It takes LACP 90s to detect a link failure in long timeout mode and 3s in short timeout mode.

Notes

- After a member interface is removed from the LACP aggregate interface, the default settings of member interface are restored. The original configuration of member interfaces may be processed by different functional modules differently, so check the interface settings after a member interface is removed from an LACP aggregate interface.
- Changing the LACP system priority may cause LACP member interfaces to be disaggregated and aggregated again.
- Changing the priority of an LACP member interface may cause the other member interfaces to be disaggregated and aggregated again.

Configuration Step

Configuring LACP Member Interfaces

- Mandatory.
- Perform this configuration on the LACP-enabled device.

Command	**port-group** *key-number* **mode** { **active | passive** }
Parameter Description	*Key-number*: Indicates the management key of an aggregate interface, that is, LACP aggregate interface number. The value range is from 1 to 4. **active**: Indicates that interfaces are added to a dynamic aggregate interface actively. **passive**: Indicates that interfaces are added to a dynamic aggregate interface passively.
Defaults	By default, no physical interfaces are added to any LACP aggregate interface.
Command Mode	Physical interface configuration mode
Usage Guide	Use this command in interface configuration mode to add member interfaces to an LACP aggregate interface.

The LACP member interface configuration at both ends of a link must be consistent.

Configuring the LACP System Priority

- Optional.
- Perform this configuration when you need to adjust the system ID priority. A smaller value indicates a higher system ID priority. The device with a higher system ID priority selects an aggregate interface.
- Perform this configuration on the LACP-enabled device.

Command	**lacp system-priority** *system-priority*
Parameter Description	*system-priority*: Indicates the LACP system priority. The value range is from 0 to 65535.
Defaults	By default, the LACP system priority is 32768.
Command	Global configuration mode

Mode	
Usage Guide	Use this command in global configuration mode to configure the LACP system priority. All the dynamic member links share one LACP system priority. Changing the LACP system priority will affect all member links. To restore the default settings, run **no lacp system-priority** in interface configuration mode.

Configuring the Priority of an LACP Member Interface

- Optional.
- Perform this configuration when you need to specify the interface ID priority. A smaller value indicates a higher interface ID priority. The interface with the highest interface ID priority will be selected as the active interface.
- Perform this configuration on the LACP-enabled device.

Command	**lacp port-priority** *port-priority*
Parameter Description	*port-priority*: Indicates the priority of an LACP member interface. The value range is from 0 to 65535.
Defaults	By default, the priority of an LACP member interface is 32768.
Command Mode	Physical interface configuration mode
Usage Guide	Use this command in global configuration mode to configure the priority of an LACP member interface. To restore the settings, run **no lacp port-priority** in interface configuration mode.

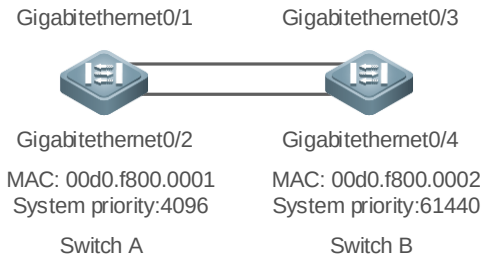
Configuring the Timeout Mode of LACP Member Interfaces

- Optional.
- To implement real-time link failure detection, configure the short timeout mode. It takes LACP 90s to detect a link failure in long timeout mode and 3s in short timeout mode.
- Perform this configuration on the LACP-enabled device, such as switch.

Command	**lacp short-timeout**
Parameter Description	N/A
Defaults	By default, the timeout mode of LACP member interfaces is long.
Command Mode	Interface configuration mode
Usage Guide	The timeout mode is supported only by physical interfaces. To restore the default settings, run **no lacp short-timeout** in interface configuration mode.

Verification

- Run **show running-config** to display the configuration.
- Run **show lacp summary** to display the LACP link status.



Command	**show lacp summary** [*key-number*]
Parameter Description	*key-name*: Indicates the number of an LACP aggregate interface.
Command	Any mode

Mode	
Usage Guide	Information about all LACP aggregate interfaces is displayed if you do not specify *key-name*.

```

1.4.3 Enabling LinkTrap

Configuration Effect

Enable the system with LinkTrap to send LinkTrap messages when aggregation links are changed.

Configuration Step

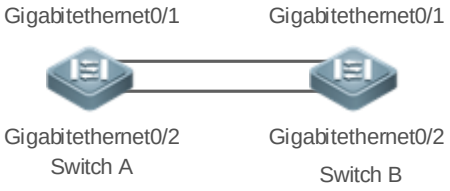
Enabling LinkTrap for an Aggregate Interface

- Optional.
- Enable LinkTrap in interface configuration mode. By default, LinkTrap is enabled. LinkTrap messages are sent when the link status or protocol status of the aggregate interface is changed.
- Perform this configuration on the AP-enabled device.

Command	**snmp trap link-status**
Parameter Description	N/A
Defaults	By default, LinkTrap is enabled.
Command Mode	Aggregate interface configuration mode
Usage Guide	Use this command in interface configuration mode to enable LinkTrap for the specified aggregate interface. After LinkTrap is enabled, LinkTrap messages are sent when the link status of the aggregate interface is changed. Otherwise, LinkTrap messages are not sent. By default, LinkTrap is enabled. To disable LinkTrap for an aggregate interface, run **no snmp trap link-status** in interface configuration mode. LinkTrap cannot be enabled for a specific member interface. To enable LinkTrap for all member interfaces, run **aggregateport member linktrap** in global configuration mode.

Enabling LinkTrap for Member Interfaces

- Optional.
- By default, LinkTrap is disabled for member interfaces.
- Perform this configuration on the AP-enabled device.



Command	**aggregateport member linktrap**
Parameter Description	N/A
Defaults	By default, LinkTrap is disabled for member interfaces.
Command Mode	Global configuration mode
Usage Guide	Use this command in global configuration mode to enable LinkTrap for all member interfaces. By default, LinkTrap messages are not sent when the link status of member interfaces is changed. To disable LinkTrap for all member interfaces, run **no aggregateport member linktrap** in global configuration mode.

Verification

- Run **show running-config** to display the configuration.
- After LinkTrap is enabled, you can monitor this feature on aggregate interfaces or their member interfaces by using the MIB software.

Configuration Example

Enabling LinkTrap for Member Interfaces

Scenario **Figure 1-5**	
Configuration Steps	● Add GigabitEthernet 0/1 and GigabitEthernet 0/2 on Switch A to static aggregate interface 1. ● Add GigabitEthernet 0/1 and GigabitEthernet 0/2 on Switch B to static aggregate interface 1. ● On Switch A, disable LinkTrap for aggregate interface 1 and enable LinkTrap for its member interfaces. ● On Switch B, disable LinkTrap for aggregate interface 1 and enable LinkTrap its AP member interfaces.

Switch A	`SwitchA# configure terminal`
	`SwitchA(config)# interface range GigabitEthernet 0/1-2`
	`SwitchA(config-if-range)# port-group 1`
	`SwitchA(config-if-range)# exit`
	`SwitchA(config)# aggregateport member linktrap`
	`SwitchA(config)# interface Aggregateport 1`
	`SwitchA(config-if-AggregatePort 3)# no snmp trap link-status`

Switch B	`SwitchB# configure terminal`
	`SwitchB(config)# interface range GigabitEthernet 0/1-2`
	`SwitchB(config-if-range)# port-group 1`
	`SwitchB(config-if-range)# exit`
	`SwitchB(config)# aggregateport member linktrap`
	`SwitchB(config)# interface Aggregateport 1`
	`SwitchB(config-if-AggregatePort 3)# no snmp trap link-status`

Verification	● Run **show running-config** to check whether LinkTrap is enabled for aggregate interface 3 and its member interfaces.
Switch A	`SwitchA# show run interface AggregatePort 1` `Building configuration...`

	Current configuration: 54 bytes interface AggregatePort 1 no snmp trap link-status SwitchA# show run | include AggregatePort aggregateport member linktrap
Switch B	SwitchB# show run interface AggregatePort 1 Building configuration... Current configuration: 54 bytes interface AggregatePort 1 no snmp trap link-status SwitchB# show run | include AggregatePort aggregateport member linktrap

1.4.4 Configuring a Load Balancing Mode

Configuration Effect

The system distributes incoming packets among member links by using the specified load balancing algorithm. The same packet flow is transmitted by one member link, whereas different packet flows are evenly distributed to various links.

Notes

N/A

Configuration Step

↘ Configuring the Global Load Balancing Algorithm of an Aggregate Interface

- Optional. Perform this configuration when you need to optimize load balancing.
- Perform this configuration on the AP-enabled device.

Command	**aggregateport load-balance** { **dst-mac** | **src-mac** | **src-dst-mac** | **dst-ip** | **src-ip** | **src-dst-ip** | **src-dst-ip-l4port** | **src-l4port** | **dst-l4port** | **src-dst-l4port** | **src-ip-src-l4port** | **src-ip-dst-l4port** | **dst-ip-src-l4port** | **dst-ip-dst-l4port** | **src-ip-src-dst-l4port** | **dst-ip-src-dst-l4port** | **src-dst-ip-src-l4port** | **src-dst-ip-dst-l4port** }
Parameter Description	**dst-mac**: Indicates that load is distributed based on the destination MAC addresses of incoming packets. **src-mac**: Indicates that load is distributed based on the source MAC addresses of incoming packets. **src-dst-ip**: Indicates that load is distributed based on source and destination IP addresses of incoming packets. **dst-ip**: Indicates that load is distributed based on the destination IP addresses of incoming packets. **src-ip**: Indicates that load is distributed based on the source IP addresses of incoming packets. **src-dst-mac**: Indicates that load is distributed based on source and destination MAC addresses of

	incoming packets. **src-dst-ip-l4port**: Indicates that load is distributed based on source IP and destination IP addresses as well as Layer-4 source and destination interface numbers. **src- l4port**: Indicates that load is distributed based on Layer 4 source interface numbers. **dst- l4port**: Indicates that load is distributed based on Layer 4 destination interface numbers. **src-dst-l4port**: Indicates that load is distributed based on Layer 4 source and destination interface numbers. **src-ip-src-l4port**: Indicates that load is distributed based on source IP addresses and Layer 4 source interface numbers. **src-ip-dst-l4port**: Indicates that load is distributed based on source IP addresses and Layer 4 destination interface numbers. **dst-ip-src-l4port**: Indicates that load is distributed based on destination IP addresses and Layer 4 source interface numbers. **dst-ip-dst-l4port**: Indicates that load is distributed based on destination IP addresses and Layer 4 destination interface numbers. **src-ip-src-dst-l4port:** Indicates that load is distributed based on source IP addresses as well as Layer 4 source and destination interface numbers. **dst-ip-src-dst-l4port**: Indicates that load is distributed based on destination IP addresses as well as Layer 4 source and destination interface numbers. **src-dst-ip-src-l4port**: Indicates that load is distributed based on source and destination IP addresses as well as Layer 4 source interface numbers. **src-dst-ip-dst-l4port**: Indicates that load is distributed based on source and destination IP addresses as well as Layer 4 destination port numbers.
Defaults	Load balancing can be based on source and destination MAC addresses or source and destination IP addresses.
Command Mode	Global configuration mode
Usage Guide	-

Verification

- Run **show running-config** to display the configuration.
- Run **show aggregateport load-balance** to display the load balancing configuration.
- Run **show aggregateport summary** to display the configuration.

Command	**show aggregateport** [*aggregate-port-number*] { **load-balance | summary** }
Parameter Description	*aggregate-port-number*: Indicates the number of an aggregate interface. **load-balance**: Displays the load balancing algorithm. **summary**: Displays the summary of each link.
Command Mode	Any mode
Usage Guide	Information about all aggregate interfaces is displayed if you do not specify the aggregate interface number.

	Hostname# show aggregateport 1 summary AggregatePort MaxPorts SwitchPort Mode Ports ---------- -------- ---------- ------ ---------- **Ag1** 32 Enabled TRUNK **Gi0/1 ,Gi0/2**

Configuration Example

Configuring a Load Balancing Mode

Scenario **Figure 1-6**	
Configuration Steps	● Add GigabitEthernet 0/1 and GigabitEthernet 0/2 on Switch A to static aggregate interface 1. ● Add GigabitEthernet 0/1 and GigabitEthernet 0/2 on Switch B to static aggregate interface 1. ● On Switch A, configure source MAC address-based load balancing for aggregate interface 1 in global configuration mode. ● On Switch B, configure destination MAC address-based load balancing for aggregate interface 1 in global configuration mode.
Switch A	SwitchA# configure terminal SwitchA(config)# interface range GigabitEthernet 0/1-2 SwitchA(config-if-range)# port-group 1 SwitchA(config-if-range)# exit SwitchA(config)# aggregateport load-balance src-mac
Switch B	SwitchB# configure terminal SwitchB(config)# interface range GigabitEthernet 0/1-2 SwitchB(config-if-range)# port-group 1 SwitchB(config-if-range)# exit SwitchB(config)# aggregateport load-balance dst-mac
Verification	● Run **show aggregateport load-balance** to display the load balancing algorithm configuration.
Switch A	SwitchA# show aggregatePort load-balance Load-balance : **Source MAC**
Switch B	SwitchB# show aggregatePort load-balance Load-balance : **Destination MAC**

1.4.5 Configuring Aggregate Interface Configuration Delivery from the AC

Configuration Effect

- After the AC delivers the aggregate interface configuration to the AP, the corresponding wired interface on the AP will be added to or removed from the corresponding aggregate interface.

Notes

- To ensure normal link aggregation, static member interfaces need to be configured consistently on the two devices of a link.
- After a member interface is added to an aggregate interface, the member interface cannot be added to other aggregate interfaces. The member interface can be added to another aggregate interface only after it is removed from the original aggregate interface.

Configuration Step

↘ Configuring Aggregate Interface Configuration Delivery from the AC

- Optional
- Perform this operation when a wired interface of a specific AP, AP group, or all APs needs to be added to the aggregate interface.

Command	**ap-interface wireport** *port-number* **port-group** *ap-number*
Parameter Description	**port-number**: Indicates the ID of the wired interface on the AP. **ap-number**: Indicates the ID of the aggregate interface.
Defaults	By default, the AC does not deliver the aggregate interface configuration.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	In AP configuration mode or AP group configuration mode, run **ap-interface wireport** *port-number* **port-group** *ap-number* to deliver the aggregate interface configuration to enable a wired interface on the AP to be added to the aggregate interface, and run **no ap-interface wireport** *port-number* **port-group** to remove a wired interface from the aggregate interface

Verification

- Run **show running-config** to display the corresponding configuration.
- Run **show aggregateport summary** to display the relationship between the aggregate interface and member interfaces.

Command	**show aggregateport summary**
Parameter Description	**ap-num**: Indicates the AP number.
Command Mode	All modes
Usage Guide	-

Command Presentation	`Hostname# show aggregateport summary`
	
	`AggregatePort MaxPorts  Ports`

	``` ------------- -------- --------------------------------- Ag1 8 Gi0/1,Gi0/2 ```

1.5 Monitoring

Displaying

Command	Description
show lacp summary [*key-number*]	Displays the LACP aggregation status. You can check information about a specific LACP aggregation group by specifying ***key*-number**.
show aggregateport { **load-balance** | [*aggregate-port-number*] **summary** }	Displays the summary or load balancing algorithm of an aggregate interface.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug lsm ap	Debugs an aggregate interface.

Configuring Ethernet Switching

1. Configuring MAC Address
2. Configuring VLAN
3. Configuring MAC VLAN
4. Configuring Super VLAN
5. Configuring VLAN Group
6. Configuring MSTP

1 Configuring MAC Address

1.1 Overview

A MAC address table contains MAC addresses, interface numbers, and VLAN IDs of the devices connected to the local device.

When a device forwards a packet, it looks up an outbound interface from its MAC address table according to the destination MAC address and VLAN ID of the packet. Then the packet is unicast, multicast, or broadcast.

This document covers dynamic, static, and filtered MAC addresses. For details about management of multicast MAC addresses, see *Configuring IGMP Snooping*.

Protocols and Standards

- IEEE 802.3: Carrier sense multiple access with collision detection (CSMA/CD) access method and physical layer specifications
- IEEE 802.1Q: Virtual Bridged Local Area Networks

1.2 Applications

Application	Description
MAC Address Learning	Forward unicast packets through MAC addresses learning.
MAC Address Change Notification	Monitor change of user devices connected to a network device through MAC address change notification.

1.2.1 MAC Address Learning

Scenario

Typically, a device maintains a MAC address table by learning MAC addresses dynamically.

As shown in Figure 1-1, the MAC address table of the device is empty. When User A communicates with User B, it sends a packet to GigabitEthernet 0/2 of the device, and the device learns the MAC address of User A and stores it in the table.

Because the table does not contain the MAC address of User B, the device broadcasts the packet to interfaces of all connected devices (User B and User C) except User A.

Figure 1-1 Step 1 of MAC Address Learning

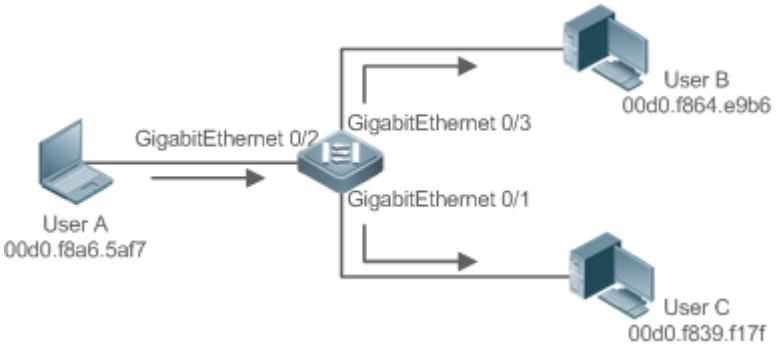


Figure 1-2 MAC Address Table 1

Status	VLAN ID	MAC Address	Interface
Dynamic	1	00d0.f8a6.5af7	GigabitEthernet 0/2

When User B receives the packet, it sends a reply packet to User A through GigabitEthernet 0/3 on the switch. Because the MAC address of User A is already in the MAC address table, the switch sends the reply unicast packet to GigabitEthernet 0/2 and learns the MAC address of User B. User C does not receive the reply packet from User B to User A.

Figure 1-3 Step 2 of MAC Address Learning

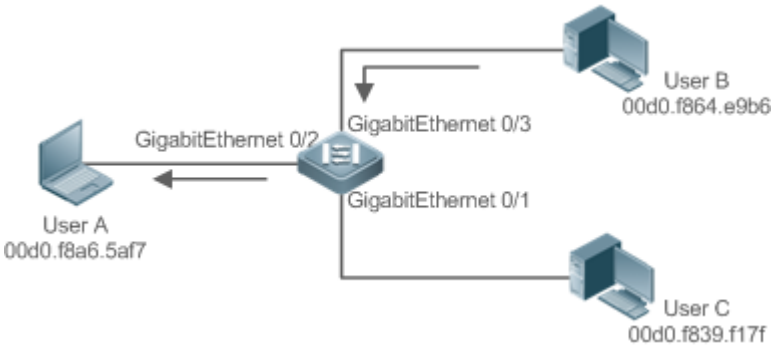

Figure 1-4 MAC Address Table 2

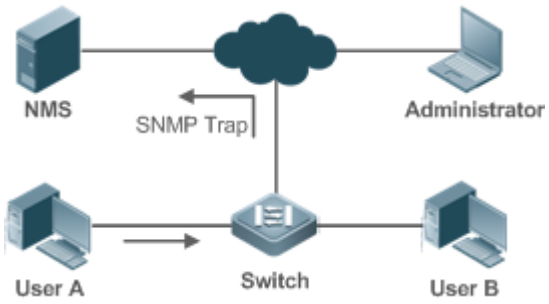
Status	VLAN ID	MAC Address	Interface
Dynamic	1	00d0.f8a6.5af7	GigabitEthernet 0/2
Dynamic	1	00d0.f8a4.e9b6	GigabitEthernet 0/3

Through interaction between User A and User B, the switch learns the MAC addresses of User A and User B. Then packets between User A and User B will be unicast without being received by User C.

Deployment



- With MAC address learning, a Layer 2 switch unicasts packets, reducing broadcast packets and network load.

1.2.2 MAC Address Change Notification

MAC address change notification provides a mechanism for the network management system (NMS) to monitor the change of user devices connected to a network device.

Scenario

Figure 1-5 MAC Address Change Notification

With MAC address change notification enabled, the device generates a notification message when the device learns a new MAC address or finishes aging a learned MAC address, and sends the message in an SNMP trap message to a specified NMS.

A notification of adding a MAC address indicates that a new user accesses a network, and a notification of deleting a MAC address indicates that a user sends no new packet within an aging time and usually the user exits the network.

When a network device is connected to a large number of devices, many MAC address changes may occur in a short time, resulting in an increase in traffic. To reduce traffic, you may configure an interval for sending MAC address change notifications. When the interval expires, all notifications generated during the interval are encapsulated into a message. When a notification is generated, it is stored in the table of historical MAC address change notifications. The administrator may know recent MAC address changes by checking the table even without the NMS.

A MAC address change notification is generated only for dynamic MAC addresses.

Deployment

- Enable MAC address change notification on a Layer 2 switch to monitor the change of devices connected to a network device.

1.3 Features

Basic Concepts

Dynamic MAC Address

A dynamic MAC address is generated through MAC address learning on a device.

Address Aging

A device only learns a limited number of MAC addresses, and inactive entries are deleted through address aging.

A device starts aging a MAC address when learning the MAC address. If the device receives no packet containing the source MAC address, it will delete the MAC address from the MAC address table when the time expires.

Unicast Forwarding

If a device finds the MAC address that matches the destination MAC address and VLAN ID of packets in its MAC address table and the outbound interface is unique, it will send the packet through the interface directly.

Broadcast Forwarding

If a device receives a packet with the destination address of ffff.ffff.ffff or no MAC address entry in the MAC address table matches the packet, it will send the packet through all the interfaces in the VLAN where the packet is from, except the inbound interface.

Features

Feature	Description
Limiting on Dynamic MAC Addresses Learned in a VLAN	Limits the number of dynamic MAC addresses in a VLAN.
Limiting on Dynamic MAC Addresses Learned on an Interface	Limits the number of dynamic MAC addresses learned on an interface.

1.3.1 Limiting on Dynamic MAC Addresses Learned in a VLAN

Working Principle

The MAC address table with a limited capacity is shared by all VLANs on the device. If a large amount of MAC addresses in the MAC address table are learned in a VLAN, MAC addresses in other VLANs cannot be learned. As a result, packets in other VLANs are broadcast. To address this issue, the device provides limiting on dynamic MAC addresses learned in a VLAN. That is, you can configure the maximum number of dynamic MAC addresses learned in a VLAN.

With this function configured, the device can only learn a limited number of dynamic MAC addresses in a VLAN. The device does not learn MAC addresses of packets exceeding the limit. Instead, the device directly forwards such packets.

You can configure the device to drop packets exceeding the limit. When the maximum number of MAC addresses learned exceeds the limit, the device stops learning MAC address and discards the packets.

- If the number of learned MAC addresses is greater than the limit, the device stops learning MAC addresses in a VLAN. The device learns MAC addresses again only when the number of MAC addresses minus the number of aged MAC addresses in the VLAN falls below the limit.
- The MAC addresses copied to a specific VLAN are not subject to the limit.

1.3.2 Limiting on Dynamic MAC Addresses Learned on an Interface

Working Principle

An interface can only learn a limited number of dynamic MAC addresses after the limit is configured. The interface does not learn MAC addresses of packets exceeding the limit. Instead, the interface directly forwards such packets.

You can configure the device to drop packets exceeding the limit. When the maximum number of MAC addresses learned exceeds the limit, the device stops learning MAC address and discards the packets.

- If the number of learned MAC addresses on an interface is greater than the limit, the device stops learning MAC addresses on the interface. The device learns MAC addresses again only when the number of MAC addresses minus the number of aged MAC addresses on the interface falls below the limit.

1.4 Configuration

Configuration	Description and Command	
Configuring a Dynamic MAC Address	⚠ (Optional) It is used to enable MAC address learning.	
	mac-address-learning	Configures MAC address learning globally or on an interface.
	mac-address-table aging-time	Configures an aging time for a dynamic MAC address.
Configuring a Static MAC Address	⚠ (Optional) It is used to bind the MAC address of a device to an interface of a switch.	
	mac-address-table static	Configures a static MAC address.
Configuring a MAC Address for Packet Filtering	⚠ (Optional) It is used to filter packets.	
	mac-address-table filtering	Configures a MAC address for packet filtering.
Configuring MAC Address Change Notification	⚠ (Optional) It is used to monitor change of user devices connected to a network device.	
	mac-address-table notification	Configures MAC address change notification globally.
	snmp trap mac-notification	Configures MAC address change notification on an interface.

1.4.1 Configuring a Dynamic MAC Address

Configuration Effect

Learn MAC addresses dynamically and forward packets in unicast mode.

Notes

- N/A

Configuration Step

↘ Configuring MAC Address Learning on Interface

- Optional.
- You can perform this configuration to disable MAC address learning on an interface.

Command	**mac-address-learning**
Parameter Description	N/A
Defaults	MAC address learning is enabled by default.
Command Mode	Interface configuration mode
Usage Guide	Perform this configuration on a Layer 2 interface, for example, a switch interface or an aggregate interface. If you run the **default interface** command in global configuration mode and Layer 2 sub-interfaces

	are configured on an interface, the default configuration of MAC address learning on the interface cannot be restored.

By default, MAC address learning is enabled. If 802.1X, IP source guard, or port security is configured on an interface, MAC address learning cannot be enabled. Access control cannot be enabled on an interface with MAC address learning disabled.

Configuring an Aging Time for a Dynamic MAC Address

- Optional.
- Configure an aging time for dynamic MAC addresses.

Command	**mac-address-table aging-time** *value*
Parameter Description	*value*: Indicates the aging time. The value is 0 or in the range from 10 to 630. 0 indicates that the MAC address aging is disabled.
Defaults	The default value is 300s.
Command Mode	Global configuration mode
Usage Guide	If the value is set to 0, MAC address aging is disabled and learned MAC addresses will not be aged.

The actual aging time may be different from the configured value, but it is not more than twice the configured value.

Verification

- Check whether a device learns dynamic MAC addresses.
- Run the **show mac-address-table dynamic** command to display dynamic MAC addresses.
- Run the **show mac-address-table aging-time** command to display the aging time of dynamic MAC addresses.

Command	**show mac-address-table dynamic** [**address** *mac-address*] [**interface** *interface-id*] [**vlan** *vlan-id*]
Parameter Description	**address** *mac-address*: Displays the information about a specific dynamic MAC address. **interface** *interface-id*: Specifies a physical interface or an aggregate interface. **vlan** *vlan-id*: Displays dynamic MAC addresses in a specific VLAN.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	N/A

```
Hostname# show mac-address-table dynamic
Vlan     MAC Address       Type        Interface
----    ------------    ------    ------------------
1    0000.0000.0001     DYNAMIC  GigabitEthernet 0/1
1    0001.960c.a740     DYNAMIC  GigabitEthernet 0/1
1    0007.95c7.dff9     DYNAMIC  GigabitEthernet 0/1
1    0007.95cf.eee0     DYNAMIC  GigabitEthernet 0/1
1    0007.95cf.f41f     DYNAMIC  GigabitEthernet 0/1
1    0009.b715.d400     DYNAMIC  GigabitEthernet 0/1
1    0050.bade.63c4     DYNAMIC  GigabitEthernet 0/1
```

Field	Description

	Vlan	VLAN where the MAC address resides.
	MAC Address	-
	Type	MAC address type
	Interface	Interface where the MAC address resides

Command	**show mac-address-table aging-time**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	N/A
	`Hostname# show mac-address-table aging-time` `Aging time: 300`

Configuration Example

Configuring a Dynamic MAC Address

Scenario Figure 1-6	
Configuration Steps	● Enable MAC address learning on an interface. ● Set the aging time for dynamic MAC addresses to 180s. ● Delete all dynamic MAC addresses in VLAN 1 on GigabitEthernet 0/1.

	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# mac-address-learning`
	`Hostname(config-if-GigabitEthernet 0/1)# exit`
	`Hostname(config)# mac aging-time 180`
	`Hostname# clear mac-address-table dynamic interface GigabitEthernet 0/1 vlan 1`

Verification	● Check MAC address learning on an interface. ● Display the aging time of dynamic MAC addresses. ● Display all dynamic MAC addresses in VLAN 1 on GigabitEthernet 0/1.

	`Hostname# show mac-address-learning`
	`GigabitEthernet 0/1 learning ability: enable`
	`Hostname# show mac aging-time`
	`Aging time : 180 seconds`
	`Hostname# show mac-address-table dynamic interface GigabitEthernet 0/1 vlan 1`
	`Vlan MAC Address Type Interface`
	`---------- -------------------- -------- -------------------`
	`1 00d0.f800.1001 STATIC GigabitEthernet 0/1`

Common Errors

Configure MAC address learning on an interface before configuring the interface as a Layer 2 interface, for example, a switch interface or aggregate interface.

1.4.2 Configuring a Static MAC Address

Configuration Effect

- Bind the MAC address of a network device to an interface of a switch.

Notes

- N/A

Configuration Step

↘ Configuring a Static MAC address

- Optional.
- Bind the MAC address of a network device to an interface of a switch.

Command	**mac-address-table static** *mac-address* **vlan** *vlan-id* **interface** *interface-id*
Parameter Description	**address** *mac-address*: Specifies a MAC address. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides. **interface** *interface-id*: Specifies a physical interface or an aggregate interface.
Defaults	By default, no static MAC address is configured.
Command Mode	Global configuration mode
Usage Guide	When the switch receives a packet containing the specified MAC address in a specified VLAN, the packet is forwarded to the bound interface.

Verification

- Run the **show mac-address-table static** command to check whether the configuration takes effect.

Command	**show mac-address-table static** [**address** *mac-address*] [**interface** *interface-id*] [**vlan** *vlan-id*]
Parameter Description	**address** *mac-address*: Specifies a MAC address. **interface** *interface-id*: Specifies a physical interface or an aggregate interface. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	N/A

	`Hostname# show mac-address-table static`
	`Vlan MAC Address Type Interface`
	`----- ----------- -------- ------------------`
	`1 00d0.f800.1001 STATIC GigabitEthernet 0/1`
	`1 00d0.f800.1002 STATIC GigabitEthernet 0/1`
	`1 00d0.f800.1003 STATIC GigabitEthernet 0/1`

Configuration Example

Configuring a Static MAC address

The following table lists the mapping between the MAC addresses, VLAN IDs, and interface numbers.

Role	MAC Address	VLAN ID	Interface Number
Web server	00d0.3232.0001	VLAN2	Gi0/10
Database server	00d0.3232.0002	VLAN2	Gi0/11
Administrator	00d0.3232.1000	VLAN2	Gi0/12

Scenario **Figure 1-7**	
Configuration Steps	● Specify the destination MAC address (*mac-address*). ● Specify the VLAN (*vlan-id*) where the MAC addresses reside. ● Specify the interface number (*interface-id*).

Device A	`Hostname# configure terminal`
	`Hostname(config)# mac-address-table static 00d0.f800.3232.0001 vlan 2 interface gigabitEthernet 0/10`
	`Hostname(config)# mac-address-table static 00d0.f800.3232.0002 vlan 2 interface gigabitEthernet 0/11`
	`Hostname(config)# mac-address-table static 00d0.f800.3232.1000 vlan 2 interface gigabitEthernet 0/12`

Verification	Display the static MAC address configuration on a device.

Device A	`Hostname# show mac-address-table static`
	`Vlan MAC Address Type Interface`
	`---------- -------------------- -------- -------------------`
	`2 00d0.f800.3232.0001 STATIC GigabitEthernet 0/10`
	`2 00d0.f800.3232.0002 STATIC GigabitEthernet 0/11`
	`2 00d0.f800.3232.1000 STATIC GigabitEthernet 0/12`

Common Errors

- Configure a static MAC address before configuring the specific interface as a Layer 2 interface, for example, a switch interface or an aggregate interface.

1.4.3 Configuring a MAC Address for Packet Filtering

Configuration Effect

- If a device receives packets containing a source MAC address or destination MAC address specified as the filtered MAC address, the packets are discarded.

Notes

- N/A

Configuration Step

Configuring a MAC Address for Packet Filtering

- Optional.
- Perform this configuration to filter packets.

Command	**mac-address-table filtering** *mac-address* **vlan** *vlan-id*
Parameter Description	**address** *mac-address*: Specifies a MAC address. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides.
Defaults	By default, no filtered MAC address is configured.
Command Mode	Global configuration mode
Usage Guide	If a device receives packets containing a source MAC address or destination MAC address specified as the filtered MAC address, the packets are discarded.

Verification

- Run the **show mac-address-table filter** command to display the filtered MAC address.

Command	**show mac-address-table filtering** [**address** *mac-address*] [**vlan** *vlan-id*]
Parameter Description	**address** *mac-address*: Specifies a MAC address. **vlan** *vlan-id*: Specifies a VLAN where the MAC address resides.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	N/A

	`Hostname# show mac-address-table filtering`
	`Vlan MAC Address Type Interface`
	`------ -------------------- -------- -----------`
	`1 0000.2222.2222 FILTER`

Configuration Example

Configuring a MAC Address for Packet Filtering

Configuration Steps	• Specify a destination MAC address (*mac-address*) for filtering. • Specify a VLAN where the MAC addresses resides.
	`Hostname# configure terminal` `Hostname(config)# mac-address-table static 00d0.f800.3232.0001 vlan 1`
Verification	Display the filtered MAC address configuration.

	`Hostname# show mac-address-table filter`
	`Vlan MAC Address Type Interface`
	`---------- -------------------- -------- -------------------`

	1 00d0.f800.3232.0001 FILTER

1.4.4 Configuring MAC Address Change Notification

Configuration Effect

- Monitor change of user devices connected to a network device.

Notes

- N/A

Configuration Step

Configuring the NMS

- Optional.
- Perform this configuration to enable an NMS to receive MAC address change notifications.

Command	**snmp-server host** *host-addr* **traps** [**version** { **1** | **2c** | **3** [**auth** | **noauth** | **priv**] }] *community-string*
Parameter Description	**host** *host-addr*: Specifies the IP address of a receiver. **version** { **1** | **2c** | **3** [**auth** | **noauth** | **priv**] }: Specifies the version of SNMP trap messages. You can also specify authentication and a security level for packets of Version 3. *community-string*: Indicates an authentication name.
Defaults	By default, the function is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling SNMP Trap

- Optional.
- Perform this configuration to send SNMP trap messages.

Command	**snmp-server enable traps**
Parameter Description	N/A
Defaults	By default, the function is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Global MAC Address Change Notification

- Optional.
- If MAC address change notification is disabled globally, it is disabled on all interfaces.

Command	**mac-address-table notification**
Parameter Description	N/A

Defaults	By default, MAC address change notification is disabled globally.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring MAC Address Change Notification on an Interface

- Optional.
- Perform this configuration to enable MAC address change notification on an interface.

Command	**snmp trap mac-notification** { **added** | **removed** }
Parameter Description	**added**: Generates a notification when an MAC address is added. **removed**: Generates a notification when an MAC address is deleted.
Defaults	By default, MAC address change notification is disabled on an interface.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Interval for Generating MAC Address Change Notifications and the Maximum Number of Entries in the Notification History Table

- Optional.
- Perform this configuration to modify the interval for generating MAC address change notifications and the maximum number of entries in the notification history table.

Command	**mac-address-table notification** { **interval** *value* | **history-size** *value* }
Parameter Description	**interval** *value*: Indicates the interval for generating MAC address change notifications, in seconds. The value range is from 1 to 3600. **history-size** *value*: Indicates the maximum number of entries in the notification history table. The value range is from 1 to 200.
Defaults	The default interval is 1 second and the default maximum number of entries in the notification history table is 50.
Command Mode	Global configuration mode
Usage Guide	N/A

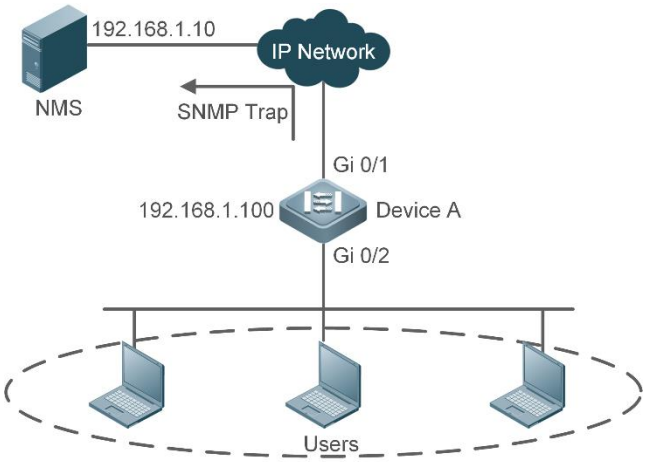
Verification

- Run the **show mac-address-table notification** command to check whether the NMS receives MAC address change notifications.

Command	**show mac-address-table notification** [**interface** [*interface-id*] | **history**]
Parameter Description	**interface**: Displays the configuration of MAC address change notification on all interfaces. *interface-id*: Displays the configuration of MAC address change notification on a specified interface. **history**: Displays the history of MAC address change notifications.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	N/A

Usage Guide

Display the configuration of global MAC address change notification.



```
Hostname#show mac-address-table notification
MAC Notification Feature : Enabled
Interval(Sec): 300
Maximum History Size : 50
Current History Size : 0
```

Field	Description
Interval(Sec)	Interval for generating MAC address change notifications
Maximum History Size	Maximum number of entries in the notification history table
Current History Size	Current number of entries in the notification history table

Configuration Example

Scenario

Figure 1-8

The figure shows an intranet of an enterprise. Users are connected to A through Gi0/2.

Perform the configuration to achieve the following effects:

- When Gi0/2 learns a new MAC address or finishes aging a learned MAC address, a MAC address change notification is generated.
- A sends the MAC address change notification in an SNMP trap message to a specified NMS.
- In a scenario where A is connected to a number of users, the configuration can prevent MAC address change notification burst in a short time so as to reduce the network load.

Configuration Steps

- Enable global MAC address change notification on A, and configure MAC address change notification on Gi0/2.
- Configure the IP address of the NMS host, and enable A to send SNMP trap messages. A communicates with the NMS through routing.
- Configure the interval for sending MAC address change notifications to 300s (1s by default).

Device A

```
Hostname# configure terminal
Hostname(config)# mac-address-table notification
Hostname(config)# interface gigabitEthernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# snmp trap mac-notification added
Hostname(config-if-GigabitEthernet 0/2)# snmp trap mac-notification removed
Hostname(config-if-GigabitEthernet 0/2)# exit
```

	Hostname(config)# snmp-server host 192.168.1.10 traps version 2c comefrom2 Hostname(config)# snmp-server enable traps Hostname(config)# mac-address-table notification interval 300
Verification	● Check whether MAC address change notification is enabled globally. ● Check whether MAC address change notification is configured on the interface. ● Display MAC addresses of interfaces, and run the **clear mac-address-table dynamic** command to simulate aging dynamic MAC addresses. ● Check whether global MAC address change notification is enabled globally. ● Display the history of MAC address change notifications.
Device A	Hostname# show mac-address-table notification MAC Notification Feature : Enabled Interval(Sec): 300 Maximum History Size : 50 Current History Size : 0 Hostname# show mac-address-table notification interface GigabitEthernet 0/2 Interface MAC Added Trap MAC Removed Trap ---------- ---------- ---------- GigabitEthernet 0/2 Enabled Enabled Hostname# show mac-address-table interface GigabitEthernet 0/2 Vlan MAC Address Type Interface ---------- ---------- -------- ---------- 1 00d0.3232.0001 DYNAMIC GigabitEthernet 0/2 Hostname# show mac-address-table notification MAC Notification Feature : Enabled Interval(Sec): 300 Maximum History Size : 50 Current History Size : 1 Hostname# show mac-address-table notification history History Index : 0 Entry Timestamp: 221683 MAC Changed Message : Operation:DEL Vlan:1 MAC Addr: 00d0.3232.0003 GigabitEthernet 0/2

Common Errors

None

1.5 Monitoring

Clearing

⚠ During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description

clear mac-address-table dynamic [**address** *mac-address*] [**interface** *interface-id*] [**vlan** *vlan-id*]	Clears dynamic MAC addresses.

Displaying

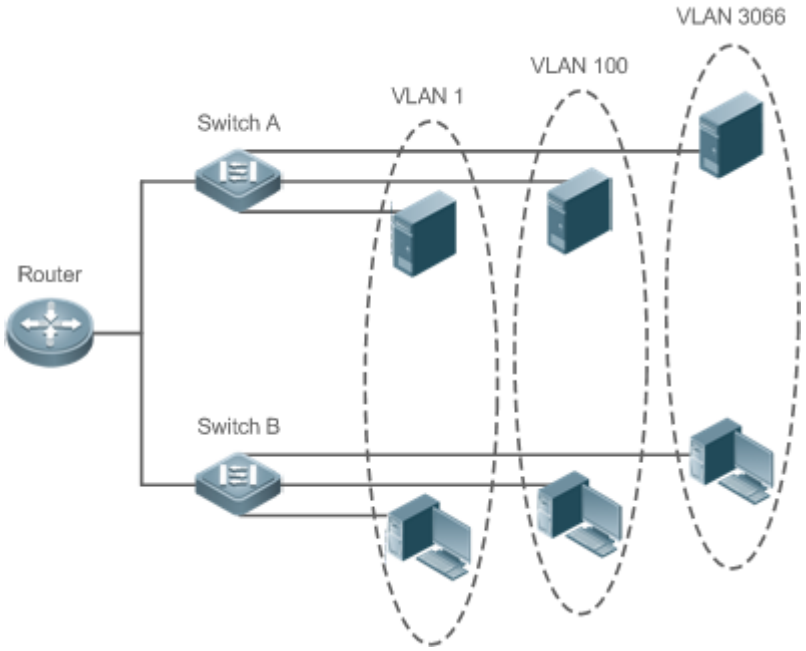
Command	Description
show mac-address-table { **dynamic** | **static** | **filter** } [**address** *mac-address*] [**interface** *interface-id*] [**vlan** *vlan-id*]	Displays the MAC address table.
show mac-address-learning	Displays MAC address learning on an interface.
show mac-address-table count [**interface** *interface-id* | **vlan** *vlan-id*]	Displays the number of address entries in the address table.
show mac-address-table aging-time	Displays the aging time for dynamic MAC addresses.
show mac-address-table notification [**interface** [*interface-id*] | **history**]	Displays the configuration and history of MAC address change notifications.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug bridge mac	Debugs MAC address operation.

1 Configuring VLAN



1.1 Overview

A Virtual Local Area Network (VLAN) is a logical network created based on a physical network. A VLAN can be categorized into Layer 2 networks of the OSI model.

A VLAN has the same attributes as a common LAN, except for limitation on the physical location. Layer 2 unicast, broadcast, and multicast frames are forwarded and transmitted within a VLAN.

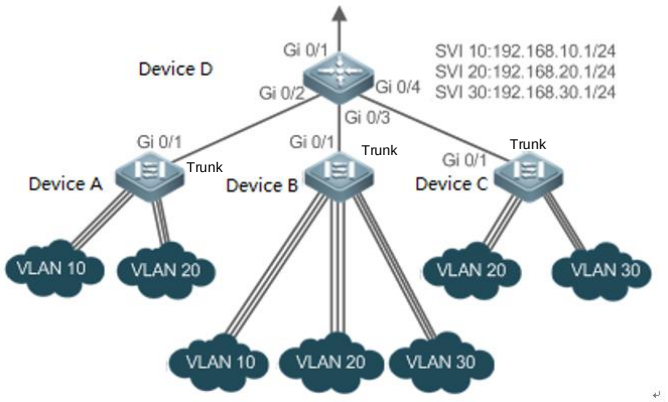
An interface can be defined as a member of a VLAN, and all terminals connected to this interface are parts of a virtual network that supports multiple VLANs. You do not need to adjust the network physically when adding, removing, and modifying users. Communication among VLANs is realized through Layer 3 devices, as shown in the following figure.

Figure 1-1

Protocols and Standards

- IEEE 802.1Q

1.2 Applications



Application	Description
Layer 2 Isolation and Layer 3 Interconnection Between VLANs	A user intranet is divided into multiple VLANs to realize Layer 2 isolation. These VLANs realize subnet interconnection based on the IP forwarding capability of the Layer 3 core switch.

1.2.1 Layer 2 Isolation and Layer 3 Interconnection Between VLANs

Scenario

The LAN of a user needs to be divided into VLAN 10, VLAN 20, and VLAN 30 to realize Layer 2 isolation. The three VLANs correspond to subnets 192.168.10.0/24, 192.168.20.0/24, and 192.168.30.0/24, respectively, and these VLANs implement subnet interconnection based on the IP forwarding capability of the Layer 3 core switch.

Figure 1-2

Remarks	Device A, Device B, and Device C are access switches. On the Layer 3 core switch Device D, configure the three VLANs, configure the interfaces for connecting the access switches as trunk interfaces, and specify an allowed VLAN list to realize Layer 2 isolation. Create the VLANs separately on the three access switches, assign an access interface for each VLAN, and configure the interfaces for connecting the core switch as trunk interfaces. Configure three SVIs on Device D as the gateway interfaces of the IP subnets corresponding to the three VLANs. Configure IP addresses for these SVIs.

Deployment

- Divide the LAN into multiple VLANs to realize Layer 2 isolation.
- Configure the SVIs on the Layer 3 switch for Layer 3 communication between VLANs.

1.3 Features

Basic Concepts

VLAN

A VLAN is a logical network created based on a physical network. A VLAN has the same attributes as a common LAN, except for limitation on the physical location. Layer 2 unicast, broadcast, and multicast frames are forwarded and transmitted within a VLAN.

The VLANs supported by Ruijie products comply with IEEE 802.1Q. A maximum of 4094 VLANs are supported, among which VLAN 1 cannot be deleted.

The configurable VLAN IDs are from 1 to 4094.

In case of insufficient hardware resources, the system returns information on VLAN creation failures.

Interface Mode

You can determine the frames allowed on an interface and the VLANs which the interface belongs to by configuring the interface mode.

Interface Mode	Description
Access interface	An access interface belongs to only one VLAN, which is specified manually.
Trunk interface (802.1Q)	A trunk interface belongs to all the VLANs of an access switch by default, and can forward the frames of all the VLANs or the frames of allowed VLANs.
Uplink interface	An uplink interface belongs to all the VLANs of an access switch by default, and can forward the frames of all the VLANs and frames from the native VLAN in tagged mode.
Hybrid interface	A hybrid interface belongs to all the VLANs of an access switch by default, and can forward frames of all the VLANs and send frames of VLANs in untagged mode. It can also transmit frames of allowed VLANs.

Overview

Feature	Description
VLAN	VLAN helps realize Layer 2 isolation.

1.3.1 VLAN

Each VLAN has an independent broadcast domain, and different VLANs are isolated at Layer 2.

Working Principle

Each VLAN has an independent broadcast domain, and different VLANs are isolated at Layer 2.

Layer 2 isolation: If no SVIs are configured for VLANs, VLANs are isolated at Layer 2. That is, users in the VLANs cannot communicate with each other.

Layer 3 interconnection: If SVIs are configured on a Layer 3 switch for VLANs, these VLANs can communicate with each other at Layer 3.

1.4 Configuration

Configuration	Description and Command	
Configuring a VLAN	(Mandatory) It is used to create a VLAN.	
	vlan	Enters a VLAN ID.
	Optional.	
	interface vlan	Creates a Layer 3 virtual interface for a VLAN.
	(Optional) It is used to rename a VLAN.	
	name	Names a VLAN.

Configuration	Description and Command	
Configuring an Access Interface	(Optional) It is used to configure an access interface to transmit flows from a single VLAN.	
	switchport mode access	Defines an interface as a Layer 2 access interface.
	switchport access vlan	Assigns an interface to a VLAN.
	add interface	Adds one access interface or a group of such interface s to the VLAN.
Configuring a Trunk Port	(Mandatory) It is used to configure the interface as a trunk interface.	
	switchport mode trunk	Defines an interface as a Layer 2 trunk interface.
	(Optional) It is used to configure trunk interfaces to transmit flows from multiple VLANs.	
	switchport trunk allowed vlan	Configures allowed VLANs for a trunk interface.
	switchport trunk native vlan	Specifies a native VLAN for a trunk interface.
Configuring an Uplink Interface	(Mandatory) It is used to configure the interface as an uplink interface.	
	switchport mode uplink	Configures an interface as an uplink interface.
	(Optional) It is used to restore the interface mode.	
	no switchport mode	Restores the interface mode.
	switchport trunk allowed vlan	Configures an allowed VLAN list for an uplink interface.
	switchport trunk native vlan	Configures a native VLAN for an uplink interface.
Configuring a Hybrid Interface	(Mandatory) It is used to configure an interface as a hybrid interface.	
	switchport mode hybrid	Configures an interface as a hybrid interface.
	(Optional) It is used to transmit frames of multiple VLANs in untagged mode.	
	no switchport mode	Restores the interface mode.
	switchport hybrid allowed vlan	Configures allowed VLANs for a hybrid interface.
	switchport hybrid native vlan	Configures a default VLAN for a hybrid interface.

1.4.1 Configuring a VLAN

Configuration Effect

- A VLAN is identified by a VLAN ID. You may add, delete, or modify VLANs 2 to 4094, but VLAN 1 is created automatically and cannot be deleted.

Notes

- N/A

Configuration Step

Creating and Modifying a VLAN

- Mandatory.
- In case of insufficient hardware resources, the system returns information on VLAN creation failures.
- Use the **vlan** *vlan-id* command to create a VLAN or enter the VLAN configuration mode.

Command	**vlan** { *vlan-id* | **range** *vlan-range* }
Parameter Description	*vlan-id*: Indicates the VLAN ID. The value range is from 1 to 4094.
Defaults	VLAN 1 is created automatically and cannot be deleted.
Command Mode	Global configuration mode
Usage Guide	If you enter a new VLAN ID, the corresponding VLAN will be created. If you enter an existing VLAN ID, the corresponding VLAN will be modified. You can use the **no vlan** *vlan-id* command to delete a VLAN. VLAN 1, VLANs where SVIs are configured, and sub-VLANs cannot be deleted.

Renaming a VLAN

- Optional.
- You cannot rename a VLAN the same as the default name of another VLAN.

Command	**name** *vlan-name*
Parameter Description	*vlan-name*: Indicates a VLAN name.
Defaults	By default, the name of a VLAN is its VLAN ID. For example, the default name of VLAN 4 is VLAN 0004.
Command Mode	VLAN configuration mode
Usage Guide	To restore the default VLAN name, use the **no name** command.

Configuring an SVI

- Optional.
- Create a Layer 3 SVI for a VLAN, enter the SVI configuration mode, and assign an IP address to the SVI so that devices in the VLAN can communicate at Layer 3.

Command	**interface vlan** *vlan-id*
Parameter Description	*vlan-id*: Indicates the VLAN ID.
Defaults	No SVI exists in a VLAN by default.
Command Mode	Global configuration mode
Usage Guide	-

Verification

- Run the **show vlan** [**id** *vlan-id*] command to check whether the VLAN configuration takes effect.

- Run the **show interface description** command to check the created SVI.
- Run the **show interface vlan** *vlan-id* command to check detailed SVI configuration.

Configuration Examples

Configuring a VLAN

Configuration Steps	• Create a VLAN and rename it **test888**.

	`Hostname# configure terminal`
	`Hostname(config)# vlan 888`
	`Hostname(config-vlan)# name test888`

Verification	• Run the **show** vlan [**id** *vlan-id*] command to check whether the VLAN configuration is correct.

	`Hostname(config-vlan)#show vlan`
	`VLAN Name Status Ports`
	`---- -------------------------------- ---------`
	`----------`
	`1 VLAN0001 STATIC`
	`888 test888 STATIC`

Configuring an SVI

Configuration Steps	• Create an SVI for VLAN 1 and assign an IP address to the SVI.

	`Hostname# configure terminal`
	`Hostname(config)# interface vlan 1`
	`Hostname(config-if-VLAN 1)# ip address 10.10.29.1/24`
	`Hostname(config-if-VLAN 1)# end`

Verification	• Run the **show interface description** command to check the created SVI.

	`Hostname#show interface description`
	`Interface Status Administrative`
	`Description`
	`---------- -------- --------------`
	`VLAN 1 up up`

	• Run the **show interface vlan** *vlan-id* command to check detailed SVI configuration.

	`Hostname# show interface vlan 1`
	`Index(dec):4097 (hex):1001`
	`VLAN 1 is UP , line protocol is UP`
	`Hardware is VLAN, address is 00d0.f822.3719 (bia 00d0.f822.3719)`
	`Interface address is: 10.10.29.1/24`
	`ARP type: ARPA, ARP Timeout: 3600 seconds`
	`Interface IPv6 address is:`
	`No IPv6 address`
	`MTU 1500 bytes, BW 1000000 Kbit`

	Encapsulation protocol is Ethernet-II, loopback not set Keepalive interval is 10 sec , set Carrier delay is 2 sec Rxload is 0/255, Txload is 0/255

1.4.2 Configuring an Access Interface

Configuration Effect

Configure a Layer 2 interface as an access interface and add it to a VLAN.

Configuration Step

Assigning an Access Interface to a Specified VLAN

- Optional.
- Use the **switchport mode access** command in interface configuration mode to specify Layer 2 interfaces (switch interfaces) as access interfaces.
- Use the **switchport access vlan** *vlan-id* command in interface configuration mode to add an access interface to a specified VLAN.

Command	**switchport mode access**
Parameter Description	N/A
Defaults	A switch interface is an access interface by default.
Command Mode	Interface configuration mode
Usage Guide	N/A

Command	**switchport access vlan** *vlan-id*
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Defaults	An access interface is added to VLAN 1 by default.
Command Mode	Interface configuration mode
Usage Guide	This command is valid for only the access interface. If an interface is assigned to a nonexistent VLAN, this VLAN will be automatically created. The **no switchport access vlan** command can be used to restore the access interface to VLAN 1.

Adding an Access Interface to a VLAN

- Optional.
- This command is executed in VLAN configuration mode and takes effect only on an access interface. After an access interface is added to a VLAN, traffic of the VLAN can be transmitted through the interface.

Command	**add interface** { *interface-type interface-number* | **range** *interface-type interface-range* }
Parameter Description	*interface-type interface-number*: Indicates a single interface. *interface-type interface-range*: Indicates multiple interface s.

Defaults	By default, all Layer 2 Ethernet interface s belong to VLAN 1.
Command Mode	VLAN configuration mode
Usage Guide	In VLAN configuration mode, add a specific access interface to a VLAN. This command is valid for only the access interface. This command has the same effect as the **switchport access vlan** *vlan-id* command. The **no add interface** { *interface-type interface-number* | **range** *interface-type interface-range* } command can be used to add the access interface specified in a VLAN (except VLAN 1) to VLAN 1.

For the two commands of adding an interface to a VLAN, the command configured later will overwrite the other one.

Verification

- Send untagged packets to an access interface. The packets are broadcast within the VLAN.
- Use **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A

Command Display	`Hostname(config-vlan)#show vlan id 20`
	`VLAN Name Status Ports`
	`---- -------------------------------- --------- ----------`
	`20 VLAN0020 STATIC Gi0/1`

Configuration Example

Adding an Access Interface to a VLAN

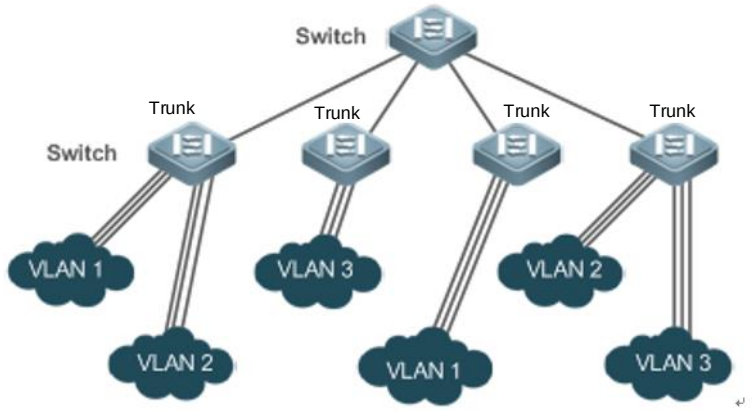
Configuration Steps	• Add an access interface to the VLAN. There are two approaches.

	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitethernet 0/3`
	`Hostname(config-if-GigabitEthernet 0/3)# switchport`
	`Hostname(config-if-GigabitEthernet 0/3)# switchport mode access`
	`Hostname(config-if-GigabitEthernet 0/3)# switchport access vlan 20`
	• Add GigabitEthernet 0/3 to VLAN 20.
	`Hostname# configure terminal`
	`SwitchA(config)#vlan 20`
	`SwitchA(config-vlan)#add interface gigabitethernet 0/3`

Verification	• Run the **show vlan** and **show interface switchport** commands to check whether the configuration takes effect.
	`Hostname(config-vlan)#show vlan` `VLAN Name Status Ports`

```
---- -------------------------------- ---------
-----------------------------------
   1 VLAN0001                         STATIC
  20 VLAN0020                         STATIC    Gi0/3

Hostname# show interface GigabitEthernet 0/3 switchport
Interface                        Switchport Mode      Access Native
Protected VLAN lists
-------------------------------- ---------- --------- ------ ------
--------- --------------
GigabitEthernet 0/3              enabled    ACCESS    20     1
Disabled  ALL
```



1.4.3 Configuring a Trunk Port

Configuration Effect

A trunk is a point-to-point link connecting one or more Ethernet interfaces to other network devices and can transmit traffic from multiple VLANs.

The trunk of Ruijie devices conforms to 802.1Q. The following figure displays a network adopting trunk connections.

Figure 1-3

You may configure an Ethernet interface or aggregate interface (See *Configuring Aggregate Interface*) as a trunk interface.

You should specify a native VLAN for a trunk interface. The untagged packets received by and sent from the trunk interface are considered to belong to the native VLAN. The default VLAN ID (PVID in IEEE 802.1Q) of this trunk interface is the native VLAN ID. Frames of the native VLAN sent through the trunk are untagged. The default native VLAN of a trunk interface is VLAN 1.

When configuring a trunk, make sure that the trunk interfaces at the two ends of the link adopt the same native VLAN.

Configuration Step

↘ **Configuring a Trunk Interface**

- Mandatory.
- Configure a trunk interface to transmit traffic from multiple VLANs.

Command	**switchport mode trunk**
Parameter Description	N/A
Defaults	The default mode is access, which can be modified to trunk.
Command Mode	Interface configuration mode
Usage Guide	To restore all properties of a trunk interface to default settings, use the **no switchport mode** command.

Defining Allowed VLANs for a Trunk Interface

- Optional.
- By default, a trunk interface transmits traffic from all the VLANs (VLANs 1 to 4094). You may configure a list of allowed VLANs to prohibit traffic of some VLANs from passing through a trunk interface.

Command	**switchport trunk allowed vlan** { **all** | [**add** | **remove** | **except** | **only**] } *vlan-list*
Parameter Description	*vlan-list*: Indicates a VLAN or a list of VLANs. VLAN IDs are connected by the hyphen (-) in order. For example: 10–20. **all**: Indicates allowed VLANs, including all VLANs. **add**: Indicates that a specific VLAN is added to the list of allowed VLANs. **remove**: Indicates that a specific VLAN is removed from the list of allowed VLANs. **except**: Indicates that all VLANs except those in the listed VLAN are added to the list of allowed VLANs. **only**: Indicates that listed VLANs are added to the list of allowed VLANs, and that other VLANs are removed from the list.
Defaults	The trunk interface and the uplink interface belong to all VLANs.
Command Mode	Interface configuration mode
Usage Guide	To restore the default allowed VLAN list of a trunk interface, use the **no switchport trunk allowed vlan** command.

Configuring a Native VLAN

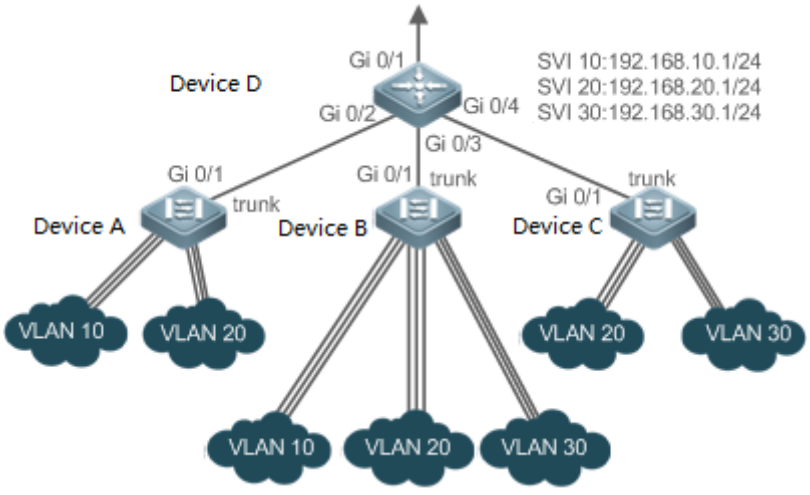
- Optional.
- A trunk interface receives and sends tagged or untagged 802.1Q frames. Traffic from the native VLAN are forwarded in untagged mode. The default native VLAN is VLAN 1.
- If a frame carries the VLAN ID of a native VLAN, its tag will be stripped automatically when it passes a trunk interface.

Command	**switchport trunk native vlan** *vlan-id*
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Defaults	The default VALN for a trunk or uplink interface is VLAN 1.
Command	Interface configuration mode

Mode	
Usage Guide	To restore the default native VLAN of a trunk interface, use the **no switchport trunk native vlan** command.

When you set the native VLAN of an interface to a nonexistent VLAN, this VLAN will not be created automatically. Besides, the native VLAN can be out of the list of allowed VLANs for this interface. In this case, traffic from the native VLAN cannot pass through the interface.

Verification



- Send tagged packets to a trunk interface. Packets are broadcast within the specified VLANs.
- Use **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A

Command Display	`Hostname(config-vlan)#show vlan id 20`
	`VLAN Name Status Ports`
	`---- -------------------------------- ---------`
	`----------`
	`20 VLAN0020 STATIC Gi0/1`

Configuration Example

Configuring Basic VLANs for Layer 2 Isolation and Layer 3 Interconnection

Scenario Figure 1-4	
Configuration Steps	Networking requirements: The LAN of a user is divided into VLAN 10, VLAN 20, and VLAN 30 to realize Layer 2 isolation. The three VLANs correspond to the IP subnets 192.168.10.0/24, 192.168.20.0/24, and 192.168.30.0/24, respectively, and these VLANs implement subnet interconnection based on the IP forwarding capability of the Layer 3 core switch. This example uses the core switch and one access switch to describe the configuration process.

	Configuration key points: ● On the Layer 3 core switch, configure the three VLANs, configure the interfaces for connecting the access switches as trunk interfaces, and specify an allowed VLAN list to realize Layer 2 isolation. ● Configure three SVIs on the core switch as the gateway interfaces of the IP subnets corresponding to the three VLANs. Configure IP addresses for these SVIs. ● Create the VLANs separately on the three access switches, assign an access interface to each VLAN, and configure the interfaces for connecting the core switch as trunk interfaces. In this example, Device A (an access switch) is used.
Device D	DeviceD#configure terminal DeviceD(config)#vlan 10 DeviceD(config-vlan)#vlan 20 DeviceD(config-vlan)#vlan 30 DeviceD(config-vlan)#exit DeviceD(config)#interface range GigabitEthernet 0/2-4 DeviceD(config-if-range)#switchport mode trunk DeviceD(config-if-range)#exit DeviceD(config)#interface GigabitEthernet 0/2 DeviceD(config-if-GigabitEthernet 0/2)#switchport trunk allowed vlan remove 1-4094 DeviceD(config-if-GigabitEthernet 0/2)#switchport trunk allowed vlan add 10,20 DeviceD(config-if-GigabitEthernet 0/2)#interface GigabitEthernet 0/3 DeviceD(config-if-GigabitEthernet 0/3)#switchport trunk allowed vlan remove 1-4094 DeviceD(config-if-GigabitEthernet 0/3)#switchport trunk allowed vlan add 10,20,30 DeviceD(config-if-GigabitEthernet 0/3)#interface GigabitEthernet 0/4 DeviceD(config-if-GigabitEthernet 0/4)#switchport trunk allowed vlan remove 1-4094 DeviceD(config-if-GigabitEthernet 0/4)#switchport trunk allowed vlan add 20,30 DeviceD#configure terminal DeviceD(config)#interface vlan 10 DeviceD(config-if-VLAN 10)#ip address 192.168.10.1 255.255.255.0 DeviceD(config-if-VLAN 10)#interface vlan 20 DeviceD(config-if-VLAN 20)#ip address 192.168.20.1 255.255.255.0 DeviceD(config-if-VLAN 20)#interface vlan 30 DeviceD(config-if-VLAN 30)#ip address 192.168.30.1 255.255.255.0 DeviceD(config-if-VLAN 30)#exit
Device A	DeviceA#configure terminal DeviceA(config)#vlan 10 DeviceA(config-vlan)#vlan 20 DeviceA(config-vlan)#exit

```
DeviceA(config)#interface range GigabitEthernet 0/2-12
DeviceA(config-if-range)#switchport mode access
DeviceA(config-if-range)#switchport access vlan 10
DeviceA(config-if-range)#interface range GigabitEthernet 0/13-24
DeviceA(config-if-range)#switchport mode access
DeviceA(config-if-range)#switchport access vlan 20
DeviceA(config-if-range)#exit
DeviceA(config)#interface GigabitEthernet 0/1
DeviceA(config-if-GigabitEthernet 0/1)#switchport mode trunk
```

Verification

Check VLAN configuration on the core switch.

- Check VLAN information, including VLAN IDs, names, statuses, and interfaces included in the VLANs.
- Check the VLAN status on Gi 0/2, Gi 0/3, and Gi 0/4.

Device D

```
DeviceD#show vlan
VLAN  Name       Status                Ports
---- --------  --------   --------------------------------
   1 VLAN0001   STATIC     Gi0/1, Gi0/5, Gi0/6, Gi0/7
                           Gi0/8, Gi0/9, Gi0/10, Gi0/11
                           Gi0/12, Gi0/13, Gi0/14, Gi0/15

	GigabitEthernet 0/4 enabled TRUNK 1 1 Disabled 20,30

Common Errors

- N/A

1.4.4 Configuring an Uplink Interface

Configuration Effect

- An uplink interface is similar to a trunk interface. Their difference is that an uplink interface only transmits tagged frames while a trunk interface sends untagged frames of the native VLAN.

Configuration Step

Configuring an Uplink Interface

- Mandatory.
- Configure an uplink interface to transmit traffic from multiple VLANs. Only tagged frames can be transmitted.

Command	**switchport mode uplink**
Parameter Description	N/A
Defaults	The default mode is access, which can be modified to uplink.
Command Mode	Interface configuration mode
Usage Guide	To restore all default properties of an uplink interface, use the **no switchport mode** command.

Defining Allowed VLANs for a Trunk Interface

- Optional.
- You may configure a list of allowed VLANs to prohibit traffic of some VLANs from passing through an uplink interface.

Command	**switchport trunk allowed vlan** { **all** | [**add** | **remove** | **except** | **only**] } *vlan-list*
Parameter Description	*vlan-list*: Indicates a VLAN or a list of VLANs. VLAN IDs are connected by the hyphen (-) in order. For example: 10–20. **all**: Indicates allowed VLANs, including all VLANs. **add**: Indicates that a specific VLAN is added to the list of allowed VLANs. **remove**: Indicates that a specific VLAN is removed from the list of allowed VLANs. **except**: Indicates that all VLANs except those in the listed VLAN are added to the list of allowed VLANs. **only**: Indicates that listed VLANs are added to the list of allowed VLANs, and that other VLANs are removed from the list.
Command Mode	Interface configuration mode
Usage Guide	To restore default allowed VLANs, use the **no switchport trunk allowed vlan** command.

Configuring a Native VLAN

- Optional.
- If a frame carries the VLAN ID of a native VLAN, its tag will not be stripped when it passes an uplink interface. This is contrary to a trunk interface.

Command	**switchport trunk native vlan** *vlan-id*
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Command Mode	Interface configuration mode
Usage Guide	To restore the default native VLAN of an uplink interface, use the **no switchport trunk native vlan** command.

Verification

- Send tagged packets to an uplink interface. Packets are broadcast within the specified VLANs.
- Use **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A

Command Display	`Hostname(config-vlan)#show vlan id 20`
	`VLAN Name Status Ports`
	`---- -------------------------------- ---------`
	`-----------------------------------`
	`20 VLAN0020 STATIC Gi0/1`

Configuration Example

Configuring an Uplink Interface

Configuration Steps	● The following is an example of configuring Gi0/1 as an uplink interface.

	`Hostname# configure terminal`
	`Hostname(config)# interface gi 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# switchport mode uplink`
	`Hostname(config-if-GigabitEthernet 0/1)# end`

Verification	● Check whether the configuration is correct.

	`Hostname# show interfaces GigabitEthernet 0/1 switchport`
	`Interface Switchport Mode Access Native`
	`Protected VLAN lists`
	`-------------------------------- ---------- --------- ------ ------`
	`--------- -----------------`

	GigabitEthernet 0/1 enabled **UPLINK** 1 1 disabled ALL

1.4.5 Configuring a Hybrid Interface

Configuration Effect

- A hybrid interface is usually used in the shared VLAN environment. By default, a hybrid interface is the same as a trunk interface. Their difference is that a hybrid interface can send frames from the VLANs except the default VLAN in untagged mode.

Configuration Step

Configuring a Hybrid Interface

- Mandatory.
- Configure a hybrid interface to transmit traffic from multiple VLANs.

Command	**switchport mode hybrid**
Parameter Description	N/A
Defaults	The default mode is access, which can be modified to hybrid.
Command Mode	Interface configuration mode
Usage Guide	To restore all default properties of a hybrid interface, use the **no switchport mode** command.

Defining Allowed VLANs for a Hybrid Interface

- Optional.
- By default, a hybrid interface transmits traffic from all the VLANs (VLANs 1 to 4094). You can configure a list of allowed VLANs to prohibit traffic of some VLANs from passing through a hybrid interface.

Command	**switchport hybrid allowed vlan** [[**add** | **only**] **tagged** | [**add**] **untaged** | **remove**] *vlan_list*
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Defaults	By default, a hybrid interface belongs to all VLANs. The interface is added to the default VLAN in untagged mode and to the other VLANs in tagged mode.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring a Native VLAN

- Optional.
- If a frame carries the VLAN ID of a native VLAN, its tag will be stripped automatically when it passes a hybrid interface.

Command	**switchport hybrid native vlan** *vlan_id*
Parameter	*vlan-id*: Indicates a VLAN ID.

Description	
Defaults	The default native VLAN is VLAN 1.
Command Mode	Interface configuration mode
Usage Guide	To restore the default native VLAN of a hybrid interface, use the **no switchport hybrid native vlan** command.

Verification

- Send tagged packets to a hybrid interface. Packets are broadcast within the specified VLANs.
- Use **show vlan** and **show interface switchport** to check whether the configuration takes effect.

Command	**show vlan** [**id** *vlan-id*]
Parameter Description	*vlan-id*: Indicates a VLAN ID.
Command Mode	Any mode
Usage Guide	N/A

Command Display	`Hostname(config-vlan)#show vlan id 20`
	`VLAN Name Status Ports`
	`---- -------------------------------- ---------`
	`----------------------------------`
	`20 VLAN0020 STATIC Gi0/1`

Configuration Example

Configuring a Hybrid Interface

Configuration Steps	The following is an example of configuring Gi0/1 as a hybrid interface.

	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# switchport mode hybrid`
	`Hostname(config-if-GigabitEthernet 0/1)# switchport hybrid native vlan 3`
	`Hostname(config-if-GigabitEthernet 0/1)# switchport hybrid allowed vlan untagged 20-30`
	`Hostname(config-if-GigabitEthernet 0/1)# end`

Verification	Check whether the configuration is correct.

	`Hostname(config-if-GigabitEthernet 0/1)#show run interface gigabitEthernet 0/1`
	
	`Building configuration...`
	`Current configuration : 166 bytes`
	
	`interface GigabitEthernet 0/1`
	` switchport`
	`switchport mode hybrid`

```
switchport hybrid native vlan 3
switchport hybrid allowed vlan add untagged 20-30
```

1.5 Monitoring

Displaying

Command	Description
show vlan [**id** *vlan-id*]	Displays the VLAN configuration.
show interface [*interface-type interface-number*] **switchport**	Displays configuration of switch interfaces.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug bridge vlan	Debugs VLANs.

1 Configuring MAC VLAN

1.1 Overview

The MAC VLAN function refers to VLAN assignment based on MAC addresses. This function is often used with dynamic VLAN assignment of 802.1X to implement secure and flexible access of 802.1X terminals. After an 802.1X user passes authentication, the access switch automatically generates a MAC VLAN entry based on the VLAN ID and user MAC address pushed by the authentication server. A network administrator can also configure the association between a MAC address and a VLAN on the switch in advance.

Protocols

- IEEE 802.1Q: Virtual Bridged Local Area Networks and Standards

1.2 Applications

Application	Description
Configuring a MAC VLAN	The MAC VLAN function is used to assign VLANs based on users' MAC addresses. When the physical location of a user device changes, for example, switching from one switch to another, you do not need to reconfigure the VLAN of the interface connected to the user device.

1.2.1 Configuring a MAC VLAN

Scenario

With popularization of mobile office, terminal devices typically do not use fixed interfaces for network access. A terminal device may use port A to access the network this time, but use port B to access the network next time. If the VLAN configurations of ports A and B are different, the terminal device will be assigned to a different VLAN for second access, and fail to use resources of the previous VLAN. If the VLAN configuration of ports A and B is the same, security issues may be introduced when port B is assigned to other terminal devices. How are hosts of different VLANs allowed to access the network on the same interface? The MAC VLAN function is introduced.

With the MAC VLAN function configured, when the physical location of a user device changes, for example, switching from one switch to another, you do not need to reconfigure the VLAN of the interface connected to the user device.

Deployment

- Push MAC VLAN entries on a Layer 2 switch or wireless device to assign VLANs based on users' MAC addresses.

1.3 Overview

Feature

Feature	Description
Configuring MAC VLAN	Configures the MAC VLAN function to assign VLANs based on users' MAC addresses.

1.3.1 Configuring MAC VLAN

Working Principle

When a switch receives a packet, the switch compares the source MAC address of the packet with the MAC address specified in a MAC VLAN entry. If they match, the switch forwards the packet to the VLAN specified in the MAC VLAN entry. If they do not match, the VLAN to which the packet belongs is still determined by the VLAN assignment rule of the interface.

To ensure that a PC is assigned to a specified VLAN regardless of the switch connected to the PC, you can perform the configuration by using an authentication server (dynamic VLAN assignment of 802.1X): After a user passes authentication, a switch dynamically creates an association between the MAC address and a VLAN based on the information provided by the authentication server. When the user goes offline, the switch automatically deletes the association. This approach requires that the MAC-VLAN association be configured on the authentication server. For details about dynamic VLAN assignment of 802.1X, see *Configuring 802.1X*.

MAC VLAN entries can be configured on both a local switch and an authentication server. The configuration can take effect only when they are consistent. If the configuration is different, the configuration performed earlier takes effect.

- MAC VLAN entries are effective only for untagged packets, but ineffective for tagged packets.
- For MAC VLAN entries dynamically generated, the specified VLANs must exist.
- VLANs specified in MAC VLAN entries cannot be super-VLANs (but can be sub-VLANs), remote VLANs, or primary VLANs (but can be secondary VLANs).
- MAC addresses specified in MAC VLAN entries must be unicast addresses.

1.4 Monitoring

Displaying

Command	Description
show mac-vlan all	Displays all the MAC VLAN entries.
show mac-vlan vlan *vlan-id*	Displays MAC VLAN entries of a specified VLAN.
show mac-vlan mac-address *mac-address*	Displays MAC VLAN entries of a specified MAC address.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug bridge mvlan	Debugs the MAC VLAN function.

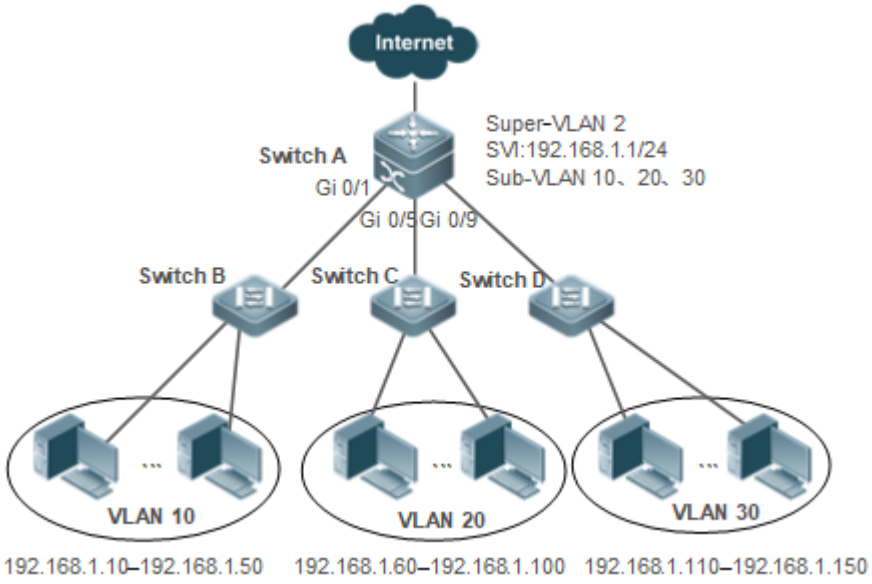
1 Configuring Super-VLAN

1.1 Overview

The super-VLAN is used to allocate Virtual Local Area Networks (VLANs). Super-VLAN, also called VLAN aggregation, is a management technology tailored for IP address optimization.

Using super-VLAN can greatly save IP addresses. Only one IP address needs to be assigned to the super-VLAN that consists of multiple sub-VLANs, which greatly saves IP addresses and facilitates network management.

1.2 Application



Application	Description
Sharing One IP Gateway Among Multiple VLANs	VLANs are assigned to implement Layer 2 isolation of access users. All VLAN users share one IP gateway to implement Layer 3 communication and communication with external networks.

1.2.1 Sharing One IP Gateway Among Multiple VLANs

Scenario

Multiple VLANs are isolated at Layer 2 on a Layer 3 device, but users of these VLANs can perform Layer 3 communication with each other in the same network segment.

Figure 1-1

Remarks	Switch A functions as the gateway or core switch. Switch B, Switch C, and Switch D function as access switches. On Switch A, configure a super-VLAN and sub-VLANs, and configure a Layer 3 interface for the

	super-VLAN and an IP address for the Layer 3 interface. On Switch B, Switch C, and Switch D, configure VLAN 10, VLAN 20, and VLAN 30, respectively, and allocate these VLANs to different departments of the company.

Deployment

On the intranet, use the super-VLAN so that multiple sub-VLANs can share one IP gateway and VLANs are mutually isolated at Layer 2.

Users in sub-VLANs can perform Layer 3 communication through the gateway of the super-VLAN.

1.3 Features

Basic Concepts

Super-VLAN

Super-VLAN, also called VLAN aggregation, is a management technology tailored for IP address optimization. It aggregates multiple VLANs to one IP network segment. No physical port can be added to a super-VLAN. The switch virtual interface (SVI) is used to manage the cross-VLAN communication of sub-VLANs. The super-VLAN cannot be used as a common 802.1Q VLAN, and is considered as the primary VLAN of sub-VLANs.

Sub-VLAN

A sub-VLAN is an independent broadcast domain. Sub-VLANs are isolated at Layer 2. Users of sub-VLANs of the same or different super-VLANs communicate with each other through Layer 3 SVIs of their own super-VLANs.

Proxy ARP

A Layer 3 SVI can be created only for a super-VLAN. Users in a sub-VLAN communicate with users in other sub-VLANs of the same super-VLAN or users in other network segments through proxy ARP and the Layer 3 SVI of the super-VLAN. When a user of a sub-VLAN sends an ARP Request packet to a user of another sub-VLAN, the gateway of the super-VLAN uses its own MAC address to send or respond to the ARP Request packet. The process is called proxy ARP.

IP Address Range of a Sub-VLAN

Based on the gateway IP address configured for the super-VLAN, an IP address range can be configured for each sub-VLAN.

Overview

Feature	Description
Super-VLAN	Create a Layer 3 interface as an SVI to allow all sub-VLANs to share the same IP network segment through proxy ARP.

1.3.1 Super-VLAN

Users of all sub-VLANs of a super-VLAN can be allocated IP addresses in the same IP address range, and share the same IP gateway. Users can implement cross-VLAN communication through this gateway. In this case, there is no need to allocate a gateway for each VLAN, which saves IP addresses.

Working Principle

IP addresses in a network segment are allocated to different sub-VLANs that belong to the same super-VLAN. Each sub-VLAN has an independent broadcast domain of the VLAN, and different sub-VLANs are isolated from each other at Layer 2. When users in sub-VLANs need to perform Layer 3 communication, the IP address of the SVI of the super-VLAN is used as the gateway address. In this way, multiple VLANs share the same IP gateway, without configuring a gateway for each VLAN. In addition, to implement Layer 3 communication between sub-VLANs and between sub-VLANs and other network segments, proxy ARP is used to forward and process ARP Request and Reply packets.

Layer 2 communication of sub-VLANs: If the SVI is not configured for the super-VLAN, sub-VLANs of the super-VLAN are isolated at Layer 2. That is, users in different sub-VLANs cannot communicate with each other. If the SVI is configured for the super-VLAN and the gateway of the super-VLAN can function as the ARP proxy, users in different sub-VLANs of the same super-VLAN can communicate with each other. This is because IP addresses of users in different sub-VLANs belong to the same network segment, and communication between these users is Layer 2 communication.

Layer 3 communication of sub-VLANs: If users in sub-VLANs of a super-VLAN need to perform Layer 3 communication across network segments, the gateway of this super-VLAN functions as the ARP proxy to respond to ARP Request packets in place of sub-VLANs.

1.4 Configuration

Configuration Item	Description and Command	
Configuring Basic Functions of the	Mandatory.	
	supervlan	Configures a super-VLAN.
	subvlan	Configures a sub-VLAN.
	proxy-arp	Enables the proxy ARP function.
	interface vlan	Creates a virtual interface for a super-VLAN.
	ip address	Configures the IP address of the virtual interface of a super-VLAN.
	Optional.	
	subvlan-address-range	Specifies the IP address range in a sub-VLAN.

1.4.1 Configuring Basic Functions of the Super-VLAN

Configuration Effect

Enable the super-VLAN function and configure an SVI for the super-VLAN to implement Layer 2 or Layer 3 communication between sub-VLANs across VLANs.

Users in all sub-VLANs of a super-VLAN share the same IP gateway. There is no need to specify a network segment for each VLAN, which saves IP addresses.

Notes

A super-VLAN does not belong to any physical interface. Therefore, the device configured with the super-VLAN cannot process packets tagged with the super-VLAN ID.

Both the super-VLAN function and the proxy ARP function of each sub-VLAN must be enabled.

An SVI and an IP address must be configured for a super-VLAN. The SVI is a virtual interface used for communication of users in all sub-VLANs.

Configuration Step

Configuring a Super-VLAN

- Mandatory.
- No physical interface exists in a super-VLAN.
- The proxy ARP function must be enabled. This function is enabled by default.
- Run the **supervlan** command to change a common VLAN into a super-VLAN.
- A super-VLAN cannot contain any physical interface. Therefore, after a common VLAN is changed into a super-VLAN, all interfaces in the VLAN exit the VLAN.

A super-VLAN is valid only after you configure sub-VLANs for this super-VLAN.

VLAN 1 cannot be configured as a super-VLAN.

A super-VLAN cannot be configured as a sub-VLAN of another super-VLAN. A sub-VLAN of a super-VLAN cannot be configured as a super-VLAN.

Command	**supervlan**
Parameter Description	N/A
Defaults	N/A
Command Mode	VLAN configuration mode
Usage Guide	By default, the super-VLAN function is disabled. No physical interface can be added to a super-VLAN. Once a VLAN is not a super-VLAN, all its sub-VLANs become common static VLANs.

Configuring a Sub-VLAN

- Mandatory.
- Physical interfaces can be added to sub-VLANs. Sub-VLANs of a super-VLAN share the gateway address of the super-VLAN and reside in the same network segment.
- The proxy ARP function must be enabled. This function is enabled by default.
- Run the **subvlan** *vlan-id-list* command to change common VLANs into sub-VLANs of a super-VLAN. These sub-VLANs can contain physical interfaces.
- The super-VLAN manages user communication in the sub-VLANs.

You must change a sub-VLAN into a common VLAN before you can delete this sub-VLAN by running the **no vlan** command.

One sub-VLAN belongs to only one super-VLAN.

Command	**subvlan** *vlan-id-list*
Parameter Description	*vlan-id-list*: Specifies multiple VLANs as sub-VLANs of a super-VLAN.
Defaults	All VLANs are common VLANs by default.
Command Mode	VLAN configuration mode
Usage Guide	Interfaces connected to user devices can be added to a sub-VLAN. You must change a sub-VLAN into a common VLAN before you can delete this sub-VLAN by running the **no vlan** [*id*] command. You cannot configure a Layer 3 SVI of the VLAN for a sub-VLAN. If you have configured a Layer 3 SVI for a super-VLAN, adding more sub-VLANs may fail due to insufficient resources. If you configure sub-VLANs for a super-VLAN, and then configure a Layer 3 SVI of the VLAN for a super-VLAN, some sub-VLANs may become common VLANs again due to insufficient resources y.

Configuring Proxy ARP

- Mandatory.
- Proxy ARP is enabled by default.
- Users in sub-VLANs can implement Layer 2 or Layer 3 communication across VLANs through the gateway proxy only after the proxy ARP function is enabled in both the super-VLAN and sub-VLANs.
- Users in sub-VLANs can communicate with users in other VLANs only after the proxy ARP function is enabled in both the super-VLAN and sub-VLANs.

The proxy ARP function must be enabled in both the super-VLAN and sub-VLANs. Otherwise, this function does not take effect.

Command	**proxy-arp**
Parameter Description	N/A
Defaults	The proxy ARP function is enabled by default.
Command Mode	VLAN configuration mode
Usage Guide	By default, the proxy ARP function is enabled. Run this command to enable the proxy ARP function in both the super-VLAN and sub-VLANs. Users in sub-VLANs can implement Layer 2 or Layer 3 communication across VLANs only after the proxy ARP function is enabled in both the super-VLAN and sub-VLANs.

Configuring a Virtual Interface for a Super-VLAN

- Mandatory.
- No physical interface can be added to a super-VLAN. You can configure the Layer 3 SVI for a VLAN.

When a super-VLAN is configure with an SVI, it allocates a Layer 3 interface to each sub-VLAN. If a sub-VLAN is not allocated a Layer 3 interface due to insufficient resources, the sub-VLAN becomes a common VLAN again.

Command	**interface vlan** *vlan-id*
Parameter Description	*vlan-id*: Indicates the ID of the super-VLAN.
Defaults	No virtual interface is configured for a super-VLAN by default.
Command Mode	Global configuration mode
Usage Guide	A Layer 3 interface must be configured as the virtual interface of a super-VLAN. For details, see *VLAN Command Reference*.

Configuring the Gateway of a Super-VLAN

- Mandatory.
- The IP gateway on the Layer 3 SVI is configured as the proxy for all users in sub-VLANs to respond to ARP Request packets.

Command	**ip address** *ip-address mask*
Parameter Description	*ip-address*: Indicates the IP address of the gateway on the virtual interface of a super-VLAN. *mask*: Indicates the mask.
Defaults	No gateway is configured for a super-VLAN by default.
Command Mode	Interface configuration mode
Usage Guide	Run this command to configure the gateway for a super-VLAN. Users of all sub-VLANs of the super-VLAN share this gateway.

Configuring the IP Address Range of the Sub-VLAN

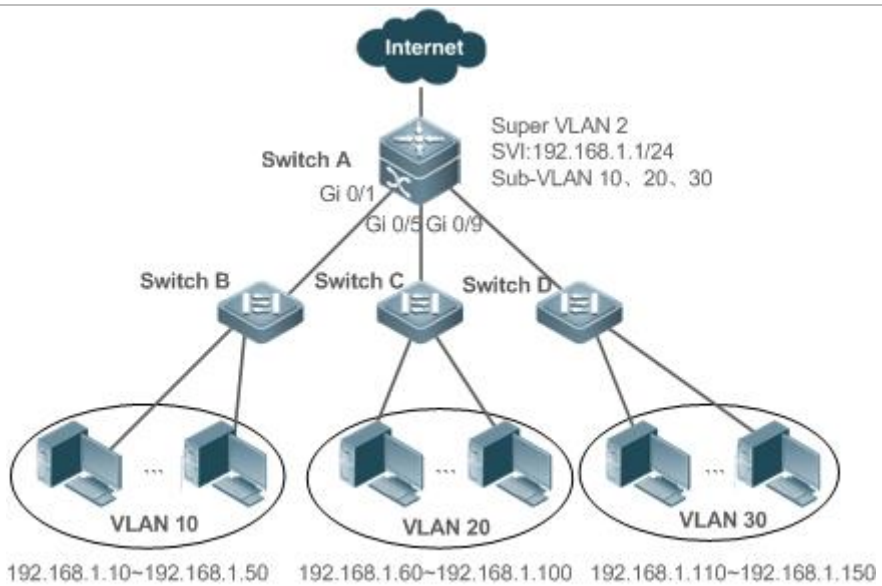
- You can allocate an IP address range to each sub-VLAN. Users in a sub-VLAN can communicate with users of other VLANs only when their IP addresses are in the specified range.
- Unless otherwise specified, you do not need to configure the IP address range.

IP addresses dynamically allocated to users through DHCP may be not in the allocated IP address range. If the IP addresses allocated through DHCP are not in the specified range, users in a sub-VLAN cannot communicate with users of other VLANs. Therefore, exercise caution when you run the **subvlan-address-range** *start-ip end-ip* command.

The IP address range of a sub-VLAN must be within the IP address range of the super-VLAN to which the sub-VLAN belongs. Otherwise, users in sub-VLANs cannot communicate with each other.

IP addresses of users in a sub-VLAN must be within the IP address range of the sub-VLAN. Otherwise, users in the sub-VLAN cannot communicate with each other.

Command	**subvlan-address-range** *start-ip-address end-ip-address*
Parameter Description	*start-ip-address*: Indicates the start IP address of a sub-VLAN. *end-ip-address*: Indicates the end IP address of a sub-VLAN.
Defaults	No IP address range is configured for a sub-VLAN by default.
Command	VLAN configuration mode



Mode	
Usage Guide	Optional. Run this command to configure the IP address range of users in a sub-VLAN. IP address ranges of different sub-VLANs of a super-VLAN cannot overlap with each other. IP address ranges of sub-VLANs of different super-VLANs can overlap each other. ⚠ The IP address range of a sub-VLAN must be within the IP address range of the super-VLAN to which the sub-VLAN belongs. Otherwise, users in sub-VLANs cannot communicate with each other. ⚠ Users in a sub-VLAN can communicate with users of other VLANs only when their IP addresses (either dynamically allocated through DHCP or statically configured) are in the configured IP address range. ⚠ IP addresses allocated through DHCP may not be in the configured IP address range. In this case, users in a sub-VLAN cannot communicate with users of other VLANs. Therefore, be cautious when using this command.

Verification

After each sub-VLAN is correlated with the gateway of the super-VLAN, users in sub-VLANs can ping each other.

Configuration Example

Configure a super-VLAN on the network to enable users in sub-VLANs of the super-VLAN to share the same network segment and the same IP gateway, so as to save IP addresses.

Scenario **Figure 1-2**	
Configuration Steps	● Configure a super-VLAN on the core switch. The configuration details are not mentioned here. ● On the access switch, configure common VLANs corresponding to sub-VLANs on the core switch.

A	`SwitchA#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`SwitchA(config)#vlan 2`

	SwitchA(config-vlan)#exit SwitchA(config)#vlan 10 SwitchA(config-vlan)#exit SwitchA(config)#vlan 20 SwitchA(config-vlan)#exit SwitchA(config)#vlan 30 SwitchA(config-vlan)#exit SwitchA(config)#vlan 2 SwitchA(config-vlan)#supervlan SwitchA(config-vlan)#subvlan 10,20,30 SwitchA(config-vlan)#exit SwitchA(config)#interface vlan 2 SwitchA(config-if-VLAN 2)#ip address 192.168.1.1 255.255.255.0 SwitchA(config)#vlan 10 SwitchA(config-vlan)#subvlan-address-range 192.168.1.10 192.168.1.50 SwitchA(config-vlan)#exit SwitchA(config)#vlan 20 SwitchA(config-vlan)#subvlan-address-range 192.168.1.60 192.168.1.100 SwitchA(config-vlan)#exit SwitchA(config)#vlan 30 SwitchA(config-vlan)#subvlan-address-range 192.168.1.110 192.168.1.150 SwitchA(config)#interface range gigabitEthernet 0/1,0/5,0/9 SwitchA(config-if-range)#switchport mode trunk
Verification	● Check whether the source device (192.168.1.10) and the destination device (192.168.1.60) can ping each other successfully.
A	SwitchA# show supervlan supervlan id supervlan arp-proxy subvlan id subvlan arp-proxy subvlan ip range ------------ ------------------- ---------- ----------------- ---------
	2 ON 10 ON 192.168.1.10 - 192.168.1.50
	20 ON 192.168.1.60 - 192.168.1.100
	30 ON 192.168.1.110 - 192.168.1.150

Common Errors

The SVI and IP gateway are not configured for the super-VLAN. Consequently, communication fails between sub-VLANs and between sub-VLANs and other VLANs.

The proxy ARP function is disabled in the super-VLAN or sub-VLANs. Consequently, users in sub-VLANs cannot communicate with users of other VLANs.

The IP address range of the sub-VLAN is configured, but IP addresses allocated to users are not in this range.

1.5 Monitoring

Displaying

debug bridge svlan	Debugs the super-VLAN002E

1 Configuring VLAN Group

1.1 Overview

Each virtual LAN (VLAN) group contains multiple VLANs. A wireless LAN (WLAN) can be associated with a VLAN group to achieve 1:N mapping, which assigns VLANs flexibly to stations (STAs).

There are two VLAN assignment modes:

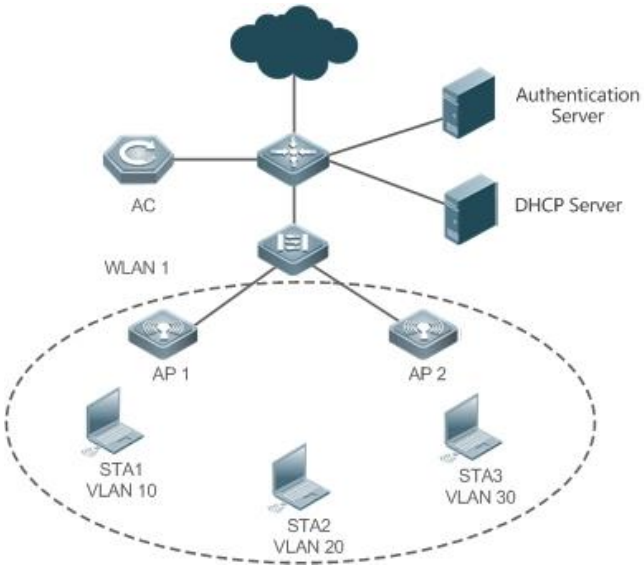
- After STAs pass 802.1X authentication, the authentication server assigns VLANs to STAs.
- The Dynamic Host Configuration Protocol (DHCP) server assigns VLANs to STAs based on the address pool.

Protocols and Standards

- N/A

1.2 Applications

Application	Description
VLAN Assignment	The VLAN group assigns VLANs to STAs.



1.2.1 VLAN Assignment

Scenario

Multiple STAs connect to the same WLAN. VLANs are assigned to STAs based on the VLAN assignment mode of the VLAN group mapped to the WLAN.

As shown in Figure 1-1, the VLAN group assigns VLANs to STA 1, STA 2, and STA 3 connected to WLAN 1.

Figure 1-1

Remarks	STAs connect to the wired network through AP 1 and AP 2. The access controller (AC) connects to APs through the wired network to manage APs in a unified manner.

1.3 Features

Basic Concepts

VLAN Group

Multiple VLANs are added to a VLAN group. When STAs connect to a WLAN, VLANs are assigned to the STAs based on the VLAN assignment mode of the VLAN group mapped to the WLAN.

VLAN Assignment Mode

Each VLAN group can assign VLANs based on VLAN delivery of 802.1X or the DHCP server address pool.

Overview

Feature	Description
802.1X-based VLAN Assignment	You can plan VLANs to be assigned after STAs pass 802.1X authentication.
DHCP-based VLAN Assignment	VLANs are assigned flexibly to STAs based on the load of each address pool.

1.3.1 802.1X-based VLAN Assignment

Working Principle

Before authentication, a STA belongs to the default VLAN of a VLAN group mapped to the connected WLAN.

The STA will be authenticated in the default VLAN. After authentication succeeds, the authentication server determines whether to assign a VLAN. If so, the packets subsequently sent by the STA will be automatically redirected to the assigned VLAN. If not, the packets will be transmitted in the default VLAN of the default VLAN group.

1.3.2 DHCP-based VLAN Assignment

Working Principle

The device checks and records the assignment status of the DHCP servers corresponding to members of VLAN groups. If a STA in a VLAN sends multiple consecutive DHCP Request packets but receives no Reply packets, the DHCP server assignment status of the VLAN will be marked as "not assignable".

When a STA connects to a WLAN, it checks whether any VLAN with its DHCP server assignment status being "assignable" exists in the VLAN group.

If so, a VLAN with its DHCP server assignment status being "assignable" is randomly assigned to the STA. Then, the STA requests an IP address from the DHCP server. After the IP address is successfully obtained, the packets subsequently sent by the STA will be automatically redirected to the VLAN.

If not, the DHCP server assignment status of all VLANs in the VLAN group will be marked as "not assignable".

1.4 Configuration

Configuration	Description and Command	
Configuring a VLAN Group	(Mandatory) It is used to create a VLAN group and configure a VLAN list, the VLAN assignment mode, and default VLAN.	
	vlan-group *group-id*	Creates a VLAN group.
	vlan-list *vlan-list*	Configures a VLAN list for a VLAN group.
	vlan-assign-mode XX	Specifies the VLAN assignment mode for a VLAN group.
	default-vlan XX	Configures the default VLAN for a VLAN group.
	(Optional) It is used to configure the VLAN group name.	
	name *vlan-group-name*	Configures the VLAN group name.
Configuring Mapping Between a WLAN and a VLAN Group Supported functions vary depending on the product version. The WS7204 and WS6812 support this function; the settled AP (AP880), wall plate AP (AP180V2), and outdoor AP (AP680(CD)) do not support this function.	(Mandatory) It is used to configure the mapping between a WLAN and a VLAN group.	
	ap-group { *ap-group-name* | **default** }	Configures the AP group of an AP.
	interface-mapping	Configures WLAN-VLAN group mapping on ACs.

1.4.1 Configuring a VLAN Group

Configuration Effect

- Create a VLAN group and complete configurations related to the VLAN group.

Notes

- N/A

Configuration Step

Creating a VLAN Group

- Mandatory.
- Create a VLAN group so as to assign VLANs to STAs in its associated WLAN.

Command	**vlan-group** *group-id*
Parameter Description	*group-id*: Indicates the ID of a VLAN group. The value range is from 1 to 128.

Defaults	No VLAN group is created.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a VLAN List for a VLAN Group

- Mandatory. Ensure that VLANs have been created.
- Add multiple VLANs to the same VLAN group if a WLAN needs to map to multiple VLANs.
- Perform the configuration on the AC.

Command	**vlan-list** *vlan-list*
Parameter Description	*vlan-list*: Indicates a VLAN list. It contains a maximum of 128 VLANs.
Defaults	No VLAN list is configured.
Command Mode	VLAN group configuration mode
Usage Guide	N/A

Configuring the VLAN Assignment Mode for a VLAN Group

- Mandatory.
- Use this command to implement the VLAN assignment policy of a VLAN group.
- Perform the configuration on the AC.

Command	**vlan-assign-mode** { **dot1x** | **mac-hash** }
Parameter Description	**dot1x**: Indicates that the authentication server assigns VLANs to STAs after 802.1X authentication succeeds. **mac-hash**: Indicates the assignment of VLANs to user terminals based on the MAC address hashing.
Defaults	No VLAN assignment mode is configured.
Command Mode	VLAN group configuration mode or global configuration mode
Usage Guide	In global configuration mode, the configurations apply to all VLAN groups. In VLAN group configuration mode, the configurations apply to the VLAN group only. Configurations in VLAN group configuration mode take precedence over those in global configuration mode. There are two VLAN assignment modes: 802.1X-based and DHCP-based. DHCP –based assignment mode is not supported.

Configuring the Default VLAN for a VLAN Group

- Mandatory.
- Perform the configuration on the AC.
- The default VLAN takes effect when the WLAN is in 802.1X-based assignment mode, that is, when the authentication server assigns the default VLAN before 802.1X authentication succeeds.

- Configure it on ACs.

Command	**default-vlan** *vlan-id*
Parameter Description	*vlan-id*: Indicates the ID of a VLAN in the VLAN list of the VLAN group.
Defaults	No default VLAN is specified.
Command Mode	VLAN group configuration mode
Usage Guide	Before configuring the default VLAN, you must add this VLAN to the destination VLAN group.

Configuring the VLAN Group Name

- Optional.
- Configure this function on the AC.

Command	**name** *vlan-group-name*
Parameter Description	*vlan-group-name*: Indicates the VLAN group name, with a maximum length of 64 bytes.
Defaults	No VLAN group name is configured by default.
Command Mode	VLAN group configuration mode
Usage Guide	It is used to configure the VLAN group name. In the case of 802.1X VLAN assignment, the authentication service is matched against the VLAN group delivered by the authentication server and selects a VLAN from the matched VLAN group through the 802.1X policy. The authentication user is redirected from the default VLAN to the VLAN. If the VLAN group name is deleted or not configured on the device, the authentication server will not deliver VLANs. The packets from the client are transmitted over the default VLAN in the default VLAN group. Do not configure the same name for different VLAN groups.

Verification

- Check the configurations of the VLAN group.

Configuration Example

Configuring a VLAN Group

Configuration Steps	• Create VLAN Group 10. • Set the VLAN assignment mode to 802.1X-based mode. • Configure a VLAN list that contains VLAN 1 to VLAN 10. • Set the default VLAN to VLAN 1. • Configure the name as **vg10**.

	`Hostname# configure terminal`
	`Hostname(config)# vlan-group 10`
	`Hostname(config-vlan-group)# vlan-assign-mode dot1x`
	`Hostname(config-vlan-group)# vlan-list 1-10`
	`Hostname(config-vlan-group)# default-vlan 1`

	Hostname(config-vlan-group)# name vg10 Hostname(config-vlan-group)# end
Verification	● Check whether the configurations of VLAN Group 10 are correct.
	Hostname# show vlan-group 10 vlan-group id mode default-vlan vlan-list ------------ ---------- ---------- ---------- 10 dot1x 1 1-10

Common Errors

- A VLAN configured in a VLAN list does not exist.
- The default VLAN configured does not exist in the VLAN list.

1.4.2 Configuring Mapping Between a WLAN and a VLAN Group

Supported functions vary depending on the product version. The WS7204 and WS6812 support this function; the settled AP (AP880), wall plate AP (AP180V2), and outdoor AP (AP680(CD)) do not support this function.

Configuration Effect

- The mapping between a WLAN and a VLAN group so that STAs can be associated with the WLAN.

Notes

- N/A

Configuration Step

Configuring the AP Group of an AP

- Mandatory.

Command	**ap-group** { *ap-group-name* | **default** }
Parameter Description	*ap-group-name*: Creates an AP group and enters the AP group configuration mode. The name of the AP group contains a maximum of 63 bytes and spaces are not allowed. **default**: Enters the default AP group configuration mode.
Defaults	An AP group named **default** is automatically created by default after the system is started. This group cannot be created or deleted.
Command Mode	Global configuration mode
Usage Guide	When the **no** form of the command is used to delete an AP group, APs of this group are automatically moved to the default group.

Configuring Mapping Between a WLAN and a VLAN Group

- Mandatory.

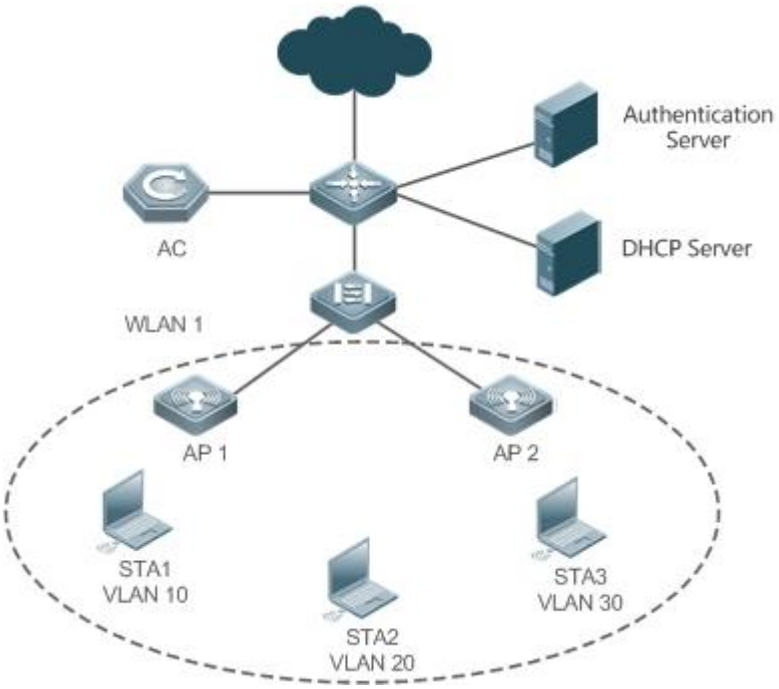
Command	**interface-mapping** *wlan-id* [*vlan-id* I **group** *vlan-group-id* I **list** *vlan-list* [**def-vlan** *def-vlan-id*]] [**radio** { *radio-id* | **6GHz** | **802.11b** | **802.11a** }] [**ap-wlan-id** *ap-wlan-id*]
Parameter	*wlan-id*: Indicates the ID of the specified WLAN. This WLAN must have been created. The value

Description	range of the settled AP (AP880) is from 1 to 16; the value range of the wall plate AP (AP180V2) is from 1 to 8; the value range of the outdoor AP (AP680(CD)) is from 1 to 16. *vlan-id*: Indicates the ID of the specified VLAN. The VLAN ID range is from 1 to 4094. vlan-group-id: Indicates the ID of the specified VLAN group. The VLAN group ID range is from 1 to 128. *vlan-list*: Indicates the specified VLAN list. The value range is from 1 to 4094. The number of VLANs allowed in the list is 1 to 32. *def-vlan-id*: Indicates the default VLAN in the VLAN list. The value ranges from 1 to 4094. r*adio-id*: Indicates the ID of the radio of a specified AP. If radio-id is not specified, the mapping is applied to all radios of all APs in the AP group. The radio ID range is from 1 to 96. **6GHz**: Indicates that the mapping is applied to all 6 GHz radios of all APs in the AP group. **802.11b**: Indicates that the mapping is applied to all 2.4 GHz radios of all APs in the AP group. **802.11a**: Indicates that the mapping is applied to all 5.8 GHz radios of all APs in the AP group. *ap-wlan-id*: Specifies the WLAN ID that is used on the AP through interface mapping. The value range is from 1 to 64.
Defaults	By default, a WLAN is not associated with any VLAN group.
Command Mode	AP group configuration mode
Usage Guide	Only the AC supports this command. ● In local forwarding mode, if the VLAN ID assigned to a terminal by using the **interface-mapping** command is the same as the VLAN ID specified by using the **ap-vlan** command, the service VLAN for data forwarding by the terminal will be determined by the access switch connected to the AP. In particular, if the VLAN ID configured by using the **interface-mapping** command is 1 (when the **ap-vlan** command is not configured, the default VLAN ID of **ap-vlan** is 1), the VLAN of the terminal for data forwarding will be determined by the access switch. ● When the **interface-mapping** command is used to configure the list mapping mode, a single VLAN ID can be added, but the VLAN ID specified in the VLAN list cannot be deleted. ● When the i**nterface-mapping** command is used to configure the list mapping mode, the VLAN members in the VLAN list must be configured with corresponding VLANs on the AC. Otherwise, the 802.1X authenticated users cannot be connected.

Verification

- Run the **show running** command to check configurations of all AP groups.

Configuration Example



Configuring Mapping Between a WLAN and a VLAN Group

Configuration Steps	● Enter the AP group configuration mode. ● Configure the mapping between a WLAN and a VLAN group.
	`Hostname(config)# ap-group default` `Hostname(config-ap-group)# interface-mapping 1 vlan-group 1`
Verification	● Run the **show running** command to check whether the configuration is correct.

Configuring 802.1X-based VLAN Assignment

In the WLAN scenario shown in Figure 1-2, leaders, employees, and guests are differentiated to access the WLAN with different privilege levels. The following configurations are required:

- Create VLAN group 100, including VLAN 10, VLAN 20, and VLAN 30.
- Map WLAN 1 to VLAN group 100. When STAs access WLAN 1, the authentication server performs 802.1X authentication for the STAs. After the authentication is complete, the authentication server assigns VLAN 10 to leaders, VLAN 20 to employees, and VLAN 30 to guests.

Scenario **Figure 1-2**	
Configuration Steps	● If 1:N mapping between a WLAN and a VLAN group is used, different VLANs can be assigned to STAs in the same WLAN. ● Set the WLAN authentication mode to 802.1X authentication so that different VLANs can be assigned to different STAs.
AP1 & AP2	APs apply the centralized forwarding in fit AP architecture by default, and are managed by the AC in a unified manner.

AC	Step 1: Create VLANs respectively for different types of users.
	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# vlan range 10,20,30`
	`Hostname(config-vlan-range)# exit`
	Step 2: Create a VLAN group, add VLAN 10, VLAN 20, and VLAN 30 to the group, and configure VLAN 30 as the default VLAN for guests.
	`Hostname(config)# vlan-group 100`
	`Hostname(config-vlan-group)# vlan-assign-mode dot1x`
	`Hostname(config-vlan-group)# vlan-list 10,20,30`
	`Hostname(config-vlan-group)# default-vlan 30`
	`Hostname(config-vlan-group)# exit`
	Step 3: Create WLAN 1, with the WLAN authentication mode set to 802.1X authentication and the encryption mode set to Advanced Encryption Standard (AES).

	Hostname(config)# wlan-config 1 office_wifi Hostname(config-wlan)# exit Hostname(config)# wlansec 1 Hostname(wlansec)# security wpa enable Hostname(wlansec)# security wpa akm 802.1x enable Hostname(wlansec)# security wpa ciphers aes enable Step 4: Configure the mapping between WLAN 1 and VLAN group 100. Hostname(config)# ap-group default Hostname(config-ap-group)# interface-mapping 1 vlan-group 100
Authentication Server	● Before establishing a new STA type on the authentication server, configure a specific VLAN.
Verification	● Check the VLAN group configuration on the AC.
AC	Hostname# show vlan-group VLAN-Group ID Default VLAN Assign-Mode VLAN-List ---------- ---------- ---------- ---------- 100 30 dot1x 10,20,30

Common Errors

- N/A

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show vlan-group [*group-id*]	Displays VLAN group information.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug bridge vgoup	Debugs the VLAN group status.

1 Configuring MSTP

1.1 Overview

The Spanning Tree Protocol (STP) is a Layer 2 management protocol. It can selectively block redundant links to eliminate Layer 2 loops and back up links.

STP is continuously updated from the Rapid Spanning Tree Protocol (RSTP) to the Multiple Spanning Tree Protocol (MSTP) as the network develops.

For the Layer 2 Ethernet, only one active link can exist between two local area networks (LANs). Otherwise, a broadcast storm will occur. To enhance reliability of a LAN, it is necessary to establish a redundant link and keep some paths in backup state. If the network is faulty and a link fails, you must switch the redundant link to the active state. Manual control is infeasible in this situation. Therefore, STP needs to automatically complete this work. STP enables devices on a LAN to provide the following functions:

- Discover and start the best tree topology on the LAN.
- Troubleshoot a fault and automatically update the network topology so that the possible best tree topology is always selected.

The LAN topology is automatically calculated based on a set of bridge parameters configured by an administrator. The best topology tree can be obtained by properly configuring these parameters.

RSTP is compatible with 802.1D STP. Similar to traditional STP, RSTP provides loop-free topology and link redundancy. It is characterized by rapid speed. If all bridges on a LAN support RSTP and are properly configured by the administrator, it takes less than 1 second (about 50 seconds for traditional STP) to re-generate a topology tree after the network topology changes.

STP and RSTP have the following defects:

- STP migration is slow. Even on point-to-point links or edge ports, it still takes twice the forward delay for ports to switch to the forwarding state.
- RSTP can rapidly converge but has the same defect with STP. Since all VLANs on a LAN share the same spanning tree, packets of all VLANs are forwarded along this spanning tree. Therefore, redundant links cannot be blocked according to specific VLANs and data traffic cannot be load balanced among VLANs.

MSTP, defined by IEEE 802.1s, resolves defects of STP and RSTP. It can rapidly converge and enable traffic of different VLANs to be forwarded along respective paths, thereby providing a better load balancing mechanism for redundant links.

Typically, STP/RSTP works based on ports, while MSTP works based on instances. An instance is a set of multiple VLANs. Binding multiple VLANs to one instance can reduce the communication overhead and resource utilization.

Ruijie devices support STP, RSTP, and MSTP, and comply with IEEE 802.1d, IEEE 802.1w, and IEEE 802.1s.

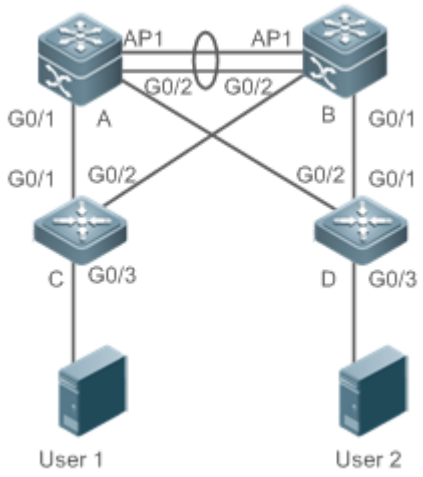
Protocols and Standards

- IEEE 802.1D: Media Access Control (MAC) Bridges
- IEEE 802.1w: Part 3: Media Access Control (MAC) Bridges—Amendment 2: Rapid Reconfiguration

- IEEE 802.1s: Virtual Bridged Local Area Networks—Amendment 3: Multiple Spanning Trees

1.2 Applications

Application	Description
Configuring MSTP	With the hierarchical network architecture, MSTP and the Virtual Router Redundancy Protocol (VRRP) are used to implement redundancy and load balancing to improve system availability of the network.



1.2.1 MSTP+VRRP Dual-Core Topology

Scenario

The MSTP+VRRP dual-core solution is often used. This solution improves system availability of a network. It uses the hierarchical network architecture composed of three layers (core layer, aggregation layer, and access layer) or two layers (core layer and access layer), forming the switching network system to provide data exchange service.

In the hierarchical network architecture, all capacity indicators, characteristics, and functions of network devices at each layer are optimized based on their network locations and roles, enhancing their stability and availability.

Figure 1-1 MSTP+VRRP Dual-Core Topology

Remarks	The topology is divided into two layers: core layer (Devices A and B) and access layer (Devices C and D).

Deployment

- Core layer: Multiple Spanning Tree instances (MSTIs) are configured to realize load balancing. For example, two MSTIs are created: MSTI 1 and MSTI 2. MSTI 1 maps VLAN 10, while MSTI 2 maps VLAN 20. Device A is the root bridge of MSTIs 0 and 1. MSTI 0 is the Common and Internal Spanning Tree (CIST), which exists by default. Device B is the root bridge of MSTI 2.
- Core layer: Devices A and B are VRRP master devices in VLAN 10 and VLAN 20, respectively.
- Access layer: Configure the port directly connected to the terminal (PC or server) as an edge port, and enable BPDU guard to prevent users from accessing unauthorized devices.

1.3 Features

Basic Concepts

BPDU

To generate a stable tree topology network, ensure that the following conditions are met:

- Each bridge has a unique ID consisting of the bridge priority and MAC address.
- The overhead of the path from the bridge to the root bridge is called the root path cost.
- A port ID consists of the port priority and port number.

Bridges exchange Bridge Protocol Data Units (BPDUs) to obtain information required for establishing the best tree topology. The BPDUs use the multicast address 01-80-C2-00-00-00 (hexadecimal notation) as the destination address.

A BPDU consists of the following elements:

- Root bridge ID assumed by the local bridge
- Root path cost of the local bridge
- Bridge ID of the local bridge
- Message Age (lifetime of the BPDU)
- Port ID (ID of the port sending the BPDU)
- Forward Delay, Hello Time, Max Age are specified in MSTP.
- Other flags, such as flags indicating network topology changes and local port status

If a port of a bridge receives a BPDU with a higher priority (smaller bridge ID and lower root path cost), the bridge saves BPDU information and transmits the information to all other ports. If the bridge receives a BPDU with a lower priority, it discards the information.

Such a mechanism allows information with higher priorities to be transmitted across the entire network. BPDU exchange results are as follows:

- A bridge is selected as the root bridge.
- Except the root bridge, each bridge has a root port, that is, a port providing the shortest path to the root bridge.
- Each bridge calculates the shortest path to the root bridge.
- Each LAN has a designated bridge located in the shortest path between the LAN and the root bridge. A port designated to connect the bridge and the LAN is called designated port.
- The root port and designated port enter the forwarding state.

Bridge ID

According to IEEE 802.1w, each bridge has a unique ID. The spanning tree algorithm selects the root bridge based on the bridge ID. The bridge ID consists of 8 bytes, of which the last 6 bytes are the MAC address of the bridge. In its first 2 bytes (as listed in the following table), the first 4 bits indicate the priority; the last 8 bits indicate the system ID and is reserved. In RSTP, the system ID is 0. Therefore, the bridge priority should be an integral multiple of 4096.

-	Priority				System ID											
bit	16	15	14	13	12	11	10	9	8	7	6	5	4	3	2	1
-	32768	16384	8192	4096	2048	1024	512	256	128	64	32	16	8	4	2	1
-	0	0	0	1	0	0	0	0	0	0	0	0	0	0	0	0

Spanning Tree Timers

The following three timers affect the performance of the entire spanning tree:

- Hello timer: Interval for periodically sending a BPDU.
- Forward Delay timer: Interval for changing the port status, that is, interval for a port to change from the listening state to the learning state or from the learning state to the forwarding state when RSTP runs in STP-compatible mode.
- Max Age timer: Maximum time-to-live (TTL) of a BPDU. When this timer elapses, the BPDU is discarded.

Port Roles and States

Each port plays a role on a network to reflect different functions in the network topology.

- Root port: Provides the shortest path to the root bridge.
- Designated port: Is used by each LAN to connect the root bridge.
- Alternate port: Is the alternative port of the root port. Once the root port loses its role, the alternate port immediately changes to the root port.
- Backup port: Is the backup of the designated port. When a bridge has two ports connected to a LAN, the port with the higher priority is the designated port while the port with the lower priority is the backup port.
- Disabled port: Is in inactive state. The port with the operation state being Down plays this role.

The following uppercase letters represent roles of different ports:

- R: root port
- D: designated port
- A: alternate port
- B: backup port

Unless otherwise specified, the ports are prioritized in descending order: R > D > A > B.

Figure 1-2

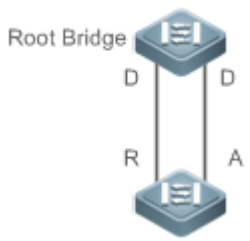


Figure 1-3

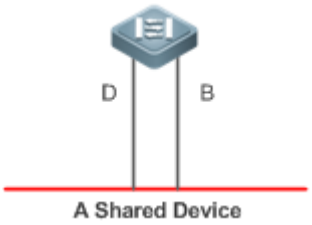

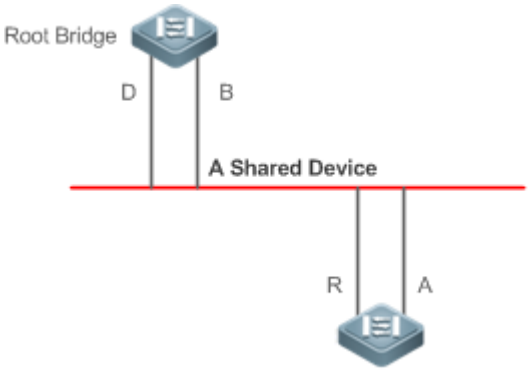

Figure 1-4

Each port has three states indicating whether to forward data packets so as to control the entire spanning tree topology:

- Discarding: Does not forward received packets or learn the source MAC address.
- Learning: Does not forward received packets but learns the source MAC address, which is a transitive state.
- Forwarding: Forwards received packets and learns the source MAC address.

For a stable network topology, only the root port and designated port can enter the forwarding state while other ports are always in discarding state.

Hop Count

Internal spanning trees (ISTs) and MSTIs calculate whether the BPDU time expires based on the hop count that is similar to the IP TTL, but not Message Age and Max Age.

You are advised to run the **spanning-tree max-hops** command in global configuration mode to configure the hop count. In a region, every time a BPDU passes through a device from the root bridge, the hop count decreases by 1. When the hop count becomes 0, the BPDU time expires and the device discards the BPDU.

To be compatible with STP and RSTP outside the region, MSTP retains Message Age and Max Age mechanisms.

Overview

Feature	Description
STP	STP, defined by IEEE 802.1D, is used to eliminate physical loops at the data link layer on a LAN.
RSTP	RSTP, defined by IEEE 802.1w, is optimized based on STP to rapidly converge the network topology.
MSTP	MSTP, defined by IEEE 802.1s, resolves defects of STP, RSTP, and Per-VLAN Spanning Tree (PVST). It can rapidly converge and forward traffic of different VLANs along respective paths, thereby providing a better load balancing mechanism for redundant links.

MSTP Optional Features	MSTP optional features include the edge port, BPDU guard, BPDU filter, TC protection, TC guard, TC filter, BPDU source MAC address check, BPDU filter, Auto Edge, root guard, and loop guard.

1.3.1 STP

STP is used to prevent broadcast storms incurred by loops and provide link redundancy.

Working Principle

For the Layer 2 Ethernet, only one active link can exist between two LANs. Otherwise, a broadcast storm will occur. To enhance reliability of a LAN, it is necessary to establish a redundant link and keep some paths in backup state. If the network is faulty and a link fails, you must switch the redundant link to the active state. Manual control is infeasible in this situation. Therefore, STP needs to automatically complete this work. STP enables devices on a LAN to provide the following functions

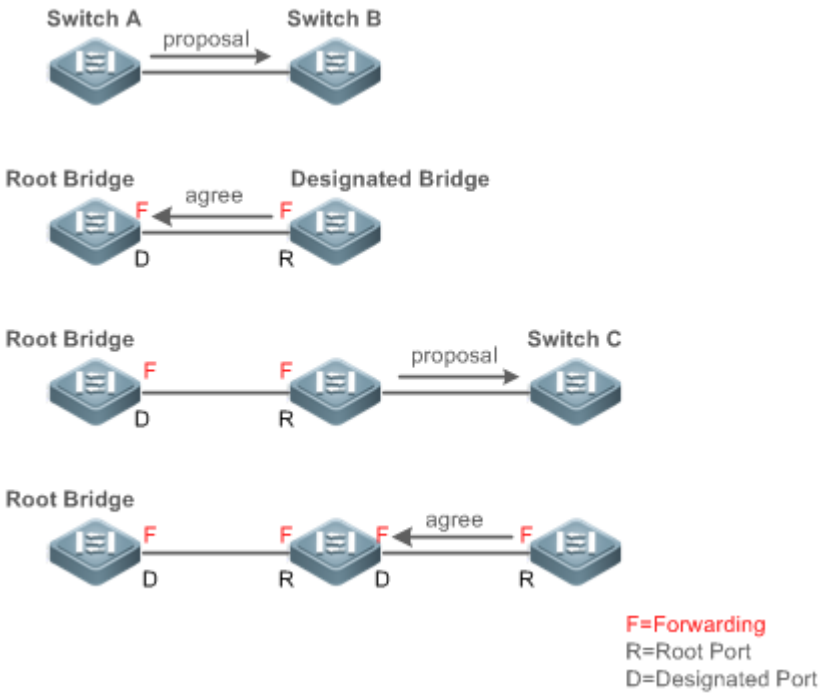
- Discover and start the best tree topology on the LAN.
- Troubleshoot a fault and automatically update the network topology so that the possible best tree topology is always selected.

The LAN topology is automatically calculated based on a set of bridge parameters configured by the administrator. The best topology tree can be obtained by properly configuring these parameters.

1.3.2 RSTP

RSTP is compatible with 802.1D STP. Similar to traditional STP, RSTP provides loop-free and redundancy services. It is characterized by rapid speed. If all bridges on a LAN support RSTP and are properly configured by the administrator, it takes less than 1 second (about 50 seconds for traditional STP) to re-generate a topology tree after the network topology changes.

Working Principle



↘ Fast Convergence of RSTP

RSTP can make ports quickly enter the forwarding state.

STP enables a port to enter the forwarding state 30 seconds (twice the value of the Forward Delay, which can be configured and has the default value of 15 seconds) after selecting a port role. Each time the topology changes, the root port and designated port reselected by each bridge enter the forwarding state 30 seconds later. Therefore, it takes about 50 seconds for the entire network topology to become the tree topology.

RSTP differs greatly from STP in the forwarding process. As shown in Figure 1-5, Switch A sends an RSTP Proposal packet to Switch B. If Switch B finds that the priority of Switch A is higher, it selects Switch A as the root bridge. In addition, the port receiving the packet is used as the root port and enters the forwarding state immediately. Then, Switch B sends an Agree packet from the root port to Switch A. If the designated port of Switch A is agreed, the port enters the forwarding state. Switch B's designated port resends a Proposal packet to extend the spanning tree by sequence. RSTP can recover the network tree topology to rapidly converge once the network topology changes.

Figure 1-5

The preceding handshake process is implemented only when ports are connected in point-to-point mode. To give the devices their full play, do not use non-P2P connections between devices.

Figure 1-6 and **Figure 1-7** show the examples of non-point-to-point connection.

Example of non-P2P connection:

Figure 1-6

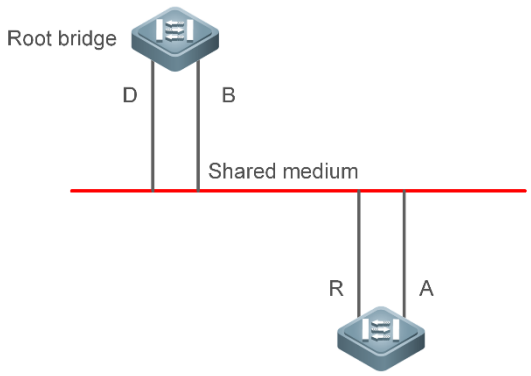


Figure 1-7

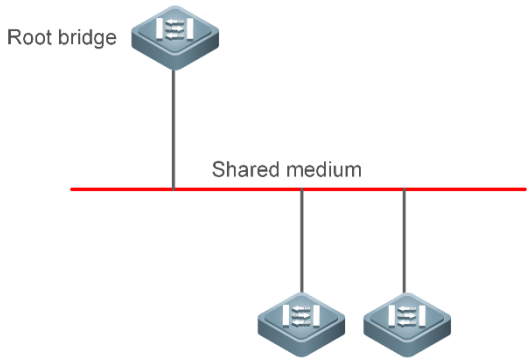

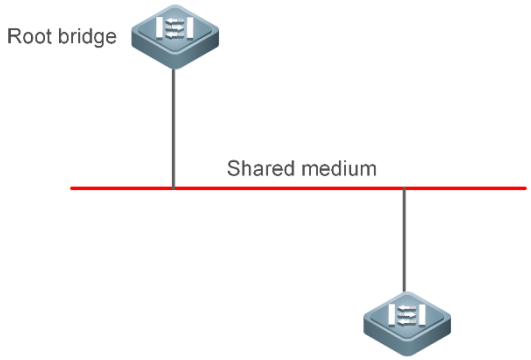

Figure 1-8 shows an example of point-to-point connection.

Figure 1-8

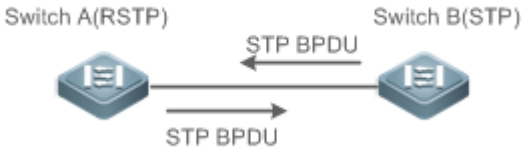
Compatibility Between RSTP and STP

RSTP is compatible with STP. RSTP automatically checks whether the connected bridge supports STP or RSTP based on the received BPDU version number. If the port connects to an STP bridge, the port enters the forwarding state 30s later.

Another problem may occur when RSTP and STP are used together. As shown in the following figures, Switch A (RSTP) connects to Switch B (STP). If Switch A finds itself connected to an STP bridge, it sends an STP BPDU. However, if Switch B is replaced with Switch C (RSTP) but Switch A still sends STP BPDUs, Switch C will assume itself connected to the STP bridge. As a result, two RSTP devices work in STP mode, reducing the efficiency.

RSTP provides the protocol migration feature to forcibly send RSTP BPDUs (the peer bridge must support RSTP). In this case, Switch A is enforced to send an RSTP BPDU and Switch C then finds itself connected to the RSTP bridge. As a result, two RSTP devices work in RSTP mode, as shown in Figure 1-9.

Figure 1-9



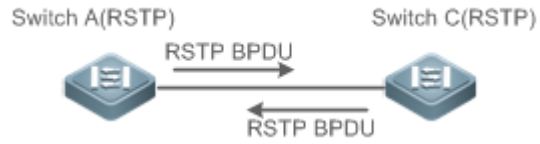


Figure 1-10

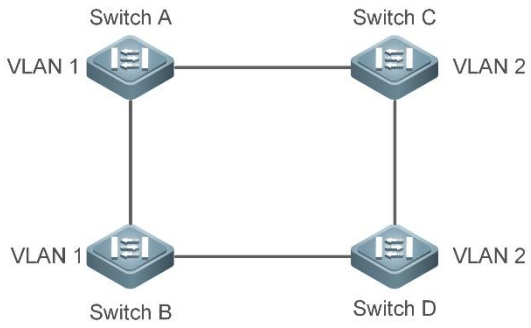
1.3.3 MSTP

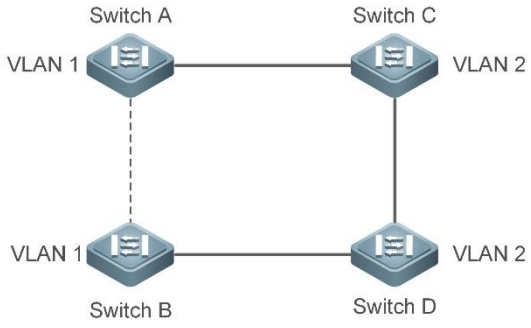
MSTP resolves defects of STP and RSTP. It can rapidly converge and forward traffic of different VLANs along respective paths, thereby providing a better load balancing mechanism for redundant links.



Working Principle

Ruijie devices support MSTP. MSTP is developed based on traditional STP and RSTP, and also provides the fast RSTP forwarding mechanism.

Since traditional spanning tree protocols are irrelevant to VLANs, problems may occur in specific network topologies.



As shown in Figure 1-11, Devices A and B are in VLAN 1, while Devices C and D are in VLAN 2, forming a loop.

Figure 1-11

If the cost of the link from Device A to Device B through Devices C and D is less than that of the link from Device A to Device B, the link between Device A and Device B enters the discarding state (as shown in Figure 1-12). Because Devices C and D are not added to VLAN 1 and cannot forward data packets of VLAN 1, VLAN 1 of Device A fails to communicate with VLAN 1 of Device B.

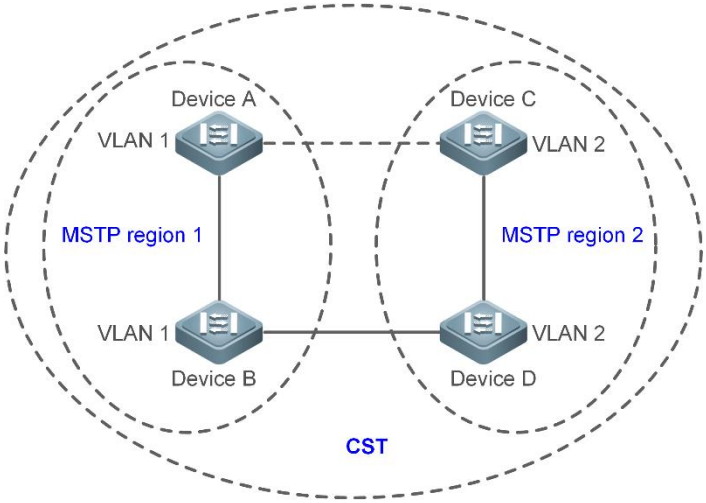


Figure 1-12

MSTP is developed to resolve this problem. It divides one or more VLANs of a device into an MSTI. Devices configured with the same MSTI form an MST region to run an independent spanning tree (called IST). The MST region implements the spanning tree algorithm with other MST regions to generate a complete spanning tree, which is called common spanning tree (CST).

Based on this algorithm, the network topology is formed shown in Figure 1-13. Devices A and B are in MSTP region 1 where no loop occurs, and therefore no link enters the discarding state. This also applies to MSTP region 2. Loops exist between MST region 1 and region 2, so a link is selected to enter the discarding state.

Figure 1-13

This prevents loops to ensure proper communication between devices in the same VLAN.

MSTP Region Division

For MSTP, you must properly divide MSTP regions and configure the same MST configuration for devices in the same MSTP region.

MST configuration includes the following items:

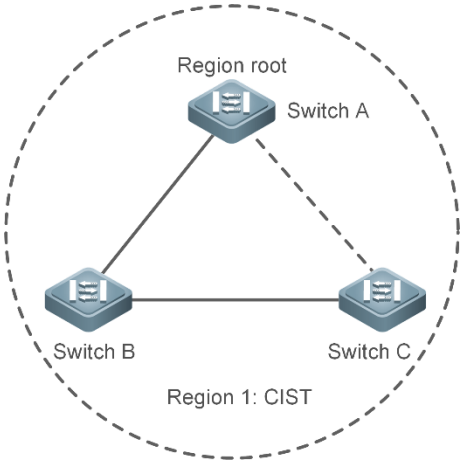
- MST configuration name: Consists of at most 32 bytes to identify an MSTP region.
- MST revision number: Consists of 16 bits to identify an MSTP region.
- MSTI-VLAN mapping table: A maximum of 64 MSTIs (with their IDs ranging from 1 to 64) are created for each device and MSTI 0 exists by default. Therefore, the system supports a maximum of 65 MSTIs. You can assign 1 to 4,994 VLANs belonging to different MSTIs (ranging from 0 to 64) as required. Unassigned VLANs belong to MSTI 0 by default. In this case, each MSTI is a VLAN group and implements the spanning tree algorithm of the MSTI specified in the BPDU, which is not affected by CIST and other MSTIs.

Run the **spanning-tree mst configuration** command in global configuration mode to enter the MST configuration mode to configure the preceding information.

MSTP BPDUs carry the preceding information. If the BPDU received by a device carries the same MST configuration with that on the device, it regards that the connected device belongs to the same MST region with itself. Otherwise, it regards the connected device originated from another MST region.

You are advised to configure the MSTI-VLAN mapping table after disabling MSTP. Then, re-enable MSTP to ensure stability and convergence of the network topology.

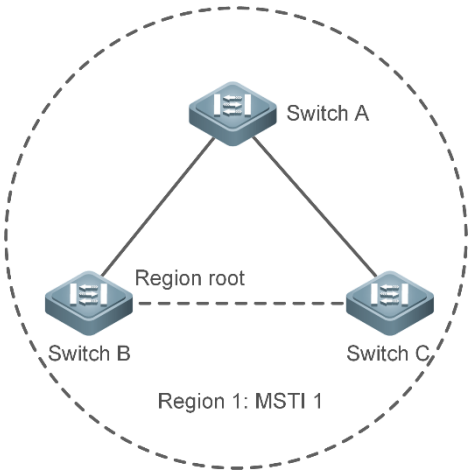
IST (Spanning Tree in an MST Region)



After MSTP regions are divided, each region selects an independent root bridge for each MSTI based on the corresponding parameters such as the bridge priority and port priority, assigns roles to each port on each device, and specifies whether the port is in forwarding or discarding state in the MSTI based on the port role.

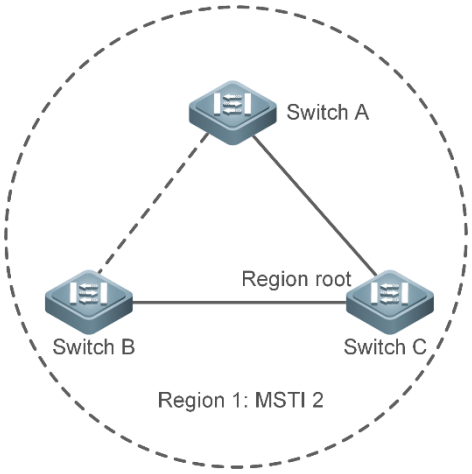
Through MSTP BPDU exchange, an IST is generated and each MSTI has their own spanning tree, in which the spanning tree corresponding to MSTI 0 and CST are uniformly called Common Instance Spanning Tree (CIST). That is, each MSTI provides a single and loop-free network topology for their own VLAN groups.

As shown in Figure 1-14, Devices A, B, and C form a loop in Region 1.



As shown in Figure 1-14, Device A has the highest priority in the CIST (MSTI 0) and thereby is selected as the region root. Then the link between A and C is enabled to enter the discarding state based on other parameters. Therefore, for the VLAN group of MSTI 0, only links from A to B and from B to C are available, eliminating the loop of this VLAN group.

Figure 1-14

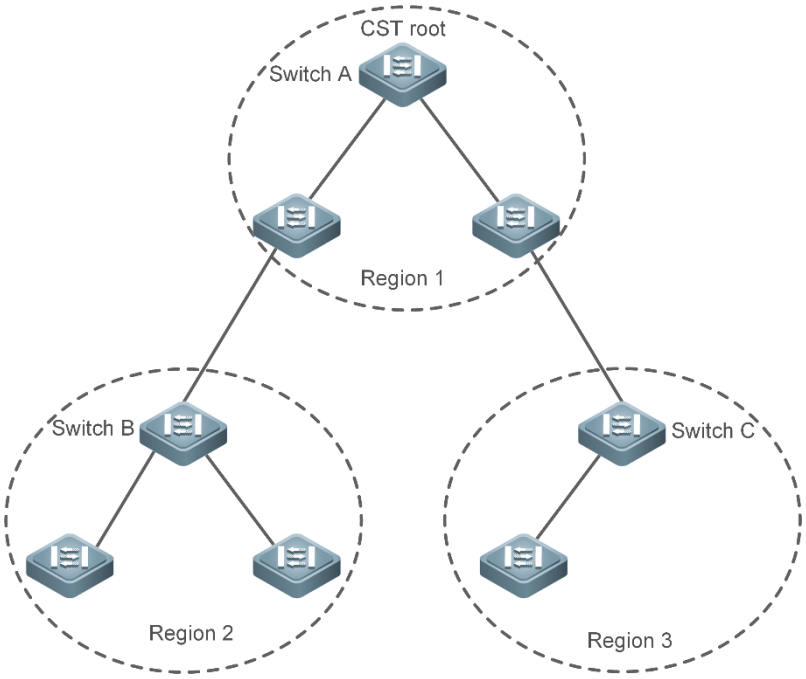


As shown in Figure 1-15, Device B has the highest priority in the MSTI 1 and thereby is selected as the region root. Then the link between B and C is enabled to enter the discarding state based on other parameters. Therefore, for the VLAN group of MSTI 1, only links from A to B and from A to C are available, eliminating the loop of this VLAN group.

Figure 1-15

As shown in Figure 1-16, Device C has the highest priority in the MSTI 2 and thereby is selected as the region root. Then the link between B and C is enabled to enter the discarding state based on other parameters. Therefore, for the VLAN group of MSTI 2, only links from B to C and from A to C are available, eliminating the loop of this VLAN group.

Figure 1-16



Note that MSTP does not consider the VLAN which a port belongs to. Therefore, you should configure the path cost and priority of a related port based on the actual VLAN configuration to prevent MSTP from incorrectly eliminating loops.

CST (Spanning Tree Between MST Regions)

Each MST region is similar to a large device for the CST. Different MST regions form a large network topology tree called CST. As shown in Figure 1-17, Device A, of which the bridge ID is the smallest, is selected as the root in the entire CST and the CIST regional root in this region. In MST region 2, since the root path cost from Device B to the CST root is lowest, Device B is selected as the CIST regional root in the region. For the same reason, Device C is selected as the CIST regional root.

Figure 1-17

The CIST regional root may be not the device of which the bridge ID is the smallest in the region but indicates the device of which the root path cost from this region to the CST root is the smallest.

For the MSTI, the root port of the CIST regional root has a new role: master port. The master port acts as the outbound port and is in forwarding state for all instance MSTIs. To make the topology more stable, the master port of each region to the CST root should be on the same device of the region if possible.

Compatibility Among MSTP, RSTP, and STP

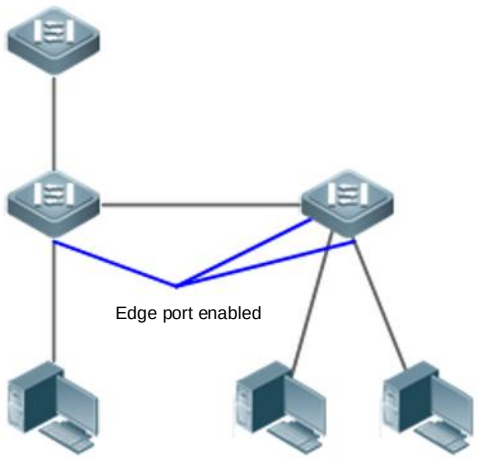
Similar to RSTP, MSTP sends STP BPDUs to be compatible with STP. For details, see *Compatibility Between RSTP and STP*.

Since RSTP processes MSTP BPDUs of the CIST, MSTP does not need to send RSTP BPDUs to be compatible with it.

Each STP or RSTP device is a single region and does not form the same region with any devices.

1.3.4 MSTP Optional Features

MSTP optional features mainly include the edge port, BPDU guard, BPDU filter, TC guard, and guard mode. The optional features are mainly used to deploy MSTP configuration based on the network topology and application characteristics on the MSTP network. This enhances stability, robustness, and attack defense capabilities of MSTP, meeting application requirements of MSTP in different customer scenarios.



Working Principle

Edge Port

If a port of a device connects directly to a network terminal, this port is configured as an edge port to directly enter the forwarding state. If the edge port is not configured, the port needs to wait for 30s to enter the forwarding state.

Figure 1-18 shows the ports that can be configured as edge ports.

Figure 1-18

If an edge port still receives BPDUs, its Port Fast Operational State is Disabled and the port enters the forwarding state according to the normal STP algorithm.

BPDU Guard

BPDU guard can be enabled globally or on a port.

You are advised to run the **spanning-tree portfast bpduguard default** command in global configuration mode to enable global BPDU guard. If a port receiving a BPDU is configured as an edge port or automatically identified as an edge port, the port immediately enters the error-disabled state to indicate the configuration error. In addition, the port is disabled, indicating that a network device may be added by an unauthorized user to change the network topology.

You are advised to run the **spanning-tree bpduguard enable** command in interface configuration mode to enable BPDU guard on a port regardless of whether the port is configured as the edge port. In this case, the port enters the error-disabled state immediately after receiving a BPDU.

BPDU Filter

BPDU filter can be enabled globally or on a port.

You are advised to run the **spanning-tree portfast bpdufilter default** command in global configuration mode to enable BPDU filter globally. In this case, the edge port does not receive or send BPDUs, and the host directly connected to the edge port cannot receive BPDUs. If the port changes its Port Fast Operational State to Disabled after receiving a BPDU, BPDU filter automatically takes ineffective.

You are advised to run the **spanning-tree bpdufilter enable** command in interface configuration mode to enable BPDU filter on a port regardless of whether the port is configured as the edge port. In this case, the port does not receive or send BPDUs but directly enters the forwarding state.

TC Protection

TC BPDUs carry the TC. If a switch receives such packets, the network topology changes and the switch will delete the MAC address table. For Layer 3 devices in this case, the forwarding module is re-enabled and the port status in the ARP entry changes. When a device is attacked by forged TC BPDUs, it will frequently perform the preceding operations, causing heavy load and affecting network stability. To prevent this problem, you can enable TC protection.

TC protection can be globally enabled or disabled only. This function is disabled by default.

When TC protection is enabled, the switch deletes TC BPDUs within a specified period (generally 4s) after receiving them and monitors whether any TC BPDU is received during the period. If a device receives TC BPDUs during this period, it deletes them when the period expires. This can prevent the device from frequently deleting MAC address entries and ARP entries.

TC Guard

TC protection ensures fewer dynamic MAC addresses and ARP entries deleted when a large number of TC BPDUs are generated on a network. However, a device receiving TC attack packets still performs many removal operations and TC BPDUs can be spread, affecting the entire network. TC guard can be used to prevent TC BPDUs from spreading globally or on a port. If TC guard is enabled globally or on a port, a port receiving TC BPDUs filters these TC BPDUs or TC BPDUs generated by itself, so TC BPDUs will not be spread to other ports. This can effectively control possible TC attacks on a network to ensure network stability. On Layer 3 devices, this function can effectively prevent the access device from flapping and causing the core route to be unreachable.

- If TC guard is used incorrectly, communication between networks is interrupted.
- You are advised to enable this function only when unauthorized TC attack packets are received on the network.
- If TC guard is enabled globally, no port spreads TC BPDUs to others. This function can be enabled only on desktop access devices.

If TC guard is enabled on a port, the topology changes incurred and TC BPDUs received on the port will not be spread to other ports. This function can be enabled only on uplink ports, particularly on ports of the aggregation device connected to the core device.

TC Filter

If TC guard is enabled on a port, the port does not forward TC BPDUs received and generated by the port to other ports performing spanning tree calculation on the device. When the status of a port changes (for example, from blocking to forwarding), the port generates TC BPDUs, indicating that the topology may have changed.

Because TC guard prevents TC BPDUs from being spread, the device may not delete MAC addresses of the port when the network topology changes, causing a data forwarding error.

TC filter is introduced to resolve this problem. TC filter does not process TC BPDUs received by ports but processes TC BPDUs in case of normal topology changes. If the port that is not configured as the edge port frequently alternates between Up and Down, MAC addresses are deleted and the core route may be unreachable. Enabling TC filter can resolve this issue, and core routing entries can be updated in a timely manner when the topology changes.

TC filter is disabled by default.

BPDU Source MAC Address Check

BPDU source MAC address check prevents BPDUs from maliciously attacking switches and causing MSTP exceptions. When the switch connected to a port on a point-to-point link is determined, you can enable BPDU source MAC address check so that the switch receives BPDUs sent only by the peer switch and discards all other BPDUs, thereby preventing malicious attacks. You can enable BPDU source MAC address check in interface configuration mode. One port can only filter one MAC address. If you run the **no bpdu src-mac-check** command to disable BPDU source MAC address check on a port, the port receives all BPDUs.

BPDU Filter

If the Ethernet length of a BPDU exceeds 1500 bytes, this BPDU will be discarded. This function prevents the device from receiving unauthorized BPDUs.

Auto Edge

If the designated port of a device does not receive a BPDU from the downlink port within a specific period (3s), the device regards a network device connected to the designated port, configures the port as an edge port, and switches the port directly into the forwarding state. The edge port will be automatically identified as a non-edge port after receiving a BPDU.

You can run the **spanning-tree autoedge disabled** command to disable Auto Edge.

This function is enabled by default.

If Auto Edge conflicts with the manually configured edge port, the edge port takes effect.

Because Auto Edge is used for rapid negotiation and forwarding between the designated port and the downlink port, STP does not support this function. If the designated port is in forwarding state, the Auto Edge configuration does not take effect on this port. It takes effect only when rapid negotiation is re-performed, for example, when the network cable is removed and reinstalled.

If BPDU filter has been enabled on a port, the port directly enters the forwarding state and is not automatically identified as an edge port.

Auto Edge applies only to the designated port.

Root Guard

During network design, the root bridge and backup root bridge are usually allocated to the same region. Due to incorrect configuration of maintenance personnel or malicious attacks on a network, the root bridge may receive the configuration with a higher priority and thereby switches to the backup root bridge, causing incorrect changes in the network topology. Root guard is used to resolve this problem.

If root guard is enabled on a port, its role in all MSTIs is forcibly configured as the designated port. Once the port receives the configuration with a higher priority, it enters the root-inconsistent (blocking) state. If the port does not receive the configuration with a higher priority within a period, it returns to its original state.

If a port enters the blocking state due to root guard, you can manually restore the port to the normal state by disabling root guard on this port or disabling spanning tree guard (running **spanning-tree guard none** in interface configuration mode).

If root guard is used incorrectly, the network link will be terminated.

If root guard is enabled on a non-designated port, this port will be forcibly configured as a designated port and enter the BKN state. This indicates that the port enters the blocking state due to root inconsistency.

If a port receiving the configuration with a higher priority in MSTI 0 enters the BKN state, this port will be enforced in BKN state in all other MSTIs.

Root guard and loop guard cannot be configured on a port simultaneously.

Loop Guard

Due to the unidirectional link failure, the root port or backup port becomes the designated port and enters the forwarding state if it does not receive BPDUs, causing a network loop. Loop guard is used to prevent this problem.

If a port enabled with loop guard does not receive BPDUs, the port switches its role but stays in discarding state till it receives BPDUs and recalculates the spanning tree.

You can enable loop guard globally or on a port.

Root guard and loop guard cannot be configured on a port simultaneously.

Before the MSTP process is restarted on a port, the port enters the blocking state. If the port still receives no BPDU after the MSTP process is restarted, the port will become a designated port and enter the forwarding state. Therefore, you should check the cause why a port enters the blocking state in loop protection and rectify the fault as soon as possible before restarting the MSTP process. Otherwise, the spanning tree topology will still become abnormal after the MSTP process is restarted.

BPDU Transparent Transmission

In IEEE 802.1Q, the destination MAC address 01-80-C2-00-00-00 of the BPDU is used as a reserved address. That is, devices compliance with IEEE 802.1Q do not forward the BPDUs received. However, devices may need to transparently transmit BPDUs during network deployment. For example, if STP is disabled on a device, the device needs to transparently transmit BPDUs so that the spanning tree between devices is properly calculated.

BPDU transparent transmission takes effect only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDUs.

1.4 Configuration

Configuration	Description and Command	
Enabling STP	(Mandatory) It is used to enable STP.	
	spanning-tree mode	Configures the STP mode.
	spanning-tree (with parameters)	Configures STP time parameters.
	spanning-tree	Enables STP
Configuring STP Compatibility	(Optional) It is used to be compatible with third-party devices.	
	spanning-tree compatible enable	Enables the compatibility mode of a port.
	clear spanning-tree detected-protocols	Performs mandatory version check for BPDUs.
Configuring an MST Region	(Optional) It is used to configure an MSTP region.	
	spanning-tree mst configuration	Enters the MST configuration mode.
Enabling Fast Convergence of RSTP	(Optional) It is used to configure whether the link type of a port is point-to-point connection.	
	spanning-tree link-type	Configures the link type.
Configuring Priorities	(Optional) It is used to configure the switch priority or port priority.	
	spanning-tree priority	Configures the switch priority.
	spanning-tree port-priority	Configures the port priority.
Configuring the Port Path Cost	(Optional) It is used to configure the path cost of a port or the default path cost calculation method.	
	spanning-tree cost	Configures the port path cost.
	spanning-tree pathcost method	Configures the default path cost calculation method.
Configuring the Maximum Hop Count of a BPDU	(Optional) It is used to configure the maximum hop count of a BPDU.	
	spanning-tree max-hops	Configures the maximum hop count of a BPDU.
Enabling the Edge Port	(Optional) It is used to enable edge port-related features.	
	spanning-tree portfast	Enables the edge port.
	spanning-tree portfast bpduguard default	Enables BPDU guard on all ports.
	spanning-tree bpduguard enable	Enables BPDU guard on a port.
	spanning-tree portfast bpdufilter default	Enables BPDU filter on all ports.
	spanning-tree bpdufilter enable	Enables BPDU filter on a port.
Enabling TC-related Features	(Optional) It is used to enable TC-related features.	
	spanning-tree tc-protection	Enables TC protection.

Configuration	Description and Command	
	spanning-tree tc-protection tc-guard	Enables TC guard on all ports.
	spanning-tree tc-guard	Enables TC guard on a port.
	spanning-tree ignore tc	Enables TC filter on a port.
Enabling BPDU Source MAC Address Check	(Optional) It is used to enable BPDU source MAC address check.	
	bpdu src-mac-check	Enables BPDU source MAC address check on a port.
Configuring Auto Edge	(Optional) It is used to configure Auto Edge.	
	spanning-tree autoedge	Enables Auto Edge on a port. This function is enabled by default.
Enabling Guard-related Features	(Optional) It is used to enable port guard features.	
	spanning-tree guard root	Enables root guard on a port.
	spanning-tree loopguard default	Enables loop guard on all ports.
	spanning-tree guard loop	Enables loop guard on a port.
	spanning-tree guard none	Disables the guard feature on a port.
Enabling BPDU Transparent Transmission	(Optional) It is used to enable BPDU transparent transmission	
	bridge-frame forwarding protocol bpdu	Enables BPDU transparent transmission.

1.4.1 Enabling STP

Configuration Effect

- Optional. Configure the STP mode.
- Optional. Configure STP time parameters.
- Enable STP globally.

Notes

- STP and Transparent Interconnection of Lots of Links (TRILL) of the data center cannot be enabled simultaneously.

Configuration Step

↘ Configuring the STP Mode

- Optional.
- Run the **spanning-tree mode** [**stp | rstp | mstp**] command to change the STP mode.
- According to 802.1 standards, STP, RSTP, and MSTP are compatible, without any configuration by the administrator. However, some vendors' devices do not conform to 802.1 standards, resulting in incompatibility. This command can be used to switch the spanning tree mode to an earlier version if other vendors' devices are incompatible with Ruijie devices.

Command	**spanning-tree mode** [**stp** | **rstp** | **mstp**]

Parameter Description	**mstp**: Indicates the Multiple Spanning Tree Protocol (MSTP), which is defined in IEEE 802.1s. **rstp**: Indicates the Rapid Spanning Tree Protocol (RSTP)), which is defined in IEEE 802.1w. **stp**: Indicates the Spanning Tree Protocol (STP)), which is defined in IEEE 802.1D.
Defaults	The default value is **mstp**.
Command Mode	Global configuration mode
Usage Guide	Some vendors' devices do not conform to 802.1 standards, resulting in incompatibility. If other vendors' devices are incompatible with Ruijie devices, run this command to switch the STP mode to an earlier version.

Configuring STP Time Parameters

- Optional.
- Run the **spanning-tree** [**forward-time** *forward* | **hello-time** *hello* | **max-age** *age* | **tx-hold-count** *tx-hold-count*] command to configure STP time parameters. One configuration command can carry only one parameter.

Command	**spanning-tree** [**forward-time** *forward*	**hello-time** *hello*	**max-age** *age*	**tx-hold-count** *tx-hold-count*]
Parameter Description	**forward-time** *forward*: Specifies the interval for changing the port status, in seconds. The value range is from 4 to 30. The default value is 15. **hello-time** *hello*: Specifies the interval for the device to send BPDUs, in seconds. The value range is from 1 to 10. The default value is 2. **max-age** *age*: Specifies the maximum timeout interval of BPDUs, in seconds. The value range is from 6 to 40. The default value is 20. **tx-hold-count** *tx-hold-count*: Configures the maximum number of BPDUs sent every second. The value range is from 1 to 10. The default value is 3.
Defaults	The default values of **forward-time**, **hello-time**, **max-age**, and **tx-hold-count** are 15, 2, 20, 20, and 3, respectively.
Command Mode	Global configuration mode
Usage Guide	The value ranges of **forward-time**, **hello-time**, and **max-age** are related. Changing the value range of one affects the value ranges of the other two parameters. The relationship is as follows: 2 x (Hello Time + 1.0 second) ≤ Max Age ≤ 2 x (Forward Delay – 1.0 second) If the preceding condition is not met, the topology may be unstable.

Enabling STP

- Mandatory. Unless otherwise specified, STP should be enabled on each device.
- Run the **spanning-tree** command to enable STP. STP is disabled by default.

Command	**spanning-tree**
Parameter Description	N/A
Defaults	STP is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Display the configuration.

Configuration Example

Enabling STP and Configuring Timer Parameters

Scenario **Figure 1-19**	
Configuration Steps	Enable STP and set the STP mode to STP on devices. Configure the timer parameters of Device A (root bridge) as follows: ● Hello Time = 4s ● Max Age = 25s ● Forward Delay = 18s

Device A	Step 1: Enable STP and set the STP mode to STP.
	`Hostname#configure terminal`
	`Hostname(config)#spanning-tree`
	`Hostname(config)#spanning-tree mode stp`
	Step 2: Configure timer parameters of Device A.
	`Hostname(config)#spanning-tree hello-time 4`
	`Hostname(config)#spanning-tree max-age 25`
	`Hostname(config)#spanning-tree forward-time 18`

Device B	Enable STP and set the STP mode to STP.
	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#spanning-tree`
	`Hostname(config)#spanning-tree mode stp`

Verification	● Run the **show spanning-tree summary** command to display the spanning tree topology and protocol configuration parameters.

Device A	`Hostname#show spanning-tree summary`
	
	`Spanning tree enabled protocol stp`
	`  Root ID    Priority    0`
	`             Address     00d0.f822.3344`
	`             this bridge is root`
	`             Hello Time   4 sec  Forward Delay 18 sec  Max Age 25 sec`
	
	`  Bridge ID  Priority    0`
	`             Address     00d0.f822.3344`
	`             Hello Time   4 sec  Forward Delay 18 sec  Max Age 25 sec`

	Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Desg FWD 20000 128 False P2p Gi0/1 Desg FWD 20000 128 False P2p
Device B	Hostname#show spanning-tree summary Spanning tree enabled protocol stp Root ID Priority 0 Address 00d0.f822.3344 this bridge is root Hello Time 4 sec Forward Delay 18 sec Max Age 25 sec Bridge ID Priority 32768 Address 001a.a917.78cc Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Altn BLK 20000 128 False P2p Bound(STP) Gi0/1 Root FWD 20000 128 False P2p Bound(STP)

Common Errors

The timer parameters will take effect only after the device has been elected as the root bridge.

1.4.2 Configuring STP Compatibility

Configuration Effect

- Enable the compatibility mode of a port to implement interconnection between Ruijie devices and third-party devices.
- Enable protocol migration to perform forcible version check, which will affect compatibility between RSTP and STP.

Notes

- If the compatibility mode is enabled on a port, this port will add different MSTI information into the to-be-sent BPDU based on the port to realize interconnection between Ruijie devices and third-party devices.

Configuration Step

↘ Enabling the Compatibility Mode on a Port

- Optional.

Command	**spanning-tree compatible enable**
Parameter Description	N/A

Command Mode	Interface configuration mode
Usage Guide	If the compatibility mode is enabled on a port, this port will add different MSTI information into the to-be-sent BPDU based on the port to realize interconnection between Ruijie devices and third-party devices.

Enabling Protocol Migration

- Optional.
- If the peer device supports RSTP, you can enforce version check on the local device to force the two devices to run RSTP.

Command	**clear spanning-tree detected-protocols** [**interface** *interface-type interface-number*]
Parameter Description	**interface** *interface-type interface-number*: Indicates a port.
Command Mode	Privileged EXEC mode
Usage Guide	This command is used to enforce a port to send RSTP BPDUs and perform forcible check on them.

Verification

- Display the configuration.

Configuration Example

Enabling STP Compatibility

Scenario Figure 1-20	
Configuration Steps	• Configure MSTIs 1 and 2 on Device A and Device B, and map MSTI 1 to VLAN 10 and MSTI 2 to VLAN 20. • Add GigabitEthernet 0/1 and GigabitEthernet 0/2 to VLAN 10 and VLAN 20 respectively, and enable STP compatibility.

Device A	Step 1: Configure MSTIs 1 and 2, and map MSTI 1 to VLAN 10 and MSTI 2 to VLAN 20.
	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#spanning-tree mst configuration`
	`Hostname(config-mst)#instance 1 vlan 10`
	`Hostname(config-mst)#instance 2 vlan 20`
	Step 2: Configure the VLAN to which the port belongs, and enable STP compatibility on the port.
	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#switchport access vlan 10`
	`Hostname(config-if-GigabitEthernet 0/1)#spanning-tree compatible enable`

	Hostname(config-if-GigabitEthernet 0/1)#interface gigabitethernet 0/2 Hostname(config-if-GigabitEthernet 0/2)#switchport access vlan 20 Hostname(config-if-GigabitEthernet 0/2)#spanning-tree compatible enable
Device B	Perform the same steps as Device A.
Verification	● Run the **show spanning-tree summary** command to check whether the spanning tree topology is correctly calculated.

Device A	Hostname#show spanning-tree summary
	
	Spanning tree enabled protocol mstp
	MST 0 vlans map : 1-9, 11-19, 21-4094
	  Root ID Priority 32768
	  Address 001a.a917.78cc
	  this bridge is root
	  Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec
	
	  Bridge ID Priority 32768

	  Address 001a.a917.78cc
	  this bridge is region root
	
	  Bridge ID Priority 32768
	  Address 001a.a917.78cc

	Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Desg FWD 20000 128 False P2p
Device B	Hostname#show spanning-tree summary Spanning tree enabled protocol mstp MST 0 vlans map : 1-9, 11-19, 21-4094 Root ID Priority 32768 Address 001a.a917.78cc this bridge is root Hello Time 2 sec Forward Delay 15 sec Max Age 20 sec Bridge ID Priority 32768 Address 00d0.f822.3344 Hello Time 4 sec Forward Delay 18 sec Max Age 25 sec Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Altn BLK 20000 128 False P2p Gi0/1 Root FWD 20000 128 False P2p MST 1 vlans map : 10 Region Root Priority 32768 Address 001a.a917.78cc this bridge is region root Bridge ID Priority 32768 Address 00d0.f822.3344 Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/1 Root FWD 20000 128 False P2p MST 2 vlans map : 20 Region Root Priority 32768 Address 001a.a917.78cc this bridge is region root Bridge ID Priority 32768 Address 00d0.f822.3344 Interface Role Sts Cost Prio OperEdge Type ---------- ---- --- ---------- -------- -------- ---------- Gi0/2 Root FWD 20000 128 False P2p

Common Errors

You are advised to configure the same VLAN list on the two sides of the link.

1.4.3 Configuring an MST Region

Configuration Effect

- This section describes how to configure an MST region to change devices in the MST region, so as to affect the network topology.

Notes

- To make multiple devices belong to the same MSTP region, configure the same name, revision number, and MSTI-VLAN mapping table for them.
- You can configure VLANs for MSTIs 0 to 64, and then the remaining VLANs are automatically allocated to MSTI 0. One VLAN belongs to only one MSTI.
- You are advised to configure the MSTI-VLAN mapping table after disabling STP. Then re-enable MSTP to ensure stability and convergence of the network topology.

Configuration Step

↘ Configuring an MST Region

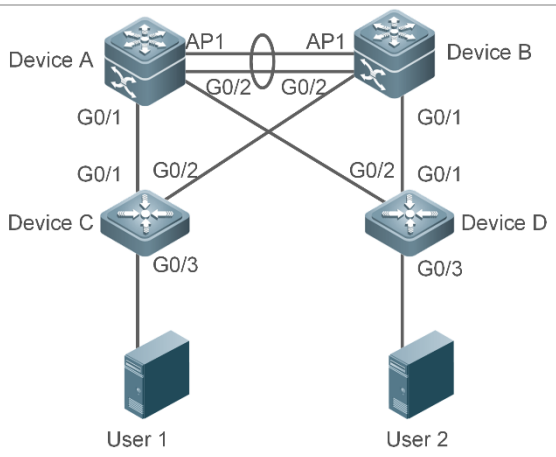
- Optional.
- Configure an MST region when multiple devices need to belong to the same MST region.
- Run the **spanning-tree mst configuration** command to configure the MST region configuration mode.
- Run the **instance** *instance-id* **vlan** *vlan-range* command to configure the MSTI-VLAN mapping.
- Run the **name** *name* command to configure the MST name.
- Run the **revision** *version* command to configure the MST version number.

Command	**spanning-tree mst configuration**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	Run this command to enter the MST configuration mode.

Command	**instance** *instance-id* **vlan** *vlan-range*
Parameter Description	*instance-id*: Indicates the MSTI ID. The value range is from 0 to 64. *vlan-range*: Indicates the VLAN ID. The value range is from 1 to 4,094.
Defaults	By default, only MSTI 0 exists, and all VLANs are mapped to MSTI 0.
Command Mode	MST configuration mode
Usage Guide	To add a VLAN group to an MSTI, run this command.

	For example, **instance 1 vlan 2-200**: Adds VLANs 2 to 200 to MSTI 1. **instance 1 vlan 2,20,200**: Adds VLANs 2, 20, and 200 to MSTI 1. You can run the **no instance** *instance-id* **vlan** *vlan-range* command to remove VLANs from an MSTI. The removed VLANs are automatically added to MSTI 0.

Command	**name** *name*
Parameter Description	*name*: Indicates the MST name. It consists of a maximum of 32 bytes.
Defaults	The name of an MST region is empty by default.
Command Mode	MST configuration mode
Usage Guide	N/A



Command	**revision** *version*
Parameter Description	*version*: Indicates the MST revision number. The value range is from 0 to 65,535.
Defaults	The default revision value of an MST region is 0.
Command Mode	MST configuration mode
Usage Guide	N/A

Verification

- Run the **show spanning-tree mst configuration** command to display the MST region configuration.

Configuration Example

Enabling MSTP to Achieve VLAN Load Balancing in the MSTP+VRRP Topology

Scenario **Figure 1-21**	
Configuration Steps	● Enable MSTP and create MSTIs 1 and 2 on Device A, Device B, Device C, and Device D. ● Configure Device A as the root bridge of MSTIs 0 and 1 and Device B as the root bridge of MSTI 2. ● Configure Device A as the VRRP master device of VLANs 1 and 10 and Device B as the

	VRRP master device of VLAN 20.

Device A	Step 1: Configure VLANs 10 and 20, and configure ports as trunk ports.
	`Hostname(config)#vlan 10`
	`Hostname(config-vlan)#vlan 20`
	`Hostname(config-vlan)#exit`
	`Hostname(config)#interface range gigabitethernet 0/1-2`
	`Hostname(config-if-range)#switchport mode trunk`
	`Hostname(config-if-range)#interface aggregateport 1`
	`Hostname(config-if-AggregatePort 1)# switchport mode trunk`
	Step 2: Enable MSTP and create MSTIs 1 and 2.
	`Hostname(config)#spanning-tree`
	`Hostname(config)# spanning-tree mst configuration`
	`Hostname(config-mst)#instance 1 vlan 10`
	`Hostname(config-mst)#instance 2 vlan 20`
	`Hostname(config-mst)#exit`
	Step 3: Configure Device A as the root bridge of MSTIs 0 and 1.
	`Hostname(config)#spanning-tree mst 0 priority 4096`
	`Hostname(config)#spanning-tree mst 1 priority 4096`
	`Hostname(config)#spanning-tree mst 2 priority 8192`
	Step 4: Configure VRRP priorities to enable Device A to act as the VRRP master device of VLAN 10, and configure the virtual gateway IP address of VRRP.
	`Hostname(config)#interface vlan 10`
	`Hostname(config-if-VLAN 10)ip address 192.168.10.2 255.255.255.0`
	`Hostname(config-if-VLAN 10) vrrp 1 priority 120`
	`Hostname(config-if-VLAN 10) vrrp 1 ip 192.168.10.1`
	Step 5: Set the VRRP priority to the default value 100 to enable Device A to act as the VRRP backup device of VLAN 20.
	`Hostname(config)#interface vlan 20`
	`Hostname(config-if-VLAN 20)ip address 192.168.20.2 255.255.255.0`
	`Hostname(config-if-VLAN 20) vrrp 1 ip 192.168.20.1`

Device B	Step 1: Configure VLANs 10 and 20, and configure ports as trunk ports.
	`Hostname(config)#vlan 10`
	`Hostname(config-vlan)#vlan 20`
	`Hostname(config-vlan)#exit`
	`Hostname(config)#interface range gigabitethernet 0/1-2`
	`Hostname(config-if-range)#switchport mode trunk`
	`Hostname(config-if-range)#interface aggregateport 1`
	`Hostname(config-if-AggregatePort 1)# switchport mode trunk`
	Step 2: Enable MSTP and create MSTIs 1 and 2.
	`Hostname(config)#spanning-tree`
	`Hostname(config)# spanning-tree mst configuration`
	`Hostname(config-mst)#instance 1 vlan 10`
	`Hostname(config-mst)#instance 2 vlan 20`
	`Hostname(config-mst)#exit`

	Step 3: Configure Device A as the root bridge of MSTI 2.
	`Hostname(config)#spanning-tree mst 0 priority 8192`
	`Hostname(config)#spanning-tree mst 1 priority 8192`
	`Hostname(config)#spanning-tree mst 2 priority 4096`
	Step 4: Configure the virtual gateway IP address of VRRP.
	`Hostname(config)#interface vlan 10`
	`Hostname(config-if-VLAN 10)ip address 192.168.10.3 255.255.255.0`
	`Hostname(config-if-VLAN 10) vrrp 1 ip 192.168.10.1`
	Step 5: Set the VRRP priority to 120 to enable Device B to act as the VRRP backup device of VLAN 20.
	`Hostname(config)#interface vlan 20`
	`Hostname(config-if-VLAN 20)vrrp 1 priority 120`
	`Hostname(config-if-VLAN 20)ip address 192.168.20.3 255.255.255.0`
	`Hostname(config-if-VLAN 20) vrrp 1 ip 192.168.20.1`

Device C	Step 1: Configure VLANs 10 and 20, and configure ports as trunk ports.
	`Hostname(config)#vlan 10`
	`Hostname(config-vlan)#vlan 20`
	`Hostname(config-vlan)#exit`
	`Hostname(config)#interface range gigabitethernet 0/1-2`
	`Hostname(config-if-range)#switchport mode trunk`
	Step 2: Enable MSTP and create MSTIs 1 and 2.
	`Hostname(config)#spanning-tree`
	`Hostname(config)# spanning-tree mst configuration`
	`Hostname(config-mst)#instance 1 vlan 10`
	`Hostname(config-mst)#instance 2 vlan 20`
	`Hostname(config-mst)#exit`
	Step 3: Configure the port connecting Device C directly to users as an edge port and enable BPDU guard.
	`Hostname(config)#interface gigabitethernet 0/3`
	`Hostname(config-if-GigabitEthernet 0/3)#spanning-tree portfast`
	`Hostname(config-if-GigabitEthernet 0/3)#spanning-tree bpduguard enable`

Device D	Perform the same steps as Device C.
Verification	● Run the **show spanning-tree summary** command to check whether the spanning tree topology is correctly calculated. ● Run the **show vrrp brief** command to check whether the VRRP master/backup devices are successfully created.

Device A	`Hostname#show spanning-tree summary`

Device D	Omitted.

Common Errors

- MST region configurations are inconsistent in the MSTP topology.
- VLANs are not created before you configure the MSTI-VLAN mapping.

- A device runs STP or RSTP in the MSTP+VRRP topology, but calculates the spanning tree according to the algorithms of different MST regions.

1.4.4 Enabling Fast Convergence of RSTP

Configuration Effect

- The link type affects fast convergence of RSTP.

Notes

- If the link type of a port is point-to-point, RSTP can rapidly converge. For details, see *Fast Convergence of RSTP*. If the link type is not configured, the device automatically sets the link type based on the duplex mode of the port. If a port works in full duplex mode, the device sets the link type to point-to-point. If a port works in half duplex mode, the device sets the link type to shared. You can also forcibly configure the link type to determine whether the port type is point-to-point.

Configuration Step

↘ Configuring the Link Type

- Optional.

Command	**spanning-tree link-type** { **point-to-point** | **shared** }
Parameter Description	**point-to-point**: Forcibly sets the link type of a port to be point-to-point. **shared**: Forcibly sets the link type of a port to be shared.
Defaults	The default connection type is **point-to-point** for full-duplex ports and **shared** for half-duplex ports.
Command Mode	Interface configuration mode
Usage Guide	If the link type of a port is point-to-point, RSTP can rapidly converge. If the link type is not configured, the device automatically sets the link type based on the duplex mode of the port.

Verification

- Run the **show spanning-tree interface** *interface-type interface-number* **link-type** command to display the configuration of the spanning tree port.
- Run the **show spanning-tree summary** command to display the link type of the port.

Configuration Example

↘ Enabling Fast Convergence of RSTP

Configuration Steps	● Set the link type of a port to point-to-point.
	`Hostname(config)#interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)#spanning-tree link-type point-to-point`
Verification	● Run the **show spanning-tree summary** command to display the link type of the port.
	`Hostname#show spanning-tree summary`

```
Spanning tree enabled protocol mstp
MST 0 vlans map : ALL
  Root ID    Priority    32768
             Address     001a.a917.78cc
             this bridge is root
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

  Bridge ID  Priority    32768
             Address     00d0.f822.3344
             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec

Interface        Role Sts Cost       Prio     OperEdge Type
---------------- ---- --- ---------- -------- -------- ----------------
Gi0/1            Root FWD 20000      128      False    P2p
```

Common Errors

If a port works in half duplex mode, the device sets the link type to shared.

1.4.5 Configuring Priorities

Configuration Effect

- The switch priority determines a device used as the root of the entire network and the topology of the entire network.
- The port priority determines the port that enters the forwarding state.

Notes

- You are advised to set a higher priority (small value) for the core device to ensure stability of the entire network. You can assign different switch priorities to different MSTIs so that each MSTI runs an independent STP based on the assigned priorities. Devices in different regions use the priority only of the CIST (MSTI 0). For the bridge ID, the switch priority has 16 optional values: 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. They are integral multiples of 4096. The default value is 32768.
- If two ports are connected to a shared device, the device selects a port with a higher priority (smaller value) to enter the forwarding state and a port with a lower priority (larger value) to enter the discarding state. If the two ports have the same priority, the device selects the port with a smaller port ID to enter the forwarding state. You can assign different port priorities to different MSTIs on a port so that each MSTI runs an independent STP based on the assigned priorities.
- Similar to the switch priority, the port priority also has 16 optional values: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. They are integral multiples of 16. The default value is 128.

Configuration Step

↘ Configuring the Switch Priority

- Optional.

- To change the root or topology of a network, configure the switch priority.

Command	**spanning-tree** [**mst** *instance-id*] **priority** *priority*
Parameter Description	**mst** *instance-id*: Indicates the ID of an MSTI. The value range is from 0 to 64. The default value is 0. **priority** *priority*: Indicates the switch priority. There are 16 optional values: 0, 4096, 8192, 12288, 16384, 20480, 24576, 28672, 32768, 36864, 40960, 45056, 49152, 53248, 57344, and 61440. They are integral multiples of 4096.
Defaults	The default bridge priority is 32768.
Command Mode	Global configuration mode
Usage Guide	Configure the switch priority to determine a device as the root of the entire network and to determine the topology of the entire network.

Configuring the Port Priority

- Optional.
- To change the preferred port entering the forwarding state, configure the port priority.

Command	spanning-tree [**mst** *instance-id*] **port-priority** *port-priority*
Parameter Description	**mst** *instance-id*: Indicates the ID of an MSTI. The value range is from 0 to 64. The default value is 0. **port-priority** *port-priority*: Indicates the port priority. There are 16 optional values: 0, 16, 32, 48, 64, 80, 96, 112, 128, 144, 160, 176, 192, 208, 224, and 240. They are integral multiples of 16.
Defaults	The default port priority is 128.
Command Mode	Interface configuration mode
Usage Guide	If a loop occurs in a region, the port with a higher priority is preferred to enter the forwarding state. If two ports have the same priority, the port with a smaller port ID is selected to enter the forwarding state.

Verification

- Run the **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id* command to display the spanning tree configuration of the port.

Configuration Example

Configuring the Port Priority

Scenario **Figure 1-22**	
Configuration Steps	● Configure the bridge priority so that Device A becomes the root bridge of the spanning tree. ● Configure the priority of GigabitEthernet 0/2 on Device A as 16 so that GigabitEthernet 0/2 on Device B can be selected as the root port.

Device A	Step 1: Enable STP and configure the bridge priority.
	`Hostname(config)#spanning-tree`
	`Hostname(config)#spanning-tree mst 0 priority 0`
	Step 2: Configure the priority of Gi 0/2.
	`Hostname(config)#interface gigabitethernet 0/2`
	`Hostname(config-if-GigabitEthernet 0/2)#spanning-tree mst 0 port-priority 16`

Device B	`Hostname(config)#spanning-tree`
Verification	● Run the **show spanning-tree summary** command to display the topology calculation result of the spanning tree.

Device A	`Hostname#show spanning-tree summary`
	
	`Spanning tree enabled protocol mstp`
	`MST 0 vlans map : ALL`
	`  Root ID    Priority    0`
	`             Address     00d0.f822.3344`
	`             this bridge is root`
	`             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec`
	
	`  Bridge ID  Priority    0`
	`             Address     00d0.f822.3344`
	`             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec`
	
	`Interface        Role Sts Cost       Prio     OperEdge Type`
	`---------------- ---- --- ---------- -------- -------- ----------------`
	`Gi0/2            Desg FWD 20000      16       False    P2p`
	`Gi0/1            Desg FWD 20000      128      False    P2p`

Device B	`Hostname#show spanning-tree summary`
	
	`Spanning tree enabled protocol mstp`
	`MST 0 vlans map : ALL`
	`  Root ID    Priority    0`
	`             Address     00d0.f822.3344`
	`             this bridge is root`
	`             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec`
	
	`  Bridge ID  Priority    32768`
	`             Address     001a.a917.78cc`
	`             Hello Time   2 sec  Forward Delay 15 sec  Max Age 20 sec`
	
	`Interface        Role Sts Cost       Prio     OperEdge Type`
	`---------------- ---- --- ---------- -------- -------- ----------------`
	`Gi0/2            Root FWD 20000      128      False    P2p`
	`Gi0/1            Altn BLK 20000      128      False    P2p`

Common Errors

The port priority will take effect only after the designated port has been changed.

1.4.6 Configuring the Port Path Cost

Configuration Effect

- Configuring the path cost of a port will determine the forwarding state of the port and the topology of the entire network.
- If the path cost of a port uses its default value, configuring the path cost calculation method affects the calculation result.

Notes

- A device selects a port as the root port if the path cost from this port to the root bridge is the lowest. Therefore, the port path cost determines the root port of the local device. The default port path cost is automatically calculated based on the port rate (Media Speed). A port with a higher rate will have a low path cost. Because this method can calculate the most proper path cost, do not change the path cost unless required. You can assign different path costs to different MSTIs on a port so that each MSTI runs an independent STP based on the assigned path costs.
- If the port path cost uses the default value, the device automatically calculates the port path cost based on the port rate. However, IEEE 802.1d-1998 and IEEE 802.1t define different path costs for the same link rate. The value is a an integer ranging from 1 to 65,535 in short mode for 802.1d-1998 and from 1 to 200,000,000 in long mode for IEEE 802.1t. The path cost of an aggregate port has two solutions:

  1. Ruijie solution: path cost of an aggregate port = port path cost x 95%

  2. Solution recommended in standards: path cost of an aggregate port = 20,000,000,000/actual link bandwidth of the aggregate port (actual link bandwidth of the aggregate port = bandwidth of a member port x number of active member ports)

  The administrator must unify the path cost calculation method on the entire network. The default standard is the private integer standard in long mode.
- The following table lists path costs automatically configured for different link rate in two solutions.

Port Rate	Port	IEEE 802.1d (Short)	IEEE 802.1t (Long)	IEEE 802.1t (Long Standard)
10M	Common port	100	2000000	2000000
	Aggregate port	95	1900000	2000000/linkupcnt
100M	Common port	19	200000	200000
	Aggregate port	18	190000	200000/linkupcnt
1000M	Common port	4	20000	20000
	Aggregate port	3	19000	20000/linkupcnt
10000M	Common port	2	2000	2000
	Aggregate port	1	1900	20000/linkupcnt

- The private integer standard in long mode is used by default. After the solution is changed to the path cost solution recommended by the standards, the path cost of an aggregate port changes with the number of member ports in Up state. If the port path cost changes, the network topology also will change.

- If an aggregate port is static, **linkupcnt** is the number of active member ports. If an aggregate port works in LACP mode, **linkupcnt** is the number of member ports forwarding data. If no member port in the aggregate port goes up, **linkupcnt** is 1. For details about the aggregate port and LACP, see the *Configuring Aggregate Interface*.

Configuration Step

Configuring the Port Path Cost

- Optional.
- To determine the port or path where data packets are forwarded preferentially, configure the port path cost.

Command	**spanning-tree** [**mst** *instance-id*] **cost** *cost*
Parameter Description	**mst** *instance-id*: Indicates the ID of an MSTI. The value range is from 0 to 64. The default value is 0. **cost** *cost*: Indicates the path cost. The value range is from 1 to 200,000,000.
Defaults	The port path cost is automatically calculated based on the link rate by default. For example, the port path cost of a 1000 Mbps port is 20,000, the port path cost of a 100 Mbps port is 200,000, and the port path cost of a 10 Mbps port is 2,000,000.
Command Mode	Interface configuration mode
Usage Guide	A larger value of *cost* indicates a higher path cost.

Configuring the Default Path Cost Calculation Method

- Optional.
- To change the path cost calculation method, configure the default path cost calculation method.

Command	**spanning-tree pathcost method** { *long* | **long** *standard* | *short* }
Parameter Description	*long*: Uses the path cost specified in 802.1t Long. *standard*: Calculates the cost according to the formula recommended in IEEE 802.1t Long Standard. *short*: Uses the path cost specified in 802.1d Short.
Defaults	The default port path cost calculation method is **long**.
Command Mode	Global configuration mode
Usage Guide	If the port path cost uses the default value, the device automatically calculates the port path cost based on the port rate.

Verification

- Run the **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id* command to display the spanning tree configuration of the port.

Configuration Example

Configuring the Port Path Cost

Scenario **Figure 1-23**	
Configuration Steps	● Configure the bridge priority so that Device A becomes the root bridge of the spanning tree. ● Configure the path cost of GigabitEthernet 0/2 on Device B is 1 so that GigabitEthernet 0/2 can be selected as the root port.
Device A	`Hostname(config)#spanning-tree` `Hostname(config)#spanning-tree mst 0 priority 0`

Device B	`Hostname(config)#spanning-tree`
	`Hostname(config)#interface gigabitethernet 0/2`
	`Hostname(config-if-GigabitEthernet 0/2)# spanning-tree cost 1`

Verification	● Run the **show spanning-tree summary** command to display the topology calculation result of the spanning tree.

Device A	`Hostname#show spanning-tree summary`
	
	`Spanning tree enabled protocol mstp`
	`MST 0 vlans map : ALL`
	`  Root ID    Priority    0`
	`             Address     00d0.f822.3344`
	`             this bridge is root`

```

Common Errors

The changed port path cost will take effect only on the receive port.

1.4.7 Configuring the Maximum Hop Count of a BPDU

Configuration Effect

- Configuring the maximum hop count of a BPDU will change the BPDU TTL and affect the network topology.

Notes

- The default maximum hop count of a BPDU is 20. You are advised not to change the default value in most situations.

Configuration Step

↘ Configuring the Maximum Hop Count

- Optional. For a large network topology, if a BPDU is transmitted for more than 20 hops, you are advised to change the maximum hop count.

Command	**spanning-tree max-hops** *hop-count*
Parameter Description	*hop-count*: Indicates the number of devices a BPDU passes through before the BPDU is discarded. The value range is from 1 to 40.
Defaults	The maximum hop count for a BPDU is 20 by default.
Command Mode	Global configuration mode
Usage Guide	In a region, the BPDU sent by the root bridge includes a hop count. Every time a BPDU passes through a device from the root bridge, the hop count decreases by 1. When the hop count becomes 0, the BPDU times out and the device discards the packet. This command specifies the number of devices a BPDU passes through in a region before the BPDU is discarded. Changing the maximum hop count will affect all MSTIs.

Verification

- Run the **show spanning-tree max-hops** command to display the maximum hop count.

Configuration Example

↘ Configuring the Maximum Hop Count of a BPDU

Configuration	● Set the maximum hop count of a BPDU to 25.

Steps	
	`Hostname(config)# spanning-tree max-hops 25`
Verification	● Run the **show spanning-tree** command to display the configuration.

	`Hostname# show spanning-tree`
	`StpVersion : MSTP`
	`SysStpStatus : ENABLED`
	`MaxAge : 20`
	`HelloTime : 2`
	`ForwardDelay : 15`
	`BridgeMaxAge : 20`
	`BridgeHelloTime : 2`
	`BridgeForwardDelay : 15`
	`MaxHops: 25`
	`TxHoldCount : 3`
	`PathCostMethod : Long`
	`BPDUGuard : Disabled`
	`BPDUFilter : Disabled`
	`LoopGuardDef : Disabled`
	
	`###### mst 0 vlans map : ALL`
	`BridgeAddr : 00d0.f822.3344`
	`Priority: 0`
	`TimeSinceTopologyChange : 2d:0h:46m:4s`
	`TopologyChanges : 25`
	`DesignatedRoot : 0.001a.a917.78cc`
	`RootCost : 0`
	`RootPort : GigabitEthernet 0/1`
	`CistRegionRoot : 0.001a.a917.78cc`
	`CistPathCost : 20000`

1.4.8 Enabling the Edge Port

Configuration Effect

- After a port is configured as the edge port, the port directly enters the forwarding state. When the port receives BPDUs, its Port Fast Operational State becomes disabled. In this case, the port can properly run the STP algorithm and enter the forwarding state.
- If BPDU guard is enabled on a port, the port enters the error-disabled state after receiving a BPDU.
- If BPDU filter is enabled on a port, the port does not send or receive BPDUs.

Notes

- Global BPDU guard takes effect only when the port is configured as the edge port.

- If BPDU filter is enabled globally, the edge port does not send or receive BPDUs. In this case, the host directly connected to the edge port does not receive any BPDUs. If the port changes its Port Fast Operational State to Disabled after receiving a BPDU, BPDU filter automatically becomes ineffective.
- Global BPDU filter takes effect only when the port is configured as the edge port.

Configuration Step

Enabling the Edge Port

- Optional.
- If a port connects directly to a network terminal, configure this port as an edge port.
- In global configuration mode, run the **spanning-tree portfast default** command to enable the edge port on all ports and the **no spanning-tree portfast default** command to disable the edge port on all ports.
- In interface configuration mode, run the **spanning-tree portfast** command to enable the edge port on a port and the **spanning-tree portfast disabled** command to disable the edge port on a port.

Command	**spanning-tree portfast default**
Parameter Description	N/A
Defaults	All ports are non-edge ports by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**spanning-tree portfast**
Parameter Description	N/A
Defaults	Ports are non-edge ports by default.
Command Mode	Interface configuration mode
Usage Guide	After a port is configured as the edge port, the port directly enters the forwarding state. When the port receives BPDUs, its Port Fast Operational State becomes disabled. In this case, the port can properly run the STP algorithm and enter the forwarding state.

Enabling BPDU Guard

- Optional.
- When device ports directly connect to network terminals, BPDU attacks on the ports may cause exceptions in the spanning tree topology. To prevent such attacks, you can enable BPDU guard on the ports. A port enabled with BPDU guard enters the error-disabled state after receiving a BPDU.
- If device ports directly connect to network terminals, you can enable BPDU guard to prevent loops on the ports. The prerequisite is that the downlink device (such as the hub) can forward BPDUs.
- In global configuration mode, run the **spanning-tree portfast bpduguard default** command to enable BPDU guard on all ports and the **no spanning-tree portfast bpduguard default** command to disable BPDU guard on all ports.

- In interface configuration mode, run the **spanning-tree bpduguard enable** command to enable BPDU guard on a port and the **spanning-tree bpduguard disabled** command to disable BPDU guard on a port.

Command	**spanning-tree portfast bpduguard default**
Parameter Description	N/A
Defaults	The global BPDU guard function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	If BPDU guard is enabled on a port, the port enters the error-disabled state after receiving a BPDU. Run the **show spanning-tree** command to display the configuration.

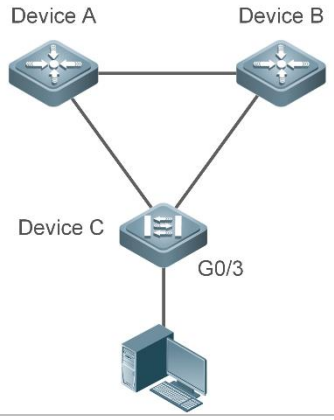
Command	**spanning-tree bpduguard enable**
Parameter Description	N/A
Defaults	BPDU guard is disabled on a port by default.
Command Mode	Interface configuration mode
Usage Guide	If BPDU guard is enabled on a port, the port enters the Error-Disabled state after receiving a BPDU.

Enabling BPDU Filter

- Optional.
- To prevent abnormal BPDUs from affecting the spanning tree topology, you can enable BPDU filter on a port to filter abnormal BPDUs.
- In global configuration mode, run the **spanning-tree portfast bpdufilter default** command to enable BPDU filter on all ports and the **no spanning-tree portfast bpdufilter default** command to disable BPDU filter on all ports.
- In interface configuration mode, run the **spanning-tree bpdufilter enable** command to enable BPDU filter on a port and the **spanning-tree bpdufilter disabled** command to disable BPDU filter on a port.

Command	**spanning-tree portfast bpdufilter default**
Parameter Description	N/A
Defaults	The global BPDU filter function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	If BPDU filter is enabled, corresponding ports do not send or receive BPDUs.

Command	**spanning-tree bpdufilter enable**
Parameter Description	N/A
Defaults	BPDU filter is disabled on a port by default.
Command Mode	Interface configuration mode



Usage Guide	If BPDU filter is enabled on a port, the port does not send or receives BPDUs.

Verification

- Run the **show spanning-tree** [**mst** *instance-id*] **interface** *interface-id* command to display the spanning tree configuration of the port.

Configuration Example

Enabling the Edge Port

Scenario **Figure 1-24**	
Configuration Steps	● Configure GigabitEthernet 0/3 of Device C as an edge port and enable BPDU guard.

Device C	`Hostname(config)#interface gigabitethernet 0/3`
	`Hostname(config-if-GigabitEthernet 0/3)# spanning-tree portfast`
	`%Warning: portfast should only be enabled on ports connected to a single host. Connecting hubs, switches, bridges to this interface when portfast is enabled, can cause temporary loops.`
	`Hostname(config-if-GigabitEthernet 0/3)#spanning-tree bpduguard enable`

Verification	● Run the **show spanning-tree interface** command to display the port configuration.

Device C	`Hostname#show spanning-tree interface gigabitethernet 0/3`
	
	`PortAdminPortFast : Enabled`
	`PortOperPortFast : Enabled`
	`PortAdminAutoEdge : Enabled`
	`PortOperAutoEdge : Enabled`
	`PortAdminLinkType : auto`
	`PortOperLinkType : point-to-point`
	`PortBPDUGuard : Enabled`
	`PortBPDUFilter : Disabled`
	`PortGuardmode : None`
	
	`###### MST 0 vlans mapped :ALL`
	`PortState : forwarding`
	`PortPriority : 128`
	`PortDesignatedRoot : 0.00d0.f822.3344`

	PortDesignatedCost : 0 PortDesignatedBridge :0.00d0.f822.3344 PortDesignatedPortPriority : 128 PortDesignatedPort : 4 PortForwardTransitions : 1 PortAdminPathCost : 20000 PortOperPathCost : 20000 Inconsistent states : normal PortRole : designatedPort

1.4.9 Enabling TC-related Features

Configuration Effect

- If TC protection is enabled on a port, the port deletes TC BPDUs within a specified time (4s typically) after receiving them, preventing MAC and ARP entry from being deleted.
- If TC guard is enabled, a port receiving TC BPDUs filters TC BPDUs received or generated by itself so that TC BPDUs are not spread to other ports. In this way, possible TC attacks are efficiently prevented to keep the network stable.
- TC filter does not process TC BPDUs received by ports but processes TC BPDUs in case of normal topology changes.

Notes

- You are advised to enable TC guard only when unauthorized TC attack packets are received on a network.

Configuration Step

↘ Enabling TC Protection

- Optional.
- In global configuration mode, run the **spanning-tree tc-protection** command to enable TC protection on all ports and the **no spanning-tree tc-protection** command to disable TC protection on all ports.
- TC protection can be enabled or disabled globally only.

Command	**spanning-tree tc-protection**
Parameter Description	N/A
Defaults	The global TC protection function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Enabling TC Guard

- Optional.
- To filter received TC BPDUs or those generated on the local port due to topology changes, you can configure TC guard for the port.

- In global configuration mode, run the **spanning-tree tc-protection tc-guard** command to enable TC guard on all ports and the **no spanning-tree tc-protection tc-guard** command to disable TC guard on all ports.
- In interface configuration mode, run the **spanning-tree tc-guard** command to enable TC guard on a port and the **no spanning-tree tc-guard** command to disable TC guard on a port.

Command	**spanning-tree tc-protection tc-guard**
Parameter Description	N/A
Defaults	The global TC guard function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Enable TC guard to prevent TC BPDUs from being spread.

Command	**spanning-tree tc-guard**
Parameter Description	N/A
Defaults	TC guard is disabled on a port by default.
Command Mode	Interface configuration mode
Usage Guide	Enable TC guard to prevent TC BPDUs from being spread.

Enabling TC Filter

- Optional.
- TC filter is disabled by default.
- To filter TC BPDUs received on a port, you can enable TC filter on the port.
- In interface configuration mode, run the **spanning-tree ignore tc** command to enable TC filter on a port and the **no spanning-tree ignore tc** command to disable TC filter on a port.

Command	**spanning-tree ignore tc**
Parameter Description	N/A
Defaults	TC filter is disabled by default.
Command Mode	Interface configuration mode
Usage Guide	If TC filter is enabled on a port, the port does not process received TC BPDUs.

Verification

- Display the configuration.

Configuration Example

Enabling TC Guard on a Port

Configuration Steps	• Enable TC guard on a port.

	Hostname(config)#interface gigabitethernet 0/1 Hostname(config-if-GigabitEthernet 0/1)#spanning-tree tc-guard
Verification	● Run the **show run interface** command to display the TC guard configuration of the port.
	Hostname#show run interface gigabitethernet 0/1 Building configuration... Current configuration : 134 bytes interface GigabitEthernet 0/1 switchport mode trunk spanning-tree tc-guard

Common Errors

- If TC guard or TC filter is incorrectly configured, an error may occur during packet forwarding of a network device. For example, when the topology changes, the device fails to delete MAC address in a timely manner, causing packet forwarding errors.

1.4.10 Enabling BPDU Source MAC Address Check

Configuration Effect

- Enable BPDU source MAC address check. Then a device receives only BPDUs with the source MAC address being the specified MAC address and discards other BPDUs.

Notes

- When the switch connected to a port on a point-to-point link is determined, you can enable BPDU source MAC address check so that the switch receives the BPDUs sent only by the peer switch.

Configuration Step

↘ Enabling BPDU Source MAC Address Check

- Optional.
- To prevent malicious BPDUs, you can enable BPDU source MAC address check.
- In interface configuration mode, run the **bpdu src-mac-check** *mac-address* command to enable BPDU source MAC address check on a port and the **no bpdu src-mac-check** command to disable BPDU source check on a port.

Command	**bpdu src-mac-check** *mac-address*
Parameter Description	*mac-address*: Indicates that only BPDUs from this MAC address can be received.
Command Mode	BPDU source MAC address check is disabled on a port by default.
Usage Guide	Interface configuration mode
	BPDU source MAC address check is enabled to prevent a switch from malicious attacks generated by manually sending BPDUs and further prevent MSTP from malfunction. To prevent malicious

	attacks, when the peer switch on the point-to-point link of a port is determined, you can enable BPDU source MAC address check so that the switch receives the BPDUs sent only by the peer switch and discards all other BPDUs. In interface configuration mode, you can configure a MAC address corresponding to the BPDU source MAC address check for a specific port. Only one MAC address can be configured on one port.

Verification

- Display the configuration.

Configuration Example

Enabling BPDU Source MAC Address Check on a Port

Configuration Steps	● Enable BPDU source MAC address check on a port.
	`Hostname(config)#interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)#bpdu src-mac-check 00d0.f800.1234`
Verification	● Run the **show run interface** command to display the spanning tree configuration of the port.

	`Hostname#show run interface gigabitethernet 0/1`
	
	`Building configuration...`
	`Current configuration : 170 bytes`
	
	`interface GigabitEthernet 0/1`
	` switchport mode trunk`
	` bpdu src-mac-check 00d0.f800.1234`
	`spanning-tree link-type point-to-point`

Common Errors

- If BPDU source MAC address check is enabled on a port, the port receives only BPDUs with the configured MAC address being the source MAC address and discards all other BPDUs.

1.4.11 Configuring Auto Edge

Configuration Effect

- Enable Auto Edge. If a designated port does not receive any BPDUs within a specified time (3s), it is automatically identified as an edge port. However, if the port receives BPDUs, its Port Fast Operational State will become Disabled.

Notes

- Unless otherwise specified, do not disable Auto Edge.

Configuration Steps

Configuring Auto Edge

- Optional.

- In interface configuration mode, run the **spanning-tree autoedge** command to enable Auto Edge on a port and the **spanning-tree autoedge disabled** command to disable Auto Edge on a port.

Command	**spanning-tree autoedge**
Parameter Description	N/A
Defaults	Auto Edge is enabled on a designated port by default.
Command Mode	Interface configuration mode
Usage Guide	If the designated port of a device does not receive a BPDU from the downlink port within a specific period (3s), the device considers that a network device is connected to the designated port, configures the port as an edge port, and switches the port directly into the forwarding state. The edge port will be automatically identified as a non-edge port after receiving a BPDU. You can run the **spanning-tree autoedge disabled** command to disable Auto Edge.

Verification

- Display the configuration.

Configuration Example

↘ Disabling Auto Edge on a Port

Configuration Steps	- Disable Auto Edge on a port.
	`Hostname(config)#interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)#spanning-tree autoedge disabled`
Verification	- Run the **show spanning-tree interface** command to display the spanning tree configuration of the port.

	`Hostname#show spanning-tree interface gigabitethernet 0/1`
	
	`PortAdminPortFast : Disabled`
	`PortOperPortFast : Disabled`
	`PortAdminAutoEdge : Disabled`
	`PortOperAutoEdge : Disabled`
	`PortAdminLinkType : point-to-point`
	`PortOperLinkType : point-to-point`
	`PortBPDUGuard : Disabled`
	`PortBPDUFilter : Disabled`
	`PortGuardmode : None`
	
	`###### MST 0 vlans mapped :ALL`
	`PortState : forwarding`
	`PortPriority : 128`
	`PortDesignatedRoot : 0.00d0.f822.3344`
	`PortDesignatedCost : 0`

	PortDesignatedBridge :0.00d0.f822.3344 PortDesignatedPortPriority : 128 PortDesignatedPort : 2 PortForwardTransitions : 6 PortAdminPathCost : 20000 PortOperPathCost : 20000 Inconsistent states : normal PortRole : designatedPort

Common Errors

- If Auto Edge is enabled on a designated port and the designated port does not receive a BPDU within 3s, the port is identified as an edge port and immediately enters the forwarding state by default. If packet loss or packet sending/receiving delay exists, you are advised to disable Auto Edge.

1.4.12 Enabling Guard-related Features

Configuration Effect

- If root guard is enabled on a port, its roles in all MSTIs are forcibly used as the designated port. Once the port receives the configuration with a higher priority, it enters the root-inconsistent (blocking) state. If the port does not receive the configuration with a higher priority within a period, it returns to its original state.
- Due to the unidirectional link failure, the root port or backup port becomes the designated port and enters the forwarding state if it does not receive BPDUs, causing a network loop. Loop guard is used to prevent this problem.

Notes

- Root guard and loop guard cannot be configured on a port simultaneously.

Configuration Step

↘ Enabling Root Guard

- Optional.
- The root bridge may receive the configuration with a higher priority due to incorrect configuration by maintenance personnel or malicious attacks on a network. As a result, the root bridge may lose its role, causing incorrect topology changes. To prevent this problem, you can enable root guard on a designated port of a device.
- In interface configuration mode, run the **spanning-tree guard root** command to enable root guard on a port and the **no spanning-tree guard root** command to disable root guard on a port.

Command	**spanning-tree guard root**
Parameter Description	N/A
Defaults	Root guard is disabled on a port by default.
Command Mode	Interface configuration mode
Usage Guide	If root guard is enabled, the root bridge will not change due to incorrect configuration or unauthorized packet attacks.

Enabling Loop Guard

- Optional.
- You can enable loop guard on a port (root port, master port, or aggregate port) to prevent it from failing to receive BPDUs sent by the designated bridge, increasing device stability. Otherwise, the network topology will change, possibly causing a loop.
- In global configuration mode, run the **spanning-tree loopguard default** command to enable loop guard on all ports and the **no spanning-tree loopguard default** command to disable root guard on all ports.
- In interface configuration mode, run the **spanning-tree guard loop** command to enable root guard on a port and the **no spanning-tree guard loop** command to disable root guard on a port.

Command	**spanning-tree loopguard default**
Parameter Description	N/A
Defaults	The global loop guard function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Enabling loop guard on a root port or backup port can prevent possible loops caused by BPDU receiving failures.

Command	**spanning-tree guard loop**
Parameter Description	N/A
Defaults	Loop guard is disabled on a port by default.
Command Mode	Interface configuration mode
Usage Guide	Enabling loop guard on a root port or backup port will prevent possible loops caused by BPDU receiving failures.

Disabling Guard

- Optional.

Command	**spanning-tree guard none**
Parameter Description	N/A
Defaults	By default, the guard function is not configured on a port.
Command Mode	Interface configuration mode
Usage Guide	N/A

Verification

- Display the configuration.

Configuration Example

Enabling Loop Guard on a Port

Scenario **Figure 1-25**	
Configuration Steps	● Configure Device A as the root bridge and Device B as a non-root bridge in a spanning tree. ● Enable loop guard on GigabitEthernet 0/1 and GigabitEthernet 0/2 of Device B.
Device A	`Hostname(config)#spanning-tree` `Hostname(config)#spanning-tree mst 0 priority 0`

Device B	`Hostname(config)#spanning-tree`
	`Hostname(config)#interface range gigabitethernet 0/1-2`
	`Hostname(config-if-range)#spanning-tree guard loop`

Verification	● Run the **show spanning-tree interface** command to display the spanning tree configuration of the port.
Device A	Omitted.

Device B	`Hostname#show spanning-tree interface gigabitethernet 0/1`
	
	`PortAdminPortFast : Disabled`
	`PortOperPortFast : Disabled`
	`PortAdminAutoEdge : Enabled`
	`PortOperAutoEdge : Disabled`
	`PortAdminLinkType : auto`
	`PortOperLinkType : point-to-point`
	`PortBPDUGuard : Disabled`
	`PortBPDUFilter : Disabled`
	`PortGuardmode  : Guard loop`
	
	`###### MST 0 vlans mapped :ALL`
	`PortState : forwarding`
	`PortPriority : 128`
	`PortDesignatedRoot : 0.001a.a917.78cc`
	`PortDesignatedCost : 0`
	`PortDesignatedBridge :0.001a.a917.78cc`
	`PortDesignatedPortPriority : 128`
	`PortDesignatedPort : 17`
	`PortForwardTransitions : 1`
	`PortAdminPathCost : 20000`
	`PortOperPathCost : 20000`
	`Inconsistent states : normal`
	`PortRole : rootPort`
	
	`Hostname#show spanning-tree interface gigabitethernet 0/2`

```
PortAdminPortFast : Disabled
PortOperPortFast : Disabled
PortAdminAutoEdge : Enabled
PortOperAutoEdge : Disabled
PortAdminLinkType : auto
PortOperLinkType : point-to-point
PortBPDUGuard : Disabled
PortBPDUFilter : Disabled
PortGuardmode  : Guard loop

###### MST 0 vlans mapped :ALL
PortState : discarding
PortPriority : 128
PortDesignatedRoot : 0.001a.a917.78cc
PortDesignatedCost : 0
PortDesignatedBridge :0.001a.a917.78cc
PortDesignatedPortPriority : 128
PortDesignatedPort : 18
PortForwardTransitions : 1
PortAdminPathCost : 20000
PortOperPathCost : 20000
Inconsistent states : normal
PortRole : alternatePort
```

Common Errors

- If root guard is enabled on the root port, master port, or aggregate port, the port may be incorrectly blocked.

1.4.13 Enabling BPDU Transparent Transmission

Configuration Effect

- If STP is disabled on a device, the device needs to transparently transmit BPDUs so that the spanning tree between devices is properly calculated.

Notes

- BPDU transparent transmission takes effect only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDUs.

Configuration Step

↘ Enabling BPDU Transparent Transmission

- Optional.
- If STP is disabled on a device that needs to transparently transmit BPDUs, enable BPDU transparent transmission.

- In global configuration mode, run the **bridge-frame forwarding protocol bpdu** command to enable BPDU transparent transmission and the **no bridge-frame forwarding protocol bpdu** command to disable BPDU transparent transmission.
- BPDU transparent transmission can be enabled only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDUs.

Command	**bridge-frame forwarding protocol bpdu**
Parameter Description	N/A
Defaults	BPDU transparent transmission is disabled by default.
Command Mode	Global configuration mode
Usage Guide	In IEEE 802.1Q, the destination MAC address 01-80-C2-00-00-00 of the BPDU is used as a reserved address. That is, devices compliance with IEEE 802.1Q do not forward the BPDUs received. However, devices may need to transparently transmit BPDUs in practice. For example, if STP is disabled on a device, the device needs to transparently transmit BPDUs so that the spanning tree between devices is properly calculated. BPDU transparent transmission takes effect only when STP is disabled. If STP is enabled on a device, the device does not transparently transmit BPDUs.

Verification

- Display the configuration.

Configuration Example

Enabling BPDU Transparent Transmission

Scenario **Figure 1-26**	
	● STP is enabled on Device A and Device C while is disabled on Device B.
Configuration Steps	● Enable BPDU transparent transmission on Device B so that STP between Device A and Device C can be correctly calculated.
Device B	`Hostname(config)#bridge-frame forwarding protocol bpdu`
Verification	● Run the **show running-config** command to check whether BPDU transparent transmission is enabled.

Device B	`Hostname#show running-config`
	
	`Building configuration...`
	`Current configuration : 694 bytes`
	`bridge-frame forwarding protocol bpdu`

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear spanning-tree counters [**interface** *interface-type interface-number*]	Clears statistics of packets sent and received on a port.
clear spanning-tree mst *instance-id* **topochange record**	Clears STP topology change information.

Displaying

Command	Description
show spanning-tree	Displays MSTP parameters and spanning tree topology information.
show spanning-tree counters	Displays statistics on sent and received BPDUs.
show spanning-tree forward-time	Displays the port status change interval.
show spanning-tree hello time	Displays the interval for periodically sending BPDUs.
show spanning-tree inconsistentports	Displays ports blocked due to root guard or loop guard.
show spanning-tree max-age	Displays the maximum timeout time of a BPDU.
show spanning-tree max-hops	Displays the maximum hop count of BPDUs.
show spanning-tree mst *instance-id*	Displays the global spanning tree configuration of a specified MSTI.
show spanning-tree pathcost method	Displays the path cost calculation method.
show spanning-tree summary	Displays the spanning tree topology and port forwarding status information.
show spanning-tree tx-hold-count	Displays the maximum number of BPDUs that can be sent every second.
show spanning-tree [**mst** *instance-id*] **interface** *interface-type interface-number* [**bpdufilter** | **bpduguard** | **link-type** | **portfast**]	Displays the spanning tree configuration and status information of a port.
show spanning-tree mst configuration	Displays the MST region configuration.
show spanning-tree mst *instance-id* **topochange record**	Displays the topology change information of a port in a specified MSTI.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug mstp all	Debugs all MSTP functions.
debug mstp gr	Debugs the MSTP GR function.
debug mstp rx	Debugs the BPDU receiving.
debug mstp tx	Debugs BPDU transmission.
debug mstp event	Debugs MSTP events.

Command	Description
debug mstp loopguard	Debugs MSTP loop guard.
debug mstp rootguard	Debugs MSTP root guard.
debug mstp bridgedetect	Debugs the bridge detect state machine.
debug mstp portinfo	Debugs the port information state machine.
debug mstp protomigrat	Debugs the port protocol migration state machine.
debug mstp topochange	Debugs MSTP topology changes.
debug mstp receive	Debugs the MSTP receiving state machine.
debug mstp roletran	Debugs the port role transition state machine.
debug mstp statetran	Debugs the port state transition state machine.
debug mstp transmit	Debugs the MSTP transmission state machine.

1 Configuring ARP

1.1 Overview

On a local area network (LAN), each IP network device has two addresses:

- Local address: The local address, found in the header of the data link layer (DLL) frame, is referred to as a DLL address. However, it is typically known as the MAC address as it is processed by the MAC sublayer within the DLL, and it uniquely identifies an IP network device on a LAN.
- Network address. Network addresses on the Internet represent IP network devices and also indicate the networks where the devices reside.

On a LAN, two IP devices can communicate with each other only after they learn the 48-bit MAC address of each other. The process of obtaining the MAC address based on the IP address is called address resolution. There are two types of address resolution protocols:

- Address Resolution Protocol (ARP), which is defined in RFC 826
- Proxy ARP, which is defined in RFC 1027

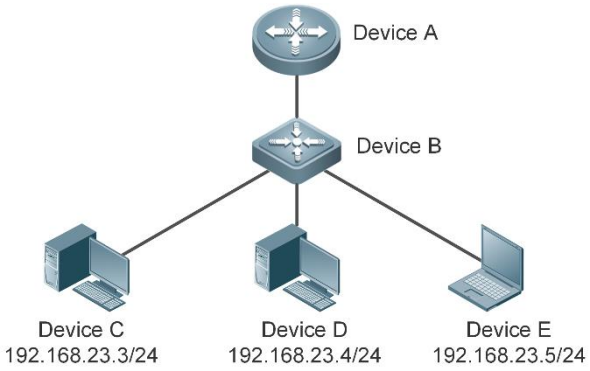
ARP is used to bind MAC addresses to IP addresses. When you enter an IP address, you can learn the corresponding MAC address through ARP. Once the MAC address is obtained, the IP-MAC mapping will be saved to the ARP cache of a network device. With the MAC address, the IP device can encapsulate DLL frames and send them to the LAN. By default, IP and ARP packets on the Ethernet are encapsulated in Ethernet II frames.

Protocols and Standards

- RFC 826: An Ethernet Address Resolution Protocol
- RFC 1027: Using ARP to implement transparent subnet gateways

1.2 Applications

Application	Description
LAN-based ARP	A user learns MAC addresses of other users on the same network segment through ARP.
Proxy ARP-based Transparent Transmission	With proxy ARP, a user can directly communicate with users on another network without knowing such a network.



1.2.1 LAN-based ARP

Scenario

ARP is required on all IPv4 LANs.

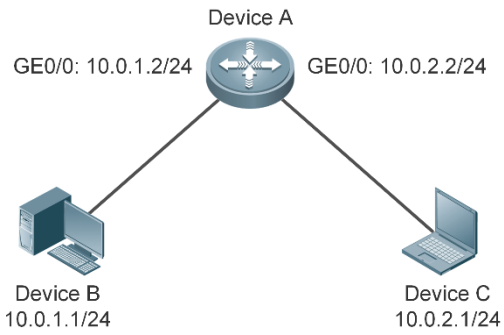
- A user needs to learn MAC addresses of other users through ARP to communicate with them.

Figure 1-1

Remarks	Device A is a router. Device B is the gateway of the network segment where terminals reside. Device C, Device D, and Device E are hosts.

Deployment

- Enable ARP on a LAN to implement IP-MAC mapping.



1.2.2 Proxy ARP-based Transparent Transmission

Scenario

Transparent transmission across IPv4 LANs is performed.

- Enable proxy ARP on the router to achieve direct communication between users on different network segments.

Figure 1-2

Remarks	Device A is connected to two LANs. Device B and Device C are hosts on different subnets. No default gateway is configured for them.

Deployment

- Enable proxy ARP on the subnet gateway. Then the gateway can act as a proxy to enable a host without any route information to obtain MAC addresses of IP users in other subnets.

1.3 Features

Overview

Feature	Description
Static ARP	You can manually specify IP-MAC mapping to prevent the device from learning incorrect ARP entries.
ARP Attributes	You can specify the ARP entry timeout, ARP request retransmission count and interval, and maximum number of unresolved ARP entries.
Trusted ARP	Trusted ARP is used to prevent ARP spoofing.
Gratuitous ARP	Gratuitous ARP is used to detect IP address conflicts and enable peripheral devices to update ARP entries.
Proxy ARP	A proxy replies to ARP request packets from other devices in different subnets.
Local Proxy ARP	A proxy replies to ARP request packets from other devices in the same subnet.
ARP Trustworthiness Detection	Neighbor Unreachable Detection (NUD) is used to ensure that correct ARP entries are learned.
Determing Host Existence Prior to ARP Proxy Service Provision	The Virtual Router Redundancy Protocol (VRRP) master responds to an ARP request packet as a proxy only when the destination IP address has been resolved.
ARP Packet Statistics Collection	ARP packet statistics are displayed.
Sending ARP Request Packets to a Specified Sub-VLAN of a Super-VLAN	In gateway authentication mode, dump terminals in a super-VLAN are deployed in authenticated VLANs, and the device proactively sends ARP request packets to a specific VLAN.

1.3.1 Static ARP

Static ARP entries can be configured manually or assigned by the authentication server. The manually configured ARP entries take precedence over delivered static ARP entries. Static ARP can prevent the device from learning incorrect ARP entries.

Working Principle

If static ARP entries are configured, the device does not proactively update ARP entries and these ARP entries permanently exist.

When the device forwards Layer 3 packets, the static MAC address is encapsulated in the Ethernet header as the destination MAC address.

Related Configuration

↘ Enabling Static ARP

Run the **arp** *ip-address mac-address type* command in global configuration mode to configure static ARP entries. By default, no static ARP entry is configured. ARP encapsulation supports only Ethernet II, which is represented by ARPA.

1.3.2 ARP Attributes

You can specify the ARP timeout, ARP request retransmission count and interval, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a card.

Working Principle

↘ ARP Timeout

The ARP timeout only applies to the dynamically learned IP-MAC mapping. When the ARP entry timeout expires, the device sends a unicast ARP request packet to detect whether the peer end is online. If it receives an ARP reply packet from the peer end, it does not delete this ARP entry. Otherwise, the device deletes this ARP entry.

When the ARP timeout is set to a smaller value, the mapping table stored in the ARP cache is more accurate but more network bandwidth is consumed.

ARP Request Retransmission Interval and Count

The device consecutively sends ARP request packets to resolve an IP address into a MAC address. A shorter retransmission interval speeds up resolution, while a higher retransmission count increases the likelihood of successfully resolving ARP entries at the expense of more bandwidth.

Maximum Number of Unresolved ARP Entries

On a LAN, ARP attacks and scanning may cause a large number of unresolved ARP entries to be generated on a gateway. As a result, the gateway fails to learn MAC addresses of users. To prevent such attacks, you can configure the maximum number of unresolved ARP entries.

Maximum Number of ARP Entries on an Interface

Configure the maximum number of ARP entries on a specified interface to prevent a waste of ARP entry resources.

Related Configuration

Configuring the ARP Timeout

Run the **arp timeout** *seconds* command in interface configuration mode to configure the ARP timeout. The default value is 3600s. You can change it as needed.

Configuring the ARP Request Retransmission Interval and Count

- Run the **arp retry interval** *seconds* command in global configuration mode to configure the ARP request retransmission interval. The default interval is 1s. You can change it as needed.
- Run the **arp retry times** *number* command in global configuration mode to configure the ARP request retransmission count. The default retransmission count is 5. You can change it as needed.

Configuring the Maximum Number of Unresolved ARP Entries

Run the **arp unresolve** *number* command in global configuration mode to configure the maximum number of unresolved ARP entries. The default value is the maximum number of ARP entries supported by the device. You can change it as needed.

Configuring the Maximum Number of ARP Entries on an Interface

Run the **arp cache interface-limit** *limit* command in interface configuration mode to configure the maximum number of ARP entries learned on an interface. The default number is 0. You can change it as needed. This command also applies to static ARP entries.

1.3.3 Trusted ARP

Working Principle

Trusted ARP entries are a special type added to the ARP table to prevent ARP spoofing. Trusted ARP entries blend characteristics of both static and dynamic ARP entries, with a priority higher than that of dynamic ARP entries but lower than that of static ARP entries. Trusted ARP has an aging mechanism similar to that of dynamic ARP. When an ARP entry ages, the device proactively sends an ARP request packet to detect whether the corresponding user exists. If the user sends a reply packet, the device considers the user active and updates the ARP timeout. Otherwise, the device deletes the ARP entry. Trusted ARP has characteristics of static ARP, that is, the device does not learn ARP packets to update the MAC address and interface ID in the ARP entry.

When a user goes online on a GSN client, the authentication server obtains the user's reliable IP-MAC mapping through the access switch, and adds trusted ARP entries to the user's gateway. This process is transparent to the network administrator and does not affect the administrator’s work on network management.

Since trusted ARP entries come from authentic sources and will not be updated, they can efficiently prevent ARP spoofing targeted at the gateway.

Related Configuration

Enabling Trusted ARP

- Run the **service trustedarp** command in global configuration mode to enable trusted ARP. This function is disabled by default.
- Run the **arp trusted user-vlan** *vid1* **translated-vlan** *vid2* command in global configuration mode to implement VLAN redirection. This function is disabled by default. If the VLAN pushed by the server differs from the VLAN in the trusted ARP entry, enable VLAN redirection.
- Run the **arp trusted aging** command in global configuration mode to enable ARP aging. Trusted ARP entries are not aged by default.
- Run the **arp trusted number** command in global configuration mode to configure the capacity of trusted ARP entries. The default value is half of the total capacity of ARP entries. You can change it as needed.

1.3.4 Gratuitous ARP

Working Principle

Gratuitous ARP packets are a special type of ARP packets where both the source and destination IP addresses are that of the local device. These packets serve two main purposes:

1 IP address conflict detection: If the device receives a gratuitous packet and finds the IP address in the packet the same as its own IP address, it sends an ARP reply packet to notify the peer end of the IP address conflict.

2 ARP update: When the MAC address of an interface changes, the device sends a gratuitous ARP packet to instruct other devices to update ARP entries.

The device can learn gratuitous ARP packets. After receiving a gratuitous ARP packet, the device checks whether the corresponding dynamic ARP entry exists. If so, the device updates the ARP entry based on information carried in the gratuitous ARP packet.

Related Configuration

Enabling Gratuitous ARP

Run the **arp gratuitous-send interval** *seconds* [*number*] command in interface configuration mode to enable gratuitous ARP. This function is disabled on interfaces by default. Typically, you need to enable this function on the gateway interface to periodically update the MAC address of the gateway on downlink devices, which prevents forged gateways.

1.3.5 Proxy ARP

Working Principle

The device enabled with proxy ARP can help a host without any routing information to obtain MAC addresses of IP users in other subnets. For example, if the device receiving an ARP request finds the source IP address on a different network segment from the destination IP address and knows the route to the destination address, the device sends an ARP reply packet containing its own Ethernet MAC address.

Related Configuration

↘ Enabling Proxy ARP

- Run the **ip proxy-arp** command in interface configuration mode to enable proxy ARP.

1.3.6 Local Proxy ARP

Working Principle

Local proxy ARP means that a device acts as a proxy in the local VLAN (common VLAN or sub VLAN).

After local proxy ARP is enabled, the device can help users to obtain MAC addresses of other users within the same subnet. For example, when port protection is enabled on the device, users connected to different ports are isolated at Layer 2. After local proxy ARP is enabled, the device receiving an ARP request packet acts as a proxy to send an ARP reply packet containing its own Ethernet MAC address. In this case, different users communicate with each other through Layer 3 routes.

Related Configuration

↘ Enabling Local Proxy ARP

- Run the **local-proxy-arp** command in interface configuration mode to enable local proxy ARP.
- This function is disabled by default.
- This command is supported only on switch virtual interfaces (SVIs).

1.3.7 ARP Trustworthiness Detection

Working Principle

The **arp trust-monitor enable** command is used to enable ARP anti-spoofing to prevent excessive useless ARP entries from occupying device resources. After ARP trustworthiness detection is enabled on a Layer 3 interface, the device receives ARP request packets from this interface:

1 If the corresponding entry does not exist, the device creates a dynamic ARP entry and performs NUD after 1s to 5s. That is, the device begins to age the newly learned ARP entry and sends a unicast ARP request packet. If the

device receives an ARP update packet from the peer end within the aging time, it stores the entry. If not, it deletes the entry.

2 If the corresponding ARP entry exists, NUD is not performed.

3 If the MAC address in the existing dynamic ARP entry is updated, the device also performs NUD.

Because this function introduces a strict confirmation procedure into the ARP learning process, it impacts the efficiency of ARP learning.

After this function is disabled, NUD is not required for learning and updating ARP entries.

Related Configuration

Enabling ARP Trustworthiness Detection

Run the **arp trust-monitor enable** command in interface configuration mode to enable ARP trustworthiness detection. This function is disabled by default.

1.3.8 Determing Host Existence Prior to ARP Proxy Service Provisioning

Supported functions are subject to the product version.

Working Principle

When two devices form a VRRP group and enabled with local ARP proxy, if the VRRP backup device sends an ARP request packet to a terminal, the VRRP master device will act as a proxy of the terminal and send an ARP reply packet to the VRRP backup device regardless of whether the terminal exists. As a result, the VRRP master device learns a large number of proxy ARP entries.

After the **arp proxy-resolved** command is configured, the VRRP master device first determines whether the ARP entry corresponding to the destination IP address exists upon receiving an ARP request packet. If such an entry exists, the VRRP master device acts as an ARP proxy; if not, it does not. Additionally, the gateway automatically broadcasts an ARP request packet to obtain the ARP entry for the destination IP address. This prevents situations where the gateway fails to act as a proxy and respond to ARP request packets for the destination IP address due to the absence of the corresponding ARP entry.

After the **no arp proxy-resolved** command is configured, if proxy conditions are met, the VRRP master device directly acts as a proxy upon receiving an ARP request packet, without determining whether the ARP entry corresponding to the destination IP address has been resolved.

Related Configuration

Configuring a Device Not to Determine Existence of the ARP Entry Corresponding to a Destination IP Address When the Device Responds to an ARP Request Packet as an ARP Proxy

- Run the **no arp proxy-resolved** command in global configuration mode.
- The **arp proxy-resolved** command is enabled by default.

1.3.9 ARP Packet Statistics Collection

Working Principle

The device counts the total number of ARP request and reply packets sent and received by each interface, and packets of unknown types on all interfaces from power-on.

1.3.10 Sending ARP Request Packets to a Specified Sub-VLAN of a Super-VLAN

Supported functions are subject to the product version.

Working Principle

When numerous sub-VLANs are present within a super-VLAN, the device defaults to broadcasting ARP request packets proactively to the super-VLAN. This can result in excessive packet replication due to the high number of sub-VLANs, potentially impacting device performance.

Most terminals (such as PCs and servers) request ARP information from the gateway before accessing the network. Therefore, there is no need for the device to proactively broadcast ARP request packets to the sub-VLANs where these terminals reside. For dumb terminals that do not proactively send free ARP request packets, run the **arp resolve vlan** *vlan-list* command to configure the device to proactively send ARP request packets to VLANs in the specified VLAN list.

Related Configuration

Configuring the Device to Send ARP Request Packets to a Specific Sub-VLAN of a Super-VLAN

- Run the **arp resolve vlan** *vlan-list* command in global configuration mode to configure the device to send ARP request packets to a specific sub-VLAN of a super-VLAN.
- The device sends ARP request packets to the super-VLAN by default.

1.4 Configuration

Configuration	Description and Command	
Enabling Static ARP	(Optional) It is used to enable static IP-MAC binding.	
	arp	Enables static ARP.
Configuring ARP Attributes	(Optional) It is used to specify the ARP timeout, ARP request retransmission interval and count, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a card.	
	arp timeout	Configures the ARP timeout.
	arp retry interval	Configures the retransmission interval of ARP request packets.
	arp retry times	Configures the retransmission count of ARP request packets.
	arp unresolve	Configures the maximum number of unresolved ARP entries.
	arp cache interface-limit	Configures the maximum number of ARP entries on an interface.

Configuration	Description and Command	
Enabling Trusted ARP	(Optional) It is used to enable ARP anti-spoofing.	
	service trustedarp	Enables trusted ARP.
	arp trusted user-vlan	Enables VLAN redirection when a trusted ARP entry is added.
	arp trusted aging	Enables trusted ARP aging.
	arp trusted	Configures the capacity of trusted ARP entries.
Enabling Gratuitous ARP	(Optional) It is used to detect IP address conflicts and enables peripheral devices to update ARP entries.	
	arp gratuitous-send interval	Enables gratuitous ARP.
Enabling Proxy ARP	(Optional) It is used to configure the device as a proxy to reply to ARP request packets from devices in different subnets.	
	ip proxy-arp	Enables proxy ARP.
Enabling Local Proxy ARP	(Optional) It is used to configure the device as a proxy to reply to ARP request packets from other devices in the same subnet.	
	local-proxy-arp	Enables local proxy ARP.
Enabling ARP Trustworthiness Detection	(Optional) It is used to configure the device to unicast ARP request packets to ensure that correct ARP entries are learned.	
	arp trust-monitor enable	Enabling ARP trustworthiness detection.
Configuring the Device to Determine Host Existence Prior to ARP Proxy Service Provisioning	(Optional) It is used to configure the VRRP Master Device to Forcibly Respond to ARP Request Packets as a Proxy.	
	no arp proxy-resolved	Configures the VRRP Master Device to Forcibly Respond to ARP Request Packets as a Proxy.
Configuring the Device to Send ARP Request Packets to a Specified Sub-VLAN of a Super-VLAN	(Optional) It is used to configure the device to send ARP request packets to a specified sub-VLAN of a super-VLAN.	
	arp resolve vlan	Configures the device to send ARP request packets to a specified sub-VLAN of a super-VLAN.

1.4.1 Enabling Static ARP

Configuration Effect

You can manually specify IP-MAC mapping to prevent the device from learning incorrect ARP entries.

Notes

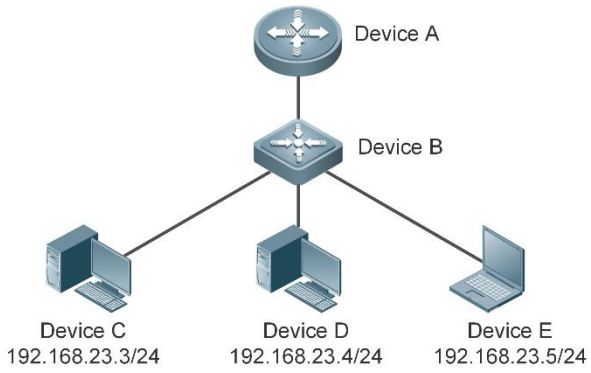
After a static ARP entry is configured, the Layer 3 switch learns the physical port corresponding to the MAC address in the static ARP entry before performing Layer 3 routing.

Configuration Step

Configuring Static ARP Entries

- Optional.
- You can configure a static ARP entry to bind the IP address of the uplink device to its MAC address to prevent MAC address change caused by ARP attacks.
- Configure static ARP entries in global configuration mode.

Verification



Run the **show running-config** command to check whether the configuration takes effect. Or, run the **show arp static** command to check whether a static ARP cache table is created.

Related Commands

Configuring Static ARP Entries

Command	**arp** *ip-address mac-address type*
Parameter Description	*ip-address*: Indicates the IP address mapped to a MAC address, which is in four-part dotted-decimal format. *mac-address*: Indicates the DLL address, consisting of 48 bits. *type*: Indicates the ARP encapsulation type. For an Ethernet interface, the keyword is **arpa**.
Command Mode	Global configuration mode
Usage Guide	The RGOS queries a 48-bit MAC address based on a 32-bit IP address in the ARP cache table. Because most hosts support dynamic ARP resolution, the static ARP mapping are not configured. Use the **clear arp-cache** command to delete dynamic ARP entries.

Configuration Example

Scenario	 ● Device A is the router. ● Device B is the gateway of the network segment where terminals reside. ● Device C, Device D, and Device E are terminals.
Configuration Steps	● Configure a static ARP entry on Device B to statically bind the IP address of Device A to the MAC address. `Hostname(config)#arp 192.168.23.1 00D0.F822.334B arpa`

Verification	● Run the **show arp static** command to display the static ARP entry.
	`Hostname#show arp static`
	`Protocol Address Age(min) Hardware Type Interface`

	Internet 192.168.23.1 <static> 00D0.F822.334B arpa 1 static arp entries exist.

Common Errors

- The MAC address in static ARP is incorrect.

1.4.2 Configuring ARP Attributes

Configuration Effect

You can specify the ARP timeout, ARP request retransmission interval and count, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a card.

Configuration Step

Configuring the ARP Timeout

- Optional.
- On a LAN, if a user goes online or offline frequently, set a small ARP timeout so that invalid ARP entries can be deleted as soon as possible.
- Configure the ARP timeout in interface configuration mode.

Configuring the ARP Request Retransmission Interval and Count

- Optional.
- If network resources are insufficient, set a large ARP request retransmission interval and a small retransmission count to reduce network bandwidth occupied.
- Configure the ARP request retransmission interval and count in global configuration mode.

Configuring the Maximum Number of Unresolved ARP Entries

- Optional.
- If network resources are insufficient, set the maximum number of unresolved ARP entries to a small value to reduce network bandwidth occupied.
- Configure the maximum number of unresolved ARP entries in global configuration mode.

Configuring the Maximum Number of ARP Entries on an Interface

- Optional.
- Configure the maximum number of ARP entries on an interface in interface configuration mode.

Verification

- Run the **show arp timeout** command to display the timeout of all interfaces.
- Run the **show running-config** command to display the ARP request retransmission interval and count, maximum number of unresolved ARP entries, maximum number of ARP entries on an interface, and maximum number of ARP entries on a card.

Related Commands

Configuring the ARP Timeout

Command	**arp timeout** *seconds*
Parameter Description	*seconds*: Indicates the timeout, in seconds. The value range is from 0 to 2147483. The default value is 3600.
Command Mode	Interface configuration mode
Usage Guide	The ARP timeout only applies to the dynamically learned IP-MAC mapping. When the ARP timeout is set to a smaller value, the mapping table stored in the ARP cache is more accurate but more network bandwidth is consumed. Unless otherwise specified, do not configure the ARP timeout.

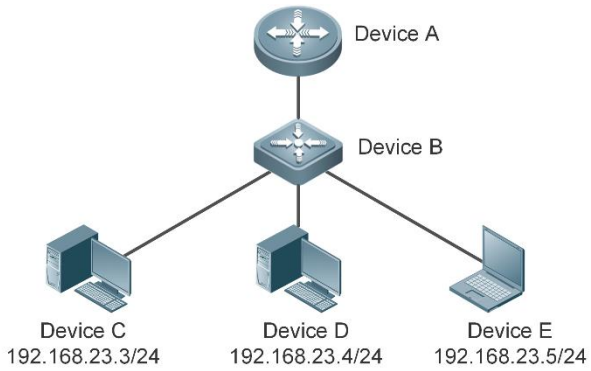
Configuring the Retransmission Interval of ARP Request Packets

Command	**arp retry interval** *seconds*
Parameter Description	*seconds*: Indicates the retransmission interval of ARP request packets, in seconds. The value range is from 1 to 3600. The default value is 1.
Command Mode	Global configuration mode
Usage Guide	If a device frequently sends ARP request packets, network performance will be affected. You can set a long ARP request retransmission interval. Ensure that this interval does not exceed the ARP timeout.

Configuring the Retransmission Count of ARP Request Packets

Command	**arp retry times** *number*
Parameter Description	number: Indicates the retransmission count of ARP request packets. The value range is from 1 to 100. When the value is set to 1, an ARP request is sent once, and will not be retransmitted. The default value is 5.
Command Mode	Global configuration mode
Usage Guide	When the device frequently sends ARP packets, problems such as network congestion may occur. You can set a small retransmission count of ARP request packets.

Configuring the Maximum Number of Unresolved ARP Entries



Command	**arp unresolve** *number*
Parameter Description	*number*: Indicates the maximum number of unresolved ARP entries. The value range is from 1 to 8192. The default value is 8192.
Command Mode	Global configuration mode
Usage Guide	If a large number of unresolved entries exist in the ARP cache table and remain in the table after a while, use this command to limit the number of unresolved ARP entries.  The maximum number of unresolved ARP entries limits the number of neighbor addresses that can be resolved at a time. If the device needs to resolve a large number of neighbor addresses, the neighbor addresses exceeding the limit will be resolved after existing neighbor addresses are resolved or the resolution time is reached. The resolution time of all neighbor addresses is longer when the maximum number of unresolved ARP entries is not set. Set the maximum

	number as required.

Configuring the Maximum Number of ARP Entries on an Interface

Command	**arp cache interface-limit** *limit*
Parameter Description	*limit*: Indicates the maximum number of ARP entries that can be learned on an interface, including configured ARP entries and dynamically learned ARP entries. The value range is from 0 to the ARP entry capacity supported by the device. The value 0 indicates that the number of ARP entries that can be learned on an interface is not limited.
Command Mode	Interface configuration mode
Usage Guide	Limiting the number of ARP entries on an interface can prevent malicious ARP attacks from generating excessive ARP entries on the device and occupying entry resources. The configured value must be equal to or greater than the number of the ARP entries learned by the interface. Otherwise, the configuration does not take effect. The configuration is subject to the ARP entry capacity supported by the device.

Configuration Example

Scenario	 ● Device A is the router. ● Device B is the gateway of the network segment where terminals reside. ● Device C, Device D, and Device E are terminals.
Configuration Steps	● Set the ARP timeout to 60 seconds on GigabitEthernet 0/1. ● Set the maximum number of learned ARP entries to 300 on GigabitEthernet 0/1. ● Set the retransmission interval of ARP request packets to 3s. ● Set the retransmission count of ARP request packets to 4. ● Set the maximum number of unresolved ARP entries to 4096.

	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#arp timeout 60`
	`Hostname(config-if-GigabitEthernet 0/1)#arp cache interface-limit 300`
	`Hostname(config-if-GigabitEthernet 0/1)#exit`
	`Hostname(config)#arp retry interval 3`
	`Hostname(config)#arp retry times 4`
	`Hostname(config)#arp unresolve 4096`

Verification	● Run the **show arp timeout** command to display the timeout of the interface. ● Run the **show running-config** command to display the ARP request retransmission interval

	and count, maximum number of unresolved ARP entries, and maximum number of ARP entries on the interface.
	Hostname#show arp timeout Interface arp timeout(sec) ---------- ---------- GigabitEthernet 0/1 60 GigabitEthernet 0/2 3600 GigabitEthernet 0/4 3600 GigabitEthernet 0/5 3600 GigabitEthernet 0/7 3600 VLAN 100 3600 VLAN 111 3600 Mgmt 0 3600 Hostname# show running-config arp unresolve 4096 arp retry times 4 arp retry interval 3 ! interface GigabitEthernet 0/1 arp cache interface-limit 300

1.4.3 Enabling Trusted ARP

Configuration Effect

- The gateway is protected against ARP spoofing.

Notes

- N/A

Configuration Step

- To deploy a GSN solution, enable trusted ARP.
- Enable trusted ARP in global configuration mode.

Verification

- Run the **show arp trusted** command to display trusted ARP entries.
- Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

↘ Enabling Trusted ARP

Command	**service trustedarp**
Parameter Description	N/A

Command Mode	Global configuration mode
Usage Guide	Trusted ARP defends against ARP spoofing on the device. It needs to be used with the GSN solution.

Enabling VLAN Redirection When a Trusted ARP Entry Is Added

Command	**arp trusted user-vlan** *vid1* **translated-vlan** *vid2*
Parameter Description	*vid1*: Indicates the VLAN ID configured on the server. *vid2*: Indicates the ID of the VLAN redirected.
Command Mode	Global configuration mode
Usage Guide	This command takes effect only after trusted ARP is enabled. Configure this command only when the VLAN pushed by the server differs from the VLAN in the trusted ARP entry.

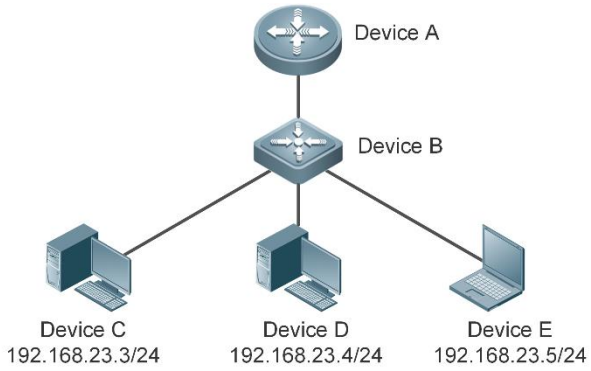
Displaying Trusted ARP Entries

Command	**show arp trusted** [*ip* [*mask*]]
Parameter Description	*ip*: Indicates the IP address. The ARP entry of the specified IP address is displayed. If **trusted** is specified, only trusted ARP entries are displayed. Otherwise, non-trusted ARP entries are displayed. *mask*: Indicates that ARP entries within the IP subnet are displayed. If **trusted** is specified, only trusted ARP entries are displayed. Otherwise, non-trusted ARP entries are displayed.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Deleting Trusted ARP Entries

Command	**clear arp-cache trusted** [*ip* [*mask*]]
Parameter Description	*ip*: Indicates the IP address, from which ARP entries are to be cleared. All dynamic ARP entries are deleted by default. *mask*: Indicates the mask of a subnet, from which ARP entries are to be cleared. Dynamic ARP entries specified by the preceding IP address are deleted by default.
Command Mode	Privileged EXEC mode
Usage Guide	After you run the **clear arp-cache trusted** command to delete all trusted ARP entries on the switch, users may fail to access the network. You are advised to use the **clear arp-cache trusted** *ip* command to delete a specified trusted ARP entry.

Enabling Trusted ARP Aging



Command	**arp trusted aging**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After you configure this command, trusted ARP entries begin to age. The aging time is the same as the dynamic ARP aging time. You can run the **arp timeout** command in interface configuration mode

	to configure the aging time.

Adjusting the Capacity of Trusted ARP Entries

Command	**arp trusted** *number*
Parameter Description	*number*: Indicates the capacity of trusted ARP entries. The minimum value is 10. The maximum number is the capacity supported by the device minus 1,024. By default, the maximum number of trusted ARP entries is half of the total capacity of ARP entries.
Command Mode	Global configuration mode
Usage Guide	To make this command take effect, enable trusted ARP first. Trusted ARP entries and other entries share the memory. If trusted ARP entries occupy much space, dynamic ARP entries may not have sufficient space. Set the number of ARP entries as needed. Do not use a large value.

Configuration Example

Scenario	 ● Device A is the router. ● Device B is the gateway of the network segment where terminals reside. ● Device C, Device D, and Device E are terminals.
Configuration Steps	● Enable trusted ARP. ● Enable VLAN redirection. ● Enable trusted ARP aging. ● Set the maximum number of trusted ARP entries to 1024.

	`Hostname(config)# service trustedarp`
	`Hostname(config)#arp trusted user-vlan 2-9 translated-vlan 10`
	`Hostname(config)#arp trusted aging`
	`Hostname(config)#arp trusted 1024`

Verification	● Run the **show running-config** command to check whether the configurations take effect.

	`Hostname# show running-config`
	`service trustedarp`
	`arp trusted user-vlan 2-9 translated-vlan 10`
	`arp trusted aging`
	`arp trusted 1024`

Common Errors

- Trusted ARP is disabled, causing a failure to assign ARP entries.

1.4.4 Enabling Gratuitous ARP

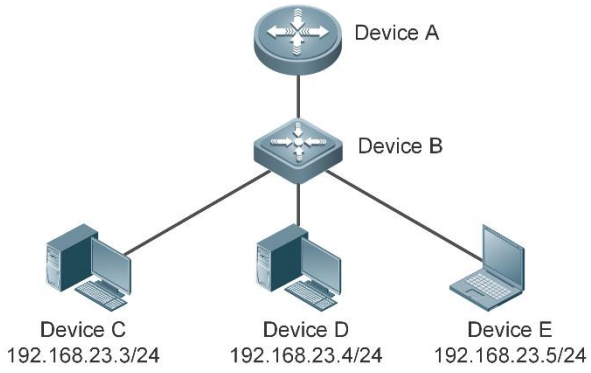
Configuration Effect

The interface periodically sends gratuitous ARP packets.

Configuration Step

- Optional.
- When a device acts as the gateway, enable gratuitous ARP on an interface to prevent users from learning incorrect gateway MAC addresses due to ARP spoofing.
- Enable gratuitous ARP in interface configuration mode.

Verification



Run the **show running-config interface** [*name*] command to check whether the configuration is successful.

Related Commands

↘ Enabling Gratuitous ARP

Command	**arp gratuitous-send interval** *seconds* [*number*]
Parameter Description	*seconds*: Indicates the interval for sending a gratuitous ARP request packets, in seconds. The value range is from 1 to 3600. *number*: Indicates the number of gratuitous ARP request packets that are sent. The default value is 1. The value range is from 1 to 100.
Command Mode	Interface configuration mode
Usage Guide	If a network interface of a device acts as the gateway for downstream devices but a downstream device pretends to be the gateway, enable gratuitous ARP on the interface to advertise itself as the real gateway.

Configuration Example

Scenario	 ● Device A is the router. ● Device B is the gateway of the network segment where terminals reside. ● Device C, Device D, and Device E are terminals.
Configuration Steps	● Configure GigabitEthernet 0/1 to send a gratuitous ARP packet every 5s.

	`Hostname(config-if-GigabitEthernet 0/1)#arp gratuitous-send interval 5`
Verification	● Run the **show running-config interface** command to check whether the configuration takes effect.

	`Hostname#show running-config interface gigabitethernet 0/1`
	
	`Building configuration...`
	`Current configuration : 127 bytes`
	`!`
	`interface GigabitEthernet 0/1`
	` duplex auto`
	` speed auto`
	` ip address 30.1.1.1 255.255.255.0`
	` arp gratuitous-send interval 5`

1.4.5 Enabling Proxy ARP

Configuration Effect

The device acts as a proxy to reply to ARP request packets from other users.

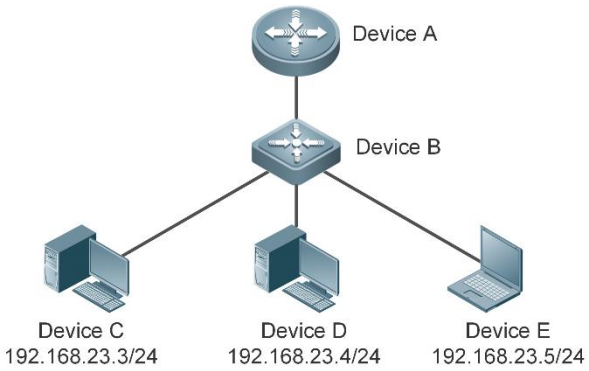
Notes

By default, proxy ARP is disabled on Layer 3 switches while enabled on routers.

Configuration Step

- Optional.
- If a user without any route information needs to obtain the MAC addresses of the IP users in other subnets, enable proxy ARP on the device so that the device can act as a proxy to send ARP replies.
- Enable proxy ARP in interface configuration mode.

Verification



Run the **show ip interface** [*name*] command to check whether the configuration takes effect.

Related Commands

↘ Enabling Proxy ARP

Command	**ip proxy-arp**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Scenario	 ● Device A is the router. ● Device B is the gateway of the network segment where terminals reside. ● Device C, Device D, and Device E are terminals.
Configuration Steps	● Enable proxy ARP on GigabitEthernet 0/1.
	`Hostname(config-if-GigabitEthernet 0/1)#ip proxy-arp`
Verification	● Run the **show ip interface** command to check whether the configuration takes effect.

	`Hostname#show ip interface gigabitethernet 0/1`
	`GigabitEthernet 0/1`
	`  IP interface state is: DOWN`
	`  IP interface type is: BROADCAST`
	`  IP interface MTU is: 1500`
	`  IP address is:`
	`    No address configured`
	`  IP address negotiate is: OFF`

	` Echo request       : 0`
	` Echo reply         : 0`
	` Unreachable        : 0`
	` Source quench      : 0`
	` Routing redirect   : 0`

1.4.6 Enabling Local Proxy ARP

Configuration Effect

The device acts as a proxy to reply to ARP request packets from other users in the same subnet.

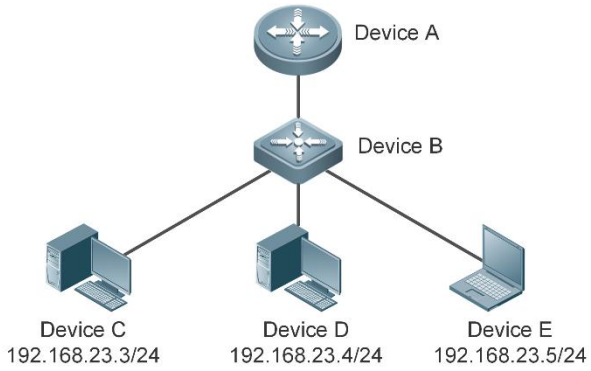
Notes

Local proxy ARP is supported only on SVIs.

Configuration Step

- Optional.
- If a user enabled with port protection needs to communicate with users in the VLAN, enable local proxy ARP on the device.
- Enable local proxy ARP in interface configuration mode.

Verification



Run the **show run interface** [*name*] command to check whether the configuration takes effect.

Related Commands

Enabling Local Proxy ARP

Command	**local-proxy-arp**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Scenario	 ● Device A is the router. ● Device B is the gateway of the network segment where terminals reside. ● Device C, Device D, and Device E are terminals.
Configuration Steps	● Enable local proxy ARP on the interface of VLAN 1.
	`Hostname(config-if-VLAN 1)#local-proxy-arp`

Verification	● Run the **show ip interface** command to check whether the configuration takes effect.

	`Hostname#show running-config interface vlan 1`
	
	`Building configuration...`
	`Current configuration : 53 bytes`
	
	`interface VLAN 1`
	` ip address 192.168.1.2 255.255.255.0`
	` local-proxy-arp`

1.4.7 Enabling ARP Trustworthiness Detection

Configuration Effect

Enable ARP trustworthiness detection. If the device receiving an ARP request packet fails to find the corresponding entry, it performs NUD. If the MAC address in the existing dynamic ARP entry is updated, the device immediately performs NUD to prevent ARP attacks.

Notes

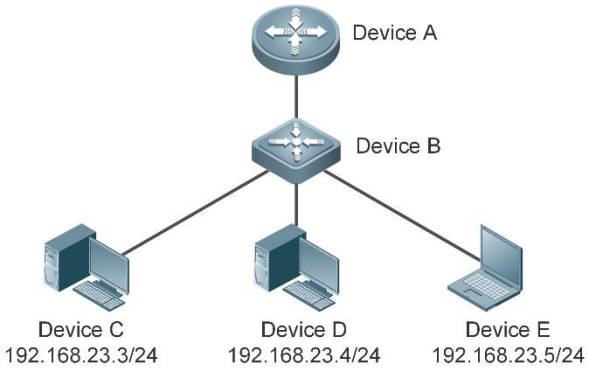
Because this function introduces a strict confirmation procedure into the ARP learning process, it impacts the efficiency of ARP learning.

Configuration Step

- Optional.
- If the device needs to learn ARP entries, enable ARP trustworthiness detection on the device. If the device receiving an ARP request packet fails to find the corresponding entry, it needs to send a unicast ARP request packet to check whether the peer end exists. If so, the device learns the ARP entry. If not, the device does not learn the ARP entry. If the MAC address in the ARP entry changes, the device will immediately perform NUD to prevent ARP spoofing.
- Enable ARP trustworthiness detection in interface configuration mode.

Verification

Run the **show running-config interface** [*name*] command to check whether the configuration take effect



Related Commands

↘ Enabling ARP Trustworthiness Detection

Command	**arp trust-monitor enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	If the corresponding ARP entry exists and the MAC address is not updated, the device enabled

	with this function does not perform NUD. If the MAC address of the existing dynamic ARP entry is updated, the device enabled with this function immediately performs NUD. After this function is disabled, the device does not perform NUD for learning or updating ARP entries.

Configuration Example

Scenario	 ● Device A is the router. ● Device B is the gateway of the network segment where terminals reside. ● Device C, Device D, and Device E are terminals.
Configuration Steps	● Enable ARP trustworthiness detection on GigabitEthernet 0/1.
	`Hostname(config-if-GigabitEthernet 0/1)#arp trust-monitor enable`
Verification	● Run the **show running-config interface** command to check whether the configuration takes effect.

	`Hostname#show running-config interface gigabitethernet 0/1`
	
	`Building configuration...`
	`Current configuration : 184 bytes`
	`!`
	`interface GigabitEthernet 0/1`
	` duplex auto`
	` speed auto`
	` ip address 30.1.1.1 255.255.255.0`
	` arp trust-monitor enable`

1.4.8 Configuring the Device to Determine Host Existence Prior to ARP Proxy Service Provisioning

Supported functions are subject to the product version.

Configuration Effect

Enable the local ARP proxy on the VRRP master device. When responding to an ARP request packet as a proxy, the VRRP master device does not need to determine whether the ARP entry corresponding to the destination IP address exists.

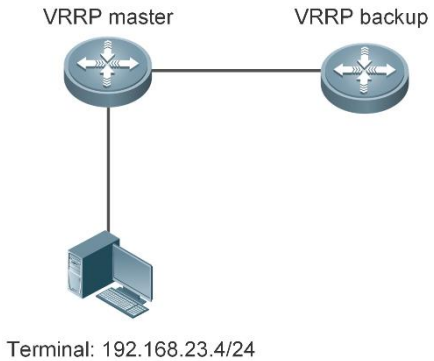
Notes

The **arp proxy-resolved** command is enabled on the device by default. That is, by default, the VRRP master device responds to an ARP request packet as a proxy only after the destination IP address has been resolved.

Configuration Step

- Optional.
- Run the **no arp proxy-resolved** command when the VRRP master device needs to forcibly respond to ARP request packets as a proxy.
- Configure this function in global configuration mode.

Verification



Run the **show running-config** command to check whether the configuration is successful.

Related Commands

Configuring the VRRP Master Device to Forcibly Respond to ARP Request Packets as a Proxy

Command	**no arp proxy-resolved**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Whether this configuration is supported depends on the actual product.

Configuration Example

Scenario	
Configuration Steps	● Configure the VRRP master device to forcibly respond to ARP request packets as a proxy, with no need to determine whether destination IP addresses have been resolved.
	`Hostname(config)#no arp proxy-resolved`
Verification	● Run the **show running-config** command to check whether the configuration is successful.
	`Hostname#show running-config` ` no arp proxy-resolved`

Common Errors

- N/A

1.4.9 Configuring the Device to Send ARP Request Packets to a Specified Sub-VLAN of a Super-VLAN

Supported functions are subject to the product version.

Configuration Effect

In gateway authentication mode, enable dumb terminals in a super-VLAN to be deployed in an authenticated VLAN, so that the device can proactively send ARP request packets to specific VLANs.

Notes

After the **arp resolve vlan** *vlan-list* command is configured, ARP request packets are sent only to VLANs in the specified VLAN list of a super-VLAN. In particular, if an authentication-exempt VLAN is configured and the authentication-exempt VLAN is not in the value specified by *vlan-list* of **arp resolve vlan**, ARP request packets will not be broadcast to the authentication-exempt VLAN.

Configuration Step

- Optional.
- Run the **arp resolve vlan** *vlan-list* command to configure the device to send ARP request packets to specified sub-VLANs of a super-VLAN.

Verification

Run the **show running-config** command to check whether the configuration is successful.

Related Commands

Configuring the Device to Send ARP Request Packets to a Specified Sub-VLAN of a Super-VLAN

Command	**arp resolve vlan**
Parameter Description	*vlan-list*: Sets the list of sub-VLANs in a super-VLAN, where ARP request packets are sent only to these sub-VLANs. **none**: Specifies that no ARP resolution request is sent to any sub-VLAN of a super-VLAN.
Command Mode	Global configuration mode
Usage Guide	Whether this configuration is supported depends on the actual product.

Configuration Example

Configuration Steps	• Enable the device to provide active ARP resolution for VLANs 10–20 and VLANs 25–30.
	`Hostname(config)# arp resolve vlan 10-20,25-30`
Verification	• Run the **show running-config** command to check whether the configuration is successful.
	`Hostname# show running-config`

	`arp resolve vlan 10-20,25-30`

Common Errors

- N/A

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear arp-cache [**interface** *interface-name* | [**trusted**] *ip* [*mask*]]	Clears dynamic ARP entries. In gateway authentication mode, dynamic ARP entries in authentication VLANs are not cleared.

Displaying

Command	Description
show arp [*interface-type interface-number* | [*ip* [*mask*] | *mac-address* | **static** | **complete** | **incomplete**]	Displays the ARP table.
show ip arp	Displays the ARP table.
show arp trusted [*ip* [*mask*]	Displays the trusted ARP table.
show arp counter	Displays the ARP entry counter.
show arp timeout	Displays the timeout of dynamic ARP entries.
show arp packet statistics [*interface*]	Displays ARP packet statistics.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug arp	Debugs ARP packet sending and receiving.
debug arp event	Debugs creation and deletion of ARP entries.

1 Configuring Proxy ARP

1.1 Overview

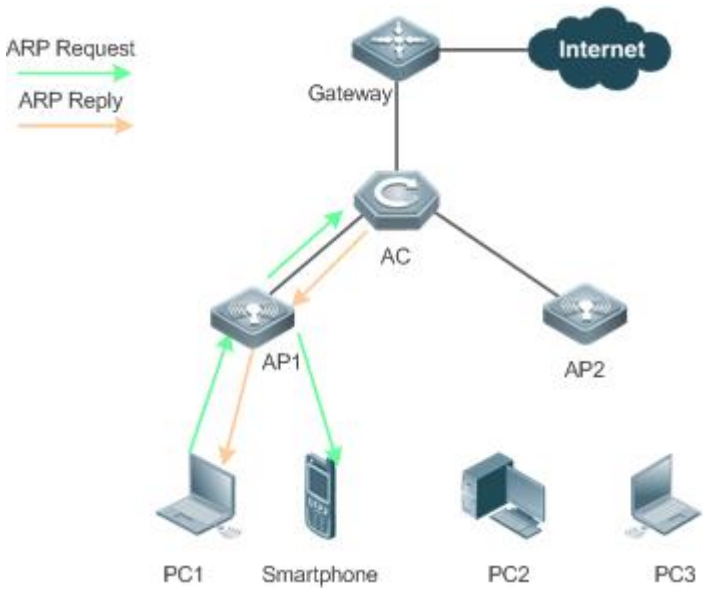
Proxy ARP enables the device to function as a proxy on a wireless local area network (WLAN) to respond to ARP request packets of another device. Because Carrier Sense Multiple Access with Collision Avoidance (CSMA/CA) is used for communication on a wireless network, proxy ARP can prevent ARP broadcast packets on one access point (AP) from being sent to another AP, which increases the bandwidth utilization of the WLAN and enhances user experience.

Protocols and Standards

N/A

1.2 Applications

Application	Description
Proxy ARP Service on a WLAN	The access controller (AC) acts as a proxy to respond to ARP request packets of any device on the WLAN.



1.2.1 Proxy ARP Service on a WLAN

Scenario

In centralized forwarding mode of the fit AP, the AC acts a proxy for ARP request packets of any device on the WLAN.

- The AC needs to learn the MAC address of a device on the WLAN before responding to this device.

Figure 1-1

Remarks	The preceding figure is the flowchart of the ARP request packets that stations (STAs) send to the gateway or other devices in centralized forwarding mode of the fit AP on the WLAN.

Deployment

- Deploy a network consisting of the gateway, AC, APs, and STAs. The AC enabled with proxy ARP (enabled by default) works as a proxy to respond to ARP request packets of STAs to prevent ARP request packets from being broadcast to other APs.
- The proxy ARP function works on the AC and is transparent to users. You can run this function without any other configurations.

1.3 Features

Basic Concepts

↘ Proxy ARP

Layer 2 proxy ARP, also called proxy ARP, enables a device on a WLAN to work as a proxy to respond to ARP request packets of another device. Because CSMA/CA is used for communication on a wireless network, proxy ARP can prevent ARP packets on one AP from being broadcast to another AP, which increases the bandwidth utilization of the WLAN and enhances user experience.

Overview

Feature	Description
Wireless Proxy ARP	The AC works as a proxy for STAs to prevent ARP request packets from being broadcast to other APs.

1.3.1 Wireless Proxy ARP

Working Principle

In typical wireless networking, a STA usually accesses the Internet through an AP and an AC. Typically, multiple STAs are associated with one AP, while multiple APs are associated with one AC. When STAs connected to one AP access STAs connected to another AP, or wireless users and wired users access each other, ARP packets must be transmitted through the AC, making it easy for deploying proxy ARP on the AC.

The working process of proxy ARP is as follows:

1 The AC learns the source IP address and source MAC address from the transmitted ARP packet to generate an ARP entry.

2 According to the ARP entry, the AC works as a proxy on the network to respond to ARP request packets of other users.

3 If the AC does not have the MAC address of the destination host, it forwards the 802.1Q-compliant ARP request packet.

4 ARP reply packets are forwarded in the same manner as 802.1Q-compliant Ethernet frames.

As shown in Figure 1-1, PC3 and PC1 obtain the MAC address of the gateway respectively. Assume that this WLAN has one AC, two APs (AP1 and AP2), and four STAs (PC1, PC2, PC3, and smartphone).

1. PC3 initiates an ARP request to the IP address of the gateway.
2. AP2 forwards this ARP request packet to PC2 and the AC.
3. From this ARP request packet, the AC learns the IP address and MAC address of PC3 and forwards this ARP request packet to the gateway, AP1, and PC1 and the smartphone connected to AP1.
4. The gateway sends an ARP reply packet to PC4 through AC. Then the AC learns the IP address and MAC address of the gateway.
5. PC1 initiates an ARP request packet to the IP address of the gateway.
6. AP1 forwards this ARP request packet to PC2 and AC.
7. The AC learns the IP and MAC address of PC1 and works as a proxy for the gateway to directly send an ARP reply packet to PC1. This is because AC has learned the MAC address of the gateway in step 4. Therefore, ARP request packets will not be broadcast to PC3 and PC4.

Related Configuration

Enabling Layer 2 Proxy ARP

- By default, Layer 2 proxy ARP is enabled.
- Run the **no proxy-arp enable** command to disable Layer 2 proxy ARP.

1.4 Configuration

Configuration	Description and Command	
Enabling Layer 2 Proxy ARP	(Optional) By default, Layer 2 proxy ARP is enabled.	
	proxy-arp enable	Enables Layer 2 proxy ARP
Enabling Proxy ARP on the Device to Only Learn ARP Entries of Wireless Ports	(Optional) By default, learning of only ARP entries on wireless ports is disabled.	
	proxy-arp learn only-wlan [**except** *ip-address*]	Enables proxy ARP on the device to learn only ARP packets of wireless ports and excluded IP addresses.

1.4.1 Enabling Layer 2 Proxy ARP

Configuration Effect

Enabling Layer 2 Proxy ARP improves wireless bandwidth efficiency and user experience.

Notes

N/A

Configuration Step

Enabling Layer 2 Proxy ARP

- By default, Layer-2 proxy ARP is enabled.
- In a wireless IPv4 scenario, enabling Layer 2 proxy ARP on AC to enhance network bandwidth utilization and user experience.

Verification

Run the **show running-config** command to check whether Layer 2 proxy ARP is enabled.

Related Commands

Disabling Layer 2 Proxy ARP

Command	**no proxy-arp enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Disabling Layer 2 Proxy ARP

Configuration Steps	• Disable Layer 2 proxy ARP.
	`Hostname(config)# no proxy-arp enable`
Verification	• Run the **show running-config** command to check whether Layer 2 proxy ARP is enabled.
	`Hostname# show running-config` `no proxy-arp enable`

Common Errors

N/A

1.4.2 Enabling Proxy ARP on the Device to Only Learn ARP Entries of Wireless Ports

Configuration Effect

Enable learning of only ARP entries on wireless ports according to the actual topology. The device can learn excluded IP addresses on wired ports. In this way, the ARP entry capacity on an AC will not be fully occupied by ARP packets on wired ports.

Notes

If there is a sufficient proxy ARP volume (queried through the **show proxy-arp statistic** command), do not enable this function. This is because learning ARP packets of wired ports helps decrease flooding of broadcast ARP packets of wired users.

Configuration Step

Enabling Proxy ARP on the Device to Learn Only ARP Packets of Wireless Ports

- By default, this function is disabled.
- If the AC that does not serve as a gateway is enabled with this function, you are advised to configure an excluded IP address so that the device learns the IP address of the gateway of the wired port.

Verification

Run the **show running-config** command to check whether this function is enabled.

Related Commands

Enabling Proxy ARP on the Device to Learn Only ARP Packets of Wireless Ports

Command	**proxy-arp learn only-wlan** [**except** *ip-address*]
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	You can enable this function when all of the following requirements are met: ● The AC works in centralized forwarding mode. ● The AC interconnects with the gateway. Configure a super-VLAN and many sub-VLANs for STAs on the gateway. ● Proxy ARP entries are easily used up due to a large number of users (run the **show proxy-arp statistics** command to display proxy ARP statistics).

Configuration Example

Enabling Proxy ARP on the Device to Learn Only ARP Packets of Wireless Ports

Configuration Steps	● Enable proxy ARP on the device to learn only ARP packets of wireless ports as well as excluded IP addresses, 192.168.21.1 and 92.168.22.1.
	`Hostname(config)# proxy-arp learn only-wlan except 192.168.21.1` `Hostname(config)# proxy-arp learn only-wlan except 192.168.22.1`
Verification	● Run the **show running-config** command to check whether this function is enabled.

	`Hostname#show running-config`
	`proxy-arp learn only-wlan except 192.168.21.1`
	`proxy-arp learn only-wlan except 192.168.22.1`

Common Errors

N/A

1.5 Monitoring

Clearing

Command	Description
clear proxy-arp [*ip-address vlan-id*]	Clears the specified proxy ARP entry.
clear proxy-arp	Clears all proxy ARP entries.

Displaying

Command	Description
show proxy-arp [*ip-address*]	Displays all proxy ARP entries.
show proxy-arp dynamic	Displays dynamic proxy ARP entries.
show proxy-arp statistics	Displays proxy ARP statistics.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug proxy-arp	Debugs receiving/sending of ARP packets.

1 Configuring IPv4 Basics

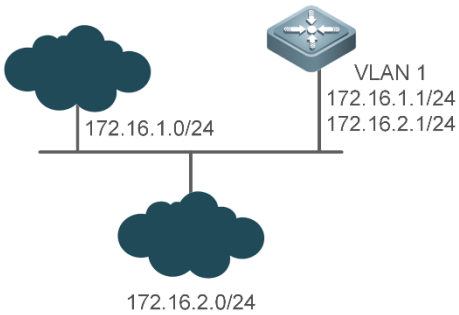
1.1 Overview

The Internet Protocol (IP) sends packets to the destination from the source by using logical (or virtual) addresses, that is, IP addresses. At the network layer, routers forward packets based on IP addresses.

Protocols and Standards

- RFC 1918: Address Allocation for Private Internets
- RFC 1166: Internet Numbers

1.2 Applications



Application	Description
Configuring an IP Address for Communication	Two networks communicate through one interface.

1.2.1 Configuring an IP Address for Communication

Scenario

A device is connected to a Local Area Network (LAN), which is divided into two network segments, namely, 172.16.1.0/24 and 172.16.2.0/24. Computers on the two network segments can communicate with the Internet through devices and computers between the two network segments can communicate with each other.

Figure 1-1 Configuring IP Addresses

Deployment

- Configure two IP addresses in VLAN 1. One is a primary IP address and the other is a secondary IP address.
- For hosts on the network segment 172.16.1.0/24, set the gateway address to 172.16.1.1. For hosts on the network segment 172.16.2.0/24, set the gateway address to 172.16.2.1.

1.3 Features

Basic Concepts

IP Address

An IP address consists of 32 bits in binary notation. To facilitate writing and description, an IP address is generally expressed in decimal notation. When the IP address is expressed in decimal notation, an IP address is divided into four groups, with eight bits in each group. The value range of each group is from 0 to 255, and groups are separated by a full stop (.). For example, the value 192.168.1.1 is an IP address expressed in decimal notation.

IP addresses are used for interconnection at the IP layer. A 32-bit IP address consists of two parts, namely, network bits and host bits. Based on values of the first several bits in the network part, IP addresses in use can be classified into four classes.

For a class A address, the most significant bit is 0, 7 bits indicate a network ID, and 24 bits indicate a local address. There are 128 class A networks in total.

Figure 1-2

		8	16 24 32
Class A IP address	0	Network ID	Host ID

For a class B address, the first two most significant bits are 10, 14 bits indicate a network ID, and 16 bits indicate a local address. There are 16,348 class B networks in total.

Figure 1-3

			8	16 24 32
Class B IP address	1	0	Network ID	Host ID

For a class C address, the first three most significant bits are 110, 21 bits indicate a network ID, and 8 bits indicate a local address. There are 2,097,152 class C networks in total.

Figure 1-4

				8	16 24 32
Class C IP address	1	1	0	Network ID	Host ID

For a class D address, the first four most significant bits are 1110 and other bits indicate a multicast address.

Figure 1-5

					8	16 24 32
Class D IP address	1	1	1	0	Multicast address	

The addresses with the first four most significant bits 1111 cannot be assigned. These addresses are called class E addresses and are reserved.

When IP addresses are planned during network construction, they should be assigned according to the network's specific requirements. If the network requires Internet connectivity, users must apply for IP addresses from the appropriate agency. In China, this process is managed by the China Internet Network Information Center (CNNIC). The Internet Corporation for Assigned Names and Numbers (ICANN) oversees the final assignment of IP addresses globally. For internal private networks, users do not need to apply for IP addresses, but assigning IP addresses randomly is discouraged. It is advisable to use dedicated private network addresses.

The following table lists reserved and available addresses.

Class	Address Range	Status
Class A network	0.0.0.0–0.255.255.255	Reserved
	1.0.0.0–126.255.255.255	Available
	127.0.0.0–127.255.255.255	Reserved
Class B network	128.0.0.0–191.254.255.255	Available
	191.255.0.0–191.255.255.255	Reserved
Class C network	192.0.0.0–192.0.0.255	Reserved
	192.0.1.0–223.255.254.255	Available
	223.255.255.0–223.255.255.255	Reserved
Class D network	224.0.0.0–239.255.255.255	Multicast address
Class E network	240.0.0.0–255.255.255.254	Reserved
	255.255.255.255	Broadcast address

Three address ranges are dedicated to private networks. These addresses are not used on the Internet. If the networks to which these addresses are assigned need to be connected to the Internet, these IP addresses need to be converted into valid Internet addresses. The following table lists private address ranges. Private network addresses are defined in RFC 1918.

Class	Address Range	Status
Class A network	10.0.0.0–10.255.255.255	1 class A network
Class B network	172.16.0.0–172.31.255.255	16 class B networks
Class C network	192.168.0.0–192.168.255.255	256 class C networks

For details about IP address assignment, TCP/UDP ports, and other codes, refer to RFC 1166.

Subnet Mask

A subnet mask is also a 32-bit value. It designates which bits in an IP address signify the network address. In a subnet mask, IP address bits corresponding to '1' bits designate the network address, while bits corresponding to '0' bits designate the host address. For instance, in class A networks, the subnet mask is 255.0.0.0. Using subnet masks allows for the division of a network into multiple subnets. Subnetting involves using some host address bits as part of the network address, reducing host capacity while increasing the number of networks. In such cases, subnet masks are referred to as subnet masks.

Broadcast Packet

Broadcast packets refer to the packets destined for all hosts on a physical network. Devices support two types of broadcast packets:

- Directed broadcast: All hosts on the specified network are packet receivers and the host bits of a destination address are all 1s.
- Limited broadcast: All hosts on all networks are packet receivers and the 32 bits of a destination address are all 1s.

ICMP Packet

The Internet Control Message Protocol (ICMP) is a sub-protocol in the TCP/IP suite for transmitting control messages between IP hosts and network devices. It is mainly used to notify corresponding devices when network exceptions occur.

TTL

The Time To Live (TTL) refers to the number of network segments where packets are allowed to pass before they are discarded. The TTL is included in an IP packet, signaling how long the packet can remain on the network before it should be discarded.

Features

Feature	Description
IP Address	The IP protocol can run on an interface only when the interface is configured with an IP address.
Broadcast Packet Processing	Broadcast addresses are configured, so broadcast packets can be forwarded and processed.
Sending ICMP Packets	ICMP packets are sent and received.
Limiting the Transmission Rate of ICMP Error Packets	This function prevents Denial of Service (DoS) attacks.
IP MTU	The Maximum Transmission Unit (MTU) of IP packets on an interface is configured.
IP TTL	The TTL of unicast packets and broadcast packets is configured.
IP Source Route	Source routes for receiving packets are checked.
IP Address Pool	The IP address pool is used to assign an IP address to the peer end through Point-to-Point Protocol (PPP) negotiation.

1.3.1 IP Address

IP addresses are obtained on an interface in the following ways:

1 Manually configuring IP addresses

2 Obtaining IP addresses through the Dynamic Host Configuration Protocol (DHCP)

3 Obtaining IP addresses through PPP negotiation

4 Borrowing IP addresses of other interfaces

These approaches are exclusive. If you configure a new approach to obtain an IP address, the old IP address will be overwritten.

For details on how to obtain IP addresses through DHCP, see *Configuring DHCP*. The following describes the other three approaches for obtaining IP addresses.

Configuring an IP Address for an Interface

A device can receive and send IP packets only after the device is configured with an IP address. The IP protocol can run on an interface only when the interface is configured with an IP address.

Configuring Multiple IP Addresses for an Interface

Multiple IP addresses can be configured for an interface, of which one is a primary IP address and the others are secondary IP addresses. The number of secondary IP addresses is not limited. However, secondary IP addresses must belong to different networks and secondary IP addresses must be on different networks from primary IP addresses. In network construction, secondary IP addresses are often used in the following situations:

- A network does not have enough host addresses. For example, a LAN now needs one class C network to allocate 254 addresses. However, when the number of hosts exceeds 254, one class C network is not enough and another

class C network is needed. In this case, two networks need to be connected. Therefore, more IP addresses are needed.

- Many legacy networks are Layer 2 bridged networks without subnetting. You can use secondary IP addresses to upgrade the network to a routing network based on the IP layer. For each subnet, one device is configured with one IP address.
- When two subnets of one network are isolated by another network, you can connect the isolated subnets by creating a subnet of the isolated network and configuring a secondary address. One subnet cannot be configured on two or more interfaces of a device.

Obtaining an IP Addresses Through PPP Negotiation

This command is supported on point-to-point interfaces only.

Through this configuration, a point-to-point interface accepts the IP address assigned by the peer end through PPP negotiation.

Borrowing an IP Addresses from Another Interface

One interface may be not configured with an IP address. To enable the interface, it must borrow an IP address from another interface.

IP addresses of Ethernet interfaces, tunnel interfaces, and loopback interfaces can be borrowed. However, these interfaces cannot borrow IP addresses from other interfaces.

The IP addresses of borrowed interfaces cannot be borrowed from other interfaces.

If a borrowed interface has multiple IP addresses, only the primary IP address can be borrowed.

The IP address of one interface can be borrowed by multiple interfaces.

IP addresses of borrowing interfaces are always consistent with and vary with IP addresses of borrowed interfaces.

Configuring an IP Address of a BVI Interface on an AP Through an AC

The configuration modes on an AC include the AP configuration mode, AP group configuration mode, and all-AP configuration mode, which are in descending order of priority. The configuration pushed to an AP has the highest priority.

In any AP configuration mode, you can configure an IP address for only one bridge virtual interface (BVI) by using the **ap-interface bvi** *num* **ip address** *ip-address network-mask* command or the **ap-interface bvi** *num***ip address dynamic** command.

On a fit AP network, if the **ap-interface bvi** *num***ip address** *ip-address network-mask* command is used, the AP needs to be assigned within different VLANs. Otherwise, an address conflict occurs. If the **ap-interface bvi** *num***ip address dynamic** command is used, the problem does not occur.

Related Configuration

Configuring an Interface with One or More IP Addresses

- By default, an interface is not configured with an IP address.
- The **ip address** command is used to configure an IP address for an interface.
- After an IP address is configured, the IP address can be used for communication when it passes conflict detection.

- The **ip address** *ip-address mask* **secondary** command can be used to configure multiple secondary IP addresses.

Borrowing an IP Address from Another Interface

- By default, an interface is not configured with an IP address.
- The **ip unnumbered** command can be used to borrow IP addresses from other interfaces.

Configuring an IP Address of a BVI on an AP Through an AC

- By default, the IP address of a BVI is not configured in AP configuration mode.
- The **ap-interface bvi** *num* **ip address** command is used to configure the IP address of a BVI of an AP on an AC.

1.3.2 Broadcast Packet Processing

Working Principle

Broadcast is classified into two types:

- Limited broadcast: The IP address is 255.255.255.255. Because such an address is prohibited by routers, the broadcast is called local network broadcast.
- Directed broadcast: All host bits are 1s, for example, 192.168.1.255/24. Broadcast packets with these IP addresses can be forwarded.

If IP network devices forward limited broadcast packets (destination IP address is 255.255.255.255), the network may be overloaded, severely impacting its performance, leading to what is known as a broadcast storm. Devices provide some approaches to contain broadcast storms within the local network and prevent their spread. Layer 2 network devices such as bridges and switches can propagate broadcast storms.

The most effective approach to prevent broadcast storms is to assign a directed broadcast address to each network. This involves using directed broadcast but not limited broadcast in the IP protocol to disseminate data.

For details about broadcast storms, see RFC 919 and RFC 922.

Directed broadcast packets refer to the broadcast packets destined for a subnet. For example, packets whose destination address is 172.16.16.255 are called directed broadcast packets. However, the node that generates the packets is not a member of the destination subnet.

After receiving directed broadcast packets, the device indirectly connected to the destination subnet forwards the packets. After directed broadcast packets reach the device directly connected to the subnet, the device converts directed broadcast packets to limited broadcast packets (destination IP address is 255.255.255.255) and broadcasts the packets to all hosts on the destination subnet at the link layer.

Related Configuration

Configuring an IP Broadcast Address

- By default, the IP broadcast address of an interface is 255.255.255.255.
- To define broadcast packets of other addresses, run the **ip broadcast-address** command on the interface.

Forwarding Directed Broadcast Packets

- By default, directed broadcast packets cannot be forwarded.

- On the specified interface, you can run the **ip directed-broadcast** command to enable directed broadcast packets forwarding. In this way, the interface can forward directed broadcast packets to networks that are directly connected. Broadcast packets can be transmitted within the destination subnet without affecting forwarding of other directed broadcast packets.
- On an interface, you can define an Access Control List (ACL) to transmit specified directed broadcast packets. After an ACL is defined, only directed broadcast packets that match the ACL are forwarded.

1.3.3 Sending ICMP Packets

Working Principle

ICMP Protocol Unreachable Packet

A device receives non-broadcast packets destined for itself, and the packets contain the IP protocol that cannot be supported by the device. The device sends an ICMP protocol unreachable packet to the source host. Besides, if the device does not know a route to forward packets, it also sends an ICMP host unreachable packet.

ICMP Redirection Packet

Sometimes, a route may be less than optimal. In this case, a device sends packets from the interface that receives packets. If a device sends packets from an interface on which it receives the packets, the device sends an ICMP redirection packet to the source, informing the source that the gateway is another device on the same subnet. In this way, the source sends subsequent packets according to the optimal path.

ICMP Mask Response Packet

Sometimes, a network device sends an ICMP mask request packet to obtain the mask of a subnet. The network device that receives the ICMP mask request packet sends a mask response packet.

Timestamp Query

RFC 792 requests the system to return the current system time when the system receives an ICMP timestamp query request.

To prevent attackers from obtaining the system time through the protocol and attacking time-based authentication protocols, you can disable the timestamp query function. Then the device directly discards received ICMP timestamp query requests.

Related Configuration

Enabling the ICMP Protocol Unreachable Packet

- By default, the ICMP Protocol unreachable packet function is enabled on an interface.
- You can run the [**no**] **ip unreachables** command to disable or enable the function.

Enabling the ICMP Redirection Packet

- By default, the ICMP redirection packet function is enabled on an interface.
- You can run the [**no**] **ip redirects** command to disable or enable the function.

Enabling the ICMP Mask Response Packet

- By default, the ICMP mask response packet function is enabled on an interface.
- You can run the [**no**] **ip mask-reply** command to disable or enable the function.

Enabling Timestamp Query

- By default, a timestamp query message is not sent.
- You can run the [**no**] **ip icmp timestamp** command to enable or disable the function.

1.3.4 Limiting the Transmission Rate of ICMP Error Packets

Working Principle

This function limits the transmission rate of ICMP error packets to prevent DoS attacks by using the token bucket algorithm.

If an IP packet needs to be fragmented but the Don't Fragment (DF) bit in the header is set to 1, the device sends an ICMP destination unreachable packet (code 4) to the source host. This ICMP error packet is used to discover the path MTU. When there are too many other ICMP error packets, the ICMP destination unreachable packet (code 4) may be not sent. As a result, the path MTU discovery function fails. To avoid this problem, you should limit the transmission rate of ICMP destination unreachable packets and other ICMP error packets respectively.

Related Configuration

Configuring the Transmission Rate of ICMP Destination Unreachable Packets Triggered by the DF Bit in the IP Header

- By default, 10 packets are transmitted at an interval of 100 milliseconds.
- The **ip icmp error-interval DF** command can be used to configure the transmission rate.

Configuring the Transmission Rate of Other ICMP Error Packets

- By default, 10 packets are transmitted at an interval of 100 milliseconds.
- The **ip icmp error-interval** command can be used to configure the transmission rate.

1.3.5 IP MTU

Working Principle

If the size of an IP packet exceeds the IP MTU, the RGOS software splits the packet. For all devices on the same physical network segment, the IP MTU of interconnected interfaces must be the same. You can adjust the link MTU of interfaces on devices. After the link MTU of interfaces is changed, the IP MTU of interfaces will be changed. The IP MTU of interfaces automatically keeps consistent with the link MTU of interfaces. However, if the IP MTU of interfaces is adjusted, the link MTU of interfaces will not be changed.

Related Configuration

Setting the IP MTU

- By default, the IP MTU of an interface is 1500.
- The **ip mtu** command can be used to set the MTU of IP packets.

1.3.6 IP TTL

Working Principle

An IP packet is transmitted from the source address to the destination address through routers. After the TTL is set, the TTL decreases by 1 every time when the IP packet passes a router. When the TTL drops to zero, the router discards the packet. This prevents infinite transmission of useless packets and waste of bandwidth.

Related Configuration

↘ Setting the IP TTL

- By default, the IP TTL of an interface is 64.
- The **ip ttl** command can be used to set the IP TTL of an interface.

1.3.7 IP Source Route

Working Principle

Devices support IP source routes. When a device receives an IP packet, it checks options such as the source route, loose source route, and record route in the IP packet header. These options are detailed in RFC 791. If the device detects that one option is enabled for the packet, an action is taken. If the device detects an invalid option, it sends an ICMP parameter error message to the source and then discards the packet.

After the IP source route is enabled, the source route option is added to an IP packet to test the throughput of a specific network or help the packet bypass the network where faults occur. However, this may cause network attacks such as source address spoofing and IP spoofing.

Related Configuration

↘ Configuring an IP Source Route

- By default, the IP source route function is enabled.
- The **ip source-route** command can be used to enable the function.

1.3.8 IP Address Pool

Working Principle

A point-to-point interface can assign an IP address to the peer end through PPP negotiation. During PPP negotiation, the server checks authentication information about the client. If the client passes authentication, the server assigns an IP address to the client (if the client is configured with an IP address and the IP address meets requirements of the server, the server approves the IP address of the client). The IP address of the peer end can be directly specified or assigned from the address pool.

Related Configuration

↘ Enabling the Address Pool Function

- By default, the address pool function is enabled.
- The **ip address-pool local** command can be used to enable the function.

Creating an Address Pool

- By default, no IP address pool is configured.
- The **ip local pool** command can be used to create an address pool.

1.4 Configuration

Configuration	Description and Command	
Configuring an IP Addresses of an Interface	(Mandatory) It is used to configure an IP address and allow the IP protocol to run on an interface.	
	ip address	Manually configures the IP address of an interface.
	ip unnumbered	Borrows an IP address from another interface.
	ap-interface bvi *num* **ip address**	Configures the IP address of a BVI on an AP through an AC.
Configuring Broadcast Forwarding	(Optional) It is used to set an IP broadcast address and enable directed broadcast forwarding.	
	ip broadcast-address	Configures an IP broadcast address.
	ip directed-broadcast	Enables directed broadcast forwarding.
Configuring ICMP Forwarding	(Optional) It is used to enable ICMP packet forwarding.	
	ip unreachables	Enables ICMP unreachable packets and host unreachable packets.
	ip redirects	Enables ICMP redirection packets.
	ip mask-reply	Enables ICMP mask response packets.
	ip icmp timestamp	Enables timestamp query.
Configuring the Transmission Rate of ICMP Error Packets	Optional.	
	ip icmp error-interval DF	Configures the transmission rate of ICMP destination unreachable packets triggered by the DF bit in the IP header.
	ip icmp error-interval	Configures the transmission rate of ICMP error packets and ICMP redirection packets.
Setting the IP MTU	(Optional) It is used to configure the IP MTU on an interface.	
	ip mtu	Sets the MTU.
Setting the IP TTL	(Optional) It is used to configure the TTL of unicast packets and broadcast packets.	
	ip ttl	Sets the TTL.

Configuration	Description and Command	
Configuring an IP Source Route	(Optional) It is used to check the source routes.	
	ip source-route	Enables the IP source route function.
Configuring an IP Address Pool	(Optional) It is used to configure an IP address pool.	
	ip address-pool local	Enables the IP address pool function
	ip local pool	Creates an IP address pool

1.4.1 Configuring an IP Addresses of an Interface

Configuration Effect

Configure an IP address of an interface for communication.

Notes

- N/A

Configuration Step

Configuring an IP Address of an Interface

- Mandatory.
- Perform the configuration in Layer 3 interface configuration mode.

Obtaining the IP Address of an Interface Through PPP Negotiation

- If a point-to-point interface is not configured with an IP address, obtain an IP address through PPP negotiation.
- Perform the configuration in Layer 3 interface configuration mode.

Borrowing an IP Address from Another Interface

- Optional.
- If a point-to-point interface is not configured with an IP address, borrow an IP address from another interface.
- Perform the configuration in Layer 3 interface configuration mode.

Verification

Run the **show ip interface** command to check whether the configuration takes effect.

Related Commands

Manually Configuring the IP Address of an Interface

Command	**ip address** *ip-address network-mask* [**secondary**]
Parameter Description	*ip-address*: Specifies the 32-bit IP address, with 8 bits for each group. The IP address is expressed in decimal notation and groups are separated by a full stop (.). *network-mask*: Specifies the 32-bit network mask. The value 1 indicates the mask bit and the value 0 indicates the host bit. Every 8 bits form one group. The network mask is expressed in decimal notation and groups are separated by a full stop (.).

	secondary: Indicates the secondary IP address.
Command Mode	Interface configuration mode
Usage Guide	N/A

Borrowing an IP Addresses from Another Interface

Command	**ip unnumbered** *interface-type interface-number*
Parameter Description	*interface-type*: Specifies the interface type. *interface-number*: Specifies the interface number.
Command Mode	Interface configuration mode
Usage Guide	An unnumbered interface indicates that the interface is enabled with the IP protocol without an IP address assigned, and needs to be associated with an interface configured with an IP address. For an IP packet generated on an unnumbered interface, the source IP address of the packet is the IP address of the associated interface. In addition, the routing protocol process decides whether to send a route update packet to the unnumbered interface according to its associated IP address. To use an unnumbered interface, pay attention to the following limitations: An Ethernet interface cannot be set to an unnumbered interface. When a serial interface encapsulates Serial Line Internet Protocol (SLIP), High-Level Data Link Control (HDLC), PPP, Link Access Procedure Balanced (LAPB), and Frame Relay (FR), the serial interface can be set to an unnumbered interface. During FR encapsulation, only a point-to-point interface can be configured as an unnumbered interface. AnX.25 interface cannot be configured as an unnumbered interface. The **ping** command cannot be used to check whether an unnumbered interface is working properly because an unnumbered interface is not configured with an IP address. However, you can monitor the status of an unnumbered interface remotely through SNMP. A device cannot be cold started through an unnumbered interface.

Configuring the IP Address of a BVI on an AP Through an AC

Command	**ap-interface bvi** *num***ip address** {*ip-address network-mask* | **dynamic**}
Parameter Description	*num*: Specifies the BVI number. *ip-address*: Specifies the 32-bit IP address, with 8 bits for each group. The IP address is expressed in decimal notation and groups are separated by a full stop (.). *network-mask*: Specifies the 32-bit network mask. The value 1 indicates the mask bit and the value 0 indicates the host bit. **dynamic:** Configures the IP address and mask of a BVI on an AP by dynamically obtaining IP addresses and masks.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	Run the command in AP configuration mode or AP group configuration mode. In other words, the configuration modes on an AC include the AP configuration mode, AP group configuration mode, and all-AP configuration mode, which are in descending order of priority. You can configure an IP address for only one BVI in any AP configuration mode. According to the priority, the AC selects the configuration of the highest priority and pushes it to the corresponding AP.

	⚠ On a fit AP network, if the **ap-interface bvi** *num* **ip address** *ip-address network-mask* command is used, the AP needs to be assigned within different VLANs. Otherwise, an address conflict occurs. If the **ap-interface bvi** *num***ip address dynamic** command is used, the problem does not occur.

Configuration Example

Configuring an IP Address for an Interface

Configuration Steps	● Configure IP address 192.168.23.110 255.255.255.0 on GigabitEthernet 0/1.

	`Hostname#configure terminal`
	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# no switchport`
	`Hostname(config-if-GigabitEthernet 0/1)#ip address 192.168.23.110 255.255.255.0`

Verification	● Run the **show ip interface** command to check whether the configuration takes effect.

	`Hostname# show ip interface gigabitethernet 0/1`
	`GigabitEthernet 0/1`
	`  IP interface state is: UP`
	`  IP interface type is: BROADCAST`
	`  IP interface MTU is: 1500`
	`  IP address is:`
	`    192.168.23.110/24 (primary)`

Configuring the IP Address of a BVI on an AP Through an AC

Configuration Steps	● Configure the IP address of BVI 2 of an AP to 192.168.2.1 255.255.255.0 in the configuration mode of **ap120**.

	`Hostname(config)#ap-config ap120`
	`You are going to config AP(ap120), which is online now.`
	`Hostname(config-ap)#ap-interface bvi 2 ip address 192.168.2.1 255.255.255.0`

Verification	● Run the **show ap-config running-config** command on the AC to check whether the configuration takes effect.

	`Hostname# show ap-config running-config`
	`ap-config ap120`
	`ap-interface bvi 2 ip address 192.168.2.1 255.255.255.0`

	● Run the **show ip interface brief** command on the AP to check whether the configuration takes effect.

	`Hostname# show ip interface brief`
	`Interface  IP-Address(Pri)  IP-Address(Sec)  Status  Protocol`
	`BVI 2  192.168.2.1/24  no address  up  up`

1.4.2 Configuring Broadcast Forwarding

Configuration Effect

Set the broadcast address of an interface to 0.0.0.0 and enable directed broadcast forwarding.

Notes

N/A

Configuration Step

Configuring an IP Broadcast Address

- Optional.
- Some old hosts may identify broadcast address 0.0.0.0 only. In this case, set the broadcast address of the target interface to 0.0.0.0.
- Perform the configuration in Layer 3 interface configuration mode.

Enabling Directed Broadcast Forwarding

- Optional.
- If you want to enable a host to send broadcast packets to all hosts in a domain that the host does not belong to, enable directed broadcast forwarding.
- Perform the configuration in Layer 3 interface configuration mode.

Verification

Run the **show running-config interface** command to check whether the configuration takes effect.

Related Commands

Configuring an IP Broadcast Address

Command	**ip broadcast-address** *ip-address*
Parameter Description	*ip-address*: Specifies the broadcast address of an IP network.
Command Mode	Interface configuration mode
Usage Guide	Typically, the destination address of IP broadcast packets is all 1s, which is expressed as 255.255.255.255. The RGOS software can generate broadcast packets of other IP addresses and receive self-defined broadcast packets and broadcast packets with the address 255.255.255.255.

Allowing Forwarding of Directed Broadcast Packets

Command	**ip directed-broadcast** [*access-list-number*]
Parameter Description	*access-list-number*: Specifies the number of an access control list (ACL). The value range is from 1 to 199 and from 1300 to 2699. After an ACL is defined, only directed broadcast packets that match the ACL are forwarded.
Command	Interface configuration mode

Mode	
Usage Guide	If the **no ip directed-broadcast** command is run on an interface, the RGOS software will discard directed broadcast packets received from the network that is directly connected.

Configuration Example

Configuration Steps	● On GigabitEthernet 0/1, set the destination address of IP broadcast packets to 0.0.0.0 and enable directed broadcast forwarding.
	`Hostname#configure terminal`
	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# no switchport`
	`Hostname(config-if-GigabitEthernet 0/1)#ip broadcast-address 0.0.0.0`
	`Hostname(config-if-GigabitEthernet 0/1)#ip directed-broadcast`

Verification	● Run the **show ip interface** command to check whether the configuration takes effect.
	`Hostname#show running-config interface gigabitethernet 0/1`
	`ip directed-broadcast`
	`ip broadcast-address 0.0.0.0`

1.4.3 Configuring ICMP Forwarding

Configuration Effect

Enable ICMP unreachable packets, ICMP redirection packets, and mask response packets on an interface.

Notes

N/A

Configuration Step

↘ Enabling ICMP Unreachable Packets

- By default, ICMP unreachable packets are enabled.
- Optional.
- The **no ip unreachables** command can be used to disable ICMP unreachable packets.
- Perform the configuration in Layer 3 interface configuration mode.

↘ Enabling ICMP Redirection Packets

- By default, ICMP redirection packets are enabled.
- Optional.
- The **no ip redirects** command can be used to disable ICMP redirection packets.
- Perform the configuration in Layer 3 interface configuration mode.

↘ Enabling ICMP Mask Response Packets

- By default, ICMP mask response messages are enabled.
- Optional.

- The **no ip mask-reply** command can be used to disable ICMP mask response packets.
- Perform the configuration in Layer 3 interface configuration mode.

Enabling Timestamp Query

- By default, timestamp query is enabled.
- Optional.
- The **no ip icmp timestamp** command can be used to disable timestamp query.
- Perform the configuration in global configuration mode.

Verification

- Run the **show ip interface** command to check whether the configuration takes effect.
- Run the **show running-config** command to check whether notifications of expired TTL are disabled.
- Run the **show running-config** command to check whether timestamp query is enabled.

Related Commands

Enabling ICMP Unreachable Packets

Command Mode	Interface configuration mode
Usage Guide	N/A

Enabling ICMP Redirection Packets

Command	**ip redirects**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Enabling ICMP Mask Response Packets

Command	**ip mask-reply**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Disabling Timestamp Query

Command	**no ip icmp timestamp**

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	● Enable ICMP unreachable packets, ICMP redirection packets, and mask response packets on GigabitEthernet 0/1.

	`Hostname# configure terminal`
	`Hostname(config)# no ip icmp timestamp`
	`Hostname(config)# interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# no switchport`
	`Hostname(config-if-GigabitEthernet 0/1)# ip unreachables`
	`Hostname(config-if-GigabitEthernet 0/1)# ip redirects`
	`Hostname(config-if-GigabitEthernet 0/1)# ip mask-reply`

Verification	● Run the **show ip interface** command to check whether the configuration takes effect.

	`Hostname# show running-config | include ip icmp timestamp`
	`no ip icmp timestamp`
	`Hostname# show ip interface gigabitethernet 0/1`
	`GigabitEthernet 0/1`
	`  ICMP mask reply is: ON`
	`  Send ICMP redirect is: ON`
	`  Send ICMP unreachabled is: ON`

1.4.4 Configuring the Transmission Rate of ICMP Error Packets

Configuration Effect

Configure the transmission rate of ICMP error packets.

Notes

N/A

Configuration Step

↘ Configuring the Transmission Rate of ICMP Destination Unreachable Packets Triggered by the DF Bit in the IP Header

- Optional.
- Perform the configuration in global configuration mode.

↘ Configuring the Transmission Rate of Other ICMP Error Packets

- Optional.
- Perform the configuration in global configuration mode.

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

Configuring the Transmission Rate of ICMP Destination Unreachable Packets Triggered by the DF Bit in the IP Header

Command	**ip icmp error-interval DF** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Indicates the refresh cycle of a token bucket. The value range is from 0 to 2147483647 and the default value is 100 ms. When the value is 0, the transmission rate of ICMP error packets is not limited. *bucket-size*: Indicates the number of tokens contained in a token bucket. The value range is from 1 to 200 and the default value is 10.
Command Mode	Global configuration mode
Usage Guide	This function limits the transmission rate of ICMP error packets to prevent DoS attacks by using the token bucket algorithm. If an IP packet needs to be fragmented but the DF bit in the header is set to 1, the device sends an ICMP destination unreachable packet (code 4) to the source host. This ICMP error packet is used to discover the path MTU. When there are too many other ICMP error packets, the ICMP destination unreachable packet (code 4) may be not sent. As a result, the path MTU discovery function becomes ineffective. To avoid this problem, you should limit the transmission rate of ICMP destination unreachable packets and other ICMP error packets respectively. You are advised to set the refresh cycle to an integral multiple of 10 milliseconds. If the refresh cycle is set to a value greater than 0 and smaller than 10 milliseconds, the refresh cycle that actually takes effect is 10 milliseconds. For example, if the refresh rate is set to 1 per 5 milliseconds, the refresh rate that actually takes effect is 2 per 10 milliseconds. If the refresh cycle is not an integral multiple of 10 milliseconds, the refresh cycle that actually takes effect is automatically converted to an integral multiple of 10 milliseconds. For example, if the refresh rate is set to 3 per 15 milliseconds, the refresh rate that actually takes effect is 2 per 10 milliseconds.

Configuring the Transmission Rate of Other ICMP Error Packets

Command	**ip icmp error-interval** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Indicates the refresh cycle of a token bucket. The value range is 0 to 2147483647, and the default value is 100 ms. When the value is 0, the transmission rate of ICMP error packets is not limited. *bucket-size*: Indicates the number of tokens contained in a token bucket. The value range is 1 to 200 and the default value is 10.
Command Mode	Global configuration mode.
Usage Guide	This function limits the transmission rate of ICMP error packets to prevent DoS attacks by using the token bucket algorithm. You are advised to set the refresh cycle to an integral multiple of 10 milliseconds. If the refresh cycle is set to a value greater than 0 and smaller than 10 milliseconds, the refresh cycle that actually takes

	effect is 10 milliseconds. For example, if the refresh rate is set to 1 per 5 milliseconds, the refresh rate that actually takes effect is 2 per 10 milliseconds. If the refresh cycle is not an integral multiple of 10 milliseconds, the refresh cycle that actually takes effect is automatically converted to an integral multiple of 10 milliseconds. For example, if the refresh rate is set to 3 per 15 milliseconds, the refresh rate that actually takes effect is 2 per 10 milliseconds.

Configuration Example

Configuration Steps	● Set the transmission rate of ICMP destination unreachable packets triggered the DF bit in the IP header to 100 packets per second and the transmission rate of other ICMP error packets to 10 packets per second.
	`Hostname(config)# ip icmp error-interval DF 1000 100` `Hostname(config)# ip icmp error-interval 1000 10`
Verification	● Run the **show running-config** command to check whether the configuration takes effect.

	`Hostname#show running-config | include ip icmp error-interval`
	`ip icmp error-interval 1000 10`
	`ip icmp error-interval DF 1000 100`

1.4.5 Setting the IP MTU

Configuration Effect

Adjust the MTU of IP packets.

Notes

N/A

Configuration Step

- Optional.
- When the IP MTU of interconnected interfaces is different on devices on the same physical network segment, set the IP MTU to the same value.
- Perform the configuration in Layer 3 interface configuration mode.

Verification

Run the **show ip interface** command to check whether the configuration takes effect.

Related Commands

↘ Setting the IP MTU

Command	**ip mtu** *bytes*
Parameter Description	*bytes*: Indicates the MTU of IP packets. The value range is from 68 bytes to 1500 bytes.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	● Set the IP MTU of GigabitEthernet 0/1 to 512 bytes.

	`Hostname#configure terminal`
	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# no switchport`
	`Hostname(config-if-GigabitEthernet 0/1)#ip mtu 512`

Verification	● Run the **show ip interface** command to check whether the configuration takes effect.
	`Hostname# show ip interface gigabitethernet 0/1` `IP interface MTU is: 512`

1.4.6 Setting the IP TTL

Configuration Effect

Modify the IP TTL of an interface.

Notes

N/A

Configuration Step

- Optional.
- Perform the configuration in Layer 3 interface configuration mode.

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

↘ Setting the IP TTL

Command	**ip ttl** *value*
Parameter Description	*value*: Indicates the TTL. The value range is from 0 to 255.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	● Set the TTL of unicast packets to 100.
	`Hostname#configure terminal` `Hostname(config)#ip ttl 100`
Verification	● Run the **show running-config** command to check whether the configuration takes effect.

	Hostname#show running-config ip ttl 100

1.4.7 Configuring an IP Source Route

Configuration Effect

Enable or disable the IP source route function.

Notes

N/A

Configuration Step

- By default, the IP source route function is enabled.
- Optional.
- The **no ip source-route** command can be used to disable the IP source route function.

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

Configuring an IP Source Route

Command	**ip source-route**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuration Steps	• Disable the IP source route function.
	Hostname#configure terminal Hostname(config)#no ip source-route
Verification	• Run the **show running-config** command to check whether the configuration takes effect.
	Hostname#show running-config no ip source-route

1.4.8 Configuring an IP Address Pool

Configuration Effect

Assign an IP address to a client through PPP negotiation.

Notes

N/A

Configuration Step

Enabling the IP Address Pool Function

- Optional.
- Perform the configuration in global configuration mode.

Creating an IP Address Pool

- Optional.
- An IP address pool can be created only after the IP address pool function is enabled. After the IP address pool function is disabled, the created address pool is automatically deleted.
- Perform the configuration in global configuration mode.

Assigning an IP Address to the Peer End through PPP Negotiation

- Optional
- Perform the configuration in Layer 3 interface configuration mode.

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

Enabling the IP Address Pool Function

Command	**ip address-pool local**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, the IP address pool function is enabled. You can configure an IP address pool to assign an IP address to the peer end through PPP negotiation. To disable the IP address pool function, run the **no ip address-pool local** command. All IP address pools configured previously will be deleted.

Creating an IP Address Pool

Command	**ip local pool** *pool-name low-ip-address* [*high-ip-address*]
Parameter Description	*pool-name*: Indicates the name of a local IP address pool. **default** indicates the default address pool name. *low-ip-address*: Indicates the smallest IP address in an IP address pool. *high-ip-address*: Indicates the largest IP address in an IP address pool, which is optional. If the largest IP address is not specified, the IP address pool contains only one IP address, that is, *low-ip-address*.
Command Mode	Global configuration mode
Usage Guide	The command is used to create one or more IP address pools to assign IP addresses to peer ends

	through PPP negotiation.

Configuration Example

Configuration Steps	● Assign an IP address from address pool **quark** to the peer end on interface dialer1.

	`Hostname#configure terminal`
	`Hostname(config)# ip address-pool local`
	`Hostname(config)# ip local pool quark 172.16.23.2 172.16.23.255`

Verification	● Run the **show running-config** command to check whether the configuration takes effect.

	`Hostname#show running-config`
	`ip local pool quark 172.16.23.2 172.16.23.255`
	`!`

1.5 Monitoring

Displaying

Command	Description
show ip interface [*interface-type interface-number* | **brief**]	Displays the IP address of an interface.
show ip packet statistics [**total** | *interface-name*]	Displays IP packet statistics.
show ip packet queuepool [*pool-name*]	Displays IP packet sending and receiving statistics of the protocol stack.
show ip raw-socket [*num*]	Displays IPv4 raw sockets.
show ip sockets	Displays all IPv4 sockets.
show ip udp [**local-port** *num*]	Displays IPv4 UDP sockets.
show ip udp statistics	Displays statistics on IPv4 UDP sockets.

1 Configuring NAT

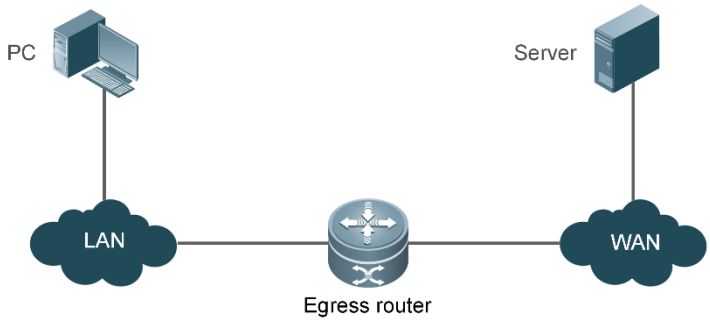
1.1 Overview

Network Address Translation (NAT) technology translates an IP address in the header of an IP data packet into another IP address. In practice, NAT enables private networks that use unregistered IP addresses to access public networks. This method conserves public IP addresses by using a small number to represent a large amount of private IP addresses.

Protocols and Standards

- RFC 1631: The IP Network Address Translator (NAT)
- RFC 2663: IP Network Address Translator (NAT) Terminology and Considerations
- RFC 2391: Load Sharing using IP Network Address Translation (LSNAT)
- RFC 4008: Definitions of Managed Objects for Network Address Translators (NAT)

1.2 Applications



Application	Description
Intranet Users' Access to the Internet	NAT allows an intranet to communicate with the Internet by translating an internal private IP address into a globally unique IP address.
External Users' Access to an Intranet Server	NAT allows external networks to access internal devices by mapping one or more internal hosts to a network server.
Source/Destination Address Translation for Internal Users	When two private networks that need to interconnect with each other are configured with the same IP address or the same global IP address is allocated to both a private network and a public network, the two network hosts with the same IP address cannot communicate. NAT allows overlapping networks to communicate.
Intranet Server Load Balancing	When the TCP traffic load of an intranet host is heavy, multiple hosts are deployed for load balancing. In this case, NAT can be used for load balancing TCP traffic.

1.2.1 Intranet Users' Access to the Internet

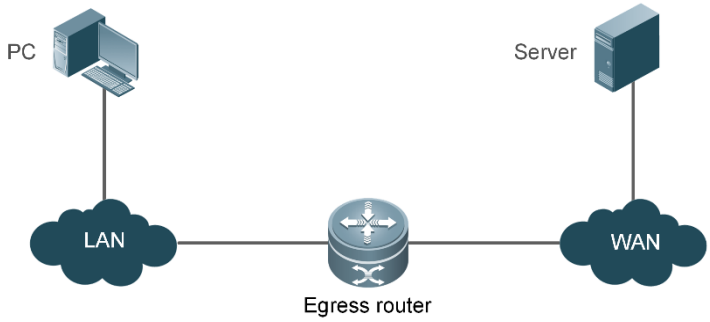
Scenario

A PC is located on an intranet, while a server is located on an extranet, as shown in Figure 1-1. Because IP addresses are about to be exhausted, only one or a few public IP addresses are allocated to the entire campus network. An egress device belongs to the intranet, and connects to the extranet. Basic NAT functions need to be configured on the egress device to allow the intranet PC to access the extranet server.

Figure 1-1

The egress device connects both the intranet and extranet.

Deployment



- Configure NAT for an intranet interface and an extranet interface.
- Configure static source address translation on the egress device.

1.2.2 External Users' Access to an Intranet Server

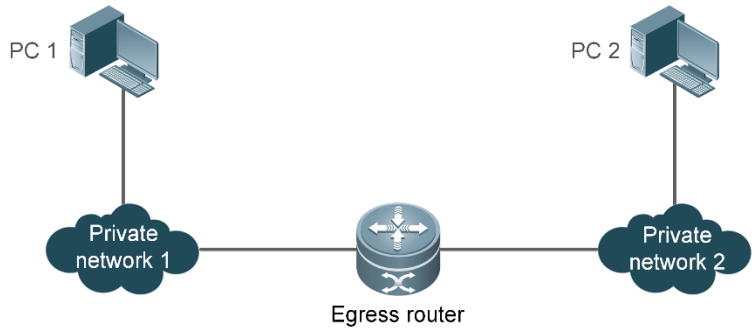
Scenario

A PC is located on an extranet, while a server (such as a web server) is located on an intranet, as shown in Figure 1-2. Because IP addresses are about to be exhausted, only one public IP address is allocated to the entire campus network. An egress device belongs to the intranet and connects to the extranet. The Network Address and Port Translation (NAPT) function is required on the egress device to enable the PC to access the intranet server; that is, port mapping applies to the web service port.

Figure 1-2

The egress device connects both the intranet and extranet.
The server is deployed on the intranet.

Deployment



- Configure NAT for an internal interface and an external interface.
- Configure server port address translation rules on the egress device.

1.2.3 Source/Destination Address Translation for Internal Users

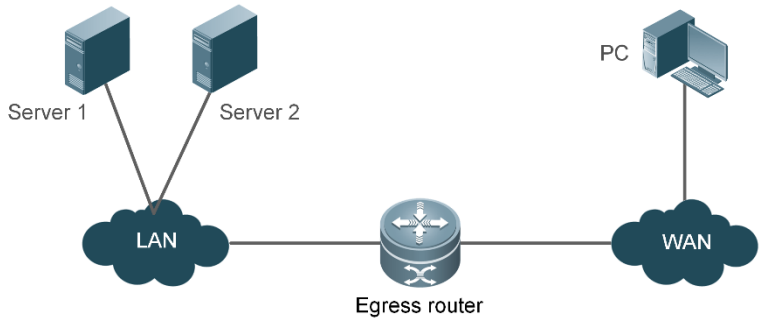
Scenario

PC 1 is located on private network 1, while PC 2 is located on private network 2, as shown in Figure 1-3. Because the two private networks are separately managed, address overlapping occurs on their IP network segments. For example, the IP addresses of PC 1 and PC 2 are configured on the same network segment 192.168.1.0/24. An egress device is located between private networks 1 and 2. The NAT function needs to be enabled on the egress device, so that PC 1 and PC 2 can access each other.

Figure 1-3

The egress device connects both private networks.

Deployment



- Configure NAT for an internal interface and an external interface.
- Configure dynamic translation of the internal source address on the egress device.
- Configure dynamic translation of the external source address on the egress device.

1.2.4 Intranet Server Load Balancing

Scenario

Server 1 and Server 2 are located on an intranet, and form a cluster, as shown in Figure 1-4. A PC is located on an extranet. Because IP addresses are about to be exhausted, only one public IP address is allocated to the entire campus network. An egress device belongs to the intranet, and connects to the extranet. The egress device needs to distribute the server access traffic of the external user to the two servers; therefore, NAT load balancing needs to be enabled on the egress device.

Figure 1-4

The egress device connects both the intranet and extranet.

Servers are deployed on the intranet.

Deployment

- Configure NAT for an internal interface and an external interface.
- Configure TCP load balancing using NAT on the egress device.

1.3 Features

Basic Concepts

Private Address and Public Address

A private address is the IP address of an intranet or an intranet host, whereas a public address is an IP address globally unique on the Internet. The Internet Assigned Numbers Authority (IANA) has stipulated the following IP addresses for use within private networks, which are not allocated for Internet use but can be used inside any institution or corporation.

- Class A private addresses: 10.0.0.0 to 10.255.255.255
- Class B private addresses: 172.16.0.0 to 172.31.255.255
- Class C private addresses: 192.168.0.0 to 192.168.255.255

NAT was initially designed to enable a private network to access a public network. Later it was extended to implement address translation for mutual access between any two networks. In this document, the two networks are called an intranet and an extranet. Typically, a private network is an intranet, and a public network is an extranet.

Static NAT

Static NAT allows one-to-one permanent mappings between internal local addresses and internal global addresses. Static NAT is used when an extranet needs to access internal hosts using a fixed global routable address.

Dynamic NAT

Dynamic NAT establishes temporary mapping relationships between internal local addresses and internal global addresses. The temporary mapping relationships will be removed if they are not used in a given period of time. Dynamic NAT can be configured in the scenario where an intranet accesses extranet services only but does not provide services, and the number of intranet hosts is greater than the number of global IP addresses.

Overview

Feature	Description
Basic NAT	Translates internal private addresses into globally unique addresses, so that the intranet and the public network can communicate with each other.
NAPT	Maps multiple internal local addresses to one internal global address, so as to resolve the problem of IP address exhaustion.
Overlapping NAT	Enables overlapping networks to communicate.
TCP Load Balancing	Resolves the problem of TCP traffic overload.
Constructing a Local Server	Enables the extranet to access the local server.
ALG	Changes only the header of an IP packet but not the payload of a specific application protocol. Therefore, the Application Level Gateway (ALG) is introduced to support application layer protocols.

1.3.1 Basic NAT

NAT is required for an intranet to communicate with an extranet by translating an internal private IP address into a globally unique IP address. You can configure static or dynamic NAT or both to implement interconnection and interworking.

Working Principle

An IP packet sent by an intranet host at 192.168.1.2 to an extranet server at 8.8.8.8 reaches an NAT device.

The NAT device checks the content of the IP packet, and finds that the IP packet is destined for an extranet. Therefore, the NAT device translates the private IP address 192.168.1.2 in the source IP address field of the IP packet into a public IP address 30.1.1.1 routable on the Internet, sends the IP packet to the extranet server, and records the mapping in its own NAT table.

The extranet server returns a response packet (in which the initial destination IP address is 30.1.1.1) to the intranet user. When the response packet reaches the NAT device, the NAT device checks the content of the response packet, looks up the mapping record in the NAT table, and replaces the initial destination IP address with the internal private IP address 192.168.1.2.

The preceding NAT process is transparent to terminals (hosts and servers in the preceding figures). For the extranet server, the IP address of the intranet host is 30.1.1.1 and the extranet server does not know the IP address 192.168.1.2. Therefore, NAT shields the private network of an enterprise.

Basic NAT includes static NAT and dynamic NAT.

Related Configuration

↘ Configuring NAT Interfaces

- A routed port is not a NAT interface by default.
- For a routed port, run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces. For a non-routed port, run the **no switchport** command and then the **ip nat inside/outside** command to specify a pair of NAT interfaces.
- NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured.

Configuring Static NAT

- Static NAT is not configured by default.
- Use the **ip nat inside source static** *local-ip global-ip* [**permit-inside**] [**netmask** mask | **match** *interface-type interface-number*] command to configure static one-to-one NAT mapping.

Configuring Dynamic NAT

- Dynamic NAT is not configured by default.
- Use the **ip nat inside source list** *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**] command to configure dynamic NAT mapping.

1.3.2 NAPT

Traditional NAT employs one-to-one address mapping, which fails to meet requirements of all hosts on intranets to communicate with extranets. For example, when the intranet lacks global IP addresses or even does not apply for global IP addresses, or has only one global IP address to connect to an Internet Service Provider (ISP) but a large number of hosts on the intranet need to access the Internet, NAPT is necessary in such scenarios.

Multiple internal local addresses can map to one internal global address using NAPT.

When NAPT mappings for a large number of public IP addresses are configured and NAPT is deployed on the egress gateway in VRRP scenarios, association between the VRRP groups and the extranet interface link status and protocol status needs to be used if attacks occur on the extranet. In addition, the advertisement count multiplier needs to be adjusted to reduce the VRRP active/standby switchover frequency. To ensure that the NAT device can send free ARP packets from local host addresses and respond to ARP requests correctly during a VRRP active/standby switchover, you should associate the NAT device with a VRRP group and restrict the rate at which gratuitous ARP packets are sent.

Working Principle

NAPT, also known as multi-to-one address translation, allows multiple internal addresses to be mapped to one public address. NAPT maps both IP addresses and port numbers; that is, source addresses of data packets from different internal addresses can be mapped to the same public address, but their port numbers are translated into different port numbers of the public address so that the same address can still be shared. NAPT implements conversion between "private IP address + port number" and "public IP address + port number".

Static NAPT

Static NAPT is used to map the specified port on a specified host on an intranet to the specified port of a global address, while static NAT maps an internal host to a global address. Static NAPT is applicable to intranet hosts that provide the information service, and provides a permanent one-to-one "IP address + port" mapping relationship.

Dynamic NAPT

Dynamic NAPT is applicable to intranet hosts that only access extranet services but do not provide any information service. It provides a temporary one-to-one "IP address + port" mapping relationship.

Related Configuration

Configuring NAT Interfaces

- A routed port is not a NAT interface by default.

- If the port is a routed port, run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces. If not, configure the port as a routed port and run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces.
- NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured.

Configuring Static NAPT

- Static NAPT is not configured by default.
- Use the **ip nat inside source static** *local-ip global-ip* [*permit-inside*] command to configure static one-to-one NAPT mapping.

Configuring Dynamic NAPT

- Dynamic NAPT is not configured by default.
- Use the **ip nat inside source list** *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**] command to configure dynamic NAPT mapping. For NAPT, only one IP address is defined in the address pool, and one IP address can be translated using NAT for up to 64,512 times. If one IP address is not enough, multiple IP addresses can be defined in the address pool.

1.3.3 Overlapping NAT

Address overlapping indicates that the same IP address is allocated to two private networks to interconnect with each other or the same global IP address is allocated to a private network and a public network. Two overlapping network hosts cannot communicate, because both hosts consider that the peer host is located on the local network. Overlapping NAT is especially designed to implement communication between two networks with the same IP address. After overlapping NAT is configured, an extranet host address will be represented as another host address on the intranet, and vice versa.

Working Principle

For mutual access between an intranet and an extranet with the same IP address, NAT needs to translate the internal address into a unique external address. In addition, NAT needs to translate the external address that overlaps with the internal address into another unique internal address.

Related Configuration

Configuring NAT Interfaces

- A routed port is not a NAT interface by default.
- If the port is a routed port, run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces. If not, configure the port as a routed port and run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces.
- NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured.

Configuring Internal Source Address Translation

- Internal source address translation is not configured by default.

- Static/Dynamic basic NAT or static/dynamic NAPT can be used for internal source address translation. For details, see 1.3.1 Basic NAT and 1.3.2 NAPT.

Configuring Static Translation of External Source Addresses

- Static translation of external source addresses is not configured by default.
- Use the **ip nat outside source static** *global-ip local-ip* command to configure static translation of external source addresses.

Configuring Dynamic Translation of External Source Addresses

- Dynamic translation of external source addresses is not configured by default.
- Use the **ip nat outside source list** *access-list-number* **pool** *pool-name* command to configure dynamic translation of external source addresses.

Configuring an ACL

- No ACL is configured by default.
- Use the **ip access-list { extended | standard } {** *id* | *name* **}** command or the **access-list** command to configure an ACL.

Configuring a Static Route

- Mandatory.
- Use the **ip route** *network net-mask* { *ip-address* | *interface* [*ip-address*] } [*distance*] [**tag** *tag*] [**permanent | track** *object-number*] [**weight** *number*] [**description** *description-text*] [**disabled** | **enabled**] [**global**] command to configure a static route, which is used to specify the network egress after internal destination address translation.

1.3.4 TCP Load Balancing

When the TCP traffic load of an intranet host is heavy, multiple hosts can be deployed to implement TCP service load balancing. In this case, NAT can be used to address this issue.

Working Principle

A NAT-enabled virtual host is created to provide the TCP service. The virtual host maps to multiple physical hosts. Then the virtual host polls and replaces destination addresses, so as to load balance traffic.

Related Configuration

Configuring NAT Interfaces

- A routed port is not a NAT interface by default.
- If the port is a routed port, run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces. If not, configure the port as a routed port and run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces.
- NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured.

Configuring an Address Pool

- No address pool is configured by default.
- Use the **ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**] command to configure an IP address pool for NAT.

Configuring an ACL

- No ACL is configured by default.
- Use the **access-list** *access-list-number* **permit** *ip-address wildcard* command to configure a destination-based ACL. Note that the extended ACL must be configured based on destination IP address matching.

Configuring Internal Destination Address Translation

- Internal destination address translation is not configured by default.
- Use the **ip nat inside destination list** *access-list-number* **pool** *pool-name* command to configure internal destination address translation. This configuration takes effect on TCP traffic only but not on other traffic, unless additional NAT configuration has been performed.

1.3.5 Constructing a Local Server

A user has deployed three servers (an FTP server, a web server, and an email server) on an intranet. The user hopes that network hosts on a WAN can access the three servers, while common users of the intranet can use the gateway for Internet access.

Working Principle

One or more internal hosts are mapped to a network server, so that users on the WAN obtain corresponding services from the network server.

Related Configuration

Configuring NAT Interfaces

- A routed port is not a NAT interface by default.
- If the port is a routed port, run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces. If not, configure the port as a routed port and run the **ip nat** { **inside | outside** } command to specify a pair of NAT interfaces.
- NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured.

Configuring Internal Address and Port Translation

- Internal address and port translation is not configured by default.
- Use the **ip nat inside source static** { **udp** | **tcp** } **local-ip port global-ip port** [**permit-inside**] command to translate specific internal addresses and ports, so that corresponding services are provided on dedicated ports. For example, TCP port 20 or 21 can be used to construct an FTP server, or TCP port 80 to construct a web server.

1.3.6 ALG

Common NAT can translate the IP address and port in the header of a UDP or TCP packet, but is ineffective for the fields in application layer data payloads. In many application layer protocols such as multimedia protocols (H323 and the like), FTP, and SQLNET, the TCP/UDP payload carries address or port information. If such address or port information cannot be translated by NAT, problems may occur.

Working Principle

ALG technology can parse application layer packet information and perform address translation for multi-channel protocols, so as to translate or process the IP addresses or ports requiring address translation or some fields requiring special processing, thereby guaranteeing application layer communication. ALG is enabled for NAT by default. The protocols that support ALG include DNS, FTP, H323, PPTP, TFTP, RTSP, and SIP.

Related Configuration

Enabling or Disabling ALG

- By default, ALG for all supported protocols is enabled.
- Use the **no ip nat translation dns** command to disable ALG for DNS.
- Use the **no ip nat translation ftp** command to disable ALG for FTP.
- Use the **no ip nat translation h323** command to disable ALG for H323.
- Use the **no ip nat translation pptp** command to disable ALG for PPTP.
- Use the **no ip nat translation tftp** command to disable ALG for TFTP.
- Use the **no ip nat translation rtsp** command to disable ALG for RTSP.
- Run the **no ip nat translation sip** command to disable ALG for SIP.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic NAT	(Mandatory) It is used to configure one-to-one NAT for internal PCs to connect to a WAN.	
	ip nat inside	Configures the interface to connect to the intranet.
	ip nat outside	Configures the interface to connect to the extranet.
	(Optional) It is used to configure static NAT.	
	ip nat inside source static *local-ip global-ip* [**permit-inside**] [**netmask** *mask*] [**match** interface]	Defines static internal source address translation.
	(Optional) It is used to configure dynamic NAT.	

Configuration	Description and Command	
	ip nat pool *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**] or **ip nat pool** *pool-name* { **netmask** *netmask* | **prefix-length** *prefix-length* } [**type rotary**] **address** *start-ip end-ip* [**match interface** *interface*]	Defines a global IP address pool. For NAT, multiple IP addresses are defined. The number of address pools to be defined depend on the number of intranet users.
	access-list *access-list-number* **permit** *ip-address wildcard*	Defines an ACL so that only addresses matching this ACL are translated.
	ip nat inside source list *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**]	Defines dynamic source address translation. The *overload* parameter is only used to ensure compatibility with mainstream vendors' devices.
Configuring NAPT	(Mandatory) It is used to configure NAPT.	
	ip nat inside	Configures the interface to connect to the intranet.
	ip nat outside	Configures the interface to connect to the extranet.
	(Optional) It is used to configure static NAPT.	
	ip nat inside source static { **UDP** *local-ip port* | **TCP** *local-ip port* } *global-ip port* [**permit-inside**]	Defines static internal source address translation.
	(Optional) It is used to configure dynamic NAPT.	
	ip nat pool *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]	Defines a global IP address pool. For NAPT, only one IP address is defined.
	access-list *access-list-number* **permit** *ip-address wildcard*	Defines an ACL so that only the addresses matching this ACL are translated.
	ip nat inside source list *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**]	Defines dynamic source address translation. The *overload* parameter is only used to ensure compatibility with mainstream vendors' devices.
Configuring Overlapping NAT	(Mandatory) It is used to enable overlapping NAT.	
	ip nat inside	Configures the interface to connect to the intranet.
	ip nat outside	Configures the interface to connect to the extranet.

Configuration	Description and Command	
	ip nat inside source static *local-ip global-ip*	Configures internal source address translation.
	⚠ (Optional) It is used to configure static NAT.	
	ip nat outside source static *global-ip local-ip*	Configures static NAT.
	⚠ (Optional) It is used to configure dynamic NAT.	
	ip nat pool *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]	Defines a global IP address pool.
	access-list *access-list-number* **permit** *ip-address wildcard*	Defines an ACL so that only the addresses matching this ACL are translated.
	ip nat outside source list *access-list-number* **pool** *pool-name*	Defines dynamic source address translation. The *overload* parameter is only used to ensure compatibility with mainstream vendors' devices.
Configuring TCP Load Balancing	⚠ (Mandatory) It is used to configure destination address polling and translation.	
	ip nat inside	Configures the interface to connect to the intranet.
	ip nat outside	Configures the interface to connect to the extranet.
	ip nat pool *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]	Defines an IP address pool, which includes all physical host addresses.
	access-list *access-list-number* **permit** *ip-address wildcard*	Defines an ACL, which matches the virtual host address only. ⚠ Ensure that an extended ACL based on destination IP address matching.
	ip nat inside destination list *access-list-number* **pool** *pool-name*	Defines dynamic internal destination address translation.
Configuring ALG	⚠ (Optional) It is used to configure ALG for relevant protocols.	
	ip nat translation { **dns** [**ttl** *ttl_time*] **| ftp** [**port** *port_num*] **| h323 | pptp | rtsp | sip | tftp** [**port** *port_num*] }	Defines ALG for relevant protocols.
Configuring Special NAT Applications	⚠ (Optional) It is used to configure special NAT applications.	
	ip nat application source list *list-num* **destination** *dest-ip* { **dest-change** *ip-address* | **src-change** *ip-address* }	Defines rules for special NAT applications.

Configuration	Description and Command	
Configuring the Interval at Which Gratuitous ARP Packets Are Sent	(Optional) It is used to configure the interval at which gratuitous ARP packets are sent from the local address of NAT.	
	ip nat keepalive [*keealive_out*]	Defines the interval at which gratuitous ARP packets are sent from the local address of NAT.

1.4.1 Configuring Basic NAT

Networking Requirements

NAT needs to be configured for an intranet to communicate with an extranet by translating an internal private IP address into a globally unique IP address. You can configure static or dynamic NAT or both to implement interconnection.

Notes

- At least one internal interface and one external interface need to be configured for basic NAT.
- The newly configured NAT rules take effect on new flows only but not on any existing flows.

Configuration Step

Configuring the NAT Internal Interface

- Mandatory.
- Configure the LAN interface to connect to the intranet as the NAT internal interface unless otherwise stated.

Configuring the NAT External Interface

- Mandatory.
- Configure the WAN interface to connect to the extranet as the NAT external interface unless otherwise stated.

Configuring Static NAT

- Optional.
- Configure static NAT in global configuration mode when a small number of users on the intranet need to access the extranet.

Configuring Dynamic NAT

- Optional.
- Configure dynamic NAT in global configuration mode when a large number of users on the intranet need to access the extranet.

Verification

N/A

Commands

Configuring the NAT Internal Interface and External Interface

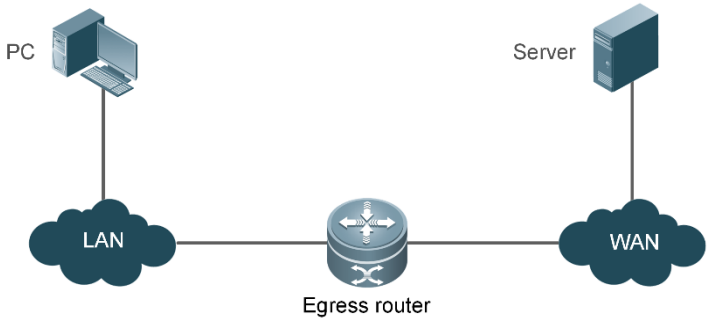
Command	**ip nat { inside | outside }**
Parameter Description	**inside**: Indicates the internal interface. **outside**: Indicates the external interface.
Command Mode	Interface configuration mode
Configuration Usage	NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured on the device.

Configuring Static NAT

Command	**ip nat inside source static** *local-ip global-ip* [**permit-inside**] [**netmask** *mask* | **match** *interface-type interface-number*]
Parameter Description	*local-ip*: Indicates the internal address. *global-ip*: Indicates the external address. **permit-inside**: Permits intranet users to access the host specified by *local-ip* using the address specified by *global-ip*. **netmask** *mask*: Indicates the network-segment-to-network-segment address. **match** *interface-type interface-number*: Specifies the egress interface.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring an Address Pool

Command	**ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]
Parameter Description	*pool-name*: Indicates the name of the address pool. *start-ip*: Indicates the start IP address. *end-ip*: Indicates the end IP address. **netmask** *mask*: Indicates the network mask of addresses. **prefix-length** *prefix-length*: Indicates the length of the network mask of addresses. **type rotary**: Specifies the type of the NAT address pool. The rotary type is round-robin assignment and guarantees the same probability for every address to be assigned. The assignment is round-robin regardless of whether **rotary** is configured. The **rotary** parameter is used to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A



Configuring Dynamic NAT

Command	**ip nat inside source list** *access-list-number* { **interface** *interface-type interface-number* | **pool** *address-pool-name* } [**overload**]
Parameter Description	*access-list-number*: Specifies the ACL number. **pool** *pool-name*: Specifies the name of an address pool.

	interface *interface-type interface-number*: Implements NAPT using the address of the external global interface. **overload**: Indicates that each global address in the address pool can be reused for NAPT. Global addresses are reused even if this parameter is not configured. This parameter is used to ensure compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

Enabling Intranet Users to Access an Extranet Server

Scenario Figure 1-1	
Configuration Steps	● Configure **ip nat inside** on the internal interface. ● Configure **ip nat outside** on the external interface. ● Configure a dynamic NAT rule.

A	`A# configure terminal`
	`A(config)# interface gigabitethernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip address 192.168.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/1)# ip nat inside`
	`A(config-if-GigabitEthernet 0/1)# exit`
	`A(config)# interface gigabitethernet 0/2`
	`A(config-if-GigabitEthernet 0/2)# ip address 200.168.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/2)# ip nat outside`
	`A(config-if-GigabitEthernet 0/2)# exit`
	`A(config)# ip nat pool net200 200.168.12.2 200.168.12.100 netmask 255.255.255.0`
	`A(config)# ip nat inside source list 1 pool net200`
	`A(config)# access-list 1 permit 192.168.12.0 0.0.0.255`

Verification	● Use the **show** command to display the configuration.

A	`Hostname# show ip nat translations`
	`Pro Inside global Inside local Outside local Outside global`
	`tcp 200.168.12.200:2063 192.168.12.65:2063 168.168.12.1:23 168.168.12.1:23`

Common Errors

- The internal or external interface is not configured.
- The ACL configuration is incorrect.

1.4.2 Configuring NAPT

Networking Requirements

Traditional NAT employs one-to-one address mapping, which fails to meet requirements of all hosts on intranets to communicate with extranets. For example, when the intranet lacks global IP addresses or even does not apply for global IP addresses, or has only one global IP address to connect to an ISP but a large number of hosts on the intranet need to access the Internet, NAPT is necessary in such scenarios.

Multiple internal local addresses can be mapped to one internal global address using NAPT.

Notes

- At least one internal interface and one external interface need to be configured for NAPT.
- The newly configured NAT rules take effect on new flows only but not on any existing flows.

Configuration Step

Configuring the NAT Internal Interface

- Mandatory.
- Configure the LAN interface to connect to the intranet as the NAT internal interface unless otherwise stated.

Configuring the NAT External Interface

- Mandatory.
- Configure the WAN interface to connect to the extranet as the NAT external interface unless otherwise stated.

Configuring Static NAPT

- Optional.
- Configure static NAPT in global configuration mode when a small number of users on the intranet need to access the extranet.

Configuring Dynamic NAPT

- Optional.
- Configure dynamic NAPT in global configuration mode when a large number of users on the intranet need to access the extranet.

Verification

N/A

Commands

Configuring the NAT Internal or External Interface

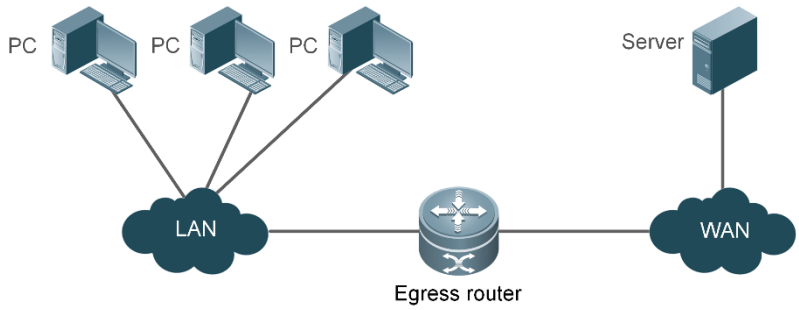
Command	ip nat { inside | outside }

Parameter Description	**inside**: Indicates the internal interface. **outside**: Indicates the external interface.
Command Mode	Interface configuration mode
Configuration Usage	NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured on the router.

Configuring Static NAPT

Command	**ip nat inside source static** { **udp** *local-ip local-port* | **tcp** *local-ip local-port* } *global-ip global-port* [**permit-inside**]
Parameter Description	**udp**: Indicates UDP. **tcp**: Indicates TCP. *local-ip*: Indicates the internal address. *local-port*: Indicates the internal local port. *global-ip*: Indicates the external address. *global-port*: Indicates the external global port. **permit-inside**: Permits intranet users to access the host specified by *local-ip* using the address specified by *global-ip*.
Command Mode	Global configuration mode
Configuration Usage	This command is used to build an internal server that external public networks can access. Internal hosts are not allowed to access the internal server using the value specified by *global-ip* unless **permit-inside** has been configured. If **permit-inside** is not configured, internal hosts can access the internal server by using the value specified by *local-ip* only.

Configuring an Address Pool



Command	**ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]
Parameter Description	*pool-name*: Indicates the name of the address pool. *start-ip*: Indicates the start IP address. *end-ip*: Indicates the end IP address. **netmask** *mask*: Indicates the network mask of addresses. **prefix-length** *prefix-length*: Indicates the length of the network mask of addresses. **type rotary**: Specifies the type of the NAT address pool. The rotary type is round-robin assignment and guarantees the same probability for every address to be assigned. The assignment is round-robin regardless of whether **rotary** is configured. The **rotary** parameter is used to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring Dynamic NAPT

Command	**ip nat inside source list** *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**]
Parameter Description	*access-list-number*: Specifies an ACL number. **pool** *pool-name*: Indicates the name of the address pool. **interface** *interface-type interface-number*: Implements NAPT using the global address of the external interface. **overload**: Indicates that each global address in the address pool can be reused for NAPT. Global addresses are reused even if this parameter is not configured. Therefore, this parameter is used only to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

Enabling Intranet User to Access an Extranet Server Through NAPT

Scenario Figure 1-2	
Configuration Steps	● Configure **ip nat inside** on the internal interface. ● Configure **ip nat outside** on the external interface. ● Configure a dynamic NAPT rule.

A	`A# configure terminal`
	`A(config)# interface gigabitethernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip address 192.168.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/1)# ip nat inside`
	`A(config-if-GigabitEthernet 0/1)# exit`
	`A(config)# interface gigabitethernet 0/2`
	`A(config-if-GigabitEthernet 0/2)# ip address 200.198.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/2)# ip nat outside`
	`A(config-if-GigabitEthernet 0/2)# exit`
	`A(config)# ip nat pool net200 200.168.12.1 200.168.12.1 netmask 255.255.255.0`
	`A(config)# ip nat inside source list 1 pool net200`
	`A(config)# access-list 1 permit 192.168.12.0 0.0.0.255`
	`A(config)# ip nat inside source static tcp 192.168.12.3 80 200.198.12.1 80`

Verification	● Use the **show** command to display the configuration.
A	`Hostname# show ip nat translations`

```
Pro Inside global      Inside local       Outside local      Outside
global
tcp 200.168.12.200:2063 192.168.12.65:2063 168.168.12.1:23

168.168.12.1:23
tcp 200.168.12.200:2066 192.168.12.68:2063 168.168.12.1:23
168.168.12.1:23
tcp 200.168.12.200:2067 192.168.12.69:2063 168.168.12.1:23
168.168.12.1:23
```

Common Errors

- The internal or external interface is not configured.
- The ACL configuration is incorrect.

1.4.3 Configuring Overlapping NAT

Networking Requirements

Address overlapping indicates that the same IP address is allocated to two private networks to interconnect with each other or the same global IP address is allocated to a private network and a public network. Two overlapping network hosts cannot communicate, because both hosts consider that the peer host is located on the local network. Overlapping NAT is especially designed to implement communication between two networks with the same IP address. After overlapping NAT is configured, an extranet host address will be represented as another host address on the intranet, and vice versa.

Notes

- Internal source address translation must be configured before overlapping NAT is configured.
- The newly configured NAT rules take effect on new flows only but not on any existing flows.

Configuration Step

↘ Configuring the NAT Internal Interface

- Mandatory.
- Configure the LAN interface to connect to the intranet as the NAT internal interface unless otherwise stated.

↘ Configuring the NAT External Interface

- Mandatory.
- Configure the WAN interface to connect to the extranet as the NAT external interface unless otherwise stated.

↘ Configuring Static Translation of External Source Addresses

- Optional.

- Configure static translation of external source addresses in global configuration mode when a small number of users on the extranet need to access the intranet.

Configuring Dynamic Translation of External Source Addresses

- Optional.
- Configure dynamic translation of external source addresses in global configuration mode when a large number of users on the extranet need to access the intranet.

Configuring an ACL

- The ACL configuration is mandatory when dynamic source address mapping is used.
- Restrict the range of users requiring source address translation on the intranet.

Configuring a Static Route

- Mandatory.
- Specify the network egress after internal destination address translation.

Verification

N/A

Commands

Configuring the NAT Inside Interface and NAT Outside Interface

Command	**ip nat { inside | outside }**
Parameter Description	**inside**: Indicates the internal interface. **outside**: Indicates the external interface.
Command Mode	Interface configuration mode
Configuration Usage	NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a certain rule. Therefore, at least one internal interface and one external interface need to be configured on the device.

Configuring Static Translation of External Source Addresses

Command	**ip nat outside source static** *global-ip local-ip*
Parameter Description	*global-ip*: Indicates the external global address. *local-ip*: Indicates the internal local address.
Command Mode	Global configuration mode
Configuration Usage	N/A

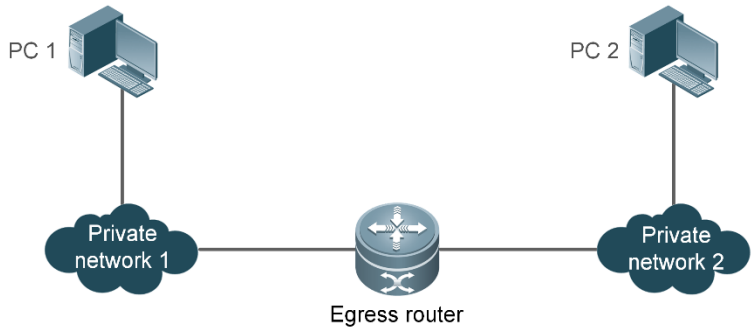
Configuring Static Translation of the External Source Address and Port

Command	**ip nat outside source static** { **tcp** *global-ip global-port* **| udp** *global-ip global-port* } *local-ip local-port*
Parameter Description	*protocol*: Indicates the protocol number. *global-ip*: Indicates the external global address.

	global-port: Indicates the external global port. *local-ip*: Indicates the internal local address. *local-port*: Indicates the internal local port.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring an Address Pool

Command	**ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]
Parameter Description	*pool-name*: Indicates the name of the address pool. *start-ip*: Indicates the start IP address. *end-ip*: Indicates the end IP address. **netmask** *mask*: Indicates the network mask of addresses. **prefix-length** *prefix-length*: Indicates the length of the network mask of addresses. **type rotary**: Specifies the type of the NAT address pool. The rotary type is round-robin assignment and guarantees the same probability for every address to be assigned. The assignment is round-robin regardless of whether **rotary** is configured. The **rotary** parameter is used to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A



Configuring Dynamic Translation of External Source Addresses

Command	**ip nat outside source list** *access-list-number* **pool** *pool-name*
Parameter Description	*access-list-number*: Indicates the ACL number. **pool** *pool-name*: Indicates the name of the address pool.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

The following configuration example describes the configuration related to static translation of external source addresses.

Static Translation of External Source Addresses

Scenario **Figure 1-3**	
Configuration Steps	● Configure **ip nat inside** on the internal interface. ● Configure **ip nat outside** on the external interface. ● Configure a rule for dynamic translation of internal source addresses. ● Configure a rule for static translation of external source addresses.

A	`A# configure terminal`
	`A(config)# interface gigabitethernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip address 192.168.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/1)# ip nat inside`
	`A(config-if-GigabitEthernet 0/1)# exit`
	`A(config)# interface gigabitethernet 0/2`
	`A(config-if-GigabitEthernet 0/2)# ip address 200.198.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/2)# ip nat outside`
	`A(config-if-GigabitEthernet 0/2)# exit`
	`A(config)# ip nat pool net200 200.168.12.2 200.168.12.100 netmask 255.255.255.0`
	`A(config)# ip nat inside source list 1 pool net200`
	`A(config)# access-list 1 permit 192.168.12.0 0.0.0.255`
	`A(config)# ip nat outside source static 192.168.12.3 172.16.10.1`
	`A(config)# ip route 172.16.10.0 255.255.255.0 200.198.12.2`

Verification	● Use the **show** command to display the configuration.

A	`Hostname# show ip nat translations`
	`Pro Inside global Inside local Outside local Outside global`
	`tcp 200.168.12.200:2063 192.168.12.65:2063 172.16.10.1:23 168.168.12.3:23`

Common Errors

- The internal or external interface is not configured.
- The ACL configuration is incorrect.
- No static route is configured or no IP address is configured for the external interface, so that the device does not know to which interface a data packet should be sent after NAT or from which interface a data packet is received after NAT.

1.4.4 Configuring TCP Load Balancing

Networking Requirements

When the TCP traffic load of an intranet host is heavy, multiple hosts can be deployed to implement TCP service load balancing. In this case, NAT can be used to address this issue. In the following configuration, a virtual host address is defined, so that all TCP connections from extranets to the virtual host are distributed by a device to multiple physical hosts, so as to implement traffic load balancing.

Notes

The newly configured NAT rules take effect on new flows only but not on any existing flows.

Configuration Step

Configuring the NAT Internal Interface

- Mandatory.
- Configure the LAN interface to connect to the intranet as the NAT internal interface unless otherwise stated.

Configuring the NAT External Interface

- Mandatory.
- Configure the WAN interface to connect to the extranet as the NAT external interface unless otherwise stated.

Configuring Dynamic Translation of Internal Destination Addresses

- Mandatory.
- Configure dynamic translation of internal destination addresses in global configuration mode for TCP load balancing.

Verification

N/A

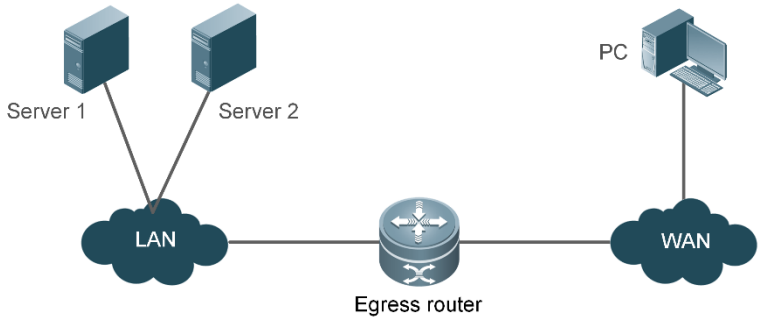
Commands

Configuring the NAT Internal and External Interfaces

Command	**ip nat { inside | outside }**
Parameter Description	**inside**: Indicates the internal interface. **outside**: Indicates the external interface.
Command Mode	Interface configuration mode
Configuration Usage	NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured on the device.

Configuring an Address Pool

Command	**ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *netmask* | **prefix-length** *prefix-length* } [**type rotary**]



Parameter Description	*pool-name*: Indicates the name of the address pool. *start-ip*: Indicates the start IP address. *end-ip*: Indicates the end IP address. **netmask** *mask*: Indicates the network mask of addresses. **prefix-length** *prefix-length*: Indicates the length of the network mask of addresses. **type rotary**: Specifies the type of the NAT address pool. The rotary type is round-robin assignment and guarantees the same probability for every address to be assigned. The assignment is round-robin regardless of whether **rotary** is configured. The **rotary** parameter is used to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	

Configuring Dynamic Translation of Inside Destination Address

Command	**ip nat inside destination list** *access-list-number* **pool** *pool-name*
Parameter Description	*access-list-number*: ACL number **pool** *pool-name*: name of the address pool
Command Mode	Global configuration mode
Configuration Usage	

Configuration Example

Enabling Extranet User to Access an Intranet Server

Scenario **Figure 1-4**	
Configuration Steps	● Configure **ip nat inside** on the internal interface. ● Configure **ip nat outside** on the external interface. ● Configure a rule for dynamic internal destination address translation.

A	`A# configure terminal`
	`A(config)# interface gigabitethernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip address 10.10.10.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/1)# ip nat inside`
	`A(config-if-GigabitEthernet 0/1)# exit`
	`A(config)# interface gigabitethernet 0/2`
	`A(config-if-GigabitEthernet 0/2)# ip address 200.198.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/2)# ip nat outside`

	A(config-if-GigabitEthernet 0/2)# exit A(config)# ip nat pool realhosts 10.10.10.2 10.10.10.3 netmask 255.255.255.0 type rotary A(config)# ip nat inside destination list 100 pool realhosts A(config)# access-list 100 permit ip any host 10.10.10.100
Verification	● Use the **show** command to display the configuration.
A	Hostname# show ip nat translations Pro Inside global Inside local Outside local Outside global tcp 10.10.10.100:23 10.10.10.2:23 100.100.100.100:1178 100.100.100.100:1178 tcp 10.10.10.100:23 10.10.10.3:23 200.200.200.200:1024 200.200.200.200:1024

Common Errors

- The internal or external interface is not configured.
- The ACL configuration is incorrect. Note that the ACL must be configured as an extended ACL based on destination IP address matching.
- The preceding configuration takes effect on TCP traffic only but not on other traffic unless additional NAT configuration has been performed.

1.4.5 Configuring ALG

Networking Requirements

NAT translates only IP address and port information in the header of a packet but does not analyze fields in the application layer data payload of the packet. However, for some special protocols, such as FTP, DNS, and FTFP, the data payloads of their packets may contain IP address or port information. If such information is not translated by NAT, problems may occur. ALG technology can parse application layer packet information and perform address translation for multi-channel protocols, so as to translate or process IP addresses or ports requiring address translation or some fields requiring special processing, thereby guaranteeing application layer communication.

Notes

- At least one internal interface and one external interface need to be configured during the ALG configuration.
- The newly configured NAT rules take effect on new flows only but not on any existing flows.

Configuration Step

↘ Configuring the NAT Internal Interface

- Mandatory.
- Configure the LAN interface to connect to the intranet as the NAT internal interface unless otherwise stated.

↘ Configuring the NAT External Interface

- Mandatory.

- Configure the WAN interface to connect to the extranet as the NAT external interface unless otherwise stated.

Configuring Static NAT

- Optional.
- Configure static NAT in global configuration mode when a small number of users on the intranet need to access the extranet.

Configuring Dynamic NAT

- Optional.
- Configure dynamic NAT in global configuration mode when a large number of users on the intranet need to access the extranet.

Configuring ALG

- Optional.
- The ALG configuration is mandatory if DNS, FTP, TFTP, PPTP, H323, RTSP, or SIP requires communication through NAT transversal.

Verification

N/A

Commands

Configuring the NAT Internal and External Interfaces

Command	**ip nat { inside | outside }**
Parameter Description	**inside**: Indicates the internal interface. **outside**: Indicates the external interface.
Command Mode	Interface configuration mode
Configuration Usage	NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a rule. Therefore, at least one internal interface and one external interface need to be configured on the device.

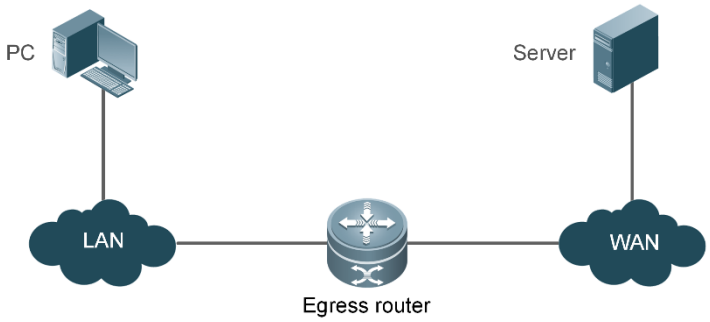
Configuring Static NAT

Command	**ip nat inside source static** *local-ip global-ip* [**permit-inside**] [**netmask** *mask* | **match** *interface-type interface-number*]
Parameter Description	*local-ip*: Indicates the internal address. *global-ip*: Indicates the external address. **permit-inside**: Permits intranet users to access the host specified by *local-ip* using *global-ip*. **netmask** *mask*: Indicates the network-segment-to-network-segment address. **match** *interface-type interface-number*: Specifies the egress interface.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring an Address Pool

Command	**ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]
Parameter Description	*pool-name*: Indicates the name of the address pool. *start-ip*: Indicates the start IP address. *end-ip*: Indicates the end IP address. **netmask** *mask*: Indicates the network mask of addresses. **prefix-length** *prefix-length*: Indicates the length of the network mask of addresses. **type rotary**: Specifies the type of the NAT address pool. The rotary type is round-robin assignment and guarantees the same probability for every address to be assigned. The assignment is round-robin regardless of whether **rotary** is configured. The **rotary** parameter is used to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring Dynamic NAT



Command	**ip nat inside source list** *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**]
Parameter Description	*access-list-number*: Specifies an ACL number. **pool** *pool-name*: Indicates the name of the address pool. **interface** *interface-type interface-number*: Implements NAPT using the global address of the external interface. **overload**: Indicates that each global address in the address pool can be reused for NAPT. Global addresses are reused even if this parameter is not configured. Therefore, this parameter is used only to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring ALG

Command	**ip nat translation** { **dns** [**ttl** *ttl_time*] **| ftp** [**port** *port_num*] **| h323 | pptp | rtsp | sip | tftp** [**port** *port_num*] }
Parameter Description	**ttl**: Defines the NAT timeout interval of a UDP connection of the DNS application. The default value is 0. *port_num*: Defines FTP and TFTP port numbers. The default FTP number is 21 and the default TFTP number is 69.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

Enabling Intranet Users to Access an Extranet Server

Scenario **Figure 1-9**	
Configuration Steps	● Configure **ip nat inside** on the internal interface. ● Configure **ip nat outside** on the external interface. ● Configure a dynamic NAT rule. ● Configure ALG.
A	A# configure terminal A(config)# interface gigabitethernet 0/1 A(config-if-GigabitEthernet 0/1)# ip address 192.168.12.1 255.255.255.0 A(config-if-GigabitEthernet 0/1)# ip nat inside A(config-if-GigabitEthernet 0/1)# exit A(config)# interface gigabitethernet 0/2 A(config-if-GigabitEthernet 0/2)# ip address 200.168.12.1 255.255.255.0 A(config-if-GigabitEthernet 0/2)# ip nat outside A(config-if-GigabitEthernet 0/2)# exit A(config)# ip nat pool net200 200.168.12.2 200.168.12.100 netmask 255.255.255.0 A(config)# ip nat inside source list 1 pool net200 A(config)# access-list 1 permit 192.168.12.0 0.0.0.255 A(config)# ip nat translation ftp 23
Verification	● Use the **show** command to display the configuration.
A	Hostname# show ip nat translations Pro Inside global Inside local Outside local Outside global tcp 200.168.12.200:2063 192.168.12.65:2063 168.168.12.1:23 168.168.12.1:23

Common Errors

- The internal or external interface is not configured.
- The ACL configuration is incorrect.

1.4.6 Configuring Special NAT Applications

Networking Requirements

For some advanced applications of NAT, source addresses or destination addresses of some specific IP packets need to be modified.

Notes

- At least one internal interface and one external interface need to be configured for special NAT applications.
- The newly configured NAT rules take effect on new flows only but not on any existing flows.

Configuration Step

Configuring the NAT Internal Interface

- Mandatory.
- Configure the LAN interface to connect to the intranet as the NAT internal interface unless otherwise stated.

Configuring the NAT External Interface

- Mandatory.
- Configure the WAN interface to connect to the extranet as the NAT external interface unless otherwise stated.

Configuring Static NAT

- Optional.
- Configure static NAT in global configuration mode when a small number of users on the intranet need to access the extranet.

Configuring Dynamic NAT

- Optional.
- Configure dynamic NAT in global configuration mode when a large number of users on the intranet need to access the extranet.

Configuring Special NAT Applications

- Optional.
- This configuration is mandatory if special address translation is required for communication of some applications.

Verification

N/A

Commands

Configuring the NAT Inside Interface and NAT Outside Interface

Command	**ip nat { inside | outside }**
Parameter Description	**inside**: Indicates the internal interface. **outside**: Indicates the external interface.
Command Mode	Interface configuration mode
Configuration Usage	NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a certain rule. Therefore, at least one internal interface and one external interface need to be configured on the device.

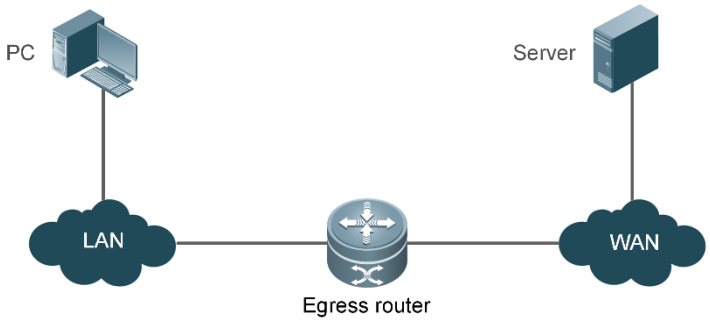
Configuring Static NAT

Command	**ip nat inside source static** *local-ip global-ip* [**permit-inside**] [**netmask** *mask* | **match** *interface-type interface-number*]
Parameter Description	*local-ip*: Indicates the internal address. *global-ip*: Indicates the external address. **permit-inside**: Permits intranet users to access the host specified by *local-ip* using *global-ip*. **netmask** *mask*: Indicates the network-segment-to-network-segment address. **match** *interface-type interface-number*: Specifies the egress interface.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring an Address Pool

Command	**ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]
Parameter Description	*pool-name*: Indicates the name of the address pool. *start-ip*: Indicates the start IP address. *end-ip*: Indicates the end IP address. **netmask** *mask*: Indicates the network mask of addresses. **prefix-length** *prefix-length*: Indicates the length of the network mask of addresses. **type rotary**: Specifies the type of the NAT address pool. The rotary type is round-robin assignment and guarantees the same probability for every address to be assigned. The assignment is round-robin regardless of whether **rotary** is configured. The **rotary** parameter is used to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring Dynamic NAT



Command	**ip nat inside source list** *access-list-number* **pool** *address-pool* **ip nat inside source list** *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**]
Parameter Description	*access-list-number*: Specifies an ACL number. **pool** *pool-name*: Indicates the name of the address pool. **interface** *interface-type interface-number*: Implements NAPT using the global address of the external interface. **overload**: Indicates that each global address in the address pool can be reused for NAPT. Global addresses are reused even if this parameter is not configured. Therefore, this parameter is used only to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring Special NAT Applications

Command	**ip nat application source list** *list-num* **destination** *global-ip* { **dest-change** *ip-address* | **src-change** *ip-address* }
Parameter Description	*local-ip*: Indicates the internal address. *global-ip*: Indicates the exteranl address. **dest-change** *ip-address port-num*: Changes the destination IP address and port of the packet that satisfies conditions. **src-change** *ip-address*: Changes the source IP address of the packet that satisfies conditions.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

Implementing the DNS Relay Service

Scenario **Figure 1-10**	
Configuration Steps	● Configure **ip nat inside** on the internal interface. ● Configure **ip nat outside** on the external interface. ● Configure a dynamic NAT rule. ● Configure special NAT applications.

A	`A#configure terminal`
	`A(config)# interface gigabitethernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/1)# ip nat inside`
	`A(config-if-GigabitEthernet 0/1)# exit`
	`A(config)# interface gigabitethernet 0/2`
	`A(config-if-GigabitEthernet 0/2)# ip address 200.168.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/2)# ip nat outside`
	`A(config-if-GigabitEthernet 0/2)# exit`
	`A(config)# ip nat pool net200 200.168.12.2 200.168.12.10 netmask 255.255.255.0`
	`A(config)# ip nat inside source list 1 pool net200`
	`A(config)# access-list 1 permit 192.168.12.0 0.0.0.255`
	`A(config)# ip nat application source list 1 destination udp 192.168.1.1 53 dest-change 202.101.98.55 53`
	`A(config)# access-list 1 permit 192.168.1.0 0.0.0.255`

Verification	-

Common Errors

- The internal or external interface is not configured.

1.4.7 Configuring the Interval at Which Gratuitous ARP Packets Are Sent

Networking Requirements

Configure the interval at which gratuitous ARP packets are sent from addresses in the NAT address pool, so as to avoid address conflicts.

Notes

- The NAT-enabled device is disabled from sending gratuitous ARP packets by default.
- Gratuitous ARP packets are sent to the external interface only.

Configuration Step

Configuring the NAT Internal Interface

- Mandatory.
- Configure the LAN interface to connect to the intranet as the NAT internal interface unless otherwise stated.

Configuring the NAT External Interface

- Mandatory.
- Configure the WAN interface to connect to the extranet as the NAT external interface unless otherwise stated.

Configuring Static NAT

- Optional.
- Configure static NAT in global configuration mode when a small number of users on the intranet need to access the extranet.

Configuring Dynamic NAT

- Optional.
- Configure dynamic NAT in global configuration mode when a large number of users on the intranet need to access the extranet.

Configuring the Interval at Which Gratuitous ARP Packets Are Sent

- Optional.
- The NAT-enabled device needs to consider some addresses matching the configured rule as local addresses. This configuration is performed to avoid address conflicts.

Verification

N/A

Commands

Configuring the NAT Internal and External Interfaces

Command	**ip nat { inside | outside }**
Parameter Description	**inside**: Indicates the internal interface. **outside**: Indicates the external interface.
Command Mode	Interface configuration mode
Configuration Usage	NAT does not work on a data packet unless a route exists between the external interface and the internal interface and the data packet meets a certain rule. Therefore, at least one internal interface and one external interface need to be configured on the device.

Configuring Static NAT

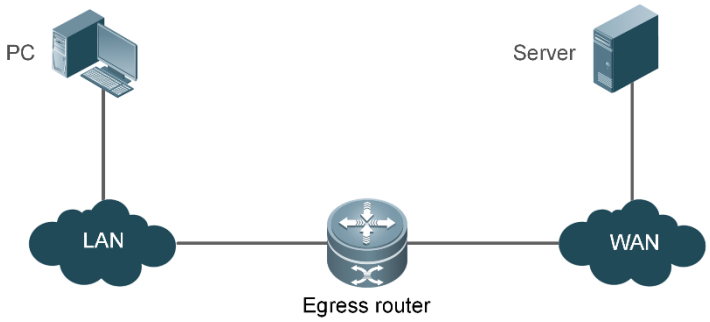
Command	**ip nat inside source static** *local-ip global-ip* [**permit-inside**] [**netmask** *mask* | **match** *interface-type interface-number*]
Parameter Description	*local-ip*: Indicates the internal address. *global-ip*: Indicates the external address. **permit-inside**: Permits intranet users to access the host specified by *local-ip* using *global-ip*. **netmask** *mask*: Indicates the network-segment-to-network-segment address. **match** *interface-type interface-number*: Specifies the egress interface.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring an Address Pool

Command	**ip nat pool** *pool-name* [*start-ip end-ip*] { **netmask** *mask* | **prefix-length** *prefix-length* } [**type rotary**]
Parameter Description	*pool-name*: Indicates the name of the address pool. *start-ip*: Indicates the start IP address. *end-ip*: Indicates the end IP address. **netmask** *mask*: Indicates the network mask of addresses. **prefix-length** *prefix-length*: Indicates the length of the network mask of addresses. **type rotary**: Specifies the type of the NAT address pool. The rotary type is round-robin assignment and guarantees the same probability for every address to be assigned. The assignment is round-robin regardless of whether **rotary** is configured. The **rotary** parameter is used to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring Dynamic NAT

Command	**ip nat inside source list** *access-list-number* { **interface** *interface-type interface-number* | **pool** *pool-name* } [**overload**]



Parameter Description	*access-list-number*: Specifies an ACL number. **pool** *pool-name*: Indicates the name of the address pool. **interface** *interface-type interface-number*: Implements NAPT using the global address of the external interface. **overload**: Indicates that each global address in the address pool can be reused for NAPT. Global addresses are reused even if this parameter is not configured. Therefore, this parameter is used only to keep compatibility with Cisco commands.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuring the Interval at Which Gratuitous ARP Packets Are Sent

Command	**ip nat keepalive** [*keealive_out*]
Parameter Description	*keealive_out*: indicates the interval at which gratuitous ARP packets are sent from the local address of NAT. The value range is from 1 to 86400.
Command Mode	Global configuration mode
Configuration Usage	N/A

Configuration Example

Sending Gratuitous ARP Packets Regularly

Scenario **Figure 1-11**	
Configuration Steps	● Configure **ip nat inside** on the internal interface. ● Configure **ip nat outside** on the external interface. ● Configure a dynamic NAT rule. ● Configure periodical sending of gratuitous ARP packets.

A	`A#configure terminal`
	`A(config)# interface gigabitethernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/1)# ip nat inside`
	`A(config-if-GigabitEthernet 0/1)# exit`
	`A(config)# interface gigabitethernet 0/2`
	`A(config-if-GigabitEthernet 0/2)# ip address 200.168.12.1 255.255.255.0`
	`A(config-if-GigabitEthernet 0/2)# ip nat outside`
	`A(config-if-GigabitEthernet 0/2)# exit`

	A(config)# ip nat pool net200 200.168.12.2 200.168.12.10 netmask 255.255.255.0 A(config)# ip nat inside source list 1 pool net200 A(config)# access-list 1 permit 192.168.12.0 0.0.0.255 A(config)# ip nat keepalive 10
Verification	-

Common Errors

- The internal or external interface is not configured.
- The NAT rule is incorrect.

1.5 Monitoring

Displaying

Command	Function
show ip nat translations [*acl_num*] [**gre** | **icmp** | **tcp** | **udp**] [**verbose**] [**vrf** *vrf_name*]	Displays NAT translation.

1 Configuring DHCP

1.1 Overview

The Dynamic Host Configuration Protocol (DHCP) is a LAN protocol based on the User Datagram Protocol (UDP) for dynamically assigning reusable network resources, for example, IP addresses.

DHCP works in client/server mode. A DHCP client sends a request message to a DHCP server to obtain an IP address and other configurations. When a DHCP client and a DHCP server are located in different subnets, they need a DHCP relay to forward DHCP request and reply packets.

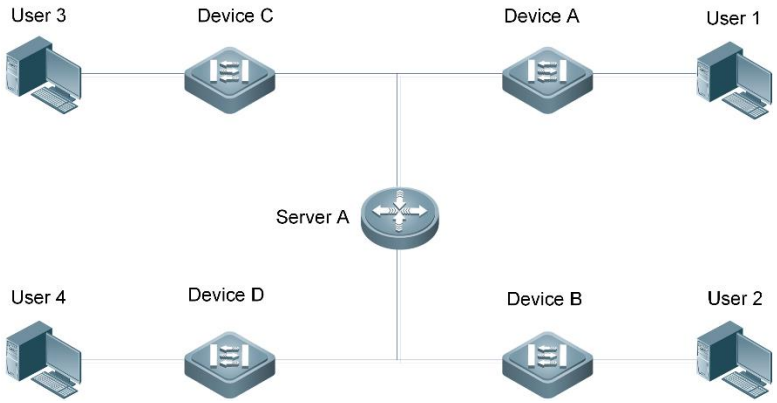
Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions
- RFC 3046: DHCP Relay Agent Information Option

1.2 Applications

Application	Description
Providing the DHCP Service on a LAN	IP addresses are assigned to clients on a local area network (LAN).
Enabling the DHCP Client	The downstream device is enabled with the DHCP client function.
Applying the DHCP Server in an MPLS Scenario	The DHCP server is deployed in L2VPN and L3VPN scenarios.
Applying an AM Rule on the DHCP Server	The DHCP server is deployed in a super-VLAN.
Applying the DHCP Relay Agent on a Wired Network	The DHCP relay agent allows users from different network segments to request IP addresses for accessing the Internet from a wired network.
Deploying the DHCP Relay Agent on a WLAN	The DHCP relay agent allows users from different network segments to request IP addresses for accessing the Internet from a WLAN.
Applying an AM Rule on the DHCP Relay	In a super-VLAN, users from different network segments request IP addresses.
Applying Address Assignment in a Cluster	Address assignment is balanced in a cluster.
Preferentially Using the DNS Addresses Obtained from an External DHCP Server in Externally on a WLAN	On a WLAN, the DNS address obtained from an external DHCP server is preferentially used on a WLAN.
Applying Class Rules on the DHCP Server	The DHCP server matches packets against class rules to obtain IP addresses in a specified network segment.

1.2.1 Providing the DHCP Service on a LAN



Scenario

Assign IP addresses to four users on a LAN.

For example, assign IP addresses to User1, User2, User3, and User4, as shown in the following figure.

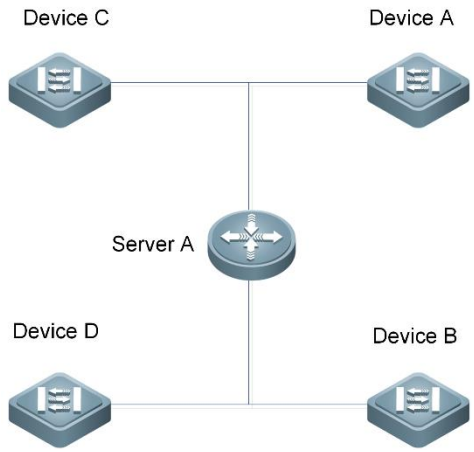
- The four users are connected to server S through devices A, B, C, and D.

Figure 1-1

Remarks	Server A is an egress gateway used as the DHCP server. Devices A, B, C and D are access devices that provide Layer 2 transparent transmission. User1, Use2, User3, and User4 are LAN users.

Deployment

- Enable the DHCP server on Server A.
- Deploy Layer 2 VLAN transparent transmission on devices A, B, C and D.
- User1, Use2, User3, and User4 initiate DHCP client requests.



1.2.2 Enabling the DHCP Client

Scenario

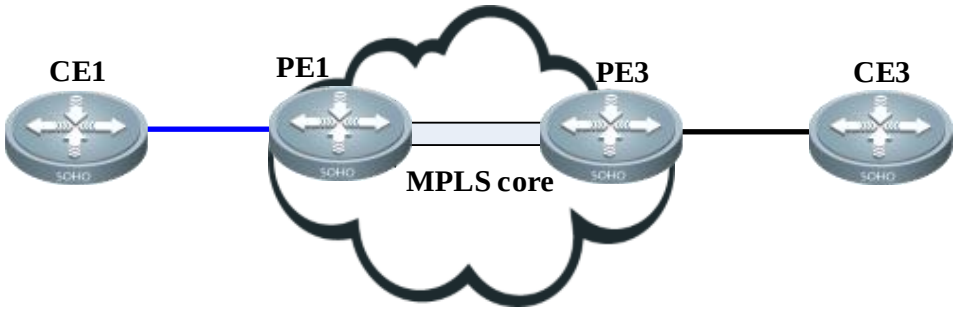
Access switches A, B, C, and D on a LAN request server S to assign IP addresses.

For example, enable the DHCP client on the interfaces of devices A, B, C and D to request IP addresses, as shown in the following figure.

Figure 1-2

Remarks	Server A is an egress gateway working as a DHCP server. Devices A, B, C, and D are access devices with the DHCP client enabled on interfaces.

Deployment



- Enable the DHCP server on server S.
- Enable the DHCP client on interfaces of devices A, B, C and D.

1.2.3 Applying the DHCP Server in an MPLS Scenario

Scenario

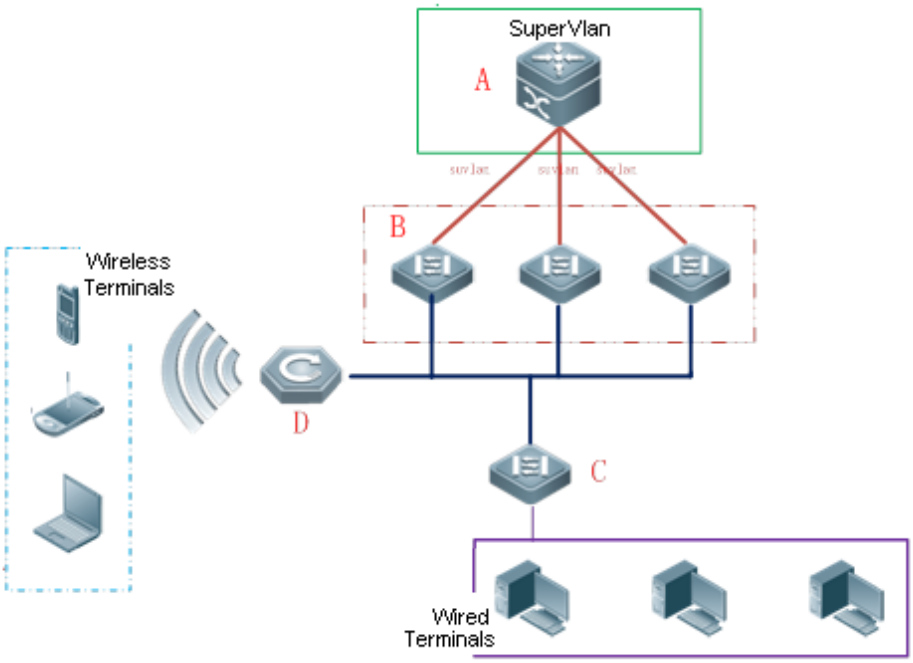
As shown in the following figure, if PE1 is a DHCP server and CE1 is a DHCP client in an L3VPN scenario, this situation is normal. If PE1 is a DHCP server and CE1 is a DHCP client in an L2VPN scenario, the AC interface on PE1 cannot be configured with an IP address, and consequently DHCP packets cannot reach the server.

Figure 1-3 MPLS Network Topology (L2VPN/L3VPN)

Remarks	In an MPLS core domain, PE1 and PE3 form a VPLS network. CE1 and CE3 are connected to the same VPLS through PE1 and PE3, respectively. CE1 is multi-homed to PE1 and PE3, and connected to the same VPLS domain. Enable the DHCP server on PE1.

Deployment

- Configure PE1 and PE3 in an L3VPN scenario, and enable the DHCP server on PE1.
- Enable the DHCP client on CE1.



1.2.4 Applying an AM Rule on the DHCP Server

Scenario

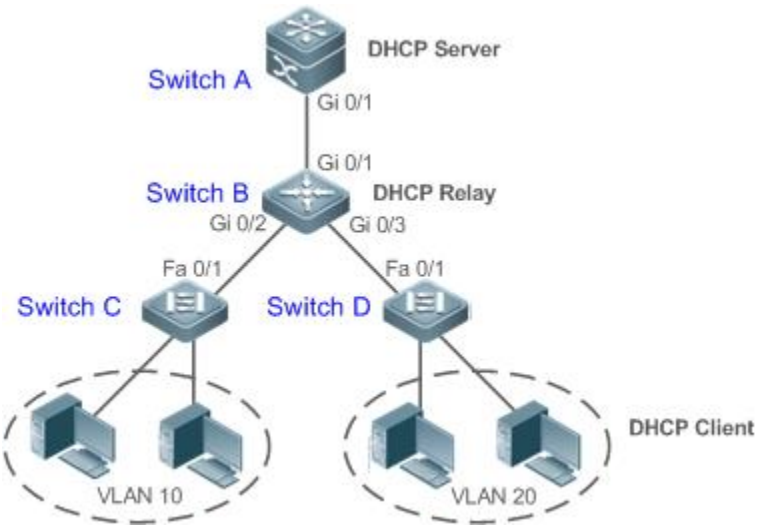
As shown in Figure 1-4, create a super-VLAN, configure an AM rule and enable the DHCP server on the core switch A. B is an aggregation switch, C an access switch, and D a wireless access device. The requirements are as follows:

- Assign IP addresses dynamically based on the VLAN and interface.
- Assign IP addresses statically based on the VLAN.
- Assign IP addresses dynamically based on the default AM rule.

Figure 1-4 Applying an AM Rule on the DHCP Server

Deployment

- Configure an AM rule, enable the DHCP server, and create a super-VLAN on A.
- Create VLANs on B and C to transparently transmit DHCP packets from wired users to A to request IP addresses.
- Enable the wireless function on D to transparently transmit DHCP packets from wireless users to A to request IP addresses.



1.2.5 Applying the DHCP Relay Agent on a Wired Network

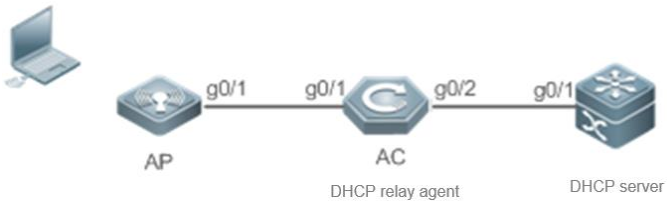
Scenario

As shown in the following figure, Switch C and Switch D function as access devices where PC users in VLAN 10 and VLAN 20 reside. Switch B functions as a gateway, and Switch A functions as a core device. The requirements are as follows:

- Switch A can function as a DHCP server to dynamically assign IP addresses from different network segments to users in different VLANs.
- Users connected to Switch C and Switch D can dynamically obtain IP addresses from different network segments.

Figure 1-5 DHCP Server Network Topology

Deployment



- Configure Layer 2 communication between Switch B and Switch C and between Switch B and Switch D.
- Specify a DHCP server address and enable the DHCP relay agent on Switch B.
- Create a DHCP address pool for users in VLAN 10 and VLAN 20 separately and enable the DHCP server on Switch A.

1.2.6 Deploying the DHCP Relay Agent on a WLAN

Scenario

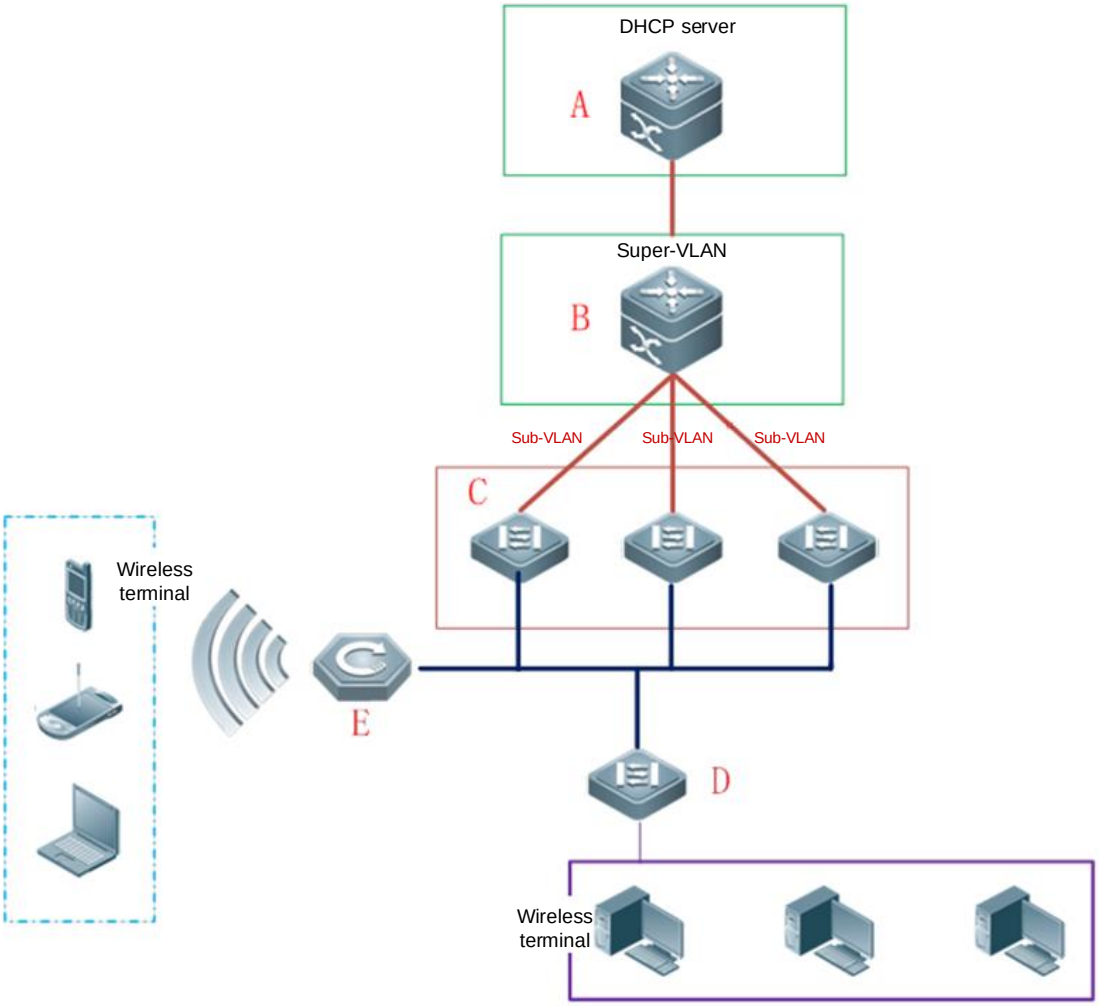
Wireless users on different network segments obtain IP addresses to access the Internet.

Figure 1-6 DHCP Relay Agent

Remarks	The AP is a wireless access point. The AC is a wireless management device and DHCP relay agent. The DHCP server is a core device that is responsible for assigning IP addresses to wireless users.

Deployment

- Connect the AP to to the AC.
- Enable the DHCP relay agent on AC.
- Enable the DHCP server on the core device.



1.2.7 Applying an AM Rule on the DHCP Relay Agent

Scenario

As shown in Figure 1-7, A is a DHCP server, B a core switch configured with a super-VLAN, an AM rule, and the DHCP relay agent, C an aggregation switch, D an access switch, and E a wireless access device. The requirements are as follows:

- The AM rule relies on VLAN and interface configurations. According to this rule, the DHCP relay agent selects a subnet address as the Giaddress for relay packets, forwarding them to the DHCP server to request an IP address for the client.
- Based on the default AM rule, the DHCP relay agent selects a subnet address as the Giaddress for relay packets, forwarding them to the DHCP server to request an IP address for the client.

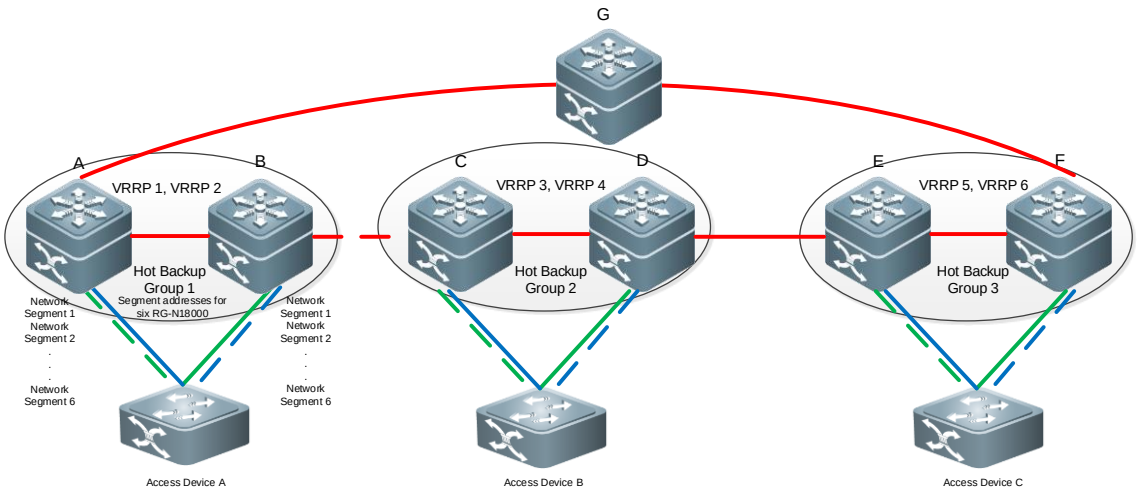
Figure 1-7 Applying AM Rule on the DHCP Relay Agent

Deployment

- Enable the DHCP server on A.
- Configure an AM rule, enable the DHCP relay agent, and create a super-VLAN on B.

- Create VLANs on C and D to transparently transmit DHCP packets from wired users to B to request IP addresses.
- Enable the wireless function on E to transparently transmit DHCP packets from wireless users to B to request IP addresses.

1.2.8 Applying Address Assignment in a Cluster



Scenario

As shown in the following figure, a cluster consists of the core ring, user VLAN, and management VLAN:

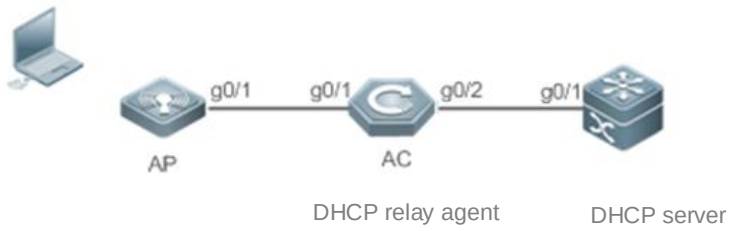
- Core ring: Seven RG-N18000 core switches form an ERPS ring, with two VRRP groups enabled on each of A/B, C/D, and E/F. That is, there are six virtual gateways. Device G serves as a backup, that is, physical gateway. Each gateway provides authentication and Internet access for 75,000 users. The DHCP server is enabled on A and B for AA hot standby, with each providing address assignment for 275,000 users. The DHCP server balances user services to the seven gateways, ensuring that each gateway provides the Internet access service for 75,000 users. DHCP snooping is enabled on each core device. Each core device encapsulates the corresponding gateway address only for DHCP packets of users served by the core device and forwards the DHCP packets to the DHCP server, without providing security functions. Each core device provides the authentication service for 75,000 users, providing responses for 5,600 users within 7s.
- User VLAN: A simple network mode is used, with a super-VLAN on the user side to ensure that the user's IP address and gateway address remain unchanged regardless of migration. Because the core ring is deployed on a large Layer 2 network, noise reduction is required to ensure the MAC or ARP entry capacity. ARP entries are not configured on the DHCP server of A and B, and DHCP snooping is used for forwarding based on the interface and VLAN to avoid ARP entry insufficiency.
- Management VLAN: This function is enabled on A and B for data hot standby of the DHCP server, and is enabled on A to G for device status monitoring through BFD.

The access loop consists of access device A, core device A, and core device B. Packets are distributed through REUP.

Figure 1-8 Integrated Address Assignment Network Topology

Remarks	A and B function as core devices and form VRRP group 1, and are enabled with the DHCP server. C and D function as core devices and form VRRP group 2. E and F function as core devices and form VRRP group 3. G is a backup.

Deployment



- On A and B, enable the DHCP server, enable the dedicated hot standby channel, and configure BFD.
- Configure two VRRP groups as user gateways on each of A, B, C, D, E, and F.

1.2.9 Preferentially Using the DNS Addresses Obtained from an External DHCP Server in Externally on a WLAN

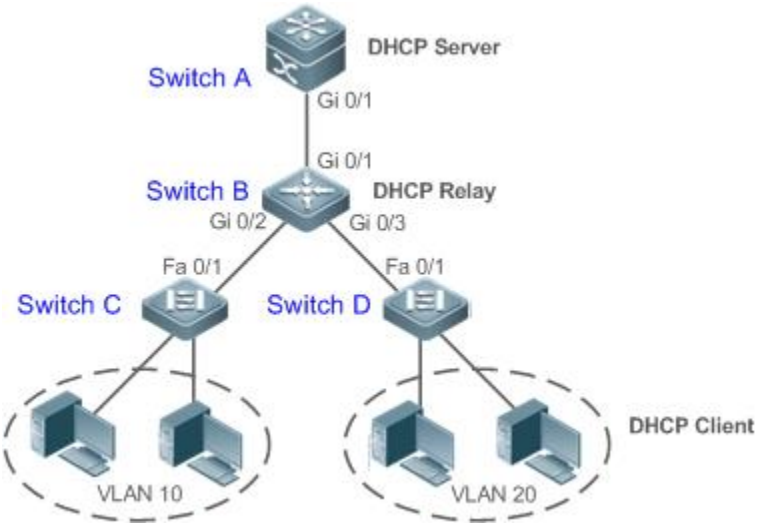
Scenario

When the WAN interface of a wireless fat AP operates in PPPoE or DHCP client mode, a DNS address can be automatically obtained from an external DHCP server and be configured on the local DHCP server, so that the user does not need to perform DNS configuration. When the fat AP serves as the DHCP server to allocate addresses, it preferentially uses the DNS address obtained from an external DHCP server.

Figure 1-9 Networking of the DHCP Server

Remarks	When an AP operates in fat AP mode and the WAN interface of the fat AP operates in PPPoE or DHCP client mode, the AP can obtain an IP address and a DNS address from an external DHCP server, and serves as the DHCP server to assign addresses to STAs.

Deployment



- Configure the AP as a fat AP and enable the PPPoE or DHCP client function on the WAN interface of the fat AP.
- Enable the DHCP server on the fat AP to assign addresses to STAs.
- Preferentially assign the DNS address obtained through PPPoE or the DHCP client to STAs.

1.2.10 Applying Class Rules on the DHCP Server

Scenario

On a LAN, users served by different access devices are assigned with addresses on different network segments to facilitate management of IP addresses and physical locations of terminals.

As shown in the following figure, two PCs belong to each of VLAN 10 and VLAN 20. Switch C and Switch D function as access devices, and each are configured with DHCP snooping and Option 82. Switch B functions as the relay agent and forwards packets to the DHCP server. Switch A used as the DHCP server is configured with the address pool and class rules. A terminal can match the corresponding class rule on the DHCP server based on Option 82 information imported by the access device, to obtain an IP address on a specified network segment.

Remarks	Switch C and Switch D function as access devices. Switch B functions as a gateway. Switch A functions as a core device.

Deployment

- Configure Switch A as the DHCP server and specify class rules.
- Configure Switch B as the DHCP relay agent.
- Configure Switch C as the access device and add DHCP snooping and Option 82.

1.3 Features

Basic Concepts

DHCP Server

Based on RFC 2131, the DHCP server assigns IP addresses to clients and manages these IP addresses.

DHCP Client

The DHCP client enables a device to automatically obtain an IP address and configurations from a DHCP server.

DHCP Relay Agent

When a DHCP client and a DHCP server are not in a same subnet, they need a DHCP relay agent to forward DHCP request and reply packets.

Lease

The lease is a period of time specified by a DHCP server for a client to use an assigned IP address. An IP address is active when being leased to a client. Before a lease expires, a client needs to renew the lease through a DHCP server. When a lease expires or is deleted from a server, the lease becomes inactive.

Excluded Address

An excluded address is a specified IP address that is not assigned to a client by a DHCP server.

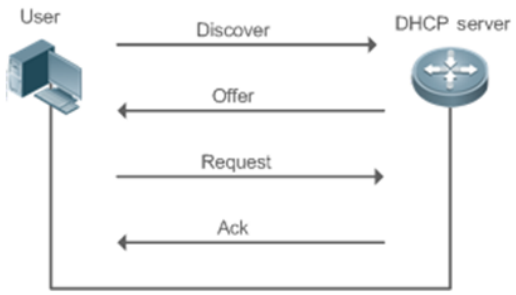
Address Pool

An address pool is a collection of IP addresses that a DHCP server may assign to clients.

Option Type

An option type is a parameter specified by a DHCP server when it provides the lease service for a DHCP client. For example, a public option include IP addresses of the default gateway, WINS server, and a DNS server. The DHCP server allows other options to be configured. Though most options are defined in RFC 2132, you can add user-defined options.

Overview



Feature	Description
DHCP Server	Enables the DHCP server on a device, so the device can assign IP addresses dynamically and pushes configurations to DHCP clients.
DHCP Relay Agent	Enables the DHCP relay agent on a device, so the device can forward DHCP request and reply packets across different network segments.
DHCP Client	Enables the DHCP client on a device, so it can obtain an IP address and the configuration automatically from a DHCP server.
AM Rule	Enables an AM rule on a device, so the device can assign IP addresses based on the rule.
Class Rule	Enables the class rule function on a device to assign IP addresses based on class rules.

1.3.1 DHCP Server

Working Principle

DHCP Working Principle

Figure 1-10

A host requests an IP address through DHCP as follows:

1 A host broadcasts a DHCP Discover packet to find DHCP servers on a network.

2 DHCP servers unicast or broadcast (based attributes of the host packet) DHCP Offer packets to the host, containing an IP address, a MAC address, a domain name, and a lease.

3 The host broadcasts a DHCP Request packet to request an IP address.

4 A DHCP server unicasts a DHCP ACK packet to the host to acknowledge the request.

A DHCP client may receive DHCP Offer packets from multiple DHCP servers, but usually it accepts only the first DHCP Offer packet. Besides, the address specified in a DHCP Offer packet is not necessarily assigned. Instead, it is retained by the DHCP server until a client sends a request.

To request an IP address, a client broadcasts a DHCP Request packet so that all DHCP servers sending DHCP Offer packets may receive the packet and release pre-allocated IP addresses.

If a DHCP Offer packet contains invalid configuration parameters, a client will send a DHCP Decline packet to the server to decline the configuration.

During negotiation, if a client does not respond to the DHCP Offer packets in a timely manner, servers will send DHCP NAK packets to the client and the client will reinitiate the process.

During network construction, the DHCP server has the following advantages:

- Low cost: Static IP address configuration costs more than DHCP-based address allocation configuration.
- Simplified configuration: Dynamic IP address assignment dramatically simplifies device configuration
- Centralized management: During configuration and management of multiple subnets, if there is any change on configuration parameters, you only need to change or update the DHCP server configuration.

Address Pool

After a server receives a client's request packet, it chooses a valid address pool, determines an available IP address from the pool through the ping mechanism, and pushes the pool and address configuration to the client. The lease is saved locally for validity check upon lease renewal.

An address pool may carry various configuration parameters, including but not limited to the following:

- IP address range: indicates the range of IP addresses that are available.
- Gateway address: A maximum of eight gateway addresses are supported.
- DNS address: A maximum of eight DNS addresses are supported.
- Lease: Based on the lease, the device notifies clients of IP address aging and lease renewal request.

VRRP Monitoring

In a Virtual Router Redundancy Protocol (VRRP) scenario, Ruijie devices enabled with DHCP provide a command to monitor the VRRP status of the interface. For an interface configured with the VRRP address and VRRP monitoring, the DHCP server only processes the DHCP clients' Request packets from a interface of the device in Master state, and discards packets from an interface of the device in backup state. If no VRRP address is configured, the DHCP server does not monitor the VRRP status, and all DHCP Request packets are processed. VRRP monitoring is configured on only Layer 3 interfaces. It is disabled by default, namely, only the master device processes the DHCP service.

IP Address Assignment Based on VLANs, Interfaces, and IP Address Ranges

After an IP address pool is deployed, the specified IP address range is assigned based on VLANs and interfaces. There are three scenarios:

1 Global configuration

2 Configuration based on VLANs, interfaces, and IP address ranges

3 Both scenarios 1 and 2: In scenario 1, addresses are assigned globally. In scenario 2, addresses in the specified IP address range are assigned only to clients of the specified VLANs and interfaces. In scenario 3, clients of the

specified VLANs and interfaces are assigned addresses in the specified IP address range, and other clients are configured with default global addresses.

Adding Trusted ARP

Trusted ARP prevents gateway-targeted ARP spoofing. Ruijie devices enabled with DHCP provide a command for delivering trusted ARP while assigning an address. After this function is enabled, the DHCP server delivers trusted ARP while assigning an IP address to the client to prevent ARP spoofing.

ARP-based Logout Detection

Ruijie devices enabled with DHCP provide a command to enable ARP-based logout detection. With this function enabled, a DHCP server will receive an ARP aging notification when a client gets offline, and start retrieving the client's address. If the client does not get online within a period of time (5 minutes by default), the DHCP server will retrieve the address and assign it to another client. If the client gets online again, the address is still valid.

Adding Bogus Server Detection

If a private DHCP server is deployed, a client interacts with this server while requesting an IP address and an incorrect address will be assigned to the client. This server is a bogus server. Ruijie devices enabled with DHCP provides a command to enable bogus server detection. After bogus server detection is enabled, the device will check whether DHCP packets carry Option 54 (Server Identifier Option). If the content of Option 54 is different from the actual DHCP server identifier, the IP address of the bogus server and interface receiving the packets will be recorded. Bogus server detection is only an after-event security function and cannot prevent an authorized DHCP server from assigning IP addresses to clients.

Preferentially Assigning the DNS Address Obtained from an External DHCP Server

When some interfaces on a device work in PPPoE or DHCP client mode, the interfaces can automatically obtain a DNS address from an external DHCP server and the address is configured on the local DHCP server. This eliminates the need to perform DNS configuration. When a device serves as the DHCP server, the device preferentially assigns STAs with the DNS address obtained from an external DHCP server.

ARP Check

The ARP check function is a supplement to the ping conflict detection function. If there is a STA with a static IP address is isolated at Layer 2 and the ping conflict detection function becomes ineffective (for example, the firewall is enabled on the STA), a STA that applies for a dynamic address may be assigned with this IP address, resulting in an IP address conflict. If the ARP check function is enabled, the device queries its ARP entries after detecting ping conflicts of assigned IP addresses. If an ARP entry exists for the IP address to be assigned and the ARP entry is different from the MAC address of the STA for which the IP address is to be assigned, the device considers that this IP address has been occupied and will not assign it to another STA.

If there are ARP attacks, you are advised to disable the ARP check function. Otherwise, the DHCP assignment service is affected. As a result, it takes a long time for a STA to apply for an IP address or the STA fails to apply for an IP address.

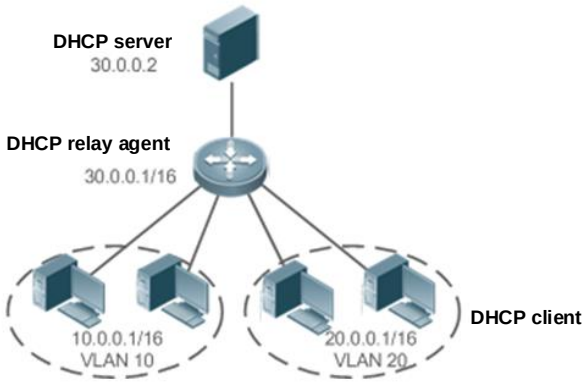
Related Configuration

Enabling the DHCP Server Globally

- By default, the DHCP server is disabled.

- Run the **service dhcp** command to enable the DHCP server.
- Run the **service dhcp** command globally to enable DHCP.

Configuring an Address Pool



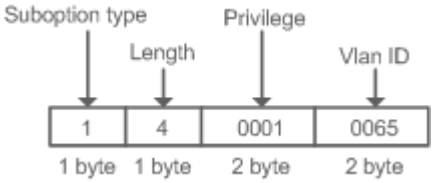
- By default, no address pool is configured.
- Run the **ip dhcp pool** command to configure an IP address range, a gateway address, and a DNS address.
- If no address pool is configured, no address will be assigned.

1.3.2 DHCP Relay Agent

Working Principle

The destination IP address of DHCP Request packets is 255.255.255.255, and these packets are forwarded within a subnet. To achieve IP address assignment across network segments, a DHCP relay agent is required. The DHCP relay agent unicasts DHCP Request packets to a DHCP server and forwards DHCP Reply packets to a DCHP client. The DHCP relay agent serves as a repeater connecting a DHCP client and a DHCP server of different network segments by forwarding DHCP Request packets and DHCP Reply packets. This model achieves management of IP addresses across multiple network segments by only one DHCP server.

Figure 1-11 DHCP Relay Agent Scenario



VLAN 10 and VLAN 20 correspond to segments 10.0.0.1/16 and 20.0.0.1/16 respectively. A DHCP server at 30.0.0.2 is on the network segment 30.0.0.1/16. To achieve management of dynamic IP addresses in VLAN 10 and VLAN 20 by the DHCP server, you only need to enable the DHCP relay agent on a gateway and configure IP address 30.0.0.2 for the DHCP server.

DHCP Relay Agent Information (Option 82)

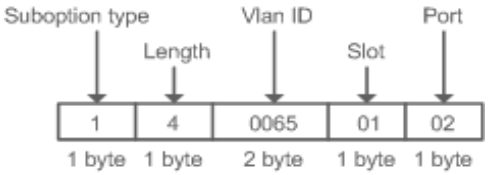
As defined in RFC 3046, Option 82 can be added to indicate a DHCP client's network information when the DHCP relay agent is deployed, so that a DHCP server may assign IP addresses of various privileges based on more accurate information. The device supports the following schemes of relay agent information:

1 Relay agent information option dot1x: This scheme should be implemented with 802.1X authentication and an authentication server. A DHCP relay agent constructs the Circuit ID sub-option based on the IP privilege delivered during 802.1X authentication and the VID of a DHCP client. See Figure 1-12.

Figure 1-12 Option Format

2 Relay agent information option82: This scheme is used without correlation with other protocol modules. A DHCP relay agent forms an Option 82 based on the physical port receiving DHCP Request packets and the MAC address of the device. The option format is shown in Figure 1-13.

Figure 1-13 Agent Circuit ID



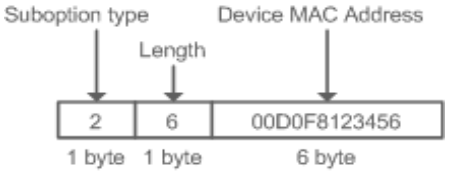


Figure 1-14 Agent Remote ID

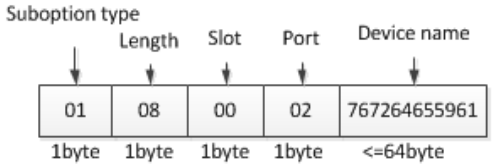
3 Relay agent information Option 82: This scheme is used without correlation with other protocol modules. Compared with previous Option 82, the option supports the custom content, which may change. By default, a DHCP relay agent forms Option 82 based on the physical interface receiving DHCP packets, and device's MAC address and name. The option format is shown in Figure 1-15.

Figure 1-15 Option 82-circuit-id



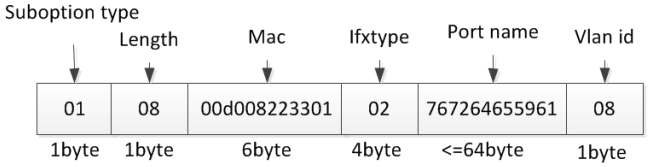


Figure 1-16 Option 82-remote-id

Server ID Check by the DHCP Relay Agent

- In DHCP scenarios, multiple DHCP servers are deployed for a network, achieving server backup to ensure uninterrupted network operation. After this function is enabled, the DHCP Request packet sent by a client contains

the **server-id** option specifying a DHCP server. To alleviate the burden on servers in specific environments, you need to enable this function on a relay agent to send a packet to a specified DHCP server but not all DHCP servers.

Related Configuration

Enabling the DHCP Relay Agent

- By default, the DHCP relay agent is disabled.
- Run the **service dhcp** command to enable the DHCP relay agent.
- You must enable the DHCP relay agent before it works.

Configuring an IP Address for the DHCP Server

- By default, no IP address is configured for a DHCP server.
- You may run the **ip helper-address** command to configure an IP address for a DHCP server. The IP address can be configured globally or on a Layer 3 interface. A maximum of 20 DHCP server addresses can be globally configured or configured on each Layer 3 interface.
- When an interface receives a DHCP Request packet, the DHCP server list on the interface takes effect first. If the interface is not configured with a DHCP server list, the global DHCP server list takes effect.

Enabling DHCP Option 82

- By default, DHCP Option 82 is disabled.
- Run the **ip dhcp relay information option82** command to enable DHCP Option82.

Enabling Server ID Check by the DHCP Relay Agent

- By default, server ID check by the DHCP relay agent is disabled.
- Run the **ip dhcp relay check server-id** command to enable server ID check by the DHCP relay agent.

Forcing a DHCP Relay Agent to Send Reply Packets

- By default, a DHCP relay agent is not forced to send Reply packets.
- Run the **ip dhcp relay force-send-reply-pack** command to force a DHCP relay agent to send Reply packets.

1.3.3 DHCP Client

Working Principle

A DHCP client broadcasts a DHCP Discover packet after entering the Init state. Then it may receive multiple DHCP Offer packets. It chooses one of them and responds to the corresponding DHCP server. Then it sends lease renewal request packets in the Renew and Rebind processes of an aging period to request lease renewal.

Related Configuration

Enabling the DHCP Client on an Interface

- By default, the DHCP client is disabled.
- Run the **ip address dhcp** command in interface configuration mode to enable the DHCP client.

- You need to enable the DHCP client before enabling the DHCP service.
- The configuration takes effect on a Layer 3 interface, for example, an SVI or a routed interface.

Defining Common Option Fields on Interfaces

- In interface configuration mode, run the **ip dhcp client class-id** command to define the Option 61 field in Request packets.
- In interface configuration mode, run the **ip dhcp client client-id** command to define the Option 60 field in Request packets.
- In interface configuration mode, run the **ip dhcp client hostname** command to define the Option 12 field in Request packets.
- In interface configuration mode, run the **ip dhcp client lease** command to define the Option 51 field in Request packets.
- In interface configuration mode, run the **ip dhcp client option-list** command to define the Option 55 field in Request packets.
- The configuration takes effect on a layer 3 interface only, for example, an SVI or a routed interface.

Releasing and Renewing a DHCP Lease

- In privilege EXEC configuration mode, run the **release-dhcp** command to release a DHCP lease.
- In privilege EXEC configuration mode, run the **renew-dhcp** command to renew a DHCP lease.

1.3.4 AM Rule

Working Principle

An AM rule defines the range of IP addresses assigned to DHCP clients based on VLANs and interfaces. It can be used to quickly identify the VLAN and interface of a faulty DHCP client and effectively assign addresses. After an AM rule is configured, all DHCP clients from the configured VLAN and interfaces may obtain IP addresses. If no AM rule is configured but a default AM rule is configured, the client obtains an IP address from the default range. If no AM rule or default AM rule is configured, the client cannot obtain an IP address.

Related Configuration

Configuring an AM Rule in Global Configuration Mode

- In global configuration mode, run the **address-manage** command to enter the AM rule configuration mode.
- Run the **match ip default** command to configure a default AM rule.
- Run the **match ip** command to configure an AM rule based on VLANs and interfaces or interfaces.

1.3.5 Class Rule

Working Principle

When STAs apply for IP addresses from different APs, Option 82 information carried by the STAs is different. Class rules are used to match Option 82 information to assign IP addresses on different network segments to STAs.

Related Configuration

Configuring Class Rules in Global Configuration Mode

- Run the **ip dhcp class** command to add class rules.
- Run the **relay agent information** command to enter the Option 82 configuration mode.
- Run the **relay-information hex** command to configure the matched Option 82 content.

Associating Configured Class Rules in Address Pool Configuration Mode

- Run the **class** command to associate class rules.
- Run the **address range** command to configure assigned IP address segments after class rules are matched.

1.4 Configuration

Configuring the DHCP Server

Configuration	Description and Command	
Configuring the DHCP Server to Dynamically Allocating IP Address	(Mandatory) It is used to enable the DHCP server to achieve dynamic IP address assignment.	
	service dhcp	Enables the DHCP server.
	ip dhcp pool	Configures an address pool.
	network	Configures the network number and subnet mask of a DHCP address pool.
	(Optional) It is used to configure properties of an address pool.	
	default-router	Configures a default gateway of a client.
	lease	Configures an address lease.
	next-server	Configures a TFTP server address.
	bootfile	Configures a boot file of a client.
	domain-name	Configures a domain name of a client.
	dns-server	Configures a domain name server.
	netbios-name-server	Configures a NetBIOS WINS server.
	netbios-node-type	Configures a NetBIOS node type on a client.
	lease-threshold	Configures an alarm threshold of an address pool.
	option	Configures a user-defined option.
	pool-status	Enables or disables an address pool.
	update arp	Adds trusted ARP while assigning addresses from a pool.
	force-no-router	Configures a user-defined option.
	manage-address-pool	Enables or disables an address pool.
	user-address-pool	Cancels gateway allocation to the client.
	class	Configure class rules to be matched.

Configuration	Description and Command	
	address range	Configures assigned IP network segments after class rules are matched.
Configuring a Static IP Address	⚠ (Optional) It is used to statically assign an IP address to a client.	
	ip dhcp pool	Configures an address pool name and enters address pool configuration mode.
	host	Configures the IP address and subnet mask of a client host.
	hardware-address	Configures a client hardware address.
	client-identifier	Configures a unique client identifier.
	client-name	Configures a client name.
Configuring Global Properties of the DHCP Server	⚠ (Optional) It is used to configure properties of a DHCP server.	
	ip dhcp excluded-address	Configures an excluded IP address.
	ip dhcp force-send-nak	Configures the DHCP server to forcibly send an NAK packet.
	ip dhcp monitor-vrrp-state	Configures VRRP monitoring.
	ip dhcp ping packets	Configures the ping count.
	ip dhcp ping timeout	Configures a ping timeout.
	ip dhcp refresh arp	Configures the DHCP server to refresh trusted ARP entries.
	ip dhcp server detect	Configures bogus server detection.
Configuring AM Rules for the DHCP Server	⚠ (Optional) It is used to configure the AM rule of a DHCP server.	
	match ip default	Configures a default AM rule based on the VLAN and interface.
	match ip ip-address	Configures an AM rule based on the VLAN and interface.

Configuring the DHCP Relay Agent

Configuration	Description and Command	
Configuring Basic DHCP Relay Functions	⚠ (Mandatory) It is used to enable the DHCP relay agent.	
	service dhcp	Enables the DHCP relay agent.
	ip helper-address	Configures an IP address of a DHCP server.
Configuring DHCP Relay Option 82	⚠ (Optional) It is used to assign IP addresses of different privileges to clients in combination with the information of a physical interface. This function cannot be used with the **dhcp option dot1x** command.	

Configuration	Description and Command	
	ip dhcp relay information option82	Enables DHCP Option 82.
Configuring Server ID Check by the DHCP Relay Agent	⚠ (Optional) It is used to enable a DHCP relay agent to send DHCP Request packets only to a specified server.	
	ip dhcp relay check server-id	Enables a DHCP relay agent to send DHCP Request packets only to a specified server
Specifying the Source Address for DHCP Relay Packets	⚠ (Optional) It is used to specify a source address for DHCP relay packets.	
	ip dhcp relay source	Sspecifies a source address for DHCP relay packets.

Configuring the DHCP Client

Configuration	Description and Command	
Configuring the DHCP Client	⚠ (Mandatory) It is used to enable the DHCP client.	
	ip address dhcp	Enables an Ethernet interface, a PPP/HDLC-encapsulated or FR-encapsulated interface to obtain IP addresses through DHCP.
Defining Fields in Request Packets on Interfaces	⚠ (Optional) It is used to define common option fields to configure the DHCP client function.	
	ip dhcp client class-id	Defines information in **class id**.
	ip dhcp client client-id	Defines information in **client id**.
	ip dhcp client hostname	Defines information in **hostname**.
	ip dhcp client lease	Defines information in **lease**.
	ip dhcp client option-list include	Defines information in **option-list**.
Releasing and Renewing the DHCP Lease	⚠ (Optional) It is used to define common option fields to configure the DHCP client function.	
	release-dhcp	Enables a DHCP client to release IP addresses.
	renew-dhcp	Enables a DHCP client to renew IP addresses.

Configuring Class Rules

Configuration	Description and Command	
Configuring Class Rules of the DHCP Server	⚠ (Optional) It is used to configure class rules.	
	ip dhcp class	Configures global class rules.
	ip dhcp use class	Configures address assignment based on class rules.

	relay agent information	Enters the Option 82 configuration mode.

1.4.1 Configuring the DHCP Server to Dynamically Allocating IP Addresses

Configuration Effect

The DHCP server provides all DHCP clients with DHCP service including assigning IP addresses and gateways.

Notes

The **service dhcp** command can be used to enable the DHCP server or DHCP relay agent, but a device cannot function both as a DHCP server and relay agent. When a device is configured with a valid address pool, it acts as a server and forwards packets. Otherwise, it serves as a relay agent.

Configuration Step

↘ Enabling the DHCP Server

- Mandatory.
- It achieves dynamic IP address assignment.
- Run the **service dhcp** command in global configuration mode.

↘ Configuring an Address Pool

- Mandatory.
- It is used to create an IP address pool.
- Run the **ip dhcp pool** command in global configuration mode.

↘ Configuring the Network Number and Subnet Mask of the Address Pool

- Mandatory.
- It defines a range of dynamically assigned addresses.
- Run the **network** command in DHCP address pool configuration mode.

↘ Configuring the Default Gateway Address of Clients

- Optional.
- It is used to configure a gateway address.
- Run the **default-router** command in DHCP address pool configuration mode.

↘ Configuring the Address Lease

- Optional.
- It is used to configure an IP address lease, which is 24 hours by default.
- Run the **lease** command in DHCP address pool configuration mode.

↘ Configuring the TFTP Server Address

- Optional.

- It is used to configure a TFTP server address.
- Run the **next-server** command in DHCP address pool configuration mode.

Configuring the Domain Name of Clients

- Optional.
- It is used to configure the domain name of a client.
- Run the **domain-name** command in DHCP address pool configuration mode.

Configuring the DNS Address

- Optional.
- It is used to configure a DNS address.
- Run the **dns** command in DHCP address pool configuration mode.

Configuring the NetBIOS WINS Server Address

- Optional.
- It is used to configure a NetBIOS WINS server address.
- Run the **netbios-name-server** command in DHCP address pool configuration mode.

Configuring the NetBIOS Node Type of Clients

- Optional.
- It is used to configure a NetBIOS node type.
- Run the **netbios-name-type** command in DHCP address pool configuration mode.

Configuring the Alarm Threshold of the Address Pool

- Optional.
- It is used to manage the number of leases. When a threshold (90% by default) is reached, an alarm will be generated.
- Run the **lease-threshold** command in DHCP address pool configuration mode.

Configuring the User-defined Option

- Optional.
- It is used to configure user-defined options.
- Run the **option** command in DHCP address pool configuration mode.

Enabling or Disabling the Address Pool

- Optional.
- It is used to enable or disable an address pool. It is enabled by default.
- Run the **pool-status** command in DHCP address pool configuration mode.

Adding Trusted ARP

- Optional.
- It is used to add trusted ARP during IP address assignment. It is disabled by default.
- Run the **update arp** command in DHCP address pool configuration mode.

Refraining from Assigning the Gateway Address

- Optional. It is used to refrain from assigning a gateway address during IP address assignment. It is disabled by default.
- Run the **force-no-router** command in DHCP address pool configuration mode.

Configuring an Address Pool Type

- It is used to identify the types of address pools, including management and user address pools.
- Run the **manage-address-pool** or **user-address-pool** command in address pool configuration mode.

Verification

Connect a DHCP client to a DHCP server.

- Check whether the client obtains configurations of the server.

Related Commands

Enabling the DHCP Server

Command	**service dhcp**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Enable the DHCP server or DHCP relay agent. When a device is configured with a valid address pool, it acts as a server and forwards packets. Otherwise, it serves as a relay agent.

Configuring an Address Pool

Command	**ip dhcp pool** *dhcp-pool*
Parameter Description	*pool-name*: Indicates the name of an address pool.
Command Mode	Global configuration mode
Usage Guide	Before assigning an IP address to a client, you need to configure an address pool name and enter the DHCP address pool configuration mode.

Configuring the Network Number and Subnet Mask of the Address Pool

Command	**network** *network-number mask* [*low-ip-address high-ip-address*]
Parameter Description	*network-number:* Indicates the network number of an IP address pool. *mask:* Indicates the subnet mask of an IP address pool. If no subnet mask is defined, the natural subnet mask is applied.
Command	DHCP address pool configuration mode

Mode	
Usage Guide	To configure dynamic address assignment, you need to configure a network number and subnet mask of an address pool to provide a DHCP server with a range of addresses. The IP addresses in a pool are assigned in order. If an address is assigned or exists on the target network segment, the next address will be checked until a valid address is assigned. The device provides available network segments by specifying start and end addresses. The configuration is optional. If the start and end address are not specified, all IP addresses on the network segment are assignable. Addresses are assigned based on the client's physical address and ID. Therefore, one client will not be assigned two leases from one address pool. If a client can connect to a server through a direct path or intermediate path, addresses may fail to be assigned. To avoid such failures, a network administrator needs to prevent path redundancy in network construction, for example, by adjusting physical links or network paths.

Configuring the Default Gateway Address of Clients

Command	**default-router** *address* [*address2…address8*]
Parameter Description	*address*: Indicates the IP address of a default gateway. Configure at least one IP address. *ip-address2…ip-address8:* A maximum of 8 gateways can be configured. This parameter is optional.
Command Mode	DHCP address pool configuration mode
Usage Guide	Configure the address of a default gateway for a client, and a server will push the gateway configuration to the client. The IP addresses of the default gateway and the client should be on the same network segment.

Configuring the Address Lease

Command	**lease** {*days* [*hours]* [*minutes*] | **infinite**}
Parameter Description	*days:* Defines a lease in the unit of days. *hours:* Defines a lease in the unit of hours, which is optional. You must define *days* before specifying *hours*. *minutes:* Defines a lease in the unit of minutes, which is optional. You must define *days* and *hours* before specifying *minutes*. **infinite:** Defines an unlimited lease.
Command Mode	DHCP address pool configuration mode
Usage Guide	The default lease of an IP address assigned by a DHCP server is 1 day. When a lease is expiring soon, a client needs to request lease renewal. Otherwise, the IP address cannot be used after the lease is expired.

Configuring the Boot Server Address for Clients

Command	**next-server** *ip-address* [*ip-address2…ip-address8*]
Parameter Description	*ip-address*:Defines the IP address of a boot server, typically a TFTP server. You need to configure at least one boot server. *ip-address2…ip-address8*: Indicates IP addresses of boot servers, which is optional. You can configure up to eight boot servers.

Command Mode	DHCP address pool configuration mode
Usage Guide	Run this command to configure servers. When multiple boot servers are defined, the first defined boot server has the highest priority. A DHCP client selects the next boot server only when it fails to communicate with the first defined boot server.

Configures the Boot File on Clients

Command	**bootfile** *filename*
Parameter Description	*file-name*: Defines a boot file name.
Command Mode	DHCP address pool configuration mode
Usage Guide	A boot file is an image file used when a client starts up. The file is usually an OS downloaded by a DHCP client.

Configuring the Domain Name of Clients

Command	**domain-name** *domain*
Parameter Description	*domain-name:* Defines a domain name of a DHCP client.
Command Mode	DHCP address pool configuration mode
Usage Guide	You can define a domain name for a client. When the client accesses network through the host name, the domain name will be added automatically to complete the host name.

Configuring the DNS Address

Command	**dns-server** { *ip-address* [*ip-address2…ip-address8*] | **use-dhcp-client** *interface-type interface-number* }
Parameter Description	*ip-address:* Defines an IP address of a DNS server. You must configure at least one IP address. *ip-address2…ip-address8:* A maximum of eight DNS server addreses can be configured. This parameter is optional. **use-dhcp-client** *interface-type interface-number:* A DHCP client learns its DNS server through RGOS software.
Command Mode	DHCP address pool configuration mode
Usage Guide	If a client accesses network resources through the domain name, you need to configure a DNS server to resolve the domain name.

Configuring the NetBIOS WINS Server Address

Command	**netbios-name-server** *address* [*address2…address8*]
Parameter Description	*address:* Defines an IP address of a WINS server. You must configure at least one IP address. *ip-address2…ip-address8:* A maximum of eight WINS server addresses can be configured. This parameter is optional.
Command Mode	DHCP address pool configuration mode

Usage Guide	WINS is a domain name service through which a Microsoft TCP/IP network resolves a NetBIOS name to an IP address. A WINS server is a Windows NT server. When a WINS server starts, it receives a registration request from a WINS client. When the client shuts down, it sends a name release message, so that computers in the WINS database and on the network are consistent.

Configuring the NetBIOS Node Type of Clients

Command	**netbios-node-type** *type*
Parameter Description	type: Defines a NetBIOS node type with one of the following approaches. 1. A hexadecimal number, ranging from 0 to FF. The followings values are available. ● 1 for b-node ● 2 for p-node ● 4 for m-node ● 8 for h-node 2. A character string: ● b-node for a broadcast node ● p-node for a peer-to-peer node ● m-node for a mixed node ● h-node for a hybrid mode
Command Mode	DHCP address pool configuration mode
Usage Guide	There are four types of NetBIOS nodes of a Microsoft DHCP client: ● Broadcast node: For such a node, the NetBIOS name is resolved through broadcast. ● Peer-to-peer node: The client sends a resolution request to the WINS server. ● Mixed node: The client broadcasts a resolution request and sends the resolution request to the WINS server. ● Hybrid node: The client sends a resolution request to the WINS server. If no reply is received, the client will broadcast the resolution request. By default, a Microsoft operating system is a broadcast or hybrid node. If no WINS server is configured, it is a broadcast node. Otherwise, it is a hybrid node.

Configuring the Alarm Threshold of the Address Pool

Command	**lease-threshold** *percentage*
Parameter Description	*percentage*: Defines the alarm threshold of an address pool, in percentage. The value range is from 60 to 100.
Command Mode	DHCP address pool configuration mode
Usage Guide	Run this command to configure the alarm threshold of an address pool. When the IP address usage of an address pool reaches the threshold, a DHCP server generates syslog alarms. The IP address usage is the ratio of assigned IP addresses to available IP addresses in an address pool. If the number of assigned IP addresses exceeds the alarm threshold, one alarm is generated every 5 minutes.

Configuring User-Defined Options

Command	**option** *code* { **ascii** *string* | **hex** *string* | **ip** *ip-address* }

Parameter Description	*code:* Defines a DHCP option code. **ascii** *string:* Defines an ASCII character string. **hex** *string:* Defines a hexadecimal character string. **ip** *ip-address:* Defines an IP address.
Command Mode	DHCP address pool configuration mode
Usage Guide	DHCP allows the configuration to be transmitted to a host through a TCP/IP network. DHCP packets contain the option field of definable content. A DHCP client should be able to receive a DHCP packet carrying at least 312 bytes option. Besides, the fixed data field in a DHCP packet is also called an option. In a WLAN, a DHCP client on an AP dynamically requests the IP address of an AC. You may configure on a DHCP server the **option** command specifying the AC address.

Enabling or Disabling the Address Pool

Command	**pool-status** {**enable	disable**}
Parameter Description	**enable***:* Enables an address pool. **disable***:* Disable an address pool. It is enabled by default.
Command Mode	DHCP address pool configuration mode
Usage Guide	The device provides a command for you to enable or disable a DHCP address pool.

Adding Trusted ARP

Command	**update arp**
Parameter Description	N/A
Command Mode	DHCP address pool configuration mode
Usage Guide	Trusted ARP is added when an address is assigned from a pool. Trusted ARP prevents ARP spoofing.

Refraining from Assigning the Gateway Address

Command	**force-no-router**
Parameter Description	N/A
Command Mode	DHCP address pool configuration mode
Usage Guide	If a client requests an IP address and a gateway address, a DHCP server assigns an IP address and a gateway address to the client. Then no gateway address is sent to the client.

Configuring an Address Pool Type

Command	**manage-address-pool**
Parameter	N/A

Description	
Command Mode	DHCP address pool configuration mode
Usage Guide	Configure the address pool as a management address pool.

Command	**user-address-pool**
Parameter Description	N/A
Command Mode	DHCP address pool configuration mode
Usage Guide	Configure the address pool as a user address pool.

Configuration Example

Configuring Address Pool

Configuration Steps	• Define an address pool **net172**. • The network segment is 172.16.1.0/24. • The default gateway address is 172.16.1.254. • The address lease is 1 day. • Excluded addresses range from 172.16.1.2 to 172.16.1.100.

	`Hostname(config)# ip dhcp excluded-address 172.16.1.2 172.16.1.100`
	`Hostname(dhcp-config)# ip dhcp pool net172`
	`Hostname(dhcp-config)# network 172.16.1.0 255.255.255.0`
	`Hostname(dhcp-config)# default-router 172.16.1.254`
	`Hostname(dhcp-config)# lease 1`

Verification	• Run the **show running-config** command to display the configuration.

	`Hostname#show running-config | begin ip dhcp`
	`ip dhcp excluded-address 172.16.1.2 172.16.1.100`
	`ip dhcp pool net172`
	`network 172.16.1.0 255.255.255.0default-router 172.16.1.254`
	`lease 1`

1.4.2 Configuring a Static IP Address

Configuration Effect

Assign specific IP addresses and push the configuration to specific DHCP clients.

Notes

N/A

Configuration Step (A)

Configuring the Address Pool Name and Entering the Address Pool Configuration Mode

- Mandatory.

- It is used to create an IP address pool.
- Run the **ip dhcp pool** command in global configuration mode.

Configuring the IP Address and Subnet Mask of Clients

- Mandatory.
- It is used to configure a static IP address and a subnet mask.
- Run the **host** command in DHCP address pool configuration mode.

Configuring the Hardware Address of Clients

- Optional.
- It is used to configure a MAC address.
- Run the **hardware** command in DHCP address pool configuration mode.

Configures the UID

- Optional.
- It is used to configure a static user identifier (UID).
- Run the **client-identifier** command in DHCP address pool configuration mode.

Configuring the Client Name

- Optional.
- It is used to configure a static client name.
- Run the **host-name** command in DHCP address pool configuration mode.

Verification

Check whether the client obtains the IP address when it is online.

Related Commands

Configuring an Address Pool

Command	**ip dhcp pool** *dhcp-pool*
Parameter Description	*pool-name*: Indicates the name of an address pool.
Command Mode	Global configuration mode
Usage Guide	Before assigning an IP address to a client, you need to configure an address pool name and enter the address pool configuration mode.

Configuring Manual IP Address Binding

Command	**host** *ip-address* [*netmask*] **client-identifier** *unique-identifier* **client-name** *name*
Parameter	*ip-address:* Defines the IP address of a DHCP client.

Description	*netmask:* Defines the subnet mask of a DHCP client. *unique-identifier:* Defines the hardware address (for example, aabb.bbbb.bb88) and identifier (for example, 01aa.bbbb.bbbb.88) of a DHCP client. *name*: Defines a client name using ASCII characters, which is optional. The name excludes a domain name. For example, name a host **mary** but not **mary.rg.com**.
Command Mode	DHCP address pool configuration mode
Usage Guide	Address binding means mapping between an IP address and a client's MAC address. There are two types of address binding: ● Manual binding: Manual binding involves manually defining static mappings of IP addresses and MAC addresses in the DHCP server database. Manual binding functions as a special address pool. ● Dynamic binding: A DHCP server dynamically assigns an IP address from a pool to a client when it receives a DHCP Request packet, creating mapping between an IP address and the client's MAC address. To configure manual binding, you need to define a host address pool and then specify a DHCP client's IP address and hardware address or identifier. A hardware address is a MAC address. A client identifier includes a network medium type and a MAC address. A Microsoft client is usually identified by a client identifier but not a MAC address. For the codes of medium types, refer to *Address Resolution Protocol Parameters* in RFC 1700. The Ethernet type is 01.

Configuring Client Hardware Addresses

Command	**hardware-address** *hardware-address* [*type*]
Parameter Description	*hardware*-address: Indicates the MAC address of a DHCP client. *type*: Identifies the hardware platform protocol of a DHCP client. The value can be a character string or numeral. Character string options: ● ethernet ● ieee802 Numeral options: ● 1 (10 M ethernet) ● 6 (IEEE 802)
Command Mode	DHCP address pool configuration mode
Usage Guide	Run this command to configure servers. This command can be used only when you assign a static IP addresses manually.

Configuration Example

Dynamic IP Address Pool

Configuration Steps	● Configure address pool **vlan 1** with IP address 20.1.1.0 and subnet mask 255.255.255.0. ● The default gateway address is 20.1.1.1. ● The lease is 1 day.
	`Hostname(config)# ip dhcp pool vlan1`

	Hostname(dhcp-config)# network 20.1.1.0 255.255.255.0 Hostname(dhcp-config)# default-router 20.1.1.1 Hostname(dhcp-config)# lease 1 0 0
Verification	● Run the **show running-config** command to display the configuration.
	Hostname(config)#show running-config | begin ip dhcp ip dhcp pool vlan1 network 20.1.1.0 255.255.255.0 default-router 20.1.1.1 lease 1 0 0

Manual Binding

Configuration Steps	● The host address is 172.16.1.101 and the subnet mask is 255.255.255.0. ● The host name is Billy.rg.com. ● The default gateway address is 172.16.1.254. ● The MAC address is 00d0.df34.32a3.
	Hostname(config)# ip dhcp pool Billy Hostname(dhcp-config)# host 172.16.1.101 255.255.255.0 Hostname(dhcp-config)# client-name Billy Hostname(dhcp-config)# hardware-address 00d0.df34.32a3 Ethernet Hostname(dhcp-config)# default-router 172.16.1.254
Verification	● Run the **show running-config** command to display the configuration.
	Hostname#show running-config | begin ip dhcp ip dhcp pool Billy host 172.16.1.101 255.255.255.0 client-name Billy hardware-address 00d0.df34.32a3 Ethernet default-router 172.16.1.254

Configuration Step (B)

Configuring an Address Pool Name and Entering the Address Pool Configuration Mode

- Mandatory.
- It is used to create an IP address pool.
- Run the **ip dhcp pool** command in address pool configuration mode.

Verification

- Check whether the client obtains the IP address when it is online.

Related Commands

Configuring an Address Pool

Command	**ip dhcp pool** *dhcp-pool*
Parameter Description	*pool-name*: Indicates the name of an address pool.
Command	Global configuration mode

Mode	
Usage Guide	Before assigning an IP address to a client, you need to configure an address pool name and enter the address pool configuration mode.

1.4.3 Configuring Global Properties of the DHCP Server

Configuration Effect

Enable a server with specific functions, for example, ping and forcible NAK response.

Notes

Configuring the command may cause exceptions on other servers.

Configuration Step

Configuring Excluded IP Address

- Optional.
- Configure some addresses or address ranges as unavailable.
- Run the **ip dhcp excluded-address** command in global configuration mode.

Configuring Compulsory NAK Reply

- Optional.
- A server replies to an invalid address request with an NAK packet.
- Run the **ip dhcp force-send-nak** command in global configuration mode.

Configuring VRRP Status Monitoring

- Optional.
- When this function is configured, DHCP packets are processed by the master server.
- Run the **ip dhcp monitor-vrrp-state** command in global configuration mode.

Configuring the Ping Count

- Optional.
- Check address reachability with the **ping** command. The default value is 2.
- Run the **ip dhcp ping packet** command in global configuration mode.

Configuring Ping Timeout

- Optional.
- Check address reachability with the **ping** command. The default value is 500 ms.
- Run the **ip dhcp ping timeout** command in global configuration mode.

Refreshing Trusted ARP

- Configure a DHCP server to refresh trusted ARP entries according to the addresses assigned from an address pool configured with the **update arp** command.

- Run the **ip dhcp refresh arp** command in global configuration mode.

Configuring Bogus Server Detection

- Optional.
- Enable this function to log a bogus server.
- Run the **ip dhcp server detect** command in global configuration mode.

Verification

Run the **dhcp-server** command, and check the configuration during address assignment.

Related Commands

Configuring an Excluded IP Address

Command	**ip dhcp excluded-address** *low-ip-address* [*high-ip-address*]
Parameter Description	*low-ip-address:* Indicates the start IP address. *high-ip-address:* Indicates the end IP address.
Command Mode	Global configuration mode
Usage Guide	Unless otherwise specified, a DHCP server assigns all the addresses from an IP address pool to DHCP clients. To reserve some addresses (for example, addresses already assigned to the server or devices), you need to configure these addresses as excluded addresses. To configure a DHCP server, you are advised to configure excluded addresses to avoid address conflict and shorten detection time during address assignment.

Configuring Forcible NAK Response

Command	**ip dhcp force-send-nak**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	On a WLAN, a DHCP client often moves from one network to another. When a DHCP server receives a lease renewal request from a client but finds that the client is on a different network segment or that the lease is expired, it replies with a NAK packet to require the client to obtain an IP address again. This prevents the client from sending request packets continually before obtaining an IP address again after timeout. The server sends a NAK packet only when it finds the client's lease record. When a DHCP client is moved to another network, a DHCP server cannot find the lease record of the client and will not reply with a NAK packet. The client sends request packets continuously before obtaining an IP address again after timeout. Consequently, it takes a long time to obtain an IP address. This situation also occurs when a DHCP server loses a lease after restart and a client requests lease renewal. In this case, you may configure a command to force the DHCP server to reply with a NAK packet even though it cannot find the lease record so that the client may obtain an IP address rapidly. Note that the command is disabled by default. If this function is enabled, only one DHCP server can be configured in a broadcast domain.

Configuring the Ping Count

Command	**ip dhcp ping packets** [*number*]
Parameter Description	*Number*: Indicates the ping count. The value range is from 0 to 10. The value 0 indicates the ping function is disabled. The default value is 2. This parameter is optional.
Command Mode	Global configuration mode
Usage Guide	By default, when a DHCP server assigns an IP address from a pool, it runs the **ping** command twice (one packet per time). If there is no response, the server considers the address as idle and assigns it to a client. If there is a response, the server considers the address as occupied and assigns another address.

Configuring the Ping Timeout

Command	**ip dhcp ping timeout** *milliseconds*
Parameter Description	*milli-seconds:* Indicates the time that the DHCP server waits for a response to the ping operation, in milliseconds. The value range is from 100 to 10000.
Command Mode	Global configuration mode
Usage Guide	By default, if a DHCP server receives no response to the ping operation within 500 ms, the servers considers the IP address as available. You can run this command to change the time for a server to wait for a response.

Refreshing Trusted ARP Entries

Command	**ip dhcp refresh arp**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, if an address pool is configured with the **update arp** command, a DHCP server will refresh trusted ARP entris while assigning an IP address from the address pool. If a client clears the trusted ARP entries, the server will not reassign them. After this command is configured, a DHCP server may refresh trusted ARP entries according to addresses assigned from an address pool configured with **update arp**.

Configuring Bogus Server Detection

Command	**ip dhcp server detect**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, bogus server detection is disabled on a DHCP server. Run this command to enable bogus server detection.

Configuration Example

Configuring Ping Parameters

Configuration Steps	● Set the ping count to 5. ● Set the ping timeout to 800 ms.
	`Hostname(config)# ip dhcp ping packet 5` `Hostname(config)# ip dhcp ping timeout 800`
Verification	● Run the **show running-config** command to display the configuration.

	`Hostname#show running-config | begin ip dhcp`
	`ip dhcp ping packet 5`
	`ip dhcp ping timeout 800`

Configuring an Excluded IP Address

Configuration Steps	● Configure the excluded IP address from 192.168.0.0 to 192.168.255.255.
	`Hostname(config)# ip dhcp excluded-address 192.168.0.0 192.168.255.255`
Verification	● Run the **show running-config** command to display the configuration.
	`Hostname#show running-config | begin ip dhcp` `ip dhcp excluded-address 192.168.0.0 192.168.255.255`

1.4.4 Configuring AM Rules for the DHCP Server

Configuration Effect

Assign IP addresses according to an AM rules based on the interface and VLAN.

Notes

This function is supported on Ethernet interfaces, gigabit interfaces, as well as FR, PPP, and HDLC interfaces.

Configuration Step

Configuring Address Management

- Mandatory. Enter the address management mode.
- Run the **address-manage** command in address management configuration mode.

Configuring AM Rules

- Mandatory. Configure AM rules based on the port and VLAN.
- Run the **match ip** command in configuration mode.

Verification

Check whether clients in different VLANs and interfaces obtain valid IP addresses.

Related Commands

Configuring the Default Range

Command	**match ip default** *ip-address netmask*

Parameter Description	*ip-address:* Defines an IP address. *netmask:* Defines a subnet mask.
Command Mode	Address management mode
Usage Guide	After this command is configured, all DHCP clients without the VLAN and interface configured are assigned IP addresses from the default address range. If this command is not configured and no other VLAN or interface is configured, IP addresses are assigned according to the normal process.

Assigning Dynamic IP Address Based on the VLAN and Interface

Command	**match ip** *ip-address netmask interface-type interface-number* [**add** | **remove**] **vlan** *vlan-list*
Parameter Description	*ip-address:* Defines an IP address. *netmask:* Defines a subnet mask. *interface:* Defines an interface name. *add/remove:* Adds or deletes a specific VLAN. *vlan-list:* Indicates a VLAN index.
Command Mode	Address management mode
Usage Guide	After this command is configured, DHCP clients are assigned IP addresses from the default address range based on the VLAN and interface.

Assigning a Static IP Address Based on a VLAN

Command	**match ip** *ip-address netmask* [**add** | **remove**] **vlan** *vlan-list*
Parameter Description	*ip-address:* Defines an IP address. *netmask:* Defines a subnet mask. *add/remove:* Adds or deletes a specific VLAN. *vlan-list:* Indicates a VLAN index.
Command Mode	Address management mode
Usage Guide	In a super-VLAN, a client may be assigned a fixed static address regardless of the super-VLAN the client resides in. You do not need to configure an AM rule for this IP address based on all sub-VLANs and interfaces, but only configure an AM rule based on the VLAN. This rule takes effect for only static address assignment.

Configuration Example

Configuring an AM Rule

Configuration Steps	● Configure the default rule. ● Configure a rule based on a specific VLAN, interface, and address range. ● Configure a rule based on a specific VLAN and address range.

	`Hostname(config)# address-manage`
	`Hostname(config-address-manage)# match ip default 172.50.128.0 255.255.128.0`
	`Hostname(config-address-manage)# match ip 10.1.5.0 255.255.255.0 Gi5/3 vlan 1005`

	`Hostname(config-address-manage)# match ip 10.1.6.0 255.255.255.0 vlan 1006`
Verification	● Run the **show running-config** command to display the configuration.

	`Hostname# show running-config`
	`address-manage`
	`match ip default 172.50.128.0 255.255.128.0`
	`match ip 10.1.5.0 255.255.255.0 Gi5/3 vlan 1005`
	`match ip 10.1.6.0 255.255.255.0 vlan 1006`

1.4.5 Configuring Basic DHCP Relay Functions

Configuration Effect

- Deploy dynamic IP management in client–relay–server mode to achieve communication between a DHCP client and a DHCP server, which are located on different network segments.

Notes

- To enable the DHCP relay, you need to configure IPv4 unicast routing on a network.

Configuration Step

↘ Enabling the DHCP Relay

- Mandatory.
- Unless otherwise specified, you need to enable the DHCP relay on a device.

↘ Configuring an IP Address for the DHCP Server

- Mandatory.
- You need to configure an IP address for a DHCP server.

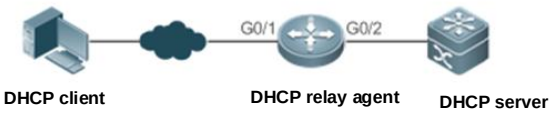
Verification

- Check whether a client obtains an IP address through the DHCP relay agent.

Related Commands

↘ Enabling the DHCP Relay

Command	**service dhcp**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A



↘ Configuring an IP Address for the DHCP Server

Command	**ip helper-address** { **cycle-mode** | *A.B.C.D* }
Parameter Description	*cycle-mode*: Indicates that DHCP Request packets are forwarded to all DHCP servers. *A.B.C.D*: Indicates the IP address of a server.

Command Mode	Global configuration mode, interface configuration mode.
Usage Guide	The configured interface must be a Layer 3 interface, such as a routed interface, SVI, and loopback interface. The configured interface must be reachable through IPv4 unicast routing.

Configuration Example

Configuring the DHCP Relay in Wired Connection Mode

Scenario Figure 1-17	
Configuration Steps	● Enable a client to obtain an IP address through DHCP. ● Enable the DHCP Relay function on a DHCP relay agent. ● Configure DHCP Server.
A	Enable a client to obtain an IP address through DHCP.

B	● Enable the DHCP relay.
	`Hostname(config)# service dhcp`
	● Configure a global IP address of a DHCP server.
	`Hostname(config)# ip helper-address 172.2.2.1`
	● Configure an IP address for the interface connected to the client.
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if)# ip address 192.1.1.1 255.255.255.0`
	● Configure an IP address for the interface connected to the server.
	`Hostname(config)# interface gigabitEthernet 0/2`
	`Hostname(config-if-gigabitEthernet 0/2)# ip address 172.2.2.2 255.255.255.0`

C	● Enable the DHCP server.
	`Hostname(config)# service dhcp`
	● Configure an address pool.
	`Hostname(config)# ip dhcp pool relay`
	`Ruijie (dhcp-config)#network 192.1.1.0 255.255.255.0`
	`Ruijie (dhcp-config)#default-router 192.1.1.1`
	● Configure an IP address for the interface connected to the relay agent.
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-gigabitEthernet 0/2)# ip address 172.2.2.1 255.255.255.0`

Verification	Check whether the client obtains an IP address. ● Check whether the client obtains an IP address. ● Check the DHCP relay configuration.
A	● The user device obtains an IP address.
B	● After loginning to the DHCP relay agent, run the **show running-config** command in privileged EXEC mode to display the DHCP relay configuration.

	Hostname# show running-config service dhcp ip helper-address 172.2.2.1 ! interface GigabitEthernet 0/1 ip address 192.1.1.1 255.255.255.0 ! interface GigabitEthernet 0/2 ip address 172.2.2.2 255.255.255.0 !

Common Errors

- The IPv4 unicast routing configuration is incorrect.
- The DHCP relay is disabled.
- No routing between DHCP relay agent and DHCP server is configured.
- No IP address is configured for the DHCP server.

1.4.6 Configuring DHCP Relay Option 82

Configuration Effect

- Through a DHCP relay agent, a server may assign IP addresses of different privileges to the clients more accurately based on option information.

Notes

- You need to enable the DHCP relay function.

Configuration Steps

Enabling Basic DHCP Relay Functions

- Mandatory.
- Unless otherwise specified, you need to enable the DHCP relay on a device.

Enables DHCP Option82

- By default, DHCP Option 82 is disabled.
- Run the **ip dhcp relay information option82** command to enable DHCP Option 82.

Verification

- Check whether the client obtains an IP address based on Option 82.

Related Commands

Enabling DHCP Option 82

Command	ip dhcp relay information option82

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When you configure the **ip dhcp relay information option82** command, the device acts as a DHCP relay agent. The device adds Option 82 to a DHCP Request packet to be forwarded to a DHCP server. The encapsulation format of **circuit-id** is slot(1):port(1):dev_name(<=64) and that of **remote-id** is user_mac(6):iftype(1):port_name(<=64):vid(2). The preceding three commands for adding Option 82 cannot be configured simultaneously, that is, only one command can take effect at a time. DHCP Option 82 is disabled if you delete an encapsulation format.

Configuration Example

↘ Enabling DHCP Option 82

Configuration Steps	● Enable DHCP Option 82.
	`Hostname(config)# ip dhcp relay information option82`
Verification	● After loginning to the DHCP relay agent, run the **show running-config** command in privileged EXEC mode to display the DHCP relay configuration.
	`Hostname#show running-config | include ip dhcp relay` `ip dhcp relay information option82`

Common Errors

- Basic DHCP relay functions are not configured or fail to be configured.

1.4.7 Configuring Server ID Check by the DHCP Relay Agent

Configuration Effect

- After you configure the **ip dhcp relay check server-id**, a DHCP relay agent will forward DHCP Request packets only to the server specified by the **option server-id** command. Otherwise, the DHCP Request packets are forwarded to all DHCP servers.

Notes

- You need to enable basic DHCP relay functions.

Configuration Steps

↘ Enabling Server ID Check by the DHCP Relay Agent

- By default, server ID check by the DHCP relay agent is disabled.
- Rrun the **ip dhcp relay check server-id** command to enable server ID check by the DHCP relay agent.

Verification

- Check whether a DHCP relay agent sends DHCP Request packets only to the server specified by the **option server-id** command.

Related Commands

Configuring Server ID Check by the DHCP Relay Agent

Command	**ip dhcp relay check server-id**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Server ID Check by the DHCP Relay Agent

Configuration Steps	• Enable the DHCP relay. The configuration is not mentioned here. • Enable server ID check by the DHCP relay agent on an interface.
	`Hostname# configure terminal` `Hostname(config)# ip dhcp relay check server-id`
Verification	After loginning to the DHCP relay agent, run the **show running-config** command in privileged EXEC mode to display the DHCP relay configuration.

	`Hostname# show running-config | include check server-id`
	`ip dhcp relay check server-id`
	`Hostname#`

Common Errors

- Basic DHCP relay functions are not configured.

1.4.8 Specifying the Source Address for DHCP Relay Packets

Configuration Effect

- After you configure the **ip dhcp relay source** command on an interface, the source address of DHCP relay packets and the **Giaddr** field in DHCP packets can be specified.

Notes

- Basic DHCP relay functions must be configured.
- Only one source IP address can be specified for DHCP relay packets on an interface.
- This function must be used with Option 82 to assign a correct subnet address to the client.

Configuration Step

Specifying the Source Address for DHCP Relay Packets

No source address is specified for DHCP relay packets by default.

- Run the **ip dhcp relay source** *ip-address* command to specify the source address for DHCP relay packets.

Verification

- After a specific source address is configured on an interface, check that this source address is used as the source address of relay packets to be sent to the DHCP server and as the value of the **Giaddr** field in the DHCP packets.

Related Commands

Specifying the Source Address for DHCP Relay Packets

Command	**ip dhcp relay source** *ip-address*
Parameter Description	*ip-address*: Specifies the source IP address.
Command Mode	Interface configuration mode
Usage Guide	For a request packet sent by the DHCP relay agent, the destination address of a DHCP Reply packet sent by the DHCP server is the value of the **Giaddr** field in the Request packet. On some networks, multiple DHCP relay agents use the same interface IP address. In this case, you need to run this command on the DHCP relay agent to add another interface's IP address to the source address and **Giaddr** field of DHCP relay packets.

Configuration Example

Specifying the Source Address for DHCP Relay Packets

Configuration Steps	• Configure basic DHCP relay functions. The configuration is not mentioned here. • On a corresponding interface, specify a source address for DHCP relay packets.
	`Hostname(config-if-GigabitEthernet 0/1)# ip dhcp relay source 1.1.1.1`
Verification	• Log in to the DHCP relay agent. In privileged EXEC mode, run the **show running-config** command to display the DHCP relay configuration.

Common Errors

Basic DHCP relay functions are not configured or fail to be configured.

1.4.9 Configuring the DHCP Client

Configuration Effect

- Enable the DHCP client on a device so that it obtains IP addresses and configurations dynamically.

Notes

- The device supports the DHCP client configuration on Ethernet, FR, PPP, and HDLC interfaces.

Configuration Steps

- Run the **ip address dhcp** command on an interface.

Verification

- Check whether the interface obtains an IP address.

Related Commands

Configuring DHCP Client

Command	**ip address dhcp**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	• The Ethernet interface, PPP interface, FR interface, and HDLC interface can dynamically obtain IP addresses through DHCP.

Configuration Example

Configuring the DHCP Client

Configuration Steps	• Configure GigabitEthernet 0/1 to dynamically obtain an IP address through DHCP.
	`Hostname(config)# interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)#ip address dhcp`
Verification	• Run the **show running-config** command to display the configuration.
	`Hostname#show running-config | begin ip address dhcp` `ip address dhcp`

1.4.10 Defining Fields in Request Packets on Interfaces

Configuration Effect

- Enable the DHCP client on a device so that you can define option fields in Request packets.

Notes

- This feature is applicable to Layer 3 interfaces.

Configuration Step

Defining the Class-id Field in Request Packets

- Optional.
- Run the **ip dhcp client class-id** command to define the class-id field.

Defining the Client-id Field in Request Packets

- Optional.
- Run the **ip dhcp client client-id** command to define the client-id field.

Defining the Hostname Field in Request Packets

- Optional.

- Run the **ip dhcp client hostname** command to define the hostname field.

Defining the Lease Field in Request Packets

- Optional.
- Run the i**p dhcp client lease** command to define the lease field.

Defining the Option-list Field in Request Packets

- Optional.
- Run the **ip dhcp client option-list include** command to define the option-list field.

Verification

- Run the **show running-config** command to check whether the configuration is successful. The device obtains a DHCP request packet and check whether the **option** field in the packet is customized.

Related Commands

Defining the class-id Field in Request Packets

Command	**ip dhcp client class-id** { **ascii** *string* | **hex** *string* }
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Defining the client-id Field in Request Packets

Command	**ip dhcp client client-id** { **ascii** *string* | **hex** *string* | **exclude interface-name** }
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Defining the hostname Field in Request Packets

Command	**ip dhcp client hostname** *string*
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Defining the lease Field in Request Packets

Command	**ip dhcp client lease** *days* [*hours*] [*minutes*]
Parameter Description	N/A

Command Mode	Interface configuration mode
Usage Guide	N/A

Defining the option-list Field in Request Packets

Command	**ip dhcp client option-list include** *string*
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Defining the class-id Field in Request Packets

Configuration Steps	● Define the class-id field as **test** on GigabitEthernet 0/1.
	`Hostname(config-if-GigabitEthernet 0/1)#ip dhcp client class-id ascii test`
Verification	● Run the **show running-config** command to display the configuration.

Defining the client-id Field in Request Packets

Configuration Steps	● Define the client-id field as 0102.0304.0506 on GigabitEthernet 0/1.
	`Hostname(config-if-GigabitEthernet 0/1)#ip dhcp client client-id hex 0102.0304.0506`
Verification	● Run the **show run** command to display the configuration.

Defining the hostname Field in Request Packets

Configuration Steps	● Define the hostname as **Hostname** on GigabitEthernet 0/1.
	`Hostname(config-if-GigabitEthernet 0/1)#ip dhcp client hostname Hostname`
Verification	● Run the **show running-config** command to display the configuration.

Defining the lease Field in Request Packets

Configuration Steps	● Set the lease to 1 hour on GigabitEthernet 0/1.
	`Hostname(config-if-GigabitEthernet 0/1)#ip dhcp client lease 0 1`
Verification	● Run the **show running-config** command to display the configuration.

Defining the option-list Field in Request Packets

Configuration Steps	● Define the option-list field as 66, 67, 43.
	`Hostname(config-if-GigabitEthernet 0/1)#ip dhcp client option-list`

	`include 66-67,43`
Verification	• Run the **show running-config** command to display the configuration.

1.4.11 Releasing and Renewing the DHCP Lease

Configuration Effect

After dynamically obtaining IP addresses, DHCP clients release or renew DHCP leases.

Notes

This function applies to DHCP clients that obtain IP addresses dynamically. After interface addresses are released, run the **renew-dhcp** command to restore dynamic addresses or run the **no ip address dhcp** command to start a new IP address request.

Configuration Step

Enabling DHCP Clients to Release Dynamic IP Addresses

- Run the **release-dhcp** command in privilege EXEC mode.

Enabling DHCP Clients to Renew Dynamic IP Addresses

- Run the **renew-dhcp** command in privilege EXEC mode.

Verification

Run the **show dhcp lease** command to check whether the configurations take effect.

Related Commands

Enabling DHCP Clients to Release Dynamic IP Addresses

Command	**release-dhcp** *type number*
Parameter Description	N/A
Command Mode	Privilege EXEC mode
Usage Guide	N/A

Enabling DHCP Clients to Renew Dynamic IP Addresses

Command	**renew-dhcp** *type number*
Parameter Description	N/A
Command Mode	Privilege EXEC mode
Usage Guide	N/A

Configuration Example

Enabling DHCP Clients to Release Dynamic IP Addresses

Configuration Steps	● Release the dynamic IP addresses obtained by VLAN 100.
	`Hostname# release-dhcp vlan 100`
Verification	● Run the **show dhcp lease** command to display the configuration.

Enabling DHCP Clients to Renew Dynamic IP Addresses

Configuration Steps	● Renew the dynamic IP addresses obtained by VLAN 100.
	`Hostname# renew-dhcp vlan 100`
Verification	● Run the **show dhcp lease** command to display the configuration.

1.4.12 Configuring Class Rules of the DHCP Server

Configuration Effect

After class rules are configured, the DHCP server can assign IP addresses on different network segments to STAs based on Option 82 information carried by the STAs.

Notes

The configured class rules take effect only after they are associated with address pools.

Configuration Step

Configuring Class Rules

- Run the **ip dhcp class** command to add class rules.
- Run the **relay agent information** command to enter the Option 82 configuration mode.
- Run the **relay-information hex** command to configure matched Option 82 content.

Associating Class Rules with Address Pools

- Run the **class** command to associate class rules.
- Run the **address range** command to configure assigned IP address segments after class rules are matched.

Verification

Run the **show running-config** command to check the configuration.

Related Commands

Configuring Class Rules

Command	**ip dhcp class** *class-name*
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Run this command to configure servers. Configure class rules if IP addresses on different network segments need to be assigned based on option information.

Configuring Address Assignment Based on Class Rules

Command	**ip dhcp use class**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Run this command to configure servers.

Entering the Option 82 Configuration Mode

Command	**relay agent information**
Parameter Description	N/A
Command Mode	Global class configuration mode
Usage Guide	Run this command on the DHCP server to enter the Option 82 configuration mode.

Configuring Option 82 Information Matching Class Rules

Command	**relay-information hex**
Parameter Description	N/A
Command Mode	Global class configuration mode
Usage Guide	Run this command on the DHCP server to configure Option 82 information matching class rules.

Associating Class Rules with Address Pools

Command	**class** *class-name*
Parameter Description	N/A
Command Mode	DHCP address pool configuration mode
Usage Guide	Run this command on the DHCP server to associate configured class rules with destination address pools.

Configuring the IP Address Range Matching a Class Rule

Command	**address range** *start-ip end-ip*
Parameter Description	N/A
Command Mode	DHCP address pool configuration mode
Usage Guide	Run this command on the DHCP server to configure the range of the IP address assigned to a STA when a class rule is matched.

Configuration Example

Configuring Class Rules

Configuration Steps	1. Create a global class rule, for example, **test-class**.

	`Hostname(config)# ip dhcp class test-class`
	2. Enter the **relay-agent-info** configuration mode.
	`Hostname(config-dhcp-class)# relay agent information`
	3. Add Option 82 information sent from a specified interface as the matching rule.
	`Hostname(config-dhcp-class-relayinfo)# relay-information hex 010400100201020301020`
	4. Associate the class rule with an address pool and specify the address network segment.
	`Hostname(config)# ip dhcp pool test-pool`
	`Hostname(dhcp-config)# class test-class`
	`Hostname(config-dhcp-pool-class)# address range 1.1.1.10 1.1.1.20`

Verification	● Run the **show running-config** command to check the configuration.

	`Hostname# show running-config`
	`ip dhcp class test-class`
	` relay agent information`
	`  relay-information hex 010400100201020301020`
	`!`
	`ip dhcp pool test-pool`
	` class test-class`
	`  address range 1.1.1.10 1.1.1.20`

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear ip dhcp binding { *address* | *}	Clears DHCP address binding.
clear ip dhcp conflict { *address* | *}	Clears DHCP address conflict.
clear ip dhcp history { * | *mac-address* }	Clears the address assigned by the DHCP server.
clear ip dhcp server statistics	Clears statistics on a DHCP server.
clear ip dhcp relay statistics	Clears statistics on a DHCP relay agent.
clear ip dhcp server rate	Clears statistics on DHCP server performance.
clear ip dhcp server detect	Clears information about a bogus DHCP server.

Displaying

Command	Description
show dhcp lease	Displays the DHCP lease.
show ip dhcp socket	Displays DHCP sockets.

Command	Description
show ip dhcp binding	Displays assigned IP addresses.
show ip dhcp pool	Displays created address pools.
show ip dhcp server statistic	Displays statistics on the DHCP server.
show ip dhcp relay statistic	Displays statistics on the DHCP relay agent.
show ip dhcp conflict	Displays conflicting addresses.
show ip dhcp history	Displays the DHCP lease history.
show ip dhcp identifier	Displays the address pool ID and address utilization of a DHCP server.
show ip dhcp server detect	Displays the bogus DHCP server.
show ip dhcp state ssid	Displays the address assignment status based on SSIDs.
show ip dhcp database	Displays the DHCP database backup status.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ip dhcp server agent	Debugs DHCP agent.
debug ip dhcp server ha	Debugs DHCP hot standby.
debug ip dhcp server pool	Debugs DHCP address pools.
debug ip dhcp server vrrp	Debugs VRRP.
debug ip dhcp server all	Debugs all DHCP servers.
debug ip dhcp client	Debugs DHCP packets.
debug ip dhcp relay	Debugs DHCP relay events.

1 Configuring DHCP Snooping

1.1 Overview

DHCP snooping monitors DHCP interaction packets between clients and servers to record and monitor users' IP addresses, filtering out unauthorized DHCP packets such as client requests and server responses. The valid user database created from DHCP snooping records can support security applications such as IP source guard.

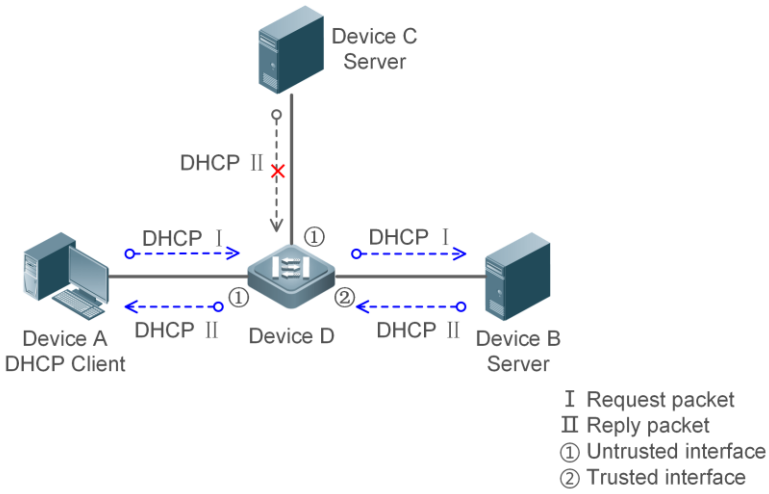
Protocols and Standards

- RFC 2131: Dynamic Host Configuration Protocol
- RFC 2132: DHCP Options and BOOTP Vendor Extensions

1.2 Applications

Application	Description
Guarding Against DHCP Service Spoofing	On a network where multiple DHCP servers are deployed, DHCP clients are allowed to obtain network configurations only from authorized DHCP servers.
Guarding Against DHCP Packet Flooding	Malicious network users may frequently send DHCP Request packets.
Guarding Against Forged DHCP Packets	Malicious network users may send forged DHCP Request packets, for example, DHCP Release packets.
Guarding Against IP or MAC Address Spoofing	Malicious network users may send forged IP packets, for example, tampered source address fields of packets.
Preventing Private IP Addresses	Network users may use private IP addresses but not obtain them from the authorized DHCP server.
Detecting ARP Attacks	Malicious users forge ARP Reply packets to intercept packets during normal users' communication.

1.2.1 Guarding Against DHCP Service Spoofing



Scenario

Multiple DHCP servers may exist on a network. It is essential to ensure that user PCs obtain network configurations exclusively from the DHCP servers within a controlled area.

Figure 1-1 is used as an example. The DHCP client can only communicate with trusted DHCP servers.

- Request packets from the DHCP client can be transmitted only to trusted DHCP servers.
- Only the Reply packets from trusted DHCP servers can be transmitted to the client.

Figure 1-1

Remarks:	Device D is an access device. Device A is a user PC. Device B is a DHCP server within the controlled area. Device C is a DHCP server out of the controlled area.

Deployment

- Enable DHCP snooping on Device D to realize DHCP packet monitoring.
- Configure the interface on Device D connecting to Device B as trusted to transfer Reply packets.
- Configure other interfaces on Device D as untrusted to filter Reply packets.

1.2.2 Guarding Against DHCP Packet Flooding

Scenario

Potential malicious DHCP clients on a network may send DHCP Request packets at high speed. As a result, authorized users cannot obtain IP addresses, and access devices are highly loaded or even break down. It is necessary to take actions to ensure network stability.

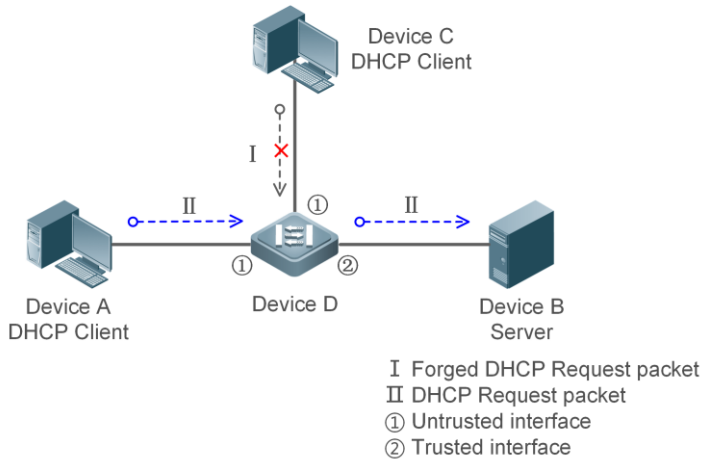
With the rate limiting function deployed, a DHCP client can only send DHCP Request packets at a rate below the limit.

- The Request packets from a DHCP client are sent at a rate below the limit.
- Packets sent at rates beyond the limit will be discarded.
- Associate DHCP snooping with ARP, and delete nonexistent entries.

Deployment

- Enable DHCP snooping on S to realize DHCP monitoring.
- Limit the rate of DHCP packets from untrusted interfaces.
- Associate DHCP snooping with ARP, and check whether users are online.

1.2.3 Guarding Against Forged DHCP Packets



Scenario

Potential malicious clients on a network may forge DHCP Request packets, consuming available IP addresses from the servers and probably preempting IP addresses assigned to authorized users. Therefore, it is necessary to filter out unauthorized DHCP packets.

For example, as shown in Figure 1-2, DHCP Request packets sent from DHCP clients will be checked.

- The source MAC address fields of Request packets from DHCP clients must match **chaddr** fields of DHCP packets.
- Release and Decline packets from clients must match entries in the DHCP snooping binding database.

Figure 1-2

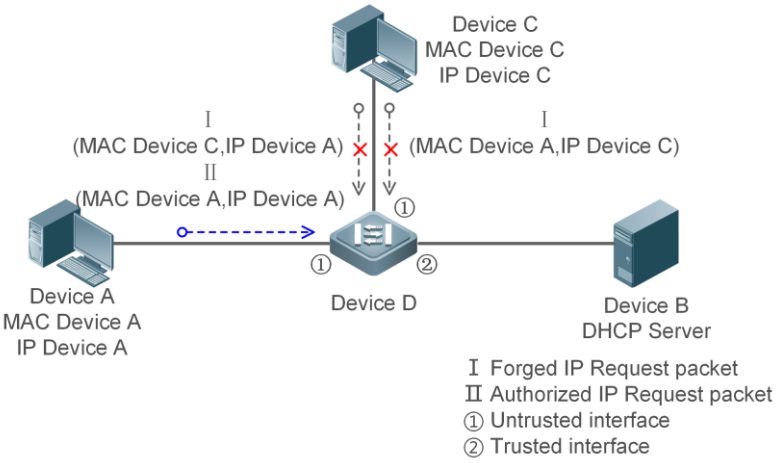
Remarks:	Device D is an access device. Device A and Device C are user PCs. Device B is a DHCP server within the controlled area.

Deployment

- Enable DHCP snooping on Device D to realize DHCP monitoring.
- Configure the interface on Device D connecting to Device B as trusted to transfer Reply packets.
- Configure other interfaces on Device D as untrusted to filter Reply packets.
- Enable source MAC address check on untrusted interfaces of Device D to filter out unauthorized packets.

1.2.4 Guarding Against IP or MAC Address Spoofing

Scenario



Check IP packets from untrusted interfaces to filter out forged IP packets based on IP address fields or IP and MAC address fields.

For example, in Figure 1-3, IP packets sent by DHCP clients will be checked.

- The source IP address fields of IP packets must match IP addresses assigned through DHCP.

- The source MAC address fields of Layer 2 packets must match the **chaddr** fields in DHCP Request packets from clients.

Figure 1-3

Remarks:	Device D is an access device. Device A and Device C are user PCs. Device B is a DHCP server within the controlled area.

Deployment

- Enable DHCP snooping on Device D to realize DHCP monitoring.
- Configure all downlink interfaces on the Device D as untrusted.
- Enable IP source guard on Device D to filter IP packets.
- Enable IP source guard based on IP and MAC addresses to check source MAC and IP address fields of IP packets.

1.2.5 Preventing Private IP Addresses

Scenario

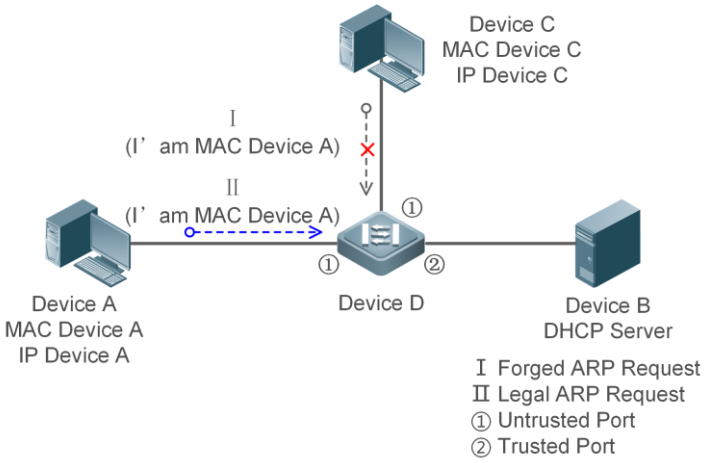
Check source addresses of IP packets from untrusted interfaces against DHCP-assigned addresses.

If the source addresses, connected interfaces, and Layer 2 source MAC addresses of interfaces in IP packets do not match DHCP snooping binding entries on the DHCP server, such packets will be discarded.

Deployment

- See Guarding Against IP or MAC Address Spoofing.

1.2.6 Detecting ARP Attacks



Scenario

Check ARP packets from untrusted interfaces and filter out the ARP packets that do not match DHCP snooping binding entries.

For example, in Figure 1-4, ARP packets sent from DHCP clients will be checked.

- The interfaces receiving ARP packets, Layer 2 MAC addresses, and source MAC addresses of ARP packets senders should match DHCP snooping binding entries.

Figure 1-4

Remarks:	Device D is an access device. Device A and Device C are user PCs. Device B is a DHCP server within the controlled area.

Deployment

- Enable DHCP snooping on Device D to realize DHCP monitoring.
- Configure all downlink interfaces on the Device D as untrusted.
- Enable IP source guard and ARP check on all the untrusted interfaces on Device D to realize ARP packet filtering.

All the preceding security control functions are only valid for DHCP snooping untrusted interfaces.

1.3 Features

Basic Concepts

DHCP Request Packets

Request packets are sent from a DHCP client to a DHCP server, including DHCP Discover packets, DHCP Request packets, DHCP Declient packets, DHCP Release packets, and DHCP Inform packets.

DHCP Reply Packets

Reply packets are sent from a DHCP server to a DHCP client, including DHCP Offer packets, DHCP ACK packets, and DHCP NAK packets.

DHCP Snooping Trusted Interfaces

Interaction packets for obtaining IP addresses through DHCP are broadcast. Consequently, unauthorized DHCP services will influence normal clients' acquisition of IP addresses, leading to service spoofing and interception. To mitigate unauthorized DHCP services, DHCP snooping interfaces are classified into trusted and untrusted interfaces.

Only DHCP Reply packets received on trusted interfaces are forwarded by access devices; packets received on untrusted interfaces are discarded. This approach allows interfaces connected to authorized DHCP servers to be designated as trusted, while all others are marked as untrusted, effectively shielding against unauthorized DHCP servers.

On the device, all Layer 2 aggregate interfaces are untrusted interfaces by default. You can specify trusted interfaces. On access points (APs), all the WLAN interfaces are untrusted and cannot be specified as trusted. In fat AP configuration mode, all the Layer 2 switching interfaces and Layer 2 encapsulation sub-interfaces are untrusted by default, and can be specified as trusted. In fit AP configuration mode, all the Layer 2 switching interfaces are untrusted by default and can be specified as trusted, and all the Layer 2 encapsulation sub-interfaces are trusted and cannot be specified as untrusted. On access controllers (ACs), all WLAN interfaces are untrusted interfaces and cannot be specified as trusted, and all the switching interfaces and Layer 2 aggregate interfaces are untrusted interfaces by default and can be specified as trusted.

DHCP Snooping Packet Suppression

To shield all the DHCP packets on a specific client, enable DHCP snooping packet suppression on its untrusted interfaces.

VLAN-based DHCP Snooping

DHCP sSnooping can work on a VLAN basis. By default, when DHCP snooping is enabled, it is valid for all the VLANs of the device. You can specify the VLAN where DHCP snooping takes effect.

DHCP Snooping Binding Database

On a DHCP network, clients may set static IP addresses randomly. This increases the difficulty in network maintenance and the possibility that authorized clients with IP addresses assigned by the DHCP server may fail to use network services normally due to address conflicts. Through snooping packets between clients and servers, the device enabled with DHCP snooping summarizes user entries including IP addresses, MAC addresses, VLAN IDs (VIDs), interfaces, and lease values to build the DHCP snooping binding database. Combined with ARP detection and ARP check, DHCP snooping controls assignment of IP addresses for authorized clients.

DHCP Snooping Rate Limiting

DHCP snooping rate limiting can be configured through the rate limiting command of Network Foundation Protection Policy (NFPP). For details about NFPP, see the *Configuring NFPP*.

DHCP Option 82

DHCP Option 82, an option for DHCP packets, is also called DHCP Relay Agent Information Option. As the option number is 82, it is known as Option 82. Option 82 is developed to enhance security of DHCP servers and improve IP address assignment. Option 82 is often configured for the DHCP relay services of a network access device such as the DHCP relay function and DHCP snooping. This option is transparent to DHCP clients, and the DHCP relay agent adds or removes the option.

Unauthorized DHCP Packets

DHCP snooping enables the device to check DHCP packets passing through a client. It discards unauthorized DHCP packets are discarded, and records user information and generates the DHCP Snooping binding database for other applications (for example, ARP detection). The following types of packets are considered unauthorized DHCP packets.

- DHCP Reply packets received on untrusted interfaces, including DHCP ACK, DHCP NAK, and DHCP Offer packets
- DHCP Request packets carrying the **giaddr** field (gateway information), which are received on untrusted interfaces
- Packets with source MAC addresses that are different from values of the **chaddr** field in DHCP packets when MAC address check is enabled
- DHCP Release packets in which the untrusted interface is inconsistent with the entry in the DHCP snooping binding database
- DHCP packets whose format is incorrect or incomplete DHCP packets

Overview

Feature	Description
Filtering Unauthorized DHCP Packets	Checks DHCP packets and discards unauthorized packet, and forwards Request packets to trusted interfaces only.
Building the Binding Database	Checks interaction between DHCP clients and the server, and generates the DHCP snooping binding database, providing the basis for other filtering modules.

1.3.1 Filtering Unauthorized DHCP Packets

Check DHCP packets from untrusted interfaces and filter out unauthorized packets to control the range in which packets are transmitted and to prevent malicious users' spoofing attacks.

Working Principle

DHCP snooping enables the device to check the receiving interfaces and other fields of packets to realize packet filtering, and to change destination interfaces of packets to control the range in which packets are transmitted.

Checking Interfaces

Upon receipt of DHCP packets, a client first determines whether the packet receiving interfaces are DHCP snooping trusted interfaces. If the receiving interface is the trusted interface, the client directly forwards the packets. If the receiving interface is the untrusted interface, the client checks the packets.

Checking Packet Encapsulation and the Length

A client checks whether packets are UDP packets and whether the destination interface is 67 or 68. It checks whether the packet length match the length field defined in protocols.

Checking Packet Fields and Types

According to the types of unauthorized packets, check **giaddr** and **chaddr** in packets and then check whetherother conditions for the type of packets are met.

Related Configuration

Enabling Global DHCP Snooping

By default, DHCP snooping is disabled.

Run the **ip dhcp snooping** command to enable DHCP snooping.

Global DHCP snooping must be enabled before VLAN-based DHCP snooping is applied.

Configuring VLAN-based DHCP Snooping

By default, when global DHCP snooping is enabled, DHCP snooping is valid for all VLANs.

Use the [**no**] **ip dhcp snooping vlan** command to enable DHCP snooping in specified VLANs or delete VLANs from the specified VLANs. The value range of the command parameter is the actual range of VLAN IDs.

Configuring Source MAC Address Check

By default, Layer 2 MAC addresses of packets and **chaddr** fields of DHCP packets are not checked.

When the **ip dhcp snooping verify mac-address** command is used, the device checks source MAC addresses and **chaddr** fields of DHCP Request packets sent from untrusted interfaces. It discards DHCP Request packets with different MAC addresses.

1.3.2 Building the Binding Database

When the DHCP server enabled with DHCP snooping detects packets exchanged with DHCP clients, it generates DHCP snooping binding entries based on information in authorized DHCP packets. All these valid entries are provided for other security modules as the basis for filtering packets.

Working Principle

The binding database is updated in a timely manner based on types of DHCP packets.

Generating Binding Entries

When a DHCP ACK packet on a trusted interface is snooped, the client's IP address, MAC address, and lease are extracted with the interface ID (wired interface index or WLAN ID) and VLAN ID. Then a binding entry is generated.

Deleting Binding Entries

A binding entry is deleted when the recorded lease of the binding entry is due, an authorized DHCP Release or Decline packet sent by the client or a DHCP NCK packet received on a trusted interface is snooped, or the **clear** command is used.

Related Configuration

You only need to enable DHCP snooping.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions	⚠ (Mandatory) It is used to enable DHCP snooping.	
	ip dhcp snooping	Enables DHCP snooping.
	ip dhcp snooping suppression	Enables DHCP snooping packet suppression.
	ip dhcp snooping vlan	Enables VLAN-based DHCP snooping.
	ip dhcp snooping verify mac-address	Configures DHCP snooping source MAC address check.

Configuration	Description and Command	
	ip dhcp snooping database write-delay	Writes the DHCP snooping binding database to the flash memory periodically.
	ip dhcp snooping database write-to-flash	Writes the DHCP snooping binding database to the flash memory manually.
	renew ip dhcp snooping database	Imports user information in the backup file to the DHCP snooping binding database.
	ip dhcp snooping database	Configures backup files of the DHCP snooping binding database.
	ip dhcp snooping trust	Configures DHCP snooping trusted interfaces.
	ip dhcp snooping bootp-bind	Enables BOOTP support.
	ip dhcp snooping check-giaddr	Enables DHCP snooping to allow the device to process relay Request packets.
	ip dhcp snooping clear-broadcast-flag	Enables the device to clear the broadcast flag bit.
Configuring Option 82	(Optional) It is used to optimize address assignment by the DHCP server.	
	ip dhcp snooping Information option	Adds Option 82 to DHCP Request packets.
	ip dhcp snooping information option format remote-id	Configures the sub-potion **remote-id** of Option 82 as a user-defined character string.
	ip dhcp snooping vlan information option format-type circuit-id string	Configures the sub-option **circuit-id** of Option 82 as a user-defined character string.

1.4.1 Configuring Basic Functions

Configuration Effect

- Enable DHCP snooping.
- Generate the DHCP snooping binding database.
- Control the transmit range of DHCP packets.
- Filter out unauthorized DHCP packets.

Notes

- The interfaces on clients connecting a trusted DHCP server must be configured as trusted.
- DHCP snooping is effective on the wired switching interfaces, Layer 2 aggregate interfaces, and Layer 2 encapsulation sub-interfaces, as well as WLAN interfaces. The configuration can be implemented in interface configuration mode and WLAN security configuration mode.

Configuration Step

Enabling Global DHCP Snooping

- Mandatory.
- Unless otherwise noted, perfrom the configuration on access devices.

Enabling or Disabling VLAN-based DHCP Snooping

- DHCP snooping can be disabled for some VLANs if not necessary.
- Unless otherwise noted, perfrom the configuration on access devices.

Configuring DHCP Snooping Trusted Ports

- Mandatory.
- Configure the interfaces connecting a trusted DHCP server as trusted.

Enabling DHCP Snooping Source MAC Address Check

- This configuration is required if the **chaddr** fields of DHCP Request packets match Layer 2 source MAC addresses of data packets.
- Unless otherwise noted, perfrom the configuration on all the untrusted interfaces of access devices.

Writing the DHCP Snooping Binding Database to the Flash Memory Periodically

- Enable this feature to save DHCP snooping binding database information upon client restart.
- STA information is not saved.
- Unless otherwise noted, perfrom the configuration on access devices.

Enabling BOOTP Support

- Optional
- Unless otherwise noted, perfrom the configuration on access devices.

Associating DHCP Snooping with ARP

- Optional.
- Unless otherwise noted, perfrom the configuration on access devices.

Enabling DHCP Snooping to Process Relay Request Packets

- Optional.
- Unless otherwise noted, perfrom the configuration on access devices.

Enabling DHCP Snooping

- Optional.
- If DHCP snooping binding entries need to be generated on a routed interface, perfrom the configuration on a Layer 3 device.

Enabling DHCP Snooping to Clear the Broadcast Flag Bit

- Optional.
- Unless otherwise noted, perfrom the configuration in large Layer 2 wireless scenarios.

Enabling Fast Aging of DHCP Snooping Migration Entries

- Optional.

Enabling Migration of DHCP Snooping Binding Entries

- Optional.

Enabling DHCP Snooping to Generate Static ARP Entries

- Optional.

Enabling DHCP Snooping Forwarding in Loose Mode

- Optional.
- Unless otherwise noted, the feature should be disabled.

Verification

Configure a client to obtain network configurations through DHCP.

- Check whether the DHCP snooping binding database is generated with entries on the client.

Related Commands

Enabling or Disabling DHCP Snooping

Command	[**no**] **ip dhcp snooping**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After global DHCP snooping is enabled, you can check DHCP snooping using the **show ip dhcp snooping** command. After DHCP Snooping is enabled, the validity of DHCP packets is checked. DHCP response packets from untrusted ports will be discarded. To ensure the normal operation of services, configure the uplink port (that is, the port connected to the DHCP server) as a trusted port.

Configuring VLAN-based DHCP Snooping

Command	[**no**] **ip dhcp snooping vlan** { *vlan-rng* | {*vlan-min* [*vlan-max*] } }
Parameter Description	*vlan-rng*: Indicates the range of VLANs. *vlan-min*: Indicates the minimum VLAN ID. *vlan-max*: Indicates the maximum VLAN ID.
Command Mode	Global configuration mode
Usage Guide	Use this command to enable or disable DHCP snooping in specified VLANs. This feature is available only after global DHCP snooping is enabled.

Configuring DHCP Snooping Packet Suppression

Command	[**no**] **ip dhcp snooping suppression**
Parameter Description	N/A

Command Mode	Interface configuration mode or WLAN security configuration mode
Usage Guide	Use this command to reject all DHCP Request packets on the interface, that is, to forbid all users on the interface to apply for addresses through DHCP.

Configuring DHCP Snooping Source MAC Address Check

Command	[**no**] **ip dhcp snooping verify mac-address**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Through source MAC address check, MAC addresses in link headers and CLIENT MAC fields in the Request packets sent by a DHCP client are checked for consistency. When source MAC address check fails, packets will be discarded.

Writing DHCP Snooping Database to the Flash Memory Periodically

Command	[**no**] **ip dhcp snooping database write-delay** [*time*]
Parameter Description	*time*: Indicates the interval between two times of writing the DHCP snooping database to the flash memory.
Command Mode	Global configuration mode
Usage Guide	Use this command to write the DHCP snooping database to the flash memory. This can avoid binding information loss after device restart. Otherwise, users have to re-obtain IP addresses.

Writing the DHCP Snooping Database to the Flash Memory Manually

Command	**ip dhcp snooping database write-to-flash**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to write dynamic user information in the DHCP snooping database in the flash memory in real time.

Importing Backup File Information to the DHCP Snooping Binding Database

Command	**renew ip dhcp snooping database**
Parameter Description	N/A
Command Mode	Privileged configuration mode
Usage Guide	Use this command to import backup file information to the DHCP snooping binding database.

Configuring DHCP Snooping Trusted Interfaces

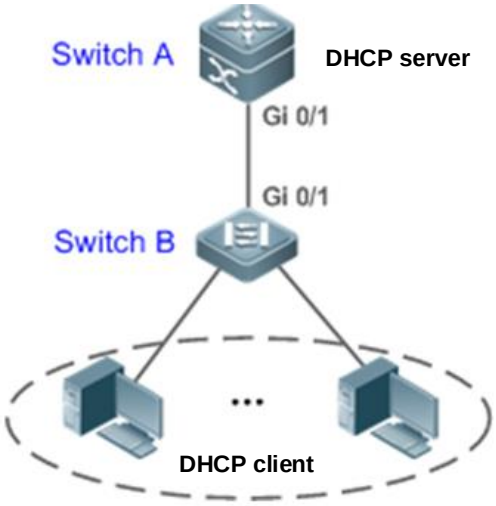
Command	[**no**] **ip dhcp snooping trust**
Parameter	N/A

Description	
Command Mode	Interface configuration mode
Usage Guide	Use this command to configure an interface connected to an authorized DHCP server as a trusted interface. The DHCP Reply packets received by trusted interfaces are forwarded, while those received by untrusted interfaces are discarded.

Enabling or Disabling BOOTP Support

Command	[**no**] **ip dhcp snooping bootp-bind**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to support the BOOPT protocol.

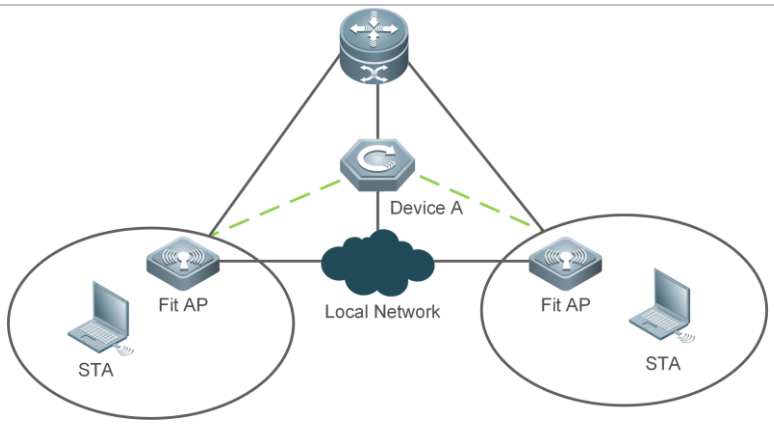
Enabling DHCP Snooping to Process Relay Request Packets



Command	[**no**] **ip dhcp snooping check-giaddr**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After the feature is enabled, services using DHCP snooping binding entries generated based on relay Request packets, such as IP source guard or 802.1x authentication, cannot be deployed. Otherwise, users fail to access the Internet. After the feature is enabled, the **ip dhcp snooping verify mac-address** command cannot be used. Otherwise, DHCP relay request packets will be discarded. As a result, users fail to obtain addresses.

Enabling DHCP Snooping to Clear the Broadcast Flag Bit

Command	[**no**] **ip dhcp snooping clear-broadcast-flag**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After the feature is enabled, the device enabled with DHCP snooping checks the broadcast flag bit for non-DHCP relay Request packets. If the flag bit is 1, it clears the flag bit. When receiving Reply packets, the device sets the flag bit to 1 and set Layer 2 and Layer 3 destination addresses as broadcast addresses.



Configuration Example

DHCP Client Obtaining IP Addresses Dynamically from an Authorized DHCP Server

Scenario **Figure 1-5**	
Configuration Steps	● Enable DHCP snooping on an access device (Switch B). ● Configure the uplink interface (GigabitEthernet 0/1) as a trusted interface.
Device B	Hostname#configure terminal Hostname(config)#ip dhcp snooping Hostname(config)#interface gigabitethernet 0/1 Hostname(config-if-GigabitEthernet 0/1)#ip dhcp snooping trust
Verification	Check the configuration on Switch B. ● Check whether DHCP snooping is enabled, and whether the configured DHCP snooping trusted interface is the uplink interface. ● Check the DHCP snooping configuration on Switch B, and check whether the trusted interface is correct.
Device B	Hostname#show running-config ! ip dhcp snooping ! interface GigabitEthernet 0/1 B#show ip dhcp snooping Switch DHCP Snooping status : ENABLE DHCP Snooping Verification of hwaddr status : DISABLE DHCP Snooping database write-delay time : 0 seconds DHCP Snooping option 82 status : DISABLE DHCP Snooping Support BOOTP bind status : DISABLE Interface Trusted Rate limit (pps) ------------------------ ------- ---------------- GigabitEthernet 0/1 YES unlimited B#show ip dhcp snooping binding Total number of bindings: 1 MacAddress IpAddress Lease(sec) Type VLAN Interface ------------------ --------------- ------------ ------------- ----- -------------------- 0013.2049.9014 172.16.1.2 86207 DHCP-Snooping 1

	GigabitEthernet 0/11

Configuring DHCP Snooping for Wireless Fit APs in Local Forwarding Scenarios

Scenario **Figure 1-6**	
Configuration Steps	● Configure DHCP snooping basic functions on the AC.
Device A	Hostname# configure terminal Hostname(config)# ip dhcp snooping
Verification	● Check the DHCP snooping configuration.
Device A	Hostname#show ip dhcp snooping Switch DHCP snooping status : ENABLE DHCP snooping Verification of hwaddr status : DISABLE DHCP snooping database write-delay time : 0 seconds DHCP snooping option 82 status : DISABLE DHCP snooping Support bootp bind status : DISABLE Interface Trusted Rate limit (pps) ------------------------ ------- ---------------- Default No unlimited

Common Errors

- The uplink interface is not configured as a DHCP trusted interface.
- Another access security option is already configured for the uplink interface, so that a DHCP trusted interface cannot be configured.

1.4.2 Configuring Option 82

Configuration Effect

- Option 82 enables the DHCP server to obtain more information for better address assignment.
- The Option82 function is transparent to clients.

Notes

- The Option 82 function for DHCP snooping and the DHCP relay agent cannot be configured simultaneously.

Configuration Step

- To optimize address allocation, perform the configuration.
- Unless otherwise noted, enable this function on access devices with DHCP snooping enabled.

Verification

Check whether DHCP snooping options are configured successfully.

Related Commands

Adding Option 82 to DHCP Request Packets

Command	[**no**] **ip dhcp snooping information option** [**standard-format | dot1x-format**]
Parameter Description	**standard**–**format**: Indicates a standard format of Option 82. **dot1x-format**: Uses the 802.1X format for Option 82.
Command Mode	Global configuration mode
Usage Guide	Use this command to add Option 82 to DHCP Request packets so that a DHCP server assigns addresses according to such information. When the 802.1X format is used, if a DHCP relay agent is deployed on the local device and the uplink interface connected to the DHCP server is an SVI, you need to disable DHCP snooping for the VLAN corresponding to the SVI.

Configuring remote-id of Option82 as a User-defined Character String

Command	[**no**] **ip dhcp snooping information option format remote-id** { **string** *ASCII-string* | **hostname** }
Parameter Description	**string** *ASCII-string*: Indicates that the sub-option **remote-id** of Option 82 is a user-defined character string. **hostname**: Indicates that the sub-option **remote-id** of Option 82 is a host name.
Configuration mode	Global configuration mode
Usage Guide	Use this command to configure the sub-option **remote-id** of Option 82, which is added to DHCP Request packets. A DHCP server assigns addresses according to Option 82 information.

Configuring circuit -id of Option 82 as a User-defined Character String

Command	[**no**] **ip dhcp snooping vlan** *vlan-id* **information option format-type circuit-id string** *ascii-string*
Parameter Description	*vlan-id*: Indicates the ID of the VLAN where a DHCP Request packet is transmitted. *ascii-string*: Indicates the user-defined string.
Configuration mode	Interface configuration mode
Usage Guide	Use this command to configure the sub-option **circuit-id** of Option 82, which is added to DHCP Request packets. A DHCP server assigns addresses according to Option 82 information.

Configuration Example

Configuring the Device to Add Option 82 to DHCP Request Packets

Configuration Steps	● Configuring basic functions of DHCP snooping. ● Configuring Option 82.
Device B	`Hostname# configure terminal` `Hostname(config)# ip dhcp snooping information option`
Verification	● Check the DHCP snooping configuration.

Device B	`Hostname#show ip dhcp snooping`
	`Switch DHCP Snooping status : ENABLE`
	`DHCP Snooping Verification of hwaddr status : DISABLE`
	`DHCP Snooping database write-delay time : 0 seconds`
	`DHCP Snooping option 82 status : ENABLE`
	`DHCP Snooping Support bootp bind status : DISABLE`
	`Interface Trusted Rate limit (pps)`
	`------------------------ ------- ----------------`
	`GigabitEthernet 0/1 YES unlimited`

Common Errors

- N/A

1.5 Monitoring

Clearing

⚠ During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear ip dhcp snooping binding [*ip*] [*mac*] [**vlan** *vlan-id*] [**interface** *interface-id*]	Clears the DHCP snooping binding database.

Displaying

Description	Command
show ip dhcp snooping	Displays the DHCP snooping configuration.
show ip dhcp snooping binding	Displays the DHCP snooping binding database.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug snooping ipv4 event	Debugs DHCP snooping events.
no debug snooping ipv4 event	Disables debugging DHCP snooping events.
debug snooping ipv4 packet	Debugs DHCP snooping packets.
no debug snooping ipv4 packet	Disables debugging DHCP snooping packets.

1 Configuring DNS Client

1.1 Overview

A Domain Name System (DNS) is a distributed database that maps domain names to IP addresses on the Internet, enabling users to access websites without needing to remember numeric IP addresses directly used by computers. The process of translating a host name into its corresponding IP address is known as domain name resolution (or host name resolution).

Protocols and Standards

- RFC 1034: DOMAIN NAMES - CONCEPTS AND FACILITIES
- RFC 1035: DOMAIN NAMES - IMPLEMENTATION AND SPECIFICATION

1.2 Applications

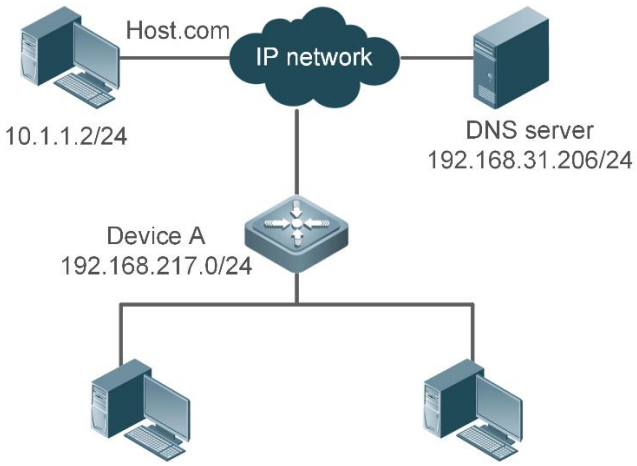
Application	Description
Static Domain Name Resolution	The device resolves domain names based on mappings between domain names and IP addresses on a device.
Dynamic Domain Name Resolution	The device obtains the IP address mapped to a domain name dynamically from a DNS server on a network.

1.2.1 Static Domain Name Resolution

Scenario

- Preset mappings between domain names and IP addresses on a device.
- When you perform domain name operations (such as ping and Telnet) through applications, the system can resolve the IP address without being connected to a server on a network.

Deployment



Preset mappings between domain names and IP addresses on a device.

1.2.2 Dynamic Domain Name Resolution

Scenario

- The DNS server is deployed on a network to provide the domain name service.
- The domain name host.com is deployed on the network.
- Device-A obtains domain name host.com from the DNS server.

Figure 1-1 Dynamic Domain Name Resolution

Deployment

Deploy the DNS server that provides domain name resolution for Device-A.

1.3 Features

Basic Concepts

DNS

DNS involves a resolver and a DNS server. The DNS server stores the mappings between domain names and IP addresses of all hosts on a network, and implements mutual conversion between them. Both the TCP and UDP port numbers of DNS are 53, and a UDP port is typically used.

Overview

Feature	Description
Domain Name Resolution	Obtains IP addresses based on domain names from a DNS server or a local database.
DNS Allowlist	Uses the DNS allowlist function to specify valid DNS server's IP address.

1.3.1 Domain Name Resolution

Working Principle

Static Domain Name Resolution

Static domain name resolution means that a user presets the mapping between a domain name and an IP address on a device. When you perform domain name operations (such as ping and Telnet) through applications, the system can resolve the IP address without being connected to a server on the network.

Dynamic Domain Name Resolution

Dynamic domain name resolution means that the DNS resolver of the system queries an external DNS server for the IP address mapped to the domain name when a user perform domain name operations through applications.

The procedure of dynamic domain name resolution is as follows:

1 A user application (such as ping or Telnet) requests the IP address mapped to a domain name from the DNS resolver of the system.

2 The DNS resolver queries the dynamic cache at first. If the domain name in the dynamic cache does not expire, the DNS resolver returns the domain name to the application.

3 If all domain names expire, the DNS resolver initiates a request for domain name-IP address conversion to the external DNS server.

4 After receiving a response from the DNS server, the DNS resolver caches and transfers the response to the application.

Related Configuration

Enabling Domain Name Resolution

- By default, domain name resolution is enabled.
- Run the **ip domain-lookup** command to enable domain name resolution.

Configuring an IP Address Mapped to a Static Domain Name

- By default, no mapping between a domain name and an IP address is configured.
- Run the **ip host** command to specify the IPv4 address mapped to a domain name.
- Run the **ipv6 host** command to specify the IPv6 address mapped to a domain name.

Configuring a DNS Server

- By default, no DNS server is configured.
- Run the **ip name-server** command to configure a DNS server.

1.3.2 DNS Allowlist

Supported functions are subject to the product version.

Working Principle

The DNS allowlist function is used to specify valid DNS servers' IP addresses on a network. After this function is enabled on a device, the device checks received DNS packets and intercepts invalid DNS packets. You can enable the DNS allowlist function globally or based on the WLAN and configure a list of valid DNS servers. When the DNS allowlist function is enabled based on the WLAN, if a DNS packet received from the WLAN is not used to access the WLAN-based valid DNS server's IP address, the device discards the packet without matching the packet with the global DNS allowlist.

Related Configuration

Enabling the DNS Allowlist

- The DNS allowlist function is disabled by default.
- Run the **ip name-server white-list enable** command to enable domain name resolution.

Configuring Valid DNS Servers' IP Addresses

- No DNS server's IP address is configured by default.
- Run the **ip name-server white-list** command to configure the DNS server's IP addresses.
- Only DNS servers' IPv4 addresses are supported, and up to six DNS servers' IP addresses can be configured.

1.4 Configuration

Configuration	Description and Command	
Configuring Static Domain Name Resolution	Optional.	
	ip domain-lookup	Enables domain name resolution.
	ip host	Configures the IPv4 address mapped to a domain name.
	ipv6 host	Configures the IPv6 address mapped to a domain name.
Configuring Dynamic Domain Name Resolution	Optional.	
	ip domain-lookup	Enables domain name resolution.
	ip name-server	Configures a DNS server.
Configuring DNS Allowlist	Optional.	
	ip name-server white-list enable	Enables the DNS allowlist function.
	ip name-server white-list [**wlan** *wlan-id*] *ip-address*	Configures valid DNS servers' IP addresses.

1.4.1 Configuring Static Domain Name Resolution

Configuration Effect

The system resolver resolves the IP address mapped to a domain name on a local device.

Configuration Step

Enabling Domain Name Resolution

- The domain name resolution function is enabled by default.
- If this function is disabled, static domain name resolution does not take effect.

Configuring the IP Address Mapped to a Domain Name

- Mandatory.
- Domain names to be used must be configured with mapped IP addresses.

Verification

- Run the **show running-config** command to check the configuration.
- Run the **show hosts** command to check the mapping between the domain name and IP address.

Related Commands

Enabling Domain Name Resolution

Command	**ip domain-lookup**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the IPv4 Address Mapped to a Domain Name

Command	**ip host** *host-name ip-address*
Parameter Description	*host-name*: Indicates a domain name. *ip-address*: Indicates a mapped IPv4 address.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the IPv6 Address Mapped to a Domain Name

Command	**ipv6 host** *host-name ipv6-address*
Parameter Description	*host-name*: Indicates a domain name. *ipv6-address*: Indicates a mapped IPv6 address.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Static Domain Name Resolution

Configuration Steps	● Set the IP address of static domain name www.test.com to 192.168.1.1 on a device. ● Set the IP address of static domain name www.testv6.com to 2001::1 on a device.

	`Hostname#configure terminal`
	`Hostname(config)# ip host www.test.com 192.168.1.1`
	`Hostname(config)# ipv6 host www.testv6.com 2001::1`
	`Hostname(config)# exit`

Verification	Run the **show hosts** command to check whether the static domain name entry is configured.

	`Hostname#show hosts`
	`Name servers are:`
	
	`Host type Address TTL(sec)`
	`www.test.com static 192.168.1.1 ---`
	`www.testv6.com static 2001::1 ---`

1.4.2 Configuring Dynamic Domain Name Resolution

Configuration Effect

The system resolver resolves the IP address mapped to a domain name through a DNS server.

Configuration Step

Enabling Domain Name Resolution

- Domain name resolution is enabled by default.
- If this function is disabled, dynamic domain name resolution does not take effect.

Configuring a DNS Server

- Mandatory.
- To use dynamic domain name resolution, you must configure an external DNS server.

Verification

Run the **show running-config** command to check the configuration.

Related Commands

Enabling Domain Name Resolution

Command	**ip domain-lookup**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring a DNS Server

Command	**ip name-server**{ *ip-address* | *ipv6-address* }&<1-6>
Parameter Description	*ip-address*: Indicates the IPv4 address of the DNS server. *Ipv6-address*: Indicates the IPv6 address of the DNS server.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Dynamic Domain Name Resolution

Scenario **Figure 1-2**	
	Device A resolves the domain name through the DNS server (192.168.10.1) on the network.
Configuration Steps	● Set the IP address of the DNS server to 192.168.10.1 on the device. ● Set the IPv6 address of the DNS server to 2001::1 on the device.

	Hostname#configure terminal Hostname(config)# ip name-server 192.168.10.1 Hostname(config)# ip name-server 2001::1 Hostname(config)# exit
Verification	Run the **show hosts** command to check whether the DNS server is specified.
	Hostname#show hosts Name servers are: 192.168.10.1 static 2001::1 static Host type Address TTL(sec)

1.4.3 Configuring DNS Allowlist

Supported functions are subject to the product version.

Configuration Effect

The system checks DNS packets received by the device and intercepts invalid DNS packets.

Configuration Step

Enabling the DNS Allowlist

- The DNS allowlist function is disabled by default.
- If this function is enabled, the device checks received DNS packets.

Configuring a DNS Server

- If no valid DNS server is configured, all DNS packets are filtered out.
- Only DNS servers' IPv4 addresses are supported.
- Up to six DNS servers' IP addresses can be configured.

Verification

Run the **show running-config** command to display the configuration.

Related Commands

Configuring the DNS Allowlist

Command	**ip name-server white-list** [**wlan** *wlan-id*] **enable**
Parameter Description	*wlan-id*: Indicates the ID of the WLAN.
Command Mode	Global configuration mode
Usage Guide	The supported configuration may vary depending on actual products.

Configuring Valid DNS Servers' IP Addresses

Command	**ip name-server white-list** [**wlan** *wlan-id*] *ip-address*
Parameter Description	*wlan-id*: Indicates the ID of the WLAN. *ip-address*: Indicates the IPv4 address of a DNS server.
Command Mode	Global configuration mode
Usage Guide	The supported configuration may vary depending on actual products.

Configuration Example

Configuring Dynamic Domain Name Resolution

Configuration Steps	• Enable the DNS allowlist function on the device. • Set the DNS server's IP address to 192.168.10.1 on the device.

	`Hostname# configure terminal`
	`Hostname(config)# ip name-server white-list enable`
	`Hostname(config)# ip name-server white-list 192.168.10.1`
	`Hostname(config)# exit`

Verification	Run the **show ip name-server white-list** command to display the DNS allowlist configuration.

	`Hostname# show ip name-server white-list`
	`white-list check: enable`
	`white-list name-server:`
	`192.168.10.1`

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear host [*host-name*]	Clears the dynamic host name cache table.

Displaying

Command	Description
show hosts [*host-name*]	Displays DNS parameters.

Displaying the DNS Allowlist

Command	Description
show ip name-server white-list [**wlan** *wlan-id*]	Displays the DNS allowlist configuration.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ip dns	Debugs the DNS function.

1 Configuring DNS Snooping

1.1 Overview

DNS snooping monitors domain name server (DNS) packets exchanged between clients and servers to record mapping table entries of domain names and IP addresses. It also filters out unauthorized DNS packets, including request packets from clients and response packets from servers.

DNS snooping provides authentication-free uniform resource locators (URLs), that is, domain name-based direct addresses.

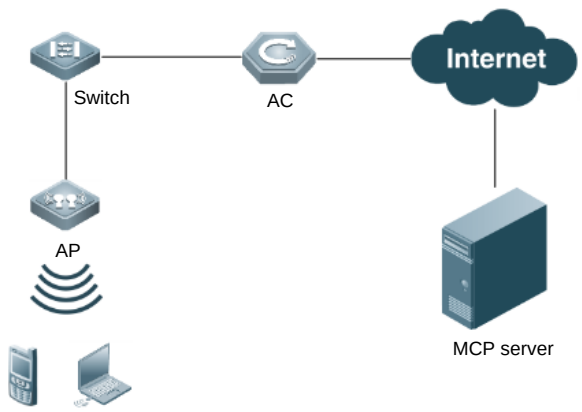
Protocols and Standards

- RFC 1034：DOMAIN NAMES - CONCEPTS AND FACILITIES
- RFC 1035：DOMAIN NAMES - IMPLEMENTATION AND SPECIFICATION

1.2 Applications

Application	Description
Applying Authentication-free URLs	Unauthenticated clients cannot access a network normally when web-based authentication is enabled on the AC. With the authentication-free URL function enabled, clients are allowed to access specific URLs without authentication.

1.2.1 Applying Authentication-free URLs



Scenario

In Figure 1-1, the AC interacts with the MCP server, to control the network access right of unauthenticated downlink clients as well as their authentication through authentication over WeChat following.

Unauthenticated clients can access only WeChat, and can pass authentication by following the WeChat public account.

Authenticated clients have unrestricted network access rights.

Figure 1-1

Remarks:	The AC indicates an access controller. The AP indicates an access point. The MCP server is a cloud server.

Deployment

- Enable authentication over WeChat following on the AC for interaction with the MCP server.

1.3 Features

Basic Concepts

Authentication-free App

Unauthenticated clients can access authentication-free apps, such as WeChat and Sina Weibo.

Authentication-free URL

Unauthenticated clients cannot access the network normally when the web-based authentication function is enabled on the AC. With the authentication-free URL function enabled, clients are allowed to access specific URLs without authentication.

CWMP

The CPE WAN Management Protocol (CWMP), initiated by the Digital Subscriber Line (DSL) forum and designated as TR-069, is commonly referred to as the TR-069 protocol. It provides the universal framework, message specification, and method and data model for managing and configuring home network devices on next-generation networks.

Implementation of the TR-069 protocol is complex. For app authentication, TR-069 provides the network channel for communication between the AC and the MCP server.

Overview

Feature	Description
Authentication-free URL	Prevents unauthenticated clients from accessing a network normally when the web-based authentication function is enabled on the AC. With the authentication-free URL function enabled, clients are allowed to access specific URLs without authentication.

1.3.1 Authentication-free URL

After the authentication-free URL function is enabled on the AC, unauthenticated clients are allowed to access specific URLs.

Working Principle

Unauthenticated clients cannot access the network normally when the web-based authentication function is enabled on the AC. With the authentication-free URL function enabled, if the AC determines that traffic of an unauthenticated client matches URL characteristics, the AC allows the traffic to pass and the client can access the specific URL without authentication.

1.4 Configuration

Configuration	Description and Command	
Configuring an Authentication-free URL	(Mandatory) It is used to configure authentication-free apps in global configuration mode.	
	free-url	Configures the authentication-free URL. Only WeChat, Sina App, certain iPhone apps, and designated URLs are supported.
	ip dns snooping enable	Enables DNS snooping.

1.4.1 Configuring an Authentication-free URL

Configuration Effect

- Allow unauthenticated clients to access the configured authentication-free URL directly.

Notes

- The authentication-free URL takes effect only after the web-based authentication function is enabled.

Configuration Step

Enabling DNS snooping

- Mandatory.
- Enable DNS snooping on the device.

Command	**ip dns snooping enable**
Parameter Description	N/A
Defaults	DNS snooping is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Run this command to enable DNS snooping.

Configuring an Authentication-free URL

- Mandatory.
- Configure an authentication-free URL on the AC.

Command	**free-url** { **weixin | sina | iphone** | **url** *url* } [**wlan** *wlan-id*]
Parameter Description	**weixin**: Indicates WeChat. **sina**: Indicates a Sina app. **iphone**: Indicates an iPhone app. *url*: Indicates a designated URL. **wlan**: Indicates a WLAN.
Defaults	No authentication-free URL is configured by default.
Command Mode	Global configuration mode
Usage	You can configure multiple authentication-free URLs.

Guide	

Verification

- Run the **show free-url** command to check the configuration.
- Check whether unauthenticated clients can access authentication-free URLs directly when the web-based authentication function is enabled on the AC.

Configuration Example

↘ Configuring WeChat as Authentication-free URL on the AC

Configuration Steps	● Enter the global configuration mode. ● Configure WeChat as an authentication-free URL.

Device	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#ip dns snooping enable`
	`Hostname(config)# free-url weixin`
	`Hostname(config)# free-url *.baidu.com`
	`Hostname(config)#exit`

Verification	● Run the **show free-url** command to check authentication-free URLs.

Device	`Hostname#show free-url`
	`Total number of domain name   : 4`
	`Total number of ip address    : 11`
	
	`====================== free-url domain name table`
	`=====================================`
	`Host                    type     Interface`
	`Vlan       Wlan`
	`*.qpic.cn               weixin   all`
	`all        all`
	`*.weixin.qq.com         weixin   all`
	`all        all`
	`weixin.qq.com           weixin   all`
	`all        all`
	`*.baidu.com             url      all`
	`all        1`
	`==========================================================================`
	`=================`
	
	`========================== free-url ip table`
	`==============================`
	`Host                    type    Address`
	`TTL(sec)`
	`*.weixin.qq.com         weixin  61.151.224.41                    2118`
	`                                140.207.135.125                  2118`

```
                                  140.207.54.47                        2118
*.qpic.cn                 weixin  140.206.160.234                      2118
                                  183.61.49.180                        151
                                  101.226.129.204                      554
                                  14.17.52.136                         16
weixin.qq.com             weixin  14.17.42.45                          800
*.baidu.com               url     115.239.210.246                      19
                                  115.239.211.235                      2286
                                  115.239.210.14                       284
                                  240e:ff:e020:932:0:ff:b04a:7a63      2024
                                  240e:ff:e020:9d1:0:ff:b055:d090      2024

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show free-url	Displays authentication-free URLs.
clear free-url	Clears authentication-free URLs.
show dns s nooping statistics	Displays DNS packet statistics.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug dns-snooping	Debugs DNS snooping.

1 Configuring Bonjour Gateway

1.1 Overview

The Bonjour gateway is used to manage clients and servers supporting the Bonjour protocol, to implement Bonjour applications on large-scale networks.

The Bonjour gateway provides the following functions:

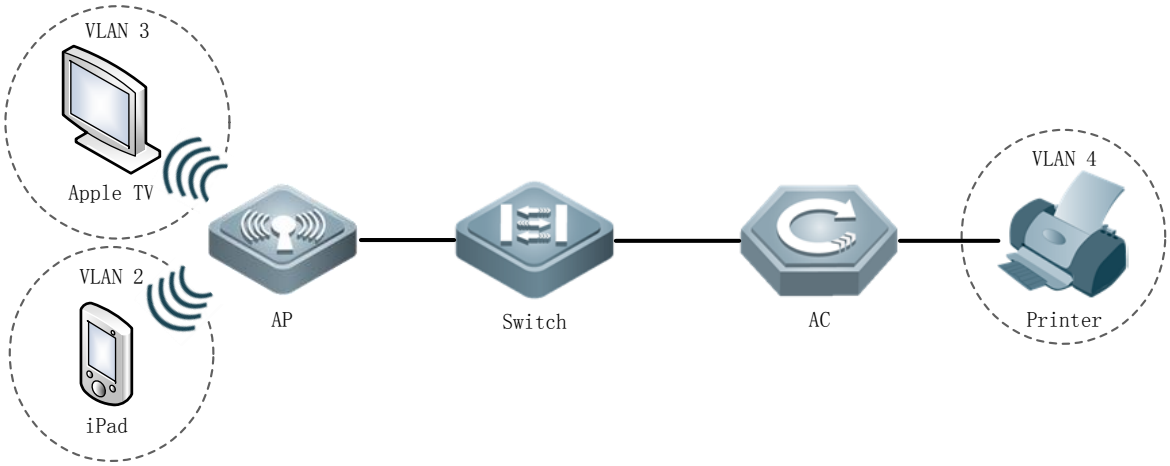
- Controls traffic of multicast Domain Network Service (mDNS) packets on a network to decrease excessive mDNS packets.
- Configures Bonjour policies and rules to manage available services on the client.
- Forwards mDNS packets of clients and servers across VLANs to enhance ease of use for networks.

Protocols and Standards

- RFC 1034: Domain Names - Concepts and Facilities
- RFC 1035: Domain Names - Implementation and Specification
- RFC 6762: Multicast DNS

1.2 Applications

Application	Description
Query Proxy and Response Forwarding	In some scenarios, the Bonjour gateway receives query packets from a client, but its service resource entries show that it does not obtain the specified service requested by the client. In this case, the Bonjour gateway needs to perform query proxy and response forwarding on the specified service. When the Bonjour gateway forwards the query packets and receives response packets about the service, it adds information about the service to Bonjour service resource entries, and forwards the response packets to the client. Then the Bonjour gateway can perform response proxy for the server.
Preemption Prohibition of the Multimedia Gateway	When different terminals use the screen projection function of Apple TV simultaneously, they may preempt resources if the Bonjour gateway is not enabled. When the Bonjour gateway is enabled, preemption is prohibited.
Automatic Server Renaming of the Multimedia Gateway	To differentiate between multiple Apple TVs on a network with the same projector name displayed on the terminals, the device provides automatic naming based on the name and IP address. This helps identify different servers.
Accurate Screen Projection of the Multimedia Gateway	If multiple Apple TVs exist on a network, multiple projector names may be displayed on the terminals, which can lead to incorrect screen projection. After the accurate screen projection function of the multimedia gateway is enabled, iPad needs to scan the QR code on the Apple TV to bind to the TV, and to detect the devices bound to the iPad. Otherwise, the iPad cannot discover any projectors.



Application	Description
Server Location Control of the Multimedia Gateway	If multiple Apple TVs exist on the network and they are connected to different APs, multiple mirroring devices may be displayed on the client. This may cause inaccurate screen mirroring. After the server location control function of the multimedia gateway is enabled, the location where an iPad goes online needs to match the location where the Apple TV server can provide services so as to discover the corresponding mirroring device.

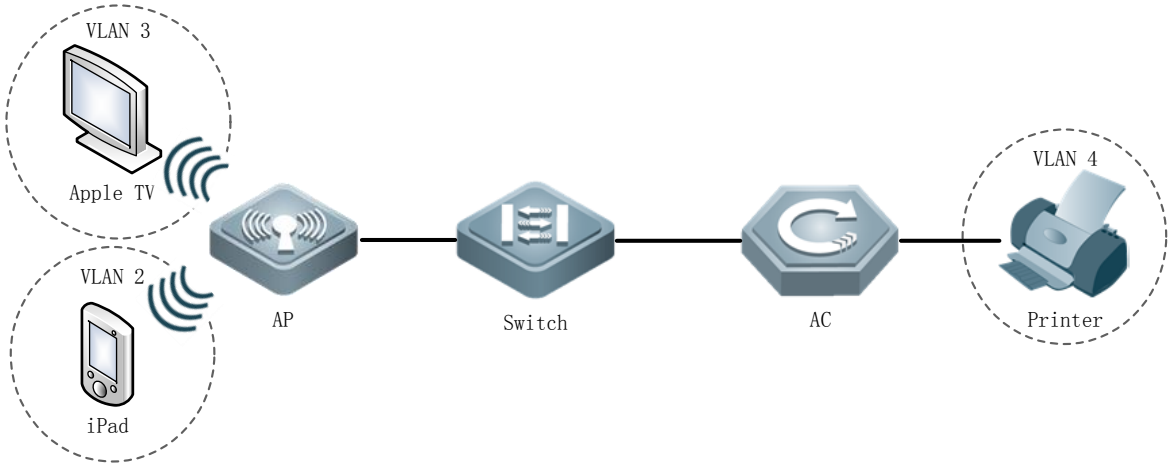
1.2.1 Query Proxy and Response Forwarding

Scenario

As shown in Figure 1-1, iPad, Apple TV, and printer are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and printer through the Bonjour gateway to communicate with them.

Figure 1-1 Bonjour Gateway Topology

Deployment



- Enable the Bonjour gateway globally to process multicast DNS request packets received on the interface.

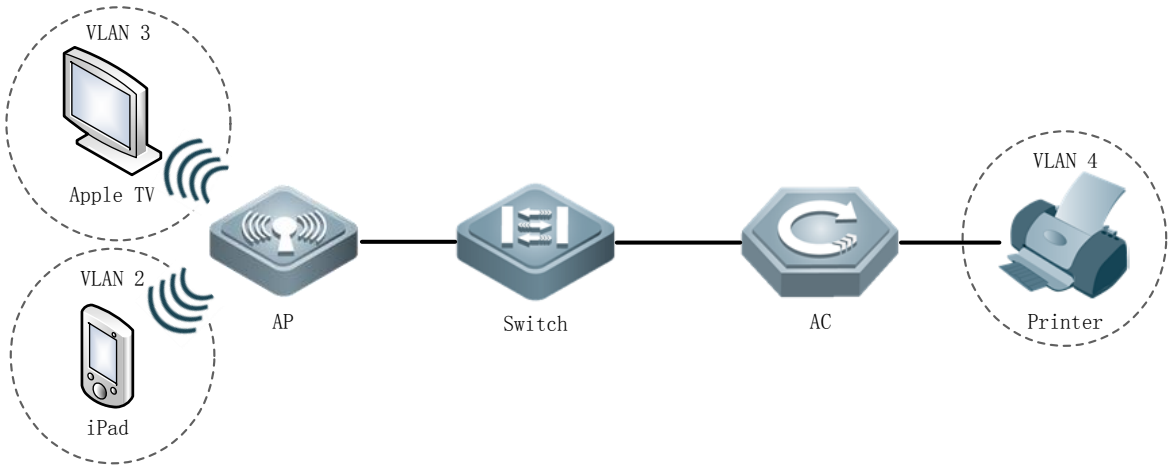
1.2.2 Preemption Prohibition of the Multimedia Gateway

Scenario

As shown in Figure 1-2, iPad, Apple TV, and printer are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and printer through the Bonjour gateway to communicate with them. When different clients use the screen projection function of Apple TV simultaneously, they may preempt resources if the Bonjour gateway is not enabled. When the Bonjour gateway is enabled, preemption prohibition can be implemented.

Figure 1-2 Bonjour Gateway Topology

Deployment



- Enable the Bonjour gateway globally to process multicast DNS request packets received on the interface and enable preemption prohibition. Preemption prohibition is forcibly enabled, and cannot be disabled.

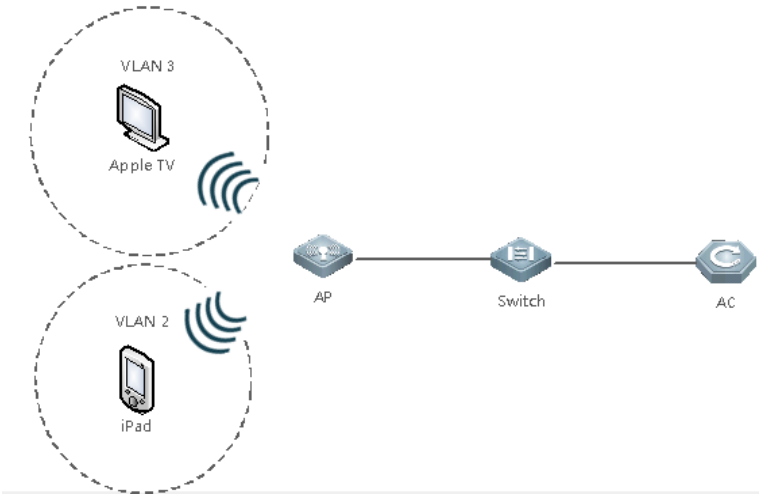
1.2.3 Automatic Server Renaming of the Multimedia Gateway

Scenario

As shown in Figure 1-3, iPad, Apple TV, and printer are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and printer through the Bonjour gateway to communicate with them. If multiple Apple TVs exist on the network, the same name may be displayed for the projectors on the clients. The device provides automatic server renaming based on names and IP addresses to differentiate them.

Figure 1-3 Bonjour Gateway Topology

Deployment



- Enable the Bonjour gateway globally to process multicast DNS request packets received on the interface and automatically rename the discovered servers.

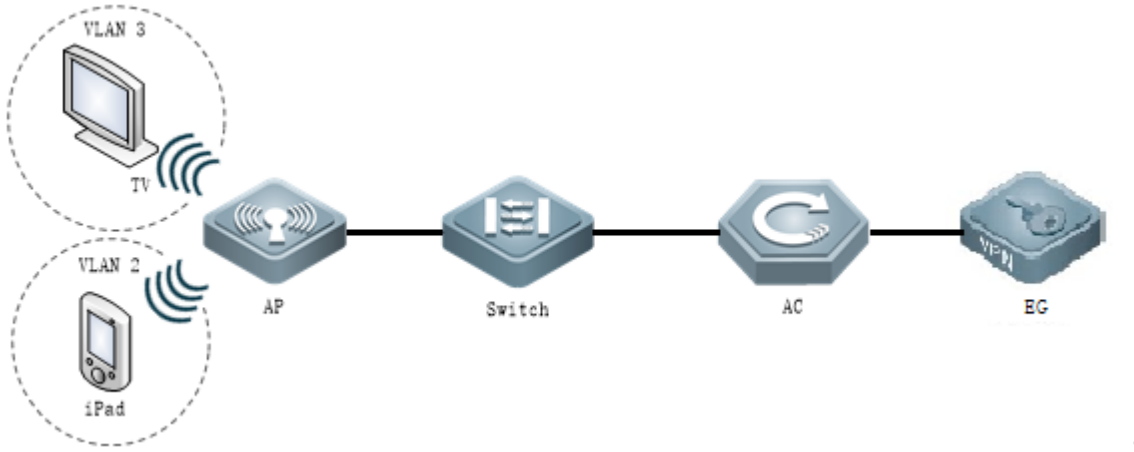
1.2.4 Accurate Screen Projection of the Multimedia Gateway

Scenario

As shown in Figure 1-4, the iPad and the Apple TV reside in different VLANs, and the AC is connected to the EG. The iPad needs to obtain the IP address of the Apple TV through the Bonjour gateway to communicate with the Apple TV. If multiple Apple TVs exist on the network, multiple projector names may be displayed on the terminals, which can lead to incorrect screen projection. After the accurate screen projection function of the multimedia gateway is enabled, iPad needs to scan the QR code on the Apple TV to bind to the TV and to detect the devices bound to the iPad. Otherwise, the iPad cannot discover any projectors.

Figure 1-4 Bonjour Gateway Topology

Deployment



- Enable the Bonjour gateway globally and then enable accurate screen projection. The terminals need to scan the QR code and bind to the Apple TV to detect and use the Bonjour screen projection service.

1.2.5 Server Location Control of the Multimedia Gateway

Scenario

As shown in the following figure, the iPad and the Apple TV are on different VLANs, and the AC is connected to the EG. The iPad needs to obtain the IP address of the Apple TV through the Bonjour gateway to communicate with the Apple TV. If there are multiple Apple TVs on the network and they are connected to different APs, multiple mirroring devices may be displayed on the client. This may cause inaccurate screen mirroring. After the server location control function of the multimedia gateway is enabled, the location where an iPad goes online needs to match the location where the Apple TV server can provide services so as to discover the corresponding mirroring device.

Figure 1 – 5 Bonjour Gateway Topology

Deployment

Enable the Bonjour gateway globally and configure the MAC address of the specified server providing the Bonjour service and the location where services are available. The iPad can discover and use the Bonjour screen mirroring service only when it is in the same location as the configured Apple TV server.

1.3 Features

Basic Concepts

↘ Bonjour

Bonjour is Apple's multicast DNS-based, zero-configuration network standard. Devices using Bonjour automatically broadcast their own service information and listen for services from other devices, much like exchanging greetings. This allows Bonjour to make systems and services on a LAN easily discoverable, even without a network administrator. It displays the names of devices and applications supporting the multicast domain name protocol on the LAN and uses multicast DNS to resolve device naming conflicts.

↘ Bonjour Gateway

The Bonjour gateway is used to manage clients and servers supporting the Bonjour protocol, to implement Bonjour applications on large-scale networks.

Overview

Feature	Description
Bonjour Gateway	The Bonjour gateway is used to manage the clients and servers supporting the Bonjour protocol, to implement Bonjour applications on large-scale networks.

1.3.1 Bonjour Gateway

Working Principle

The Bonjour gateway is used to manage clients and servers supporting the Bonjour protocol, to implement Bonjour applications on large-scale networks.

The Bonjour gateway provides the following functions.

Response Proxy

Servers send Bonjour response packets on a network to advertise the services they support. After receiving the response packets, the Bonjour gateway establishes Bonjour service resource entries, and directly sends response packets to the clients that query services contained in the entries.

Query Proxy and Response Forwarding

In some cases, the Bonjour gateway receives query packets from a client, but its service resource entries show that it does not obtain the specified service requested by the client. In this case, the Bonjour gateway needs to perform query proxy and response forwarding on the specified service. When the Bonjour gateway forwards the query packets and receives response packets about the service, it adds information about the service to the Bonjour service resource entries, and forwards the response packets to the client. Then the Bonjour gateway can perform response proxy for the server.

Screen Preemption Prohibition

When different clients use the screen projection function of Apple TV simultaneously, they may preempt resources if the Bonjour gateway is not enabled. When the Bonjour gateway is enabled, preemption prohibition can be implemented.

Automatic Renaming of Servers

If multiple Apple TVs exist on a network, the same name may be displayed for the projectors on the clients. This function enables automatic server renaming based on names and IP addresses to differentiate them.

Accurate Screen Projection

If multiple Apple TVs exist on a network, multiple projector names may be displayed on the terminals. After the accurate screen projection function of the multimedia gateway is enabled, the terminals need to scan the QR code on the Apple TV to bind to the TV to discover bound TV devices.

1.4 Configuration

Configuration	Description and Command	
Enabling the Bonjour Gateway	(Mandatory) It is used to create the Bonjour gateway service.	
	bonjour-gateway enable	Enables the Bonjour gateway.
	Optional.	
Configuring Bonjour Policies and Rules	Optional.	
	bonjour-gateway global-strategy	Applies a specified Bonjour policy globally.
	bonjour-gateway strategy	Applies a specified Bonjour policy on interfaces.
	bonjour-gateway strategy-mode	Creates a Bonjour policy.
	service type	Configures a service rule.
	service vlan range	Configures a VLAN that allows forwarding query and response packets.

Configuration	Description and Command	
Configuring Preemption Prohibition and Automatic Renaming	**service wired/wireless**	Enables service discovery in wired or wireless mode.
	bonjour-gateway airplay-preemption disable	Disables preemption prohibition.
	bonjour-gateway airplay-rename disable	Disables automatic renaming.
Active Query of Bonjour Services	⚠ Optional.	
	bonjour-gateway query enable	Enables the active query of Bonjour services.
	bonjour-gateway query interval	Configures the interval for actively querying Bonjour services.
Accurate Screen Projection	⚠ Optional.	
	bonjour-gateway airplay-fixed enable	Enables Bonjour accurate screen projection.
	bonjour-gateway airplay-fixed mac-map	Adds the MAC address binding entry for a device.
Server Location Control	⚠ (Optional)	
	bonjour-gateway service-mac	Configures server location and service scope control.

1.4.1 Enabling the Bonjour Gateway

Configuration Effect

- Implement Bonjour applications on large-scale networks after the Bonjour gateway is enabled.

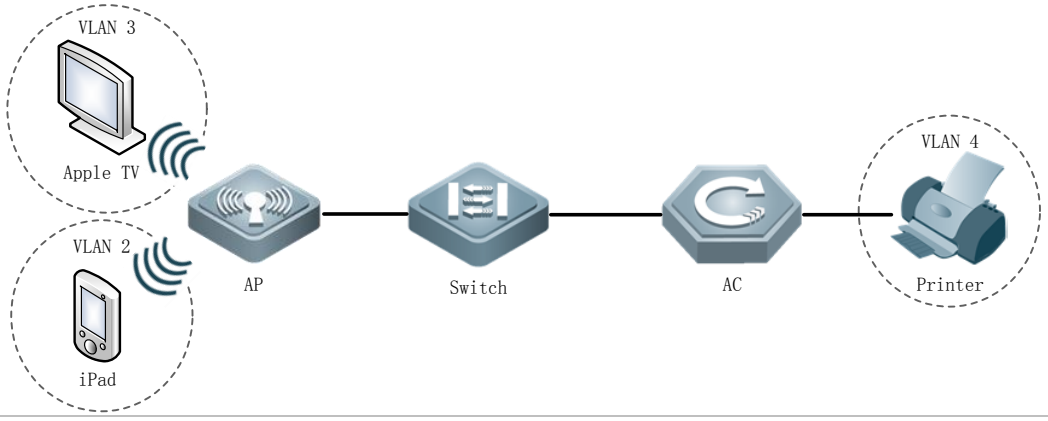
Notes

- The Bonjour gateway must be enabled on Layer 3 interfaces.

Configuration Step

↘ Enabling the Bonjour Gateway

- Mandatory.



Command	**bonjour-gateway enable**
Parameter Description	N/A
Defaults	The Bonjour gateway is disabled by default.
Command Mode	Global configuration mode or interface configuration mode
Usage Guide	After this function is configured, multicast is enabled on all or specified Layer 3 interfaces to forward multicast packets. The global Bonjour gateway must be enabled before the Bonjour gateway is enabled on a specified interface.

Verification

- Run the **show run** command to display the Bonjour gateway configuration.

Configuration Example

Enabling the Bonjour Gateway

Scenario **Figure 1-5**	● iPad, Apple TV, and printer are located in different VLANs. iPad needs to obtain the IP addresses of Apple TV and printer through the Bonjour gateway to communicate with them.
	
Configuration Steps	● Enable the Bonjour gateway.

	`Hostname#configure terminal`
	`Hostname(config)#`
	`Hostname(config)#interface vlan 2`
	`Hostname(config-if-vlan 2 )#bonjour-gateway enable`

Verification	● Check whether the Bonjour gateway is enabled.
	`Hostname#show run | begin interface vlan 2`
	`Current configuration : 491 bytes`
	
	`interface vlan 2`
	` bonjour-gateway enable`
	`!`

1.4.2 Configuring Bonjour Policies and Rules

Configuration Effect

- Configure Bonjour policies and rules to manage available services on the client.

Configuration Step

Creating a Bonjour Policy

- Optional.
- Run the **bonjour-gateway strategy-mode** command to create a Bonjour policy.

Command	**bonjour-gateway strategy-mode** *name*
Parameter	*name*: Indicates the name of a Bonjour policy.

Description	
Defaults	No Bonjour policy is created by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway strategy-mode** command is used to create a Bonjour policy. The **no bonjour-gateway strategy-mode** command is used to delete a Bonjour policy. By default, no Bonjour policy is created. A maximum of 100 Bonjour policies can be created on the device.

Configuring a Service Discovery Rule

- Optional.
- Run the **service { wired | wireless } disable** command to configure a service discovery rule.

Command	**service { wired | wireless } disable**
Parameter Description	N/A
Defaults	Services can be discovered in both wired and wireless modes by default.
Command Mode	Bonjour gateway mode
Usage Guide	The **service { wired | wireless } disable** command is used to configure a service discovery rule. The **no service { wired | wireless } disable** command is used to delete a service discovery rule. By default, service discovery is allowed in both wired and wireless modes.

Configuring a Service Instance

- Optional.
- Run the **service type** command to create a service rule.

Command	**service type** *type* **{ instance** *name* | **disable }**
Parameter Description	*type*: Indicates the type of a service that can be found by the client. *name*: Indicate the instance name of a service that needs to be searched for by the client.
Defaults	The client can find all services by default.
Command Mode	Bonjour gateway mode
Usage Guide	The **service type** command is used to set a service rule. The **no service type** command is used to delete a service rule. By default, the client can find all services. After the **no service type** command is configured, the corresponding service cannot be found.

Configuring a Service VLAN

- Optional.
- Run the **service vlan range** command to configure a VLAN that allows forwarding query and response packets when a specified Bonjour policy is applied.

Command	**service vlan { range** *vlan-id-list* **| access-vlan }**
Parameter Description	*vlan-id-list*: Indicates the VLAN list. **access-vlan**: Allows forwarding query and response packets in the VLAN to which connected clients belong.

Defaults	All query and response packets are forwarded by default.
Command Mode	Bonjour gateway mode
Usage Guide	The **service vlan range** command is used to configure a VLAN that allows forwarding query and response packets, and discard the query and response packets outside the VLAN. The **no service vlan** command is used to delete the settings. By default, all query and response packets are forwarded.

Applying a Specified Bonjour Policy Globally

- Optional.
- Run the **bonjour-gateway global-strategy** command to apply a specified Bonjour policy globally.

Command	**bonjour-gateway global-strategy** *name*
Parameter Description	*name*: Indicates the name of a Bonjour policy.
Defaults	No Bonjour policy is applied globally by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway global-strategy** command is used to apply a specified Bonjour policy globally. The **no bonjour-gateway global-strategy** command is used to cancel the applied Bonjour policy. By default, no Bonjour policy is applied globally. That is, when the Bonjour gateway is enabled, only the default service type is supported by default, and services can be found in both wired and wireless modes.

Applying a Specified Bonjour Policy

- Optional.
- Run the **bonjour-gateway strategy** command to apply a specified Bonjour policy on Layer 3 interfaces.

Command	**bonjour-gateway strategy** *name*
Parameter Description	*name*: Indicates the name of a Bonjour policy.
Defaults	No Bonjour policy is applied to Layer 3 interfaces by default.
Command Mode	Interface configuration mode
Usage Guide	The **bonjour-gateway strategy** command is used to apply a specified Bonjour policy to Layer 3 interfaces. The **no bonjour-gateway strategy** command is used to cancel the applied Bonjour policy. By default, no Bonjour policy is applied to Layer 3 interfaces.

Verification

- Run the **show run** command to display the Bonjour gateway configuration.

Configuration Example

Configuring a Bonjour Policy

Scenario	See Figure 1-2.

Configuration Steps	● Configure a Bonjour policy.

	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# bonjour-gateway strategy-mode teacher`
	`Hostname(config-bonjour-gateway)#service type ftp ip 10.0.0.5`
	`Hostname(config-bonjour-gateway)#service vlan range 5`
	`Hostname(config-bonjour-gateway)#service vlan access-vlan`
	`Hostname(config-bonjour-gateway)#exit`
	`Hostname(config)#`
	`Hostname(config)#interface vlan 2`
	`Hostname(config-if-vlan 1)#bonjour-gateway enable`
	`Hostname(config-if-vlan 1)# bonjour-gateway strategy teacher`

Verification	● Check whether the Bonjour gateway is enabled.
	`Hostname#show run | begin interface VLAN 1`
	`Current configuration : 491 bytes`
	
	`interface VLAN 2`
	` bonjour-gateway enable`
	` bonjour-gateway strategy teacher`
	`!`
	● Check whether a Bonjour policy is configured.
	`Hostname#show run | begin bonjour-gateway`
	`Current configuration : 491 bytes`
	
	`bonjour-gateway strategy-mode teacher`
	` service type ftp ip 10.0.0.5`
	` service vlan range 5`
	` service vlan access-vlan`
	`!`

1.4.3 Configuring Preemption Prohibition and Automatic Renaming

Configuration Effect

- Configure preemption prohibition and automatic renaming.

Configuration Step

↘ Disabling Preemption Prohibition

- Optional.
- Run the **bonjour-gateway airplay-preemption disable** command to disable preemption prohibition.

Command	**bonjour-gateway airplay-preemption disable**
Parameter Description	N/A

Defaults	Preemption prohibition is enabled by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway airplay-preemption disable** command is used to disable preemption prohibition.

Disabling Automatic Renaming

- Optional.
- Run the **bonjour-gateway airplay-rename disable** command to disable automatic renaming.

Command	**bonjour-gateway airplay-rename disable**
Parameter Description	N/A
Defaults	Automatic renaming is enabled by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway airplay-rename disable** command is used to disable automatic renaming.

Verification

- Run the **show run** command to display the Bonjour gateway configuration.

Configuration Example

Disabling Automatic Renaming

Scenario	See Figure 1-2.
Configuration Steps	• Disable automatic renaming.

	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# bonjour-gateway airplay-rename disable`

Verification	• Check whether automatic renaming is disabled.
	`Hostname#show run | begin bonjour-gateway`
	`Current configuration : 491 bytes`
	
	`bonjour-gateway airplay-rename disable!`

Common Errors

N/A

1.4.4 Active Query of Bonjour Services

Configuration Effect

- To implement response proxy, the Bonjour gateway needs to maintain Bonjour service resource entries. When the active query of Bonjour services is enabled, the Bonjour gateway can guarantee real-timeliness of Bonjour service resource entries.

Configuration Step

Enabling Active Query of Bonjour Services

- Optional.
- Run the **bonjour-gateway query enable** command to enable active query of Bonjour services.

Command	bonjour-gateway query enable
Parameter Description	N/A
Defaults	Active query of Bonjour services is disabled by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway query enable** command is used to enable active query of Bonjour services. The **no bonjour-gateway query enable** command is used to disable active query of Bonjour services. By default, active query of Bonjour services is disabled.

Configuring the Interval for Sending Query Packets to a Discovered Service

- Optional.
- Run the **bonjour-gateway query interval** command to configure the interval for sending query packets to a discovered service.

Command	**bonjour-gateway query interval** *number*
Parameter Description	*number*: Indicates the interval for sending query packets to a discovered service, in seconds. The value range is from 5 to 600.
Defaults	The interval for sending query packets to a discovered service is 15s by default.
Command Mode	Global configuration mode
Usage Guide	The **bonjour-gateway query interval** command is used to configure the interval for sending query packets to a discovered service. The **no bonjour-gateway query interval** command is used to restore the default settings. By default, the interval for sending query packets to a discovered service is 15s.

Verification

- Run the **show run** command to display the Bonjour gateway configuration.

Configuration Example

Enabling Active Query of Bonjour Services

Scenario	See Figure 1-2.
Configuration Steps	• Enable active query of Bonjour services.

	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#bonjour-gateway query enable`
	`Hostname(config)#bonjour-gateway query interval 20`

Verification	● Check whether active query of Bonjour services is enabled.
	`Hostname#show run | begin bonjour-gateway`
	`Current configuration : 491 bytes`
	
	`bonjour-gateway query enable`
	`bonjour-gateway query interval 20`
	`!`

1.4.5 Accurate Screen Projection

Configuration Effect

- With the Bonjour accurate screen projection function enabled, the device responds to the terminals according to the binding relationship. Run the **bonjour-gateway airplay-fixed enable** command to enable this function.

Notes

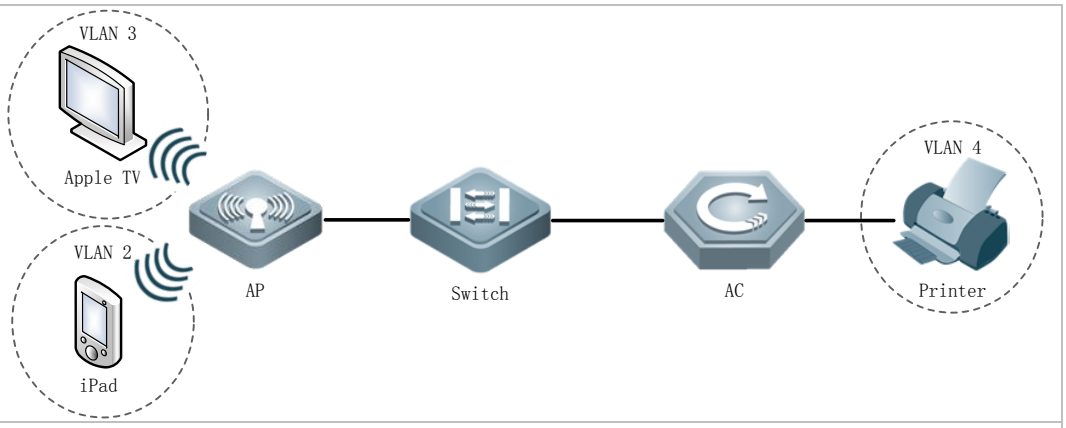
- The Bonjour gateway must be enabled first.

Configuration Step

↘ Enabling Accurate Screen Projection

- Mandatory.

Command	**bonjour-gateway airplay-fixed enable**
Parameter Description	N/A
Defaults	Accurate screen projection is disabled by default.
Command Mode	Global configuration mode
Usage Guide	After accurate screen projection is enabled, the device returns a unicast response to a specified terminal based on MAC address binding, instead of providing the multicast response service to the terminal. This command is used to enable accurate screen projection.



Verification

- Run the **show run** command to display the Bonjour accurate screen projection configuration.

Configuration Example

↘ Enabling Accurate Screen Projection

Scenario **Figure 1-1**	● As shown in the following figure, iPad, Apple TV, and printer reside in different VLANs. iPad needs to obtain the IP address of Apple TV through the Bonjour gateway to communicate with Apple TV and printer.

	
Configuration Steps	● Enable accurate screen projection.

	`Hostname#configure terminal`
	`Hostname(config)#`
	`Hostname(config)#bonjour-gateway airplay-fixed enable`

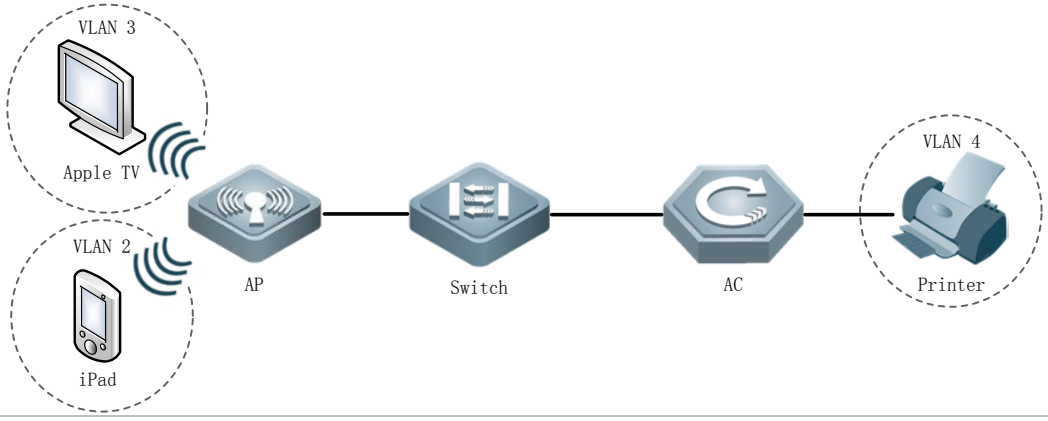
Verification	● Check whether the Bonjour accurate screen projection is enabled.
	`Hostname#show run | include fixed`
	`bonjour-gateway airplay-fixed enable`
	`Hostname#`

Common Errors

N/A

Adding the Binding Entry of the STA's and TV's MAC Addresses on a Device

- Optional.
- Run the **bonjour-gateway airplay-fixed mac-map stamac** *mac1* **tvmac** *mac2* [**ttl** *number*] command to add the binding entry of the STA's and TV's MAC addresses.



Command	**bonjour-gateway airplay-fixed mac-map stamac** *mac1* **tvmac** *mac2* **tvname** *name* [**ttl** *number*]
Parameter Description	*mac1:* Indicates the MAC address of the STA. *mac2:* Indicates the MAC address of the TV. *name*: Indicates the name of the TV. *number*: Indicate the time to live (TTL) of MAC address binding entries, in minutes. The default value is 1440 minutes (1 day).
Defaults	No binding entry is configured by default.
Command Mode	Global configuration mode
Usage Guide	Run the **bonjour-gateway airplay-fixed enable** command to enable accurate screen projection before you configure binding entries. The **bonjour-gateway airplay-fixed mac-map stamac** *mac1* **tvmac** *mac2* **tvname** *name* [**ttl** *number*] command is used to add the binding entry of STA's and TV's MAC addresses. The default TTL of the entry is 1440 minutes (that is, 1 day) and can be configured as required. The **no bonjour-gateway airplay-fixed mac-map stamac** *mac1* command is used to delete a binding entry. No binding entry is configured on the device by default.

Verification

- This command is an action command. The configuration of this command cannot be displayed by the **show run** command. Run the **show bonjour-gateway mac-map info** command to display the added entries.

Configuration Example

Adding the MAC Address Binding Entry for a Device

Scenario **Figure 1-7**	• As shown in the following figure, iPad, Apple TV, and printer reside in different VLANs. iPad needs to obtain the IP address of Apple TV through the Bonjour gateway to communicate with Apple TV and printer.
	
Configuration Steps	• Add the binding entry of the STA's and TV's MAC addresses on a device.

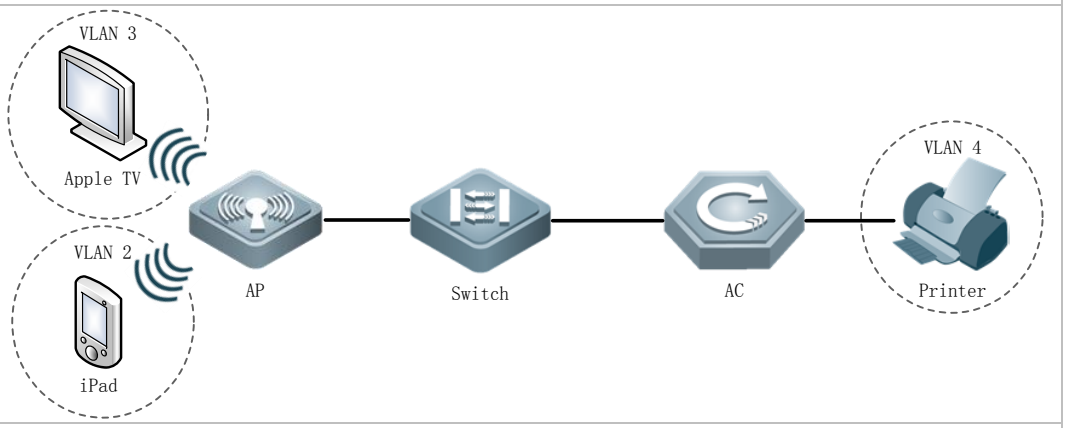
	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#bonjour-gateway airplay-fixed enable`
	`Hostname(config)#bonjour-gateway airplay-fixed mac-map stamac fe80.4c4e.0708 tvmac 509a.3a5b.6048 tvname sta1 ttl 2`

Verification	• Check whether the MAC address binding entry have been added.
	`Hostname#show bonjour-gateway mac-map info`
	`Map Number: 2`
	
	`STA MAC  TV MAC  TIME TO LIVE  TV NAME`
	`----------  ----------  ----------  ----------`
	`fe80.4c4e.a7b8  509a.3a5b.6048  86400  sta1`
	`fe80.4c4e.0708  509a.3a5b.6048  120  sta2`
	`Hostname#`

Configuring the Upper Limit for MAC Address Binding Entries

- Mandatory.

Command	**bonjour-gateway airplay-fixed mac-map limit** *num*
Parameter Description	*num:* Indicates the upper limit for binding entries. The value range is from 1 to 2000.
Defaults	The upper limit for binding entries is not configured by default.
Command	Global configuration mode



Mode	
Usage Guide	After this command is configured, if the number of MAC address binding entries for accurate screen projection exceeds the configured upper limit, new binding entries cannot be added and a prompt is displayed.

Verification

- Run the **show run** command to display the upper limit for binding entries.

Configuration Example

Configuring the Upper Limit for MAC Address Binding Entries

Scenario **Figure 1-8**	• As shown in the following figure, iPad, Apple TV, and printer reside in different VLANs. iPad needs to obtain the IP address of Apple TV through the Bonjour gateway to communicate with Apple TV and printer.
	
Configuration Steps	• Configure the upper limit for MAC address binding entries.

	`Hostname#configure terminal`
	`Hostname(config)#`
	`Hostname(config)#bonjour-gateway airplay-fixed mac-map limit 200`

Verification	• Check the upper limit for MAC address binding entries.
	`Hostname#sh run | include fixed`
	`bonjour-gateway airplay-fixed mac-map limit 200`
	`Hostname#`

Common Errors

N/A

1.4.6 Server Location Control

Configuration Effect

- After Bonjour server location control is configured, the Bonjour gateway responds to clients based on the server location matching relationship.

Notes

- The Bonjour gateway must be enabled first.

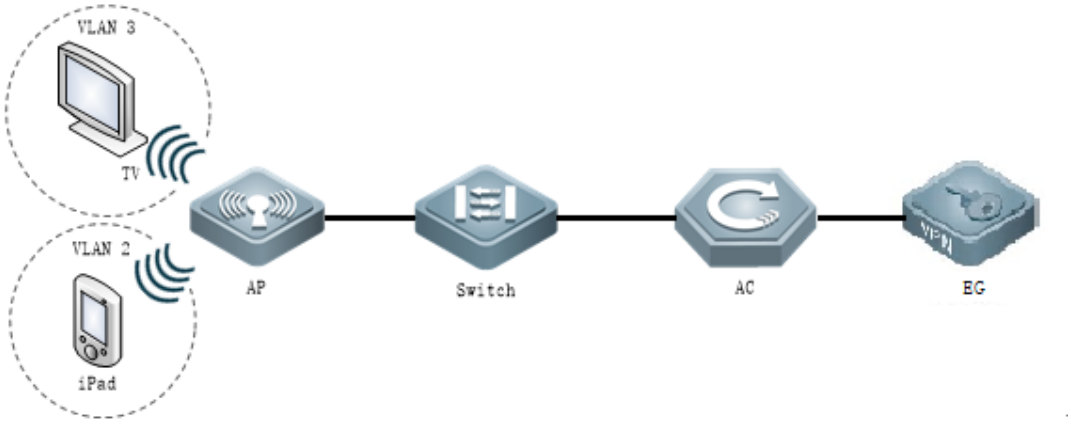
Configuration Steps

Configuring Server Location Control

- Mandatory.

Command	**bonjour-gateway service-mac** *mac-address* **location-type** { **ap-location** | **ap-name** | **ap-group** } **match** { *string* | **same** }
Parameter Description	*mac-address*: Indicates the MAC address of the server that provides services. **ap-location**: Matches against the AP location. **ap-name**: Matches against the AP name. **ap-group**: Matches against the AP group. *string*: Indicates the AP location, AP name, and AP group name when combined with **ap-location**/**ap-name**/**ap-group**. **same**: Indicates that the connected AP shares the same AP location, AP name, AP group with the server when combined with **ap-location**/**ap-name**/**ap-group**.
Defaults	Bonjour server location control is disabled.
Command Mode	Global configuration mode
Usage Guide	This command is used to specify the MAC address of a server that can provide services, and the server can provide services at the configured location. When the server access the Internet through a wired connection instead of being connected to an AP. Therefore, the **same** parameter is invalid. You can directly specify the location, name, and AP group name of the AP that provides services. After this command is run, only the configured server can respond to requests, and the unconfigured server cannot provide services for the device. When the **same** or *string* parameter is used for accurate screen mirroring control, and a roaming client is still connected to the original AP rather than the AP connected to the server in the conference room, the roaming client needs to be disconnected and then reconnected.

Verification



Run the **show running-config** command to check whether the configuration is successful.

Run the **show bonjour-gateway location info** command to check whether the configuration is successful.

Configuration Examples

Enabling Bonjour AP Name-based Location Control on the Server Connected to the AP to Provide Screen Mirroring Service

Scenario Figure1 -7	As shown in the following figure, the iPad and Apple TV are on different VLANs. The iPad needs to obtain the IP address of the Apple TV through the Bonjour gateway to communicate with the Apple TV. The MAC address of the Apple TV is f46d.3fe9.69d4. The iPad can obtain the screen mirroring service only when connected to the AP820-AR.

	
Configuration Steps	In global configuration mode on the AC, specify the server whose MAC address is f46d.3fe9.69d4 to provide services only for clients connected to the AP820-AR.

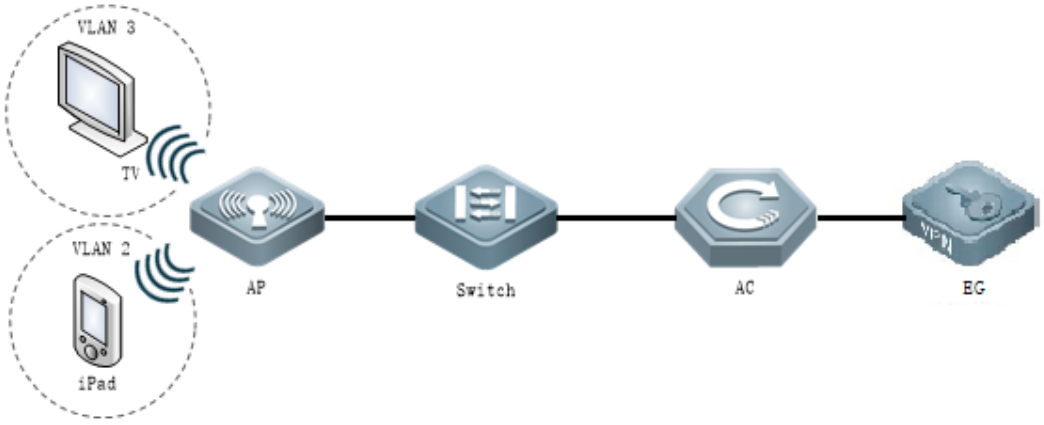
	`Hostname(config)#ap-config 7085.c487.fda2`
	`You are going to config AP(7085.c487.fda2), which is online now.`
	`Hostname(config-ap)#ap-name ap820-ar`
	`Hostnameconfig-ap)#exit`
	`Hostname(config)# bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-name match ap820-ar`

Verification	● Run the **show running-config** command on the AC to check whether the Bonjour server location control is configured.
	`Hostname# show running-config | include location-type`
	`bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-name match ap820-ar`

	● Run the **show bonjour-gateway location info** command on the AC to check whether the configuration is successful.
	`Hostname#show bonjour-gateway location info`
	`Total number of config service mac: 1`
	`SERVICE MAC SERVICE_AP MAC LOCATION TYPE MATCH NAME`
	`---------- ---------- ---------- ----------`
	`f46d.3fe9.69d4 7085.c487.fda2 ap-name name ap820-ar`

Enabling Bonjour AP Group-based Location Control on the Server Connected to the AP to Provide Screen Mirroring Service

Scenario Figure1 -8	As shown in the following figure, the iPad and Apple TV are on different VLANs. The iPad needs to obtain the IP address of the Apple TV through the Bonjour gateway to communicate with the Apple TV. The MAC address of the Apple TV is f46d.3fe9.69d4. The iPad can obtain the screen mirroring service only when it goes online by associating with the AP in the AP group where the Apple TV is online.

Configuration Steps	In global configuration mode on the AC, specify the server whose MAC address is f46d.3fe9.69d4 to provide services only for clients connected to the AP in the AP group where the server is online.
	`Hostname(config)# bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-group match same`

Verification	● Run the **show running-config** command on the AC to check whether the Bonjour server location control is configured.
	`Hostname# show running-config | include location-type`
	`bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-group match same`

	● Run the **show bonjour-gateway location info** command on the AC to check whether the configuration is successful.
	`Hostname#show bonjour-gateway location info`
	`Total number of config service mac: 1`
	`SERVICE MAC SERVICE_AP MAC LOCATION TYPE MATCH NAME`
	`---------- ---------- ---------- ----------`
	`f46d.3fe9.69d4 7085.c487.fda2 ap-group same group1`

Enabling Bonjour AP Location-based Location Control on the Server Connected to the AP to Provide Screen Mirroring Service

Scenario Figure1 -9	As shown in the following figure, the iPad and Apple TV are on different VLANs. The iPad needs to obtain the IP address of the Apple TV through the Bonjour gateway to communicate with the Apple TV. The MAC address of the Apple TV is f46d.3fe9.69d4. The iPad that go online at the same AP location can obtain the screen mirroring service provided by the Apple TV.

	
Configuration Steps	In global configuration mode on the AC, specify the server whose MAC address is f46d.3fe9.69d4 to provide services only for the iPad that goes online with the AP location set to test. Regardless of whether the iPad is connected to AP 1 or AP 2, the iPad can obtain the service provided by the Apple TV.

	`Hostname(config)#ap-config AP1`
	`Hostname(config-ap)#location test`
	`Hostname(config-ap)#exit`
	`Hostname(config)#ap-config AP2`
	`Hostname(config-ap)#location test`
	`Hostname(config-ap)#exit`
	`Hostname(config)# bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-location match test`

Verification	● Run the **show running-config** command on the AC to check whether the Bonjour server location control is configured.
	`Hostname# show running-config | include location-type`
	`bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-location match any`

	● Run the **show bonjour-gateway location info** command on the AC to check whether the configuration is successful.
	`Hostname#show bonjour-gateway location info`
	`Total number of config service mac: 1`
	`SERVICE MAC SERVICE_AP MAC LOCATION TYPE MATCH NAME`
	`---------- ---------- ---------- ----------`
	`f46d.3fe9.69d4 7085.c487.fda2 ap-location name test`

Enabling Bonjour Location Control on the Server Connected to a Wired Network to Provide Screen Mirroring Service

Scenario	The Apple TV access the Internet through a wired connection instead of being connected to an AP. The iPad needs to obtain the IP address of the Apple TV through the Bonjour gateway to communicate with the Apple TV. The MAC address of the Apple TV is f46d.3fe9.69d4. The iPad can only obtain the screen mirroring service when connected to the AP at location_1.

Configuration Steps	The Apple TV is not directly connect to APs. Therefore, the **same** keyword cannot be used. You can precisely configure the AP location, AP name, and AP group name that can be matched to provide services. The server with the MAC address of f46d.3fe9.69d4 can only provide services for clients connected to the AP at location_1.

	`Hostname(config)#ap-config 7085.c487.fda2`
	`You are going to config AP(7085.c487.fda2), which is online now.`
	`Hostname(config-ap)#location location_1`
	`Hostname(config-ap)#exit`
	`Hostname(config)# bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-location match location_1`

Verification	● Run the **show running-config** command on the AC to check whether the Bonjour server location control is configured.
	`Hostname# show running-config | include location-type`
	`bonjour-gateway service-mac f46d.3fe9.69d4 location-type ap-location match location_1`

	● Run the **show bonjour-gateway location info** command on the AC to check whether the configuration is successful.
	`Hostname#show bonjour-gateway location info`
	`Total number of config service mac: 1`
	`SERVICE MAC SERVICE_AP MAC LOCATION TYPE MATCH NAME`
	`---------- ---------- ---------- ----------`
	`f46d.3fe9.69d4 -- ap-location name location_1`

Common Errors

N/A

1.5 Monitoring

Displaying

Command	Description
show bonjour-gateway service-database	Displays information about the discovered Bonjour service.
show bonjour-gateway service-database ip *address*	Displays information about the discovered Bonjour service of a specified IP address.
show bonjour-gateway strategy-mode	Displays Bonjour policy information.
show bonjour-gateway mac-map info [json]	Displays MAC address binding entry information.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description

debug bonjour error	Debugs the Bonjour gateway error.
debug bonjour stamng	Debugs preemption of the Bonjour gateway.

1 Configuring IPv6 Basics

1.1 Overview

As the Internet evolves rapidly and IPv4 address space becomes increasingly scarce, IPv4 limitations become obvious. Extensive research and development have been focused on the next-generation Internet Protocol (IPng). The IPng working group of the Internet Engineering Task Force (IETF) has developed a new protocol called IP Version 6 (IPv6), as outlined in RFC 2460.

Main Features

↘ Larger Address Space

Compared with 32 bits in an IPv4 address, the length of an IPv6 address is extended to 128 bits. Therefore, the address space has approximately 2^{128} addresses. IPv6 adopts a hierarchical address allocation mode to support address allocation of multiple subnets from the Internet core network to the intranet subnet.

↘ Simpler Packet Header Format

To minimize the packet header overhead, the design principle of the IPv6 packet header involves moving some non-essential and optional fields to the extended header. As a result, although an IPv6 address is four times longer than an IPv4 address, the IPv6 packet header is only twice as large as its IPv4 counterpart. This design makes device forwarding more efficient. For instance, the absence of a checksum in the IPv6 packet header means that devices don't need to process fragments, as fragmentation is handled by the initiator.

↘ Efficient Hierarchical Addressing and Routing Structure

IPv6 uses a convergence mechanism and defines a flexible hierarchical addressing and routing structure. Multiple networks at the same layer are represented as a uniform network prefix on the upstream device, greatly reducing routing entries maintained by the device and routing and storage overheads of the device.

↘ Easy Management: Plug and Play (PnP)

IPv6 provides automatic discovery and auto-configuration functions to simplify management and maintenance of network nodes. For example, Neighbor Discovery (ND), MTU Discovery, Router Advertisement (RA), Router Solicitation (RS), and auto-configuration technologies provide services for PnP. Particularly, IPv6 offers two types of auto-configuration: stateful and stateless auto-configuration. In IPv4, the Dynamic Host Configuration Protocol (DHCP) realizes auto-configuration of the host IP address and related parameters. IPv6 inherits this auto-configuration service from IPv4 and calls it stateful auto-configuration (see DHCPv6). Besides, IPv6 also offers the stateless auto-configuration service. During stateless auto-configuration, a host automatically obtains the local address of the link, address prefix of the local device, and other related configuration.

↘ Security

Internet Protocol Security (IPsec), which is an optional extension for IPv4, is integrated into IPv6 to provide security for IPv6 packets. IPv6 includes two mechanisms for this purpose: Authentication Header (AH) and Encapsulated Security

Payload (ESP). AH ensures data integrity and authenticates the source of IP packets to verify that they originate from the nodes specified by source addresses. Meanwhile, ESP provides data encryption to enable end-to-end confidentiality.

Better QoS Support

A new field in the IPv6 packet header defines how to identify and process data streams. The Flow Label field in the IPv6 packet header is used to authenticate a data flow and allow users to specify QoS requirements. A device can identify all packets belonging to a specific data stream based on this field and process these packets according to user requirements.

NDP for Neighboring Node Interaction

IPv6 Neighbor Discovery Protocol (NDP) uses a series of Internet Control Message Protocol Version 6 (ICMPv6) packets to implement interactive management of neighboring nodes (nodes on the same link). IPv6 uses NDP packets and efficient multicast/unicast ND packets but not broadcast-based Address Resolution Protocol (ARP) and Control Message Protocol Version 4 (ICMPv4) router discovery packets.

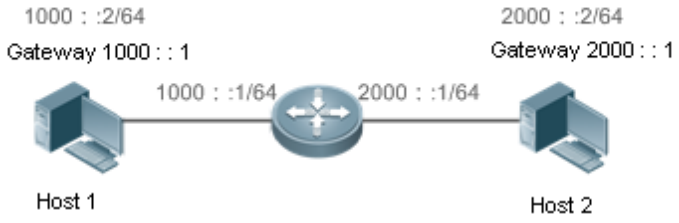
Extensibility

With strong extensibility, IPv6 features can be added to the extended packet header following the IPv6 packet header. Unlike IPv4, the IPv6 packet header can support at most 40 bytes of options. For an IPv6 packet, the length of the extended packet header is restricted only by the maximum number of bytes in the packet.

Protocols and Standards

- RFC 4291 - IPVersion6AddressingArchitecture
- RFC 2460 - Internet Protocol, Version 6 (IPv6) Specification
- RFC 4443 - Internet Control Message Protocol (ICMPv6) for the Internet Protocol Version 6 (IPv6) Specification
- RFC 4861 - Neighbor Discovery for IP version 6 (IPv6)
- RFC 4862 - IPv6 Stateless Address Auto-configuration
- RFC 5059 - Deprecation of Type 0 Routing Headers in IPv6
- RFC8106 - IPv6 Router Advertisement Options for DNS Configuration

1.2 Applications



Application	Description
Communication Based on IPv6 Addresses	Two PCs communicate with each other using IPv6 addresses.

1.2.1 Communication Based on IPv6 Addresses

Scenario

As shown in Figure 1-1, Host 1 and Host 2 communicate with each other using IPv6 addresses.

Figure 1-1

Deployment

Hosts can use stateless address auto-configuration or DHCPv6 address assignment mode. After addresses are configured, hosts can communicate with each other using IPv6 addresses.

1.3 Features

Overview

Feature	Description
IPv6 Address Format	The IPv6 address format makes IPv6 have a larger address space and a more flexible representation.
IPv6 Address Type	IPv6 identifies network applications based on addresses.
IPv6 Packet Header Format	IPv6 simplifies fixed and extended packet headers to improve the data packet processing and forwarding efficiency of the device.
IPv6 PMTUD	A host dynamically discovers and adjusts the MTU on the data Tx path, saving router resources and improving IPv6 network efficiency.
IPv6 Neighbor Discovery	ND functions include router discovery, prefix discovery, parameter discovery, address auto-configuration, address resolution (similar to ARP), next-hop determination, Neighbor Unreachability Detection (NUD), Duplicate Address Detection (DAD), and redirection.
Configuring the Interface to Generate a Default Route Based on the RA Packet ● By default, no default route is generated based on the RA packet. ● Run the **ipv6 nd ra default route** command in interface configuration mode to generate a default route based on the RA packet. IPv6 Source Routing	This feature is used to specify the intermediate nodes that a packet passes through along the path to the destination address. It is similar to the IPv4 loose source routing option and loose record routing option.
Limiting the Rate for Sending ICMPv6 Error Messages	This feature prevents DoS attacks.

Feature	Description
IPv6 Hop Limit	This feature prevents useless unicast packets from being unlimitedly transmitted on the network and wasting network bandwidth.
Enabling Suppression of Broadcasting NS Packets to Authentication VLANs	In gateway authentication mode, the device is suppressed from broadcasting NS packets to authentication VLANs.
Configuring the Device Enabled with IPv6 ND to Allocate Different Prefixes to Different Users	Different IPv6 prefixes can be allocated to different users.
Enabling ND Packet Rate Statistics Collection	You can count the number of ND packets sent and received on all IPv6 interfaces, and their corresponding rates.
Binding the DNS Address Pool to the IPv6 Interface	The DNS address pool is bound to the IPv6 interface to carry the DNS address information in the DNS address pool when the interface announces router advertisement (RA) information.

1.3.1 IPv6 Address Format

An IPv6 address is represented in X:X:X:X:X:X:X:X format, where X is a 4-digit hexadecimal integer (16 bits). Each address consists of 8 integers, with a total of 128 bits (each integer contains 4 hexadecimal digits and each digit contains 4 bits). The following are three valid IPv6 addresses:

- 2001:ABCD:1234:5678:AAAA:BBBB:1200:2100
- 800:0:0:0:0:0:0:1
- 1080:0:0:0:8:800:200C:417A

These integers are hexadecimal, where A to F represent 10 to 15. Each integer in the address must be represented, except leading zeros in each integer. If an IPv6 address contains a string of zeros (as shown in the preceding second and third examples), a double colon (::) can be used to represent these zeros. That is, 800:0:0:0:0:0:0:1 can be represented as 800::1.

A double colon indicates that this address can be expanded to a full 128-bit format. This notation can only be used when the 16-bit groups being replaced are all zeros, and a double colon can appear only once in an IPv6 address.

In environments with both IPv4 and IPv6, an IPv6 address can include an IPv4 address in its least significant 32 bits. This mixed representation is formatted as X:X:X:X:X:X:d.d.d.d, where X represents hexadecimal values and d represents 8-bit decimal values. For example, the IPv6 address 0:0:0:0:0:0:192.168.20.1 can be abbreviated to ::192.168.20.1. Common uses include IPv4-compatible IPv6 addresses and IPv4-mapped IPv6 addresses. IPv4-compatible addresses, such as ::1.1.1.1, are now obsolete, while IPv4-mapped addresses, such as ::FFFF:1.1.1.1, are used to represent IPv4 addresses within an IPv6 format.

An IPv6 address is divided into two parts: subnet prefix and interface ID. It can be expressed with an additional value based on an address allocation method such as Classless Inter-Domain Routing (CIDR). This additional value shows how many bits of the address represent the network part. Essentially, the IPv6 address includes the prefix length, which is separated from the address by a slash. For example, in 12AB::CD30:0:0:0:0/60, the prefix length for routing is 60 bits.

Related Configuration

↘ **Configuring an IPv6 Address**

- No IPv6 address is configured on interfaces by default.
- Run the **ipv6 address** command to configure an IPv6 address on an interface.
- A host can communicate with others using the configured IPv6 address based on DAD.

1.3.2 IPv6 Address Type

RFC 4291 defines three types of IPv6 addresses:

- Unicast address: ID of a single interface. Packets destined to a unicast address are sent to the interface identified by this address.
- Multicast address: ID of an interface group (interfaces belong to different nodes). Packets destined to a multicast address are sent to all interfaces included in this address.
- Anycast address: ID of an interface group. Packets destined to an anycast address are sent to one interface included in this address (the nearest interface according to the routing protocol).

IPv6 does not define broadcast addresses.

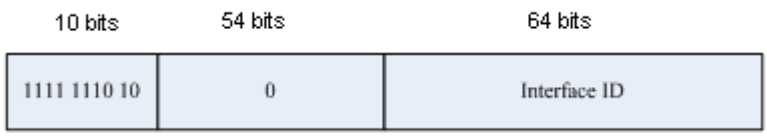
These three types of addresses are described as follows.

Unicast Addresses

Unicast addresses fall into five types: unspecified address, loopback address, link-local address, site-local address, and global unicast address. Site-local addresses have been abolished. Except unspecified, loopback, and link-local addresses, all other addresses are global unicast addresses.

- Unspecified address

The unspecified address is 0:0:0:0:0:0:0:0, which is abbreviated to ::. It has two purposes:



1. If a host has no unicast address upon startup, it uses the unspecified address as the source address to send an RS packet to obtain prefix information from the gateway and thereby generate a unicast address.
2. When an IPv6 address is configured for a host, the device detects whether the address conflicts with addresses of other hosts on the same network segment and uses the unspecified address as the source address to send a Neighbor Solicitation (NS) packet (similar to a free ARP packet).

- Loopback address

The loopback address is 0:0:0:0:0:0:0:1, which is usually abbreviated to ::1. Similar to IPv4 address 127.0.0.1, the loopback address is often used by a node to send itself packets.

- Link-local address

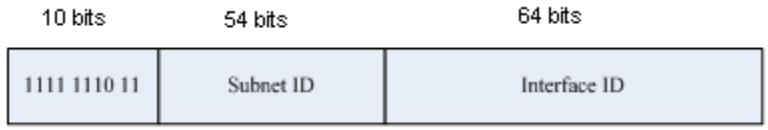


Figure 1-2 Format of a Link-local Address

The link-local address is used on a single network link to assign IDs to hosts. The address identified by the first 10 bits in the prefix is the link-local address. A device does not forward packets in which the source or destination address contains the link-local address. The intermediate 54 bits in the address are all 0s. The last 64 bits represent the interface ID, which allows a single network to connect to (2^{64}-1) hosts.

- Site-local address

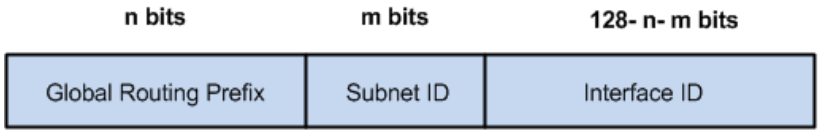

Figure 1-3 Format of a Site-local Address

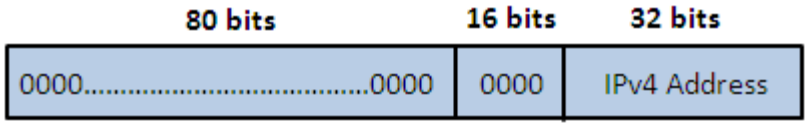
A site-local address is used to transmit data within a site. A device does not forward packets in which the source or destination address contains the site-local address to the Internet. That is, these packets can be forwarded only within the site. A site can be assumed as an enterprise's local area network (LAN). The addresses are similar to IPv4 private addresses such as 192.168.0.0/16. RFC 3879 has abolished site-local addresses. New addresses do not support the first 10 bits as the prefix and are all regarded as global unicast addresses. Existing addresses can continue to use this prefix.

- Global unicast address

Figure 1-4 Format of a Global Unicast Address

Among global unicast addresses, there is a type of IPv4-embedded IPv6 addresses, including IPv4-compatible IPv6 addresses and IPv4-mapped IPv6 addresses. They are used for interconnection between IPv4 and IPv6 nodes.

Figure 1-5 Format of an IPv4-compatible IPv6 Address



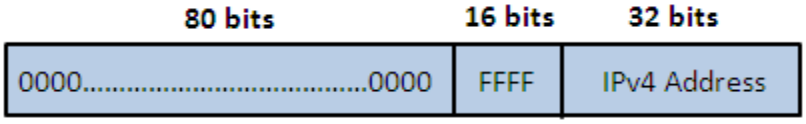


Figure 1-6 Format of an IPv4-mapped IPv6 Address

IPv4-compatible IPv6 addresses are mainly used on automatic tunnels. Nodes on automatic tunnels support both IPv4 and IPv6. Using these addresses, IPv4 devices transmit IPv6 packets over tunnels. IPv4-compatible IPv6 addresses have been abolished; IPv4-mapped IPv6 addresses are used by IPv6 nodes to access IPv4-only nodes. For example, if an IPv6 application on an IPv4/IPv6 host requests to resolve the name of an IPv4-only host, the name server dynamically generates an IPv4-mapped IPv6 address and returns it to the IPv6 application.

↘ Multicast Addresses

The format of an IPv6 multicast address is as follows:

| 8 | 4 | 4 | 112 bits |

+--------+----+----+---+

|11111111|flgs|scop| group ID |

+--------+----+----+---+

The first byte in the address is all 1s, representing a multicast address.

- Flag field

The flag field consists of 4 bits. Only the fourth bit is specified to indicate whether this address is a known multicast address assigned by the Internet Assigned Numbers Authority (IANA) or a temporary multicast address in a certain scenario. If the flag bit is 0, this address is a known multicast address. If the flag bit is 1, this address is a temporary multicast address. The remaining three flag bits are reserved for future use.

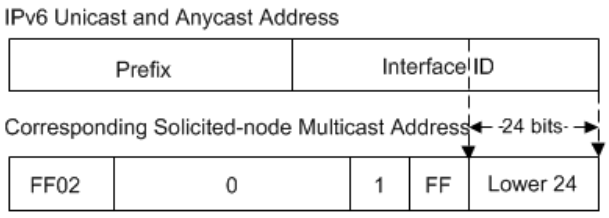
- Scope field

The scope field consists of 4 bits to indicate the multicast range. That is, a multicast group includes the local node, local link, local site, and any node in the IPv6 global address space.

- Group ID field

The group ID consists of 112 bits to identify a multicast group. A multicast ID can represent different groups based on the flag and scope fields.

IPv6 multicast addresses are prefixed with FF00::/8. One IPv6 multicast address usually identifies interfaces on a series of different nodes. After a packet is sent to a multicast address, the packet is then forwarded to the interfaces on each node identified by this multicast address. For a node (host or device), you must add the following multicast addresses:



1. Multicast address for all nodes on the local link, that is, FF02::1
2. Solicited-node multicast address, prefixed with FF02:0:0:0:0:1:FF00:0000/104

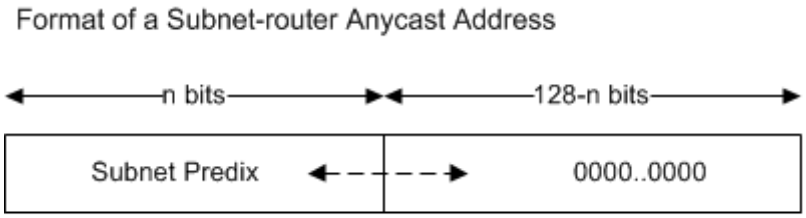
If the node is a device, it also has to be added to the multicast address of all devices on the local link, that is, FF02::2.

The solicited-node multicast address corresponds to the IPv6 unicast and anycast address. You must add a corresponding solicited-node multicast address for each configured unicast and anycast address of an IPv6 node. The solicited-node multicast address is prefixed with FF02:0:0:0:0:1:FF00:0000/104. The remaining 24 bits are composed of the least significant 24 bits of the unicast or anycast address. For example, if the unicast address is FE80::2AA:FF:FE21:1234, the solicited-node multicast address is FF02::1:FF21:1234.

The solicited-node multicast address is usually used in NS packets.

Figure 1-7 Format of an Solicited-node Multicast Address

Anycast Addresses



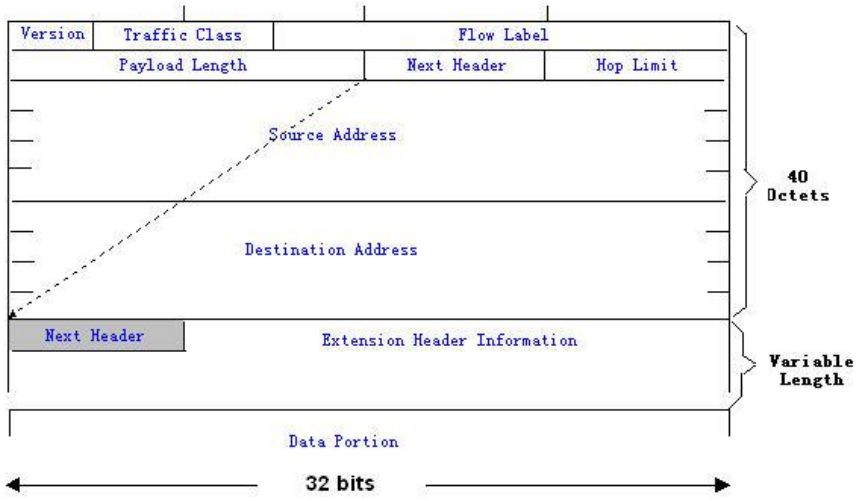
Similar to a multicast address, an anycast address can also be shared by multiple nodes. The difference is that only one node in the anycast address receives data packets, while all nodes in a multicast address receive data packets. Anycast addresses are allocated within the standard IPv6 unicast address space, so they share the same formats as unicast addresses. Each node that is part of an anycast address must be explicitly configured for proper identification.

Anycast addresses can be allocated only to devices and cannot be used as source addresses of packets.

RFC 2373 redefines an anycast address called subnet-router anycast address. Figure 1-8 shows the format of a subnet-router anycast address. Such an address consists of the subnet prefix followed by a series of 0s (interface ID).

The subnet prefix identifies a specified link (subnet). Packets destined to the subnet-router anycast address will be forwarded to a device on this subnet. A subnet-router anycast address is usually used by the application on a node to communicate with a device on a remote subnet.

Figure 1-8



Related Configuration

Configuring an IPv6 Address

- No IPv6 address is configured on interfaces by default.
- Run the **ipv6 address** command to configure the IPv6 unicast address and anycast address of an interface.
- After an interface goes Up, it will automatically join the corresponding multicast group.

1.3.3 IPv6 Packet Header Format

Figure 1-9 Format of the IPv6 Packet Header

The IPv4 packet header is expressed in the unit of 4 bytes. The IPv6 packet header consists of 40 bytes, in the unit of 8 bytes. The IPv6 packet header has the following fields:

- Version

This field consists of 4 bits. In an IPv6 address, this field must be 6.

- Traffic Class

This field consists of 8 bits. It indicates the service provided by this packet, similar to the ToS field in an IPv4 address.

- Flow Label

This field consists of 20 bits to identify packets belonging to the same service flow. One node can act as the Tx source of multiple service flows. The flow label and source address uniquely identify one service flow.

- Payload Length

This field consists of 16 bits, including the packet payload length and the length of IPv6 extended options (if available). That is, it includes the IPv6 packet length except the IPv6 packet header.

- Next Header

This field indicates the protocol type in the header field following the IPv6 packet header. Similar to the Protocol field in the IPv4 address header, the Next Header field is used to indicate whether the upper layer uses TCP or UDP. It can also be used to signal the presence of the IPv6 extension header.

- Hop Limit

This field consists of 8 bits. Each time a device forwards a packet, the field value is reduced by 1. If the field value reaches 0, this packet will be discarded. It is similar to the Lifetime field in the IPv4 packet header.

- Source Address

This field consists of 128 bits and indicates the sender address in an IPv6 packet.

- Destination Address

This field consists of 128 bits and indicates the receiver address in an IPv6 packet.

IPv6 defines the following extension headers.

- Hop-By-Hop Options

This extension header must follow the IPv6 packet header. It consists of option data to be checked on each node along the path.

- Routing Options (Type 0 routing header)

This extension header indicates the nodes that a packet passes through from the source address to the destination address. It consists of the address list of passerby nodes. The initial destination address in the IPv6 packet header is the first address among addresses in the routing header, but not the final destination address of the packet. After the node corresponding to the destination address in the IPv6 packet header receives a packet, it processes the IPv6 packet header and routing header, and sends the packet to the second address, third address, and so on in the routing header list till the packet reaches the final destination address.

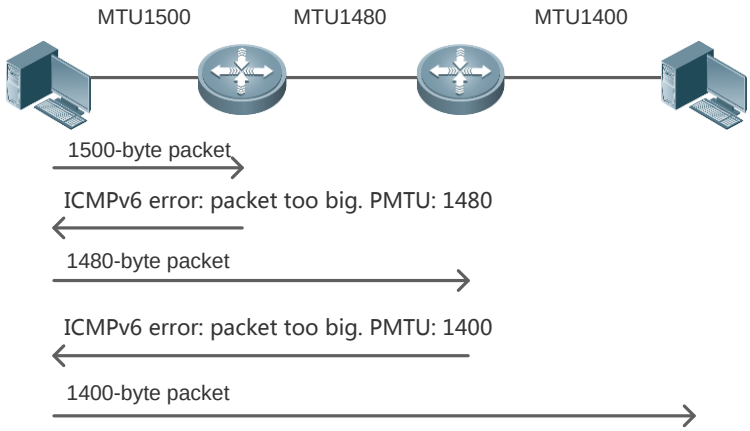
- Fragment

The source node uses this extension header to fragment the packets of which the length exceeds the path MTU (PMTU).

- Destination Options

This extension header replaces the option fields of IPv4. The Destination Options field can only be filled with integral multiples of 64 bits (8 bytes) if required. This extension header can be used to carry information to be checked by the destination node.

- Upper-layer header



This extension header indicates the protocol used at the upper layer, such as TCP (6) and UDP (17).

Another two extension headers of AH and ESP will be described in *Configuring IPSec*.

1.3.4 IPv6 PMTUD

Similar to IPv4 Path MTU Discovery (PMTUD), IPv6 PMTUD allows a host to dynamically discover and adjust the MTU on the data Tx path. If the length of a data packet to be sent by a host is greater than the PMTU, the host fragments packets. In this manner, the IPv6 device does not need to perform fragmentation, saving device resources and improving the IPv6 network efficiency.

Figure 1-10

As shown in Figure 1-10, if the length of a packet to be sent by the host is greater than the PMTU, the router discards this packet and sends an ICMPv6 Packet Too Big message containing its PMTU to the host. The host then fragments the packet based on the new PMTU. In this manner, the router does not need to perform fragmentation, saving resources and improving the IPv6 network efficiency.

Related Configuration

Configuring the IPv6 MTU of an Interface

- The default IPv6 MTU is 1500 on an Ethernet interface.
- Run the **ipv6 mtu** command to change the IPv6 MTU of an interface.

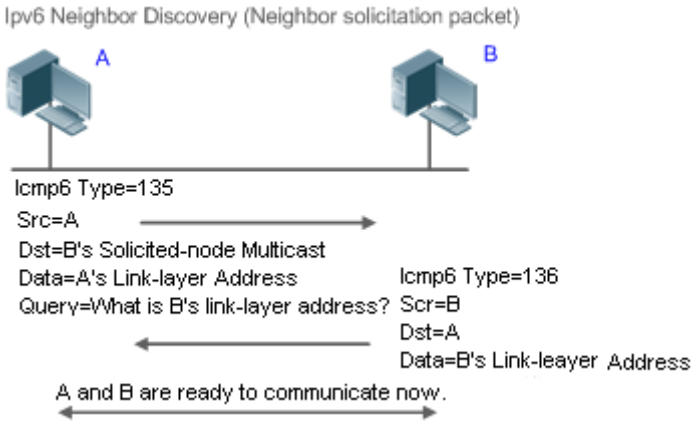
Configuring a Static PMTU

- Run the **ipv6 path-mtu** command to configure a static PMTU.

Configuring the Aging Time for a Dynamic PMTU

- The default aging time is 10 minutes.
- Run the **ipv6 path-mtu age** command to configure the aging time of the dynamic PMTU.

1.3.5 IPv6 Neighbor Discovery



NDP is a basic part of IPv6. Its main functions include router discovery, prefix discovery, parameter discovery, address auto-configuration, address resolution (similar to ARP), next-hop determination, NUD, DAD, and redirection. NDP defines five ICMP packets: RS (ICMP type: 133), RA (ICMP type: 134), NS (similar to ARP request, ICMP type: 135), NA (similar to ARP reply, ICMP type: 136), and ICMP Redirect (ICMP type: 137).

All the preceding ICMP packets carry one or more options, which may be optional in some cases but crucial in other cases. NDP defines five main options: Source Link-Layer Address Option, Type=1; Target Link-Layer Address Option, Type=2; Prefix Information Option, Type=3; Redirection Header Option, Type=4; MTU Option, Type=5.

Address Resolution

When a node attempts to communicate with another, the node has to obtain the link-layer address of the peer end by sending it an NS packet. In this packet, the destination address is the solicited-node multicast address corresponding to the IPv6 address of the destination node. This packet also contains the link-layer address of the source node. After receiving this NS packet, the peer end replies with an NA packet in which the destination address is the source address of the NS packet, that is, link-layer address of the solicited node. After receiving the NA packet, the source node can communicate with the destination node.

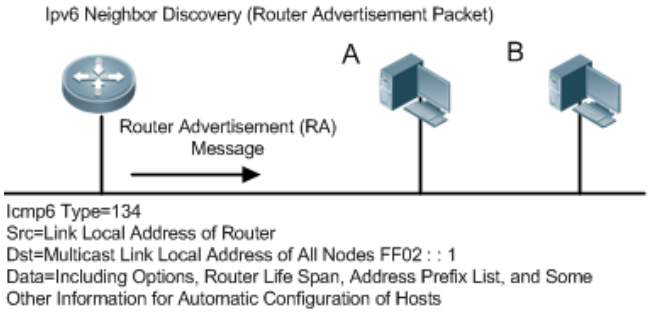
Figure 1-11 Address Resolution Process

NUD

If the reachable time of a neighbor has elapsed but an IPv6 unicast packet needs to be sent to it, the device performs NUD.

While performing NUD, the device can continue to forward IPv6 packets to the neighbor.

DAD



To know whether the IPv6 address configured for a host is unique, the device needs to perform DAD by sending an NS packet in which the source IPv6 address is the unspecified address.

If a device detects an address conflict, this address is set to the duplicate status so that the device cannot receive IPv6 packets with this address being the destination address. Meanwhile, the device also starts a timer for this duplicate address to periodically perform DAD. If no address conflict is detected in re-detection, this address can be properly used.

Router, Prefix, and Parameter Discovery

A device periodically sends RA packets to all local nodes on the link.

Figure 1-12 RA Packet Sending Process

An RA packet usually contains the following content:

- One or more IPv6 address prefixes (used for on-link determination or stateless address auto-configuration)
- Validity of the IPv6 address prefix
- Host auto-configuration mode (stateful or stateless)
- Default device information (whether the device acts as the default device; interval for acting as the default device if the device is used as the default one)
- Other information provided for host configuration, such as the hop limit, MTU, and NS retransmission interval
- Route priority

RA packets can be also used as replies to the RS packets sent by a host. Using RS packets, a host can obtain the auto-configured information immediately upon startup, without waiting for the RA packets sent by the device. If no unicast address is configured for a newly started host, the host uses the unspecified address (0:0:0:0:0:0:0:0) as the source address in the RS packet. Otherwise, the host uses the configured unicast address as the source address and the multicast address of all local routing devices (FF02::2) as the destination address in the RS packet. As a reply to the RS packet, the RA packet uses the source address of the RS packet as the destination address (if the source address is the unspecified address, it uses the multicast address of all local nodes (FF02::1).

In an RA packet, the following parameters can be configured:

- Ra-interval: Interval for sending the RA packet.
- Ra-lifetime: Lifetime of a router, that is, whether the device acts as the default router on the local link and the interval for acting as the default router.
- Prefix: Prefix of an IPv6 address on the local link. It is used for on-link determination or stateless address auto-configuration, including other parameter configurations related to the prefix.
- Ns-interval: NS packet retransmission interval.
- Reachabletime: Period when the device regards a neighbor reachable after detecting a Confirm Neighbor Reachability event.
- Ra-hoplimit: Number of hop of the RA packet, which is used to set the hop limit for a host to send a unicast packet.
- Ra-mtu: MTU of the RA packet.
- Managed-config-flag: Whether a host receiving this RA packet obtains the address through stateful auto-configuration.
- Other-config-flag: Whether a host receiving this RA packet uses DHCPv6 to obtain other information except the IPv6 address for auto-configuration.

- RDNSS and DNSSL options: Provide IPv6 terminals with the address of the DNS recursive query server and a search list of DNS domain names.

Configure the preceding parameters when configuring IPv6 interface attributes.

Redirection

If a router receiving an IPv6 packet finds a better next hop, it sends the ICMP Redirect packet to inform the host of the better next hop. The host will directly send the IPv6 packet to the better next hop next time.

Maximum Number of Unresolved ND Entries

- To prevent malicious scanning of network segments that generates a large number of unresolved neighbor entries and consumes excessive memory, you can configure a limit on the maximum number of unresolved neighbor entries.

Maximum Number of ND Options

- To prevent forged ND packets from carrying an excessive number of ND options that can overwhelm the device's CPU, you can configure the maximum number of ND options.

Maximum Number of Neighbor Learning Entries on an Interface

- To prevent neighbor learning attacks that consume device neighbor table entries, use up memory, and impact forwarding performance, you can configure the maximum number of interface neighbor learning entries.

Related Configuration

Enabling IPv6 Redirection

- By default, ICMPv6 Redirect packets can be sent on IPv6 interfaces.
- Run the **no ipv6 redirects** command in interface configuration mode to prohibit an interface from sending Redirect packets.

Configuring IPv6 DAD

- By default, an interface sends one NS packet to perform IPv6 DAD.
- Run the **ipv6 nd dad attempts** *value* command in interface configuration mode to configure the number of NS packets consecutively sent by DAD. The value 0 indicates disabling DAD for IPv6 addresses on this interface.
- Run the **no ipv6 nd dad attempts** command to restore the default configuration.
- By default, the device performs DAD on duplicate IPv6 addresses every 60s.
- Run the **ipv6 nd dad retry** value command in global configuration mode to configure the DAD interval. The value 0 indicates disabling DAD for the device.
- Run the **no ipv6 nd dad retry** command to restore the default configuration.

Configuring the Reachable Time of a Neighbor

- The default reachable time of an IPv6 neighbor is 30s.
- Run the **ipv6 nd reachable-time** *milliseconds* command in interface configuration mode to change the reachable time of a neighbor.

Configuring the Stale Time of a Neighbor

- The default stale time of an IPv6 neighbor is 1 hour. After the time elapses, the device performs NUD.
- Run the **ipv6 nd stale-time** *seconds* command in interface configuration mode to change the stale time of a neighbor.

Configuring Prefix Information

- By default, the prefix in an RA packet on an interface is the prefix configured in the **ipv6 address** command on the interface.
- Run the **ipv6 nd prefix** command in interface configuration mode to add or delete prefixes and prefix parameters that can be advertised.

Enabling or Disabling RA Packet Suppression

- By default, an IPv6 interface does not send RA packets.
- Run the **no ipv6 nd suppress-ra** command in interface configuration mode to disable RA packet suppression.

Configuring the Maximum Number of Unresolved ND Entries

- The default value is 0, indicating that unresolved ND entries are not limited. It depends on the ND entry capacity supported by the device.
- Run the **ipv6 nd unresolved** *number* command in global configuration mode to restrict the number of unresolved neighbors. After the entries exceed this restriction, the device does not proactively resolve subsequent packets.

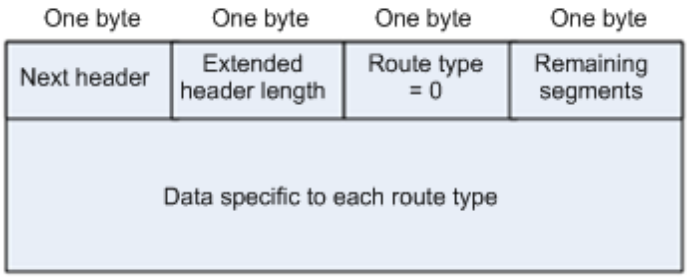
Configuring the Maximum Number of ND Options

- Run the **ipv6 nd max-opt** *value* command in global configuration mode to restrict the number of ND options to be processed. The default value is 10.

Configuring the Maximum Number of ND Entries Learned on an Interface

- Run the **ipv6 nd cache interface-limit** *value* command in interface configuration mode to restrict the number of neighbors learned on an interface. The default value is 0, indicating that neighbors learned on an interface are not limited.

Configuring the Interface to Generate a Default Route Based on the RA Packet



- By default, no default route is generated based on the RA packet.
- Run the **ipv6 nd ra default route** command in interface configuration mode to generate a default route based on the RA packet.

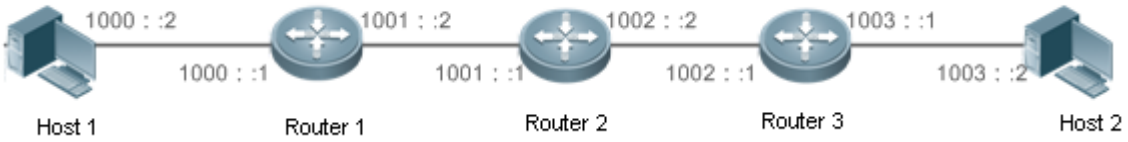
1.3.6 IPv6 Source Routing

Working Principle

Similar to the IPv4 loose source routing and loose record routing options, the IPv6 routing header is used to specify the intermediate nodes that the packet passes through along the path to the destination address.

Figure 1-13 Format of the IPv6 Routing Header

The Segments Left field is used to indicate how many intermediate nodes are specified in the routing header for the packet to pass through from the current node to the final destination address.



Two routing types are defined: Type 0 and Type 2. The Type 2 routing header is used for mobile communication. RFC 2460 defines the Type 0 routing header (similar to the loose source routing option of IPv4).

Figure 1-14 Format of the Type 0 Routing Header

The following example describes the application of the Type 0 routing header, as shown in Figure 1-15.

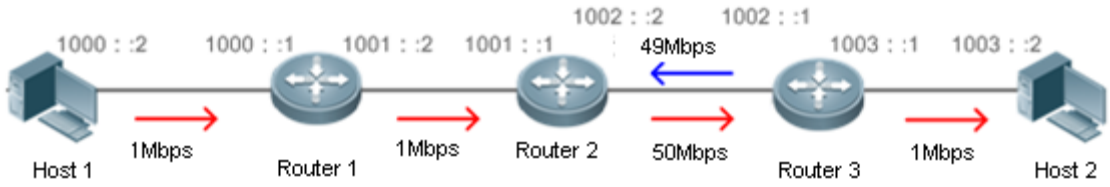
Figure 1-15

Host 1 sends Host 2 a packet specifying the intermediate nodes Router 2 and Router 3. The following table lists the changes of fields related to the IPv6 header and routing header during forwarding.

Transmission Node	Fields in the IPv6 Header	Fields Related to the Type 0 Routing Header
Host 1	Source address=1000::2 Destination address=1001::1 (Address of Router 2)	Segments Left=2 Address 1=1002::1 (Address of Router 3) Address 2=1003::2 (Address of Host 2)
Router 1	No change	
Router 2	Source address=1000::2 Destination address=1002::1 (Address of Router 3)	Segments Left=1 Address 1=1001::1 (Address of Router 2) Address 2=1003::2 (Address of Host 2)
Router 3	Source address=1000::2 Destination address=1003::2 (Address of Host 2)	Segments Left=0 Address 1=1001::1 (Address of Router 2) Address 1=1002::2 (Address of Router 3)
Host 2	No change	

The forwarding process is as follows:

1 Host 1 sends a packet in which the destination address is Router 2's address 1001::1, the Type 0 routing header is filled with Router 3's address 1002::1 and Host 2's address 1003::2, and the value of the Segments Left field is 2.



2 Router 1 forwards this packet to Router 2.

3 Router 2 changes the destination address in the IPv6 header to Address 1 in the routing header. That is, the destination address becomes Router 3's address 1002::1, Address 1 in the routing header becomes Router 2's address 1001::1, and the value of the Segments Left field becomes 1. Then Router 2 forwards the packet to Router 3.

4 Router 3 changes the destination address in the IPv6 header to Address 2 in the routing header. That is, the destination address becomes Host 2's address 1003::2, Address 2 in the routing header becomes Router 3's address 1002::1, and the value of the Segments Left field becomes 0. Then Router 3 forwards the packet to Host 2.

The Type 0 routing header may be used to initiate DoS attacks. As shown in Figure 1-16, Host 1 sends packets to Host 2 at 1 Mbps and forges a routing header to cause multiple round-trips between Router 2 and Router 3 (50 times from Router 2 to Router 3 and 49 times from Router 3 to Router 2). At this time point, the routing header generates the traffic amplification effect:" 50 Mbps from Router 2 to Router 3 and 49 Mbps from Router 3 to Router 2." Considering security, RFC 5095 abolished the Type 0 routing header.

Figure 1-16

IPv6 Packet
Source Address 1000::2
Destination Address 1001:1

Segments Left in the Type 0 Routing Header: 100
Address 1: 1002::1
Address 2: 1001::1
Address 3: 1002::1
Address 4: 1002::1
...
Address 99: 1002::1
Address 100: 100:3::2

Host 1 sends packets to Host 2, passing through Router 2, Router 3, Router 2, and Router 3, ...
Each packet is sent 50 times from Router 2 to Router 3 and 49 times from Router 3 to Router 2.

Related Configuration

Enabling IPv6 Source Routing

- The Type 0 routing header is not supported by default.
- Run the **ipv6 source-route** command in global configuration mode to enable IPv6 source routing.

1.3.7 Limiting the Rate for Sending ICMPv6 Error Messages

Working Principle

The destination node or intermediate router sends ICMPv6 error messages to report the errors incurred during IPv6 data packet forwarding and transmission. There are mainly four types of error messages: Destination Unreachable, Packet Too Big, Time Exceeded, and Parameter Problem.

When receiving an invalid IPv6 packet, a device discards the packet and sends back an ICMPv6 error message to the source IPv6 address. When attacks of invalid IPv6 packets occur, the device may continuously reply to ICMPv6 error messages till device resources are exhausted and thereby fail to provide services. To solve this problem, you can restrict the rate for sending ICMPv6 error messages.

If the length of an IPv6 packet to be forwarded exceeds the IPv6 MTU of the outbound interface, the router discards this IPv6 packet and sends back an ICMPv6 Packet Too Big message to the source IPv6 address. This error message is mainly used for IPv6 PMTUD. If the rate for sending ICMPv6 error messages is limited due to excessive other ICMPv6 error messages, ICMPv6 Packet Too Big messages may be filtered, causing a failure of IPv6 PMTUD. Therefore, you are advised to separately limit the rates for sending ICMPv6 Packet Too Big messages and other ICMPv6 error messages.

ICMPv6 Redirect messages are not ICMPv6 error messages, and the rates of ICMPv6 Redirect messages and other ICMPv6 error message are limited together.

Related Configuration

Configuring the Rate for Sending ICMPv6 Packet Too Big Messages

- The default rate is 10 per 100 ms.
- Run the **ipv6 icmp error-interval too-big** command to configure the rate for sending ICMPv6 Packet Too Big messages.

Configuring the Rate for Sending Other ICMPv6 Error Messages

- The default rate is 10 per 100 ms.
- Run the **ipv6 icmp error-interval** command to configure the rate for sending other ICMPv6 error messages.

1.3.8 IPv6 Hop Limit

Working Principle

An IPv6 data packet passes through routers from the source address and destination address. If a hop limit is configured, it decreases by one each time the packet passes through a router. When the hop limit decreases to 0, the router discards the packet to prevent the useless packet from being unlimitedly transmitted on the network and wasting network bandwidth. The hop limit is similar to the TTL of IPv4.

Related Configuration

Configuring the IPv6 Hop Limit

- The default IPv6 hop limit of a device is 64.
- Run the **ipv6 hop-limit** command to configure the IPv6 hop limit of a device.

1.3.9 Enabling Suppression of Broadcasting NS Packets to Authentication VLANs

Working Principle

In gateway authentication mode, all sub-VLANs in a super-VLAN are authenticated VLANs by default. Users in an authenticated VLAN can access a network only after being authenticated. After a user is authenticated, a static ND entry is generated on the device. Therefore, when accessing an authenticated user, the device does not need to send NS packets to the authenticated VLAN to which the authenticated user belongs.

In gateway authentication mode, the device is enabled with suppression of broadcasting NS packets to authentication VLANs by default. If the device needs to access non-authenticated users in an authenticated VLAN, disable the suppression function.

Related Configuration

Enabling Suppression of Broadcasting NS Packets to Authentication VLANs

- In interface configuration mode, run the **ipv6 nd suppress-auth-vlan-ns** command to enable suppression of broadcasting NS packets to authentication VLANs.
- The device is enabled with suppression of broadcasting NS packets to authentication VLANs by default.
- This function can be configured only on SVIs and takes effect only in gateway authentication mode.

1.3.10 Configuring the Device Enabled with IPv6 ND to Allocate Different Prefixes to Different Users

Working Principle

A specific prefix pool can be configured on an interface so that the device assigns different IPv6 prefixes to different users connected to the interface.

Related Configuration

Configuring a Prefix Bound to an Interface

- In global configuration mode, run the **ipv6 local pool** *pool-name ipv6-prefix/prefix-length prefix-length* command to configure the address pool to be assigned.
- In interface configuration mode, run the **ipv6 nd prefix pool** *pool-name* command to configure the name of the prefix pool to which the interface is bound.

1.3.11 Enabling ND Packet Rate Statistics Collection

Working Principle

The device counts the number of ND (RS/RA/NS/NA) packet received or sent by the gateway, and calculates the ND packet rate in a given period of time.

Related Configuration

Configuring the Interval for ND Packet Rate Statistics Collection

- In global configuration mode, run the **ipv6 nd rate-statistics interval** *seconds* command.

1.3.12 Binding the DNS Address Pool to the IPv6 Interface

Working Principle

The DNS address pool is bound to the IPv6 interface to carry the DNS address information in the DNS address pool when the interface announces router advertisement (RA) information.

Related Configuration

Configuring the IPv6 Interface to Bind the DNS Address Pool

- In interface configuration mode, run the **ipv6 nd ra dns import-rdnss** *pool-name* command to configure the name of the DNS address pool to be bound to the IPv6 interface.
- By default, no DNS address pool is bound to the IPv6 interface.

1.4 Configuration

Configuration	Description and Command
Configuring an IPv6	(Mandatory) It is used to configure IPv6 addresses and enable IPv6.

Configuration	Description and Command	
Address	**ipv6 enable**	Enables IPv6 on an interface.
	ipv6 address	Configures the IPv6 unicast address of an interface.
	ipv6 general-prefix	Configures a general IPv6 prefix.
Configuring IPv6 NDP	(Optional) It is used to enable IPv6 redirection on an interface.	
	ipv6 redirects	Enables IPv6 redirection on an interface.
	(Optional) It is used to enable DAD.	
	ipv6 nd dad attempts	Configures the number of consecutive NS packets sent during DAD.
	ipv6 nd dad retry	Configures the interval for address conflict detection.
	(Optional) It is used to configure ND parameters.	
	ipv6 nd reachable-time	Configures the reachable time of a neighbor.
	ipv6 nd prefix	Configures the address prefix to be advertised in an RA packet.
	ipv6 nd suppress-ra	Enables RA packet suppression on an interface.
	ipv6 nd managed-config-flag	Configures the **managed address configuration** flag bit of the RA packet.
	ipv6 nd ra-hoplimit	Configures the hop count of an RA packet.
	ipv6 nd ra-interval	Configures the interval for sending RA packets.
	ipv6 nd ra-lifetime	Configures the device lifetime of the RA packet sent on the interface.
	ipv6 nd ra-mtu	Configures the MTU of RA packets.
	ipv6 nd resolve vlan	Configures the device to proactively send NS packets to specific sub-VLANs in the super-VLAN.
	ipv6 nd stale-time	Configures the period for the neighbor to maintain the state.
	ipv6 ns-linklocal-src	Configures the local address of the link as the source IP address for sending neighbor requests.
	(Optional) It is used to configure the maximum number of unresolved ND entries.	
	ipv6 nd unresolved	Configures the maximum number of unresolved ND entries.
	(Optional) It is used to configure the maximum number of ND packet option fields.	
	ipv6 nd max-opt	Configures the maximum number of ND packet option fields.
	(Optional) It is used to configure the maximum number of neighbors learned on an interface.	
	ipv6 nd cache interface-limit	Configures the maximum number of neighbors learned on an interface.
	(Optional) It is used to configure the interval for the interface to retransmitting	

Configuration	Description and Command	
	Neighbor Solicitation (NS) packets.	
	ipv6 nd ns-interval	Configures the interval for the interface to retransmitting NS packets.
	⚠ (Optional) It is used to configure the interface to generate a default route based on the received RA.	
	ipv6 nd ra default route	Configures the interface to generate a default route based on the received RA.

Configuring the NS Retransmission Interval of the Interface
Configuration Steps
Set the Neighbor Solicitation (NS) retransmission interval to 2 seconds.
`Hostname(config-if-GigabitEthernet 0/1)# ipv6 nd ns-interval 2000`
Verification
Run the **show running-config** command to check whether the configuration takes effect.
`Hostname#show running-config`
`!`
`interface GigabitEthernet 0/1`
`ipv6 nd ns-interval 2000`
`!`
	⚠ (Optional) It is used to restrict the MTU of IPv6 packets sent on an interface.	

	ipv6 mtu	Configures the IPv6 MTU.

Configuration	Description and Command	

↘ **Configuring the Interface to Generate a Default Route Based on the Received RA**
 	
Configuration Steps Configure the VLAN 1 interface to generate a default route based on the RA.
`Hostname(config)#interface VLAN 1`
`Hostname(config-if-VLAN 1)#ipv6 nd ra default route`
Verification Run the **show running-config** command to check whether the configuration takes effect.
`Hostname#show running-config`
`!`
`interface VLAN 1`
`ipv6 nd ra default route`
`!`
Enabling PMTUD		

Enabling IPv6 Source Routing	⚠ (Optional) It is used to enable IPv6 source routing.	
	ipv6 source-route	Configures the device to forward IPv6 packets carrying the routing header.
Configuring the Rate for	⚠ Optional.	

Configuration	Description and Command	
Sending ICMPv6 Error Messages	**ipv6 icmp error-interval too-big**	Configures the rate for sending ICMPv6 Packet Too Big messages.
	ipv6 icmp error-interval	Configures the rates for sending other ICMPv6 error messages and ICMPv6 Redirect packets.
Configuring the IPv6 Hop Limit	⚠ (Optional) It is used to restrict the hop limit of IPv6 unicast packets sent on an interface.	
	ipv6 hop-limit	Configures the IPv6 hop limit.
Enabling Suppression of Broadcasting NS Packets to Authentication VLANs	⚠ (Optional) It is used in gateway authentication mode to enable suppression of broadcasting NS packets to authentication-free VLANs.	
	ipv6 nd suppress-auth-vlan-ns	Enables suppression of broadcasting NS packets to authentication VLANs.
Configuration Effect	⚠ (Optional) It is used to carry the DNS address information in the DNS address pool when the interface announces the RA information.	
	ipv6 nd ra dns import-rdnss *pool-name*	Binds the DNS address pool to the IPv6 interface.

1.4.1 Configuring an IPv6 Address

Configuration Effect

Configure the IPv6 address of an interface to implement IPv6 network communication.

Configuration Step

↘ Enabling IPv6 on an Interface

- Optional. If you do not want to enable IPv6 by configuring an IPv6 address, run the **ipv6 enable** command.

↘ Configuring the IPv6 Unicast Address of an Interface

- Mandatory.

Verification

Run the **show ipv6 interface** command to check whether the configured address takes effect.

Related Commands

↘ Enabling IPv6 on an Interface

Command	**ipv6 enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	IPv6 can be enabled on an interface by running the **ipv6 enable** command in interface configuration

	mode or configuring an IPv6 address on the interface. If an IPv6 address is configured on an interface, IPv6 is automatically enabled on this interface. In this case, IPv6 cannot be disabled even when you run the **no ipv6 enable** command.

Configuring the IPv6 Unicast Address of an Interface

Command	**ipv6 address** *ipv6-address*/*prefix-length* **ipv6 address** *ipv6-prefix*/*prefix-length* **eui-64** **ipv6 address** *prefix-name sub-bits/prefix-length* [**eui-64**]
Parameter Description	*ipv6-address*: Indicates the IPv6 address, which must comply with the address format defined in RFC 4291. Separated by a colon (:), each address field consists of 16 bits and is represented by hexadecimal digits. *ipv6-prefix*: Indicates the IPv6 address prefix, which must comply with the address format defined in RFC 4291. *prefix-length*: Indicates the length of the IPv6 address prefix, that is, the part representing the network in the IPv6 address. *prefix-name*: Indicates the name of the universal prefix. This specified universal prefix is used to create the interface address. *sub-bits*: Indicates the subprefix bits and host bits of the address to be concatenated with the prefixes provided by the general prefix specified with the *prefix-name* parameter. This value is combined with the universal prefix to create the interface address. This value must comply with the format defined in RFC 4291. *eui-64*: Indicates the created IPv6 address that consists of the configured address prefix and 64-bit interface ID.
Command Mode	Interface configuration mode
Usage Guide	If an IPv6 interface is created and is Up state, the system automatically generates a link-local address for this interface. The IPv6 address of an interface can also be created by the universal prefix mechanism: IPv6 address = Universal prefix + Sub prefix + Host bits The universal prefix can be configured by running the **ipv6 general-prefix** command or learned by the prefix discovery function of the DHCPv6 client (see *Configuring DHCPv6*). The sub prefix and host bits are specified by *sub-bits* and *prefix-length* parameters in the **ipv6 address** command. If you run the **no ipv6 address** command without specifying an address, all manually configured addresses will be deleted. Run the **no ipv6 address** *ipv6-prefix/prefix-length* **eui-64** command to delete the configured address.

Configuring a General IPv6 Prefix

Command	**ipv6 general-prefix** *prefix-name ipv6-prefix* | *prefix-length*
Parameter Description	*prefix-name*: Specifies the name of a general prefix. *ipv6-prefix*: Specifies the network prefix value of a general prefix. This value must be represented in colon hexadecimal notation as defined in RFC 4291. *prefix-length*: Specifies the length of a general prefix.
Command Mode	Global configuration mode

Usage Guide	A general prefix can facilitate network numbering. A prefix defined in a general prefix can be referenced by a longer specific prefix. When the general prefix changes, the specific prefixes that reference the general prefix will change accordingly. When a network ID changes, only the general prefix needs to be changed. A general prefix can contain several prefixes. The longer specific prefix is typically used for configuring IPv6 addresses on an interface.

Configuring an Interface to Borrow the IPv6 Unicast Address of Another Interface

Command	**ipv6 unnumbered** *interface-id*
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Borrowing the address of another interface can save IPv6 address resources. This command is only supported on PPP interfaces. If the **ipv6 unnumbered** command is configured on an interface, the IPv6 function is enabled automatically on the interface. You cannot disable IPv6 on the interface even by running the **no ipv6 enable** command.

Configuration Example

Configuring an IPv6 Address on an Interface

Configuration Steps	● Enable IPv6 on GigabitEthernet 0/1 and add IPv6 address 2000::1 to the interface.

	`Hostname(config)#interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 enable`
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 address 2000::1/64`

Verification	● Run the **show ipv6 interface** command to verify that an address is successfully added to GigabitEthernet 0/1.

	`Hostname(config-if-GigabitEthernet 0/1)#show ipv6 interface gigabitethernet 0/1`
	
	`interface GigabitEthernet 0/1 is Down, ifindex: 1`
	`  address(es):`
	`  Mac Address: 00:00:00:00:00:00`
	`  INET6: FE80::200:FF:FE00:1 [ TENTATIVE ], subnet is FE80::/64`
	`  INET6: 2000::1 [ TENTATIVE ], subnet is 2000::/64`
	`  Joined group address(es):`
	`  MTU is 1500 bytes`
	`  ICMP error messages limited to one every 100 milliseconds`
	`  ICMP redirects are enabled`
	`  ND DAD is enabled, number of DAD attempts: 1`
	`  ND reachable time is 30000 milliseconds`
	`  ND advertised reachable time is 0 milliseconds`

	ND retransmit interval is 1000 milliseconds ND advertised retransmit interval is 0 milliseconds ND router advertisements are sent every 200 seconds<160--240> ND router advertisements live for 1800 seconds

1.4.2 Configuring IPv6 NDP

Configuration Effect

Configure NDP-related attributes, for example, enable IPv6 redirection and DAD.

Notes

RA packet suppression is enabled on interfaces by default. To configure a device to send RA packets, run the **no ipv6 nd suppress-ra** command in interface configuration mode.

Configuration Step

Enabling IPv6 Redirection on an Interface

- Optional. IPv6 redirection is enabled by default.
- To disable IPv6 redirection on an interface, run the **no ipv6 redirects** command.

Configuring the Number of Consecutive NS Packets Sent During DAD

- Optional.
- To disable DAD for IPv6 addresses on an interface or change the number of consecutive NS packets sent during DAD, run the **ipv6 nd dad attempts** command.

Configuring the Reachable Time of a Neighbor

- Optional.
- To change the reachable time of a neighbor, run the **ipv6 nd reachable-time** command.

Configuring the Address Prefix to Be Advertised in an RA Packet

- By default, the prefix in an RA packet on an interface is the prefix configured in the **ipv6 address** command on the interface.

Enabling or Disabling RA Packet Suppression on an Interface

- Optional.
- If a device needs to send RA packets, run the **no ipv6 nd suppress-ra** command.

Configuring the Maximum Number of Unresolved ND Entries

- Optional.
- If a large number of unresolved ND entries are generated due to scanning attacks, run the **ipv6 nd unresolved** command to restrict the number of unresolved neighbors.

Configuring the Maximum Number of ND Options

- Optional.
- If a device needs to process more options, run the **ipv6 nd max-opt** command.

Configuring the Maximum Number of ND Entries Learned on an Interface

- Optional.
- If the number of IPv6 hosts is controllable, run the **ipv6 nd cache interface-limit** command to restrict the number of neighbors learned on an interface. This prevents ND learning attacks from occupying the memory and affecting device performance.

Configuring the Interval for Retransmitting NS Packets on an Interface

- Optional.
- If a large number of IPv6 hosts are deployed on a network, prolong the interval for transmitting NS packets. When the status of many interfaces change, frequent NS packet handling consumes the memory and affect device performance, resulting in exceptions. This function addresses this issue.

Configuring the Interface to Generate a Default Route Based on the Received RA

- Optional.
- Only in case of DHCPv6 stateful address auto-configuration, run the **ipv6 nd ra default route** command to automatically generate a default route.
- Verification

Run the following commands to check whether the configuration is correct:

- **show ipv6 interface** *interface-type interface-num*: Check whether the configurations such as the redirection function, reachable time of a neighbor, and NS sending interval take effect.
- **show ipv6 interface** *interface-type interface-num* **ra-info**: Check whether the prefix and other information configured for RA packets are correct.

Related Commands

Enabling IPv6 Redirection on an Interface

Command	**ipv6 redirects**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	All ICMPv6 error messages are transmitted at a limited rate. By default, a maximum number of 10 ICMPv6 error messages are transmitted per second (10 pps).

Configuring the Number of Consecutive NS Packets Sent During DAD

Command	**ipv6 nd dad attempts** *value*
Parameter Description	*value*: Indicates the number of NS packets.
Command	Interface configuration mode

Mode	
Usage Guide	You need to enable DAD before configuring an IPv6 address on an interface. Then the address is in tentative state. If no address conflict is detected by DAD, this address can be correctly used. If an address conflict is detected and the interface ID of this address uses EUI-64, duplicate link-layer addresses exist on this link. In this case, the system automatically disables this interface to prevent IPv6-related operations on this interface. In this case, you must configure a new address and restart the interface to re-enable DAD. When an interface changes from Down to Up, DAD is re-enabled for the addresses on this interface.

Configuring the Interval for Address Conflict Detection

Command	**ipv6 nd dad retry** *value*
Parameter Description	*value*: Specifies the interval for address conflict detection. The default value is 60s. The value 0 indicates that the function is disabled.
Command Mode	Global configuration mode
Usage Guide	Before configuring a new IPv6 address for an interface, enable address conflict detection on the interface. If a conflict address is detected, the device does not receive the IPv6 packet destined to the conflicting address. This command is used to perform conflict detection again when the interval expires. If there is no conflict, the address can be used.

Configuring the Reachable Time of a Neighbor

Command	**ipv6 nd reachable-time** *milliseconds*
Parameter Description	*milliseconds*: Indicates the reachable time of a neighbor, in milliseconds. The value range is from 0 to 3600000. The default value is 30s.
Command Mode	Interface configuration mode
Usage Guide	A device detects unreachable neighbors based on the configured reachable time. The shorter the configured reachable time, the faster the device detects unreachable neighbors, but this also increases network bandwidth and device resource usage. Therefore, do not set a small value. The configured value is advertised in an RA packet and is also used on the device. If the value is 0, the reachable time is not specified on the device and the default value is recommended.

Configuring the Address Prefix to Be Advertised in an RA Packet

Command	**ipv6 nd prefix** { *ipv6-prefix*/*prefix-length* | **default** } { [[*valid-lifetime* { **infinite** | *preferred-lifetime* }] | [**at** *valid-date preferred-date*] | [**infinite** { **infinite** | *preferred-lifetime* }]] [**off-link** | **no-autoconfig**] * | **no-advertise** }
Parameter Description	*ipv6-prefix*: Indicates the network ID of IPv6, which must comply with the address representation format in RFC 4291. *prefix-length*: Indicates the length of the IPv6 address prefix. A slash (/) must be added, which is followed by the prefix. *valid-lifetime*: Indicates the period when a host receiving the prefix of an RA packet regards the prefix valid. The value range is from 0 to 4294967295. The default value is 30 days. *preferred-lifetime*: Indicates the preferred period when a host receiving the prefix of an RA packet regards the prefix valid. The value range is from 0 to 4294967295. The default value is 7 days.

	at *valid-date preferred-date*: Indicates the valid date and preferred deadline configured for the RA prefix. It uses the format of *dd+mm+yyyy+hh+mm*. **infinite**: Indicates that the prefix is permanently valid. **default**: Indicates that the default parameter configuration is used. **no-advertise**: Indicates that the prefix is not advertised by a router. **off-link**: If the prefix of the destination address in the IPv6 packet sent by a host matches the configured prefix, the device regards the destination address on the same link and directly reachable. This parameter indicates that this prefix does not require on-link determination. **no-autoconfig**: Indicates that the prefix in the RA packet received by a host cannot be used for address auto-configuration.
Command Mode	Interface configuration mode
Usage Guide	This command can be used to configure parameters related to each prefix, including whether to advertise this prefix. By default, an RA packet uses the prefix configured by running the **ipv6 address** command. Run the **ipv6 nd prefix** command to add other prefixes. Run the **ipv6 nd prefix default** command to configure the default parameters for an interface. That is, if no parameter is specified when a prefix is added, use the parameters configured in the **ipv6 nd prefix default** command as the parameters of the new prefix. The default parameter configurations are abandoned once a parameter is specified for the prefix. That is, when you use the **ipv6 nd prefix default** command to modify the default parameter configurations, only the prefix configured for the default parameters changes and configurations of the prefix remain the same. **at** *valid-date preferred-date*: You can specify the valid date by specifying a fixed time for each prefix in an RA packet or specifying the deadline. If the deadline is specified, the valid date of the prefix in each RA packet decreases till it becomes 0.

Enabling or Disabling RA Packet Suppression on an Interface

Command	**ipv6 nd suppress-ra**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	To enable RA packet suppression on an interface, run the **ipv6 suppress-ra** command.

Configuring the Managed Address Configuration Flag Bit of RA Packets

Command	**ipv6 nd managed-config-flag**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	This flag determines whether the host that receives the RA packet obtains an IP address through stateful auto configuration. If the flag is set, the host obtains an IP address through stateful auto configuration. Otherwise, it is not used.

Configuring the Hop Count of RA Packets

Command	**ipv6 nd ra-hoplimit** *value*
Parameter Description	*value*: Specifies the hop count of RA packets. The value range is from 0 to 255 and the default value is 64.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the Interval for Sending RA Packets

Command	**ipv6 nd ra-interval** { *seconds* | **min-max** *min_value max_value* }
Parameter Description	*seconds*: Specifies the interval for sending RA packets, in seconds. The default value is 600s. **min-max**: Indicates the maximum and minimum interval for sending RA packets, in seconds. *min_value*: Indicates the minimum interval for sending RA packets, in seconds. *max_value*: Indicates the maximum interval for sending RA packets, in seconds.
Command Mode	Interface configuration mode
Usage Guide	If the device serves as the default device, the interval cannot be longer than the lifetime of the device. To ensure that other devices along the link occupies network bandwidth while sending RA packets, the actual interval for sending RA packets will vary by 20% around the set value. If **min-max** is specified, the actual interval for sending RA packets will be selected between the minimum value and maximum value.

Configuring the Device Lifetime of RA Packets Sent on the Interface

Command	**ipv6 nd ra-lifetime** *seconds*
Parameter Description	*seconds*: Specifies the lifetime of a device used as the default device of an interface, in seconds. The value range is from 0 to 9000 and the default value is 64.
Command Mode	Interface configuration mode
Usage Guide	The router lifetime field is available in each RA packet. It specifies the time during which the hosts along the link of the interface can select the device as the default device. If the value is set to 0, the device will not serve as the default device any longer. If it is not set to 0, it must be larger than or equal to the interval for sending RA packets (ra-interval).

Configuring the MTU of RA Packets

Command	**ipv6 nd ra-mtu** *value*
Parameter Description	*value*: Indicates the MTU. The value range is from 0 to 1500. The default value is the same as the IPv6 MTU.
Command Mode	Interface configuration mode
Usage Guide	If it is specified as 0, RA packets will not carry the MTU option.

Configuring the Device to Proactively Send NS Packets to Specific Sub-VLANs in the Super-VLAN

Command	**ipv6 nd resolve vlan** { *vlan-list* **| none** }
Parameter Description	*vlan-list*: Specifies the list of sub-VLANs where NS packets are broadcast. If this parameter is not specified, the device proactively broadcasts NS packets to sub-VLANs of a super-VLAN in a VLAN

	list. **none**: Indicates that NS packets are not broadcast to any sub-VLAN in a super-VLAN.
Command Mode	Global configuration mode
Usage Guide	In the scenario where a super-VLAN has many sub-VLANs, when the device proactively broadcasts and resolves ND packets, the device will send NS packets to the super-VLAN by default. Due to a large number of sub-VLANs, packets will be replicated in large quantities, which will affect the device performance. Most terminals (such as PCs and servers) request the ND neighbor of the gateway before accessing a network. Therefore, there is no need to proactively broadcast NS packets to the sub-VLANs where the terminals reside. For dumb terminals (that do not proactively send NA packets), the **ipv6 nd resolve vlan** *vlan-list* command can be deployed in the VLANs specified by *vlan-list*. In this case, the device proactively sends NS packets to these VLANs to generate ND entries. After the **ipv6 ns resolve vlan** *vlan-list* command is run, the device broadcasts NS packets to the sub-VLANs specified in *vlan-list* in the super-VLAN. In particular, if an authentication-free VLAN is configured and the authentication-free VLAN is not specified by *vlan-list*, NS packets are not broadcast to the authentication-free VLAN. Supported functions vary depending on the product version.

Configuring the Period for the Neighbor to Maintain the State

Command	**ipv6 nd stale-time** *seconds*
Parameter Description	*seconds*: Specifies the period for the neighbor to maintain the state, in seconds. The value range is from 0 to 86400. The default value is 3,600.
Command Mode	Global configuration mode
Usage Guide	This command is used to set the period for the neighbor to maintain the state. After the period expires, neighbor unreachability detection is performed. The shorter the period, the faster the neighbor is found unreachable. Moreover, more network bandwidth and device resources are consumed. Therefore, do not use a small value.

Configuring the Local Link Address as the Source Address for Sending Neighbor Requests

Command	**ipv6 ns-linklocal-src**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Maximum Number of Unresolved ND Entries

Command	**ipv6 nd unresolved** *number*
Parameter Description	*number*: Indicates the maximum number of unresolved ND entries.
Command	Global configuration mode

Mode	
Usage Guide	To prevent malicious scanning attacks from creating a large number of unresolved ND entries and occupying entry resources, you can restrict the number of unresolved ND entries.

Configuring the Maximum Number of ND Options

Command	**ipv6 nd max-opt** *value*
Parameter Description	*value*: Indicates the number of supported ND options.
Command Mode	Global configuration mode
Usage Guide	Configure the maximum number of ND options processed by a device, such as link-layer address option, MTU option, redirection option, and prefix option.

Configuring the Maximum Number of ND Entries Learned on an Interface

Command	**ipv6 nd cache interface-limit** *value*
Parameter Description	*value*: Indicates the maximum number of neighbors learned by an interface.
Command Mode	Interface configuration mode
Usage Guide	Restricting the number of ND entries learned on an interface can prevent malicious neighbor attacks. If this number is not restricted, a large number of ND entries will be generated on the device, occupying excessive memory. The configured value must be greater than or equal to the number of ND entries learned by the interface. Otherwise, the configuration does not take effect. The value depends on the ND entry capacity supported by the device.

Configuring the Interval for the Interface to Retransmit NS Packets

Command	**ipv6 nd ns-interval** *milliseconds*
Parameter Description	*milliseconds*: Indicates the interval for retransmitting NS packets.
Command Mode	Interface configuration mode
Usage Guide	The configured value will be advertised through RA packets and will be used by the device itself. You are not advised to set a short interval.

Configuring the Interface to Generate a Default Route Based on the Received RA

Command	**ipv6 nd ra default route**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Only in case of DHCPv6 stateful address auto-configuration, run the **ipv6 nd ra default route** command to automatically generate a default route. The **ipv6 address autoconfig default** command also generates a default route, so you can only configure the **ipv6 address autoconfig default** or **ipv6 nd ra default route** command at only one

layer-3 interface for one device.

If the interface is bound to a multi-protocol VRF with no IPv6 address family configured, you cannot enable the feature of generating a default route on the interface. To enable the feature, configure an IPv6 address family for the multi-protocol VRF first.

Configuration Example

Enabling IPv6 Redirection on an Interface

Configuration Steps	● Enable IPv6 redirection on GigabitEthernet 0/1.
	`Hostname(config)# interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)#ipv6 redirects`
Verification	● Run the **show ipv6 interface** command to check whether the configuration takes effect.

	`Hostname#show ipv6 interface gigabitethernet 0/1`
	
	`interface GigabitEthernet 0/1 is Down, ifindex: 1`
	`  address(es):`
	`  Mac Address: 00:00:00:00:00:00`
	`  INET6: FE80::200:FF:FE00:1 [ TENTATIVE ], subnet is FE80::/64`
	`  Joined group address(es):`
	`  MTU is 1500 bytes`
	`  ICMP error messages limited to one every 100 milliseconds`
	`  ICMP redirects are enabled`
	`  ND DAD is enabled, number of DAD attempts: 1`
	`  ND reachable time is 30000 milliseconds`
	`  ND advertised reachable time is 0 milliseconds`
	`  ND retransmit interval is 1000 milliseconds`
	`  ND advertised retransmit interval is 0 milliseconds`
	`  ND router advertisements are sent every 200 seconds<160--240>`
	`  ND router advertisements live for 1800 seconds`

Configuring IPv6 DAD

Configuration Steps	● Configure the interface to send three consecutive NS packets during DAD.
	`Hostname(config)# interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)# ipv6 nd dad attempts 3`
Verification	● Run the **show ipv6 interface** command to check whether the configuration takes effect.

	`Hostname#show ipv6 interface gigabitethernet 0/1`
	
	`interface GigabitEthernet 0/1 is Down, ifindex: 1`
	`  address(es):`
	`  Mac Address: 00:00:00:00:00:00`
	`  INET6: FE80::200:FF:FE00:1 [ TENTATIVE ], subnet is FE80::/64`
	`  Joined group address(es):`

	MTU is 1500 bytes ICMP error messages limited to one every 100 milliseconds ICMP redirects are enabled ND DAD is enabled, number of DAD attempts: 3 ND reachable time is 30000 milliseconds ND advertised reachable time is 0 milliseconds ND retransmit interval is 1000 milliseconds ND advertised retransmit interval is 0 milliseconds ND router advertisements are sent every 200 seconds<160--240> ND router advertisements live for 1800 seconds

Configuring Prefix Information in an RA Packet

Configuration Steps	● Add a prefix 1234::/64 to GigabitEthernet 0/0.
	Hostname(config-if-GigabitEthernet 0/1)#ipv6 nd prefix 1234::/6
Verification	● Run the **show ipv6 interface** command to check whether the configuration takes effect.
	Hostname#show ipv6 interface gigabitEthernet 0/1 ra-info GigabitEthernet 0/1: DOWN (RA is suppressed) RA timer is stopped waits: 0, initcount: 0 statistics: RA(out/in/inconsistent): 0/0/0, RS(input): 0 Link-layer address: 00:00:00:00:00:00 Physical MTU: 1500 ND router advertisements live for 1800 seconds ND router advertisements are sent every 200 seconds<160--240> Flags: !M!O, Adv MTU: 1500 ND advertised reachable time is 0 milliseconds ND advertised retransmit time is 0 milliseconds ND advertised CurHopLimit is 64 Prefixes: <total: 1> 1234::/64(Def, CFG, vltime: 2592000, pltime: 604800, flags: LA)

Configuring the Maximum Number of Unresolved ND Entries

Configuration Steps	● Set the maximum number of unresolved ND entries to 200.
	Hostname(config)# ipv6 nd unresolved 200
Verification	● Run the **show running-config** command to check whether the configuration takes effect.
	Hostname#show running-config ipv6 nd unresolved 200 !

Configuring the Maximum Number of ND Options

Configuration Steps	● Set the maximum number of ND options to 20.
	`Hostname(config)# ipv6 nd max-opt 20`
Verification	● Run the **show running-config** command to check whether the configuration takes effect.

	`Hostname#show running-config`
	
	`ipv6 nd max-opt 20`
	`!`

Configuring the Maximum Number of ND Entries Learned on an Interface

Configuration Steps	● Set the maximum number of ND entries learned on an interface to 100.
	`Hostname(config-if-GigabitEthernet 0/1)# ipv6 nd cache interface-limit 100`
Verification	● Run the **show running-config** command to check whether the configuration takes effect.

	`Hostname#show running-config`
	`!`
	`interface GigabitEthernet 0/1`
	`ipv6 nd cache interface-limit 100`
	`!`

Configuring the NS Retransmission Interval of the Interface

Configuration Steps Set the Neighbor Solicitation (NS) retransmission interval to 2 seconds.

```
Hostname(config-if-GigabitEthernet 0/1)# ipv6 nd ns-interval 2000
```

Verification Run the **show running-config** command to check whether the configuration takes effect.

```
Hostname#show running-config
!
interface GigabitEthernet 0/1
 ipv6 nd ns-interval 2000
!
```

Configuring the Interface to Generate a Default Route Based on the Received RA

Configuration Steps Configure the VLAN 1 interface to generate a default route based on the RA.

```
Hostname(config)#interface VLAN 1
Hostname(config-if-VLAN 1)# ipv6 nd ra default route
```

Verification Run the **show running-config** command to check whether the configuration takes effect.

```
Hostname#show running-config
!
interface VLAN 1
 ipv6 nd ra default route
!
```

1.4.3 Enabling PMTUD

Configuration Effect

When sending an IPv6 packet, a host fragments the packet based on the PMTU.

Notes

The IPv6 MTU of an interface must be less than or equal to the interface MTU.

Configuration Step

Configuring the IPv6 MTU of an Interface

- Optional.

Configuring a Static PMTU

- Optional.

Configuring the Aging Time for a Dynamic PMTU

- Optional.

Verification

- Run the **show running-config** command to check whether the configuration is correct.
- Run the **show ipv6 interface** command to check whether the IPv6 MTU of an interface is correct.
- Obtain the locally sent IPv6 packets of which the length exceeds the PMTU. The packet obtaining result shows that the IPv6 packet is fragmented based on the PMTU.

Related Commands

Configuring the IPv6 MTU of an Interface

Command	**ipv6 mtu** *bytes*
Parameter Description	*bytes*: Indicates the MTU of an IPv6 packet, in bytes. The value range is from 1280 to 1500.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

Configuring the IPv6 MTU of an Interface

Configuration Steps	● Change the IPv6 MTU of GigabitEthernet 0/1 to 1300.
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 mtu 1300`
Verification	● Run the **show ipv6 interface** command to check whether the configuration takes effect.
	`Hostname(config-if-GigabitEthernet 0/1)#show ipv6 interface`

```
interface GigabitEthernet 0/1 is Down, ifindex: 1
  address(es):
    Mac Address: 00:d0:f8:22:33:47
    INET6: FE80::2D0:F8FF:FE22:3347 [ TENTATIVE ], subnet is FE80::/64
    INET6: 1020::1 [ TENTATIVE ], subnet is 1020::/64
    INET6: 1023::1 [ TENTATIVE ], subnet is 1023::/64
  Joined group address(es):
  MTU is 1300 bytes
  ICMP error messages limited to one every 100 milliseconds
  ICMP redirects are enabled
  ND DAD is enabled, number of DAD attempts: 1
  ND reachable time is 30000 milliseconds
  ND advertised reachable time is 0 milliseconds
  ND retransmit interval is 1000 milliseconds
  ND advertised retransmit interval is 0 milliseconds
  ND router advertisements are sent every 200 seconds<160--240>
  ND router advertisements live for 1800 seconds
```

1.4.4 Enabling IPv6 Source Routing

Configuration Effect

RFC 5095 abolished the Type 0 routing header. Devices do not support the Type 0 routing header by default. The **ipv6 source-route** command can be used in global configuration mode to enable IPv6 source routing.

Configuration Step

↘ Enabling IPv6 Source Routing

- Optional.
- To enable IPv6 source routing, run the **ipv6 source-route** command.

Verification

The device can properly forward packets carrying the Type 0 routing header.

Related Commands

↘ Enabling IPv6 Source Routing

Command	ipv6 source-route
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Because the Type 0 header may cause the device prone to DoS attacks, the device does not forward IPv6 packets carrying the routing header by default, but still processes IPv6 packets with itself being the destination address and the Type 0 routing header.

Configuration Example

Enabling IPv6 Source Routing

Configuration Steps	● Enable IPv6 source routing.
	`Hostname(config)#ipv6 source-route`
Verification	● Run the **show running-config** command to check whether the configuration takes effect.
	`Hostname#show running-config | include ipv6 source-route` `ipv6 source-route`

1.4.5 Configuring the Rate for Sending ICMPv6 Error Messages

Configuration Effect

Configure the rate for sending ICMPv6 error messages.

Configuration Step

Configuring the Rate for Sending ICMPv6 Packet Too Big Messages

- Optional.
- If a device receives many IPv6 packets with the packet length exceeding the IPv6 MTU of the outbound interface and thereby sends many ICMPv6 Packet Too Big messages to consume much CPU resources, run the **ipv6 icmp error-interval too-big** command to restrict the rate for sending error messages.

Configuring the Rate for Sending Other ICMPv6 Error Messages

- Optional.
- If a device receives many invalid IPv6 packets and thereby generates many ICMPv6 error messages, run the **ipv6 icmp error-interval** command to restrict the rate for sending ICMPv6 error messages. This command does not affect the rate for sending ICMPv6 Packet Too Big messages.

Verification

Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

Configuring the Rate for Sending ICMPv6 Packet Too Big Messages

Command	**ipv6 icmp error-interval too-big** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Indicates the refresh period of a token bucket, in milliseconds. The value range is from 0 to 2147483647. The default value is 100. If the value is 0, the rate for sending ICMPv6 error messages is not restricted. *bucket-size*: Indicates the number of tokens in a token bucket. The value range is from 1 to 200. The default value is 10.
Command Mode	Global configuration mode
Usage Guide	To prevent DoS attacks, use the token bucket algorithm to restrict the rate for sending ICMPv6 error

	messages. If the length of an IPv6 packet to be forwarded exceeds the IPv6 MTU of the outbound interface, the router discards this IPv6 packet and sends back an ICMPv6 Packet Too Big message to the source IPv6 address. This error message is mainly used for IPv6 PMTUD. If there are excess other ICMPv6 error messages, ICMPv6 Packet Too Big messages cannot be sent, causing a failure of IPv6 PMTUD. Therefore, you are advised to separately restrict the rates for sending ICMPv6 Packet Too Big messages and other ICMPv6 error messages. Because the precision of the timer is 10 milliseconds, you are advised to set the refresh period of a token bucket to an integer multiple of 10 milliseconds. If the refresh period of the token bucket is between 0 and 10, the actual refresh period is 10 milliseconds. For example, if the sending rate is set to 1 every 5 milliseconds, two error messages are sent every 10 milliseconds. If the refresh period of the token bucket is not an integer multiple of 10 milliseconds, it is automatically converted to an integer multiple of 10 milliseconds. For example, if the sending rate is set to 3 every 15 milliseconds, two tokens are refreshed every 10 milliseconds.

Configuring the Rate for Sending Other ICMPv6 Error Messages

Command	**ipv6 icmp error-interval** *milliseconds* [*bucket-size*]
Parameter Description	*milliseconds*: Indicates the refresh period of a token bucket, in milliseconds. The value range is from 0 to 2147483,647. The default value is 100. If the value is 0, the rate for sending ICMPv6 error messages is not restricted. *bucket-size*: Indicates the number of tokens in a token bucket. The value range is from 1 to 200. The default value is 10.
Command Mode	Global configuration mode
Usage Guide	To prevent DoS attacks, use the token bucket algorithm to restrict the sending rate of ICMPv6 error messages. Since the precision of the timer is 10 milliseconds, it is recommended to set the refresh period of a token bucket to an integer multiple of 10 milliseconds. If the refresh period of the token bucket is between 0 and 10, the actual refresh period is 10 milliseconds. For example, if the sending rate is set to 1 every 5 milliseconds, two error messages are sent every 10 milliseconds in actual situations. If the refresh period of the token bucket is not an integer multiple of 10 milliseconds, it is automatically converted to an integer multiple of 10 milliseconds. For example, if the sending rate is set to 3 every 15 milliseconds, two tokens are refreshed every 10 milliseconds in actual situations.

Configuration Example

Configuring the Rate for Sending ICMPv6 Error Messages

Configuration Steps	● Set the rate for sending ICMPv6 Packet Too Big messages to 100 pps and that of other ICMPv6 error messages to 10 pps.
	`Hostname(config)#ipv6 icmp error-interval too-big 1000 100` `Hostname(config)#ipv6 icmp error-interval 1000 10`
Verification	● Run the **show running-config** command to check whether the configuration takes effect.

	Hostname#show running-config | include ipv6 icmp error-interval ipv6 icmp error-interval 1000 10 ipv6 icmp error-interval too-big 1000 100

1.4.6 Configuring the IPv6 Hop Limit

Configuration Effect

Configure the number of hops of a unicast packet to prevent the packet from being unlimitedly transmitted.

Configuration Step

Configuring the IPv6 Hop Limit

- Optional.
- To change the number of hops of a unicast packet, run the **ipv6 hop-limit value** command.

Verification

- Run the **show running-config** command to check whether the configuration is correct.
- Obtain IPv6 unicast packets sent by a host. The packet obtaining result shows that the hop-limit field value in the IPv6 header is the same as the configured hop limit.

Related Commands

Configuring the IPv6 Hop Limit

Command	**ipv6 hop-limit value**
Parameter Description	*value*: Indicates the number of hops of a unicast packet sent by the device. The value range is from 1 to 255.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the IPv6 Hop Limit

Configuration Steps	• Change the IPv6 hop limit of a device to 250.
	Hostname(config)#ipv6 hop-limit 250
Verification	• Run the **show running-config** command to check whether the configuration takes effect.
	Hostname#show running-config ipv6 hop-limit 254

Common Errors

N/A

1.4.7 Enabling Suppression of Broadcasting NS Packets to Authentication VLANs

Configuration Effect

Enable suppression of broadcasting NS packets to authentication VLANs on an SVI.

Notes

This function can be configured only on SVIs and takes effect only in gateway authentication mode.

Configuration Step

Enabling Suppression of Broadcasting NS Packets to Authentication VLANs

- Optional.
- In gateway authentication mode, you can use this command to enable suppression of broadcasting NS packets to authentication VLANs.

Verification

- Run the **show running-config** command to display the configuration.

Related Commands

Enabling Suppression of Broadcasting NS Packets to Authentication VLANs

Command	**ipv6 nd suppress-auth-vlan-ns**
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	Use the **no** form of this command to disable this function.

Configuration Example

Disabling Suppression of Broadcasting NS Packets to Authentication VLANs

Configuration Steps	• Disable suppression of broadcasting NS packets to authentication VLANs.
	`Hostname(config-if-VLAN 2)# no ipv6 nd suppress-auth-vlan-ns`
Verification	• Run the **show running-config interface vlan 2** command to display the configuration.
	`Hostname# show running-config interface vlan 2` `no ipv6 nd suppress-auth-vlan-ns`

Common Errors

N/A

1.4.8 Binding the DNS Address Pool to the IPv6 Interface

1.4.9 Configuration Effect

Bind the DNS address pool to the IPv6 interface to carry the DNS address information in the DNS address pool when the interface announces RA information.

Notes

N/A

Configuration Steps

↘ Configuring the Interface Binding Prefix

- Optional.
- In interface configuration mode, run the **ipv6 nd ra dns import-rdnss** *pool-name* command to configure the name of the DNS address pool to be bound to the IPv6 interface.

Verification

- Run the **show running-config** command to check whether the configuration takes effect.

Related Commands

↘ Configuring the Name of the DNS Address Pool to Be Bound to the IPv6 Interface

Command	**ipv6 nd ra dns import-rdnss** *pool-name*
Parameter Description	*pool-name*: Indicates the name of the DNS address pool.
Command Mode	Interface configuration mode
Usage Guide	DHCPv6 sends the DNS address pool information of the server to TCP/IP. If a DNS address pool name is bound to the interface, the announced RA route information carries the DNS address information in the DNS address pool.

Configuration Example

↘ Binding the DNS Address Pool to the IPv6 Interface

Configuration Steps Bind the ruijie DNS address pool to the GigabitEthernet 0/1 interface.

```
Hostname(config)# interfaceGigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 dhcp client pd ruijie
Hostname(config-if-GigabitEthernet 0/1)# ipv6 nd ra dns import-rdnss ruijie
```

Verification Run the **show running-configinterface** GigabitEthernet 0/1 command to check whether the configuration takes effect.

```
Hostname#show running-config interface GigabitEthernet 0/1
ipv6 nd ra dns import-rdnss ruijie
```

Common Errors

N/A

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear ipv6 neighbors [*interface-type interface-number*]	Clears dynamically learned neighbors.

Displaying

Command	Description
show ipv6 address [*interface-name*]	Displays IPv6 addresses.
show ipv6 general-prefix	Displays information about the general prefix.
show ipv6 interface [[*interface-id*] [ra-info]] [brief [*interface-id*]]	Displays IPv6 information about an interface.
show ipv6 neighbors [**verbose**] [*interface-id*] [*ipv6-address*]	Displays neighbor information.
show ipv6 neighbors statistics	Displays statistics on IPv6 neighbor tables.
show ipv6 neighbor statistics per-mac [*interface-name*] [*mac-address*]	Displays the number of ND entries corresponding to each MAC address.
show ipv6 nd-packet [**interface** *interface-name*] **statistics**	Displays statistics on ND packets.
show ipv6 raw-socket [*num*]	Displays all IPv6 raw sockets.
show ipv6 routers [*interface-type interface-number*]	Displays information about neighbor routers and RA packets.
show ipv6 sockets	Displays all IPv6 sockets.
show ipv6 udp [**local-port** *num*] [**peer-port** *num*]	Displays all IPv6 UDP sockets.
show ipv6 udp statistics	Displays statistics on IPv6 UDP sockets.
show ipv6 nd ra received rdnss [**interface** *interface-name*]	Displays the rdnss information.
show ipv6 nd ra received dnssl [**interface** *interface-name*]	Displays the dnssl information.
show ipv6 nd ra dns server	Displays the server address information of the DNS recursive resolution service provided by the RDNSS option in the RA packet as well as the suppression status of the RDNSS option and the interface information.

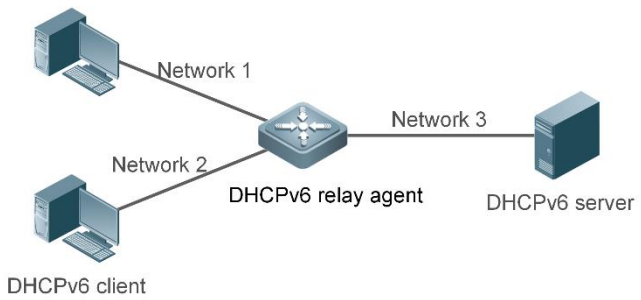
Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ipv6 nd	Debugs ND entry learning.

1 Configuring DHCPv6

1.1 Overview



The Dynamic Host Configuration Protocol for IPv6 (DHCPv6) allows a DHCP server to transfer configurations (such as IPv6 addresses) to IPv6 nodes.

Compared with other IPv6 address allocation methods, such as manual configuration and stateless automatic address configuration, DHCPv6 provides address allocation, prefix delegation, and configuration parameter allocation.

- DHCPv6 is a stateful protocol for automatically configuring addresses and flexibly adding and reusing network addresses. It records allocated addresses and enhances network manageability.
- Using prefix delegation of DHCPv6, uplink network devices can allocate address prefixes to downlink network devices, enabling flexible station-level automatic configuration and control of station address space.
- The DHCPv6 configuration parameter allocation addresses the issue of obtaining parameters through a stateless automatic address configuration protocol, allocating DNS server addresses and domain names to hosts.
- DHCPv6 works on the client/server model. A DHCPv6 client requests configurations, while a DHCPv6 server provides them. If the DHCPv6 client and DHCPv6 server are on different network links, they can interact with each other through using a DHCPv6 relay agent.

The DHCPv6 client usually discovers the DHCPv6 server by reserving multicast addresses within a link; therefore, the DHCPv6 client and DHCPv6 server must be able to directly communicate with each other. That is, they must be deployed within the same link. This may complicate management and upgrade, resulting in extra deployments (a DHCPv6 server is deployed for each subnet). The DHCPv6 relay agent can solve these problem by enabling a DHCPv6 client to send messages to a DHCPv6 server on a different link. The DHCP relay agent is often deployed within the link where a DHCPv6 client resides and is used to relay interaction messages between the DHCPv6 client and DHCPv6 server. The DHCP relay agent is transparent to the DHCPv6 client.

Figure 1-1

Protocols and Standards

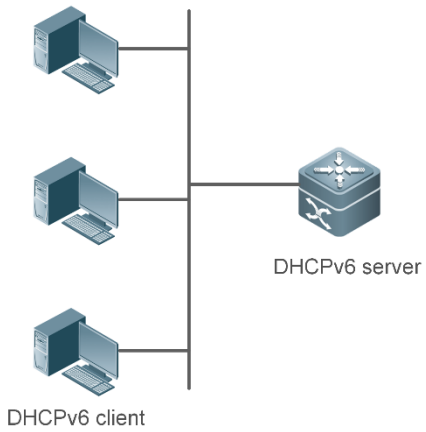
- RFC 3315: Dynamic Host Configuration Protocol for IPv6
- RFC 3633: IPv6 Prefix Options for Dynamic Host Configuration Protocol (DHCP) Version 6
- RFC 3646: DNS Configuration Options for Dynamic Host Configuration Protocol for IPv6 (DHCPv6)
- RFC 3736: Stateless DHCP Service for IPv6

- RFC 5417: Control And Provisioning of Wireless Access Points (CAPWAP) Access Controller DHCP Option

1.2 Applications

Application	Description
Requesting/Allocating Addresses and Configuration Parameters	A DHCPv6 client requests addresses from a DHCPv6 server. The DHCPv6 server allocates addresses and configuration parameters to the DHCPv6 client.
Requesting/Allocating Prefixes	The DHCPv6 client requests a prefix from the DHCPv6 server. The DHCPv6 server allocates a prefix to the DHCPv6 client and then the DHCPv6 client configures IPv6 addresses by using this prefix.
Relay Service	The DHCPv6 relay is used to enable communication between the DHCPv6 client and DHCPv6 server on different links.

1.2.1 Requesting/Allocating Addresses and Configuration Parameters



Scenario

On a subnet, a DHCPv6 client requests addresses from a DHCPv6 server. The DHCPv6 server allocates addresses and configuration parameters to the DHCPv6 client.

In Figure 1-2:

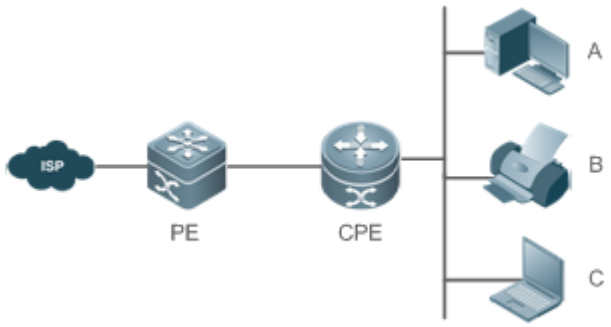
- The DHCPv6 server is configured with IPv6 addresses, DNS servers, domain names, and other configuration parameters to be allocated.
- A host works as a DHCPv6 client to request an IPv6 address from the DHCPv6 server. After receiving the request, the DHCPv6 server selects an available address and allocates the address to the host.
- The host can also request a DNS server, a domain name, and other configuration parameters from the DHCPv6 server.

Figure 1-2

Deployment

- Run the DHCPv6 client on a host in the subnet to obtain an IPv6 address and other parameters.

- Run the DHCPv6 server on a device and configure the IPv6 address and other parameters to allocate the IPv6 address and parameters.



1.2.2 Requesting/Allocating Prefixes

Scenario

As shown in Figure 1-3, an uplink device (PE) allocates an IPv6 address prefix to a downlink device (CPE). The CPE generates a new address prefix for the internal subnet based on the obtained prefix. Hosts on the internal subnet of the CPE are configured with addresses through Router Advertisement (RA) messages by using the new address prefix.

- The PE used aa a DHCPv6 server provides the prefix delegation service.
- The CPE used aa a DHCPv6 client requests an address prefix from the PE. After obtaining the address prefix, the CPE generates a new address prefix for the internal subnet and sends an RA messages to hosts on the internal subnet.
- The hosts on the internal subnet where the CPE resides configure their addresses based on the RA message sent by the CPE.

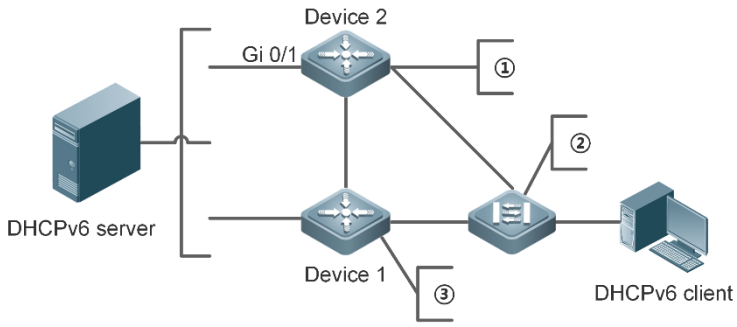
Figure 1-3

Remarks	● The Provider Edge (PE) works as a DHCPv6 server for providing prefixes and is also called a delegating router. ● The Customer Premises Equipment (CPE) works as a DHCPv6 client for requesting prefixes and is also called a requesting router. ● A, B, and C are hosts.

Deployment

- Run the DHCPv6 server on the PE to implement the prefix delegation service.
- Run the DHCPv6 client on the CPE to obtain address prefixes.
- Deploy IPv6 ND between the CPE and the hosts to configure the host addresses on the subnet through RA messages.

1.2.3 Relay Service



Scenario

The DHCPv6 relay agent provides the relay service for the DHCPv6 client ad DHCPv6 server on different links to enable communication between them.

In Figure 1-4:

- Device 1 is enabled with the DHCPv6 relay agent and destined to 3001::2.
- Device 2 wants to forward messages to other servers through a next-level relay service. Enable the DHCPv6 relay agent on Device 2, set the destination address to FF02::1:2 (all servers and relay multicast addresses), and specify the egress interface as the Layer 3 interface gi 0/1.

Figure 1-4

①Layer 3 gateway enabled with the DHCPv6 relay agent

②Layer 2 access device enabled with LDRA

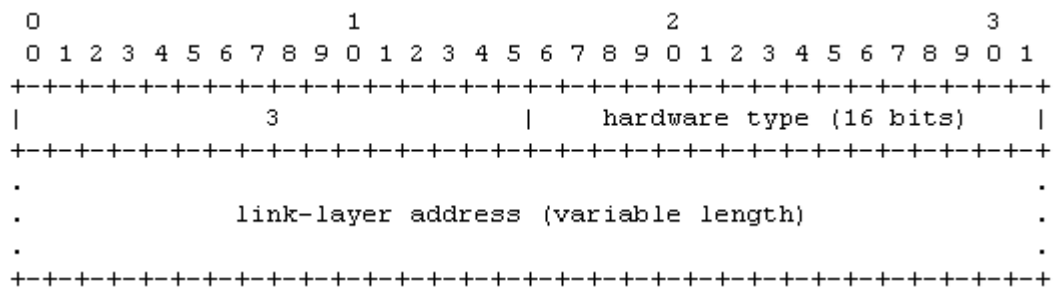
③Layer 3 gateway enabled with the DHCPv6 relay agent

Deployment

- Enable the DHCPv6 relay agent on device 1 and specify the address as 3000::1.
- Enable the DHCPv6 relay agent on device 2 and specify the address as FF02::1:2.

1.3 Features

Basic Concept



DUID

The DHCP Unique Identifier (DUID) identifies a DHCPv6 device. As defined in RFC 3315, each DHCPv6 device (DHCPv6 client, relay, or server) must have a DUID, which is used for mutual authentication during DHCPv6 message exchange.

RFC 3315 defines three types of DUIDs:

- DUID Based on Link-Layer address plus Time (DUID-LLT)
- DUID Assigned by Vendor Based on Enterprise Number (DUID-EN)
- Link-Layer address (DUID-LL)

DHCPv6 devices use DUID-LLs. The format of a DUID-LL is as follows.

The values of *DUID-LL*, *Hardware type*, and *Link-layer address* are 0x0003, 0x0001 (indicating the Ethernet), and device's MAC address respectively.

IA

A DHCPv6 server allocates Identity Associations (IAs) to DHCPv6 clients. Each IA is uniquely identified by an identity association identifier (IAID). IAIDs are generated by DHCPv6 clients. A one-to-one mapping is established between IAs and clients. An IA may contain several addresses, which can be allocated by the client to other interfaces. An IA may contain one of the following types of addresses:

- Non-temporary Addresses (NAs), namely, globally unique addresses.
- Temporary Addresses (TAs), which are hardly used
- Prefix Delegation (PD)

Based on the address type, IAs are classified into IA_NA, IA_TA, and IA_PD (three IA-Types). The DHCPv6 server supports only IA_NA and IA_PD.

Binding

DHCPv6 binding data on a DHCPv6 server records the IA and other configurations allocated to each client. A client can request multiple bindings. The address binding data on a server is present in the form of an address binding table with DUID, IA-Type, and IAID as the indexes. A binding containing configurations uses the DUID as the index.

DHCPv6 Conflict

When an address allocated by a DHCPv6 client is in conflict, the client sends a Decline message to notify the DHCPv6 server that the address is rebound. Then the server adds the address to the address conflict queue. The server will not allocate the addresses in the address conflict queue. The server supports query and clearing of address information in the address conflict queue.

Message Type

RFC 3315 stipulates that DHCPv6 uses UDP ports 546 and 547 for message exchange. In particular, a DHCPv6 client uses port 546 for receiving messages, while a DHCPv6 server and DHCPv6 relay agent use port 547 for receiving messages. RFC 3315 defines the following types of messages that can be exchanged among the DHCPv6 server, client, and relay agent:

- Messages that may be sent by a DHCPv6 client to a DHCPv6 server include Solicit, Request, Confirm, Renew, Rebind, Release, Decline, and Information-request messages.
- Messages that may be sent by a DHCPv6 server to a DHCPv6 client include Advertise, Reply, and Reconfigure messages.

- Messages that may be sent by a DHCPv6 relay agent to another DHCPv6 relay agent or a DHCPv6 server include Relay-forward messages.
- Messages that may be sent by a DHCPv6 relay agent to another DHCPv6 relay agent or a DHCPv6 server include Relay-reply messages.

The DHCPv6 server does not support the Reconfigure message.

The DHCPv6 client does not support the Confirm and Reconfigure messages.

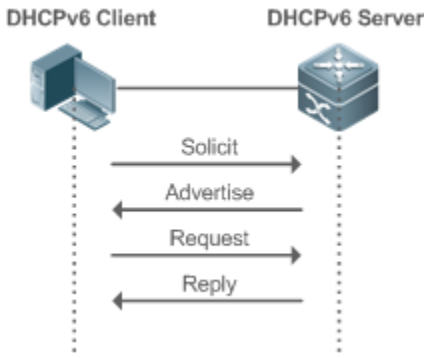
Overview

Feature	Description
Requesting or Allocating Addresses	Dynamically obtains or allocates IPv6 addresses on a network in the client/server model.
Requesting or Allocating Prefixes	Dynamically obtains or allocates IPv6 prefixes on a network in the client/server model.
Stateless Service	Provides stateless configuration service for hosts on a network.
Relay Service	Provides the DHCPv6 server service for hosts on different networks by using the relay service.

1.3.1 Requesting or Allocating Addresses

A DHCPv6 client can request an IPv6 address from a DHCPv6 server.

After being configured with available addresses, a DHCPv6 server can provide IPv6 addresses to hosts on a network, record allocated addresses and improve the network manageability.



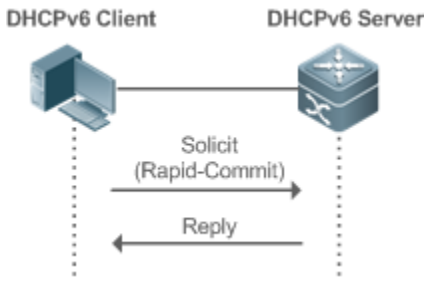
Working Principle

Network hosts serve as DHCPv6 clients to communicate with the DHCPv6 server to implement address allocation, update, confirmation, release, and other operations through message exchange.

Four-Message Exchange

Figure 1-5 shows the four-message exchange process.

Figure 1-5



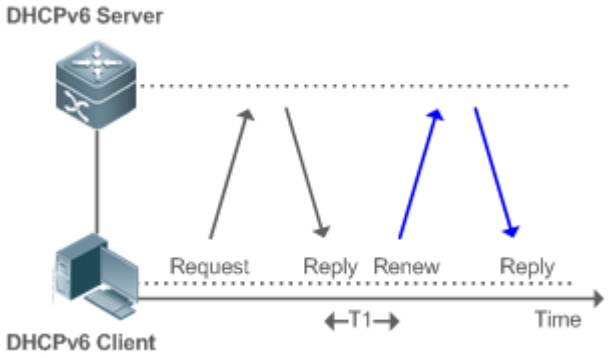
- A DHCPv6 client sends a Solicit message whose destination address is FF02::1:2 and destination port number is 547 within the local link to request address, prefix, and configuration parameter allocation. All DHCPv6 servers or DHCPv6 relay agents within the link will receive the Solicit message.

- After receiving the Solicit message, a DHCPv6 server will send an Advertise message in the unicast mode if it can provide the information requested in the Solicit message. The Advertise message includes the address, prefix, and configuration parameters.
- The DHCPv6 client may receive the Advertise message from multiple DHCPv6 servers. After selecting the most suitable DHCPv6 server, the DHCPv6 client sends a Request message whose destination address is FF02::1:2 and destination port number is 547 to request address, prefix, and configuration parameter allocation.
- After receiving the Request message, the DHCPv6 server creates a binding locally and sends a Reply message in unicast mode. The Reply message includes the address, prefix and configuration parameters that the DHCPv6 server will allocate to the DHCPv6 client. The DHCPv6 client obtains address, prefix, or configuration parameters based on the information in the Reply message.

Two-Message Exchange

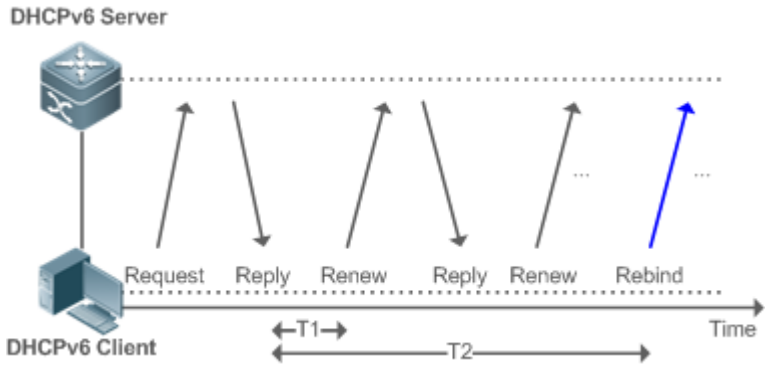
Two-message exchange can be used to complete address, prefix, and parameter configuration for DHCPv6 clients more quickly.

Figure 1-6



- A DHCPv6 client sends a Solicit message whose destination address is FF02::1:2 and destination port number is 547 within the local link to request address, prefix, and configuration parameter allocation. The Solicit message contains Rapid Commit.
- If a DHCPv6 server supports the Rapid Commit option, the DHCPv6 server creates a binding locally and sends a Reply message in unicast mode. The Reply message includes the address, prefix, and configuration parameters to be allocated to the DHCPv6 client. The DHCPv6 client completes configuration based on the information in the Reply message.

Update and Rebinding



The DHCPv6 server provides the control address and the updated T1 and T2 in the IA of the message sent to the DHCPv6 client.

Figure 1-7

- The DHCPv6 client will multicast a Renew message to the DHCPv6 server for updating the address and prefix after T1 seconds. The Renew message contains the DUID of the DHCPv6 server and the IA information to be updated.
- After receiving the Renew message, the DHCPv6 server checks whether the DUID value in the Renew message is equal to the DUID value of the local device. If so, the DHCPv6 server updates the local binding and sends a Reply message in unicast mode. The Reply message contains the new T1 and other parameters.

Figure 1-8

- If no response is received after the DHCPv6 client sends a Renew message to the DHCPv6 server, the DHCPv6 client will multicast a Rebind message to the DHCPv6 server for rebinding the address and prefix after T2 expires.
- After receiving the Rebind message, the DHCPv6 server (perhaps a new DHCPv6 server) sends a Reply message according to the content of the Rebind message.

Release

If a DHCPv6 client needs to release an address or a prefix, the DHCPv6 client needs to send a Release message to a DHCPv6 server to notify the DHCPv6 server of the released addresses or prefixes. In this way, the DHCPv6 server can allocate these addresses and prefixes to other DHCPv6 clients.

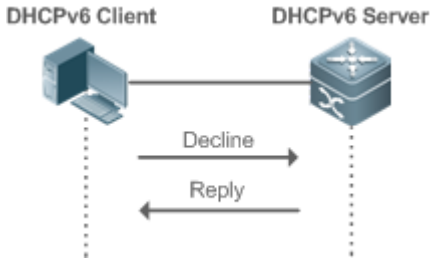
Figure 1-9

- After receiving the Release message, the DHCPv6 server removes the corresponding bindings based on the addresses or prefixes in the Release message, and sends a Reply message carrying the state option to the DHCPv6 client.

Confirmation

After moving to a new link (for example, after restart), a DHCPv6 client will send a Confirm message to the DHCPv6 server on the new link to check whether the original addresses are still available.

Figure 1-10



- After receiving the Confirm message, the DHCPv6 server performs confirmation based on the address information in the Confirm message, and sends a Reply message carrying the state option to the DHCPv6 client. If the confirmation fails, the DHCPv6 client may initiate a new address allocation request.

DHCPv6 Conflict

If the DHCPv6 client finds that the allocated addresses have been used on the link after address allocation is completed, the DHCPv6 client sends a Decline message to notify the DHCPv6 server of the address conflict.

Figure 1-11

- The DHCPv6 client adds IA information of the conflicted addresses to the Decline message.
- After receiving the Decline message, the DHCPv6 server marks the addresses in the Decline message as declined and will not allocate these addresses. Then the DHCPv6 server sends a Reply message carrying the state option to the DHCPv6 client. You can manually clear addresses marked as declined to facilitate re-allocation.

Related Configuration

Enabling the DHCPv6 Server Function on an Interface

- By default, an interface is not enabled with the DHCPv6 server function.
- You can run the **ipv6 dhcp server** command to enable the DHCPv6 server function for the interface.

⚠ The DHCPv6 server function must be enabled on a Layer 3 interface.

Allocating Addresses Through the DHCPv6 Server

- You can run the **ipv6 dhcp pool** command to create an address pool.
- You can run the **iana-address** command to configure addresses to be allocated and values of **preferred lifetime** and **valid lifetime**.

Clearing Conflicted Addresses Through the DHCPv6 Server

- By default, the DHCPv6 server does not clear conflicted addresses that are detected.
- You can run the **clear ipv6 dhcp conflict** command to clear conflicted addresses so that these addresses can be reused.

Enabling the DHCPv6 Client Address Request Function on an Interface

- By default, an interface is not enabled with the DHCPv6 client address request function.
- You can run the **ipv6 dhcp client ia** command to enable or disable the DHCPv6 client address request function for the interface.

The DHCPv6 client address request function is effective only on a Layer 3 interface.

1.3.2 Requesting or Allocating Prefixes

Configure available prefixes on the DHCPv6 server. By using prefix delegation of DHCPv6, uplink network devices can allocate address prefixes to downlink network devices, which implements flexible station-level automatic configuration and control of station address space.

Working Principle

Downlink network devices serve as DHCPv6 clients to exchange messages with the DHCPv6 server to implement address allocation, update, release, and other operations. Downlink network devices obtain, update, rebind, and release prefixes by using the four- or two-message exchange mechanism similar to that for allocating addresses. However, prefix allocation is different from address allocation in the following aspects:

- In message exchange using the prefix delegation, the Confirm and Decline messages are not used.
- If a DHCPv6 client moves to a new link and needs to check whether the prefix information is available, it performs confirmation through Rebind and Reply message exchange.
- The IA type in various messages is IA_PD.

For the message exchange using prefix delegation, see Requesting or Allocating Addresses.

Related Configuration

Enabling the DHCPv6 Server Function on an Interface

- By default, an interface is not enabled with the DHCPv6 server function.
- You can run the **ipv6 dhcp server** command to enable the DHCPv6 server function for the interface.

The DHCPv6 server function is effective only on a layer-3 interface.

Configuring Prefix Delegation of the DHCPv6 Server

- By default, the DHCPv6 server has no address pool and is not configured with prefixes.

- You can run the **ipv6 dhcp pool** command to create an address pool.
- You can run the **prefix-delegation** command to allocate specified prefixes to a specific DHCPv6 client.
- You can run the **prefix-delegation pool** command to configure a prefix pool so that all prefixes requested by the DHCPv6 client are allocated from this pool.

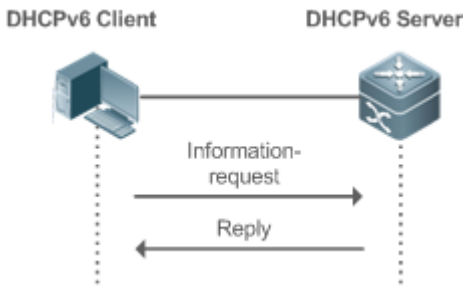
Enabling the DHCPv6 Client Prefix Request Function on an Interface

By default, an interface is not enabled with the DHCPv6 client prefix request function.

You can run the **ipv6 dhcp client pd** command to enable the DHCPv6 client prefix request function for the interface.

The DHCPv6 client prefix request function is effective only on a Layer 3 interface.

1.3.3 Stateless Service



When a DHCPv6 client needs only configuration parameters, the DHCPv6 stateless service can be used to obtain related configuration parameters which cannot be obtained through a stateless automatic address configuration protocol, such as the DNS server address.

Working Principle

Network hosts serve as DHCPv6 clients to exchange messages with the DHCPv6 server to obtain and update configuration parameters.

Message Exchange Using the Stateless Service

Figure 1-12

- A DHCPv6 client sends an Information-request message to a DHCPv6 server to request stateless messages. Usually, this message does not contain the DUID of the specified DHCPv6 server.
- The DHCPv6 server sends a Reply message containing configuration parameters to the DHCPv6 client.

Related Configuration

Enabling the DHCPv6 Server Function on an Interface

- By default, an interface is not enabled with the DHCPv6 server function.
- You can run the **ipv6 dhcp server** command to enable the DHCPv6 server function for the interface.

The DHCPv6 server function is effective only on a Layer 3 interface.

Stateless Service of a DHCPv6 Server

- By default, the DHCPv6 server has no pool and is not configured with configuration parameters.

- You can run the **ipv6 dhcp pool** command to create an address pool.
- You can run the **dns-server** command to add a DNS server.
- You can run the **domain-name** command to add a domain name.
- You can run the **option52** command to add the IPv6 address of the CAPWAP AC.
- You can run the **excluded-address** command to add an excluded address on a DHCPv6 server.

Stateless Service of a DHCPv6 Client

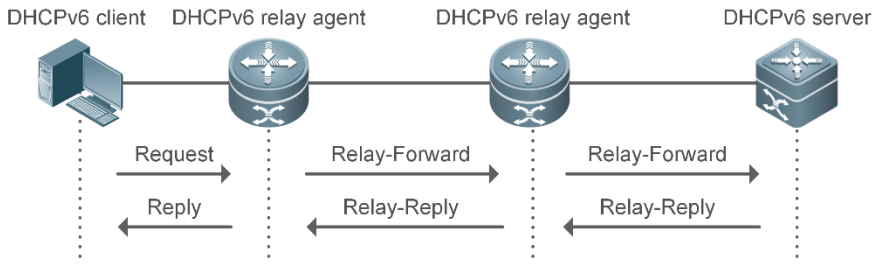
- By default, an interface is not enabled with the stateless service of the DHCPv6 client.
- If a host receives an RA message containing the O flag, it will enable the stateless service.

1.3.4 Relay Service

When the DHCPv6 client and DHCPv6 server are on different links, the DHCPv6 client can relay related messages to the DHCPv6 server through the DHCPv6 relay agent. The DHCPv6 server also relays the response to the DHCPv6 client through the relay agent.

Working Principle

When receiving a message from the DHCPv6 client, the DHCPv6 relay agent creates a Relay-forward message. This message contains the original message from the DHCPv6 client and some options added by the relay agent. Then the relay agent sends the Relay-forward message to a specified DHCPv6 server or a specified multicast address FF05::1:3.



After receiving the Relay-forward message, the DHCPv6 server extracts the original message from the DHCPv6 client for processing. Then the DHCPv6 server constructs a response to the original message, encapsulates the response in a Relay-reply message, and then sends the Relay-reply message to the DHCPv6 relay agent.

After receiving the Relay-reply message, the DHCPv6 relay agent extracts the original message from the DHCPv6 server for processing, and forwards the message to the DHCPv6 client.

Multi-level relay agents are allowed between the DHCPv6 client and DHCPv6 server.

DHCPv6 Relay Agent

Figure 1-13

- The DHCPv6 relay agent performs message encapsulation and decapsulation between the DHCPv6 client and DHCPv6 server to enable communication between the DHCPv6 client and DHCPv6 server on different links.

1.4 Configuration

Configuration	Description and Command	
Configuring the DHCPv6 Server	(Mandatory) It is used to create a DHCPv6 server configuratio pool.	
	ipv6 dhcp pool	Configures an address pool for the DHCPv6 server.
	(Optional) It is used to allocate prefixes.	
	prefix-delegation	Configures prefixes of statically bound addresses on the DHCPv6 server.
	prefix-delegation pool	Configures the DHCPv6 server to allocate prefixes from a local prefix pool.
	ipv6 local pool	Configures a local IPv6 prefix pool.
	(Optional) It is used to allocate configuration parameters.	
	dns-server	Configures the DNS server on the DHCPv6 server.
	domain-name	Configures the domain name of the DHCPv6 server.
	option52	Configures the IPv6 address of the CAPWAP AC on the DHCPv6 server.
	excluded-address	Configures excluded addresses on the DHCPv6 server.
	(Mandatory) It is used to enable the DHCPv6 server.	
	ipv6 dhcp server	Enables the DHCPv6 server on an interface.
Configuring the DHCPv6 Relay	(Mandatory) It is used to enable the DHCPv6 relay agent.	
	ipv6 dhcp relay destination	Configures the DHCPv6 relay agent.
Configuring the DHCPv6 Client	(Mandatory) It is used to request addresses or prefixes.	
	ipv6 dhcp client ia	Enables the DHCPv6 client and requests IANA addresses.
	ipv6 dhcp client pd	Enables the DHCPv6 client and requests address prefixes.
	(Optional) It is used to enable a host that receives an RA message to request stateless service through the DHCPv6 client.	
	ipv6 nd other-config-flag	Sets the O flag in the RA message on the device that sends the RA message so that the host that receives the RA message can request stateless service through the DHCPv6 client.

1.4.1 Configuring the DHCPv6 Server

Configuration Effect

An uplink device can automatically allocate DHCPv6 addresses, prefixes, and configuration parameters to a downlink device.

Notes

- To provide the DHCPv6 server, you must specify an address pool.
- Do not use the long name of the address pool.
- When enabling the DHCPv6 server, you must specify a pool.
- Only the Switch Virtual Interface (SVI), routed interface, and Layer 3 aggregate interface support this configuration.

Configuration Step

Configuring a DHCPv6 Server Pool

- Mandatory.
- Unless otherwise specified, you should configure a pool on all devices that need to provide the DHCPv6 server.

Configuring Address Prefixes to Be Allocated on the DHCPv6 Server

- Optional.
- To provide the address allocation service, configure address prefixes to be allocated on all devices that need to provide the DHCPv6 server.

Configuring Prefixes of Static Addresses on the DHCPv6 Server

- Optional.
- To provide the prefix delegation service for statically bound addresses, configure prefixes of statically bound addresses on all devices that need to provide the DHCPv6 server.

Configuring the DHCPv6 Server to Allocate Prefixes from a Local Prefix Pool

- Optional.
- To provide the prefix delegation service, specify a local prefix pool on all devices that need to provide the DHCPv6 server.

Configuring a Local IPv6 Prefix Pool

- Optional.
- To provide the prefix delegation service through a prefix pool, specify a local prefix pool on all devices that need to provide the DHCPv6 server.

Configuring the DNS Server on the DHCPv6 Server

- Optional.
- To allocate DNS servers, configure the DNS server on all devices that need to provide the DHCPv6 server.

Configuring Domain Names on the DHCPv6 Server

- Optional.
- To allocate domain names, configure domain names on all devices that need to provide the DHCPv6 server.

Configuring the IPv6 Address of the CAPWAP AC on the DHCPv6 Server

- Optional.
- To allocate CAPWAP AC information, configure the IPv6 address of the CAPWAP AC on all devices that need to provide the DHCPv6 server.

Enabling the DHCPv6 Server

- Mandatory.
- Unless otherwise specified, you should enable the DHCPv6 server on specific interfaces of all devices that need to provide the DHCPv6 server.

Verification

The DHCPv6 server allocates addresses, prefixes, or configuration parameters to DHCPv6 clients.

- The DHCPv6 client obtains required information.
- The DHCPv6 server successfully creates a local binding.

Related Commands

Configuring a DHCPv6 Server Pool

Command	**ipv6 dhcp pool** *poolname*
Parameter Description	***poolname***: Indicates the name of a user-defined DHCPv6 pool.
Command Mode	Global configuration mode
Usage Guide	Run the **ipv6 dhcp pool** command to create a DHCPv6 server pool. After configuring this command, you enter the DHCPv6 pool configuration mode, in which you can configure pool parameters such as the prefix and DNS server. After creating a DHCPv6 server pool, you can run the **ipv6 dhcp server** command to associate the pool with the DHCPv6 server on an interface.

Configuring Prefixes of Statically Bound Addresses on the DHCPv6 Server

Command	**prefix-delegation** *ipv6-prefix/prefix-length client-DUID*[**lifetime** { *valid-lifetime* | *preferred-lifetime* }]
Parameter Description	*ipv6-prefix/prefix-length*: Indicates an IPv6 address prefix and the prefix length. *client-DUID*: Indicates the DUID of a client. **lifetime**: Sets the valid time of the prefix allocated to a client. This keyword must be configured with *valid-lifetime* and *preferred-lifetime*. *valid-lifetime*: Indicates the valid time of the prefix allocated to the client. *preferred-lifetime*: Indicates the time when a prefix is preferentially allocated to a client.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	You can run the **prefix-delegation** command to manually configure a prefix list for an IA_PD of a client and specify the valid time of these prefixes.

	Use the *client-DUID* parameter to specify the client to which the address prefix is allocated. The address prefix will be allocated to the first IA_PD of the client. After receiving a request for the address prefix from the client, the DHCPv6 server checks whether a static binding is available. If so, the DHCPv6 server directly returns the static binding. If not, the DHCPv6 server allocates the address prefix from another prefix source.

Configuring the DCHPv6 Server to Allocate Prefixes from a local Prefix Pool

Command	**prefix-delegation pool** *poolname*
Parameter Description	*poolname*: Indicates the name of a user-defined local prefix pool.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	Run the **prefix-delegation pool** command to configure a prefix pool for a DHCPv6 server to allocate prefixes to clients. The **ipv6 local pool** command is used to configure a prefix pool. When receiving a prefix request from a client, the DHCPv6 server selects an available prefix from the prefix pool and allocates the prefix to the client. When the client does not use this prefix, the DHCPv6 server retrieves the prefix .

Configuring a Local IPv6 Prefix Pool

Command	**ipv6 local pool** *poolname prefix/prefix-length assigned-length*
Parameter Description	*poolname*: Indicates the name of a local prefix pool. *prefix/prefix-length*: Indicates the prefix and prefix length. *assigned-length*: Indicates the length of the prefix allocated to a user.
Command Mode	Global configuration mode
Usage Guide	Run the **ipv6 local pool** command to create a local prefix pool. If the DHCPv6 server needs prefix delegation, you can run the **prefix-delegation pool** command to specify a local prefix pool. Then prefixes will be allocated from the specified local prefix pool.

Configuring the DNS Server on the DHCPv6 Server

Command	**dns-server** *ipv6-address*
Parameter Description	*ipv6-address*: Indicates the IPv6 address of the DNS server.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	You can run the **dns-server** command for multiple times to configure multiple DNS server addresses. A new DNS server address will not overwrite old DNS server addresses.

Configuring Domain Names on the DHCPv6 Server

Command	**domain-name** *domain*
Parameter Description	*domain*: Defines a domain name to be allocated to a user.
Command Mode	DHCPv6 pool configuration mode

Usage Guide	You can run the **domain-name** command for multiple times to create multiple domain names. A new domain name will not overwrite old domain names.

Configuring the option52 on the DHCPv6 Server

Command	**option52** *ipv6-address*
Parameter Description	*ipv6-address*: Specifies the IPv6 address of the CAPWAP AC.
Command Mode	DHCPv6 pool configuration mode
Usage Guide	You can run the **option52** command to configure IPv6 addresses for multiple CAPWAP ACs. A new CAPWAP AC IPv6 address will not overwrite old IPv6 addresses.

Enabling the DHCPv6 Server

Command	**ipv6 dhcp server** *poolname* **[rapid-commit] [preference** *value***]**
Parameter Description	*poolname*: Indicates the name of a user-defined DHCPv6 pool. **rapid-commit**: Permits the two-message exchange process. **preference** *value*: Configures the priority of the advertise message. The value range is from 0 to 255. The default value is 0.
Command Mode	Interface configuration mode
Usage Guide	Run the **ipv6 dhcp server** command to enable the DHCPv6 server on an interface. When the **rapid-commit** keyword is configured, the two-message exchange with a client is permitted during allocation of address prefixes and other configurations. After this keyword is configured, if the Solicit message from a client contains the **rapid-commit** option, the DHCPv6 server will send a Reply message directly. If **preference** is set to a non-0 value, the Advertise message sent by the DHCPv6 server contains the **preference** option. The **preference** field affects the server selection by a client. If an Advertise message does not contain this field, the value of **preference** is considered 0. If the value of **preference** received by the client is 255, the client sends a request to the server immediately to obtain configurations. The DHCPv6 client, server, and relay functions cannot be configured on an interface simultaneously.

Configuration Example

Configuring the DHCPv6 Server

Configuration Steps	● Configure a pool named **pool1**. ● Configure prefixes of statically bound addresses on the DHCPv6 server. ● Configure two DNS servers. ● Configure the domain name. ● Enable the DHCPv6 server on an interface.
	`Hostname# configure terminal` `Hostname(config)# ipv6 dhcp pool pool1`

	Hostname(config-dhcp)# prefix-delegation 2008:2::/64 0003000100d0f82233ac Hostname(config-dhcp)# dns-server 2008:1::1 Hostname(config-dhcp)# dns-server 2008:1::2 Hostname(config-dhcp)# domain-name example.com Hostname(config-dhcp)#exit Hostname(config)# interface GigabitEthernet 0/1 Hostname(config-if)# ipv6 dhcp server pool1
Verification	● Run the **show ipv6 dhcp pool** command to display the created pool.
	Hostname# show ipv6 dhcp pool DHCPv6 pool: pool1 Static bindings: Binding for client 0003000100d0f82233ac IA PD prefix: 2008:2::/64 preferred lifetime 3600, valid lifetime 3600 IANA address range: 2008:50::1/64 -> 2008:50::ffff:ffff:ffff:ffff/64 preferred lifetime 1000, valid lifetime 2000 DNS server: 2008:1::1 DNS server: 2008:1::2 Domain name: example.com

Common Errors

- The specified pool name is long.
- The number of pools exceeds the limit (256).
- The configuration is not performed on the SVI, routed interface, or Layer 3 aggregate interface.
- The number of interfaces configured with the DHCPv6 server exceeds the limit (256).
- The specified value of **valid lifetime** is smaller than that of **preferred lifetime**.
- An invalid IA_NA address is specified.
- The number of address ranges exceeds the limit (20).
- When prefixes of statically bound addresses are configured, the specified DUIDs are long.
- The number of prefixes of statically bound addresses exceeds the system limit (1024).
- When a local prefix pool is configured, the specified value of **valid lifetime** is greater than that of **preferred lifetime**.
- The number of DNS servers exceeds the limit (10).
- The number of domain names exceeds the limit (10).
- The number of Option 52 addresses exceeds the limit (10).

1.4.2 Configuring the DHCPv6 Relay Agent

Configuration Effect

- A DHCPv6 relay agent can be configured to implement communication between the DHCPv6 client and server on different links for address allocation, prefix delegation, and parameter allocation.

Notes

- A destination address must be specified. If the destination address is a multicast address (such as FF05::1:3), you also need to specify an egress interface.

Configuration Step

Configuring the DHCPv6 Relay Agent

- Mandatory.
- Unless otherwise specified, you should configure the DHCPv6 relay agent on all devices that need to provide the DHCPv6 relay agent.

Verification

- The DHCPv6 client and DHCPv6 server exchange messages through the relay agent.
- Check whether the interface is enabled with the DHCPv6 relay agent.
- Check whether the DHCPv6 relay agent can receive and send messages.

Related Commands

Configuring the DHCPv6 Relay Agent

Command	**ipv6 dhcp relay destination** *ipv6-address* [*interface-type interface-number*]
Parameter Description	*ipv6-address*: Specifies the destination address of the relay agent. *interface-type*: Specifies the type of the destination interface (optional). *interface-number*: Specifies the number of the destination interface (optional).
Command Mode	Interface configuration mode
Usage Guide	All DHCPv6 messages from clients received by an interface enabled with the DHCPv6 relay agent will be encapsulated and sent to a specified destination address (or multiple destination addresses) through a specified interface (optional).

Configuration Example

Configuring the DHCPv6 Relay Agent

Configuration Steps	● Specify an interface enabled with the relay agent to forward received DHCPv6 client messages to a specified destination address through the specified interface (optional).

	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#interface vlan 1`
	`Hostname(config-if)#ipv6 dhcp relay destination 3001::2`
	`Hostname(config-if)#ipv6 dhcp relay destination ff02::1:2 vlan 2`

Verification	● Run the **show ipv6 dhcp relay destination all** command to display the configured destination addresses.

	Interface:VLAN 1 Destination address(es) Output Interface 3001::2 ff02::1:2 VLAN 2

Common Errors

- The configuration is not performed on the SVI, routed interface, or Layer 3 aggregate interface.

1.4.3 Configuring the DHCPv6 Client

Configuration Effect

- Enable a device to automatically request IPv6 addresses or related parameters from a server.

Notes

- The configuration must be performed on Layer 3 interfaces.

Configuration Steps

↘ Enabling the DHCPv6 Client and Requesting IANA Addresses

- Mandatory.
- Unless otherwise specified, you should enable the DHCPv6 client address request function on all devices that need to request addresses.

↘ Enabling the DHCPv6 Client and Requesting Address Prefixes

- Mandatory.
- Unless otherwise required, the DHCPv6 client prefix request function should be enabled on each device that requires a DHCPv6 request prefix.

↘ Enabling the Stateless Service of the DHCPv6 Client

- It is mandatory if the DHCPv6 client needs to obtain configuration parameters.

Verification

- Check whether the interface is enabled with the DHCPv6 client and check the addresses, prefixes, and other configuration obtained on the interface.

Related Commands

↘ Enabling the DHCPv6 Address Request Function

Command	**ipv6 dhcp client ia** [**rapid-commit**]
Parameter Description	**rapid-commit**: Permits the simplified message exchange process.
Command Mode	Interface configuration mode

Usage Guide	If the DHCPv6 client mode is not enabled, this command will enable the DHCPv6 client mode on the interface. After the **ipv6 dhcp client ia** command is configured, an IANA address request will be sent to the DHCPv6 server. The **rapid-commit** keyword permits the two-message exchange process between the client and server. If this keyword is configured, the Solicit message sent by the client contains the **rapid-commit** option.

Enabling the DHCPv6 Client Prefix Request

Command	**ipv6 dhcp client pd** *prefix-name* [**rapid-commit**]
Parameter Description	*prefix-name*: Indicates an IPv6 general prefix. **rapid-commit**: Permits the simplified message exchange process.
Command Mode	Interface configuration mode
Usage Guide	If the DHCPv6 client mode is not enabled, this command will enable the DHCPv6 client mode on the interface. After the **ipv6 dhcp client pd** command is configured, a prefix request will be sent to the DHCPv6 server. After receiving the prefix, the client will save the prefix in the IPv6 general prefix pool. Then, other commands and applications can use this prefix. The **rapid-commit** keyword permits the two-message exchange process between the client and server. If this keyword is configured, the Solicit message sent by the client contains the **rapid-commit** option.

Configuring the Stateless Service

Command	**ipv6 nd other-config-flag**
Parameter Description	-
Command Mode	Interface configuration mode
Usage Guide	Configure this command on a host that sends the RA message. Then, the host that receives the RA message obtains stateless configurations through the DHCPv6 client.

Configuration Example

Enabling the DHCPv6 Address Request Function

Configuration Steps	● Configure the DHCPv6 client address request function on an interface.
	`Hostname(config)# interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)# ipv6 dhcp client ia`
Verification	● Run the **show ipv6 dhcp interface** command to display whether the interface is enabled with the DHCPv6 client.

	`Hostname#show ipv6 dhcp interface gigabitethernet 0/1`
	`GigabitEthernet 0/1 is in client mode`
	`  Rapid-Commit: disable`

Enabling the DHCPv6 Client Prefix Request

Configuration Steps	● Configure the DHCPv6 client prefix request function on an interface.
	`Hostname(config)# interface gigabitethernet 0/1` `Hostname(config-if-GigabitEthernet 0/1)# ipv6 dhcp client pd pd_name`
Verification	● Run the **show ipv6 dhcp interface** command to display whether the interface is enabled with the DHCPv6 client.

	`Hostname#show ipv6 dhcp interface gigabitethernet 0/1`
	`GigabitEthernet 0/1 is in client mode`
	`  Rapid-Commit: disable`

Enabling the DHCPv6 Stateless Service

Configuration Steps	● Configure this command on an interface that sends RA messages.

	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitethernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# ipv6 nd other-config-flag`

Verification	● Run the **show ipv6 dhcp interface** command to check whether an interface of the host obtains configuration parameters.

	`Hostname#show ipv6 dhcp interface gigabitethernet 0/2`
	`GigabitEthernet 0/2 is in client mode`
	`  DNS server: 2001::1`
	`  Rapid-Commit: disable`

Common Errors

- The DHCPv6 client address request is enabled on non-Layer-3 interfaces.
- The DHCPv6 address request is enabled on interfaces enabled with the DHCPv6 relay agent or DHCPV6 server.
- The DHCPv6 client prefix request is enabled on non-Layer-3 interfaces.
- The DHCPv6 prefix request is enabled on interfaces enabled with the DHCPv6 relay agent or DHCPV6 server.

1.5 Monitoring

Clearing

⚠ During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear ipv6 dhcp binding [*ipv6-address*]	Clears DHCPv6 bindings.
clear ipv6 dhcp server statistics	Clears DHCPv6 server statistics.
clear ipv6 dhcp conflict { *ipv6-address* | * }	Clears conflicted addresses on the DHCPv6 server.
clear ipv6 dhcp relay statistics	Clears statistics on sent and received messages after the DHCPv6 relay agent is enabled on the device.
clear ipv6 dhcp client *interface-type interface-number*	Restarts the DHCPv6 client.

Displaying

Command	Description
show ipv6 dhcp	Displays the DUID of a device.
show ipv6 dhcp binding [*ipv6-address*]	Displays address bindings on the DHCPv6 server.
show ipv6 dhcp interface [*interface-name*]	Displays the DHCPv6 interface.
show ipv6 dhcp pool [*poolname*]	Displays the DHCPv6 pool.
show ipv6 dhcp conflict	Displays conflicted DHCPv6 addresses.
show ipv6 dhcp server statistics	Displays statistics on the DHCPv6 server.
show ipv6 dhcp relay destination { **all** | *interface-type interface-number* }	Displays the destination address of the DHCPv6 relay agent.
show ipv6 dhcp relay statistics	Displays the statistics on sent and received messages after the DHCPv6 relay is enabled on a device.
show ipv6 local pool [*poolname*]	Displays the local IPv6 prefix pool.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ipv6 dhcp [**detail**]	Debugs DHCPv6.

1 Configuring DHCPv6 Snooping

1.1 Overview

Dynamic Host Configuration Protocol for IPv6 (DHCPv6) snooping records and monitors the user IP address usage by intercepting DHCPv6 packets between a DHCPv6 server and the DHCPv6 clients. It can also filter invalid DHCPv6 packets, including DHCPv6 request packets from the clients and DHCPv6 response packets from the server. The user data entries generated by DHCPv6 snooping can be used by security applications such as IPv6 source guard.

The following section describes DHCPv6 snooping.

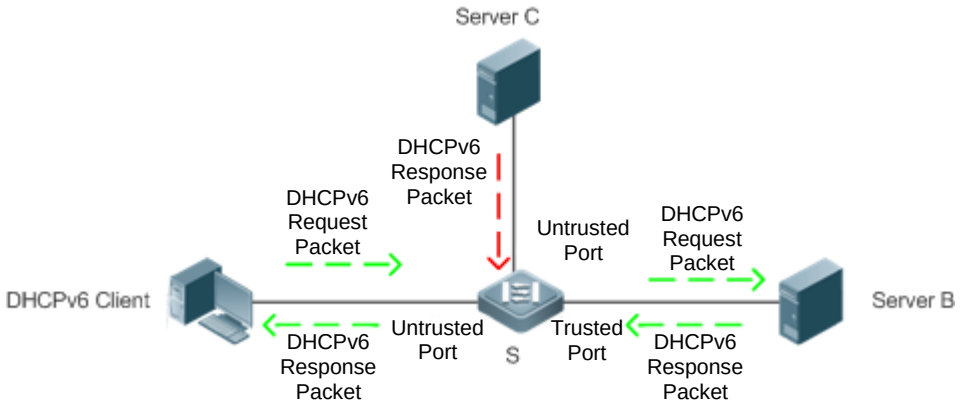
Protocols and Standards

- RFC 3315: Dynamic Host Configuration Protocol for IPv6
- RFC 5007: DHCPv6 Leasequery
- RFC 5460: DHCPv6 Bulk Leasequery

1.2 Applications

Application	Description
Defense Against DHCPv6 Spoofing Attacks	Allows DHCPv6 clients to obtain network configuration parameters only from the valid DHCPv6 server when multiple DHCPv6 servers exist on the network.
Defense Against Bogus DHCPv6 Packet Attacks	Defends against malicious users who send bogus DHCPv6 request packets, such as DHCPv6-Release packets.
Defense Against IPv6/MAC Spoofing Attacks	Defends against malicious users who send bogus IPv6 packets, for example, with the source address field tampered.
Defense Against Untrusted IPv6 Addresses	Detects network users who use untrusted IPv6 addresses, instead of the IPv6 addresses obtained from the DHCPv6 server.

1.2.1 Defense Against DHCPv6 Spoofing Attacks



Scenario

Multiple DHCPv6 servers may exist on the network. User PCs can obtain network configuration parameters only from DHCPv6 servers within the specified range.

As shown in the following figure, the DHCPv6 client can communicate with only the trusted DHCPv6 server.

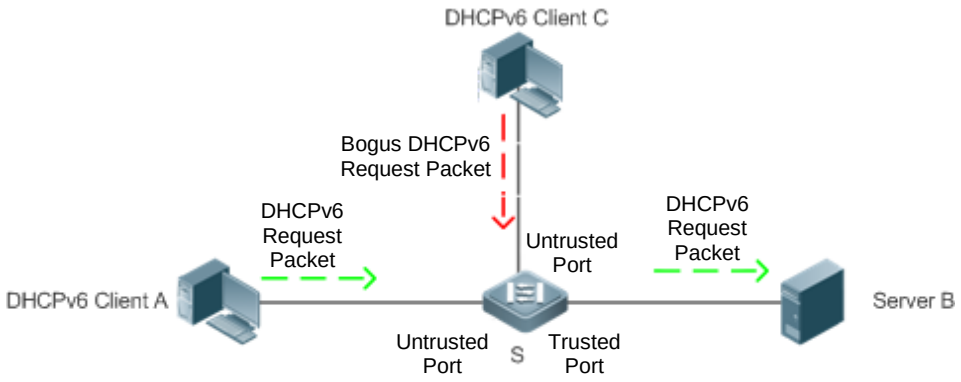
- The request packets of the DHCPv6 client can be transmitted only to the trusted DHCPv6 server.
- Only the response packets of the trusted DHCPv6 server can be transmitted to the DHCPv6 client.

Figure 1-1

Notes	S is the access device. DHCPv6 Client is a user PC. Server B is a trusted DHCPv6 server. Server C is an untrusted DHCPv6 server.

Deployment

- Enable DHCPv6 snooping on the access device S to monitor DHCPv6 packets.
- Configure the port connecting the access device S to DHCPv6 Server B as a DHCPv6 trusted port to forward response packets.
- Configure other ports of the access device S as DHCPv6 untrusted ports to filter response packets.



1.2.2 Defense Against Bogus DHCPv6 Packet Attacks

Scenario

Malicious users may exist on the network and they send bogus DHCPv6 request packets. These packets consume available IPv6 addresses of DHCPv6 servers and preempt IPv6 addresses of valid users. Therefore, invalid DHCPv6 packets on the access network must be filtered.

As shown in the following figure, the access device checks DHCPv6 request packets sent by DHCPv6 clients. The Release and Decline packets of the clients can be forwarded only if they match the records in the internal snooping database.

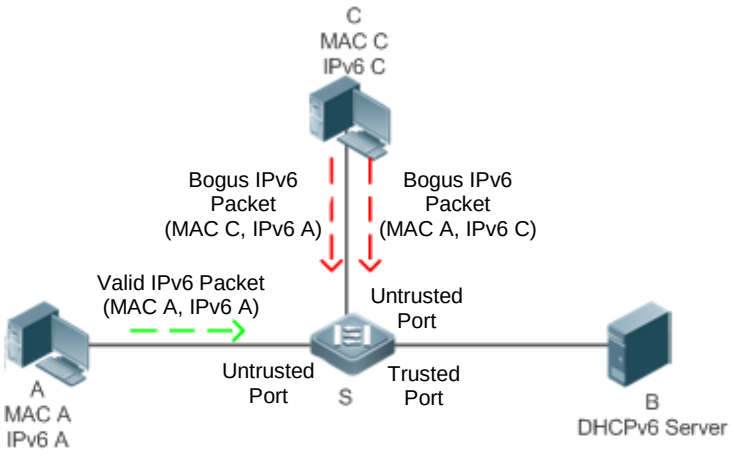
Figure 1-2

Notes	S is the access device. A and C are user PCs. B is a DHCPv6 server within the specified range.

Deployment

- Enable DHCPv6 snooping on the access device S to monitor DHCPv6 packets.
- Configure the port connecting the access device S to DHCPv6 Server B as a DHCPv6 trusted port to forward response packets.
- Configure other ports of the access device S as DHCPv6 untrusted ports to filter DHCPv6 packets.

1.2.3 Defense Against IPv6/MAC Spoofing Attacks



Scenario

When the access device checks IPv6 packets from untrusted ports to filter bogus IPv6 packets, it can check only the IP field or both the IP and MAC fields.

As shown in the following figure, the access device checks IPv6 packets sent by DHCPv6 clients.

- The source address field in an IPv6 packet must be the same as the IPv6 address allocated by the DHCPv6 server.
- The source MAC address of a Layer 2 packet must be the same as the user MAC address in the DHCPv6 request packet of the client.

Figure 1-3

Notes	S is the access device. A and C are user PCs. B is a DHCPv6 server within the specified range.

Deployment

- Enable DHCPv6 snooping on the access device S to monitor DHCPv6 packets.
- Configure all the downlink ports of the access device S as DHCPv6 untrusted ports.
- Enable IPv6 source guard on the access device S to filter IPv6 packets.
- Set the matching mode of IPv6 source guard on the access device S to IPv6+MAC to check both the MAC and IPv6 fields of IPv6 packets.

1.2.4 Defense Against Untrusted IPv6 Addresses

Scenario

The access device checks whether the source IPv6 addresses of IPv6 packets from untrusted ports are the same as those allocated by the DHCPv6 server.

If the source IPv6 address, port number, or Layer 2 source MAC address of an IPv6 packet does not match the record allocated by the DHCPv6 server to which the access device connects, the access device discards the IPv6 packet.

The operating process of the access device in this scenario is the same as that in the previous section.

Deployment

Same as those in the "Defense Against IPv6/MAC Spoofing Attacks" section.

1.3 Features

Basic Concepts

DHCPv6 Request Packets

DHCPv6 request packets are sent by DHCPv6 clients to the DHCPv6 server, including the following types:

- DHCPv6-Solicit: Detects available DHCPv6 servers.
- DHCPv6-Request: Requests the IP address or other configuration information.
- DHCPv6-Confirm: Confirms whether the obtained IP address is still valid.
- DHCPv6-Rebind: Rebinds an IP address when the client fails to communicate with the previous server.
- DHCPv6-Release: Releases the currently released IP address.
- DHCPv6-Decline: Rejects the IP address allocated by the server.
- DHCPv6-Renew: Requests to renew the currently allocated IP address.
- DHCPv6-Inform_Req: Requests extra configuration information, not involving IP address allocation.
- DHCPv6-Leasequery: Queries the lease information of clients.

DHCPv6 Response Packet

DHCPv6 response packets are sent by DHCPv6 servers to DHCPv6 clients to respond to requests from the clients. The packet types are the same as those of DHCPv6 request packets.

DHCPv6 Snooping Trust Port

DHCPv6 exchange packets for obtaining the IPv6 address or prefix are broadcast. Therefore, if an invalid DHCPv6 server exists on the network, users may fail to obtain IPv6 addresses or user information may be stolen through the invalid DHCPv6 server. To prevent this problem, DHCPv6 snooping divides ports into trusted ports and untrusted ports. A device forwards only DHCPv6 packets from the trusted ports and discards DHCPv6 packets from all the untrusted ports. This ensures that only response packets from valid DHCPv6 servers can be forwarded to clients, preventing impact of invalid DHCPv6 servers on clients.

- On a switch, all the switch ports and Layer 2 aggregate ports are untrusted ports by default, and you can specify a designated port as the trusted port.
- On an Access Point (AP), all the WLAN ports are untrusted ports, and you cannot specify a designated port as the trusted port.
- When an AP works in FAT mode, all the Layer 2 switch ports and Layer 2 encapsulation sub-interfaces are untrusted ports by default, and you can specify a designated port as the trusted port.
- When an AP works in FIT mode, all the Layer 2 switch ports are untrusted ports by default, and you can specify a designated port as the trusted port. All the Layer 2 encapsulation sub-interfaces are trusted ports, and you cannot specify a designated port as the untrusted port.

- On an Access Controller (AC), all the WLAN ports are untrusted ports, and you cannot specify a designated port as the trusted port. All the switch ports and Layer 2 aggregate ports are untrusted ports by default, and you can specify a designated port as the trusted port.

DHCPv6 Snooping Request Packet Filtering

If DHCPv6 packets are prohibited for a specific user, all the DHCPv6 packets sent by the user device must be masked. The DHCPv6 request packet filtering feature can be configured on an untrusted port to filter all the DHCPv6 request packets received by this port.

VLAN-based DHCPv6 Snooping

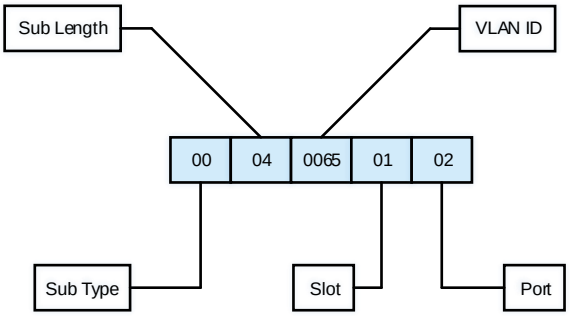
The DHCPv6 snooping feature is applied to VLANs. By default, if DHCPv6 snooping is enabled on a device, this feature takes effect in all the VLANs of the device. You can enable or disable DHCPv6 snooping in a specific VLAN to implement refined management.

DHCPv6 Snooping User Database

It is common that users on the DHCPv6 network randomly configure static IPv6 addresses. This increases the network maintenance difficulty and may lead to network access failures of users who obtain IPv6 addresses from valid DHCPv6 servers due to address conflicts. To resolve this problem, the DHCPv6 snooping feature monitors packets exchanged between clients and servers to collect the IPv6 addresses obtained by users as well as the MAC address, VLAN ID, port, and lease time of users. The information is integrated into user data entries to build the DHCPv6 snooping user database. In this way, DHCPv6 snooping can effectively control valid IPv6 address usage by users to ensure network stability and security.

DHCPv6 Options 18 and 37

The network administrator wants to allocate IP addresses based on the information of connected network devices when managing IP addresses. To achieve this purpose, when a network device performs DHCPv6 snooping, it adds device information of users to DHCP request packets in DHCPv6 Option fields.



- RFC 3315 defines the DHCPv6 protocol, which uses Option 18 to carry the user device information.
- RFC 4649 defines the DHCPv6 Relay Agent options, among which Option 37 carries the user device information.

Option 18: Interface ID

- Default content: VLAN ID of the port that receives request packets from DHCPv6 clients and the port index. (The value of the port index is the combination of the slot ID and port number.) For wireless access, all the fields are set to 0.
- Extended content: custom strings, applicable to wired interfaces (such as switch ports, Layer 2 aggregate ports, and Layer 2 encapsulation sub-interfaces).
- Applicable scope: The default and custom content is applicable to wired interfaces, such as switch ports, Layer 2 aggregate ports, and Layer 2 encapsulation sub-interfaces.

Two formats are available for filling the **Interface ID** field: standard format and extended format. Only one format can be used on a network. When the standard format is used, only the default content can be filled into sub-options of the **Interface ID** field, as shown in the following figure.

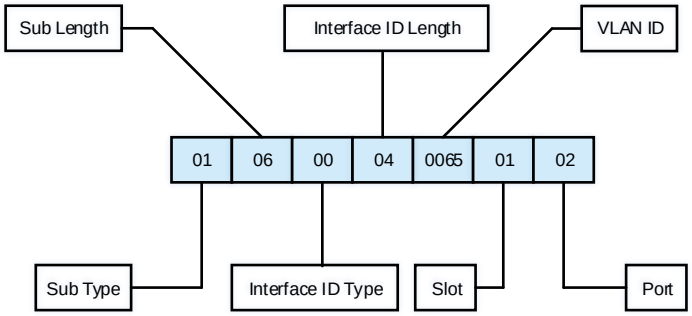


Figure 1-4

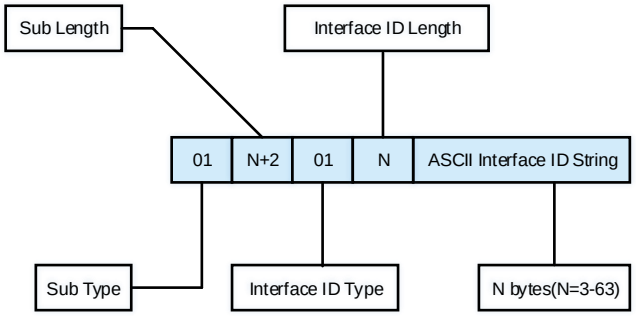
If custom content is required, use the extended format. In extended format, both custom content and extended content can be filled in. To distinguish the content, the one-byte **Interface ID Type** field and the one-byte **Interface ID Length** field are added next to the **Sub Length** field. For the **Interface ID Type** field, the value 0 indicates default content and the value 1 indicates extended content.

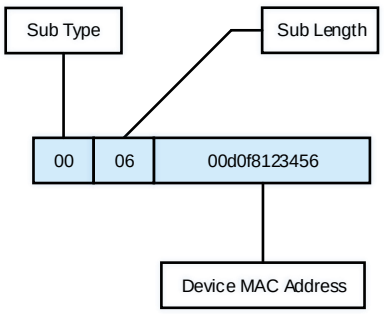


Format of Filling Default Content

Figure 1-5

Format of Filling Extended Content

Figure 1-6



Option 37: Remote ID

- Default content: bridge MAC address of the DHCPv6 relay that receives DHCPv6 clients' request packets
- Extended content: custom strings

Two formats are available for filling the **Remote ID** field: standard format and extended format. Only one format can be used on a network. When the standard format is used, only the default content can be filled into sub-options of the **Remote ID** field, as shown in the following figure.

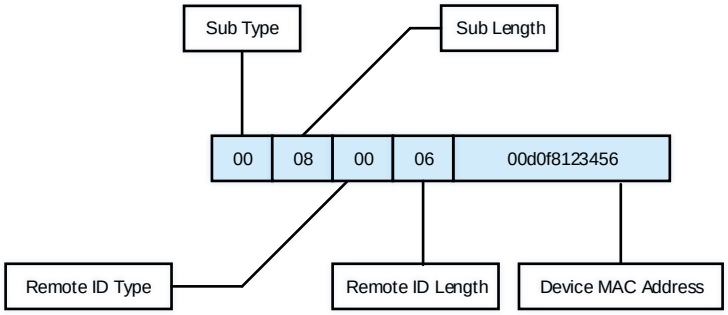


Figure 1-7

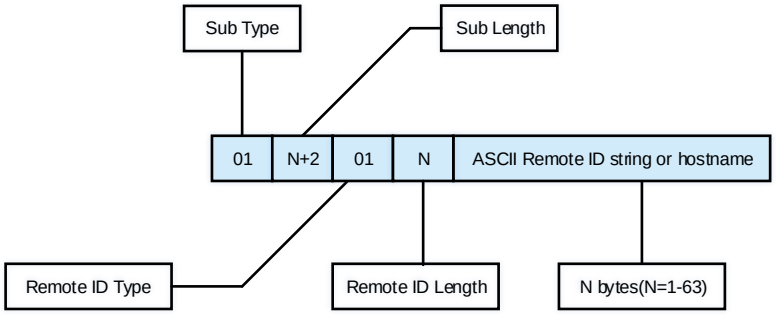
If custom content is required, use the extended format. In extended format, both custom content and extended content can be filled in. To distinguish the content, the one-byte **Remote ID Type** field and the one-byte **Remote ID Length** field are added next to the **Sub Length** field. If the **Remote ID Type** field is set to 0, default content is filled. If the **Remote ID Type** field is set to 1, extended content is filled.



Format of Filling Default Content

Figure 1-8

Format of Filling Extended Content

Figure 1-9

Notes:

Option 18: the **Interface ID** field, the port index is the combination of the slot ID and the port number. The port type can be wired interfaces, such as switch ports, Layer 2 aggregate ports, and Layer 2 encapsulation sub-interfaces. The port number indicates the sequence of the port in a slot. For Layer 2 aggregate ports, the port number is the aggregate port ID. For example, the port number of Fa0/10 is 10, the port number of AP 11 is 11, and the port number of WLAN 1 is 1.

The slot ID indicates the sequence of the slot in a device. A stacking device is numbered as a single device. The slot ID starts from 0, and an aggregate port locates in the last slot. You can run the **show slots** command to view the slot ID.

Example 1:

```
Ruijie#show slots (Only the information of the Dev and Slot columns is displayed.)
  Dev Slot
  --- ----
  1   0    ------>The slot ID is 0.
  1   1    ------>The slot ID is 1.
  1   2    ------>The slot ID is 2.
```

The slot ID of the aggregate port is 3.

Example 2:

```
Ruijie#show slots (Only the information of the Dev and Slot columns is displayed.)
  Dev Slot
  --- ----
  1   0    ------>The slot ID is 0.
  1   1    ------>The slot ID is 1.
  1   2    ------>The slot ID is 2.
  2   0    ------>The slot ID is 3.
  2   1    ------>The slot ID is 4.
  2   2    ------>The slot ID is 5.
```

The slot ID of the aggregate port is 6.

Invalid DHCPv6 Packet

DHCPv6 snooping checks the validity of DHCPv6 packets passing through the device, discards invalid DHCPv6 packets, records user information, and generates a DHCPv6 snooping binding database for query by other features. The following types of packets are regarded as invalid DHCPv6 packets:

- DHCPv6 response packets received by untrusted ports. For details, see "DHCPv6 Response Packets" in the "Basic Concepts" section.
- DHCPv6 packets received by untrusted ports that pass through the DHCPv6 relay, including the DHCPv6-Relay-Forw and DHCPv6-Relay-Reply packets.
- DHCPv6-Relay-Reply packets received by trusted ports, whose outbound interfaces are untrusted ports in the corresponding table.

- DHCPv6-Release packets, for which no user is found in the DHCPv6 snooping user database based on the Layer 2 source MAC address and VID.
- DHCPv6-Release packets whose IPv6 addresses or prefixes do not exist in the DHCPv6 snooping user database.
- DHCPv6-Release packets whose IPv6 addresses or prefixes exist in the DHCPv6 snooping user database, but the untrusted ports receiving these packets different from those stored in the DHCPv6 snooping user database.
- DHCPv6 packets of incorrect format or incomplete packets.

Overview

Feature	Description
Invalid DHCPv6 Packet Filtering	Checks the validity of exchanged DHCPv6 packets, discards invalid packets, and forwards only valid request packets to trusted ports.
User Database Establishment	Monitors packets exchanged between DHCPv6 clients and DHCPv6 servers and generates a DHCPv6 snooping user database to provide basis for other security modules to filter packets.

1.3.1 Invalid DHCPv6 Packet Filtering

This feature checks the validity of DHCPv6 packets from untrusted ports and filters invalid packets. This feature also controls the transmission range of DHCPv6 packets to prevent spoofing by malicious users.

Working Principle

During the monitoring process, the device checks the ports receiving packets and the fields in the packets to filter packets. The device also modifies the destination ports of packets to control the transmission range of DHCPv6 packets.

↘ Checking the Port

After receiving a DHCPv6 packet, the device checks whether the port receiving the DHCPv6 packet is a trusted port. If yes, the device directly forwards the packet without checking its validity or generating a binding or prefix record. If no, the device checks the packet validity.

↘ Checking Packet Encapsulation and Integrity

The device checks whether the packet is a UDP packet and whether the destination port is 546 or 547. The device checks whether the actual length of the packet is the same as that of the **Length** field defined in the protocol.

↘ Checking the Packet Type and Fields in the DHCPv6 Packet

The device checks whether the packet passes through a relay based on the description of invalid packet types in the "Basic Concepts" section. Then, the device checks whether the packet type meets the restriction conditions specific for this type.

1.3.2 User Database Establishment

The device monitors packets exchanged between DHCPv6 clients and DHCPv6 servers and generates DHCPv6 snooping binding entries and prefix entries based on the valid DHCPv6 packet information. All these entries are provided to other security

modules of the device as a valid user information table for filtering network packets. After the DHCPv6 snooping feature is enabled, the device automatically creates and updates user data.

Working Principle

During the monitoring process, the device continuously updates the binding database and prefix database based on the DHCPv6 packet type.

Generating a Binding or Prefix Record

When the device detects a DHCPv6-Reply packet from a trusted port, it extracts the client IPv6 address or prefix, client MAC address, and lease time from the packet. After that, the device generates a binding or prefix record based on the client's port ID (wired interface index or wireless WLAN ID) and the VLAN that the client resides recorded by the device.

Deleting the Binding or Prefix Record

When the recorded lease time expires, a client sends a valid DHCPv6-Release or DHCPv6-Decline packet, or the user proactively deletes a binding or prefix record by running the **clear** command, the corresponding binding or prefix record is deleted.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic DHCPv6 Snooping Features	⚠ (Mandatory) It is used to enable the DHCPv6 snooping service.	
	ipv6 dhcp snooping	Enables the DHCPv6 snooping feature.
	⚠ (Optional)	
	ipv6 dhcp snooping vlan	Configures the DHCPv6 snooping feature in the specified VLANs.
	ipv6 dhcp snooping database write-delay	Enables periodic saving of DHCPv6 snooping binding and prefix records.
	ipv6 dhcp snooping database write-to-flash	Manually saves DHCPv6 snooping binding and prefix records.
	renew ipv6 dhcp snooping database	Manually imports user records stored in the flash file into the DHCPv6 snooping user database.
	ipv6 dhcp snooping trust	Configures a DHCPv6 snooping trusted port.
	ipv6 dhcp snooping link-detection	Deletes dynamic binding entries from the port in Link Down state.
Configuring DHCPv6 Option 18 or 37	⚠ (Optional) It is used to optimize DHCPv6 server address allocation.	
	ipv6 dhcp snooping Information option [**standard-format**]	Adds Option 18 or 37 to DHCPv6 request packets.

	ipv6 dhcp snooping information option format remote-id	Configures the remote ID in extended format.
	ipv6 dhcp snooping vlan information option format-type interface-id string	Configures a custom string for the interface ID in extended format.
	ipv6 dhcp snooping vlan information option change-vlan-to vlan	Configures VLAN mapping for the interface ID in extended format.

1.4.1 Configuring Basic DHCPv6 Snooping Features

Configuration Effect

- Enable the DHCPv6 snooping service.
- Generate DHCPv6 snooping binding and prefix databases.
- Control the transmission range of DHCPv6 packets.
- Filter invalid DHCPv6 packets.

Notes

- The port connecting the device to a trusted DHCPv6 server must be set as a trusted port.
- The port on which DHCPv6 snooping takes effect can be a switch port, Layer 2 aggregate port, Layer 2 encapsulation sub-interface, or wireless WLAN port. You can configure the port in interface mode or wireless security mode.
- Entry deletion upon port Link Down takes effect only on wired interfaces.

Configuration Steps

↘ Enabling the DHCPv6 Snooping Service Globally

- Mandatory.
- This feature is enabled on the access device, unless otherwise specified.

↘ Configures the DHCPv6 snooping feature in the specified VLANs.

- The DHCPv6 snooping feature is disabled in some VLANs.
- This feature is enabled on the access device, unless otherwise specified.

↘ Configuring a DHCPv6 Trusted Port

- Mandatory.
- The port connecting the device to a trusted DHCPv6 server is set as a trusted port.

↘ Deleting Dynamic Binding Entries from the Port in Link Down State

- This feature can be enabled to reduce hardware entry usage over stable network connections and delete entries from the port in Link Down state in time.
- This feature is enabled on the access device, unless otherwise specified.

Related Commands

Configuring Basic DHCPv6 Snooping Features

Command	**ipv6 dhcp snooping**
Parameter Description	N/A
Defaults	This feature is disabled.
Command Mode	Global configuration mode
Usage Guide	After DHCPv6 snooping is enabled globally, run the **show ipv6 dhcp snooping** command to check whether the DHCPv6 snooping feature is enabled.

Configuring the DHCPv6 Snooping Feature in the Specified VLANs

Command	**ipv6 dhcp snooping vlan** { *vlan-first* [*vlan-last*] | *vlan-rang* }
Parameter Description	*vlan-first*: Indicates the start VLAN ID in which the DHCPv6 snooping feature takes effect. The value range is from 1 to 4094. *vlan-last*: Indicates the last VLAN ID in which the DHCPv6 snooping feature takes effect. The value range is from 1 to 4094. *vlan-rang*: Indicates the VLAN range in which the DHCPv6 snooping feature takes effect, such as 1, 3–5, 7, and 9–11.
Defaults	After DHCPv6 snooping is enabled globally, the DHCPv6 snooping feature takes effect in all VLANs.
Command Mode	Global configuration mode
Usage Guide	● You can run this command to enable the DHCPv6 snooping feature in the specified VLANs. You can also run the **no ipv6 dhcp snooping vlan** { *vlan-first* [*vlan-last*] | *vlan-rang* } command to disable the DHCPv6 Snooping feature in the specified VLANs or VLANs in the specified range. ● This command can be used only when the DHCPv6 snooping feature is enabled.

Periodically Writing Data from the DHCPv6 Snooping Database to the Flash File

Command	**ipv6 dhcp snooping database write-delay** delay-*seconds*
Parameter Description	*delay-seconds*: Indicates the period for writing data from the DHCPv6 snooping database to the flash file, in seconds. The value range is from 600 to 86400.
Defaults	This feature is disabled.
Command Mode	Global configuration mode
Usage Guide	● You can run this command to write data from the DHCPv6 snooping database to the flash file. If the user information is lost after device restart, users must re-obtain IP addresses to communicate with the device. ● High storage frequency reduces the lifespan of the flash memory.

Writing Data from the DHCPv6 Snooping Database to the Flash File

Command	ipv6 dhcp snooping database write-to-flash
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	You can run this command to immediately write dynamic user information from the DHCPv6 snooping database to the flash file.

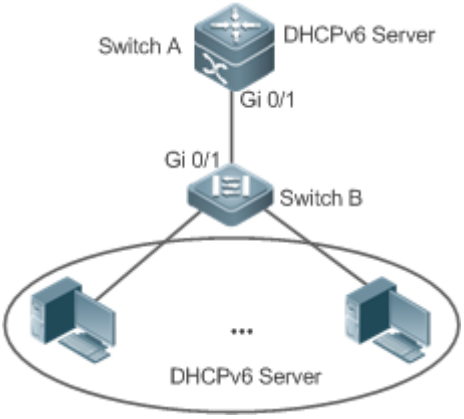
Importing Data from the Current Flash File to the DHCPv6 Snooping Binding Database

Command	renew ipv6 dhcp snooping database
Parameter Description	N/A
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	● You can run this command to immediately write data from the flash file to the DHCPv6 snooping database. ● Lease expiration records in the flash file are ignored. ● Only the records unavailable in the database are imported.

Configuring a Port as the Trusted Port

Command	ipv6 dhcp snooping trust
Parameter Description	N/A
Defaults	All ports are untrusted ports.
Command Mode	Interface configuration mode
Usage Guide	● Generally, uplink ports connected to the trusted DHCPv6 servers are configured as trusted ports. ● You can run this command to configure a port connected to a valid DHCPv6 server as the trusted port. The trusted port normally forwards received DHCPv6 response packets, but an untrusted port discards received DHCPv6 response packets. ● This command immediately takes effect on a Layer 2 switch port, aggregate port, or Layer 2 encapsulation sub-interface. This command fails on other ports.

Deleting Dynamic Binding Entries from the Port in Link Down State



Command	ipv6 dhcp snooping link-detection
Parameter Description	N/A
Defaults	This feature is disabled.

Command Mode	Global configuration mode
Usage Guide	This feature can be enabled to reduce hardware entry usage and delete entries from the port in Link Down state in time.

Configuration Example

The following configuration examples describe only the configurations related to the DHCPv6 snooping feature.

Configuring the DHCPv6 Snooping Feature

Scenario **Figure 1-10**	
Configuration Steps	● Enable the DHCPv6 snooping feature on the access device (Switch B in this example). ● Configure the uplink port (Gi 0/1 in this example) as the trusted port.

B	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#ipv6 dhcp snooping`
	`Hostname(config)#interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 dhcp snooping trust`
	`Hostname(config-if-GigabitEthernet 0/1)#end`

Verification	Check whether the DHCPv6 snooping feature is enabled on Switch B and whether the uplink port is configured as the trusted port. Check whether the client can normally obtain an IPv6 address from the valid DHCPv6 server.
B	`Hostname#show ipv6 dhcp snooping`

```
DHCPv6 snooping status : ENABLE
Interface                    Trusted   Filter DHCPv6
-------------------------    -------    -------------
GigabitEthernet 0/1          YES          DISABLE
Hostname#show ipv6 dhcp snooping binding
Total number of bindings: 1
NO.   MacAddress          IPv6 Address                                  Lease(sec)
VLAN  Interface
----- -----------------  ---------------------------------------- ----------
-- ----- --------------------
1     00d0.f801.0101     2001::10                                      42368
2     GigabitEthernet 0/1
```

Common Errors

- The uplink port is not configured as the DHCPv6 trusted port.
- Another access security option is configured on the uplink port, so the port fails to be configured as the DHCPv6 trusted port.

1.4.2 Configuring DHCPv6 Option 18 or 37

Configuration Effect

- The DHCPv6 server can obtain more information to better allocate IP addresses.
- DHCPv6 options are transparent to DHCPv6 clients, which are not aware of the enabling status of this feature.

Configuration Steps

- Option 18 or 37 can be configured for optimization.
- This feature is enabled on the DHCPv6 snooping-capable access device, unless otherwise specified.

Related Commands

↘ **Adding Option 18 or 37 to DHCPv6 Request Packets**

Command	**ipv6 dhcp snooping information option** [**standard-format**]
Parameter Description	**standard-format**: Configures the standard format for filling DHCPv6 Option 18 or 37. If this keyword is not specified, the extended format is used.
Defaults	This feature is disabled.
Command Mode	Global configuration mode
Usage Guide	You can run this command to add DHCPv6 Option 18 or 37 to DHCPv6 request packets. After that, the DHCPv6 server allocates IP addresses based on the Option 18 or 37 information.

↘ **Configuring a Custom String for Option 37 (Remote ID)**

Command	**ipv6 dhcp snooping information option format remote-id** { **string** *string* | **hostname** }
Parameter Description	*string*: Indicates a custom string for Option 37 (Remote ID) in extended format. The string can be up to 63 characters. **hostname**: Configures a host name for Option 37 (Remote ID) in extended format.
Defaults	This feature is disabled.
Configuration Mode	Global configuration mode
Usage Guide	You can run this command to configure a custom string for Option 37 (Remote ID) in extended format. After that, the DHCPv6 server allocates IP addresses based on the Option 37 information.

Configuring a Custom String for Option 18 (Interface ID)

Command	**ipv6 dhcp snooping vlan** *vlan-id* **information option format-type interface-id string** *string*
Parameter Description	*vlan-id*: Indicates the VLAN to which DHCPv6 request packets belong. *string*: Indicates the custom string for filling Option 18 (Interface ID). The string can contain 3 to 36 characters.
Defaults	This feature is disabled.
Configuration Mode	Interface configuration mode
Usage Guide	You can run this command to configure a custom string for Option 18 (Interface ID) in extended format. After that, the DHCPv6 server allocates IP addresses based on the Option 18 information.

Changing the VLAN Filled in Option 18 (Interface ID) to the Specified VLAN

Command	**ipv6 dhcp snooping vlan** *vlan-id* **information option change-vlan-to vlan** *vlan-id*
Parameter Description	*vlan-id* (first): Indicates the VLAN to which DHCPv6 request packets belong. *vlan-id* (second): Indicates the VLAN to be filled in Option 18 (Interface ID).
Defaults	This feature is disabled.
Configuration Mode	Interface configuration mode
Usage Guide	You can run this command to configure a VLAN mapping for Option 18 (Interface ID) in extended format. After that, the DHCPv6 server allocates IP addresses based on the Option 18 information.

Configuration Example

Configuring DHCPv6 Option 18 or 37

Configuration Steps	Enable Option 18 or 37 on the DHCPv6 snooping-capable device and set the extended filling format.

	`Hostname# configure terminal`
	`Hostname(config)# ipv6 dhcp snooping information option`
	`Hostname(config)# end`

Verification	Check the DHCPv6 snooping configuration.
	`Hostname#show ipv6 dhcp snooping`

```
DHCPv6 snooping status : ENABLE
DHCPv6 snooping database write-delay time : 0 seconds
DHCPv6 snooping binding-delay time : 0 seconds
DHCPv6 DHCPv6 snooping option 18/37 status : ENABLE
DHCPv6 snooping link detection           : DISABLE
Interface               Trusted    Filter DHCPv6
---------------------   -------    -------------
FastEthernet0/10        YES        DISABLE
```

Common Errors

N/A

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear ipv6 dhcp snooping binding [*mac* | *ipv6-address* | **interface** *interface-id* | **vlan** *vlan-id* | **wlan** *wlan-id*]	Clears dynamic user information from the DHCPv6 snooping database.
clear ipv6 dhcp snooping prefix [*mac* | *ipv6-address* | **interface** *interface-id* | **vlan** *vlan-id* | **wlan** *wlan-id*]	Clears all entries in the DHCPv6 snooping prefix database.
clear ipv6 dhcp snooping statistics	Clears the statistics on DHCPv6 packets processed by DHCPv6 snooping.

Displaying

Command	Description
show ipv6 dhcp snooping	Displays the DHCPv6 snooping configuration.
show ipv6 dhcp snooping vlan	Displays the VLANs in which DHCPv6 snooping is effective.
show ipv6 dhcp snooping binding	Displays all dynamic binding entries in the DHCPv6 snooping binding database.
show ipv6 dhcp snooping prefix	Displays all entries in the DHCPv6 snooping prefix database.
show ipv6 dhcp snooping statistics	Displays the statistics on packets processed by DHCPv6 snooping.
show ipv6 source binding	Displays all static binding entries that are added manually and all dynamic binding entries in the DHCPv6 snooping binding database.

1 Configuring ND Snooping

1.1 Overview

The Neighbor Discovery Protocol (NDP) is vulnerable to address spoofing attacks and router advertisement (RA) attacks because it lacks built-in security features. However, it is complex to enhance security by deploying an external encryption and authentication mechanism. Neighbor Discovery (ND) Snooping is used to monitor ND packets on a network to filter out invalid address spoofing packets and RA packets. It monitors IPv6 users on the network and binds detected IPv6 users to interfaces to prevent IP address spoofing, ensuring a secure and reliable IPv6 network.

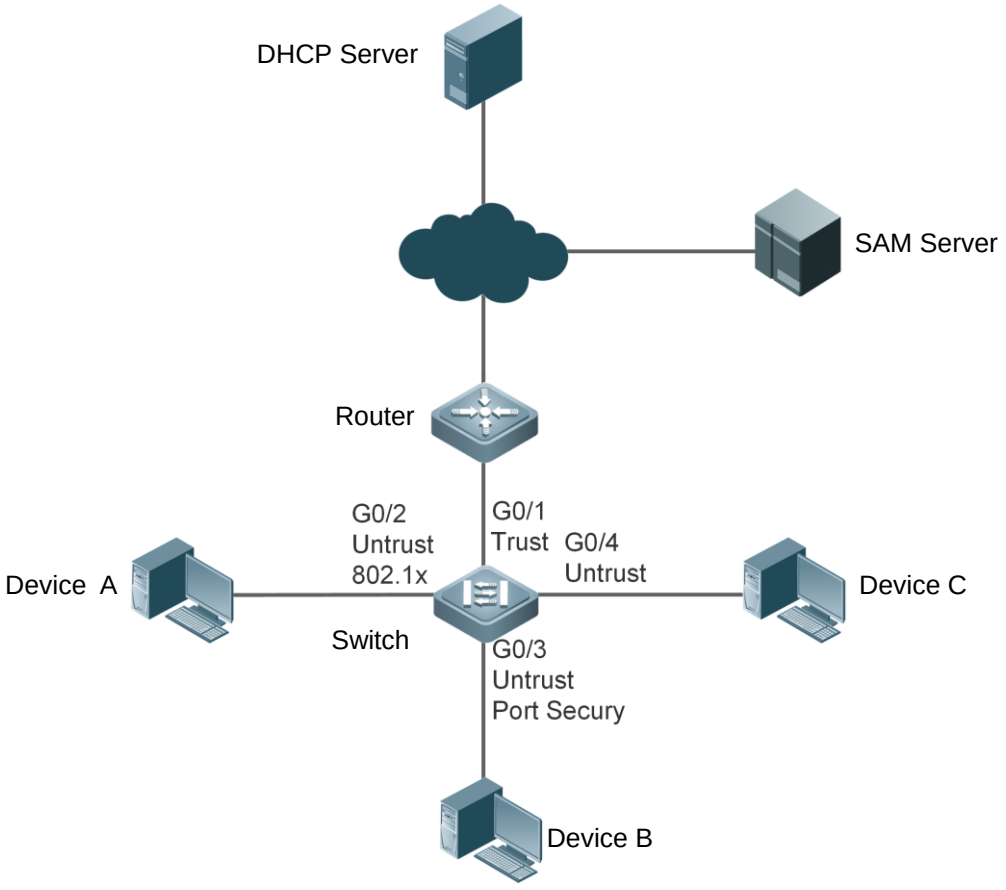
The following section describes only ND snooping.

Protocols and Standards

- RFC 2464: Transmission of IPv6 Packets over Ethernet Networks
- RFC 4861: Neighbor Discovery for IP version 6 (IPv6)
- RFC 4862: IPv6 Stateless Address Autoconfiguration
- RFC 6620: FCFS SAVI: First-Come, First-Served Source Address Validation Improvement for Locally Assigned IPv6 Addresses

1.2 Applications

Application	Description
Stateless Address Autoconfiguration	Users use stateless address autoconfiguration (SLAAC) to assign IPv6 addresses and configure IPv6 ND snooping to improve IPv6 network security.
Stateful Address Autoconfiguration	Users use DHCPv6 to assign IPv6 addresses, enable DHCPv6 snooping, and deploy ND snooping to improve IPv6 network security.
Manual Configuration	Users manually assign IPv6 addresses and configure ND snooping to improve IPv6 network security.



1.2.1 Stateless Address Autoconfiguration

Scenario

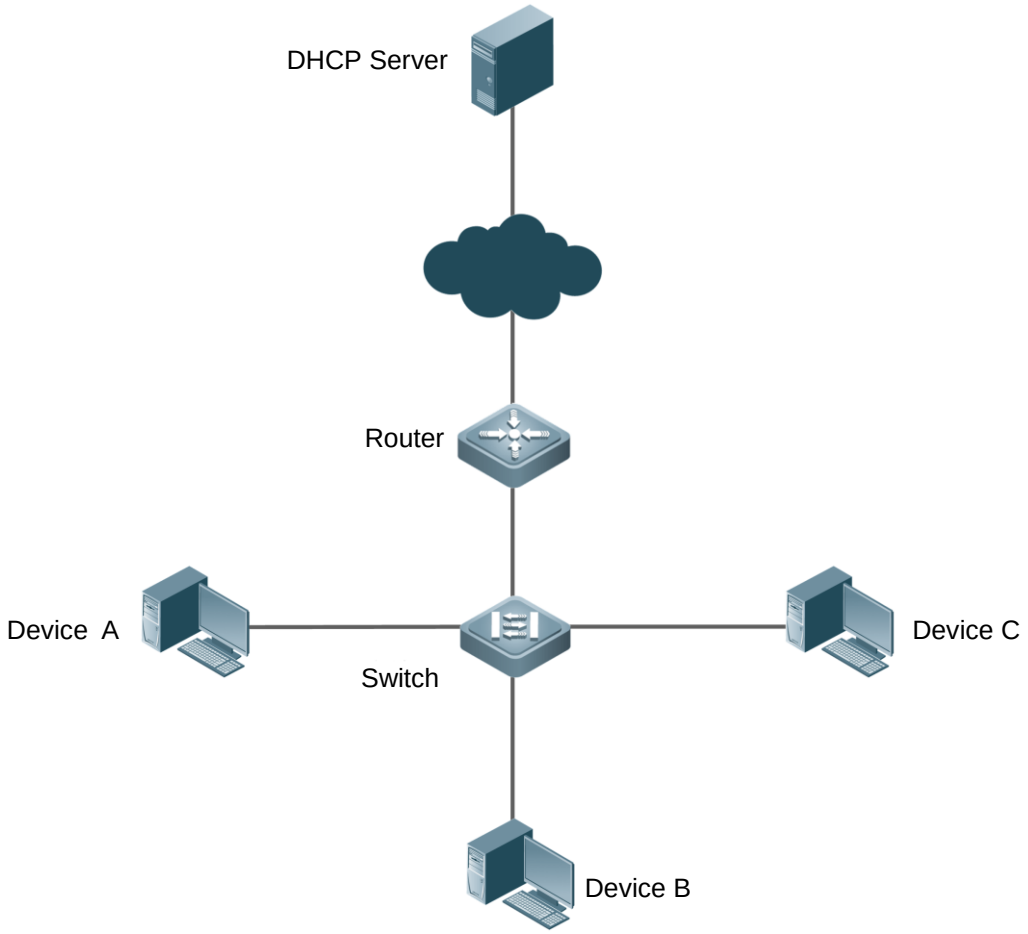
Users use SLAAC to assign IPv6 addresses and configure ND snooping to improve IPv6 network security.

- Filter invalid address spoofing packets and RA packets.
- Monitor users who access the IPv6 network and bind these IPv6 addresses to user hosts to prevent IPv6 address spoofing.
- Automatically adapt to IPv6 network configuration changes.

Figure 1-1 Network Topology of SLAAC

Notes	The switch is the access device. Device A is a PC. Device B is a PC. Device C is a PC.

Deployment



- Enable IPv6 ND snooping on the switch to monitor ND packets.
- Configure trusted interfaces.
- Enable only ND guard against address spoofing attacks.
- Enable SLAAC user monitoring.

1.2.2 Stateful Address Autoconfiguration

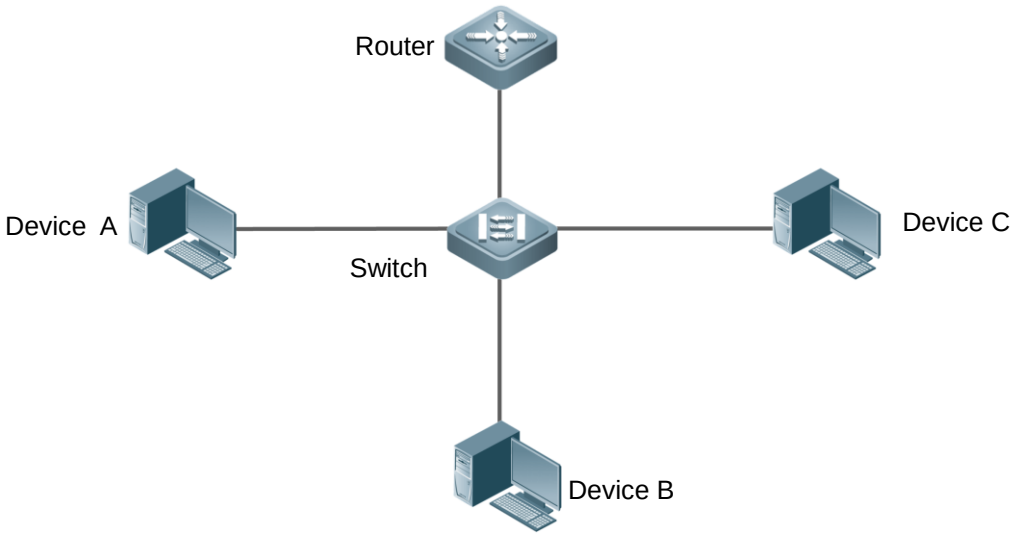
Scenario

Users use DHCPv6 to assign IPv6 addresses, enable DHCPv6 snooping, and deploy IPv6 ND snooping to achieve ND guard against RA attacks and ND guard against address spoofing attacks.

Figure 1-2 Network Topology of Stateful Address Autoconfiguration

Notes	The switch is the access device. Device A is a PC. Device B is a PC. Device C is a PC.

Deployment



- Enable IPv6 ND snooping on the switch to monitor ND packets.
- Configure trusted interfaces.
- Enable only ND guard against address spoofing attacks.

1.2.3 Manual Configuration

Scenario

Users manually assign IPv6 addresses and deploy the IPv6 ND snooping feature to achieve ND guard against RA attacks and ND guard against address spoofing attacks. This is achieved without the need to deploy other security policies.

Figure 1-3 Network Topology of Manual Configuration

Notes	The switch is the access device. Device A is a PC. Device B is a PC. Device C is a PC.

Deployment

- Enable IPv6 ND snooping on the switch to monitor ND packets.
- Configure trusted interfaces.
- Enable only ND guard against address spoofing attacks on key nodes.
- Manually add a gateway as a key node.

1.3 Features

Basic Concepts

NDP

NDP is a core protocol of the IPv6 protocol suite. It combines and optimizes protocols such as the Address Resolution Protocol (ARP), Internet Control Message Protocol (ICMP) Router Discovery, and ICMP Redirect in IPv4. As a basic IPv6 protocol, NDP also provides the prefix discovery, neighbor unreachability detection (NUD), duplicate address detection (DAD), and address autoconfiguration functions.

- Address resolution: a method to determine the link-layer address (LLA) of a target node. The address resolution function of NDP replaces ARP in IPv4 and uses the NUD method to check the reachability status between neighbors.
- Stateless Address Autoconfiguration: It is a unique automatic address configuration mechanism in NDP, including a series of related functions, such as router discovery, automatic interface ID generation, and DAD. Through SLAAC, nodes on a link can automatically obtain global unicast IPv6 addresses.
- Redirection: When a better router for reaching the destination network is found on the local link, the original router needs to send advertisements to nodes, for the nodes to change related configurations.

Features

Feature	Description
ND Snooping	ND snooping is used to monitor ND packets on a network to filter out invalid ARP packets and RA packets, monitor IPv6 users on the network, and bind detected IPv6 users to interfaces to prevent IP address spoofing.

1.3.1 ND Snooping

Working Principle

ND snooping is used to monitor ND packets on a network to filter out invalid ARP packets and RA packets, monitor IPv6 users on the network, and bind detected IPv6 users to interfaces to prevent IP address spoofing.

ND snooping supports the following functions:

ND Guard

When SLAAC is used, IPv6 nodes use RA information to configure interface IPv6 addresses and obtain the prefixes of direct-connected network segments, gateway IP addresses, and maximum transmission units (MTUs) of links. In addition, routers can use ND redirect packets to modify the next-hop information of related routes in the routing tables of hosts. In this case, attackers can send invalid RA and redirect packets and modify routing table information (such as the gateway IP address) of the victim host to initiate denial-of-service (DoS) or man-in-the-middle (MITM) attacks. This type of attacks for spoofing hosts' routing information is called RA attacks.

During unicast communication between IPv6 nodes, the NDP is used for address resolution to obtain LLAs of neighboring nodes. Then, the parsed LLAs are encapsulated into frames to be sent. Five types of ND packets can carry the LLA, and the receiving nodes regard the packets as trusted. Therefore, attackers can send forged ND packets and modify the mappings between IP addresses and LLAs in the neighbor table of the victim node to initiate DoS or MITM attacks. This type of attacks for spoofing the mappings between IP addresses and LLAs on nodes is called address spoofing attacks.

To prevent the preceding two types of attacks, ND snooping classifies interfaces on network devices into trusted interfaces and untrusted interfaces. Trusted interfaces are used to connect trusted nodes, such as routers and servers, and untrusted interfaces are used to connect untrusted nodes, such as PCs. The device forwards ND packets received on trusted interfaces while discarding redirect and RA packets received on untrusted interfaces to prevent RA attacks. For router solicitation (RS), neighbor solicitation (NS), and neighbor advertisement (NA) packets received on untrusted interfaces, the device checks the packet validity and discards invalid ones to prevent address spoofing attacks.

For NS and NA packets, the device checks mappings of the four elements, namely, source/destination IP addresses, VLAN ID (VID), Media Access Control (MAC) address, and inbound interface, to determine the packet validity. The mappings of the four elements of host nodes are provided by monitoring SLAAC users. If an NA packet received on an untrusted interface carries information that can be set only by a router (R bit is set), the packet is regarded as invalid.

Security check on ND packets from all host nodes prevent gateway address spoofing attacks. To guard against only gateway address spoofing attacks, see "ND Auto-guard Against Gateway Attacks." ND guard against RA attacks is regardless of the preceding factors. You can enable ND guard against address spoofing attacks by running the corresponding command. ND guard against RA attacks is enabled as long as ND snooping is enabled.

ND Auto-guard Against Gateway Attacks

Gateway address spoofing is a common attack form and causes severe adverse impact. If gateway address spoofing attacks are eliminated, a network is free from most address spoofing attacks. In addition, you can save significant system resources when only ND auto-guard against gateway attacks is enabled. To facilitate use, ND snooping supports not only manual gateway information configuration but also automatic gateway information acquisition.

A gateway is one of key nodes on a network. ND snooping supports ND guard against address spoofing attacks on key nodes. That is, ND packets received from untrusted interfaces are checked only to determine whether they are forged ND packets of key nodes, so as to discard forged packets. This significantly reduces the CPU load of network devices, resource consumption, and dependency on other security features, such as the features mentioned in the description about ND guard. Gateway information can be obtained automatically or manually. Key node information is automatically generated from the obtained gateway information to implement ND guard against gateway address spoofing attacks.

During automatic gateway information acquisition, ND snooping allows automatic learning of gateway information by snooping RA packets on the network. If the gateway changes, ND snooping automatically updates the gateway information. The whole process is transparent to network administrators and does not require special configuration. If you choose to manually configure an IPv6 network, you can add gateway information and server information as key node information to guard against server address spoofing attacks.

SLAAC User Monitoring

Users configured by SLAAC are called SLAAC users. During SLAAC, the network administrator does not know how many IPv6 users exist on the network and therefore cannot deploy related management policies.

If a network attack occurs, the network administrator can obtain the attacker's IP address. However, the network administrator can only locate the specific network segment based on the IP address but cannot locate the specific network device port or physical client. To resolve this issue, you can monitor SLAAC users on the network to obtain related user information. SLAAC user monitoring can be configured only on untrusted interfaces.

ND Snooping and CPP

Network devices consume certain CPU resources to check ND packet security. To prevent attackers from initiating DoS attacks by sending a large number of ND packets, network devices can use the CPU Protection Policy (CPP) function to control the rate and priority of ND packets on the entire device. After the ND snooping function is enabled, the CPP function is enabled automatically for ND packets.

ND Snooping and NFPP

The CPP function is used for overall control of ND packets on the entire device. Moreover, the Network Foundation Protection Policy (NFPP) function can be used to limit the rate of ND packets based on interfaces. The NFPP function takes effect only on ND packets destined for the CPU.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic ND Snooping Features	(Mandatory) It is used to establish the ND snooping service.	
	ipv6 nd snooping enable	Enables the ND snooping feature.
	(Optional) It is used to configure some attributes of ND snooping.	
	ipv6 nd snooping enable vlan	Enables ND snooping in a VLAN.
	ipv6 nd snooping bind lifetime	Configures the lease for ND snooping binding entries.
	ipv6 nd snooping bind limit	Configures the capacity for ND snooping binding table.
	ipv6 nd snooping bind warning-threshold	Configures the capacity alarm threshold for ND snooping binding entries.
	ipv6 nd snooping tentative wait	Configures the wait time for the device enabled with ND snooping for a DAD response.
Configuring ND Guard	(Optional) It is used to configure ND guard.	
	ipv6 nd snooping trust	Configures an interface as an ND snooping trusted interface.
	ipv6 nd snooping check address-resolution	Enables ND guard against address spoofing attacks.
	ipv6 nd snooping detect packet	Configures the number of detection packets to be sent and the interval for sending detection packets when conflicted packets are received.
	ipv6 nd snooping detect wait	Configures the wait time for the device enabled with ND snooping for a detection packet response.
	ipv6 nd snooping nd-check only	Configures ND snooping to work only in ND packet validity check mode.
	ipv6 nd snooping prefix	Configures IPv6 address prefix manually.
	ipv6 nd snooping log enable	Enables the function of logging ND snooping key information.

	ipv6 nd snooping log limit	Configures the capacity of ND snooping key information logs.
	ipv6 nd snooping syslog enable	Enables system prompts for ND snooping key information.
	ipv6 nd snooping syslog frequency	Configures the frequency of ND snooping key information prompts.

1.4.1 Configuring Basic ND Snooping Features

Configuration Effect

Enable ND snooping to ensure IPv6 network security.

Notes

N/A

Configuration Steps

Enabling ND Snooping

- Mandatory.
- To make ND snooping take effect, you must enable ND snooping on the device.

Command	**ipv6 nd snooping enable**
Parameter Description	N/A
Defaults	ND snooping is disabled.
Command Mode	Global configuration mode
Usage Guide	The monitored SLAAC user information can be used in ND guard against spoofing attacks and other security policies.

Enabling ND Snooping for VLANs

- Optional.

Command	**ipv6 nd snooping enable vlan** { *vlan-rng* | *vid* [*vid*] }
Parameter Description	*vlan-rng:* Indicates the VLAN ID or VLAN ID range. The value of ***vlan-rng*** can be a single VLAN or a VLAN range. When you specify a VLAN range, separate the VLAN IDs by commas (,). Continuous VLAN IDs can be shortened by connecting the first and last VLAN IDs by a hyphen (-). VLAN IDs in the range may not be in order. *vid*: Indicates the VLAN ID. The value range is from 1 to 4094.
Defaults	ND snooping is enabled in all VLANs.
Command Mode	Global configuration mode

Usage Guide	If SLAAC snooping is not required in some VLANs, you can run this command to disable ND snooping in these VLANs.

Configuring the Lease for ND Snooping Binding Entries

- Optional.
- When the aging time of an entry expires, the device enabled with ND snooping sends a probe packet to check whether the user is still online. An excessively short lease indicates frequent probes, while an excessively long lease will overload the device memory. It is recommended that the lease time be increased by 100s for every 1,000 users on the basis of the default value.

The lease time of an ND snooping binding entry is not the lease time of an ND entry. When the lease time of the former expires, the device enabled with ND snooping sends a probe packet to the user to detect whether the user is still online. This prevents the binding entry from occupying the memory space for a long time. The lease time of the latter is the available time of the IP address obtained by the user from the router, which is a part of the RA packets.

Command	**ipv6 nd snooping bind lifetime** *num*
Parameter Description	*num*: Indicates the lease time of an entry, in seconds. The value range is from 5 to 604800.
Defaults	The lease time of ND snooping binding entries is 3600 seconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the lease time for an entry to prevent binding entries from occupying the memory space for a long time.

Configuring the Capacity for ND Snooping Binding Table

- Optional.

You can configure the capacity for the binding table to limit the number of users on the network.

Command	**ipv6 nd snooping bind limit** *num*
Parameter Description	*num*: Indicates the capacity of the ND snooping binding table. This parameter varies based on the product version. The actual capacity of the product prevails.
Defaults	The capacity of the ND snooping binding table varies based on the product version. The actual capacity of the product prevails.
Command Mode	Global configuration mode, interface configuration mode, or WLAN security configuration mode
Usage Guide	This command is used to configure the capacity for binding entries. The configured value cannot be smaller than the number of existing binding entries.

Configuring the Capacity Alarm Threshold for ND Snooping Binding Entries

Optional.

Command	**ipv6 nd snooping bind warning-threshold** *num*

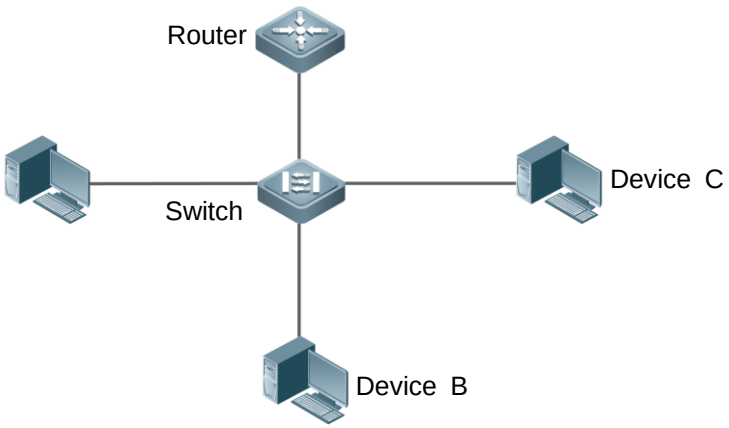
Parameter Description	*num*: Indicates the ratio of the capacity alarm threshold for the binding entries to the capacity of binding entries, in percentage (%). The value range is from 15 to 100.
Defaults	The capacity alarm threshold is not configured for ND snooping binding entries.
Command Mode	Global configuration mode, interface configuration mode, or WLAN security configuration mode
Usage Guide	● This command is used to configure a capacity alarm threshold for the binding entries. For example, if ***num*** is set to 60, an alarm is triggered when the current number of entries exceeds 60% of the configured capacity and a prompt is displayed when the current number of entries is less than 60% of the configured capacity. ● When the configuration is removed, ***num*** is set to 0. In this case, no capacity alarm is triggered. ● When this command is configured on an interface and the capacity for binding entries is not limited on the interface (that is, the **num** parameter in the **ipv6 nd snooping bind limit** command is set to 0), no capacity alarm is triggered.

Configuring the Wait Time for a DAD Response

- Optional.
- When receiving a DAD_NS packet from a client, the device enabled with ND snooping considers that the client intends to use this address. However, it does not mean that the client has the right to use this address. Only if the device does not receive a conflicting packet within a period of time, it considers that the terminal can use this address. The period is the wait time for a DAD response.

⚠ The wait time is only a reference value in ND snooping and may be inaccurate.

Command	**ipv6 nd snooping tentative wait** *time*
Parameter Description	*time*: Indicates the wait time, in milliseconds. The value range is from 50 to 5000.
Defaults	The wait time of the device enabled with ND snooping for a DAD response is 500 ms.
Command Mode	Global configuration mode
Usage Guide	When the device enabled with ND snooping receives a DAD_NS packet (for duplicate address check) from a client, the device creates an entry in **TENTATIVE** state. The entry is changed to a formal binding entry after a period of time.



Verification

Run the **show running-config** command to check the ND snooping configuration status.

Configuration Example

Enabling ND Snooping

Scenario	
Figure 1-4	

	 Users manually assign IPv6 addresses and deploy the IPv6 ND snooping feature to achieve ND guard against RA attacks and ND guard against address spoofing attacks. This is achieved without the need to deploy other security policies.
Configuration Steps	● Enable ND snooping globally. ● Disable ND snooping on the VLANs that do not need ND snooping.

Switch	`Hostname#configure terminal`
	`Enter configuration commands, one per line. End with CNTL/Z.`
	`Hostname(config)# ipv6 nd snooping enable`
	`Hostname(config)# no ipv6 nd snooping enable vlan 100`
	`Hostname(config)# no ipv6 nd snooping enable vlan 4,5-7,15`
	`Hostname(config)#`

Verification	● Check whether ND snooping is enabled.
	`Hostname#show running-config | begin ipv6 nd`
	`Current configuration : 491 bytes`
	
	`ipv6 nd snooping enable`
	`no ipv6 nd snooping enable vlan 100`
	`no ipv6 nd snooping enable vlan 4,5-7,15`
	`!`

Common Errors

N/A

1.4.2 Configuring ND Guard

Configuration Effect

The IPv6 ND snooping feature is configured to achieve ND guard against RA attacks and ND guard against address spoofing attacks.

Notes

ND snooping must be enabled for all VLANs before user binding is enabled.

Configuration Steps

Configuring an Interface as a Trusted Interface

- Optional.
- When a network interface is connected to an internal network device, there is no attack. You can set the interface as a trusted interface.
- By default, the trust status of all interfaces is untrust. You can run commands to set the trust status of an interface to trust.

Command	**ipv6 nd snooping trust**
Parameter Description	N/A
Defaults	All interfaces are untrusted interfaces.
Command Mode	Interface configuration mode
Usage Guide	• This command is used to configure an interface as an ND snooping trusted interface. RA and RR packets received on trusted interfaces are forwarded, and such packets received on untrusted interfaces are discarded. • This command can be configured only on Layer 2 switch ports, aggregate ports, or encapsulation sub-interfaces. When this command is configured on other types of interfaces, the configuration will fail. ⚠ Typically, uplink interfaces, that is, interfaces connected to trusted gateways are configured as trusted interfaces.

Enabling ND Guard Against Address Spoofing Attacks

- Optional.
- You are advised to configure ND guard against address spoofing attacks in a complex network environment.

Command	**ipv6 nd snooping check address-resolution**
Parameter Description	N/A
Defaults	ND guard against address spoofing attacks is disabled.
Command Mode	Interface configuration mode, WLAN security configuration mode
Usage Guide	When ND guard against address spoofing attacks is enabled, the IPv6 address and Media Access Control (MAC) address fields in neighbor solicitation (NS), neighbor advertisement (NA), and router solicitation (RS)

	packets received on an interface are checked to determine whether they match the binding entries. ND packets that do not match the binding entries are discarded. ⚠ The entries for ND guard against address spoofing attacks come from the Source Address Validation Improvement (SAVI) binding table instead of the ND snooping binding table.

Configuring the Number and Interval for Sending Detection Packet When Conflicted Packets Are Received

- Optional.
- When the lease of a binding entry for ND snooping expires or the device receives an NS or NA packet with an address that conflicts with that in a binding entry, the device sends a detection packet to the interface recorded in the binding entry. This command is used to set the number of detection packets to be sent and the interval for sending detection packets.

⚠ The interval is only a reference value in ND snooping for sending packets and may be inaccurate.

Command	**ipv6 nd snooping detect packet** *num* **interval** *time*
Parameter Description	*num*: Indicates the number of detection packets to be sent. The value range is from 1 to 10. *time*: Indicates the wait time, in milliseconds. The value range is from 50 to 5000.
Defaults	Two detection packets are sent at an interval of 250 ms.
Command Mode	Global configuration mode
Usage Guide	When the device with ND snooping enabled receives an NS or NA packet with an address that conflicts with that in a binding entry or the lease of a binding entry expires, the device sends a detection packet to the interface recorded in the binding entry. This command is used to set the number of detection packets to be sent and the interval for sending detection packets.

Configuring the Wait Time for a Detection Packet Response

- Optional.

Command	**ipv6 nd snooping detect wait** *time*
Parameter Description	*time*: Indicates the wait time, in milliseconds. The value range is from 50 to 5000. ⚠ The wait time is only a reference value in ND snooping and may be inaccurate.
Defaults	The wait time varies based on the product version. The actual wait time of the product prevails.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the wait time for a detection packet response after the device with ND snooping enabled sends a detection packet. If no response is received within the wait time, the device deletes the corresponding entry.

Configuring ND Snooping to Work Only in ND Packet Validity Check Mode

- Optional.

This command is usually configured in the DHCPv6-only scenario of SAVI to check the validity of ND packets between DHCPv6 users.

Command	**ipv6 nd snooping nd-check only**
Parameter Description	N/A
Defaults	ND snooping does not work only in ND packet validity check mode.
Command Mode	Global configuration mode
Usage Guide	This command can be configured when ND snooping entries do not need to be generated but the ND packet validity needs to be checked. This command takes effect only after ND snooping is enabled.

Configuring IPv6 Address Prefix Manually

- Optional.

Command	**ipv6 nd snooping prefix vlan** *vid ipv6-prefix*
Parameter Description	*vid*: Indicates the access VLAN. The value range is from 1 to 4094. *ipv6-prefix*: Indicates the IPv6 address prefix.
Defaults	No static IPv6 address prefix is configured.
Command Mode	Global configuration mode
Usage Guide	This command can be used to configure an IPv6 address prefix when a valid IPv6 address prefix entry needs to be configured.

Enabling the Function of Logging ND Snooping Key Information

- Optional.
- When the device enabled with ND snooping detects that an attacker has initiated an address spoofing attack or RA attack, the information about the attacker is recorded to the memory via attack logs.
- When this function is disabled, information logs related to ND attacks recorded in the memory will be cleared.

Command	**ipv6 nd snooping log enable**
Parameter Description	N/A
Defaults	The function of logging ND snooping key information is disabled.
Command Mode	Global configuration mode
Usage Guide	When the ND guard or ND auto-guard against gateway attacks function is enabled, the function of logging ND snooping key information can be enabled. When the device receives packets for address spoofing attacks or RA attacks, it will record the attacker information to the memory via attack logs.

Configuring the Capacity of ND Snooping Key Information Logs

- Optional.
- After the function of logging key information is enabled to record information logs related to ND attacks, information about ND attackers is recorded to the memory. If the capacity for storing attack logs reaches the upper limit, new attack logs replace the earliest ones.

Command	**ipv6 nd snooping log limit** *num*
Parameter Description	*num*: Indicates the capacity. The value range is from 50 to 5000.
Defaults	The capacity of ND snooping key information logs varies based on the product version. The actual capacity of the product prevails.
Command Mode	Global configuration mode
Usage Guide	When the capacity value for recording ND snooping key information logs is configured and the capacity for address spoofing or RA attack logs reaches the upper limit, new attack logs will replace the earliest logs.

Enabling System Prompts for ND Snooping Key Information

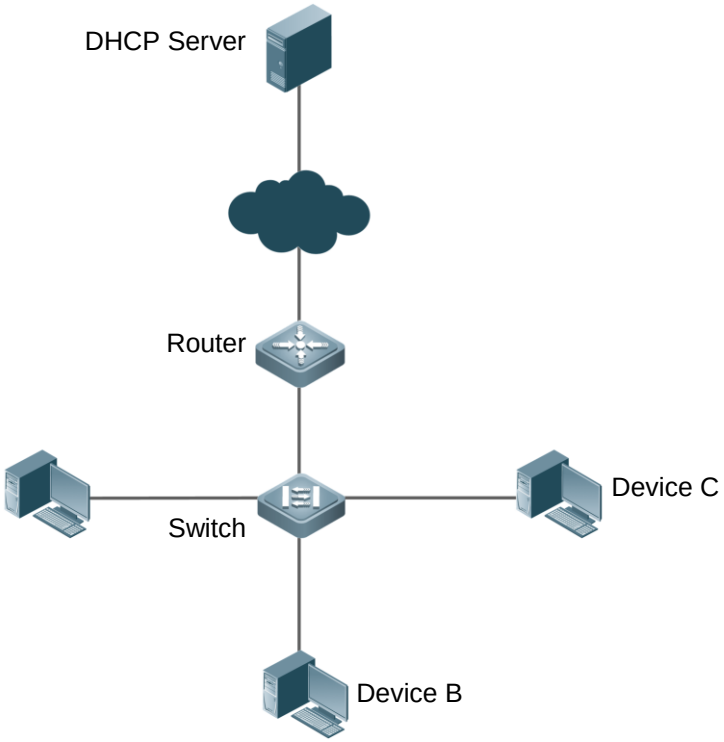
- Optional.
- When the device enabled with ND snooping detects that an attacker has initiated an address spoofing attack or RA attack, the attacker information will be displayed as system prompt.

Command	**ipv6 nd snooping syslog enable**
Parameter Description	N/A
Defaults	System prompts for ND snooping key information are disabled.
Command Mode	Global configuration mode
Usage Guide	When the ND guard against address spoofing attacks or ND guard against RA attacks function is enabled, the ND snooping key information log recording function is enabled. When the device receives packets for address spoofing attacks or RA attacks, it will display the attacker information as system prompt.

Configuring the Frequency of ND Snooping Key Information Prompts

- Optional.
- This command is used to configure the frequency of ND snooping key information prompts, that is, the maximum number of system prompts generated every second.
- When key information is generated, such as information about address spoofing attacks, RA attacks, capacity threshold alarms, and entry capacity alarms, the system generates corresponding prompt logs.

Command	**ipv6 nd snooping syslog frequency** *num*
Parameter Description	*num*: Indicates the frequency of system prompts, in times/s. The value range is from 1 to 65535.
Defaults	The frequency of ND snooping key information prompts is 5/s.
Command	Global configuration mode



Mode	
Usage Guide	This command is used to configure the frequency of ND snooping key information prompts, that is, the maximum number of system prompts generated per minute. When key information is generated, such as information about address spoofing attacks, RA attacks, capacity threshold alarms, and entry capacity alarms, the system generates corresponding prompt logs. However, when the number of logs generated within one minute is greater than the configured frequency, the system displays logs within the frequency range only and discards remaining logs to prevent the screen from frequent refreshing. ⚠ The log limiting function is implemented based on the system time, while the log display is implemented based on the user time. Therefore, the number of logs with the same time on the console is [0,2 x *num*].

Verification

Run the **show running-config** command to check the ND snooping configuration status.

Configuration Example

↘ Stateful Address Autoconfiguration

Scenario Figure 1-5	 Users use DHCPv6 to assign IPv6 addresses, enable DHCPv6 snooping, and deploy IPv6 ND snooping to achieve ND guard against RA attacks and ND guard against address spoofing attacks.
Configuration Steps	● Enable ND snooping. ● Configure GigabitEthernet 0/1 as an ND snooping trusted interface.

	● Enable only ND guard against address spoofing attacks.
Switch	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#ipv6 nd snooping enable Hostname(config)#interface gigabitEthernet 0/1 Hostname(config-if-GigabitEthernet 0/1)#ipv6 nd snooping trust Hostname(config-if-GigabitEthernet 0/1)# interface fastethernet 0/2 Hostname(config-if-GigabitEthernet 0/1)#ipv6 nd snooping check address-resolution
Verification	Run the **show running-config** command to check the ND snooping configuration status.

Common Errors

N/A

1.5 Monitoring

Clearing

Command	Description
clear ipv6 nd snooping prefix [**vlan** *vid*]	Clears prefixes snooped in a VLAN.
clear ipv6 nd snooping binding [**vlan** *vid*]	Clears snooped SLAAC users.
clear ipv6 nd snooping packet [**interface** *interface-type interface-id*]	Clears ND snooping packet statistics on an interface.

Displaying

Command	Description
show ipv6 nd snooping prefix	Displays snooped prefix information.
show ipv6 nd snooping binding [*ip-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-id*]	Displays monitored ND snooping binding entries.
show ipv6 nd snooping log	Displays ND snooping key information logs recorded in the memory.
show ipv6 nd snooping packet	Displays ND snooping packet statistics on an interface.

Debugging

⚠ System resources are consumed when debugging information is output. Therefore, disable debugging immediately after use.

Command	Description

debug ipv6 nd snooping	Debugs ND snooping events.

1 ND Proxy

1.1 Overview

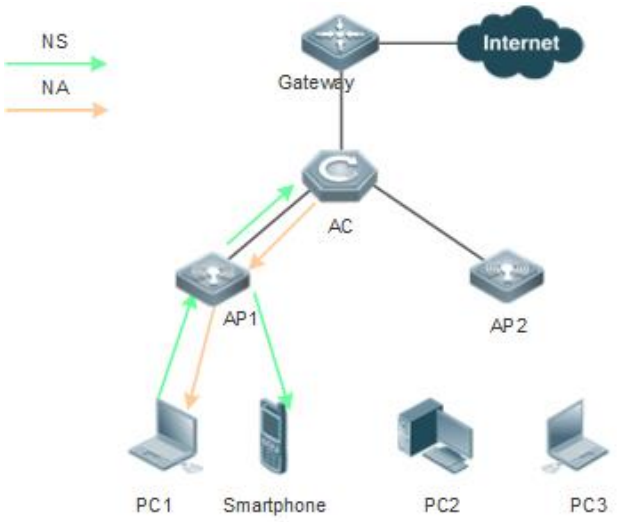
ND proxy, provided by the Access Controller (AC), can act as a proxy for a device on a Wireless Local Area Network (WLAN) to respond to multicast Neighbor Solicitation (NS) packets from another device. Since Carrier Sense Multiple Access/Collision Avoidance (CSMA/CA) is used for wireless network users, ND proxy can prevent multicast NS packets from being propagated beyond the coverage area of an Access Point (AP) to another AP. This increases the bandwidth utilization of the WLAN and improves the experience of wireless users.

Protocols and Standards

N/A

1.2 Applications

Applications	Description
Providing the ND Proxy Service on a WLAN	The AC acts as the proxy to respond to multicast NS packets from any device within a WLAN.



1.2.1 Providing the ND Proxy Service on a WLAN

Scenario

In centralized forwarding mode of the fit AP architecture, the AC acts as a proxy to respond to the multicast NS packets from any device within a WLAN.

- The AC needs to learn the MAC address of a device within a WLAN before acting as a proxy to respond.

Figure 1-1

Note:	The preceding diagram illustrates the flow of ND packets when a wireless user sends requests to a gateway or other devices in centralized forwarding mode of the fit AP architecture.

Deployment

Build a network consisting of a gateway, an AC, APs, and stations (STAs). On this network, the AC acts as a proxy to respond to the multicast NS packets from a STA through ND proxy (which is enabled by default). This prevents multicast NS packets from being sent to other APs.

- ND proxy operates on the AC, with no additional configuration.

1.3 Features

Basic Concepts

↘ ND Proxy

The Layer 2 ND proxy is a special function of ACs. It acts as a proxy for a device to respond to to the multicast NS requests from another device within the same Local Area Network (LAN). Due to the communication mechanism of CSMA/CA between wireless network users, the ND proxy function can reduce the spread of multicast NS packets from the coverage area of an AP to that of another AP. This increases the bandwidth utilization of the wireless network and improves the experience of wireless users.

Feature

Feature	Description
Layer 2 ND Proxy	The AC acts as a proxy to respond to multicast NS packets of a STA through this function. This prevents the spread of multicast NS requests to other APs.
Static ND Binding Entry	A static ND binding entry is configured manually by an administrator. It is not updated by the device and will exist permanently.

1.3.1 Layer 2 ND Proxy

Working Principle

On a typical wireless network, STAs usually access the Internet through APs and ACs. Typically, multiple wireless users are connected to one AP, and multiple APs are connected to one AC. When wireless users on an AP access those on another AP, or when wireless and wired users access each other, NS packets must pass through the AC. This makes it easy for the AC to implement ND proxy.

The working process of ND proxy includes the following steps:

1. The AC learns source IP and MAC addresses of NS packets passing through it or learns the destination address and MAC address in the source link-layer address carried by Neighbor Advertisement (NA) packets to generate ND proxy entries.
2. The AC acts as a proxy to respond to NS packets from other users based on learned entries.
3. If no information about the target host is learned, multicast NS packets are forwarded in compliance with 802.1Q.
4. NA packets are forwarded in the same manner as Ethernet frames in compliance with 802.1Q.

In Figure 1-1, PC3 and PC1 obtain the gateway MAC address one after another. Assume that there is an AC, two APs, and four STAs on this local network.

1 PC3 initiates an NS packet destined for the IPv6 address of the gateway.

2 AP2 forwards this NS packet to PC2 and the AC.

3 The AC learns the IPv6 address and MAC address of PC3 through the NS packet and forwards it to the gateway, AP1, PC1, and the smartphone on AP1.

4 The gateway responds with an NA packet to PC3. When the response packet passes through the AC, the AC learns the IPv6 address and MAC address of the gateway.

5 PC1 initiates an NS packet destined for the IPv6 address of the gateway.

6 AP1 forwards this NS packet to the smartphone and AC.

7 The AC learns the IPv6 address and MAC address of PC1, and takes place of the gateway to send an NA packet to PC1. In step 4, the AC has already learned the MAC address of the gateway and can respond to NS packets, so multicast NS packets will not be broadcast to PC2 and PC3.

Aging mechanism of ND proxy entries:

The mechanism adopts the Least Recently Used (LRU) algorithm. The entries that are not used recently are aged out first, and the aging speed is configured based on the number of entries:

1 When the number of entries exceeds 20,000, configure the device to age 10 entries per second.

2 When the number of entries exceeds 10,000 and is less than 20,000, configure the device to age one entry per second.

3 When the number of entries exceeds 1,000 and is less than 10,000, configure the device to age one entry every 10 seconds.

4 When the number of entries is less than 1,000, configure the device to age one entry every 100 seconds.

Related Configuration

↘ Configuring the Layer 2 ND Proxy Function

- The Layer 2 ND proxy function is enabled by default.
- You can use the **no proxy-nd enable** command to disable the Layer 2 ND proxy function.

1.3.2 Static ND Binding Entry

Working Principle

A static ND binding entry is manually configured by an administrator. It is not updated by the device and will exist permanently. The static ND binding entry can prevent the device from learning incorrect binding entries, which results in proxy errors and thus affects the network.

Related Configuration

↘ Configuring a Static Layer 2 ND Binding Entry

- No static ND binding entry is configured by default.

- You can use the **proxy-nd** *ipv6-address vid mac interface-id* command in global configuration mode to configure the Layer 2 ND binding entry.

1.4 Configuration

Configuration	Description and Command	
Configuring the Layer 2 ND Proxy Function	⚠ (Mandatory) It is used to enable the Layer 2 ND proxy function on the device.	
	proxy-nd enable	Enables the Layer 2 ND proxy function.
Configuring a Static Layer 2 ND Proxy Entry	⚠ (Optional)	
	proxy-nd *ipv6-address vid mac interface-id*	Configures a static ND binding entry.

1.4.1 Configuring the Layer 2 ND Proxy Function

Configuration Effect

Enabling the Layer 2 ND proxy function according to the actual topology can increase the bandwidth utilization of a wireless network and enhance the experience of wireless users.

Notes

N/A

Configuration Step

↘ Configuring the Layer 2 ND Proxy Function

- Mandatory.
- In a wireless IPv6 environment, enabling the Layer 2 ND proxy function on the AC can increase the bandwidth utilization of the wireless network and improve the experience of wireless users.

Verification

- Run the **show proxy-nd statistics** command to check the configuration.

Related Commands

↘ Enabling the Layer 2 ND Proxy Function

Command	**proxy-nd enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Enabling the Layer 2 ND Proxy Function

Configuration Steps	● Use this command to enable the Layer 2 ND proxy function.
	`Hostname(config)# proxy-nd enable`
Verification	● Run the **show proxy-nd statistics** command to check the configuration.

	`Hostname# show proxy-nd statistics`
	`Nd Proxy: Enable`
	`Total Entry: 100`
	`Dynamic Entry: 99`
	`Static Entery: 1`
	`Next Aging Time: 5 Seconds`
	`Droped Packets: 0`

Common Errors

N/A

1.4.2 Configuring a Static Layer 2 ND Proxy Entry

Configuration Effect

Configuring the static mapping between the IP address and the MAC address of a device or a host in a VLAN prevents static ND binding entries from being updated incorrectly and prevents the AC from incorrectly acting as a proxy for other devices, which affect the network.

Notes

N/A

Configuration Step

Configuring a Static Layer 2 ND Proxy Binding Entry

- Optional.
- On the device enabled with the Layer 2 ND proxy function, you can configure the static mapping between the IP address and the MAC address of the uplink device. This prevents the device from changing the MAC address of the ND binding entry on the uplink device due to NS attacks.

Verification

- Run the **show proxy-nd static** or **show running-config** command to display the static Layer 2 ND proxy binding entry.

Related Commands

Enabling the Layer 2 ND Proxy Function

Command	**proxy-nd** *ipv6-address vid mac interface-id*
Parameter Description	N/A

Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Enabling the Layer 2 ND Proxy Function

Configuration Steps	● Define an address pool **net172**. ● The network segment is 172.16.1.0/24. ● The default gateway is 172.16.1.254. ● The address lease is 1 day. ● Excluded addresses range from 172.16.1.2 to 172.16.1.100.

	`Hostname(config)# ip dhcp excluded-address 172.16.1.2 172.16.1.100`
	`Hostname(dhcp-config)# ip dhcp pool net172`
	`Hostname(dhcp-config)# network 172.16.1.0 255.255.255.0`
	`Hostname(dhcp-config)# default-router 172.16.1.254`
	`Hostname(dhcp-config)# lease 1`

Verification	● Run **show running-config** to check the configuration.

	`Hostname# show running-config`
	`!`
	`GigabitEthernet 0/1`

Common Errors

N/A

1.5 Monitoring

Clearing

Command	Description
clear proxy-nd <*ipv6-address vlan-id*>	Deletes specified ND proxy entries.
clear proxy-nd < *interface-id*>	Deletes all ND proxy entries in a specified VLAN.
clear proxy-nd	Deletes all ND proxy entries.

Displaying

Command	Description
show proxy-nd	Displays all ND proxy entries.
show proxy-nd dynamic	Displays all dynamic ND proxy entries.
show proxy-nd static	Displays all static ND proxy entries.
show proxy-nd <*ipv6-address vlan-id*>	Displays specified ND proxy entries.
show-: bgp statistics	Displays statistics about the ND proxy.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug proxy-nd [**vid** *vid*] [**interface** *interface-id*] [**dst-ipv6** *ipv6-address*] [**src-ipv6** *ipv6-address*] [**src-mac** *src-mac*] [**dst-mac** *dst-mac*]	Displays the sending and receiving of ND packets.
debug- event	Displays information about added, deleted, or updated ND binding entries.
debug proxy-nd error	Displays errors in processing ND packets and ND binding entries.
debug proxy-nd all	Enables all the debugging.

1 Configuring Tunnel

1.1 Overview

Tunnel interfaces are virtual interfaces used to implement tunneling. A tunnel interface provides a standard transmission link and you do not need to specify a transport protocol or payload protocol. Each tunnel interface represents a transmission link.

Tunneling involves the following parts:

- Payload protocol: Is used to encapsulate data transmitted over tunnels. For example, IPv4 and IPv6 protocols work as payload protocols. Generic routing encapsulation (GRE) tunnels can carry IPv4 or IPv6 data.
- Bearer protocol: Is used for secondary encapsulation and identification of data to be transmitted. Among the tunnels described in this document, only the GRE tunnel uses a bearer protocol. The other tunnels use the IPv4 and IPv6 protocols. Packets are encapsulated with outer IPv4 and IPv6 headers.
- Transport protocol: Is used to transmit data encapsulated for the second time through a bearer protocol.

In practice, the tunnel mode can be used to establish communication between two private networks running the same protocol through a heterogeneous public network.

Tunneling is applicable to the following scenarios:

- Because tunneling supports different payload protocols, it allows communication between local networks running non-IP protocols through a single network (IP network). It enables protocols with hop count limitations to operate over a broader range because tunneling uses the routing capabilities of the IP protocol.
- Tunneling allows discrete subnets to be connected through a single IP network.
- Tunneling enables the provision of the virtual private network (VPN) over a wide area network (WAN).

Because tunneling encapsulates the payload for transmission, this introduces processing complexity, and the following changes need to be considered:

- Because a tunnel is a logical link, it appears to be a single hop during routing. However, its path cost may involve multiple hops. When you use a tunnel for transmission, note that the route of the tunnel link is different from the actual route.
- In tunnel transmission, the payload is encapsulated into the transport protocol. Consider the tunnel configuration during access control list (ACL) configuration. Note that the transmission bandwidth and maximum transmission unit (MTU) allowed by payload protocols are smaller than the theoretical values.

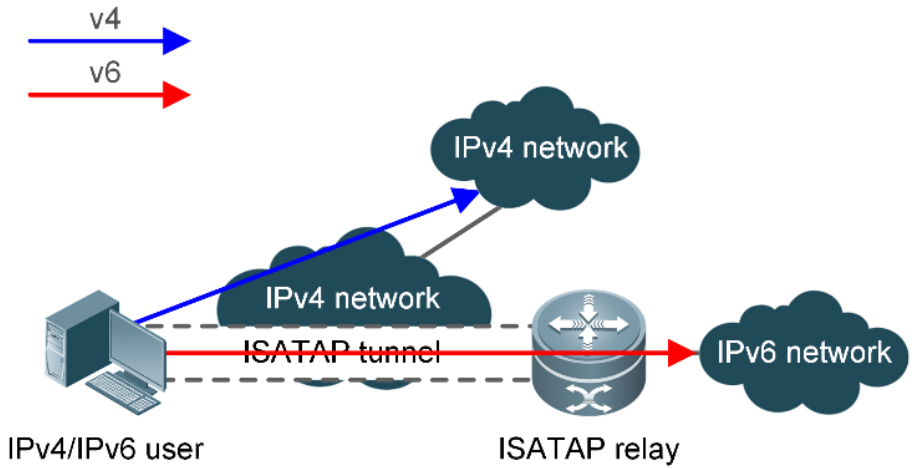
1.2 Applications



Application	Description
Accessing IPv6 Sites on a Campus Network	Tunneling is used for access to IPv6 sites on a campus network.
Accessing the IPv6 Backbone Network on a Campus Network	Tunneling is used for access to the IPv6 backbone network on a campus network.

1.2.1 Accessing IPv6 Sites on a Campus Network

Scenario

IPv6 servers are deployed on some campus networks, and PCs need to access the servers. The Intra-Site Automatic Tunnel Addressing Protocol (ISATAP) can be used to realize the access.

Figure 1-1

Remarks	The ISATAP relay supports tunneling. Users on the campus network can access IPv4 servers directly through the IPv4 network, but need to access IPv6 servers through the ISATAP tunnel.

Deployment

- IPv4 and IPv6 users access the IPv4 network by using IPv4 addresses.
- IPv4 and IPv6 users access the IPv6 network through the ISATAP tunnel.
- The ISATAP tunnel is established between PCs and the ISATAP relay (router).

1.2.2 Accessing the IPv6 Backbone Network on a Campus Network

Scenario

Upgrade the existing campus network to one that supports IPv6 or create a new campus network that supports IPv6 by using the 6to4 automatic tunnel.

1.3 Features

Basic Concepts

MTU of a Tunnel Interface

- The MTU of a tunnel interface is smaller than that of a regular interface, such as a regular IPv4 over IPv4 tunnel. The maximum amount of data carried by a packet transmitted over the Ethernet is 1460 bytes, excluding the Layer 2 IP header. Therefore, the MTU of a tunnel interface is 1480 bytes, not 1500 bytes of a standard Ethernet interface.

PMTU of a Tunnel Interface

- A tunnel interface represents a virtual link. For an IPv4 over IPv4 tunnel, the MTU of a tunnel interface is the MTU of a tunnel link, that is, the MTU of the path between the local and peer ends of the tunnel. When the routing path between the local and peer ends is changed, the path MTU (PMTU) may also be changed, which will affect the MTU of the tunnel interface.

Tunnel Encapsulation Limit

- Tunnel encapsulation is supported. For example, an IPv4 packet can be encapsulated with two or more IPv4 headers and then transmitted over an IPv4 over IPv4 tunnel. Tunnel encapsulation is intended for security guarantee and is seldom used. The amount of data to be transmitted is reduced after tunnel encapsulation. After data is routed through the forwarding information base (FIB), if the outbound interface is another tunnel interface, tunnel encapsulation occurs. If the outbound interface is the local tunnel interface, infinite encapsulation occurs. Such a situation can be detected and information will be displayed.

Overview

Feature	Description
Automatic MTU Adjustment	Dynamically adjusts the MTU of a tunnel interface based on changes of the path MTU of the tunnel link.
Tunnel Encapsulation Limit	Increases the maximum number of nested encapsulations of packets as needed, which is seldom used.
Tunnel Data Validity Check	Adds the checksum to the data transmitted in GRE tunnels to check whether an error occurs during transmission.

1.3.1 Automatic MTU Adjustment

The MTU of a tunnel interface is subject to the MTU of a tunnel link, that is, PMTU. The MTU of the tunnel interface will be changed if a path is changed or the PMTU is changed. The automatic MTU adjustment feature is used to detect these changes and automatically adjust the MTU of the tunnel interface based on the changes.

Working Principle

When a device receives an Internet Control Message Protocol (ICMP) error packet (PACKET TOO BIG) that is an encapsulated IP packet), the faulty tunnel can be located based on encapsulation information. The MTU of the tunnel interface will be changed based on information in the packet.

Related Configuration

↘ Enabling Automatic MTU Adjustment on a Tunnel Interface

By default, automatic MTU adjustment is disabled on a tunnel interface.

To enable or disable automatic MTU adjustment on a tunnel interface, run the **tunnel path-mtu-discovery** command.

For tunnel encapsulation, automatic MTU adjustment needs to be enabled only for the outermost tunnel. The MTU of each inner tunnel is equal to the MTU of the outermost tunnel minus the length of the outer encapsulated header.

1.3.2 Tunnel Encapsulation Limit

In many cases, tunnel encapsulation is a deployment error and is actively deployed only in few cases. By default, products allow four nested encapsulations of a packet at most. Administrators can use a command to change the limit.

Working Principle

If the peer end of tunnel interface A is a regular outbound interface, tunnel Interface A is considered as a regular tunnel interface.

If the peer end of tunnel interface A is another tunnel interface, tunnel Interface A is considered as a nested tunnel interface. If the outbound tunnel is a regular tunnel interface, tunnel Interface A is called a single-nested tunnel. If the outbound tunnel is a single-nested tunnel, tunnel Interface A is called a double-nested tunnel.

If the peer end of tunnel interface A is itself, infinite recursive encapsulation occurs. When the device detects infinite recursive encapsulation, it will output logs and disable tunnel Interface A.

If the peer end of the tunnel is another tunnel interface, routing is performed based on the peer address of the tunnel interface. The actual outbound interface will be determined after multiple times of routing.

If the number of nested encapsulations on a tunnel interface exceeds the upper limit, the device will output logs and disable the tunnel interface.

Note that the tunnel encapsulation limit is specific to the device and differs from the maximum number of encapsulated headers in a packet over a network.

Related Configuration

Configuring the Tunnel Encapsulation Limit on a Tunnel Interface

By default, the maximum number of nested encapsulations of a packet on a tunnel interface is four. To change this limit, run the **tunnel nested-limit** command.

1.3.3 Tunnel Data Validity Check

In a GRE tunnel enabled with data validity check, the receiver checks validity of the packets sent by the peer end to determine whether the packets are tampered during transmission. For long-distance transmission, if application of data carried by a GRE tunnel do not support validity check, you can enable tunnel data validity check.

Working Principle

A GRE tunnel calculates the checksum of the data to be encapsulated at the sender and encapsulates the checksum in the packet before sending the packet out.

Upon receiving the packet, the receiver recalculates the checksum and compares the calculated value to the checksum field in the packet. If the two do not match, the receiver considers that an error occurs in the packet and discards it.

Related Configuration

Enabling Tunnel Data Validity Check on a Tunnel Interface

By default, data validity check is disabled on a tunnel interface.

To enable or disable data validity check on a tunnel interface, run the **tunnel checksum** command.

Tunnel data validity check takes effect only when it is enabled on both ends of a GRE tunnel.

1.4 Configuration

Configuration	Description and Command	
Configuring a Tunnel Interface	⚠ (Mandatory) It is used to create tunnels.	
	Interface tunnel	Creates a tunnel interface.

Configuration	Description and Command	
	tunnel source	Configures the local address of a tunnel.
Configuring an Encapsulation Mode	(Optional) It is used to configure a tunnel mode.	
	tunnel mode	Configures a tunnel encapsulation mode.
Configuring a Peer Address	(Optional) It is used to configure the peer address of a tunnel.	
	tunnel destination	Configures the peer address of a tunnel.
Configuring the ToS of a Tunnel	(Optional) It is used to configure the type of service (ToS) of a tunnel.	
	tunnel tos	Configures the ToS of a tunnel.
Configuring the TTL of a Tunnel	(Optional) It is used to configure the time to live (TTL) of a tunnel.	
	tunnel ttl	Configures the TTL of a tunnel.
Configuring Tunnel Reachability Detection	(Optional) It is used to configure reachability detection for a transmission network.	
	keepalive	Configures reachability detection for a tunnel.
Configuring PMTU Discovery	(Optional) It is used to configure PMTU discovery for a transmission network.	
	tunnel path-mtu-discovery	Configures PMTU discovery for a tunnel.
Configuring the Tunnel Encapsulation Limit	(Optional) It is used to configure the maximum number of nested encapsulations of a packet.	
	tunnel nested-limit	Configures the maximum number of nested encapsulations of a packet.
Configuring Tunnel Data Validity Check	(Optional) It is used to enable data validity check for GRE tunnels.	
	tunnel checksum	Enables data validity check for GRE tunnels.
Configuring a Tunnel Key	(Optional) It is used to configure the check key of a tunnel.	
	tunnel key	Configures the check key of a GRE tunnel.

1.4.1 Configuring a Tunnel Interface

Configuration Effect

- Create a tunnel interface.

Configuration Steps

Creating a Tunnel Interface

- Run the **interface tunnel** *number* command in global configuration mode to create a tunnel interface.
- The tunneling service is available only after a tunnel interface is created.

Verification

- Run the **show interfaces tunnel** *number* command to check whether the tunnel interface is created successfully.

Related Commands

Configuring a Tunnel Interface

Command	**interface tunnel** *number*
Parameter Description	*number*: Indicates the number of a tunnel interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Checking the Tunnel Configuration

Command	**show interfaces tunnel** *number*
Parameter Description	*number*: Indicates the number of a tunnel interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Creating a Tunnel Interface

Configuration Steps	● Create a tunnel interface.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# end`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`……`
	`Tunnel protocol/transport is gre ip`

Common Errors

- A tunnel interface cannot be created due to insufficient memory.
- A tunnel interface cannot be created due to insufficient hardware resources.

1.4.2 Configuring an Encapsulation Mode

Configuration Effect

- Configure an encapsulation mode in tunnel interface configuration mode when you need to use a tunnel in non-default encapsulation mode.

Configuration Step

Configuring an Encapsulation Mode

- Optional.
- The default encapsulation mode is **tunnel mode gre ip**.
- To change the default encapsulation mode, run the **tunnel mode** command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** *number* command to check whether the tunnel encapsulation mode is configured.

Related Commands

Configuring a Tunnel Mode

Command	**tunnel mode** { **gre ip** | | **ipv6ip** [**6to4** | **isatap**] }
Parameter Description	**gre ip**: Indicates that a packet is encapsulated with a GRE header and an IPv4 header in sequence and then is transmitted over a new IPv4 network. **ipv6ip 6to4**: The transmission network is IPv4 network, and GRE for the route is not at the IP layer. The user network is IPv6 network. The IPv4 address of the peer end does not need to be configured. It is used for connection between IPv6 networks. **ipv6ip isatap**: The transmission network is IPv4 network, and GRE for the route is not at the IP layer. The user network is IPv6 network. The IPv4 address of the peer end does not need to be configured. It is used for quick deployment of IPv6 networks.
Command Mode	Interface configuration mode
Usage Guide	Both ends of a tunnel must be configured with the same encapsulation mode. Otherwise, the tunnel cannot work.

Configuration Example

Configuring the IPv4 over IPv4 Encapsulation Mode

Configuration Steps	● Configure the IPv4 over IPv4 encapsulation mode on a tunnel interface.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# tunnel mode ipip`
	`Hostname(config)# end`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`……`
	`  Tunnel protocol/transport is ipv6ip`

Common Errors

N/A

1.4.3 Configuring a Local Address

Configuration Effect

- Configure the local address of a tunnel.

Notes

- The local address of a tunnel must match the transport protocol used by the tunnel. Otherwise, the tunnel interface will not go Up (be disabled).
- When the local address is specified indirectly by configuring another interface, the local address is the primary IPv4 address or the first global public IPv6 address of IPv6.

Configuration Step

↘ Configuring a Local Address

- Mandatory.
- Run the **tunnel source** command in tunnel interface configuration mode to specify the local address of a tunnel.

Verification

- Run the **show interfaces tunnel** *number* command to display the local address of the tunnel.

Related Commands

↘ Configuring a Local Address

Command	**tunnel source** { *ip-address* | *interface-name interface-number* }
Parameter Description	**ip-address**: Indicates an IPv4 or IPv6 address. *Interface-name interface-number*: Indicates a Layer 3 interface.
Command Mode	Interface configuration mode
Usage Guide	If you specify an IPv4 or IPv6 address directly, you need to configure the address of the device.

Configuration Example

↘ Configuring a Local Address

Configuration Steps	● Configure the local address of a tunnel as 1.1.1.1.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# tunnel mode ipv6ip`
	`Hostname(config-if-Tunnel 1)# tunnel source 1.1.1.1`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`  Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable`

	Tunnel TOS/Traffic Class not set, Tunnel TTL 254 Tunnel config nested limit is 0, current nested number is 0 Tunnel protocol/transport ipv6ip Tunnel transport VPN is no set ……

1.4.4 Configuring a Peer Address

Configuration Effect

- A manual tunnel can be used (the tunnel interface is Up) only after its peer address is configured.

Notes

- Peer addresses cannot be configured for automatic tunnels.

Configuration Steps

Configuring a Peer Address

- The peer addresses must be configured for all tunnels except 6RD, 6to4, and ISATAP tunnels.
- Run the **tunnel destination** command in interface configuration mode to configure the peer address of a tunnel.

Verification

- Run the **show interfaces tunnel** command to check whether the destination address is configured.

Related Commands

Configuring a Peer Address

Command	**tunnel destination** *ip-address*
Parameter Description	***ip-address***: Indicates an IPv4 or IPv6 address.
Command Mode	Interface configuration mode
Usage Guide	The peer address of a manual tunnel must be configured. The protocol suite type of the configured peer address must be consistent with the transport protocol used by the tunnel. If they are inconsistent, the tunnel interface will be disabled (Down).

Configuration Example

Configuring a Peer Address

Configuration Steps	● Configure the peer address of a tunnel as 2.2.2.2.
	Hostname# configure terminal Hostname(config)# interface tunnel 1 Hostname(config-if-Tunnel 1)# tunnel mode ipv6ip Hostname(config-if-Tunnel 1)# tunnel destination 2.2.2.2
Verification	● Check the configuration of the tunnel interface.

Configuration Steps	● Configure the peer address of a tunnel as 2.2.2.2.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# tunnel mode ipv6ip`
	`Hostname(config-if-Tunnel 1)# tunnel destination 2.2.2.2`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`  Tunnel source: UNKNOWN, destination 2.2.2.2, unrouteable`
	`  Tunnel TOS/Traffic Class not set, Tunnel TTL 254`
	`  Tunnel config nested limit is 0, current nested number is 0`
	`  Tunnel protocol/transport ipv6ip`
	`  ……`

Common Errors

- A peer address is configured for an automatic tunnel.
- The peer address configured for a tunnel is the same as that of another tunnel.

1.4.5 Configuring the ToS of a Tunnel

Configuration Effect

- Specify the ToS or Traffic Class field in the transport protocol header.

Notes

- If the ToS or Traffic Class field in the transport protocol header is not specified, the ToS or Traffic Class field of the protocol is copied to the header.

Configuration Step

↘ Configuring the ToS of a Tunnel

- Optional.
- To change the priority of tunnel data on a network, run the **tunnel tos** command in interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether the ToS is configured.

Related Commands

↘ Configuring the ToS of a Tunnel

Command	**tunnel tos** *number*
Parameter Description	***number***: Indicates the ToS of a tunnel.

Command Mode	Interface configuration mode
Usage Guide	By default, if the IPv4 protocol is used for the inner bearer and outer encapsulation in a tunnel, the ToS bytes in the inner IPv4 header are copied to the outer IPv4 header. If the IPv6 protocol is used for the inner bearer and outer encapsulation in a tunnel, the 8-bit Traffic Class in the inner IPv6 header is copied to the outer IPv6 header. In other cases, the ToS field in the outer IPv4 header and the Traffic Class field in the IPv6 header are 0.

Configuration Example

Configuring the ToS of a Tunnel

Configuration Steps	● Configure the ToS of a tunnel.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# tunnel mode ipv6ip`
	`Hostname(config-if-Tunnel 1)# tunnel tos 2`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`  Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable`
	`  Tunnel TOS/Traffic Class 0x2, Tunnel TTL 254`
	`  Tunnel config nested limit is 0, current nested number is 0`
	`  Tunnel protocol/transport ipv6ip`
	`  Tunnel transport VPN is VPN1`
	`……`

1.4.6 Configuring the TTL of a Tunnel

Configuration Effect

- Specify the TTL or hop limit of tunnel encapsulation protocol headers.

Configuration Step

Configuring the TTL of a Tunnel

- Optional.
- By default, the TTL is 254.
- To change the hop limit of a tunnel, run the **tunnel ttl** command.

Verification

- Run the **show interfaces tunnel** command to check whether the TTL is configured.

Related Commands

Configuring the TTL of a Tunnel

Command	**tunnel ttl** *hop-limit*
Parameter Description	*hop-limit*: Indicates the hop limit of a tunnel.
Command Mode	Global configuration mode
Usage Guide	The hop limit specifies the maximum number of routers that a packet can pass through. The default value is 254. This command is used to change the hop limit.

Configuration Example

Configuring the TTL of a Tunnel

Configuration Steps	● Configure the TTL of a tunnel.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# tunnel mode ipv6ip`
	`Hostname(config-if-Tunnel 1)# tunnel ttl 3`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`  Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable`
	`  Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3`
	`  Tunnel config nested limit is 0, current nested number is 0`
	`  Tunnel protocol/transport ipv6ip`
	`  Tunnel transport VPN is VPN1`

1.4.7 Configuring Tunnel Reachability Detection

Configuration Effect

- Determine availability of tunnels more accurately through tunnel reachability detection.

Configuration Step

Configuring Tunnel Reachability Detection

- Tunnel reachability detection is optional for manual tunnels. Automatic tunnels do not support reachability detection.
- To dynamically monitor availability of tunnel links, configure tunnel reachability detection in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether tunnel reachability detection is configured.

Related Commands

Configuring Tunnel Reachability Detection

Command	**keepalive** [*seconds* [*retries*]]
Parameter Description	***seconds***: Indicates the interval at which keepalive packets are retransmitted, in seconds. *retries*: Indicates the number of times keepalive packets are retransmitted.
Command Mode	Interface configuration mode
Usage Guide	Manual tunnels support reachability detection, whereas automatic tunnels do not support it. By default, tunnel reachability detection is disabled. A tunnel interface is Up if the route to the destination IP address can be found in the routing table of the device. After tunnel reachability detection is enabled, the tunnel interface is Up if keepalive packets are sent and received correctly.

Configuration Example

Configuring Tunnel Reachability Detection

Configuration Steps	● Configure tunnel reachability detection.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config)# tunnel mode ipv6ip`
	`Hostname(config)# keepalive 3 5`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`Index(dec):11 (hex):b`
	`…`
	`  Keepalive interval is 3 sec ,retries 5.`

1.4.8 Configuring PMTU Discovery of a Tunnel

Configuration Effect

- Configure PMTU discovery to allow the MTU of a tunnel interface to be adjusted automatically based on the changes of the route MTU. Before this feature is configured, the MTU of the tunnel interface is equal to the MTU of the transport protocol minus the length of the header encapsulated through a transport protocol.

Configuration Step

Configuring PMTU Discovery

- PMTU discovery is optional for manual tunnels. Automatic tunnels do not support PMTU discovery.
- To dynamically monitor and adjust MTUs of tunnel links, configure PMTU discovery in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether PMTU discovery is configured.

Related Commands

Configuring PMTU Discovery

Command	**tunnel path-mtu-discovery** [**age-timer** {*aging-mins* | **infinite**} | **min-mtu** *mtu-bytes*]
Parameter Description	*aging-mins*: Indicates the interval at which the MTU of a tunnel interface ages, in minutes. **infinite** indicates that the MTU never ages. *mtu-bytes*: Indicates the minimum value of the MTU. The value range is from 92 to 65535. The default value is 92.
Command Mode	Global configuration mode
Usage Guide	Use this command to dynamically monitor and automatically change MTUs of tunnel links. You can configure the monitoring frequency and the lower limit of MTU change. PMTU discovery has three states: ● **init**: Detection is not initiated. ● **learning**: Dynamic learning is in progress. ● **keep**: Dynamic MTU adjustment is completed and the next round of adjustment is ready. PMTU discovery depends on the "ICMP Packet Too Big" error packet returned by a device. If the packet is filtered by an intermediate device, discovery results will be inaccurate.

Configuration Example

Configuring PMTU Discovery

Configuration Steps	● Configure PMTU discovery.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config)# tunnel mode ipv6ip`
	`Hostname(config)# tunnel path-mtu-discovery`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`…`
	`Tunnel transport VPN is no set`
	`  Path MTU Discovery state:init, ager 10 mins, min MTU 92`

Common Errors

- PMTU discovery is enabled for automatic tunnels.

1.4.9 Configuring the Tunnel Encapsulation Limit

Configuration Effect

- Change the maximum number of nested encapsulations allowed by the outer protocol of a tunnel.

Notes

- In many cases, the tunnel encapsulation limit does not need to be changed.

Configuration Step

Configuring the Tunnel Encapsulation Limit

- By default, the device allows a maximum of four nested encapsulations of a packet, which can meet most service requirements.
- To change the limit, run the **tunnel nested-limit** *number* command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether the tunnel encapsulation limit is configured.

Related Commands

Configuring the Tunnel Encapsulation Limit

Command	**tunnel nested-limit** *number*
Parameter Description	*number*: Indicates the maximum number of nested encapsulations of a packet. The value range is from 0 to 10. The default value is 4.
Command Mode	Interface configuration mode
Usage Guide	The device automatically discovers nested encapsulations and prevents excessive nested encapsulations. Only manual tunnels support the tunnel encapsulation limit, whereas automatic tunnels do not support it. The tunnel encapsulation limit is specific to a device and indicates the maximum number of times a packet is encapsulated from its entry to the device until its exit.

Configuration Example

Configuring the Tunnel Encapsulation Limit

Configuration Steps	● Configure the tunnel encapsulation limit.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# tunnel mode ipv6ip`
	`Hostname(config-if-Tunnel 1)# tunnel nested-limit 8`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`  Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable`
	`  Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3`
	`  Tunnel config nested limit is 8, current nested number is 0`
	`  Tunnel protocol/transport ipv6ip`
	`  Tunnel transport VPN is VPN1`
	`……`

Common Errors

- The tunnel encapsulation limit is configured for automatic tunnels.

1.4.10 Configuring Tunnel Data Validity Check

Configuration Effect

- Configure tunnel data validity check to determine whether data carried by tunnels is changed during transmission. If data is changed, the device considers the data as corrupted and discards it. If application of data carried by a tunnel do not support validity check, you can enable data validity check of the tunnel.

Notes

- Only GRE tunnels support data validity check.

Configuration Step

Configuring Tunnel Data Validity Check

- Optional.
- If application protocols do not support data validity check, you can enable data validity check of GRE tunnels.
- To enable tunnel data validity check, run the **tunnel checksum** command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether tunnel data validity check is enabled.

Related Commands

Configuring Tunnel Data Validity Check

Command	**tunnel checksum**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Use this command to enable data validity check of a GRE tunnel if service data carried in the GRE tunnel does not support validity check. Data validity check must be configured on both ends of a tunnel. The sender adds the checksum to an encapsulated packet. The receiver calculates the checksum of the packet and compares it to the checksum provided by the sender. If they are consistent, the packet is valid. Otherwise, the packet is invalid.

Configuration Example

Configuring Tunnel Data Validity Check

Configuration Steps	• Configure data validity check in a tunnel.
	`Hostname# configure terminal`

	Hostname(config)# interface tunnel 1 Hostname(config-if-Tunnel 1)# tunnel mode gre ip Hostname(config-if-Tunnel 1)# tunnel checksum
Verification	● Check the configuration of the tunnel interface.

	Hostname# show interfaces tunnel 1
	……
	Tunnel attributes:
	  Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable
	  Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3
	  Tunnel config nested limit is 8, current nested number is 0
	  Tunnel protocol/transport gre ip
	  Key disabled, Sequencing disabled
	  Checksumming of packets enabled
	  Tunnel transport VPN is VPN1
	……

Common Errors

- Data validity check is configured for regular tunnels (non-GRE tunnels).

1.4.11 Configuring a Tunnel Key

Configuration Effect

- By configuring the key of a tunnel interface, the device can ensure security of both ends of the tunnel and prevents malicious probes and attacks.

Notes

- Each packet encapsulated in the GRE format contains the configured key, but the attempt to ensure security through the key is inconsiderate.
- Both ends of a tunnel must use the same key settings.

Configuration Step

↘ Configuring a Tunnel Key

- Optional.
- You can configure different keys to segregate the data carried in a GRE tunnel.
- To configure a tunnel key, run the **tunnel key** *key-value* command in tunnel interface configuration mode.

Verification

- Run the **show interfaces tunnel** command to check whether the tunnel key is configured.

Related Commands

↘ Configuring a Tunnel Key

Command	**tunnel key** *key-value*

Parameter Description	*key-value*: Indicates the value of a tunnel key. The value range is from 0 to 2147483647.
Command Mode	Interface configuration mode
Usage Guide	The sender encapsulates the key in a packet. The receiver compares the local key to the key in the packet. If they are inconsistent, the packet is discarded.

Configuration Example

Configuring a Tunnel Key

Configuration Steps	● Configure a tunnel key.

	`Hostname# configure terminal`
	`Hostname(config)# interface tunnel 1`
	`Hostname(config-if-Tunnel 1)# tunnel mode gre ip`
	`Hostname(config-if-Tunnel 1)# tunnel key 10`

Verification	● Check the configuration of the tunnel interface.

	`Hostname# show interfaces tunnel 1`
	`……`
	`Tunnel attributes:`
	`  Tunnel source 1.1.1.1, destination UNKNOWN, unrouteable`
	`  Tunnel TOS/Traffic Class 0x2, Tunnel TTL 3`
	`  Tunnel config nested limit is 8, current nested number is 0`
	`  Tunnel protocol/transport gre ip`
	`    Key 0xa, Sequencing disabled`
	`    Checksumming of packets enabled`
	`   Tunnel transport VPN is VPN1`
	`……`

Common Errors

- Tunnel keys are configured for regular tunnels (non-GRE tunnels).

1.5 Monitoring

Displaying

Command	Description
show interfaces tunnel *number*	Displays the information about a tunnel interface.
show tunnel statistics	Displays the configurable tunnel capacity and the number of used tunnels.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug tunnel	Enables tunnel interface debugging.

1 Configuring TCP

1.1 Overview

The Transmission Control Protocol (TCP) is a transport-layer protocol providing reliable connection-oriented and IP-based services for the application layer.

Internetwork data flows in 8-bit bytes are sent from the application layer to the TCP layer, and then fragmented into packet segments of a proper length through TCP. The Maximum Segment Size (MSS) is typically limited by the Maximum Transmission Unit (MTU) of the data link layer. Then packets are sent to the IP layer and then to the TCP layer of a receiver through the network.

TCP assigns a sequence number to each byte to prevent packet loss. This ensures that packets destined for the peer are received in order. Then the receiver responds with a TCP ACK packet upon receiving a packet. If the sender does not receive ACK packets in the specified Round-Trip Time (RTT), the corresponding packets (assumed lost) will be retransmitted.

- TCP uses the checksum function to check data integrity. Besides, MD5-based authentication can be used to verify data.
- Timeout retransmission and piggyback mechanism are adopted to ensure reliability.
- The Sliding Window Protocol is adopted to control flows. Unidentified packets in a window should be retransmitted.

Protocols and Standards

- RFC 793: Transmission Control Protocol
- RFC 1122: Requirements for Internet Hosts -- Communication Layers
- RFC 1191: Path MTU Discovery
- RFC 1213: Management Information Base for Network Management of TCP/IP-based Internets: MIB-II
- RFC 2385: Protection of BGP Sessions via the TCP MD5 Signature Option
- RFC 4022: Management Information Base for the Transmission Control Protocol (TCP)

1.2 Applications

Application	Description
Optimizing TCP Performance	To avoid TCP packet fragmentation on a link with a small MTU, Path MTU Discovery (PMTUD) is enabled.
Detecting TCP Connection Exception	TCP checks whether the peer works normally.

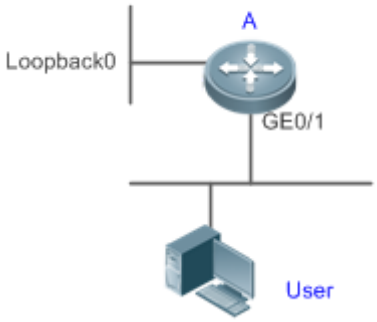
1.2.1 Optimizing TCP Performance

Scenario

For example, a TCP connection is established between A and D, as shown in Figure 1-1. The MTU of the link between A and B is 1500 bytes, 1300 bytes between B and C, and 1500 bytes between C and D. To optimize TCP transmission performance, avoid packet fragmentation between B and C.

Figure 1-1

Deployment



- Enable PMTUD on A and D.

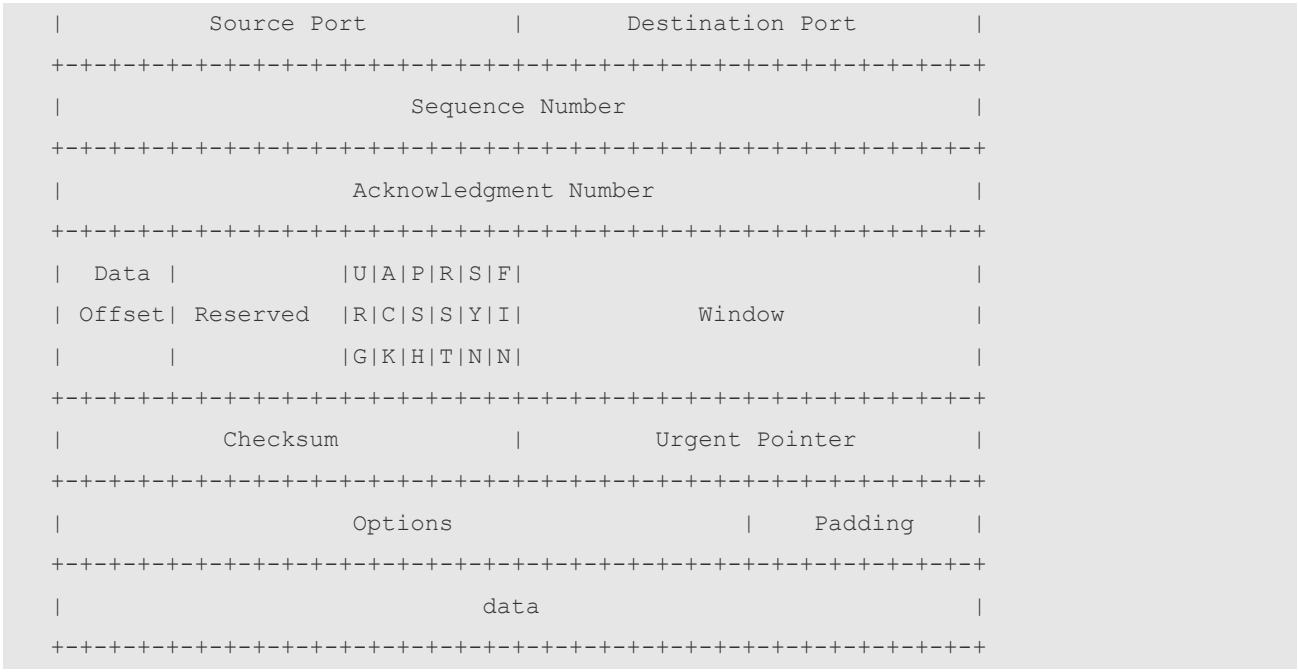
1.2.2 Detecting TCP Connection Exceptions

Scenario

In Figure 1-2, a user logs in to A through Telnet but the user's computer is shut down abnormally. In case of TCP retransmission timeout, the user's TCP connection remains for a long period. Therefore, TCP keepalive can be used to rapidly detect TCP connection exceptions.

Figure 1-2

Deployment



- Enable TCP keepalive on A.

1.3 Features

Basic Concepts

TCP Header Format

```
 0                   1                   2                   3
 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

- **Source Port**: Is a 16-bit source port number.
- **Destination Port**: Is a 16-bit destination port number.
- **Sequence Number**: Is a 32-bit sequence number.
- **Acknowledgment Number**: Is a 32-bit number that identifies the next sequence number that the receiver is expecting to receive.
- **Data Offset**: Is a 4-bit number that indicates the total number of bytes in the TCP header (option included) divided by 4.
- A flag bit is 6-bit. URG indicates that the urgent pointer field is significant; ACK indicates that the acknowledgment field is significant; PSH indicates the push function; RST indicates that the TCP connection is reset; SYN indicates that the sequence number is synchronized (used during TCP connection establishment); FIN indicates that the sender does not have data to be sent (used during TCP connection termination).
- **Window**: Is of 16 bits. It specifies the amount of data that may be transmitted from the peer between ACK packets.
- **Checksum**: Is a 16-bit checksum.
- **Urgent Pointer**: Is 16-bit and indicates the offset of urgent data relative to the sequence number. It is available only when URG is set.

TCP Three-Way Handshake

- The process of TCP three-way handshake is as follows:

1 A client sends a SYN packet to the server.

2 The server receives the SYN packet and responds with a SYN ACK packet.

3 The client receives the SYN packet from the server and responds with an ACK packet.

- After the three-way handshake, the client and server are connected successfully and ready for data transmission.

Overview

Feature	Description
Configuring SYN Timeout	Configures a timeout waiting for a response packet after an SYN or SYN ACK packet is sent.
Configuring the Window Size	Configures a window size.
Configuring Reset Packet Sending	Configures the device to send TCP reset packets after receiving port unreachable packets.
Configuring the MSS	Configures an MSS for a TCP connection.
Configuring the MSS for SYN Packet	Changes the MSS in an SYN packet.
PMTU	Discovers the smallest MTU on the TCP transmission path, and adjusts the size of TCP packets based on the MTU to avoid fragmentation.
TCP Keepalive	Checks whether the peer works normally.

1.3.1 Configuring SYN Timeout

Working Principle

A TCP connection is established after three-way handshake: The sender sends an SYN packet, the receiver replies with a SYN ACK packet, and then the sender replies with an ACK packet.

- If the receiver does not reply with a SYN ACK packet after the sender sends an SYN packet, the sender keeps retransmitting the SYN packet for a specified number of times or until the timeout period expires.
- If the receiver replies with a SYN ACK packet after the sender sends an SYN packet but the sender does not reply with an ACK packet, the receiver keeps retransmitting the SYN ACK packet for a specified number of times or until the timeout period expires. (This occurs in the case of SYN flooding.)

Related Configuration

Configuring the TCP SYN Timeout

- The default TCP SYN timeout is 20 seconds.
- Run the **ip tcp synwait-time** *seconds* command in global configuration mode to configure an SYN timeout. The value range is from 5 to 300, in seconds.
- In case of SYN flooding, shortening the SYN timeout reduces consumed resources. However, this mechanism is invalid for continuous SYN flooding. When a device proactively requests to establish a connection with an external device, for example, through Telnet, shortening the SYN timeout reduces user's waiting time. You may prolong the SYN timeout properly on un unstable network.

The **ip tcp syntime-out** command in version 10.x is not used but is compatible in version 11.0. If this command is executed, it will be converted to the **ip tcp synwait-time** command.

In version 10.x, the configuration applies to only IPv4 TCP. In version 11.0 or later, it applies to both IPv4 TCP and IPv6 TCP.

1.3.2 Configuring the Window Size

Working Principle

Data from the peer is cached in the TCP receiving buffer and subsequently read by applications. The TCP window size indicates the size of free space of the receiving buffer. For the connection involves high bandwidth and much data, increasing the window size dramatically enhances TCP transmission performance.

Related Configuration

Configuring the Window Size

- Run the **ip tcp window-size** *size* command in global configuration mode to configure a window size. The value range is from 128 to 10737418240 (65535<< 14), in bytes. The default value is 65535 bytes. If the window size is greater than 65535 bytes, window increasing will be enabled automatically.
- The window size advertised to the peer is the smaller value between the configured window size and the free space of the receiving buffer.

In version 10.x, the configuration applies to only IPv4 TCP. In version 11.0 or later, it applies to both IPv4 TCP and IPv6 TCP.

1.3.3 Configuring Reset Packet Sending

Working Principle

When TCP packets are distributed to applications, if the TCP connection that a packet belongs to cannot be identified, the local end sends a reset packet to the peer to terminate the TCP connection. Attackers may use port unreachable packets to attack the device.

Related Configuration

Configuring the Device to Send TCP Reset Packets After Receiving Port Unreachable Packets

By default, the device is enabled to send TCP reset packets upon receiving port unreachable packets.

Run the **no ip tcp send-reset** command in global configuration mode to disable the device from sending TCP reset packets upon receiving port unreachable packets.

After this function is enabled, attackers may use port unreachable packets to attack the device.

The **ip tcp not-send-rst** command in version 10.x is not used but compatible in version 11.0. If this command is executed, it will be converted to the **no ip tcp send-reset** command.

In version 10.x, the configuration applies to only IPv4 TCP. In version 11.0 or later, it applies to both IPv4 TCP and IPv6 TCP.

1.3.4 Configuring the MSS

Working Principle

The MSS refers to the total amount of data contained in a TCP segment excluding TCP options.

Three-way handshake is implemented through MSS negotiation. Both parties add the MSS option to SYN packets, indicating the largest amount of data that the local end can handle, namely, the amount of data allowed from the peer. Both parties use the smaller MSS between them as the advertised MSS.

The MSS is calculated as follows:

- IPv4 TCP: MSS = Outbound interface's MTU – IP header size (20-byte) – TCP header size (20-byte)
- IPv6 TCP: MSS = IPv6 PMTU – IPv6 header size (40-byte) –TCP header size (20-byte)

In version 10.x, the configuration applies to only IPv4 TCP. In version 11.0 or later, it applies to both IPv4 TCP and IPv6 TCP.

The effective MSS is the smaller one between the calculated MSS and the configured MSS.

If a connection supports certain options, the option length (with **data offset** considered) should be deducted from an MSS. For example, 20 bytes for MD5 digest (with **data offset** considered) should be subtracted from the MSS.

Related Configuration

Configuring the MSS

- Run the **ip tcp mss** *max-segment-size* command in global configuration mode to set an MSS. The value range is from 68 to 1000, in bytes. By default, the MSS is calculated based on the MTU. If an MSS is configured, the effective MSS is the smaller one between the calculated MSS and the configured MSS.
- A small MSS reduces transmission performance. You can promote TCP transmission by increasing the MSS. Choose an MSS by referring to the interface's MTU. If the former is larger, TCP packets will be fragmented and transmission performance will be lowered.

1.3.5 Configuring the MSS for SYN Packets

Working Principle

When a client initiates a TCP connection, it negotiates with the server on the total amount of data contained in a TCP segment through the MSS field in TCP SYN packets. The MSS value in the SYN packets indicates the largest amount of data that the server sends in a single and unfragmented piece.

For example, in Figure 1-3, the MSS negotiated between a PC and a HTTP server is 1460, but TCP packets carrying 1460-byte data should be fragmented as they cannot directly pass R1 and R2 connected by a tunnel with an MTU of less than 1500. Change the MSS in SYN packets on interfaces (1) and (2) of R2 to enable TCP packets to pass R1 and R2.

Figure 1-3

Related Configuration

Configuring the MSS for TCPv4 SYN Packets

- By default, the MSS in TCPv4 SYN packets is not changed.
- Run the **ip tcp adjust-mss** *max-segment-size* command in interface configuration mode to set the MSS. The value range is from 500 to 1460, in bytes.
- To avoid packet fragmentation in the case of a small PMTU, you may configure the MSS for TCPv4 SYN packets. The MSS in TCPv4 SYN packets will change to the configured value once the device receives the packets. You may configure an MSS considering the interface MTU.

This configuration applies to a new connection but is invalid for an existing TCP connection.

Configuring the MSS for TCPv6 SYN Packets

- By default, the MSS in TCPv6 SYN packets is not changed.
- Run the **ipv6 tcp adjust-mss** *max-segment-size* command in interface configuration mode to configure the MSS for TCPv6 SYN packets. The value range is from 1220 to 1440, in bytes.
- To avoid packet fragmentation in the case of a small PMTU, you may configure the MSS for TCPv4 SYN packets. The MSS in TCPv4 SYN packets will change to the configured value once the device receives the packets. You may configure an MSS value considering the interface MTU.

This configuration applies to a new TCPv6 connection but is invalid for an existing TCPv6 connection.

1.3.6 PMTUD

Working Principle

The Path MTU Discovery (PMTUD) stipulated in RFC 1191 is used to discover the smallest MTU in a TCP path to avoid fragmentation, enhancing network bandwidth utilization. The process of TCPv4 PMTUD is described as follows:

1 The source sends TCP packets with the Don't Fragment (DF) bit set in the outer IP header.

2 If the outbound interface's MTU of a router in the TCP path is smaller than the IP packet length, the packet will be discarded and an ICMP error packet carrying this MTU will be sent to the source.

3 Through parsing the ICMP error packet, the source knows the smallest MTU in the path.

4 The size of subsequent data segments sent by the source will not surpass the MSS, which is calculated as follows:

TCP MSS = PMTU – IP header size – TCP header size

Related Configuration

Enabling PMTUD

By default, PMTUD is disabled.

Run the **ip tcp path-mtu-discovery** command to enable PMTUD in global configuration mode.

In version 10.x, the configuration applies to both IPv4 TCP and IPv6 TCP. In version 11.0 or later, it applies to only IPv4 TCP. TCPv6 PMTUD is enabled permanently and cannot be disabled.

1.3.7 TCP Keepalive

Working Principle

You may enable TCP keepalive to check whether the peer works normally. If a peer end does not send packets to the local end for a period of time (namely idle period), the local end starts sending keepalive packets successively to the peer end for several times. If no response packet is received, the TCP connection is considered inactive and then ended.

Related Configuration

Enabling Keepalive

- By default, TCP keepalive is disabled.

- Run the **ip tcp keepalive** [**interval** *num1*] [**times** *num2*] [**idle-period** *num3*] command to in global configuration mode to enable TCP keepalive.

In version 10.x, the configuration applies to only IPv4 TCP. In version 11.0 or later, it applies to both IPv4 TCP and IPv6 TCP.

1.4 Configuration

Configuration	Description and Command	
Optimizing TCP Performance	(Optional) It is used to optimize TCP connection performance.	
	ip tcp synwait-time	Configures a timeout for TCP connection.
	ip tcp window-size	Configures a TCP window size.
	ip tcp send-reset	Configures the device to send TCP reset packets after receiving port unreachable packets.
	ip tcp mss	Configures the MSS for TCP connections.
	ip tcp adjust-mss	Configures the MSS for TCPv4 SYN packets.
	ipv6 tcp adjust-mss	Configures the MSS for TCPv6 SYN packets.
	ip tcp path-mtu-discovery	Enables PMTUD.
Detecting TCP Connection Exception	(Optional) It is used to detect whether the peer works normally.	
	ip tcp keepalive	Enables TCP keepalive.

1.4.1 Optimizing TCP Performance

Configuration Effect

- Ensure optimal TCP performance and prevent fragmentation.

Notes

N/A

Configuration Step

Configuring the SYN Timeout

- Optional.
- Perform this configuration on both ends of a TCP connection.

Configuring TCP Window Size

- Optional.
- Perform this configuration on both ends of a TCP connection.

Configuring the Device to Send TCP Reset Packets After Receiving Port Unreachable Packets

- Optional.
- Perform this configuration on both ends of a TCP connection.

Configuring MSS

- Optional.
- Perform this configuration on both ends of a TCP connection.

Configuring the MSS for TCPv4 SYN Packets

- Optional.
- If the MTU between two routers in TCP transmission is small, you may configure the MSS on the routers.

Configuring the MSS for TCPv6 SYN Packets

- Optional.
- If the MTU between two routers in TCPv6 transmission is small, you may configure the MSS on the routers.

Enabling PMTUD

- Optional.
- Perform this configuration on both ends of a TCP connection.

Verification

N/A

Related Commands

Configuring SYN Timeout

Command	**ip tcp synwait-time** *seconds*
Parameter Description	*seconds*: Indicates the SYN packet timeout, in seconds. The value range is from 5 to 300. The default value is 20 seconds.
Command Mode	Global configuration mode
Usage Guide	In case of SYN flooding, shortening the SYN timeout reduces consumed resources. However, this mechanism is invalid for continuous SYN flooding. When a device proactively requests to establish a connection with an external device, for example, through Telnet, shortening the SYN timeout reduces user's waiting time. You may prolong the SYN timeout properly on un unstable network.

Configuring TCP Window Size

Command	**ip tcp window-size** *size*
Parameter Description	*size*: Indicates a TCP window size, in bytes. The value range is from 128 to 10737418240 (65535<< 14). The default value is 65535 bytes.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Device to Send TCP Reset Packets After Receiving Port Unreachable Packets

Command	**ip tcp send-reset**

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	By default, the device is enabled to send TCP reset packets upon receiving port unreachable packets.

Configuring the MSS

Command	**ip tcp mss** *max-segment-size*
Parameter Description	*max-segment-size*: Indicates the maximum segment size, in bytes. The value range is from 68 to 10000. By default, the MSS is calculated based on the MTU.
Command Mode	Global configuration mode
Usage Guide	This command defines the MSS for a TCP connection to be established. The negotiated MSS for a new connection should be smaller than this MSS. If you want to reduce the MSS, run this command. Otherwise, do not perform the configuration.

Configuring the MSS for TCPv4 SYN Packets

Command	**ip tcp adjust-mss** *max-segment-size*
Parameter Description	*max-segment-size*: Indicates the maximum segment size, in bytes. The value range is from 500 to 1460.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring the MSS for TCPv6 SYN Packet

Command	**ipv6 tcp adjust-mss** *max-segment-size*
Parameter Description	*max-segment-size*: indicates the maximum segment size, in bytes. The value range is from 1220 to 1440.
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuring PMTUD

Command	**ip tcp path-mtu-discovery** [**age-timer** *minutes* **| age-timer infinite**]
Parameter Description	**age-timer** *minutes*: Indicates the interval for a new probe after a PMTU is discovered, in minutes. The value range is from 10 to 30. The default value is 10 minutes. **age-timer infinite**: No probe is implemented after a PMTU is discovered.
Command Mode	Global configuration mode
Usage Guide	PMTUD is defined in RFC 1191 to improve bandwidth utilization. When TCP is applied to bulk data transmission, this function can enhance transmission performance. According to RFC 1191, after discovering the PMTU, TCP can use a larger MSS after a certain period to probe for a new PMTU. This interval is specified by the **age-timer** parameter. When the device detects that the PMTU is smaller than the MSS negotiated by both ends of the TCP connection, the

	device will attempt to discover a larger PMTU according to the configured interval. This probe process will continue until the PMTU reaches the MSS, or until the timer is stopped manually. To stop the timer, use the **age-timer infinite** parameter.

Configuration Example

↘ Enabling PMTUD

Configuration Steps	● Enable PMTUD for a TCP connection. Adopt the default age timer settings.

	`Hostname# configure terminal`
	`Hostname(config)# ip tcp path-mtu-discovery`
	`Hostname(config)# end`

Verification	● Run the **show tcp pmtu** command to display the IPv4 TCP PMTU.

	`Hostname# show tcp pmtu`
	`Number Local Address Foreign Address PMTU`
	`1 192.168.195.212.23 192.168.195.112.13560 1440`

	● Run the **show ipv6 tcp pmtu** command to display the IPv6 TCP PMTU.

	`Hostname# show ipv6 tcp pmtu`
	`Number Local Address Foreign Address PMTU`
	`1 1000::1:23 1000::2.13560 1440`

Common Errors

N/A

1.4.2 Detecting TCP Connection Exceptions

Configuration Effect

- Check whether the peer works normally.

Notes

N/A

Configuration Step

↘ Enabling TCP Keepalive

- Optional.

Verification

N/A

Related Commands

↘ Enabling TCP Keepalive

Command	**ip tcp keepalive** [**interval** *num1*] [**times** *num2*] [**idle-period** *num3*]

Parameter Description	**interval** *num1*: Indicates the interval for sending keepalive packets, in seconds. The value range is from 1 to120. The default value is 75 seconds. **times** *num2*: Indicates the maximum number of times for sending keepalive packets. The value range is from 1 to 10. The default value is 6. **idle-period** *num3*: Indicates the time when the peer sends no packets to the local end, in seconds. The value range is from 60 to 1800. The default value is15 minutes.
Command Mode	Global configuration mode
Usage Guide	You can enable TCP keepalive to check whether the peer works normally. The function is disabled by default. Assume that the TCP keepalive function is enabled, with the default interval, number of times, and idle period. The user device does not receive packets from the other end within 15 minutes and then starts sending Keepalive packets every 75 seconds for 6 times. If the user device receives no TCP packets, the TCP connection is considered inactive and then terminated.

Configuration Example

↘ Enabling TCP Keepalive

Configuration Steps	● Enable TCP keepalive on a device with **interval** and **idle-period** set to 3 minutes and 60 seconds respectively. If the user device receives no TCP packets from the other end after sending keepalive packets four times, the TCP connection is considered inactive.

	`Hostname# configure terminal`
	`Hostname(config)# ip tcp keepalive interval 60 times 4 idle-period 180`
	`Hostname(config)# end`

Verification	● A user logs in to a device through Telnet, and then shuts down the local device. Run the **show tcp connect** command on the remote device to observe the time when IPv4 TCP connection is deleted.

Common Errors

N/A

1.5 Monitoring

Displaying

Command	Description
show tcp connect [**local-ip** *a.b.c.d*] [**local-port** *num*] [**peer-ip** *a.b.c.d*] [**peer-port** *num*]	Displays basic information on IPv4 TCP connections.
show tcp connect statistics	Displays IPv4 TCP connection statistics.
show tcp pmtu [**local-ip** *a.b.c.d*] [**local-port** *num*] [**peer-ip** *a.b.c.d*] [**peer-port** *num*]	Displays IPv4 TCP PMTU.
show tcp port [*num*]	Displays IPv4 TCP port information.
show tcp parameter	Displays TCP parameters.
show tcp statistics	Displays TCP statistics.

Command	Description
show ipv6 tcp connect [**local-ipv6** *X:X:X:X::X*] [**local-port** *num*] [**peer-ipv6** *X:X:X:X::X*] [**peer-port** *num*]	Displays basic information on IPv6 TCP connections.
show ipv6 tcp connect statistics	Displays IPv6 TCP connection statistics.
show ipv6 tcp pmtu [**local-ipv6** *X:X:X:X::X*] [**local-port** *num*] [**peer-ipv6** *X:X:X:X::X*] [**peer-port** *num*]	Displays IPv6 TCP PMTU.
show ipv6 tcp port [*num*]	Displays IPv6 TCP port information.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug ip tcp packet [**in** | **out**] [**local-ip** *a.b.c.d*] [**peer-ip** *a.b.c.d*] [**global**] [**local-port** *num*] [**peer-port** *num*] [**deeply**]	Displays debugging information on IPv4 TCP packets.
debug ip tcp transactions [**local-ip** *a.b.c.d*] [**peer-ip** *a.b.c.d*] [**local-port** *num*] [**peer-port** *num*]	Displays debugging information on IPv4 TCP connections.
debug ipv6 tcp packet [**in** | **out**] [**local-ipv6** *X:X:X:X::X*] [**peer-ipv6** *X:X:X:X::X*] [**global**] [**local-port** *num*] [**peer-port** *num*] [**deeply**]	Displays the debugging information on IPv6 TCP packets.
debug ipv6 tcp transactions [**local-ipv6** *X:X:X:X::X*] [**peer-ipv6** *X:X:X:X::X*] [**local-port** *num*] [**peer-port** *num*]	Displays debugging information on IPv6 TCP connections.

1 Configuring IPv4/IPv6 REF

1.1 Overview

On the device that do not support hardware-based forwarding, IPv4 and IPv6 packets are forwarded by software. The device uses the IPv4/IPv6 Ruijie Express Forwarding (REF) technology to optimize the forwarding performance of software.

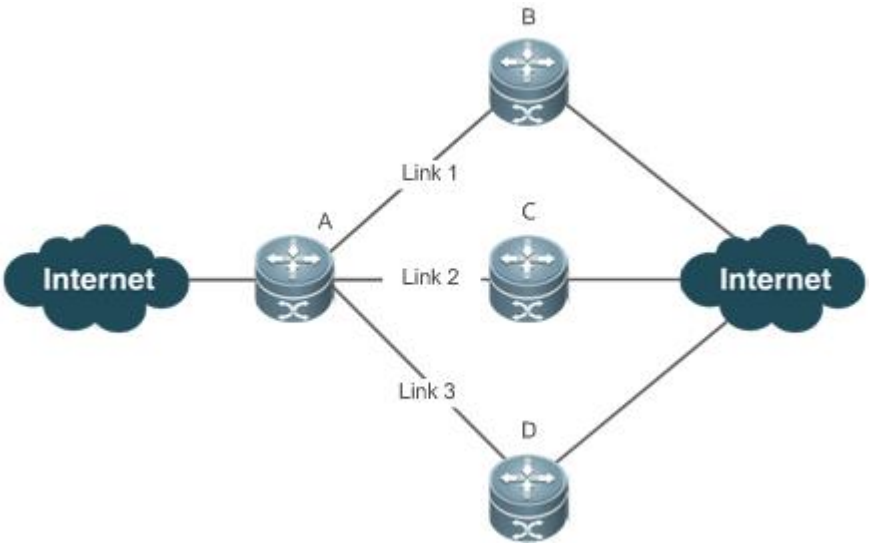
REF maintains two tables: forwarding table and adjacency table. The forwarding table is used to store route information. The adjacency table is derived from the ARP table and IPv6 neighbor table, and contains link layer information for the next hop.

REF is used to proactively resolve next hops and implement load balancing.

Protocols and Standards

N/A

1.2 Applications



Application	Description
Load Balancing	During network routing, when a route prefix is associated with multiple next hops, REF can implement load balancing among multiple next hops.

1.2.1 Load Balancing

Scenario

As shown in Figure 1-1, a route prefix is associated with three next hops on device A, namely, link 1, link 2, and link 3. By default, REF implements load balancing based on the destination IP address. Load balancing can be implemented based on source and destination IP addresses.

Figure 1-1

Remarks	A is a device that runs REF. B, C, and D are forwarding devices.

Deployment

- Run REF on device A.

1.3 Features

Basic Concepts

IPv4/IPv6 REF involves the following basic concepts.

Routing Table

An IPv4/IPv6 routing table stores routes to the specific destinations and contains topology information. During packet forwarding, IPv4/IPv6 REF selects packet transmission paths based on the routing table.

Adjacent Node

An adjacent node contains outbound interface information about routed packets, for example, next hop, next component to be processed, and link layer encapsulation. When a packet is matched with an adjacent node, the packet is directly encapsulated and then forwarded. An adjacent node table is often organized into a hash table to facilitate query and update; next hop information is organized into a load balancing entry to support load balancing. An adjacent node may not contain next hop information. It may contain indexes of next components (such as other line cards and multi-service cards) to be processed.

Proactive Resolution

REF supports next hop resolution. If the MAC address of the next hop is unknown, REF will proactively resolve the next hop. IPv4 REF requests the ARP module for next hop resolution, while IPv6 REF applies the ND module for resolution.

Packet Forwarding Path

Packets are forwarded based on their IPv4/IPv6 addresses. If the source and destination IPv4/IPv6 addresses of a packet are specified, the forwarding path of this packet is determined.

1.3.1 Load Balancing Policies

Load balancing is configured to distribute traffic load among multiple network links.

Working Principle

REF supports two load balancing modes. In the REF model, a route prefix is associated with multiple next hops, that is, a multi-path route is used. The route will be associated with a load balancing table and implement weight-based load balancing. When an IPv4/IPv6 packet is matched with a load balancing entry based on the longest prefix match, REF performs hash calculation based on the IPv4/IPv6 address of the packet and selects a path to forward the packet.

IPv4/IPv6 REF supports two types of load balancing policies: load balancing based on destination IP address and based on the source and destination IP addresses.

Related Configuration

Configuring Load Balancing Based on IPv4 Source and Destination Addresses

- By default, load balancing is implemented based on IPv4 destination addresses.
- Run the **ip ref load-sharing** { **original** | **original**-**only** } command to configure load balancing.
- Then load balancing is implemented based on IPv4 source and destination addresses.

Configuring Load Balancing Based on IPv6 Source and Destination Addresses

- By default, load balancing is implemented based on IPv6 destination addresses.
- Run the **ipv6 ref load-sharing original** command to configure the load balancing.
- Then load balancing is implemented based on IPv6 source and destination addresses.

1.4 Configuration

Configuration	Description and Command	
Configuring Load Balancing Policies	⚠ Optional.	
	ip ref load-sharing { original | original-only }	Enables the load balancing algorithm based on IPv4 source and destination addresses.
	ipv6 ref load-sharing original	Enables the load balancing algorithm based on IPv6 source and destination addresses.

1.4.1 Configuring Load Balancing Policies

Configuration Effect

REF supports the following two types of load balancing policies:

- Destination address-based load balancing indicates performing hash calculation based on the destination address of a packet. The path with a greater weight is more likely to be selected. This policy is used by default.
- Load balancing based on source and destination addresses indicates hash calculation based on source and destination addresses of a packet. The path with a greater weight is more likely to be selected.

Notes

N/A

Configuration Step

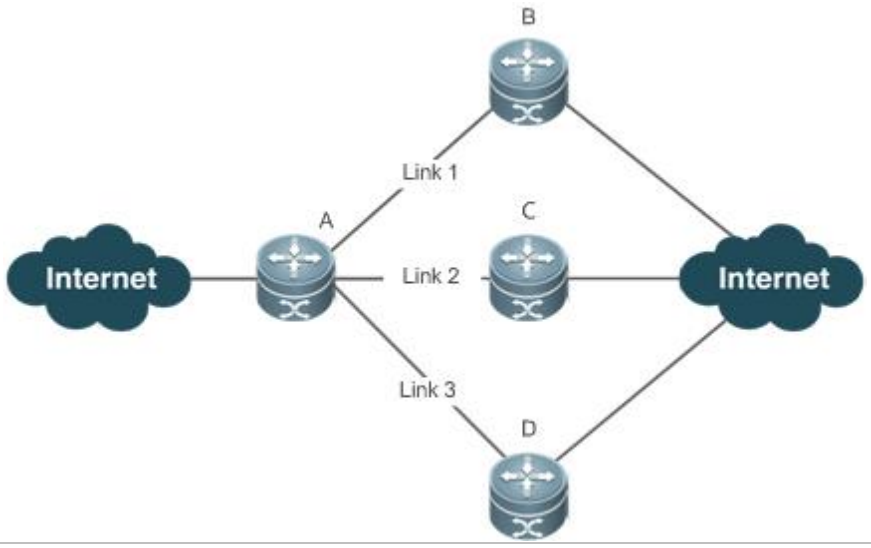
- Optional.
- Perform this configuration if you want to implement load balancing based on source and destination IP addresses.
- Perform this configuration on a router that connects multiple links.

Verification

- Run the **show ip ref adjacency statistic** command to display the IPv4 load balancing policy.
- Run the **show ipv6 ref adjacency statistic** command to display the IPv6 load balancing policy.

Related Commands

Configuring Load Balancing Based on IPv4 Source and Destination Addresses



Command	**ip ref load-sharing** { **original** | **original-only** }
Parameter Description	**Original**: Configures load balancing based on IPv4 source and destination addresses. **original-only**: Configures load balancing based on IPv4 source addresses.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Load Balancing Based on IPv6 Source and Destination Addresses

Command	**ipv6 ref load-sharing original**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring Load Balancing Based on Source and Destination IP Addresses

Scenario **Figure 1-2**	
	A route prefix is associated with three next hops on device A, namely, link 1, link 2, and link 3.
Configuration Steps	● Configure load balancing based on IPv4 source and destination IP addresses on device A.

A	`A#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`A(config)#ip ref load-sharing original`

Verification	
	`A #show ip ref adjacency statistics` `adjacency balance table statistic:`

```
    source-dest-address load-sharing
    balance: 0

adjacency node table statistic:
    total  : 3
    local  : 1
    glean  : 0
    forward: 0
    discard: 0
    mcast  : 1
    punt   : 1
    bcast  : 0
```

1.5 Monitoring

Displaying REF Packet Statistics

REF packet statistics includes the number of forwarded packets and the number of packets discarded due to various causes. You can determine whether packets are forwarded as expected by displaying and clearing REF packet statistics.

Command	Description
show ip ref packet statistics	Displays IPv4 REF packet statistics.
clear ip ref packet statistics	Clears IPv4 REF packet statistics.
show ipv6 ref packet statistics	Displays IPv6 REF packet statistics.
clear ipv6 ref packet statistics	Clears IPv6 REF packet statistics.

Displaying Adjacency Information

You can run the following commands to display adjacency information.

Command	Description
show ip ref adjacency [**glean** | **local** | *ip-address* | **interface** *interface_type interface_number* | **discard** | **statistics**]	Displays gleaned adjacencies, local adjacencies, adjacencies of a specified IP address, adjacencies associated with a specified interface, and all adjacent nodes in IPv4 REF.
show ipv6 ref adjacency [**glean** | **local** | *ipv6-address* | **interface** *interface_type interface_number* | **discard** | **statistics**]	Displays gleaned adjacencies, local adjacencies, adjacencies of a specified IPv6 address, adjacencies associated with a specified interface, and all adjacent nodes in IPv6 REF.

Displaying Active Resolution Information

You can run the following commands to display next hops to be resolved.

Command	Description
show ip ref resolve-list	Displays the next hop to be resolved .
show ipv6 ref resolve-list	Displays the next hop to be resolved.

Displaying Packet Forwarding Path Information

Packets are forwarded based on their IPv4/IPv6 addresses. If source and destination IPv4/IPv6 addresses of a packet are specified, the forwarding path of this packet is determined. Run the following commands and specify the IPv4/IPv6 source and destination addresses of a packet. The forwarding path of the packet is displayed, for example, the packet is discarded, sent to a CPU, or forwarded. Furthermore, the interface that forwards the packet is displayed.

Command	Description
show ip ref exact-route *source-ipaddress destination_ipaddress*	Displays the forwarding path of a packet. oob indicates the out-of-band management network.
show ipv6 ref exact-route *source-ipv6-address destination-ipv6-address*	Displays the forwarding path of an IPv6 packet. oob indicates the out-of-band, management network.

Displaying Route Information in an REF Table

Run the following commands to display route information in an REF table.

Command	Description
show ip ref route [**default** | {*ip-address mask*}| **statistics**]	Displays route information in the IPv4 REF table. The parameter **default** indicates a default route. oob indicates the out-of-band management network.
show ipv6 ref route [**default** | **statistics** | *prefix/len*]	Displays route information in the IPv6 REF table. The parameter **default** indicates a default route. oob indicates the out-of-band management network.

1 Configuring FPM

1.1 Overview

The flow platform (FPM) is designed to accelerate packet processing. By identifying flow attributes of IP packets before service processing, the FPM enhances the efficiency of service handling. As a core component of the system, the FPM is initialized at startup. This document provides configuration commands for configuring and managing the FPM. Typically, the default configuration of the FPM is sufficient to meet practical needs.

The following sections describe the FPM only.

Protocols and Standards

N/A

1.2 Applications

Application	Description
Configuring the Packet Receiving Threshold	When the device receives a large number of repeated TCP connection requests on a local area network (LAN), perform FPM configuration to effectively defend against such attacks.
Configuring Loose TCP Status Check	Perform an active/standby switchover in the AS environment.

1.2.1 Configuring the Packet Receiving Threshold

Scenario

When the device receives a large number of repeated TCP connection requests on a LAN, no valid connection can be established if the device cannot receive any handshake response packet from the peer. In this case, attacks may occur. You can perform FPM configuration to restrict the number of TCP connection requests, so as to effectively defend against such attacks.

Protocols

- Enable the strict packet status tracing function on the forwarding device.
- Configure a low TCP-SYN-SENT packet threshold.

1.2.2 Configuring Loose TCP Status Check

Scenario

Loose TCP status check needs to be configured on the device to prevent flow interruption during an active/standby switchover of the device. Then a connection can be established and packets can be forwarded as long as one end sends an ACK packet, so that the connection is not interrupted during the active/standby switchover.

Protocols

- Configure loose TCP status check on the backup device.

1.3 Features

Basic Concepts

Flow Entry

A flow entry is a physical resource for the device to identify and manage all connections of an IP session, and records basic information about the current IP session. The corresponding protocols include Internet Control Message Protocol (ICMP), Transmission Control Protocol (TCP), User Datagram Protocol (UDP), and Raw Internet Protocol (RAWIP).

Overview

Feature	Description
Transparent Transmission of Packets When the Flow Table Is Full	Ensures that existing flows are not interrupted when the flow table is full.
Flow Entry Aging	Reclaims invalid flow entries.
Number of Packets Permitted in a Flow	Prevents IP packet flooding attacks.
TCP Status Tracing	Filters out packets on invalid TCP connections.
Loose TCP Status Check	Allows establishment of a connection with only ACK packets.

1.3.1 Transparent Transmission of Packets When the Flow Table Is Full

Working Principle

Acceleration of IP service processing relies on a flow table. Flow table resources are configured based on the device hardware configuration and typically meet application requirements. However, in extreme environments, flow table resources may be exhausted, preventing new flows from being established. With this feature, when the flow table is full, packets are transparently transmitted without establishing any flow on the device, and service processing is not accelerated. This approach ensures that service flows are not interrupted.

1.3.2 Flow Entry Aging

Working Principle

Aging of a flow entry occurs when the device proactively withdraws the flow entry after a specified period of inactivity. This mechanism helps address the issue of flow table saturation, which can prevent new sessions from being established during a session attack. To manage this, the flow table aging feature is used. The aging time should be adjusted based on the type of data and the state of the flows. For instance, the aging time for a TCP flow in the SYN state differs from that of a TCP flow in ESTABLISHED state. In cases such as port scanning attacks, where system resources are consumed by numerous connections, configuring appropriate aging time values for different flow states can help efficiently reclaim flow entries and prevent interruptions. Setting the right aging time helps reduce unnecessary flow entries while still supporting the exchange of service data flows.

1.3.3 Number of Packets Permitted in a Flow

Working Principle

A count of the number of packets processed for each flow in its current state is maintained. By configuring the number of packets allowed through for each flow state, you can effectively address the issue of other packets not being processed in a timely manner during high-volume attacks of a particular type of packet, thus ensuring the exchange of service data flows.

1.3.4 TCP Status Tracing

Working Principle

A complete handshake process is required for establishment of a TCP connection; otherwise, the connection is invalid or packets are attack packets. The FPM needs to trace the state of TCP connections, so as to distinguish flows that are established over TCP session connections in various states and determine whether the connections are valid. In some special scenarios such as asymmetrical routing, the state of TCP connections cannot be traced and this function should be disabled.

1.3.5 Loose TCP Status Check

Working Principle

A complete handshake process is required for establishment of a valid TCP connection. In some cases such as active/standby switchover, however, a handshake process may have been performed for the current TCP connection but no corresponding information exists. In such cases, the system requires only ACK packets. In this case, the FPM provides loose TCP status check.

1.4 Configuration

Configuration	Description and Command	
Disabling Transparent Transmission of Packets When the Flow Table Is Full	(Optional) It is used to disable the device from transparently transmitting packets when the flow table is full.	
	ip session direct-trans-disable	Disables the device from transparently transmitting packets when the flow table is full.
Configuring the Flow Entry Aging Time	(Optional) It is used to configure the aging time.	
	ip session timeout	Configures the flow entry aging time.
Configuring the Number of Packets Permitted in a Flow	(Optional) It is used to configure the number of packets that can be received for each flow in certain state.	
	ip session threshold	Configures the number of packets that can be received for each flow in certain state.
Enabling the TCP Status Tracing Function	(Optional) It is used to enable the TCP status tracing function.	
	ip session tcp-state-inspection-enable	Enables the TCP status tracing function.
Configuring Loose TCP Status Check	(Optional) It is used to enable the loose TCP status transition check function.	

Configuration	Description and Command	
	ip session tcp-loose	Enables the loose TCP status transition check function.

1.4.1 Disabling Transparent Transmission of Packets When the Flow Table Is Full

Networking Requirements

- For some special services such as Network Address Translation (NAT) applied on devices, the FPM should not allow transparent transmission of packets when no flow is established.

Notes

- By default, packets can be transparently transmitted without flow establishment when the flow table is full.

Configuration Step

- Optional.
- By default, packets can be transparently transmitted without flow establishment when the flow table is full. You can use the **ip session direct-trans-disable** command to disable the function.

Command	**ip session direct-trans-disable**
Parameter Description	N/A
Defaults	Packets can be transparently transmitted without flow establishment when the flow table is full.
Command Mode	Global configuration mode
Usage Guide	Use the **no** form of this command to enable the transparent transmission function.

Verification

- Use the **show running-config** command to check whether the configuration includes **ip session direct-trans-disable**. If not, the transparent transmission function is enabled.

Configuration Example

Scenario	If the NAT service is required on the wireless device, you need to disable the transparent transmission function because the NAT service does not allow transparent transmission of IP packets without flow establishment.
Configuration Steps	Disable transparent transmission of packets without flow establishment when the flow table is full.
	`Hostname# configure terminal` `Hostname(config)# ip session direct-trans-disable`
Verification	Use the **show running-config** command to verify that the configuration includes **ip session direct-trans-disable**.

Common Errors

N/A

1.4.2 Configuring the Flow Entry Aging Time

Networking Requirements

- Make use of system flow table resources so as to reduce invalid flow entries in the flow table and meet the requirement for exchanging service data flows.

Notes

- There is a default aging time upon system initialization, which can meet requirements in most scenarios. Therefore, the configuration is optional.
- Because a certain time is required before the system detects the corresponding flow, the actual aging time is later than the configured aging time.

Configuration Step

Configuring the Aging Time

- Optional.
- By default, a flow entry ages within the default aging time. If the default aging time does not meet the requirement, you can use the **ip session timeout** command to change it. A longer aging time indicates a longer time-to-live (TTL) of the flow entry.
- Perform this configuration on the corresponding forwarding device.

Command	**ip session timeout** {**icmp-closed | icmp-connected | icmp-started | rawip-closed | rawip-connected | rawip-established | rawip-started | tcp-close-wait | tcp-closed | tcp-established | tcp-fin-wait1 | tcp-fin-wait2 | tcp-syn-receive | tcp-syn-sent | tcp-syn-sent2 | tcp-time-wait | udp-closed | udp-started | udp-connected | udp-established**} { *num* }
Parameter Description	**icmp-closed**: Sets the aging time of ICMP flows in closed state, which is 10 seconds by default and ranges from 5 to 60. **icmp-connected**: Sets the aging time of ICMP flows in connected state, which is 10 seconds by default and ranges from 5 to 120. **icmp-started**: Sets the aging time of ICMP flows in started state, which is 10 seconds by default and ranges from 5 to 120. **rawip-closed**: Sets the aging time of RAWIP flows in closed state, which is 10 seconds by default and ranges from 5 to 60. **rawip-connected**: Sets the aging time of RAWIP flows in connected state, which is 300 seconds by default and ranges from 10 to 300. **rawip-established**: Sets the aging time of RAWIP flows in established state, which is 300 seconds by default and ranges from 10 to 600. **rawip-started**: Sets the aging time of RAWIP flows in started state, which is 300 seconds by default and ranges from 10 to 300. **tcp-close-wait**: Sets the aging time of TCP flows in tcp-close-wait state, which is 60 seconds by default and ranges from 10 to 120. **tcp-closed**: Sets the aging time of TCP flows in tcp-closed state, which is 10 seconds by default and ranges from 5 to 20.

	tcp-established: Sets the aging time of TCP flows in tcp-established state, which is 1,800 seconds by default and ranges from 300 to 604,800. **tcp-fin-wait1**: Sets the aging time of TCP flows in tcp-fin-wait1 state, which is 60 seconds by default and ranges from 10 to 120. **tcp-fin-wait2**: Sets the aging time of TCP flows in tcp-fin-wait2 state, which is 60 seconds by default and ranges from 10 to 120. **tcp-syn-sent**: Sets the aging time of TCP flows in tcp-syn-sent state, which is 10 seconds by default and ranges from 5 to 30. **tcp-syn_sent2**: Sets the aging time of TCP flows in tcp-syn_sent2 state, which is 10 seconds by default and ranges from 5 to 30. **tcp-syn-receive**: Sets the aging time of TCP flows in tcp-syn-receive state, which is 10 seconds by default and ranges from 5 to 30. **tcp-time-wait**: Sets the aging time of TCP flows in tcp-time-wait state, which is 10 seconds by default and ranges from 5 to 60. **udp-closed**: Sets the aging time of UDP flows in closed state, which is 10 seconds by default and ranges from 5 to 60. **udp-connected**: Sets the aging time of UDP flows in connected state, which is 30 seconds by default and ranges from 10 to 300. **udp-established**: Sets the aging time of UDP flows in established state, which is 600 seconds by default and ranges from 120 to 600. **udp-started**: Sets the aging time of UDP flows in started state, which is 10 seconds by default and ranges from 10 to 300. **num**: Sets the aging time
Defaults	Default values are used by default.
Command Mode	Global configuration mode
Usage Guide	Use the **no** form of the command to restore the default aging time.

Verification

- Use the **show running-config** command to check whether the configuration includes **ip session timeout**. If not, the default aging time applies.

Configuration Example

Scenario	If there are a large number of UDP-established flows which occupy a great space of the flow table on the forwarding device, you can shorten the aging time of the UDP-established flows to improve aging efficiency.
Configuration Steps	If the firewall card is used for forwarding, set the aging time of flows in udp-established state to 120 seconds.
	`Hostname# configure terminal` `Hostname(config)# ip session timeout udp-established 120`
Verification	The aging time should be 120 seconds. Use the **show running-config** command to verify that the configuration contains the following item: `ip session timeout udp-established 120` This indicates that the aging time is 120s.

Common Errors

N/A

1.4.3 Configuring the Number of Packets Permitted in a Flow

Networking Requirements

- By configuring the number of packets allowed through for each flow state, you can effectively address the issue of other packets not being processed in a timely manner during high-volume attacks of a particular type of packet, thus ensuring the exchange of service data flows.

Notes

- There is a default packet count upon system initialization, which can meet requirements in most scenarios. Therefore, the configuration is optional.
- The check function is disabled by default. To enable the check function, you need to configure packet threshold check for flows in various states first.

Configuration Step

- Optional.
- By default, a flow is determined according to the default number of packets permitted to pass in the flow. If the default number of packets permitted to pass does not meet the requirement, you can use the **ip session** [*dev*] [*slot*] **threshold** command to change the number of packets allowed to pass in the corresponding flow. A greater value indicates more packets permitted to pass in the flow.
- Perform this configuration on each forwarding device as necessary.

Command	**ip session threshold** { icmp-closed | **icmp-started** | rawip-closed | **tcp-syn-sent** | **tcp-syn-receive** | **tcp-closed | udp-closed** } *num*
Parameter Description	**icmp-closed**: Sets the number of packets permitted to pass in each ICMP flow in closed state, which is 10 by default and ranges from 1 to 2000000000. **icmp-started**: Sets the number of packets permitted to pass in each ICMP flow in started state, which is 300 by default and ranges from 5 to 2000000,000. **rawip-closed**: Sets the number of packets permitted to pass in each RAWIP flow in closed state, which is 10 by default and ranges from 1 to 2000000000. **tcp-syn-sent**: Sets the number of packets permitted to pass in each TCP flow in syn-send state, which is 10 by default and ranges from 10 to 2000000,000. **tcp-syn-receive**: Sets the number of packets permitted to pass in each TCP flow in syn-receive state, which is 20 by default and ranges from 5 to 2000000000. **tcp-closed**: Sets the number of packets permitted to pass in each TCP flow in closed state, which is 20 by default and ranges from 5 to 2000000000. **udp-closed**: Sets the number of packets permitted to pass in each UDP flow in closed state, which is 10 by default and ranges from 1 to 2000000000. *num*: Sets the number of packets permitted to pass
Command Mode	Global configuration mode

Usage Guide	Use the **no** form of the command to restore the default number of packets permitted to pass.

Verification

- Use the **show running-config** command to check whether the configuration includes **ip session threshold**. If not, the default values about the number of packets permitted to pass is used.

Configuration Example

Scenario	When a large number of ping packets exist on a network, a flooding attack may occur. You can configure the number of packets permitted to pass in each ICMP flow in icmp-started state, so as to deny such ping packets.
Configuration Steps	If a firewall card is used for forwarding, set the number of packets permitted to pass in each ICMP flow in icmp-started state to 10.
	`Hostname# configure terminal` `Hostname(config)# ip session threshold icmp-started 10`
Verification	The number should be 10. Use the **show running-config** command to verify that the configuration contains the following item: `ip session threshold icmp-started 10` This indicates that the number of packets permitted to pass in each ICMP flow in icmp-started state is 10.

Common Errors

N/A

1.4.4 Enabling the TCP Status Tracing Function

Networking Requirements

- The TCP status tracing function needs to be enabled on corresponding devices.

Notes

- By default, the TCP status tracing function is disabled on devices.

Configuration Step

- Optional.
- The TCP status tracing function is disabled by default. You can use the **ip session tcp-state-inspection-enable** command to enable it.

Command	**ip session tcp-state-inspection-enable**
Parameter Description	N/A
Defaults	The TCP status tracing function is disabled.
Command Mode	Global configuration mode
Usage Guide	Use the **no** form of this command to restore the default setting of the TCP status tracing function.

Verification

- Use the **show running-config** command to check whether the configuration includes **ip session tcp-state-inspection-enable**. If no, the TCP status tracing function is disabled.

Configuration Example

Scenario	The TCP status tracing function needs to be enabled on the wireless forwarding device.
Configuration Steps	Enable the TCP status tracing function on the device.
	`Hostname# configure terminal` `Hostname(config)# ip session tcp-state-inspection-enable`
Verification	Use the **show running-config** command to verify that the configuration includes **ip session tcp-state-inspection-enable**.

Common Errors

N/A

1.4.5 Configuring Loose TCP Status Check

Networking Requirements

- A flow can be directly established with only ACK packets.

Notes

- By default, a flow cannot be directly established for ACK packets on firewalls, and can be directly established for ACK packets on EG devices.
- This configuration is optional.

Configuration Step

- Optional.
- By default, the loose TCP status check function is disabled on firewalls. You can use the **ip session tcp-loose** command to enable the loose TCP status check function. By default, the loose TCP status check function is enabled on all wireless and EG devices.
- The loose TCP status check function is required on the standby device in a scenario such as active/standby switchover.

Command	**ip session tcp-loose**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use the **no** form of this command to restore the default configuration.

Verification

- Use the **show running-config** command to check whether the configuration includes **ip session tcp-loose**. If not, the loose TCP status check function is disabled.

Configuration Example

Scenario	If the device functions as the firewall card of the backup device, an active/standby switchover is required. Perform this configuration on the backup device.
Configuration Steps	Enable the loose TCP status check function on the device.
	`Hostname# configure terminal` `Hostname(config)# ip session tcp-loose`
Verification	Use the **show running-config** command to verify that the configuration includes **ip session tcp-loose**.

Common Errors

N/A

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Function
clear ip fpm counters	Clears counters about IPv4 packets.
clear ip v6fpm counters	Clears counters about IPv6 packets.

Displaying

Command	Function
show ip fpm counters	Displays the counters about the IPv4 packets.
show ip v6fpm counters	Displays the counters about the IPv6 packets.
show ip fpm flows	Displays IPv4 packet flow information.
show ip fpm flows filter	Displays IPv4 packet flow information except specific IPv4 packet flows.
show ip v6fpm flows	Displays IPv6 packet flow information.
show ip fpm statistics	Displays IPv4 flow statistics.
show ip v6fpm statistics	Displays IPv6 flow statistics.

1 Configuring SAVI

1.1 Overview

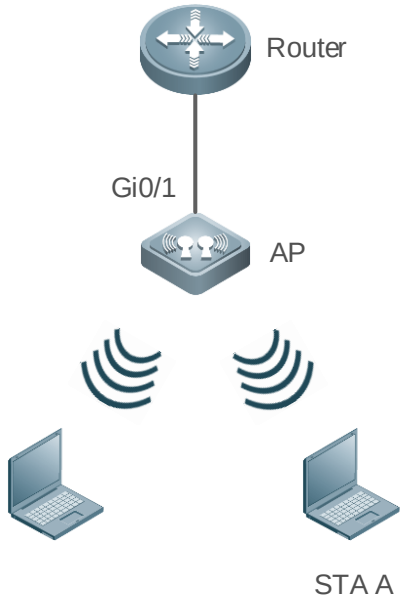
Source Address Validation Improvement (SAVI) establishes binding entries between the source IPv4/IPv6 addresses and anchors (or source MAC addresses and port numbers of access devices) for access devices through Control Packet Snooping (CPS) so as to verify the source addresses of IP packets through a specified interface. The records in the binding table are sourced from ND snooping, DHCPv6 snooping, and the static address configuration. Only packets whose source addresses match binding entries will be forwarded. This ensures the authenticity of source addresses of data packets over the network.

This document mainly describes the application of SAVI over IPv6 networks in stateful address configuration (typically DHCPv6), stateless address autoconfiguration (SLAAC), and static address configuration scenarios.

Protocols and Standards

- RFC 3315: Dynamic Host Configuration Protocol for IPv6 (DHCPv6)
- RFC 4861: Neighbor Discovery for IP version 6
- RFC 4862: IPv6 Stateless Address Autoconfiguration
- RFC 6959: SAVI Threat Scope
- RFC 6620: FCFS SAVI Improvement for Locally Assigned IPv6 Addresses
- RFC 8074: SAVI for Mixed Address Assignment Methods Scenario
- RFC 7039: SAVI Framework
- RFC 7513: Solution for DHCP

1.2 Applications



Application	Description
SLAAC-Only Scenario	Users use SLAAC to generate IPv6 addresses for communication.
DHCPv6-Only Scenario	Users use stateful address autoconfiguration to generate IPv6 addresses for communication.
SLAAC and DHCPv6 Hybrid Deployment Scenario	Users use stateful or stateless address autoconfiguration to generate IPv6 addresses for communication.

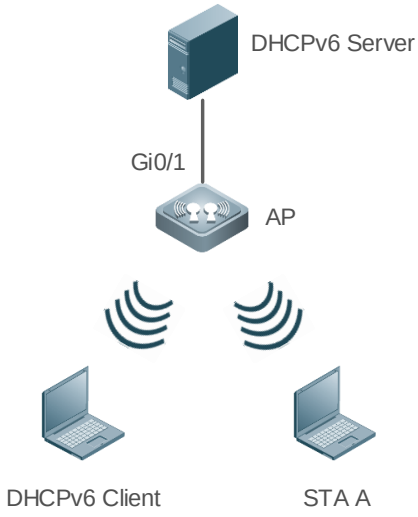
1.2.1 SLAAC-Only Scenario

Scenario

In this scenario, the hosts connect to the access device with SAVI enabled. The hosts can use only the addresses automatically configured through SLAAC for communication except the static address configured on the SAVI device.

Deployment

- Enable neighbor discovery (ND) snooping on device AP to monitor the SLAAC process.
- Configure uplink interface Gi0/1 on access device AP as an ND snooping trusted interface.
- Enable SAVI on access device AP and enable the device to receive SLAAC binding entries.
- Enable IPv6 packet filtering in the specified WLAN on the AP.



Notes	Device AP is enabled with SAVI. SLAAC User indicates a client whose IPv6 address is configured via SLAAC. STA A indicates a common client.

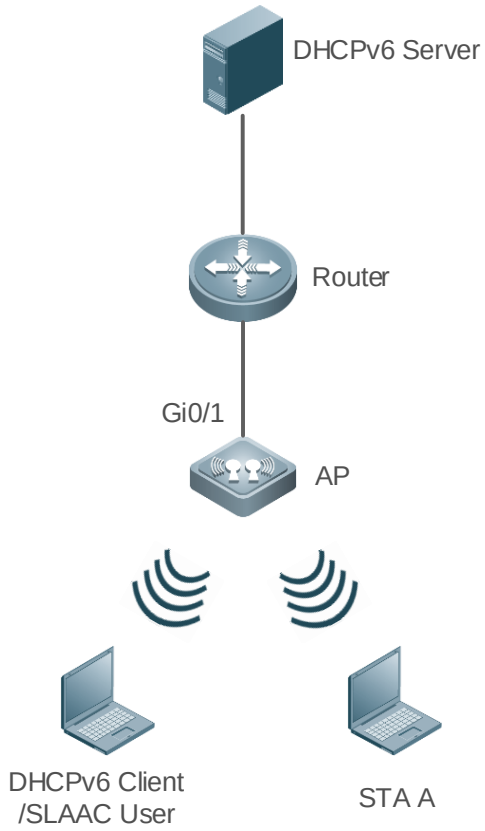
1.2.2 DHCPv6-Only Scenario

Scenario

In this scenario, the hosts connect to the access device with SAVI enabled. The hosts can use only the addresses dynamically obtained through DHCPv6 for communication except the static address configured on the SAVI device.

Deployment

- Enable DHCPv6 snooping on device AP to monitor the DHCPv6 process.
- Configure uplink interface Gi0/1 on access device AP as a DHCPv6 snooping trusted interface.
- Enable SAVI on access device AP and enable the device to receive DHCPv6 binding entries.
- Enable IPv6 packet filtering in the specified WLAN on the AP.



Notes	Device AP is enabled with SAVI. DHCPv6 Client obtains an IPv6 address via DHCPv6. STA A indicates a common client.

1.2.3 SLAAC and DHCPv6 Hybrid Deployment Scenario

Scenario

In this scenario, the hosts connect to the access device with SAVI enabled. The hosts use the addresses dynamically obtained through DHCPv6 or SLAAC for communication except the static address configured on the SAVI device.

Deployment

- Enable DHCPv6 snooping and ND snooping on access device AP to monitor the dynamic address obtaining.
- Configure uplink interface Gi0/1 of access device AP as a DHCPv6 snooping and ND snooping trusted interface.
- Enable SAVI on access device AP and enable the device to receive DHCPv6 and SLAAC binding entries.
- Enable IPv6 packet filtering in the specified WLAN on the AP.

Notes	Device AP is enabled with SAVI.

	DHCPv6 Client/SLAAC User indicates a client that can obtain an IPv6 address through SLAAC or DHCPv6. STA A indicates a common client.

1.3 Features

Basic Concepts

Source IPv6 Address

It indicates the source IPv6 address field in IPv6 packets.

Source MAC Address

It indicates the source MAC address field in Layer 2 packets.

Filtering Based on the Source IPv6 Address

The IPv6 packet filtering policy checks only source IPv6 addresses of all IPv6 packets (ND packets are not checked, and DHCPv6 packets are not checked if DHCPv6 snooping is enabled on a device) passing through an interface. Only packets whose source IPv6 addresses match SAVI binding entries can pass through the interface.

Filtering Based on the Source IPv6 Address and Source MAC Address

The IPv6 packet filtering policy checks the source IPv6 addresses and source MAC addresses of all IPv6 packets and allows only the packets matching the SAVI binding entries to pass through.

ND Snooping

ND snooping enables a device to snoop the SLAAC process of a client, extract the client's IPv6 address and MAC address from a packet, and generate a binding entry based on extracted information together with the client's port number (wired interface index or WLAN ID) and VLAN ID recorded by the device.

DHCPv6 Snooping

DHCPv6 snooping enables a device to snoop the process that a client obtains a dynamic IPv6 address through DHCPv6, extract the client's IPv6 address, MAC address, and lease from a packet, and generate a binding entry based on extracted information together with the client port number (wired interface index or WLAN ID) and client VLAN ID recorded by the device.

Overview

Feature	Description
Checking the Source Address Fields of Packets	Checks IPv6 packets passing through an interface based on the source IPv6 addresses or source IPv6 addresses and MAC addresses.

1.3.1 Checking the Source Address Fields of Packets

IPv6 packets passing through an interface are checked based on source IPv6 addresses or source IPv6 addresses and MAC addresses. This prevents malicious users from forging packets to launch attacks.

Working Principle

A device with SAVI enabled checks the source addresses of packets passing through an interface (wired switch port, Layer 2 aggregate port, or Dot11 radio interface). The source address can also refer to a WLAN ID. Only packets whose source addresses match the SAVI binding entries or those statically configured by the administrator can pass through the interface. There are two matching methods:

Filtering Based on the Source IPv6 Address

Packets whose source IPv6 addresses match the IPv6 address set in the binding entries can pass through an interface.

Filtering Based on the IPv6 Address and MAC Address

The device with SAVI enabled forwards only packets whose Layer 2 source MAC addresses and Layer 3 source IPv6 addresses match a binding entry.

1.4 Configuration

Configuration	Description and Command	
Configuring the SAVI Service	(Mandatory) It is used to enable the SAVI service.	
	savi ipv6 check source ip-address	Enables source IPv6 address check or source IPv6-MAC check in interface configuration mode.
	(Optional)	
	savi ipv6 source binding	Configures static binding users in global configuration mode.
	savi ipv6 check source exclude-vlan	Disables the check on IPv6 packets from a specified VLAN in interface configuration mode.
	savi ipv6 bind-source add	Adds the source of binding entries in global configuration mode.
	savi ipv6 check permit link-local	Configures SAVI to permit packets from link-local addresses and unspecified addresses in global configuration mode.

1.4.1 Configuring the SAVI Service

Configuration Effect

- The source IPv6 address field in incoming IPv6 packets is checked.

Notes

- After SAVI is enabled, an interface will deny all data packets whose source IPv6 addresses are not in the binding list. Only ICMPv6 packets with types 133, 134, 135, 136, 137, and 143 are permitted to pass through the interface; DHCPv6 packets are also permitted to pass through the interface after DHCPv6 snooping is enabled.
- SAVI-related commands can be configured only after SAVI is enabled globally.

Configuration Steps

Adding the Source of SAVI Binding Entries

- This function is enabled by default. Binding entries generated during the SLAAC and DHCPv6 processes are snooped and used as the sources of dynamic binding entries by default. Binding entries can also be statically configured.

Command	**savi ipv6 bind-source add** { **dhcp** | **slaac** }
Parameter Description	**dhcp**: Uses binding entries snooped and generated during the DHCPv6 process as a source of SAVI binding entries. **slaac**: Uses binding entries snooped and generated during the SLAAC process as a source of SAVI binding entries.
Command Mode	Global configuration mode
Usage Guide	Use ND snooping to snoop the SLAAC process. When entries snooped by ND snooping are configured as a source of SAVI binding entries, ND snooping needs to be enabled. DHCPv6 snooping is used to snoop the DHCPv6 process. When entries snooped by DHCPv6 snooping are configured as a source of SAVI binding entries, DHCPv6 snooping needs to be enabled.

Enabling SAVI on an Interface

- By default, SAVI is disabled on an interface.
- You can run the **savi ipv6 check source ip-address** [**mac-address**] command to enable or disable SAVI on an interface.

Typically, SAVI needs to work with DHCPv6 snooping or ND snooping. Therefore, DHCPv6 snooping or ND snooping should also be enabled. DHCPv6 snooping or ND snooping can be enabled either before or after SAVI is enabled on a Ruijie device.

Typically, SAVI is not enabled on DHCPv6 snooping or ND snooping trusted interfaces.

After SAVI is enabled on an interface, the permit rules of IPv6 packets are related to the IPv6 address binding mode of global IP address and MAC address binding. The default address binding mode is the strict mode. In this mode, if IPv4 SAVI is enabled but IPv6 SAVI is disabled on an interface, all IPv6 packets will be denied on the interface. When IPv4 SAVI is enabled but IPv6 SAVI is disabled on all interfaces, it is recommended that the IPv6 address binding mode of global IP address and MAC address binding be set to the loose mode. For details, see the "Global IP Address and MAC Address Binding Configuration" section.

Command	**savi ipv6 check source ip-address** [**mac-address**]
Parameter Description	**mac-address**: Configures SAVI filtering based on IPv6 and MAC addresses.
Command Mode	Interface configuration mode or WLAN security configuration mode
Usage Guide	By enabling SAVI on an interface through this command, users can detect packets based on the IPv6 addresses or IPv6 addresses and MAC addresses.

Disabling SAVI for Packets from a Specified VLAN on an Interface

- By default, SAVI takes effect for packets from all VLANs after being enabled on an interface.
- To disable SAVI for packets from a specified VLAN on an interface, run the **savi ipv6 check source exclude-vlan** *vid* command.

After SAVI is enabled on an interface, you can run this command to permit IPv6 packets from some VLANs.

Command	**savi ipv6 check source exclude-vlan** *vid*
Parameter Description	*vid*: Indicates the ID of a VLAN from which packets are permitted on an interface.
Command Mode	Interface configuration mode or WLAN security configuration mode
Usage Guide	Use this command to permit IPv6 packets from a specified VLAN.

Adding a Static User Record to the IPv6 Source Address Binding Database

- By default, the authorized user set that SAVI verifies is entirely derived from the binding users through DHCPv6 snooping or ND snooping.
- You can run the **savi ipv6 source binding** command to add static binding user records.

Command	**savi ipv6 source binding** *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-name interface-number* | **ip-mac** | **ip-only** | **wlan** *wlan-id* }
Parameter Description	*mac-address*: Indicates the MAC address of a statically added user. **vlan** *vlan-id*: Indicates the VLAN ID of a statically added user. The value range is from 1 to 4094. *ipv6-address*: Indicates the IPv6 address of a statically added user. **interface** *interface-name interface-number*: Indicates the wired access interface to which a statically added user is connected. **ip-mac**: Specifies that the IP address and MAC address binding type is used globally. **ip-only**: Specifies the IPv6 address binding type is used globally. **wlan** *wlan-id*: Indicates the WLAN to which a statically added user belongs. The value range is from 1 to 4094.
Command Mode	Global configuration mode
Usage Guide	Use this command to permit packets from a specified user.

Configuring SAVI to Permit Packets with Link-Local Addresses and Unspecified Addresses

- If SAVI is enabled on an interface, SAVI denies IPv6 packets from all users not in the binding list by default.
- The **savi ipv6 check permit link-local** command permits all IPv6 packets with fe80::/10 and ::/128 as source addresses.

This command is typically configured in a DHCPv6-only scenario. In this scenario, fe80::/10 addresses cannot be obtained through DHCPv6.

Command	**savi ipv6 check permit link-local**
Parameter Description	-
Command Mode	Global configuration mode
Usage Guide	After SAVI is enabled on an interface, SAVI checks the validity of source IPv6 addresses in IPv6 packets transmitted through the interface. After configuring this command, SAVI permits all IPv6 packets with fe80::/10 and ::/128 as source addresses.

Verification

Run the monitoring command provided by the device to display SAVI filtering entries.

Configuration Example

SAVI in an SLAAC-Only Scenario

Configuration Steps	● Enable ND snooping.
	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 nd snooping trust`
	`Hostname(config-if-GigabitEthernet 0/1)#exit`
	`Hostname(config)#ipv6 nd snooping enable`
	● Enable SAVI.
	`Hostname(config)# wlansec 1`
	`Hostname(config-wlansec)# savi ipv6 check source ip-address mac-address`
	`Hostname(config-wlansec)# end`

Verification	● Check the SAVI filtering entries. `Hostname# show savi ipv6 check source`

SAVI in a DHCPv6-Only Scenario

Configuration Steps	● Enable DHCPv6 snooping.
	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 dhcp snooping trust`
	`Hostname(config-if-GigabitEthernet 0/1)#exit`
	`Hostname(config)#ipv6 dhcp snooping`
	● Enable SAVI.
	`Hostname(config)# savi ipv6 check permit link-local`
	`Hostname(config)# wlansec 1`
	`Hostname(config-wlansec)# savi ipv6 check source ip-address mac-address`
	`Hostname(config-wlansec)# end`

Verification	● Check the SAVI filtering entries. `Hostname# show savi ipv6 check source`

SAVI in an SLAAC and DHCPv6 Hybrid Deployment Scenario

Configuration Steps	● Enable ND snooping.
	`Hostname# configure terminal`
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 nd snooping trust`
	`Hostname(config-if-GigabitEthernet 0/1)#exit`
	`Hostname(config)#ipv6 nd snooping enable`
	● Enable DHCPv6 snooping.
	`Hostname(config)# interface gigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)#ipv6 dhcp snooping trust`
	`Hostname(config-if-GigabitEthernet 0/1)#exit`
	`Hostname(config)#ipv6 dhcp snooping`
	● Enable SAVI.

	`Hostname(config)# wlansec 1`
	`Hostname(config-wlansec)# savi ipv6 check source ip-address mac-address`
	`Hostname(config-wlansec)# end`

Verification	● Check the SAVI filtering entries. `Hostname# show savi ipv6 check source`

Adding a Static Binding User

Configuration Steps	● Add a statically binding user.
	`Hostname# configure terminal`
	`Hostname(config)#savi ipv6 source binding 1000.1000.1000 vlan 1 2018:7::21 ip-mac`
	`Hostname(config)# end`

Verification	● Check static filtering entries.
	`Hostname(config)#show savi ipv6 check source`
	`Total entries found: 1`
	`No. Ipv6 Address Mac Address VLAN Interface Filter`
	`------ ---------- ---------- ---- --------- -------`
	`0 2018:7::21 1000.1000.1000 1 GLOBAL IP+MAC`

Common Misconfigurations

- SAVI is enabled on a DHCPv6 snooping or ND snooping trusted interface.

1.5 Monitoring

Displaying

Command	Description

show savi ipv6 source binding [*ipv6-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-name interface-number* **| wlan** *wlan-id*] [**type** { **dhcp** | **slaac** | **static** }]	Displays information of the IPv6 source address binding database.
show savi ipv6 check source [*ipv6-address* | **interface** *interface-name interface-number* | **wlan** *wlan-id*]	Displays effective IPv6 SAVI filtering entries.

Configuring IP Routing

1. Configuring Route Management
2. Configuring RIP
3. Configuring OSPFv2
4. Configuring Routing Policies
5. Configuring PBR
6. Configuring Keys

1 Configuring Route Management

1.1 Overview

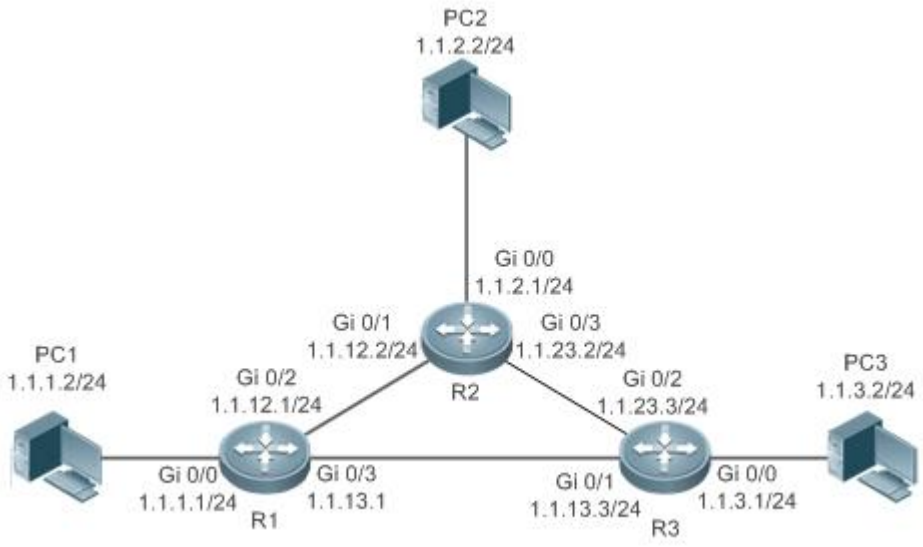
The network service module (NSM) manages the routing table, consolidates routes sent by various routing protocols, and selects and sends preferred routes to the routing table. Routes discovered by various routing protocols are stored in the routing table. These routes are classified into three types by source:

- Direct route: Is the route discovered by a link-layer protocol and is also called interface route.
- Static route: Is manually configured by a network administrator. A static route is easy to configure and has low requirements on the system, which makes it to be fit for a small-sized network that is stable and has a simple topology. However, when the network topology changes, the static route must be manually reconfigured and cannot automatically adapt to topological changes.
- Dynamic route: Is discovered by a dynamic routing protocol.

1.2 Applications

Application	Description
Basic Functions of a Static Route	Manually configure a route.
Floating Static Route	Configure a standby route in the multipath scenario.
Load Balancing Static Route	Configure load balancing static routes in the multipath scenario.
Correlation Between a Static Route and Track	Correlate a static route with track in the multipath scenario.

1.2.1 Basic Functions of a Static Route



Scenario

On a network with a simple topology, you can configure only static routes to implement interworking. Properly configuring and using static routes can improve the network performance and guarantee the bandwidth for important network applications.

As shown in Figure 1-1, to implement interworking between PC1, PC2, and PC3, you can configure static routes on R1, R2, and R3.

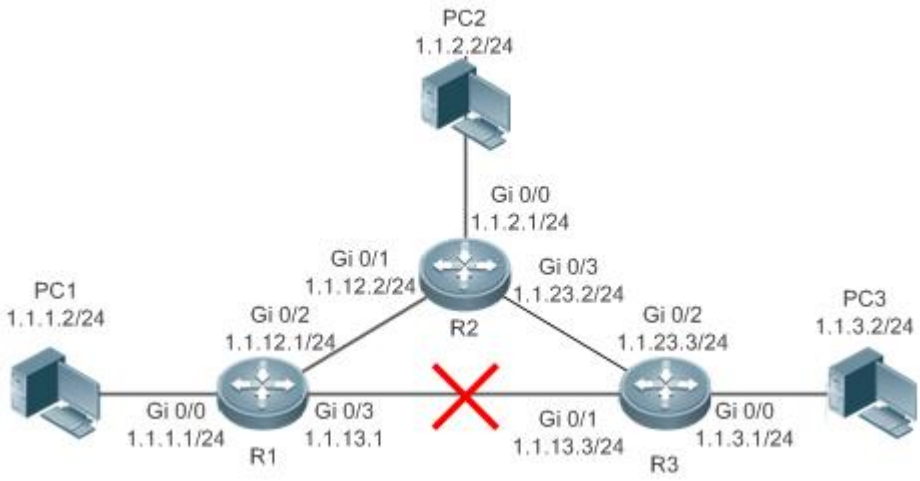
- On R1, configure a route to the network segment of PC2 through R2, and a route to the network segment of PC3 through R3.
- On R2, configure a route to the network segment of PC1 through R1, and a route to the network segment of PC3 through R3.
- On R3, configure a route to the network segment of PC1 through R1, and a route to the network segment of PC2 through R2.

Figure 1-1

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R1, R2, and R3.

1.2.2 Floating Static Route



Scenario

If no dynamic routing protocol is configured, you can configure floating static routes to implement dynamic switching of routes to prevent communication interruption caused by network connection failures.

In Figure 1-2, to prevent communication interruption caused by a line failure between R1 and R3, you can configure a floating static route respectively on R1 and R3. Normally, packets are forwarded on a path with a small administrative distance. If a link on this path is Down, the route is automatically switched to the path with a large administrative distance.

- On R1, configure two routes to the network segment of PC3, including a route through R3 (default distance = 1) and a route through R2 (default distance = 2).
- On R3, configure two routes to the network segment of PC1, including a route through R1 (default distance = 1) and a route through R2 (default distance = 2).

Figure 1-2

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R1, R2, and R3.

1.2.3 Load Balancing Static Route

Scenario

If there are multiple paths to the same destination, you can configure load balancing routes. Unlike floating routes, the administrative distances of load balancing routes are the same. Packets are distributed among these routes based on the balanced forwarding policy.

As shown in Figure 1-3, load balancing routes are configured respectively on R1 and R3, so that packets sent to the network segment of PC3 or PC1 are load balanced between two routes, including a route through R2 and a route through R4.

- On R1, configure two routes to the network segment of PC3, including a route through R2 and a route through R4.
- On R3, configure two routes to the network segment of PC1, including a route through R2 and a route through R4.

Figure 1-3

Remarks
- Load balancing is conducted based on source IP addresses by default.

- Use the **aggregateport load-balance** command on the switch to change the load balancing mode of ECMP routing.
- Use the **ip ref load-sharing original** command on the device to specify the load balancing policy for IPv4 routes.
- Use the **ipv6 ref load-sharing original** command on the device to specify the load balancing policy for IPv6 routes.

Deployment

- Configure the address and subnet mask of each interface.
- Configure static routes on R1, R2, R3, and R4.
- Configure the load balancing policy on R1 and R3.

1.2.4 Correlation Between a Static Route and Track

Whether this function is supported depends on the actual product version.

In scenarios with floating routes or load balancing routes are deployed, sometimes a fault may occur in a line but the interface status is normal; therefore, the static route cannot detect its unreachability. To solve this problem, check the reachability of the next hop of the static route. When the next hop is unreachable, switch to the backup route.

You can check whether the next hop of the static route is reachable by associating the static route with the track module.

As shown in Figure 1-4, to prevent static routes from being configured on R1 and R2, correlate the static routes with track.

- Configure static routes on R1 and R2, and specify the outbound interface or next hop as the interconnection interface.
- Correlate static routes on R1 and R2 with track, and check connectivity of the next hop of the static routes.

Figure 1-4

Deployment

- Configure IP addresses and masks for interfaces.
- Configure a track detection port.
- Configure static routes on R1 and R2, and correlate them with track.

1.3 Overview

Feature	Description
Route Computation	Generates a valid route on a device.

Optimal Route Selection	Selects an optimal route to forward packets.
Default Route	Forwards all packets and helps reduce the size of a routing table.
Route Reliability	Quickly detects routing failures and restores communication.

1.3.1 Route Computation

Routing Function

Routing functions are classified into IPv4 and IPv6 routing functions. If the routing functions are disabled, a device cannot forward packets based on routes.

Dynamic Route

A dynamic routing protocol learns remote routes and dynamically updates routes by exchanging routes with neighbors. If a neighbor is the next hop of a route and this neighbor fails, the route is unreachable.

Static Route

On a network with a simple topology, you can configure only static routes to implement interworking. Properly configuring and using static routes can improve the network performance and guarantee the bandwidth for important network applications.

Whether a static route is active is computed based on the status of the local interface. When the link status of the outbound interface of a static route is Up and assigned an IP address, this route is active and can be used for packet forwarding.

1.3.2 Optimal Route Selection

Administrative Distance

When multiple routing protocols generate routes to the same destination, priorities of these routes are determined based on the administrative distance. A smaller administrative distance indicates a higher priority.

Equal-Cost Route

If multiple routes to the same destination have different next hops but the same administrative distance, these routes are equal-cost routes. Packets are distributed among these routes to implement load balancing based on the balanced forwarding policy.

On a specific device, the total number of equal-cost routes is limited. Routes beyond the limit do not participate in packet forwarding.

Floating Route

If multiple routes to the same destination have different next hops and different administrative distances, these routes are floating routes. The route with the smallest administrative distance will be first selected for packet forwarding. If this route is unreachable, a route with a larger administrative distance is further selected for forwarding, thus preventing communication interruption caused by a network line failure.

1.3.3 Default Route

In the forwarding routing table, the route with the destination network segment 0.0.0.0 and the subnet mask 0.0.0.0 is the default route. Packets that cannot be forwarded by other routes will be forwarded by the default route. The default route can be statically configured or generated by a dynamic routing protocol.

Default Gateway

On a Layer 2 device, the **ip default gateway** command can be used to generate a default route.

Static Default Route

On a Layer 3 switch, a static route with the network segment 0.0.0.0 and the subnet mask 0.0.0.0 is configured to generate the default route.

Default Network

The default network is configured to generate a default route. If the **ip default-network** command is configured to specify a network (a classful network, such as a Class A, B, or C network), and information about this network exists in the routing table, the router will use this network as the default network and the next hop of this network is the default gateway. As the network specified by the **ip default-network** command is a classful one, if this command is used to identify a subnet in a classful network, the router automatically generates a static route of the classful network but not any default route.

1.3.4 Route Reliability

When a device on a network fails, some routes may become unreachable, causing traffic interruptions. Real-time detection of reachability of the next hop of the route can result in immediate route recalculation or switching to a backup route when a failure occurs.

Correlation with Track

Whether this function is supported depends on the actual product version.

A track object can be used to track whether an IP address is reachable or whether an interface is Up. Correlating dynamic or static routing protocols with track can enable them to quickly detect unreachability of the next hop and respond promptly.

1.4 Configuration

Configuration Item	Description and Command	
Configuring a Static Route	(Mandatory) It is used to configure a static route.	
	ip route	Configures an IPv4 static route.
	ipv6 route	Configures an IPv6 static route.
Configuring a Default Route	(Optional) It is used to configure the default gateway.	
	ip default gateway	Configures an IPv4 default gateway on a Layer 2 device.

Configuration Item	Description and Command	
	ipv6 default gateway	Configures an IPv6 default gateway on a Layer 2 device.
	ip route 0.0.0.0 0.0.0.0 *gateway*	Configures an IPv4 default gateway on a Layer 3 device.
	ipv6 route ::/0 *ipv6-gateway*	Configures an IPv6 default gateway on a Layer device.
	ip default network	Configures an IPv4 default network on a Layer 3 device.
Configuring Route Limitations	(Optional) It is used to limit the number of equal-cost routes and number of static routes, or disable routing.	
	maximum-paths	Configures the maximum number of equal-cost routes.
	ip static route-limit	Configures the maximum number of IPv4 static routes.
	ipv6 static route-limit	Configures the maximum number of IPv6 static routes.
	no ip routing	Disables IPv4 routing.
	noipv6 unicast-routing	Disables IPv6 routing.

1.4.1 Configuring a Static Route

Configuration Effect

- Generate a static route in the routing table. Use the static route to forward packets to a remote network.

Notes

- This configuration cannot be performed on a Layer 2 device.
- If the **no ip routing** command is configured on a Layer 3 switch, you cannot configure IPv4 static routes on this switch, and existing IPv4 static routes will also be deleted. Before the device is restarted, reconfiguring the **ip routing** command can restore the deleted IPv4 static routes. After the device is restarted, deleted IPv4 static routes cannot be restored.
- To correlate static routes with track, you must first create a track object using the **track** command.

Configuration Step

Configuring a Static IPv4 Route

Configure the following command on an IPv4-enabled router.

Command	**ip route** *network net-mask* { *ip-address* [**global**] | *interface* [*ip-address*] } [*distance* | **description** *description-text* | [**disabled** | **enabled**] | [**track** *object-number*] [**permanent**] | **tag** *tag* | **weight** *number*] *	
Parameter Description	*network*	Indicates the address of the destination network.
	net-mask	Indicates the mask of the destination network.
	ip-address	(Optional) Indicates the next-hop address of the static route. You must specify at least one of *ip-address* and *interface,* or both of them. If *ip-address* is not specified, a static direct route is configured.
	global	(Optional) Indicates that the next hop belongs to a global VRF.

	interface	(Optional) Indicates the next-hop outbound interface of the static route. You must specify at least one of *ip-address* and *interface,* or both of them. If *interface* is not specified, a recursive static direct route is configured. The outbound interface is obtained by the next hop in the routing table.
	distance	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	description*description-text*	(Optional) Indicates the description of the static route. The value is a string of 1 to 60 characters. By default, no description is configured.
	disabled/enabled	(Optional) Indicates whether the static route is enabled. The default value is **enabled**.
	track *object-number*	(Optional) Correlates with track. *object-number* specifies the track object ID. Correlation with track is disabled by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	tag *tag*	(Optional) Indicates the tag of the static route. The default value is 0.
	weight *number*	(Optional) Indicates the weight of the static route. The default value is 1.
	all	(Optional) Deletes all static routes.
Defaults	By default, no static route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is **ip route** *networknet-maskip-address.* When correlating static routes with the track object that is detected in Down state, the static route becomes invalid and cannot be used for packet forwarding.	

Configuring an IPv6 Static Route

Configure the following command on an IPv6-enabled router.

Command	**ipv6 route** *ipv6-prefix/prefix-length* { *ipv6-address* | *interface* [*ipv6-address*] } [*distance* | **description** *description-text* | **tag** *tag* | **weight** *number*] *	
Parameter Description	*ipv6-prefix*	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC 4291.
	prefix-length	Indicates the length of an IPv6 prefix. Note that a slash (/) must be added following the length.
	ipv6-address	(Optional) Indicates the next-hop address of the static route. You must specify at least one of *ipv6-address* and *interface,* or both of them. If *ipv6-address* is not specified, a static direct route is configured.
	interface	(Optional) Indicates the next-hop outbound interface of the static route. You must specify at least one of *ipv6-address* and *interface,* or both of them. If *interface* is not specified, a recursive static direct route is configured. The outbound interface is obtained by the next hop in the routing table.
	distance	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	description*description-text*	(Optional) Indicates the description of the static route. The value is a string of 1 to 60 characters. By default, no description is configured.

	tag *tag*	(Optional) Indicates the tag value of a static route. The value range is from 1 to 4294967295 and the default value is 0.
	weight *number*	(Optional) Indicates the weight of a static route, which must be specified when you configure equal-cost routes. The value range is from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
Defaults	By default, no static route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is **ipv6 route***ipv6-prefix / prefix-lengthipv6-address.*	

Verification

- Run the **show ip route** command to display the IPv4 routing table and check whether the configured IPv4 static route takes effect.
- Run the **show ipv6 route** command to display the IPv6 routing table and check whether the configured IPv6 static route takes effect.

Configuration Example

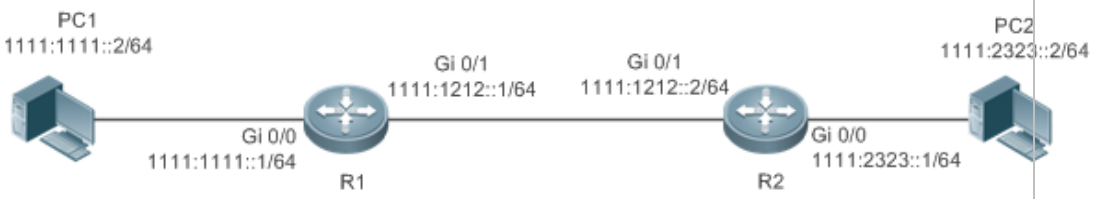
Configuring Static Routes to Implement Interworking of the IPv4 Network

Scenario Figure 1-5	
Configuration Steps	● Configure interface addresses on each device.

R1	`R1#configure terminal`
	`R1(config)#interface gigabitEthernet 0/0`
	`R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0`
	`R1(config-if-GigabitEthernet 0/0)# exit`
	`R1(config)#interface gigabitEthernet 0/2`
	`R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0`
	`R1(config-if-GigabitEthernet 0/0)# exit`
	`R1(config)#interface gigabitEthernet 0/3`

	R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0
R2	R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/3 R2(config-if-GigabitEthernet 0/3)# ip address 1.1.23.2 255.255.255.0
R3	R3#configure terminal R3(config)#interface gigabitEthernet 0/0 R3(config-if-GigabitEthernet 0/0)# ip address 1.1.3.1 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/1 R3(config-if-GigabitEthernet 0/1)# ip address 1.1.13.3 255.255.255.0 R3(config-if-GigabitEthernet 0/0)# exit R3(config)#interface gigabitEthernet 0/2 R3(config-if-GigabitEthernet 0/2)# ip address 1.1.23.3 255.255.255.0
	● Configure static routes on each device.
R1	R1#configure terminal R1(config)#ip route 1.1.2.0 255.255.255.0 GigabitEthernet 0/2 1.1.12.2 R1(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.13.3
R2	R2#configure terminal R2(config)#ip route 1.1.1.0 255.255.255.0 GigabitEthernet 0/1 1.1.12.1 R2(config)# ip route 1.1.3.0 255.255.255.0 GigabitEthernet 0/3 1.1.23.3
R3	R3#configure terminal R3(config)#ip route 1.1.2.0 255.255.255.0 GigabitEthernet 0/2 1.1.23.2 R3(config)# ip route 1.1.1.0 255.255.255.0 GigabitEthernet 0/1 1.1.13.1
Verification	● Display the routing table.
R1	R1# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is no set C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.1.1/32 is local host. S 1.1.2.0/24 [1/0] via 1.1.12.2, GigabitEthernet 0/2 S 1.1.3.0/24 [1/0] via 1.1.13.3, GigabitEthernet 0/2 C 1.1.12.0/24 is directly connected, GigabitEthernet 0/2

	C 1.1.12.1/32 is local host. C 1.1.13.0/24 is directly connected, GigabitEthernet 0/3 C 1.1.13.1/32 is local host.
R2	R2# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is no set S 1.1.1.0/24 [1/0] via 1.1.12.1, GigabitEthernet 0/0 C 1.1.2.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.2.1/32 is local host. C 1.1.23.0/24 is directly connected, GigabitEthernet 0/3 C 1.1.23.2/32 is local host.
R3	R3# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is no set S 1.1.1.0/24 [1/0] via 1.1.13.1, GigabitEthernet 0/2 S 1.1.2.0/24 [1/0] via 1.1.23.2, GigabitEthernet 0/2 C 1.1.3.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.3.1/32 is local host. C 1.1.13.0/24 is directly connected, GigabitEthernet 0/1 C 1.1.13.3/32 is local host. C 1.1.23.0/24 is directly connected, GigabitEthernet 0/2 C 1.1.23.3/32 is local host.



Correlating an IPv4 Static Route with Track

Scenario **Figure 1-6**	

Configuration Steps	● Configure static routes on R1 and R2, and specify the outbound interface or next hop as the interconnection interface. ● Correlate the static routes on R1 and R2 with track, and check connectivity of the next hop of the static routes.
R1	R1# configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit R1(config)#track 2 interface gigabitEthernet 0/1 line-protocol R1(config)# ip route 1.1.2.0 255.0.0.0 gigabitEthernet 0/1 1.1.12.2 track 2
R2	R2# configure terminal R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R1(config-if-GigabitEthernet 0/1)# exit R1(config)#track 2 interface gigabitEthernet 0/1 line-protocol R1(config)# ip route 1.1.1.0 255.0.0.0 gigabitEthernet 0/1 1.1.12.1 track 2

Verification	● Check the track status.
	● Check the static routes correlated with track.
	R1# show track 2
	Track 2
	Interface gigabitEthernet 0/1
	  The state is Up, delayed Down (5 secs remaining)
	  1 change, current state last: 300 secs
	  Delay up 0 secs, down 0 secs
	
	R1#show ip route track-table
	ip route 1.1.2.0 255.0.0.0 GigabitEthernet 0/1 1.1.12.2 track 2 up

Configuring Static Routes to Implement Interworking of the IPv6 Network

Scenario Figure 1-7	
Configuration Steps	● Configure interface addresses on each device.
R1	R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ipv6 address 1111:1111::1/64 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/1

	R1(config-if-GigabitEthernet 0/1)# ipv6 address 1111:1212::1/64
R2	R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)#ipv6 address 1111:2323::1/64 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ipv6 address 1111:1212::2/64
	● Configure static routes on each device.
R1	R1#configure terminal R1(config)# ipv6 route 1111:2323::0/64 gigabitEthernet 0/1
R2	R2#configure terminal R2(config)#ipv6 route 1111:1111::0/64 gigabitEthernet 0/1
Verification	● Display the routing table.
R1	R1# show ipv6 route IPv6 routing table name - Default - 10 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area C 1111:1111::/64 via GigabitEthernet 0/0, directly connected L 1111:1111::1/128 via GigabitEthernet 0/0, local host C 1111:1212::/64 via GigabitEthernet 0/1, directly connected L 1111:1212::1/128 via GigabitEthernet 0/1, local host S 1111:2323::/64 [1/0] via GigabitEthernet 0/1, directly connected C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/1, local host
R2	R2# show ipv6 route IPv6 routing table name - Default - 10 entries Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area C 1111:2323::/64 via GigabitEthernet 0/0, directly connected

	L 1111:2323::1/128 via GigabitEthernet 0/0, local host C 1111:1212::/64 via GigabitEthernet 0/1, directly connected L 1111:1212::1/128 via GigabitEthernet 0/1, local host S 1111:1111::/64 [1/0] via GigabitEthernet 0/1, directly connected C FE80::/10 via ::1, Null0 C FE80::/64 via GigabitEthernet 0/0, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/0, local host C FE80::/64 via GigabitEthernet 0/1, directly connected L FE80::2D0:F8FF:FEFB:C092/128 via GigabitEthernet 0/1, local host

Common Errors

- The link on the interface is not Up.
- No IP address is configured for the interface.
- The static routes are correlated with track, but a track object is not configured.

1.4.2 Configuring a Default Route

Configuration Effect

- Generate a default route in the routing table. The default route is used to forward packets that cannot be forwarded by other routes.

Notes

- On a Layer 2 device, the **ip default-gateway** or **ipv6 default-gateway** command can be used to configure the gateway.
- On a Layer 3 switch, the **ip route** 0.0.0.0 0.0.0.0 *gateway* or **ipv6 route** ::/0 *ipv6-gateway* command can be used to configure the default gateway.
- If **no ip routing** or **no ipv6 unicast-routing** is configured on a Layer 3 device, the **ip default-gateway** or **ipv6 default-gateway** command can be used to configure the gateway.

Configuration Step

↘ Configuring an IPv4 Gateway on a Layer 2 Device

Command	**ip default-gateway** *gateway*
Parameter Description	*Gateway:* Indicates the IPv4 gateway address.
Defaults	No IPv4 gateway is configured.
Command Mode	Global configuration mode
Usage Guide	-

↘ Configuring an IPv6 Gateway on a Layer 2 Device

Command	**ipv6 default-gateway** *gateway*
Parameter	*gateway:* Indicates the IPv6 gateway address.

Description	
Defaults	No IPv6 gateway is configured.
Command Mode	Global configuration mode
Usage Guide	-

Configuring the IPv4 Default Gateway on a Layer 3 Switch

Command	**ip route 0.0.0.0 0.0.0.0** { *ip-address* [**global**] | *interface* [*ip-address*] } [*distance* | **description** *description-text* | [**disabled** | **enabled**] | [**track** *object-number*] [**permanent**] | **tag** *tag* | **weight** *number*] *	
Parameter Description	**0.0.0.0**	Indicates the address of the destination network.
	0.0.0.0	Indicates the mask of the destination network.
	ip-address	(Optional) Indicates the next-hop address of the static route. You must specify at least one of *ip-address* and *interface,* or both of them. If *ip-address* is not specified, a static direct route is configured.
	global	(Optional) Indicates that the next hop belongs to a global VRF.
	interface	(Optional) Indicates the next-hop outbound interface of the static route. You must specify at least one of *ip-address* and *interface,* or both of them. If *interface* is not specified, a recursive static direct route is configured. The outbound interface is obtained by the next hop in the routing table.
	distance	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	description*description-text*	(Optional) Indicates the description of the static route. The value is a string of 1 to 60 characters. By default, no description is configured.
	disabled/enabled	(Optional) Indicates whether the static route is enabled. The default value is **enabled**.
	track *object-number*	(Optional) Correlates with track. *object-number* specifies the track object ID. Correlation with track is disabled by default.
	permanent	(Optional) Indicates the flag of the permanent route. The static route is not a permanent route by default.
	tag *tag*	(Optional) Indicates the tag value of the static route. The value range is from 1 to 4294967295 and the default value is 0.
	weight *number*	(Optional) Indicates the weight of the static route. The default value is 1. The value range is from 1 to 8.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is **ip route0.0.0.0 0.0.0.0** *ip-address.*	

Configuring the IPv6 Default Gateway on a Layer 3 Switch

Command	**ipv6 route ::/0** { *ipv6-address* | *interface* [*ipv6-address*] } [*distance* | **description** *description-text* | **tag** *tag* | **weight** *number*] *	
Parameter Description	**::**	Indicates the IPv6 prefix, which must comply with the address expression specified in RFC 4291.

	0	Indicates the length of the IPv6 prefix. Note that a slash (/) must be added following the length.
	Ipv6-address	(Optional) Indicates the next-hop address of the static route. You must specify at least one of *ipv6-address* and *interface,* or both of them. If *ipv6-address* is not specified, a static direct route is configured.
	interface	(Optional) Indicates the next-hop outbound interface of the static route. You must specify at least one of *ipv6-address* and *interface,* or both of them. If *interface* is not specified, a recursive static direct route is configured. The outbound interface is obtained by the next hop in the routing table.
	distance	(Optional) Indicates the administrative distance of the static route. The administrative distance is 1 by default.
	description*description-text*	(Optional) Indicates the description of the static route. The value is a string of 1 to 60 characters. By default, no description is configured.
	tag *tag*	(Optional) Indicates the tag value of the static route. The value range is from 1 to 4294967295 and the default value is 0.
	weight *number*	(Optional) Indicates the weight of a static route, which must be specified when you configure equal-cost routes. The value range is from 1 to 8. When the weights of all equal-cost routes of a route are summed up, the sum cannot exceed the maximum number of equal-cost routes that can be configured for the route. Weighting of equal-cost routes of a route indicates the traffic ratio of these routes. The weight is 1 by default.
Defaults	By default, no static default route is configured.	
Command Mode	Global configuration mode	
Usage Guide	The simplest configuration of this command is **ipv6 route** ::/0 *ipv6-gateway.*	

Configuring the IPv4 Default Network

Command	**ip default-network** *network*	
Parameter Description	*network*	Indicates the address of the network. The network must be a Class A, B, or C network.
Defaults	By default, no default network is configured.	
Command Mode	Global configuration mode	
Usage Guide	If the network specified by the **ip default-network** command exists, a default route is generated and the next hop to this network is the default gateway. If the network specified by the **ip default-network** command does not exist, the default route is not generated.	

Verification

- On devices where routing is disabled, use the **show ip redirects** or **show ipv6 redirects** command to display the default gateway.
- On a device where routing is enabled, run the **show ip route** or **show ipv6 route** command to display the default route.

Configuration Example

Configuring IPv4 Default Routes to Implement Interworking

Scenario **Figure 1-8**	
Configuration Steps	● Configure IP addresses on Layer 3 devices.
R1	R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/1 R1(config-if-GigabitEthernet 0/1)# ip address 1.1.12.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit
R2	R2#configure terminal R2(config)#interface gigabitEthernet 0/0 R2(config-if-GigabitEthernet 0/0)# ip address 1.1.2.1 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit R2(config)#interface gigabitEthernet 0/1 R2(config-if-GigabitEthernet 0/1)# ip address 1.1.12.2 255.255.255.0 R2(config-if-GigabitEthernet 0/0)# exit
R1	● Configure an IPv6 default gateway on R1. R1#configure terminal R1(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.2
R2	R2#configure terminal R2(config)#ip route 0.0.0.0 0.0.0.0 GigabitEthernet 0/1 1.1.12.1
Verification	● Display the routing table.
R1	R1# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is 1.1.12.2 S* 0.0.0.0/0 [1/0] via 1.1.12.2, GigabitEthernet 0/1 C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.1.1/32 is local host. C 1.1.12.0/24 is directly connected, GigabitEthernet 0/1 C 1.1.12.1/32 is local host.

1.4.3 Configuring Route Limitations

Configuration Effect

- Limit the number of equal-cost routes and number of static routes, or disable routing.

Configuration Step

Configuring the Maximum Number of Equal-Cost Routes

Command	**maximum-paths***number*
Parameter Description	*number :* Indicates the maximum number of equal-cost routes. The value range is from 1 to 64. The actual range varies from products.
Defaults	The default value varies from products.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the maximum number of next hops in the equal-cost route. In load balancing mode, the number of routes on which traffic is load balanced does not exceed the configured number of equal-cost routes.

Configuring the Maximum Number of IPv4 Static Routes

Command	**ip static route-limit***number*
Parameter Description	*number:* Indicates the upper limit of routes. The value range is from 1 to 10000.
Defaults	By default, a maximum of 1024 IP static routes can be configured.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the maximum number of IPv4 static routes. If the maximum number of IPv4 static routes is reached, no more IPv4 static route can be configured.

Configuring the Maximum Number of IPv6 Static Routes

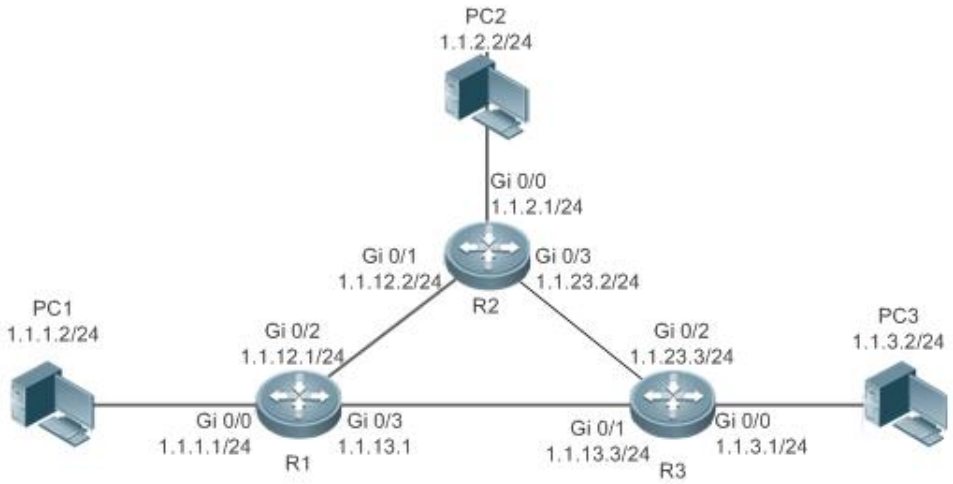
Command	**ipv6 static route-limit** *number*
Parameter Description	*number :* Indicates the upper limit of routes. The value range is from 1 to 10000.
Defaults	By default, a maximum of 1000 IPv6 static routes can be configured.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure the maximum number of IPv6 static routes. If the maximum number of IPv6 static routes is reached, no more IPv6 static route can be configured.

Disabling IPv4 Routing

Command	**no ip routing**
Parameter Description	N/A
Defaults	By default, IP routing is enabled.
Command	Global configuration mode

Mode	
Usage Guide	Run this command to disable IPv6 routing. If the device functions only as a bridge or a voice over IP (VoIP) gateway, the device does not need to use the IPv4 routing function. In this case, you can disable the IPv4 routing function of the device.

Disabling IPv6 Routing



Command	no ipv6 unicast-routing
Parameter Description	N/A
Defaults	By default, IPv6 routing is enabled.
Command Mode	Global configuration mode
Usage Guide	Run this command to disable IPv6 routing. If the device functions only as a bridge or a VoIP gateway, the device does not need to use the IPv6 routing function. In this case, you can disable the IPv6 routing function of the device

Verification

- Run the **show run** command to display the configuration file and verify that the preceding configuration commands exist.

Configuration Example

Configuring a Maximum of Two Static Routes

Scenario Figure 1-9	
Configuration Steps	• On R1, configure the IP addresses, static routes, and maximum number of static routes.
	R1#configure terminal R1(config)#interface gigabitEthernet 0/0 R1(config-if-GigabitEthernet 0/0)# ip address 1.1.1.1 255.255.255.0 R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/2 R1(config-if-GigabitEthernet 0/2)# ip address 1.1.12.1 255.255.255.0

	R1(config-if-GigabitEthernet 0/0)# exit R1(config)#interface gigabitEthernet 0/3 R1(config-if-GigabitEthernet 0/3)# ip address 1.1.13.1 255.255.255.0 R1(config-if-GigabitEthernet 0/3)# exit R1(config)#ip route 1.1.3.0 255.255.255.0 1.1.13.3 R1(config)#ip route 1.1.4.0 255.255.255.0 1.1.12.2 R1(config)#ip route 1.1.5.0 255.255.255.0 1.1.12.2 R1(config)#ip static route-limit 2 % Exceeding maximum static routes limit.
Verification	● Check the static routes that really take effect in the routing table.
	R1(config)# show ip route Codes: C - Connected, L - Local, S - Static R - RIP, O - OSPF, B - BGP, I - IS-IS N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2 E1 - OSPF external type 1, E2 - OSPF external type 2 SU - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2 IA - Inter area, * - candidate default Gateway of last resort is no set C 1.1.1.0/24 is directly connected, GigabitEthernet 0/0 C 1.1.1.1/32 is local host. S 1.1.3.0/24 [1/0] via 1.1.13.3 S 1.1.4.0/24 [1/0] via 1.1.12.2 C 1.1.12.0/24 is directly connected, GigabitEthernet 0/2 C 1.1.12.1/32 is local host. C 1.1.13.0/24 is directly connected, GigabitEthernet 0/3 C 1.1.13.1/32 is local host.

1.5 Monitoring

Clearing

⚠ During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear ip route	Clears the routing table cache.

Displaying

Command	Description
show ip redirects	Displays the default IPv4 gateway.
show ip route [*network* [*mask* [**longer-prefix**]] | **count** | **ecmp** [*network* [*mask*]] | **normal** [*network* [*mask*]] | *protocol* [*process-id*] | **weight**]	Displays IPv4 routing table information.
show ip route summary [**all**]	Displays IPv4 routing table statistics.

Command	Description
show ip route track-table	Displays information of the track correlated with IPv4 routes.
show ipv6 redirects	Displays the default IPv6 gateway.
show ipv6 route [*ipv6-prefix/prefix-length* [**longer-prefixes**] | *protocol* [*process-id*] | **weight**]]	Displays IPv6 routing table information.
show ipv6 route summary [**all**]	Displays IPv6 routing table statistics.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug nsm kernel ucast- v4	Debugs IPv4 route management.
debug nsm kernel ucast-v6	Debugs IPv6 route management.
debug nsm kernel frr	Enables the debugging of fast reroute (FRR).
debug nsm kernel default-network	Debugs default network management.
debug nsm events	Debugs internal events of route management.
debug nsm packet send	Debugs sending of route management and routing protocol messages.
debug nsm packet recv	Debugs receiving of route management and routing protocol messages.

1 Configuring RIP

1.1 Overview

The Routing Information Protocol (RIP) is a unicast routing protocol applied on IPv4 networks. RIP-enabled routers exchange routing information to obtain routes to remote networks.

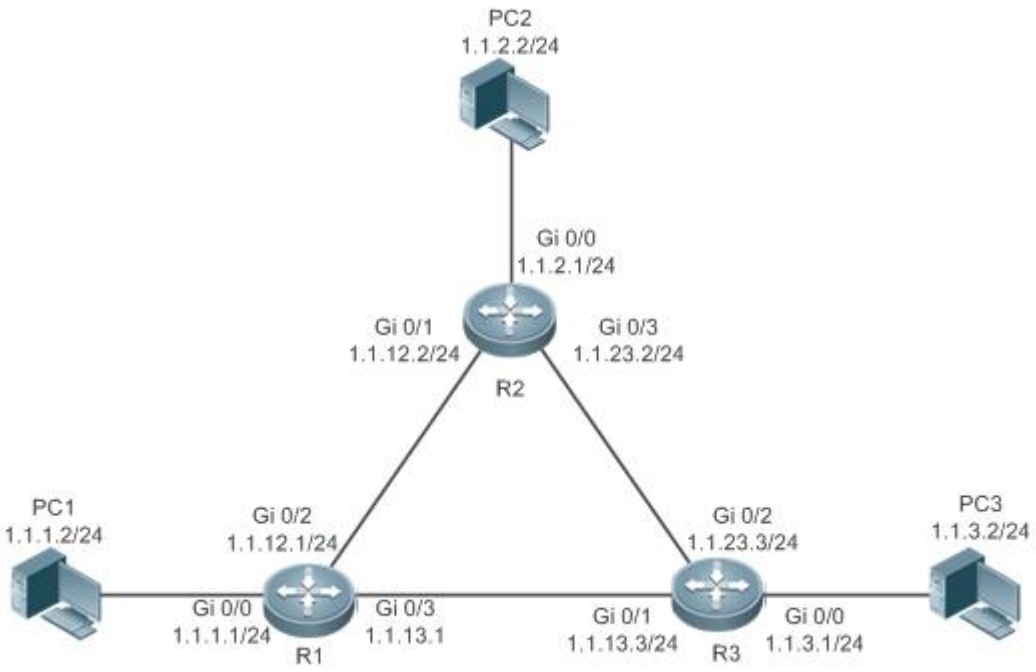
As an Interior Gateway Protocol (IGP), RIP can run only within an autonomous system (AS) and is applicable to small-sized networks whose longest path involves less than 16 hops.

Protocols and Standards

- RFC 1058: Defines RIP version 1 (RIPv1).
- RFC 2453: Defines RIP version 2 (RIPv2).

1.2 Applications

Application	Description
Basic RIP Application	Routing information is automatically maintained through RIP on a small-sized network.



1.2.1 Basic RIP Application

Scenario

On a network with a simple architecture, you can configure RIP to implement interworking. Configuring RIP is simpler than configuring other IGP protocols such as the Open Shortest Path First (OSPF). Compared with static routing, RIP can dynamically adapt to the network architecture changes and is easier to maintain.

As shown in Figure 1-1, to implement interworking between PC1, PC2, and PC3, you can configure RIP routes on R1, R2, and R3.

Figure 1-1

Deployment

- Configure IP addresses and gateways on three PCs.
- Configure IP addresses and subnet masks on three routers.
- Configure RIP on three routers.

1.3 Features

Basic Concepts

IGP and EGP

An IGP runs within an AS. For example, RIP is an IGP.

An Exterior Gateway Protocol (EGP) runs between ASs. For example, BGP is an EGP.

Classful and Classless Routing Protocols

Protocols can be classified based on the type of routes supported:

- Classful routing protocol: Supports classful routes. For example, RIPv1 is a classful routing protocol.
- Classless routing protocol: Supports classless routes. For example, RIPv2 is a classless routing protocol.

Overview

Feature	Description
RIPv1 and RIPv2	RIP is available in two versions: RIPv1 and RIPv2.
Exchanging Routing Information	By exchanging routing information, RIP-enabled devices can automatically obtain routes to a remote network and update routes in real time.

Feature	Description
Routing Algorithm	Based on the distance-vector algorithm, RIP uses the vector addition method to compute routing information.
Avoiding Routing Loops	RIP uses split horizon and poison reverse to avoid routing loops.
Security Measures	RIP uses authentication and source address verification to ensure protocol security.
Reliability Measures	RIP uses Graceful Restart (GR) to enhance protocol reliability.

1.3.1 RIPv1 and RIPv2

Two RIP versions are available: RIPv1 and RIPv2.

Working Principle

RIPv1

RIPv1 packets are broadcast, with broadcast address 255.255.255.255 and UDP port 520. RIPv1 cannot identify the subnet mask, and supports only classful routes.

RIPv2

RIPv2 packets are multicast, with multicast address 224.0.0.9 and UDP port 520. RIPv2 can identify the subnet mask, and supports classless routes, summarized route, and supernetting routes. RIPv2 supports cleartext authentication and Message Digest 5 (MD5) authentication.

Related Configuration

Enabling the RIP Process

The RIP process is disabled by default.

Run the **router rip** command to enable the RIP process.

You must enable the RIP process on a device; otherwise, all functions related to RIP cannot take effect.

Running RIP on an Interface

By default, RIP does not run on an interface.

Run the **network** command to define an address range. RIP runs on interfaces that belong to this address range.

After RIP runs on an interface, RIP packets can be exchanged on the interface and RIP can learn routes to the network segments directly connected to the device.

Defining the RIP Version

By default, an interface receives RIPv1 and RIPv2 packets, and sends RIPv1 packets.

Run the **version** command to define the version of RIP packets sent or received on all interfaces.

Run the **ip rip send version** command to define the version of RIP packets sent on an interface.

Run the **ip rip receive version** command to define the version of RIP packets received on an interface.

⚠ If the versions of RIP running on adjacent routers are different, the RIPv1-enabled router will learn incorrect routes.

Preventing an Interface from Sending or Receiving Packets

By default, a RIP-enabled interface is allowed to send and receive RIP packets.

Run the **no ip rip receive enable** command to prevent an interface from receiving RIP packets.

Run the **no ip rip send enable** command to prevent an interface from sending RIP packets.

Run the **passive-interface** command to prevent an interface from sending broadcast or multicast RIP packets.

Configuring a Mode for Sending RIP Packets

By default, RIPv1 packets are broadcast and RIPv2 are multicast.

Run the **ip rip v2-broadcast** command to broadcast RIPv2 packets on an interface.

Run the **neighbor** command to unicast RIP packets to a specified neighboring router.

1.3.2 Exchanging Routing Information

Compared with static routing, dynamic routing protocols have a significant advantage. By exchanging routing information, devices can automatically obtain routes to a remote network and update them in real time.

Working Principle

Initialization

After RIP is enabled on a router, the router sends a request packet to its neighboring router, requesting for all routing information, that is, the routing table. After receiving the request packet, the neighboring router returns a response packet containing the local routing table. After receiving the response packet, the router updates the local routing table, and sends an update packet to the neighboring router, informing the neighboring router of routing update information. After receiving the update packet, the neighboring router updates the local routing table, and sends the update packet to other adjacent routers. After a series of updates, all routers can obtain and retain the latest routing information.

Periodical Update

By default, periodical update is enabled for RIP. Adjacent routers exchange complete routing information with each other every 30s (update timer), that is, the entire routing table is sent to neighboring routers. One update packet contains at most 25 routes. Therefore, many update packets may be required to send the entire routing table. You can set the sending delay between update packets to avoid loss of routing information.

For every non-local route, if the route is not updated within 180s (invalid timer), the metric of the route is changed to 16 (unreachable). If the route is still not updated in the next 120s (flush timer), the route is deleted from the routing table.

Triggered Update

After the triggered update function is enabled, periodical update is automatically disabled. When routing information changes on a router, the router immediately sends routes related to the change (instead of the complete routing table) to the neighboring router, and use acknowledgment and retransmission mechanisms to ensure that the neighboring router receives the routes successfully. Compared with periodical update, triggered update helps reduce flooding and accelerates route convergence.

Events that can trigger update include router startup, interface status change, changes in routing information (such as the metric), and receiving of a request packet.

Route Summarization

When sending routing information to a neighboring router, the RIP-enabled router summarizes subnet routes that belong to the same classful network into a route, and sends the summarized route to the neighboring router. For example, summarize 80.1.1.0/24 (metric=2) and 80.1.2.0/24 (metric=3) into 80.0.0.0/8 (metric=2), and set the metric of the summarized route to the optimal value.

Only RIPv2 supports route summarization. Route summarization can reduce the size of the routing table and improve the efficiency of routing information exchange.

Supernetting Route

If the subnet mask length of a route is smaller than the natural mask length, this route is called supernetting route. For example, in the route 80.0.0.0/6, 80.0.0.0 is a Class A network address and the natural mask is 8 bits, so route 80.0.0.0/6 is a supernetting route.

Only RIPv2 supports supernetting routes.

Default Route

In the routing table, a route to the destination network 0.0.0.0/0 is called default route.

The default route can be learned from a neighboring router, or sent to a neighboring router.

Route Redistribution

For RIP, other types of routes (such as direct routes, static routes, and routes of other routing protocols) are called external routes.

External routes (excluding the default route) can be redistributed to RIP and advertised to neighbors.

Route Filtering

Filtering conditions can be configured to limit routing information exchanged between adjacent routers. Only the routing information that meets filtering conditions can be sent or received.

Related Configuration

Sending Delay Between Update Packets

By default, update packets are sent continuously without any delay.

Run the **output-delay** command to set the sending delay between update packets.

RIP Timers

By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Run the **timers basic** command to change values of RIP timers.

Increasing the value of the flush timer can reduce route flapping. Decreasing the value of the flush timer helps accelerate route convergence.

The values of RIP timers must be consistent on adjacent routers. Unless otherwise required, you are advised not to change RIP timers.

Triggered Update

By default, periodical update is enabled.

Run the **ip rip triggered** command to enable triggered updates on the interface and disable periodical update.

Run the **ip rip triggered retransmit-timer** command to modify the retransmission interval of update packets. The default value is 5s.

Run the **ip rip triggered retransmit-count** command to modify the maximum retransmission times of update packets. The default value is 36.

Route Summarization

By default, route summarization is automatically enabled if an interface is allowed to send RIPv2 packets.

Run the **no auto-summary** command to disable route summarization.

Run the **ip rip summary-address** command to configure route summarization on an interface.

Supernetting Route

By default, supernetting routes can be sent if an interface is allowed to send RIPv2 packets.

Run the **no ip rip send supernet-routes** command to prevent the device from sending supernetting routes.

Default Route

Run the **ip rip default-information** command to advertise the default route to neighbors on an interface.

Run the **default-information originate** command to advertise the default route to neighbors from all interfaces.

Route Redistribution

Run the **redistribute** command to redistribute external routes (excluding the default route) to RIP and advertise them to neighbors.

Route Filtering

Run the **distribute-list out** command to set filtering rules to limit routing information sent by the device.

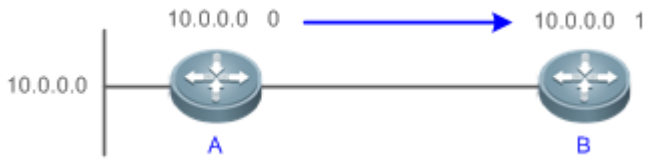
Run the **distribute-list in** command to set filtering rules to limit routing information received by the device.

1.3.3 Routing Algorithm

Based on the distance-vector algorithm, RIP uses the vector addition method to compute routing information.

Working Principle

Distance-Vector Algorithm



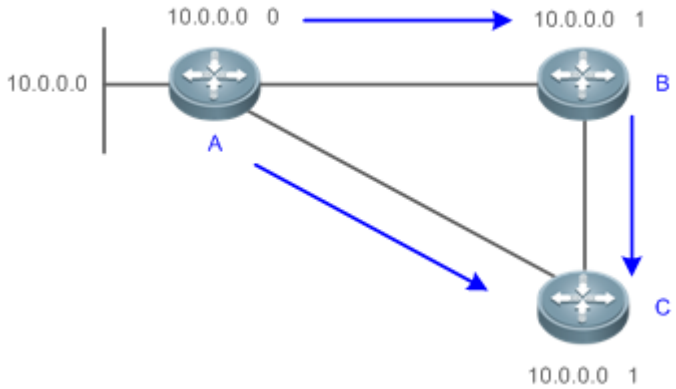
RIP is based on the distance-vector algorithm. The distance-vector algorithm treats a route as a vector that consists of the destination network and distance (metric). The router obtains a route from its neighbor and adds the distance vector (from itself to the neighbor) to the route to form its own route.

RIP uses the hop count to evaluate the distance (metric) to the destination network. By default, the hop count from a router to its directly connected network is 0, the hop count from a router to a network that can be reached through the router is 1, and so on. That is, the metric is equal to the number of routers from the local network to the destination network. To restrict the convergence time, RIP defines that the metric must be an integer between 0 and 15. If the

metric is equal to or greater than 16, the destination network or host is unreachable. For this reason, RIP cannot be applied on a large-scale network.

As shown in Figure 1-2, Router A is connected to the network 10.0.0.0. Router B obtains the route (10.0.0.0,0) from Router A and adds metric 1 to the route to obtain its own route (10.0.0.0,1), and the next hop points to Router A.

Figure 1-2



Selecting the Optimal Route

If multiple routes to the same destination network is available, a RIP-enabled router preferentially selects the route with the smallest metric.

As shown in Figure 1-3, Router A is connected to the network 10.0.0.0. Router C obtains the route (10.0.0.0,0) from Router A and the route (10.0.0.0,1) from Router B. Router C will select the route that is obtained from Router A and add metric 1 to this route to form its own route (10.0.0.0,1), and the next hop points to Router A.

Figure 1-3

When routes originated from different sources exist on a router, the route with the smallest distance is preferentially selected.

Route Source	Default Distance
Directly-connected network	0
Static route	1
OSPF route	110
IS-IS route	115
RIP route	120
Unreachable route	255

Related Configuration

Changing the Distance

By default, the distance of a RIP route is 120.

Run the **distance** command to change the distance of a RIP route.

Changing the Metric

For a RIP route that is proactively discovered by a device, the default metric is equal to the number of hops from the local network to the destination network. For a RIP router that is manually configured (default or redistributed route), the default metric is 1.

Run the **offset-list in** command to increase the metric of a received RIP route.

Run the **offset-list out** command to increase the metric of a sent RIP route.

Run the **default-metric** command to change the default metric of a redistributed route.

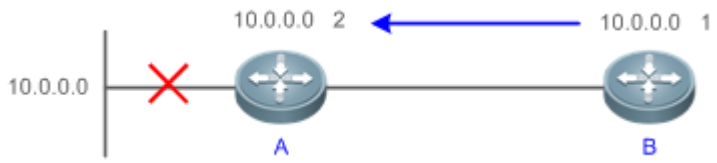
Run the **redistribute** command to change the metric of a route when the route is redistributed.

Run the **default-information originate** command to change the metric of a default route when the default route is introduced.

Run the **ip rip default-information** command to change the metric of a default route when the default route is created.

1.3.4 Avoiding Routing Loops

RIP uses split horizon and poison reverse to avoid routing loops.



Working Principle

Routing Loop

A RIP routing loop occurs due to defects of the distance-vector algorithm.

As shown in Figure 1-4, Router A is connected to the network 10.0.0.0, and sends an update packet every 30s. Router B receives the route 10.0.0.0 from Router A every 30s. If Router A is disconnected from 10.0.0.0, the route to 10.0.0.0 will be deleted from the routing table on Router A. Then the update packet sent by Router A no longer contains this route. Because Router B does not receive an update packet related to 10.0.0.0, Router B determines that the route to 10.0.0.0 is valid within 180s and uses the update packet to send this route to Router A. Because the route to 10.0.0.0 does not exist on Router A, the route learned from Router B is added to the routing table. Router B determines that data can reach 10.0.0.0 through Router A, and Router A determines that data can reach 10.0.0.0 through Router B. In this case, a routing loop is formed.

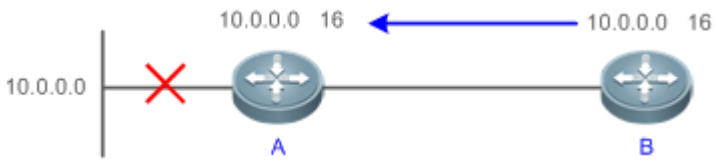
Figure 1-4

Split Horizon

Split horizon can prevent routing loops. After split horizon is enabled on an interface, a route received on this interface will not be sent out from this interface.

As shown in Figure 1-5, after split horizon is enabled on the interface between Router A and Router B, Router B will not send the route 10.0.0.0 back to Router A. Router B will learn that 10.0.0.0 is not reachable 180s later.

Figure 1-5



Poison Reverse

Poison reverse can also prevent routing loops. Compared with split horizon, poison reverse is more reliable, but results in more protocol packets, which makes network congestion more severe.

After poison reverse is enabled on an interface, a route received from this interface will be sent out from this interface again, but the metric of this router will be changed to 16 (unreachable).

As shown in Figure 1-6, after learning the route 10.0.0.0 from Router A, Router B sets the metric of this route to 16 and sends the route back to Router A. After this route becomes invalid, Router B advertises the route 10.0.0.0 (metric = 16) to Router A to accelerate the process of deleting the route from the routing table.

Figure 1-6

Related Configuration

Split Horizon

By default, split horizon is enabled.

Run the **no ip rip split-horizon** command to disable split horizon.

Poison Reverse

By default, poison reverse is disabled.

Run the **ip rip split-horizon poisoned-reverse** command to enable poison reverse. After poison reverse is enabled, split horizon is automatically disabled.

1.3.5 Security Measures

RIP uses authentication and source address verification to ensure protocol security.

Working Principle

Authentication

RIPv2 supports authentication, but RIPv1 does not.

After authentication is enabled on an interface, routing information cannot be exchanged between adjacent devices if authentication fails. The authentication function is used to prevent unauthorized devices from accessing the RIP routing domain.

RIPv2 supports cleartext authentication and MD5 authentication.

Source Address Verification

When a RIP-enabled device receives an update packet, it checks whether the source IP address in the packet and the IP address of the inbound interface are on the same network segment. If not, the device drops the packet. Source address verification is used to ensure that RIP routing information is exchanged only between adjacent routing devices.

- Source address verification is invalid for the interface with the unnumbered IP address.
- If the triggered update function is enabled, source address verification is automatically enabled (not configurable).
- If split horizon is disabled, source address verification is automatically enabled (not configurable).

Related Configuration

Authentication

By default, authentication is disabled.

Run the **ip rip authentication mode text** command to enable cleartext authentication on an interface.

Run the **ip rip authentication mode md5** command to enable MD5 authentication on an interface.

Run the **ip rip authentication text-password** command to set the password for cleartext authentication on an interface.

Run the **ip rip authentication key-chain** command to reference the key in the configured key chain as the authentication key on an interface.

Source Address Verification

By default, source address verification is enabled.

Run the **no validate-update-source** command to disable source address verification.

1.3.6 Reliability Measures

RIP uses GR to enhance protocol reliability.

Working Principle

GR

GR ensures uninterrupted data transmission when the protocol is restarted. If RIP is restarted on a GR-enabled device, the forwarding table before restart will be retained and a request packet will be sent to the neighbor so that the route can be learned again. During the GR period, RIP completes route re-convergence. After the GR period expires, RIP updates the forwarding entry and advertises the routing table to the neighbor.

Related Configuration

GR

By default, GR is disabled.

Run the **graceful-restart** command to enable GR.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic RIP Functions	(Mandatory) It is used to build a RIP routing domain.	
	router rip	Enables a RIP routing process and enters routing process configuration mode.
	network	Runs RIP on interfaces in the specified address range.
	version	Defines the RIP version.
	ip rip split-horizon	Enables split horizon or poison reverse on an interface.
	passive-interface	Configures a passive interface.
Controlling Interaction of RIP Packets	(Optional) It is used to change the default mechanism for sending or receiving RIP packets.	
	neighbor	Unicasts RIP packets to a specified neighbor.
	ip rip v2-broadcast	Broadcasts RIPv2 packets on an interface.
	ip rip receive enable	Allows the interface to receive RIP packets.
	ip rip send enable	Allows the interface to send RIP packets.
	ip rip send version	Defines the version of RIP packets sent on an interface.
	ip rip receive version	Defines the version of RIP packets received on an interface.
Enabling Triggered Update	Optional.	
	ip rip triggered	Enables triggered update on an interface.
Enabling Source Address Verification	Optional.	
	validate-update-source	Enables source address verification.
Enabling Authentication	(Optional) Only RIPv2 supports authentication.	
	ip rip authentication mode	Enables authentication and sets the authentication mode on an interface.
	ip rip authentication text-password	Configures the password for cleartext authentication on an interface.
	ip rip authentication key-chain	Configures the authentication key chain on an interface.
Enabling Route Summarization	(Optional) Only RIPv2 supports route summarization.	
	auto-summary	Enables automatic summarization of RIP routes.
	ip rip summary-address	Configures route summarization on an interface.
Enabling Supernetting	(Optional) Only RIPv2 supports supernetting routes.	

Configuration	Description and Command	
Routes	**ip rip send supernet-routes**	Enables advertisement of RIP supernetting routes on an interface
Advertising the Default Route or External Routes	⚠ Optional.	
	ip rip default-information	Advertises the default route to neighbors on an interface.
	default-information originate	Advertises the default route to neighbors.
	redistribute	Redistributes routes and advertises external routes to neighbors.
Setting Route Filtering Rules	⚠ Optional.	
	distribute-list in	Filters the received RIP routing information.
	distribute-list out	Filters the sent RIP routing information.
Changing Route Selection Parameters	⚠ Optional.	
	distance	Changes the administrative distance (AD) of a RIP route.
	offset-list	Increases the metric of a received or sent RIP route.
	default-metric	Configures the default metric of an external route redistributed to RIP.
Changing Values of Timers	⚠ Optional.	
	timers basic	Changes the update timer, invalid timer, and flush timer.
	output-delay	Sets the sending delay between RIP route update packets.
Enabling GR	⚠ Optional.	
	graceful-restart	Configures the GR capability.

1.4.1 Configuring Basic RIP Functions

Configuration Effect

- Build a RIP routing domain on a network.
- Routers in the domain obtain routes to a remote network through RIP.

Notes

- IPv4 addresses must be configured.
- IPv4 unicast routes must be enabled.

Configuration Step

↘ Enabling a RIP Routing Process

- Mandatory.

- Unless otherwise required, this configuration must be performed on each router in the RIP routing domain.

Associating with the Local Network

- Mandatory.
- Unless otherwise required, this configuration must be performed on each router in the RIP routing domain.
- Unless otherwise required, the local network associated with RIP should cover network segments of all Layer 3 interfaces.

Defining the RIP Version

- If RIPv2 functions (such as the variable length subnet mask and authentication) are required, enable RIPv2.
- Unless otherwise required, you must define the same RIP version on each router.

Enabling Split Horizon or Poison Reverse

- By default, split horizon is enabled and poison reverse is disabled.
- Unless otherwise required, enable split horizon on each interface connected to the broadcast network, such as the Ethernet. (Retain the default setting.)
- Unless otherwise required, enable split horizon on each interface connected to the point-to-point (P2P) network, such as the PPP and HDLC. (Retain the default setting.)
- It is recommended that split horizon and poison reverse be disabled on an interface connected to a non-broadcast multi-access (NBMA) network, such as FR and X.25; otherwise, some devices may fail to learn complete routing information.
- If the secondary IP address is configured for an interface connected to a non-broadcast network, it is recommended that split horizon and poison reverse be disabled.

Configuring a Passive Interface

- To suppress update packets on a RIP interface, configure the interface as a passive interface.
- Use the passive interface to set the boundary of the RIP routing domain. The network segment of the passive interface belongs to the RIP routing domain, but RIP packets cannot sent over the passive interface.
- If RIP routes need to be exchanged on an interface (such as the interconnected interface of the router) in the RIP routing domain, this interface cannot be configured as a passive interface.

Verification

- Check the routing table on a router to verify that the route to a remote network can be obtained through RIP.

Related Commands

Enabling a RIP Routing Process

Command Syntax	**router rip**
Parameter Description	N/A
Command	Global configuration mode

Mode	
Configuration Usage	This command is used to create a RIP routing process and enter the routing process configuration mode.

Associating with the Local Network

Command Syntax	**network** *network-number* [*wildcard*]
Parameter Description	*network-number*: Indicates the number of a network. *wildcard*: Defines the IP address comparison bit. The value 0 indicates exact match, and the value 1 indicates that the bit is not compared.
Command Mode	Routing process configuration mode
Configuration Usage	RIP can run and learn direct routes and RIP packets can be exchanged only on an interface whose address is within the range defined by **network**. If **network 0.0.0.0 255.255.255.255** is configured, all interfaces are covered. If *wildcard* is not configured, the classful address range is used by default, that is, the interfaces whose addresses fall into the classful address range participate in RIP operations.

Defining the RIP Version

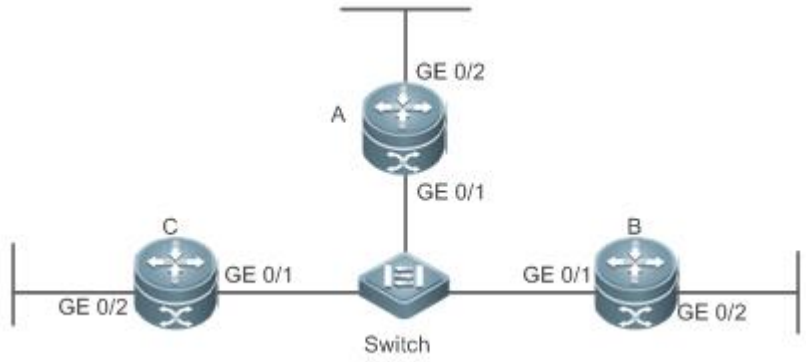
Command Syntax	**version** { **1** | **2** }
Parameter Description	**1**: Indicates RIPv1. **2**: Indicates RIPv2.
Command Mode	Global configuration mode
Configuration Usage	This command takes effect on the router. You can run this command to define the version of RIP packets sent or received on all interfaces.

Enabling Split Horizon

Command Syntax	**ip rip split-horizon** [**poisoned-reverse**]
Parameter Description	**poisoned-reverse**: Indicates poison reverse.
Command Mode	Interface configuration mode
Configuration Usage	After poison reverse is enabled, split horizon is automatically disabled.

Configuring a Passive Interface

Command Syntax	**passive-interface** { **default** | *interface-type interface-num* }
Parameter Description	**default**: Indicates all interfaces. ***interface-type interface-num***: Specifies an interface.
Command	Routing process configuration mode



Mode	
Configuration Usage	First, run the **passive-interface default** command to configure all interfaces as passive interfaces. Then, run the **no passive-interface** *interface-type interface-num* command to cancel the interfaces used for interconnection between routers in the domain.

Configuration Example

Building a RIP Routing Domain

Scenario

Figure 1-7

Remarks	The interface IP addresses are as follows: A: GE0/1: 110.11.2.1/24; GE0/2: 155.10.1.1/24 B: GE0/1: 110.11.2.2/24; GE0/2: 196.38.165.1/24 C: GE0/1: 110.11.2.3/24; GE0/21: 17.102.0.1/16

Configuration Steps

- Configure the interface IP addresses on all routers.
- Configure basic RIP functions on all routers.

A

```
A# configure terminal
A(config)# interface GigabitEthernet 0/1
A(config-if-GigabitEthernet 0/1)# ip address 110.11.2.1 255.255.255.0
A(config-if-GigabitEthernet 0/1)# exit
A(config)# interface GigabitEthernet 0/2
A(config-if-GigabitEthernet 0/2)# ip address 155.10.1.1 255.255.255.0
A(config)# router rip
A(config-router)# version 2
A(config-router)# network 0.0.0.0 255.255.255.255
A(config-router)# passive-interface default
A(config-router)# no passive-interface GigabitEthernet 0/1
```

B

```
B# configure terminal
B(config)# interface GigabitEthernet 0/1
B(config-if-GigabitEthernet 0/1)# ip address 110.11.2.2 255.255.255.0
B(config-if-GigabitEthernet 0/1)# exit
B(config)# interface GigabitEthernet 0/2
B(config-if-GigabitEthernet 0/2)# ip address 196.38.165.1 255.255.255.0
B(config-if-GigabitEthernet 0/2)# exit
B(config)# router rip
B(config-router)# version 2
B(config-router)# network 0.0.0.0 255.255.255.255
```

	B(config-router)# passive-interface default B(config-router)# no passive-interface GigabitEthernet 0/1
C	C# configure terminal C(config)# interface GigabitEthernet 0/1 C(config-if-GigabitEthernet 0/1)# ip address 110.11.2.3 255.255.255.0 C(config-if-GigabitEthernet 0/1)# exit C(config)# interface GigabitEthernet 0/2 C(config-if-GigabitEthernet 0/2)# ip address 117.102.0.1 255.255.0.0 C(config-if-GigabitEthernet 0/2)# exit C(config)# router rip C(config-router)# version 2 C(config-router)#no auto-summary C(config-router)# network 0.0.0.0 255.255.255.255 C(config-router)# passive-interface default C(config-router)# no passive-interface GigabitEthernet 0/1
Verification	● Check routing tables on Router A, Router B, and Router C. Verify that RIP learns the routes to remote networks (contents marked in blue).

Common Errors

- The IPv4 address is not configured on an interface.
- The RIP version is not defined on a device, or the RIP version on the device is different from that on other routers.
- The address range configured by the **network** command does not cover the IP address of a specific interface.
- The **wildcard** parameter in the **network** command is not correctly configured. The value 0 indicates exact match, and the value 1 indicates that the bit is not compared.
- The interface used for interconnection between devices is configured as a passive interface.

1.4.2 Controlling Interaction of RIP Packets

Configuration Effect

Change the default running mechanism of RIP and manually control the interaction mode of RIP packets, including:

- Allow an interface to send or prohibit it from unicasting RIP packets to a specified neighbor.
- Allow an interface to send or prohibit it from sending unicast RIPv2 packets but not broadcast packets to a specified neighbor.
- Allow an interface to send or prohibit it from receiving RIP packets.
- Allow an interface to send or prohibit it from sending RIP packets.
- Allow an interface to send or prohibit it from receiving RIP packets of a specified version.

- Allow an interface to send or prohibit it from sending RIP packets of a specified version.

Notes

- Basic RIP functions must be configured.
- On an interface connected to a neighbor device, the configured version of sent RIP packets must be the same as the version of received RIP packets.

Configuration Step

Unicasting RIP Route Update Packets to a Specified Neighbor

- Configure this function if only some of devices connected to an interface are required to receive updated routing information.
- By default, RIPv1 uses the IP broadcast address (255.255.255.255) to advertise routing information, whereas RIPv2 uses the multicast address (224.0.0.9) to advertise routing information. If you do not wish all devices on the broadcast network or NBMA network to receive routing information, configure a corresponding interface as the passive interface and specify the neighbors that can receive routing information. This command does not affect the receiving of RIP packets. RIPv2 packets are broadcast on an interface.
- Unless otherwise required, this function must be enabled on a router that unicasts update packets.

Broadcasting RIPv2 Packets on an Interface

- This function must be configured if the neighbor router does not support the receiving of multicast RIPv2 packets.
- Unless otherwise required, this function must be configured on each router interface that broadcasts RIPv2 packets.

Allowing an Interface to Receive RIP Packets

- This function is enabled by default, and must be disabled if an interface is not allowed to receive RIP packets.
- Unless otherwise required, this function must be configured on each router interface that is not allowed to receive RIP packets.

Allowing an Interface to Send RIP Packets

- This function is enabled by default, and must be disabled if an interface is not allowed to send RIP packets.
- Unless otherwise required, this function must be configured on each router interface that is not allowed to send RIP packets.

Allowing an Interface to Send RIP Packets of a Specified Version

- This function must be configured if the version of RIP packets that can be sent on an interface is required to be different from the global configuration.
- Unless otherwise required, this function must be configured on each router interface that is allowed to send RIP packets of a specified version.

Allowing an Interface to Receive RIP Packets of a Specified Version

- This function must be configured if the version of RIP packets that can be received on an interface is required to be different from the global configuration.

- Unless otherwise required, this function must be configured on each router interface that is allowed to receive RIP packets of a specified version.

Verification

Run the **debug ip rip packet** command to verify the packet sending result and packet type.

Related Commands

Unicasting RIP Route Update Packets to a Specified Neighbor

Command Syntax	**neighbor** *ip-address*
Parameter Description	*ip-address:* Indicates the IP address of the neighbor. It should be the address of the network directly connected to the local device.
Command Mode	Routing process configuration mode
Configuration Usage	You can first run the **passive-interface** command in routing process configuration mode to configure the related interface as a passive interface, and then specify the neighbors that can receive routing information. This command does not affect the receiving of RIP packets. After an interface is configured as a passive interface, the interface does not send the request packets even after the device is restarted.

Broadcasting RIPv2 Packets on an Interface

Command Syntax	**ip rip v2-broadcast**
Parameter Description	N/A
Command Mode	Interface configuration mode
Configuration Usage	The default behavior is determined by the **version** command. The configuration result of this command can overwrite the default configuration of the **version** command. This command affects the behavior of sending RIP packets on the interface, and the interface is allowed to send RIPv1 and RIPv2 packets simultaneously. If this command does not contain any parameter, the behavior of receiving RIP packets is determined by the **version** command.

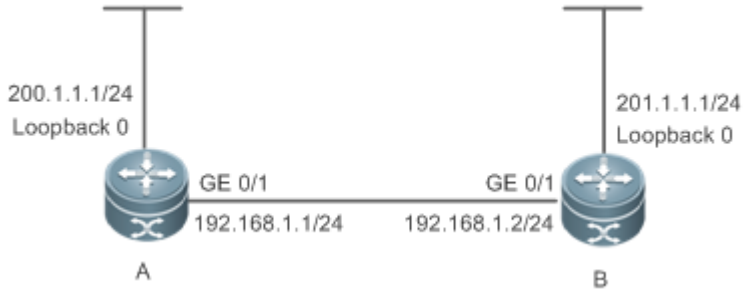
Allowing an Interface to Receive RIP Packets

Command Syntax	**ip rip receive enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Configuration Usage	To prohibit an interface from receiving of RIP packets, use the **no** form of this command. This command takes effect only on the interface. You can use the **default** form of the command to restore the default setting, that is, allow the interface to receive RIP packets.

Allowing an Interface to Send RIP Packets

Command Syntax	**ip rip send enable**
Parameter Description	N/A
Command Mode	Interface configuration mode
Configuration Usage	To prohibit an interface from sending RIP packets, use the **no** form of this command in interface configuration mode. This command takes effect only on the interface. You can use the **default** form of the command to restore the default setting, that is, allow the interface to send RIP packets.

Allowing an Interface to Send RIP Packets of a Specified Version



Command Syntax	**ip rip send version** [**1**] [**2**]
Parameter Description	**1**: Indicates that only RIPv1 packets are sent. **2**: Indicates that only RIPv2 packets are sent.
Command Mode	Interface configuration mode
Configuration Usage	The default behavior is determined by the **version** command. The configuration result of this command can overwrite the default configuration of the **version** command. This command affects the behavior of sending RIP packets on the interface, and the interface is allowed to send RIPv1 and RIPv2 packets simultaneously. If this command does not contain any parameter, the behavior of receiving RIP packets is determined by the **version** command.

Allowing an Interface to Receive RIP Packets of a Specified Version

Command Syntax	**ip rip receive version** [**1**] [**2**]
Parameter Description	**1**: Indicates that only RIPv1 packets are received. **2**: Indicates that only RIPv2 packets are received.
Command Mode	Interface configuration mode
Configuration Usage	The default behavior is determined by the **version** command. The configuration result of this command can overwrite the default configuration of the **version** command. This command affects the behavior of sending RIP packets on the interface, and the interface is allowed to send RIPv1 and RIPv2 packets simultaneously. If this command does not contain any parameter, the behavior of receiving RIP packets is determined by the **version** command.

Configuration Example

Prohibiting an Interface from Sending RIP Packets

Scenario **Figure 1-8**	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Prohibit an interface of Router A from sending RIP packets.

A	`A# configure terminal`
	`A(config)# interface GigabitEthernet 0/1`
	`Ruijie(config-if-GigabitEthernet 0/1)# no ip rip send enable`

Verification	● Run the **debug ip rip packet send** command on Router A, and verify that packets cannot be sent.

A	`A# debug ip rip packet recv`
	`*Nov 4 08:19:31: %RIP-7-DEBUG: [RIP] Prepare to send BROADCAST response...`
	`*Nov 4 08:19:31: %RIP-7-DEBUG: [RIP] Building update entries on GigabitEthernet 0/1`
	`*Nov 4 08:19:31: %RIP-7-DEBUG: 117.0.0.0/8 via 0.0.0.0 metric 1 tag 0`
	`*Nov 4 08:19:31: %RIP-7-DEBUG: [RIP] Interface GigabitEthernet 0/1 is disabled to send RIP packet!`

Common Errors

- A compatibility error occurs because the RIP version configured on the neighbor is different from that configured on the local device.

1.4.3 Enabling Triggered Update

Configuration Effect

- Enable the RIP triggered update function. When this function is configured, RIP does not periodically send route update packets.

Notes

- Basic RIP functions must be configured.
- It is recommended that split horizon with poison reverse be enabled; otherwise, invalid routing information may exist.
- Ensure that the triggered update function is enabled on each router on the same link; otherwise, routing information cannot be exchanged properly.

Configuration Step

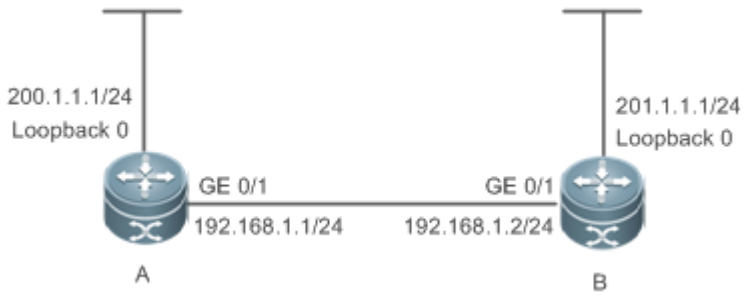
Enabling Triggered Update

- This function must be enabled if on-demand links are configured on the WAN interface.
- The triggered update function can be enabled when the interface has only one neighbor, or when the interface has multiple neighbors but the device interacts with these neighbors in unicast mode.
- It is recommended that triggered update be enabled on a WAN interface running PPP, Frame Relay (FR), or X.25 to meet requirements of on-demand links.
- If the triggered update function is enabled on an interface, source address verification is performed regardless of whether source address verification is enabled by the **validate-update-source** command.
- Unless otherwise required, triggered update must be enabled on on-demand links of each router.

Verification

When the RIP triggered update function is enabled, RIP cannot periodically send route update packets. RIP sends the route update packets to the WAN interface only in one of the following cases:

- A route request packet is received.
- RIP routing information changes.
- The interface state changes.
- The router is started.



Related Commands

Enabling Triggered Update

Command Syntax	**ip rip triggered** { **retransmit-timer** *timer* | **retransmit-count** *count* }
Parameter Description	**retransmit-timer** *timer*: Configures the interval at which update request or response packets are retransmitted. The default value is 5s. The value range is from 1 to 3600. **retransmit-count** *count*: Configures the maximum retransmission count of update request or response packets. The default value is 36. The value range is from 1 to 3600.
Command Mode	Interface configuration mode
Configuration Usage	You can run the **ip rip triggered** command to enable the triggered update function. When this function is enabled, the RIP periodical update function is automatically disabled. Therefore, the acknowledgment and retransmission mechanisms must be used to ensure that update packets are successfully sent or received on the WAN. You can use the **retransmit-timer** and **retransmit-count** parameters to specify the retransmission interval and maximum retransmission count of request and update packets.

Configuration Example

Enabling Triggered Update

Scenario **Figure 1-9**	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● On Router A, enable the RIP triggered update function, and set the retransmission interval and maximum retransmission count of request and update packets to 10s and 18, respectively.

A	`A# configure terminal`
	`A(config)# interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# encapsulation ppp`
	`A(config-if-GigabitEthernet 0/1)# ip rip triggered`
	`A(config-if-GigabitEthernet 0/1)# ip rip triggered retransmit-timer 10`
	`A(config-if-GigabitEthernet 0/1)# ip rip triggered retransmit-count 18`
	`A(config-if-GigabitEthernet 0/1)# ip rip split-horizon poisoned-reverse`
	`A(config)# router rip`
	`A(config-router)# network 192.168.1.0`
	`A(config-router)# network 200.1.1.0`

B	`B# configure terminal`
	`B(config)# interface GigabitEthernet 0/1`
	`B(config-if-GigabitEthernet 0/1)# encapsulation ppp`
	`B(config-if-GigabitEthernet 0/1)# ip rip triggered`
	`B(config-if-GigabitEthernet 0/1)# ip rip split-horizon poisoned-reverse`
	`B(config)# router rip`
	`B(config-router)# network 192.168.1.0`
	`B(config-router)# network 201.1.1.0`

Verification	● On Router A and Router B, check the RIP database and verify that corresponding routes are permanent.

A	`A# sho ip rip database`
	`201.1.1.0/24  auto-summary`
	`201.1.1.0/24`
	`[1] via 192.168.12.2 GigabitEthernet 0/1  06:25  permanent`

B	`B# sho ip rip database`
	`200.1.1.0/24  auto-summary`
	`200.1.1.0/24`
	`  [1] via 192.168.12.1 GigabitEthernet 0/1  06:25  permanent`

Common Errors

- The triggered update function is enabled when the RIP configurations at both ends of the link are consistent.
- The triggered update function is not enabled on all routers on the same link.

1.4.4 Enabling Source Address Verification

Configuration Effect

- The source address of the received RIP route update packet is verified.

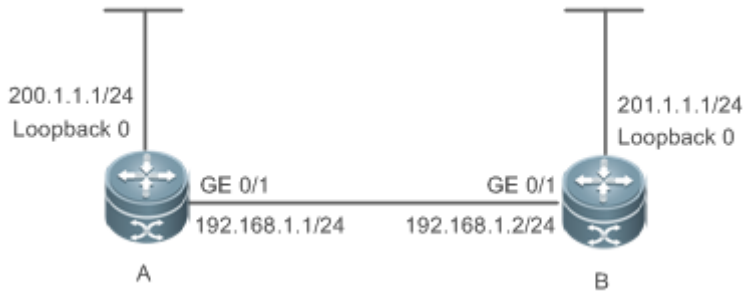
Notes

- Basic RIP functions must be configured.

Configuration Step

↘ Enabling Source Address Verification

- This function is enabled by default, and must be disabled if not required.
- After split horizon is disabled on an interface, the RIP routing process will perform source address verification on the update packet regardless of whether the **validate-update-source** command is executed in routing process configuration mode.
- Source address verification is invalid for the interface with the unnumbered IP address regardless of whether the **validate-update-source** command is executed in routing process configuration mode.
- Unless otherwise required, this function must be disabled on each router that does not require source address verification.



Verification

- Only the route update packets coming from the same IP subnet neighbor are received.

Related Commands

Command Syntax	**validate-update-source**
Parameter Description	N/A
Command Mode	Routing process configuration mode
Configuration Usage	Source address verification of update packets is enabled by default. After this function is enabled, the source address of RIP route update packets is verified. This ensure that the RIP routing process receives only route update packets coming from the same IP subnet neighbor.

Configuration Example

Scenario **Figure 1-10**	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Disable source address verification of update packets on all routers.

A	`A# configure terminal`
	`A(config)# router rip`
	`A(config-router)# no validate-update-source`

B	`B# configure terminal`
	`B(config)# router rip`
	`B(config-router)# no validate-update-source`

Verification	● On Router A, check the routing table and verify that the entry 201.1.1.0/24 is loaded. ● On Router B, check the routing table and verify that the entry 200.1.1.0/24 is loaded.
A	`A# show ip route rip` `R    201.1.1.0/24 [120/1] via 192.168.2.2, 00:06:11, GigabitEthernet 0/1`
B	`B# show ip route rip` `R    200.1.1.0/24 [120/1] via 192.168.1.1, 00:06:11, GigabitEthernet 0/1`

1.4.5 Enabling Authentication

Configuration Effect

- Prevent the device from learning unauthenticated and invalid routes or advertising valid routes to unauthorized devices, ensuring stability of the system and protecting the system against intrusions.

Notes

- Basic RIP functions must be configured.
- Only RIPv2 supports authentication of RIP packets, and RIPv1 does not.

Configuration Step

↘ Enabling Authentication and Specifying the Keychain Used for RIP Authentication

- This configuration is mandatory if authentication must be enabled.
- If the keychain is already specified in interface configuration mode, run the **key chain** command in global configuration mode to define the keychain; otherwise, RIP packets may fail to be authenticated.
- Unless otherwise required, this configuration must be performed on each router that requires authentication.

↘ Defining the RIP Authentication Mode

- This configuration is mandatory if authentication must be enabled.
- The RIP authentication modes configured on all devices that need to directly exchange RIP routing information must be the same; otherwise, RIP packets may fail to be exchanged.
- If cleartext authentication is used, but the keychain for cleartext authentication is not configured or associated, authentication is not performed. Similarly, if MD5 authentication is used, but the keychain is not configured or associated, authentication is not performed.
- Unless otherwise required, this configuration must be performed on each router that requires authentication.

Enabling RIP Cleartext Authentication and Configuring the Keychain

- This configuration is mandatory if authentication must be enabled.
- If RIP cleartext authentication should be enabled, use this command to configure the keychain for cleartext authentication. Alternatively, you can obtain the keychain for cleartext authentication by associating the keychain. The keychain obtained using the second method takes precedence over that obtained using the first method.
- Unless otherwise required, this configuration must be performed on each router that requires authentication.

Verification

- RIP cleartext authentication provides only limited security because the password transferred through packets is visible.
- RIP MD5 authentication can provide higher security because the password transferred through packets is encrypted using the MD5 algorithm.
- Routes can be learned properly if correct authentication parameters are configured.
- Routes cannot be learned if the incorrect authentication parameters are configured.

Related Commands

Enabling Source Address Verification

Command Syntax	**ip rip authentication key-chain** *name-of-keychain*
Parameter Description	*name-of-keychain*: Specifies the name of the keychain used for RIP authentication.
Command Mode	Interface configuration mode
Configuration Usage	The specified keychain must be defined by the **key chain** command in global configuration mode in advance.

Defining the RIP Authentication Mode

Command Syntax	**ip rip authentication mode** { **text** | **md5** }
Parameter Description	**text:** Indicates that the RIP authentication mode is cleartext authentication. **md5:** Indicates that the RIP authentication mode is MD5 authentication.
Command Mode	Interface configuration mode

Configuration Usage	For all devices that need to directly exchange RIP routing information, the RIP authentication mode of these devices must be the same.

Enabling RIP Cleartext Authentication and Configuring the Keychain

Command Syntax	**ip rip authentication text-password** [**0** | **7**] *password-string*
Parameter Description	**0**: Indicates that the key is displayed in cleartext. **7**: Indicates that the key is displayed in cipher text. *password-string*: Indicates the keychain used for cleartext authentication. The keychain is a string of 1 to 16 bytes.
Command Mode	Interface configuration mode
Configuration Usage	This commands takes effect only in cleartext authentication mode.

Configuration Example

Configuring Basic RIP Functions and Enabling MD5 Authentication

Scenario Figure 1-11	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Configure the authentication type and MD5 authentication key on all routers.

A	`A# configure terminal`
	`A(config)# key chain hello`
	`A(config-keychain)# key 1`
	`A(config-keychain-key)# key-string world`
	`A(config-keychain-key)# exit`
	`A(config-keychain)# exit`
	`A(config)# interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip rip authentication mode md5`
	`A(config-if-GigabitEthernet 0/1)# ip rip authentication key-chain hello`

B	`B# configure terminal`
	`B(config)# key chain hello`
	`B(config-keychain)# key 1`
	`B(config-keychain-key)# key-string world`
	`B(config-keychain-key)# exit`

	B(config-keychain)# exit B(config)# interface GigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)# ip rip authentication mode md5 B(config-if-GigabitEthernet 0/1)# ip rip authentication key-chain hello
Verification	● On Router A, check the routing table and verify that the entry 201.1.1.0/24 is loaded. ● On Router B, check the routing table and verify that the entry 200.1.1.0/24 is loaded.
A	A# show ip route rip R 201.1.1.0/24 [120/1] via 192.168.1.2, 00:06:11, GigabitEthernet 0/1
B	A# show ip route rip R 200.1.1.0/24 [120/1] via 192.168.1.1, 00:06:11, GigabitEthernet 0/1

Common Errors

- The keys configured on routers that need to exchange RIP routing information are different.
- The authentication modes configured on routers that need to exchange RIP routing information are different.

1.4.6 Enabling Route Summarization

Configuration Effect

Route summarization reduces the size of the routing table, improves the routing efficiency, avoids route flapping to some extent, and improves scalability and effectiveness of the network.

- If a summarized route exists, sub-routes included by the summarized route cannot be queried in the routing table, which greatly reduces the size of the routing table.
- Advertising a summarized route is more efficient than advertising individual routes because a summarized route is processed first when RIP looks up the database. Furthermore, all sub-routes are ignored when RIP looks up the database, which reduces the processing time required.

Notes

- Basic RIP functions must be configured.
- The range of supernetting routes is larger than that of the classful network. Therefore, automatic route summarization is invalid for supernetting routes.
- RIPv1 always performs automatic route summarization. If the detailed routes should be advertised, you must set the RIP version to RIPv2.

Configuration Step

Enabling Automatic Route Summarization

- This function is enabled by default.
- To learn specific subnet routes but not summarized network routes, you must disable automatic route summarization.
- You can disable automatic route summarization only in RIPv2. RIPv1 always performs automatic route summarization.

Configuring RIP Route Summarization on an Interface

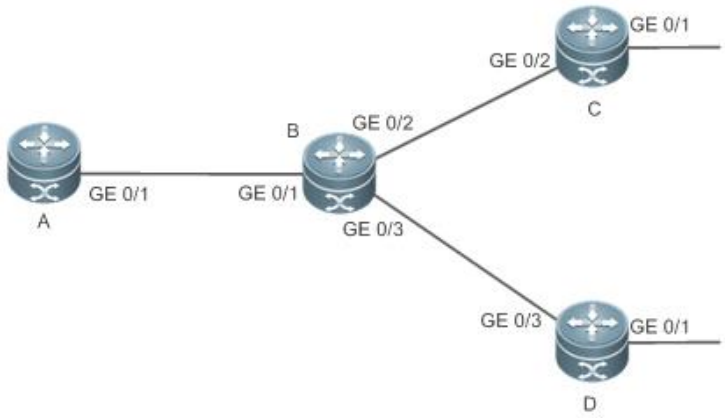
- This function must be configured if classful subnets need to be summarized.
- The **ip rip summary-address** command is used to summarize an address or a subnet on a specified interface. RIP automatically summarizes subnet routes to the classful network boundary. Each classful subnet can be configured only in the **ip rip summary-address** command.
- The summarization range configured in this command cannot be supernetting routes, that is, the configured subnet mask length cannot be smaller than the natural mask length of the network.
- Unless otherwise required, this configuration should be performed on a router that requires classful subnet summarization.

Verification

Verify that the routes are summarized in the routing table of the peer end.

Related Commands

Enabling Automatic Route Summarization



Command Syntax	**auto-summary**
Parameter Description	N/A
Command Mode	Routing process configuration mode
Configuration Usage	Route summarization is enabled by default for RIPv1 and RIPv2. You can disable automatic route summarization only in RIPv2. RIPv1 always performs automatic route summarization.

Configuring RIP Route Summarization on an Interface

Command Syntax	**ip rip summary-address** *ip-address ip-network-mask*
Parameter Description	*ip-address*: Indicates the IP address to be summarized. *ip-network-mask*: Indicates the subnet mask of the IP address to be summarized.
Command Mode	Interface configuration mode
Configuration Usage	This command is used to summarize an address or a subnet on a specified interface.

Configuration Example

Configuring Route Summarization

Scenario **Figure 1-12**	 **Remarks**: Interfaces' IP addresses are as follows: A: GE0/1: 192.168.1.1 B: GE0/1: 192.168.1.2; GE0/2: 172.16.2.1; GE0/3: 172.16.3.1 C: GE0/2: 172.16.2.2; GE0/3: 172.16.4.2 D: GE0/2: 172.16.3.2; GE0/3: 172.16.5.2
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Configure route summarization on Router B.

	`B# configure terminal`
	`B(config)# interface GigabitEthernet 0/1`
	`B(config-if-GigabitEthernet 0/1)# ip rip summary-address 172.16.0.0 255.255.0.0`
	`B(config)# router rip`
	`B(config-router)# version 2`
	`B(config-router)# no auto-summary`

Verification	● Check the routing table on Router A, and verify that the entry 172.16.0.0/16 is generated.
	`A# show ip route rip` `R 172.16.0.0/16 [120/2] via 192.168.1.2, 00:01:04, GigabitEthernet 0/1`

Common Errors

- Basic RIP functions are not configured or fail to be configured.

1.4.7 Enabling Supernetting Routes

Configuration Effect

- Allow RIP to send RIP supernetting routes on a specified interface.

Notes

- Basic RIP functions must be configured.

Configuration Step

↘ **Enabling Supernetting Routes**

- If a supernetting route is detected when a RIPv1-enabled router detects RIPv2 route response packets, the router will learn an incorrect route because RIPv1 ignores the subnet mask in routing information of packets. In this case, the **no** form of the command must be used on the RIPv2-enabled router to prohibit supernetting routes from being advertised on the related interface. This command takes effect only on the current interface.
- The command is effective only when RIPv2 packets are sent on the interface, and is used to control the sending of supernetting routes.

Verification

Verify that the peer router cannot learn the supernetting route.

Related Commands

Command Syntax	**ip rip send supernet-routes**
Parameter Description	N/A
Command Mode	Interface configuration mode
Configuration Usage	By default, an interface is allowed to send RIP supernetting routes.

Configuration Example

Disabling Supernetting Routes

Scenario Figure 1-13	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Prohibit RIP supernetting routes from being sent on GigabitEthernet 0/1 of Router B.

	`B# configure terminal`
	`B(config)# ip route 207.0.0.0 255.0.0.0 Null 0`
	`B(config)# ip route 208.1.1.0 255.255.255.0 Null 0`
	`B(config)# router rip`
	`B(config-router)# redistribute static`
	`B(config)# interface GigabitEthernet 0/1`
	`B(config-if-GigabitEthernet 0/1)# no ip rip send supernet-routes`

Verification	● Check the routing table on Router A, and verify that Router A can learn only the non-supernetting route 208.1.1.0/24, but not the supernetting route 207.0.0.0/8.
	`A#show ip route rip` `R  208.1.1.0/24 [120/1] via 192.168.1.2, 00:06:11, GigabitEthernet 0/1`

1.4.8 Advertising the Default Route or External Routes

Configuration Effect

- In the RIP domain, introduce a unicast route of another AS so that the unicast routing service to this AS can be provided for users in the RIP domain.
- In the RIP domain, inject a default route to another AS so that the unicast routing service to this AS can be provided for users in the RIP domain.

Notes

- Basic RIP functions must be configured.
- Route redistribution cannot introduce default routes of other protocols to the RIP routing domain.

Configuration Step

↘ Advertising the Default Route to Neighbors

This function must be enabled if required.

By default, a default route is not generated, and the metric of the default route is 1.

If the RIP process can generate a default route using this command, RIP does not learn the default route advertised by the neighbor.

Unless otherwise required, this configuration should be performed on a router that needs to advertise the default route.

↘ Advertising the Default Route to Neighbors on an Interface

This function must be enabled if required.

By default, a default route is not configured and the metric of the default route is 1.

After this command is configured on an interface, a default route is generated and advertised through this interface.

Unless otherwise required, this configuration should be performed on a router that needs to advertise the default route.

↘ Redistributes Routes and Advertises External Routes to Neighbors

This function must be enabled if routes of other protocols need to be redistributed.

The default settings are as follows:

- If OSPF redistribution is configured, the device redistributes the routes of all sub-types of the OSPF process.
- If IS-IS redistribution is configured, the device redistributes the level-2 routes of the IS-IS process.
- In other cases, the device redistributes all external routes.
- The metric of a redistributed route is 1 by default.
- The route map is not associated by default.

During route redistribution, the device does not need to convert the metric of one routing protocol to the metric of another routing protocol because different routing protocols use different metric measurement methods. RIP measures the metric based on the hop count, and OSPF measures the metric based on the bandwidth. Therefore, the computed metrics cannot be compared with each other. During route redistribution, configure a symbolic metric; otherwise, route redistribution fails.

Unless otherwise required, this configuration should be performed on a router that needs to redistribute routes.

Verification

- On a neighboring device, verify that a default route exists in the RIP routing table.
- On the local and neighboring devices, verify that external routes (routes to other ASs) exist in the RIP routing table.

Related Commands

Advertising the Default Route to Neighbors

Command Syntax	**default-information originate** [**always**] [**metric** *metric-value*] [**route-map** *map-name*]
Parameter Description	**always:** Enables RIP to generate a default route regardless of whether the local router has a default route. **metric** *metric-value:* Indicates the initial metric of the default route. The value range is from 1 to 15. **route-map** *map-name:* Indicates the associated route map name. By default, no route map is associated.
Command Mode	Routing process configuration mode
Configuration Usage	If a default route exists in the routing table of a router, RIP does not advertise the default route to external entities by default. You need to run the **default-information originate** command in routing process configuration mode to advertise the default route to neighbors. If the **always** parameter is selected, the RIP routing process advertises a default route to neighbors regardless of whether the default route exists, but this default route is not displayed in the local routing table. To check whether the default route is generated, run the **show ip rip database** command to check the RIP routing information database. To further control the behavior of advertising the RIP default route, specify **route-map**. For example, use **set metric** to set the metric of the default route. You can use the **metric** parameter to set the metric of the advertised default value, but the priority of this configuration is lower than that of the set metric rule of the **route-map** parameter. If the **metric** parameter is not configured, the default route uses the default metric configured for RIP. You still need to run the **default-information originate** command to introduce the default route generated by **ip default-network** to RIP.

Advertising the Default Route to Neighbors on an Interface

Command Syntax	**ip rip default-information** { **only** | **originate** } [**metric** *metric-value*]
Parameter Description	**only**: Indicates that only the default route is advertised. **originate**: Indicates that the default route and other routes are advertised. **metric** *metric-value:* Indicates the metric of the default route. The value range is from 1 to 15.
Command Mode	Interface configuration mode
Configuration	If you configure the **ip rip default-information** command for the interface and the

Usage	**default-information originate** command for the RIP process, only the default route configured for the interface is advertised. If **ip rip default-information** is configured for one interface, RIP does not learn the default route advertised by the neighbor.

Redistributes Routes and Advertises External Routes to Neighbors

Command Syntax	**redistribute** { **bgp** | **connected** | **isis** [*area-tag*] | **ospf** *process-id* | **static** } [{ **level-1 | level-1-2 | level-2** }] [**match** { **internal | external** [**1 | 2**] **| nssa-external** [**1 | 2**] }] [**metric** *metric-value*] [**route-map** *route-map-name*]
Parameter Description	**bgp**: Indicates redistribution from BGP. **connected**: Indicates redistribution from direct routes. **isis** *area-tag*: Indicates redistribution from IS-IS. *area-tag* indicates the IS-IS process ID. **ospf** *process-id*: Indicates redistribution from OSPF. *process-id* indicates the OSPF process ID. The value range is from 1 to 65535. **static**: Indicates redistribution from static routes. **level-1** | **level-1-2** | **level-2**: Is used only when IS-IS routes are redistributed. Only the routes of the specified level are redistributed. **match**: Is used only when OSPF routes are redistributed. Only the routes that match the filtering conditions are redistributed. **metric** *metric-value*: Sets the metric of the redistributed route. The value range is from 1 to 16. **route-map** *route-map-name*: Sets the redistribution filtering rule.
Command Mode	Routing process configuration mode
Configuration Usage	When you configure redistribution of IS-IS routes without specifying the **level** parameter, only level-2 routes can be redistributed by default. If you specify the **level** parameter during initial configuration of redistribution, routes of the specified level can be redistributed. If both **level-1** and **level-2** are configured, the two levels are combined and saved as **level-1-2**. If you configure redistribution of OSPF routes without specifying the **match** parameter, OSPF routes of all sub-types can be distributed by default. The latest setting of the **match** parameter is used as the initial **match** parameter. Only routes that match the sub-types can be redistributed. You can use the **no** form of the command to restore the default value of **match**. The configuration rules for the **no** form of the **redistribute** command are as follows: 1. If some parameters are specified in the **no** form of the command, default values of these parameters will be restored. 2. If no parameter is specified in the **no** form of the command, the entire command will be deleted. For example, if **redistribute isis 112 level-2** is configured, you can run the **no redistribute isis 112 level-2** command to restore the default value of **level-2**. As level-2 itself is the default value of the parameter, the configuration saved is still **redistribute isis 112 level-2** after the preceding **no** form of the command is executed. To delete the entire command, run the **no redistribute isis 112** command.

Configuration Example

Redistributing Routes and Advertising External Routes to Neighbors

Scenario **Figure 1-14**	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● On Router B, configure redistribution of static routes.

B	`B# configure terminal`
	`B(config)# router rip`
	`B(config-router)# redistribute static`

Verification	● On Router A, check the routing table and verify that the entry 172.10.10.0/24 is loaded.
	`A# show ip route rip` `R    172.10.10.0/24 [120/1] via 192.168.1.2, 00:06:11, GigabitEthernet 0/1`

1.4.9 Setting Route Filtering Rules

Configuration Effect

- Routes that do not meet filtering criteria cannot be loaded to the routing table, or advertised to neighbors. In this way, users within the network can be prevented from accessing specified destination networks.

Notes

- Basic RIP functions must be configured.
- For filtering rules of sent routes, you must configure route redistribution first, and then filter the redistributed routes.

Configuration Step

↘ Filtering the Received RIP Routing Information

- This function must be configured if required.
- To prevent the device from receiving some specified routes, you can configure the route distribution control list to process all the received route update packets. If no interface is specified, route update packets received on all interfaces will be processed.
- Unless otherwise required, this configuration should be performed on a router that requires route filtering.

↘ Filtering the Sent RIP Routing Information

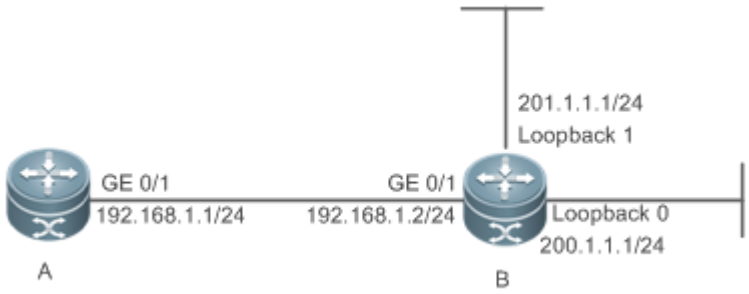
- This function must be configured if required.
- If this command does not contain any optional parameter, route update advertisement control takes effect on all interfaces. If the command contains the interface parameter, route update advertisement control takes effect only on the specified interface. If the command contains other routing process parameters, route update advertisement control takes effect only on the specified routing process.
- Unless otherwise required, this configuration should be performed on a router that requires route filtering.

Verification

- Run the **show ip route rip** command to verify that the routes that have been filtered out are not loaded to the routing table.

Related Commands

Filtering the Received RIP Routing Information

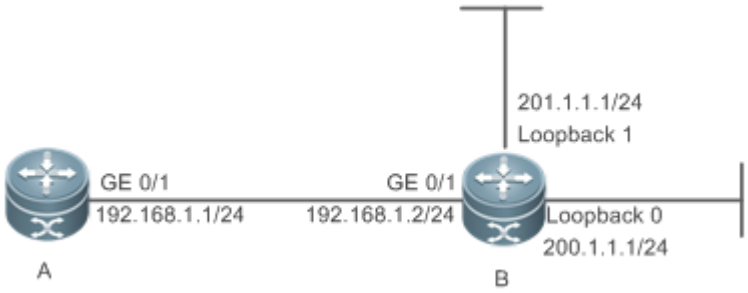


Command Syntax	**distribute-list** { [*access-list-number* | *name*] | **prefix** *prefix-list-name* [**gateway** *prefix-list-name*] } **in** [*interface-type interface-number*]
Parameter Description	*access-list-number* | *name*: Specifies the access list. Only routes permitted by the access list can be received. **prefix** *prefix-list-name*: Uses the prefix list to filter routes. **gateway** *prefix-list-name*: Uses the prefix list to filter the route sources. *interface-type interface-number*: Indicates that the distribution list is applied to the specified interface.
Command Mode	Routing process configuration mode
Configuration Usage	N/A

Filtering the Sent RIP Routing Information

Command Syntax	**distribute-list** { [*access-list-number* | *name*] | **prefix** *prefix-list-name* } **out** [*interface* **|** [**bgp | connected | isis** [*area-tag*] **| ospf** *process-id* **| rip | static**]]
Parameter Description	*access-list-number* | *name*: Specifies the number of an access control list (ACL). Only routes permitted by the ACL can be sent. **prefix** *prefix-list-name*: Uses the prefix list to filter routes. *Interface*: Applies route update advertisement control only on the specified interface. **bgp**: Applies route update advertisement control only on the routes introduced from BGP. **connected**: Applies route update advertisement control only on direct routes introduced through redistribution. **isis** [*area-tag*]: Applies route update advertisement control only on the routes introduced from IS-IS. *area-tag* specifies an IS-IS process. **ospf** *process-id*: Applies route update advertisement control only on the routes introduced from OSPF. *process-id* specifies an OSPF process. **rip**: Applies route update advertisement control only on RIP routes. **static**: Applies route update advertisement control only on static routes introduced through redistribution.
Command Mode	Routing process configuration mode
Configuration Usage	N/A

Configuration Example



Filtering the Received RIP Routing Information

Scenario **Figure 1-15**	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Enable the RIP routing process to control routes received over GigabitEthernet 0/1 and receive only the route 200.1.1.0.

A	`A# configure terminal`
	`A(config)# router rip`
	`A(config-router)# distribute-list 10 in GigabitEthernet 0/1`
	`A(config-router)# no auto-summary`
	`A(config)# access-list 10 permit 200.1.1.0 0.0.0.255`

Verification	● On Router A, check the routing table and verify that only the entry 200.1.1.0/24 exists.
A	`A# show ip route rip` `R    200.1.1.0/24 [120/1] via 192.168.1.2, 00:06:11, GigabitEthernet 0/1`

Filtering the Sent RIP Routing Information

Scenario **Figure 1-16**	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Enable the RIP routing process to advertise only the route 200.1.1.0/24.

B	`B# configure terminal`
	`B(config)# router rip`
	`B(config-router)# redistribute connected`
	`B(config-router)# distribute-list 10 out`
	`B(config-router)# version 2`
	`B(config)# access-list 10 permit 200.1.1.0 0.0.0.255`

Verification	● Check the routing table on Router A, and verify that route on the network segment 200.1.1.0 exists.
A	`A# show ip route rip`

	`R  200.1.1.0/24 [120/1] via 192.168.1.2, 00:06:11, GigabitEthernet 0/1`

Common Errors

- Filtering fails because the filtering rules of the access list are not properly configured.

1.4.10 Changing Route Selection Parameters

Configuration Effect

- Change RIP routes to enable the traffic to pass through specified nodes or prevent it passing through specified nodes.
- Change the sequence that a router selects various types of routes so as to change the priorities of RIP routes.

Notes

- Basic RIP functions must be configured.

Configuration Step

Changing the Administrative Distance of a RIP Route

- Optional.
- This configuration is mandatory if you wish to change the priorities of RIP routes on a router that runs multiple unicast routing protocols.

Increasing the Metric of a Received or Sent RIP Route

- Optional.
- Unless otherwise required, this configuration should be performed on a router where the metrics of routes need to be adjusted.

Configuring the Default Metric of an External Route Redistributed to RIP

- Optional.
- Unless otherwise required, this configuration must be performed on an ASBR to which external routes are introduced.

Verification

Run the **show ip rip** command to display the configured administrative distance. Run the **show ip rip data** command to display the metrics of redistributed routes to verify that the configuration takes effect.

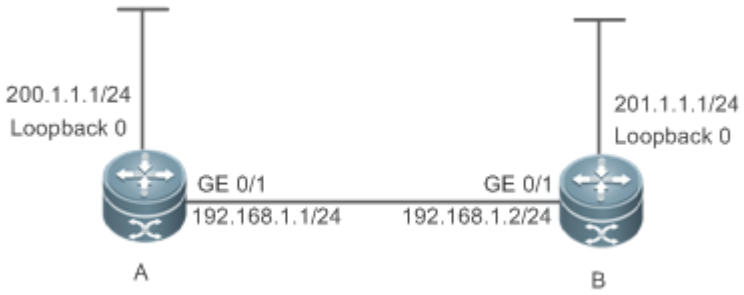
Related Commands

Changing the Administrative Distance of a RIP Route

Command Syntax	**distance** *distance* [*ip-address wildcard*]
Parameter Description	*distance*: Sets the administrative distance of a RIP route. The value is an integer ranging from 1 to 255.

	ip-address: Indicates the prefix of the source IP address of the route. *wildcard*: Defines the IP address comparison bit. The value 0 indicates accurate matching, and the value 1 indicates that no comparison is performed.
Command Mode	Routing process configuration mode
Configuration Usage	Run this command to configure the administrative distance of a RIP route.

Increasing the Metric of a Received or Sent RIP Route



Command Syntax	**offset-list** { *access-list-number* | *name* } { **in** | **out** } *offset* [*interface-type interface-number*]
Parameter Description	*access-list-number* | *name*: Specifies the number of name of an access control list (ACL). **In**: Uses the ACL to modify the metric of a received route. **out**: Uses the ACL to modify the metric of a sent route. *offset*: Indicates the offset of the modified metric. The value range is from 0 to 16. *interface-type*: Uses the ACL on the specified interface. *interface-number*: Specifies the interface number.
Command Mode	Routing process configuration mode
Configuration Usage	Run this command to increase the metric of a received or sent RIP route. If the interface is specified, the configuration takes effect only on the specified interface; otherwise, the configuration takes effect globally.

Configuring the Default Metric of an External Route Redistributed to RIP

Command Syntax	**default-metric** *metric-value*
Parameter Description	*metric-value:* Indicates the default metric. The valid value range is from 1 to 16. If the value is equal to or greater than 16, the RGOS determines that this route is unreachable.
Command Mode	Routing process configuration mode
Configuration Usage	This command must be used together with the routing protocol configuration command **redistribute**.

Configuration Example

Increasing the Metric of a Received or Sent RIP Route

Scenario **Figure 1-17**	

Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Increase by 7 the metric of each RIP route in the range specified by ACL 7. ● Increase by 7 the metric of each learned RIP route in the range specified by ACL 8.

A	`A# configure terminal`
	`A(config)# access-list 7 permit host 200.1.1.0`
	`A(config)# access-list 8 permit host 201.1.1.0`
	`A(config)# router rip`
	`A(config-router)# offset-list 7 out 7`
	`A(config-router)# offset-list 8 in 7`

Verification	● Check the routing table on Router A and Router B to verify that the metrics of RIP routes are 8.
A	`A# show ip route rip` `R    201.1.1.0/24 [120/8] via 192.168.1.2, 00:06:11, GigabitEthernet 0/1`
B	`B# show ip route rip` `R    200.1.1.0/24 [120/8] via 192.168.1.1, 00:06:11, GigabitEthernet 0/1`

1.4.11 Changing Values of Timers

Configuration Effect

- Change values of RIP timers to accelerate or slow down the change of the protocol state or occurrence of an event.

Notes

- Basic RIP functions must be configured.
- Changing protocol control parameters may result in protocol running failures. Therefore, you are advised not to change values of timers.

Configuration Step

↘ Changing Values of the Update Timer, Invalid Timer, and Flush Timer

This configuration must be performed if you need to adjust RIP timers.

By adjusting the timers, you can reduce the convergence time and fault rectification time of the routing protocol. For routers connected to the same network, values of the three RIP timers must be the same. In most situations, you are advised not to modify the RIP timers unless otherwise required.

Setting timers to small values on a low-speed link brings risks because a lot of update packets consume the bandwidth. You can set timers to small values on the Ethernet or a 2 Mbps (or above) link to reduce the convergence time of network routes.

Unless otherwise required, this configuration should be performed on a router where RIP timers need to be modified.

↘ Setting the Sending Delay Between RIP Route Update Packets

This configuration must be performed if you need to adjust the sending delay between RIP update packets.

Run the **output-delay** command to increase the sending delay between packets on a high-speed device so that a low-speed device can receive and process all update packets.

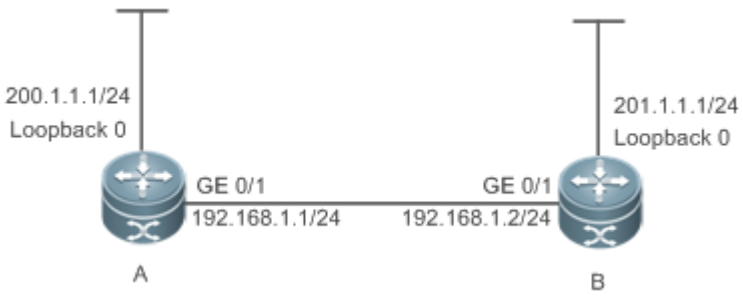
Unless otherwise required, this configuration should be performed on a router where the sending delay needs to be adjusted.

Verification

Run the **show ip rip** command to display settings of RIP timers.

Related Commands

Modifying the Update Timer, Invalid Timer, and Flush Timer



Command Syntax	**timers basic** *update invalid flush*
Parameter Description	*update*: Indicates the interval at which the device sends the route update packets, in seconds. Each time an update packet is received, the invalid timer and flush timer are reset. By default, a routing update packet is sent every 30s. *invalid*: Indicates the time after which the route in the routing list becomes invalid because the route is not updated, in seconds. It is counted from the last time when a valid update packet is received. The duration of the invalid timer must be at least three times the duration of the update timer. If no update packet is received before the invalid timer expires, the corresponding route enters the invalid state. If the update packet is received before the invalid timer expires, the timer is reset. The default value of the invalid timer is 180s. *flush*: Indicates the route flushing time, in seconds. It is counted from the time when the RIP route enters the invalid state. When the flush timer expires, the route in the invalid state will be deleted from the routing table. The default duration of the flush timer is 120s.
Command Mode	Routing process configuration mode
Configuration Usage	By default, the update timer is 30s, the invalid timer is 180s, and the flush timer is 120s.

Setting the Sending Delay Between RIP Route Update Packets

Command Syntax	**output-delay** *delay*
Parameter Description	*delay:* Sets the sending delay between packets, in milliseconds. The value range is from 8 to 50.
Command Mode	Interface configuration mode
Configuration Usage	Typically, a RIP route update packet is 512 bytes long and can contain 25 routes. If the number of routes to be updated exceeds 25, more than one update packet will be sent as fast as possible. When a high-speed device sends a lot of update packets to a low-speed device, the low-speed device may not be able to process all update packets in a timely manner, causing a loss of routing information. In this case, you need to run the **output-delay** command to increase the sending delay between packets on a high-speed device so that a low-speed device can receive and process all update packets.

Configuration Example

Setting the Sending Delay Between RIP Route Update Packets

Scenario **Figure 1-18**	
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● Configure the sending delay of update packets on Router A.

A	`A# configure terminal`
	`A(config)# router rip`
	`A(config-router)# output-delay 30`

Verification	● Capture packets on Router A and compare the sending time of update packets before and after the configuration, and verify that a delay of 30 ms is introduced.

Common Errors

For routers connected to the same network, values of the three RIP timers are not the same.

1.4.12 Enabling GR

Configuration Effect

- When a distributed route switches services from the active card to the standby card, traffic forwarding continues.
- When the RIP process is being restarted, traffic forwarding continues.

Notes

- Basic RIP functions must be configured.
- The GR period is at least twice the RIP route update period.
- During the RIP GR process, ensure that the network is stable.

Configuration Step

Configuring the GR Capability

This configuration must be performed if RIP needs to be gracefully restarted to ensure data forwarding during hot standby switchover.

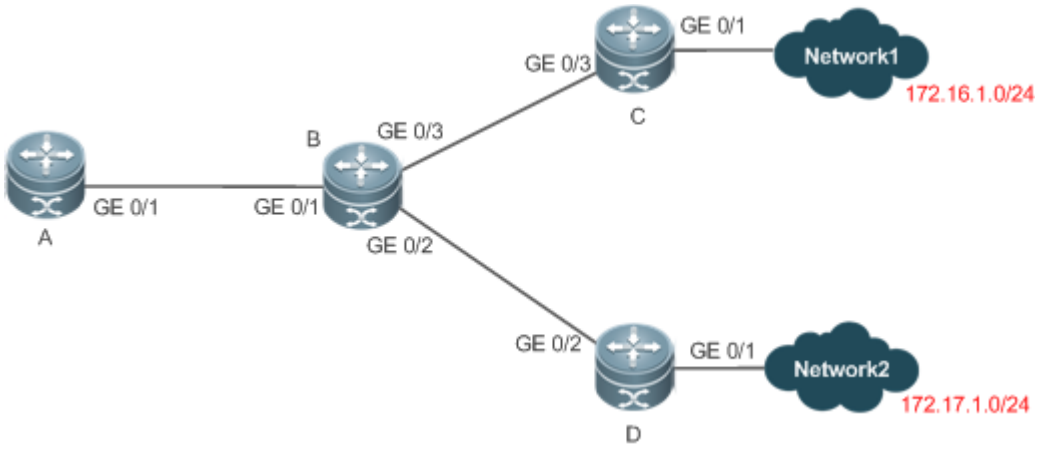
The GR function is configured based on the RIP process. You can configure different parameters for different RIP processes according to the actual situation.

The GR period is the maximum time from restart of the RIP process to completion of GR. During this period, the forwarding table before the restart is retained, and the RIP route is restored so as to restore the RIP state before the restart. After the restart period expires, RIP exits from the GR state and performs common RIP operations.

Unless otherwise required, this configuration should be performed on every router that needs to be gracefully restarted.

Verification

- Run the **show ip rip** command to display the GR state and configured time.
- Trigger a hot standby switchover, and verify that data forwarding is not interrupted.



Related Commands

Configuring the GR Capability

Command Syntax	**graceful-restart** [**grace-period** *grace-period*]
Parameter Description	**graceful-restart**: Enables the GR function. **grace-period**: Explicitly configures the grace period. *grace-period*: Indicates the GR period. The value range is from 1s to 1800s. The default value is twice the update time or 60s, which is the smaller.
Command Mode	Routing process configuration mode
Configuration Usage	This command allows you to explicitly modify the GR period. Note that GR must be completed after the update timer of the RIP route expires and before the invalid timer of the RIP route expires. An inappropriate GR period cannot ensure uninterrupted data forwarding during the GR process. A typical case is as follows: If the GR period is longer than the duration of the invalid timer, GR is not completed when the invalid timer expires. The route is not re-advertised to the neighbor, and forwarding of the route of the neighbor stops after the invalid timer expires, causing interruption of data forwarding on the network. Unless otherwise required, you are advised not to adjust the GR period. If it is necessary to adjust the GR period, ensure that the GR period is longer than the duration of the update timer but shorter than the duration of the invalid timer based on the configuration of the **timers basic** command.

Configuration Example

Configuring the GR Capability

Scenario **Figure 1-19**	 **Remarks**: Interfaces' IP addresses are as follows: A: GE 0/1:192.168.1.1 B: GE 0/1: 192.168.1.1; GE 0/2: 192.168.2.1: GE 0/3: 192.168.3.1 C: GE 0/1: 192.168.4.2; GE 0/3: 192.168.3.2 D: GE 0/1: 192.168.5.2; GE 0/2: 192.168.2.2
Configuration Steps	● Configure IP addresses for interfaces on all routers. (The configuration is not mentioned here.) ● Configure basic RIP functions on all routers. (The configuration is not mentioned here.) ● On Router B, enable the GR function.

	`B# configure terminal`
	`B(config)# router rip`
	`B(config-router)# graceful-restart grace-period 90`

Verification	● Trigger a hot standby switchover on Router B, and verify that the routing tables of destination Network 1 and Network 2 remain unchanged on Router A during the switchover. ● Trigger a hot standby switchover on Router B, ping destination Network 1 from Router A, and verify that traffic forwarding is not interrupted during the switchover.

1.5 Monitoring

Displaying

Command	Description
show ip rip	Displays basic information about a RIP process.
show ip rip database [*network-number network-mask*] [**count**]	Displays the RIP routing table.
show ip rip external [**connected** | **ospf** *process-id* | **static**]	Displays information about external routes redistributed by RIP.
show ip rip interface [*interface-type interface-number*]	Displays RIP interface information.
show ip rip peer [*ip-address*]	Displays RIP neighbor information.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description

Command	Description
debug ip rip event	Debugs events that occur when the RIP process is running.
debug ip rip nsm	Debugs interaction with the NSM process.
debug ip rip packet [**interface** *interface-type interface-number* | **recv** | **send**]	Debugs sent and received packets.
debug ip rip restart	Debugs the RIP GR process.
debug ip rip route	Debugs the route changes of the RIP process.

1 Configuring OSPFv2

1.1 Overview

Open Shortest Path First (OSPF) is an Interior Gateway Protocol (IGP) that is used within the Autonomous System (AS) to allow routers to obtain a route to a remote network.

OSPF Version 2 (OSPFv2) is applicable to IPv4, and OSPF Version 3 (OSPFv3) is applicable to IPv6. The protocol running mechanism and most configurations are the same.

OSPF has the following characteristics:

- Wide scope of application: OSPF is applicable to a larger-scale network that supports hundreds of routers.
- Fast convergence: Once the network topology changes, notifications can be quickly sent between routers to update routes.
- No self-loop: Only the link status information is synchronized between routers. Each router computes routes independently, and a self-loop will not occur.
- Area division: A large routing domain is divided into multiple small areas to save system resources and network bandwidth and ensure stability and reliability of routes.
- Route classification: Routes are classified into several types to support flexible control.
- Equivalent routes: OSPF supports equivalent routes.
- Authentication: OSPF supports packet authentication to ensure security of protocol interaction.
- Multicast transmission: Protocol packets are sent using the multicast address to avoid interfering with irrelevant entities and save system resources.

In this chapter, the term "router" refers to any network device that supports the routing function. These network devices can be L3 switches, routers, or firewall.

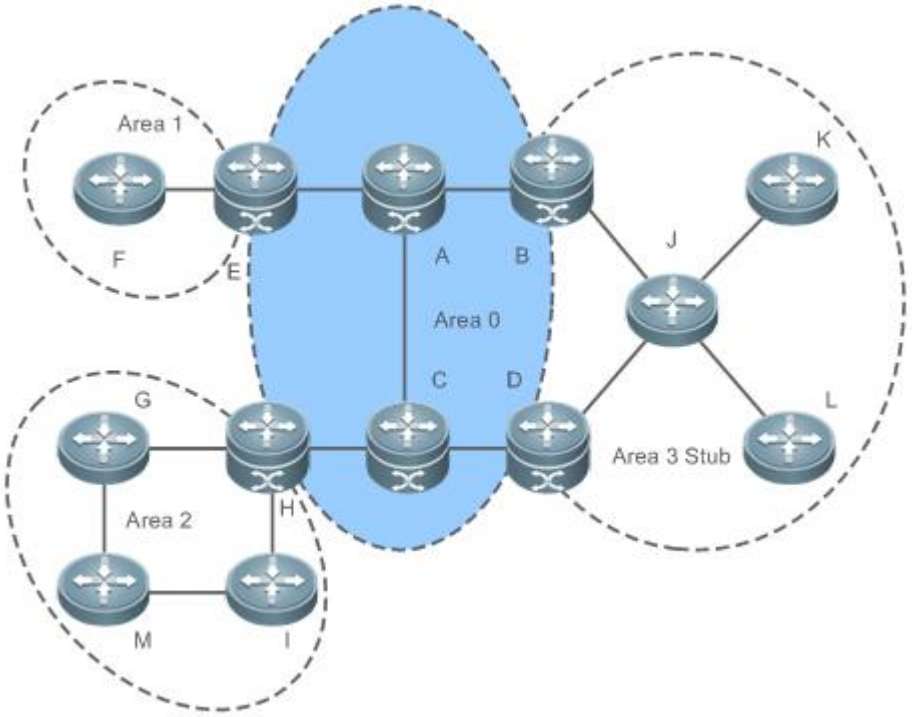
Unless otherwise specified, "OSPF" in the following descriptions refers to OSPFv2.

Protocols and Standards

RFC2328	This memo documents version 2 of the OSPFprotocol. OSPF is a link-state routing protocol.
RFC 2370	This memo defines enhancements to the OSPFprotocol to support a new class of link-state advertisements (LSA) called Opaque LSAs. Opaque LSAs provide a generalized mechanism to allow for the future extensibility of OSPF.
RFC3137	This memo describes a backward-compatible technique that may be used by OSPF (Open Shortest Path First) implementations to advertise unavailability to forward transit traffic or to lower the preference level for the paths through such a router.
RFC3623	This memo documents an enhancement to the OSPF routing protocol, whereby an OSPF router can stay on the forwarding path even as its OSPF software is restarted.

RFC3630	This document describes extensions to the OSPFprotocol version 2 to support intra-area Traffic Engineering (TE), using Opaque Link State Advertisements.
RFC3682	The use of a packet's Time to Live (TTL) (IPv4)or Hop Limit (IPv6) to protect a protocol stack from CPU-utilization based attacks has been proposed in many settings.
RFC3906	This document describes how conventional hop-by-hop link-state routing protocols interact with new Traffic Engineering capabilities to create Interior Gateway Protocol (IGP) shortcuts.
RFC4576	This document specifies the necessary procedure, using one of the options bits in the LSA (Link State Advertisements) to indicate that an LSA has already been forwarded by a PE and should be ignored by any other PEs that see it.
RFC4577	This document extends that specification by allowing the routing protocol on the PE/CE interface to be the OSPF protocol.
RFC4750	This memo defines a portion of the Management Information Base (MIB) for use with network management protocols in TCP/IP-based Internets. In particular, it defines objects for managing version 2 of the Open Shortest Path First Routing Protocol. Version 2 of the OSPF protocol is specific to the IPv4 address family.

1.2 Applications



Application	Description
Intra-Domain Interworking	OSPF runs within the AS, which is divided into several areas.

1.2.1 Intra-Domain Interworking

Scenario

OSPF runs within the AS. If the number of routers exceeds 40, it is recommended that the AS be divided into several areas. Generally, high-end devices featuring reliable performance and fast processing speed are deployed in a backbone area, and low-end or medium-range devices with relatively lower performance can be deployed in a normal area. All normal areas must be connected to the backbone area. It is recommended that a normal area located on the stub be configured as a stub area. As shown in Figure 1-1, the network is divided into four areas. Communication between these areas must go through the backbone area, which is area 0.

Figure 1-1 Division of the OSPF Areas

Remarks	A, B, C, D, E, and H are located in the backbone area, and are backbone routers. Area 3 is configured as a stub area.

Deployment

- OSPF runs on all routers within the AS to implement unicast routing.

1.3 Features

Basic Concepts

Routing Domain

All routers in an AS must be interconnected and use the same routing protocol. Therefore, the AS is also called routing domain.

An AS on which OSPF runs is also called OSPF routing domain, or OSPF domain for short.

OSPF Process

OSPF supports multiple instances, and each instance corresponds to an OSPF process.

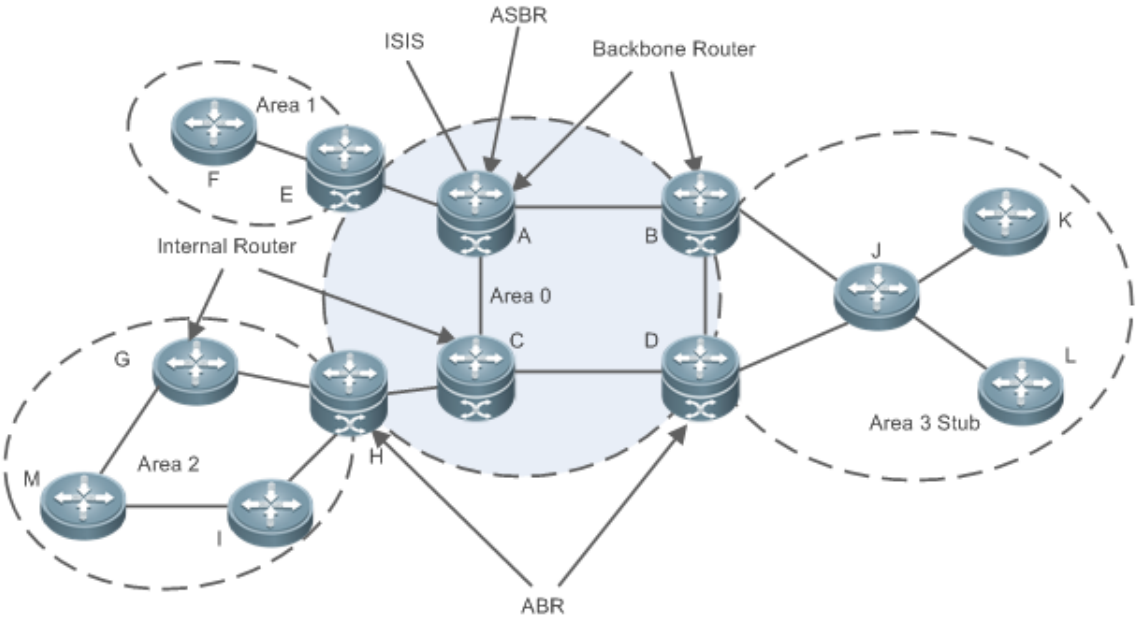
One or more OSPF processes can be started on a router. Each OSPF process runs OSPF independently, and the processes are mutually isolated.

The process ID takes effect only on the local router, and does not affect exchange of OSPF packets on adjacent interfaces.

RouterID

The router ID uniquely identifies a router in an OSPF domain. Router IDs of any two routers cannot be the same.

If multiple OSPF processes exist on a router, each OSPF process uses one router ID. Router IDs of any two OSPF processes cannot be the same.



Area

OSPF supports multiple areas. An OSPF domain is divided into multiple areas to ease the computing pressure of a large-scale network.

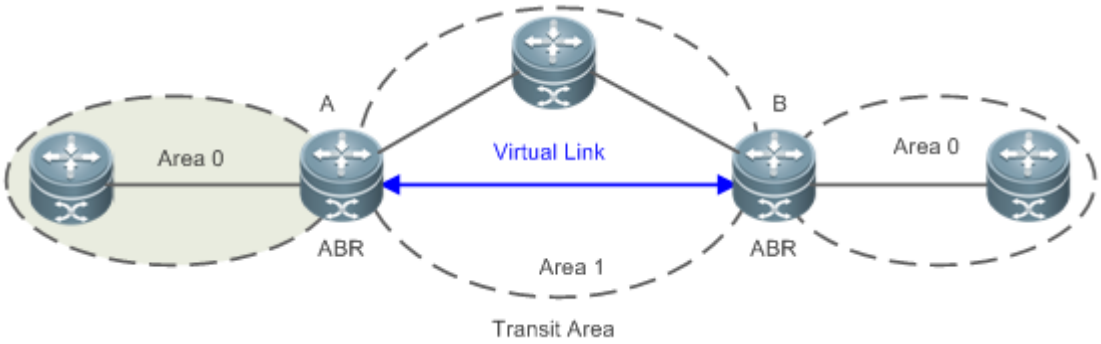
An area is a logical group of routers, and each group is identified by an area ID. The border between areas is a router. A router may belong to one area or multiple areas. One network segment (link) can belong to only one area, or each OSPF-enabled interface must belong to a specified area.

Area 0 is the backbone area, and other areas are normal areas. Normal areas must be directly connected to the backbone area.

Figure 1-2 Division of the OSPF Areas

OSPF Router

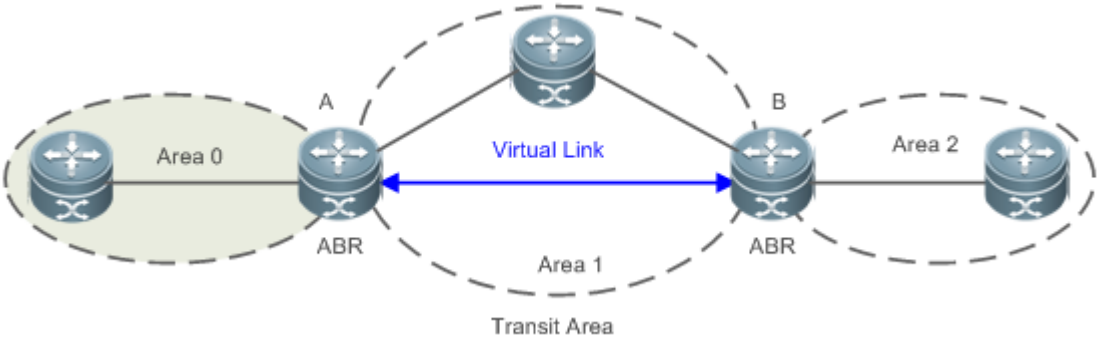
The following types of routers are defined in OSPF, and assigned with different responsibilities:



- Internal router
  All interface of an interval router belong to the same OSPF area. As shown in Figure 1-3, A, C, F, G, I, M, J, K, and L are internal routers.
- Area border router (ABR)
  An ABR is used to connect the backbone area with a normal area. An ABR belongs to two or more areas, and one of the areas must be the backbone area. As shown in Figure 1-3, B, D, E, and H are ABRs.
- Backbone router
  A backbone router has at least one interface that belongs to the backbone area. All ABRs and all routers in area 0 are backbone routers. As shown in Figure 1-, A, B, C, D, E, and H are backbone routers.

- AS boundary router (ASBR)
  An ASBR is used to exchange routing information with other ASs. An ASBR is not necessarily located on the border of an AS. It may be a router inside an area, or an ABR. As shown in Figure 1-3, A is an ASBR.

Virtual Link



OSPF supports virtual links. A virtual link is a logical link that belongs to the backbone area. It is used to resolve the problems such as a discontinuous backbone area or a failure to directly connect a normal area to the backbone area on the physical network. A virtual link supports traversal of only one normal area, and this area is called transit area. Routers on both ends of a virtual link are ABRs.

Figure 1-3 Discontinuous Backbone Area on the Physical Network

As shown in Figure 1-, a virtual link is set up between A and B to connect two separated area 0s. Area 1 is a transit area, and A and B are ABRs of area 1.

Figure 1-4 Failure to Directly Connect a Normal Area to the Backbone Area on the Physical Network

As shown in Figure 1-, a virtual link is set up between A and B to extend area 0 to B so that area 0 can be directly connected to area 2 on B. Area 1 is a transit area, A is an ABR of area 1, and B is an ABR of area 0 and area 2.

LSA

OSPF describes the routing information by means of Link State Advertisement (LSA).

LSA Type	Description
Router-LSA(Type 1)	This LSA is originated by every router. It describes the link state and cost of the router, and is advertised only within the area where the originating router is located.
Network-LSA(Type 2)	This LSA is originated by a designated routers (DR) on the NBMA network. It describes the link state in the current network segment, and is advertised only within the area where the DR is located.

LSA Type	Description
Network-summary-LSA(Type 3)	This LSA is originated by an ABR. It describes a route to another area, and is advertised to areas except totally stub areas or Not-So-Stubby Area (NSSA) areas.
ASBR-summary-LSA(Type 4)	This LSA is originated by an ABR. It describes a route to an ASBR, and is advertised to areas except areas where the ASBR is located.
AS-external-LSA(Type 5)	This LSA is originated by an ABR. It describes a route to a destination outside the AS, and is advertised to all areas except the stub and NSSA areas.
NSSA LSA(Type 7)	This LSA is originated by an ABR. It describes a route to a destination outside the AS, and is advertised only within the NASSA areas.
Opaque LSA(Type 9/Type 10/Type 11)	Opaque LSAs provide a generalized mechanism to allow for the future extensibility of OSPF, wherein, ● Type 9 LSAs are only advertised within the network segment where interfaces resides. The Grace LSA used to support graceful restart (GR) is one of Type 9 LSAs. ● Type 10 LSAs are advertised within an area. The LSA used to support Traffic Engineering (TE) is one of Type 10 LSAs. ● Type 11 LSAs are advertised within an AS. At present, there are no application examples of Type 11 LSAs.

Stub areas, NSSA areas, totally stub areas, and totally NSSA areas are special forms of normal areas and help reduce the load of routers and enhance reliability of OSPF routes.

OSPF Packet

The following table lists the protocol packets used by OSPF. These OSPF packets are encapsulated in IP packets and transmitted in multicast or unicast mode.

Packet Type	Description
Hello	Hello packets are sent periodically to discover and maintain OSPF neighbor relationships.
Database Description (DD)	DD packets carry brief information about the local Link-State Database (LSDB) and are used to synchronize the LSDBs between OSPF neighbors.
Link State Request (LSR)	LSR packets are used to request the required LSAs from neighbors. LSR packets are sent only after DD packets are exchanged successfully between OSPF neighbors.
Link State Update (LSU)	LSU packets are used to send the required LSAs to peers.
Link State Acknowledgment (LSAck)	LSAck packets are used to acknowledge the received LSAs.

Overview

Feature	Description
Link-State Routing Protocols	Run OSPF on the router to obtain routes to different destinations on the network.
OSPF Route Management	Plan or optimize OSPF routes through manual configuration to implement management of OSPF routes.

Feature	Description
Enhanced Security and Reliability	Use authentication, MTU verification and GR to enhance security, stability, and reliability of OSPF.
Network Management	Use functions such as the management information base (MIB) and Syslog to facilitate OSPF management.

1.3.1 Link-State Routing Protocols

OSPF is a type of link-state routing protocols. Its working process is as follows:

- Neighbor discovery → Bidirectional communication
  An OSPF neighbor relationship is set up between adjacent routers, and bidirectional communication is maintained.
- Database synchronization → Full adjacency
  A router uses LSAs to advertise all its link states. LSAs are exchanged between neighbors and the link state database (LSDB) is synchronized to achieve full adjacency.
- Shortest Path Tree (SPT) computation → Formation of a routing table
  The router computes the shortest path to each destination network based on the LSDB and forms an OSPF routing table.

Working Principle

↘ Neighbor Discovery → Bidirectional Communication

Routers send Hello packets through all OSPF-enabled interfaces (or virtual links). If Hello packets can be exchanged between two routers, and parameters carried in the Hello packets can be successfully negotiated, the two routers become neighbors. Routers that are mutually neighbors find their own router IDs from Hello packets sent from neighbors, and bidirectional communication is set up.

A Hello packet includes, but is not limited to, the following information:

- Router ID of the originating router
- Area ID of the originating router interface (or virtual link)
- Subnet mask of the originating router interface (or virtual link)
- Authentication information of the originating router interface (or virtual link)
- Hello interval of the originating router interface (or virtual link)
- Neighbor dead interval of the originating router interface (or virtual link)
- Priority of the originating router interface (used for DR/BDR election)
- IP addresses of the DR and Backup Designated Router (BDR)
- Router ID of the neighbor of the originating router

↘ Database Synchronization → Full Adjacency

After bidirectional communication is set up between neighbor routers, the DD, LSR, LSU, and LSAck packets are used to exchange LSAs and set up the adjacency. The brief process is as follows:

- A router generates an LSA to describe all link states on the router.

- The LSA is exchanged between neighbors. When a router receives the LSA from its neighbor, it copies the LSA and saves the copy in the local LSDB, and then advertises the LSA to other neighbors.
- When the router and its neighbors obtain the same LSDB, full adjacency is achieved.

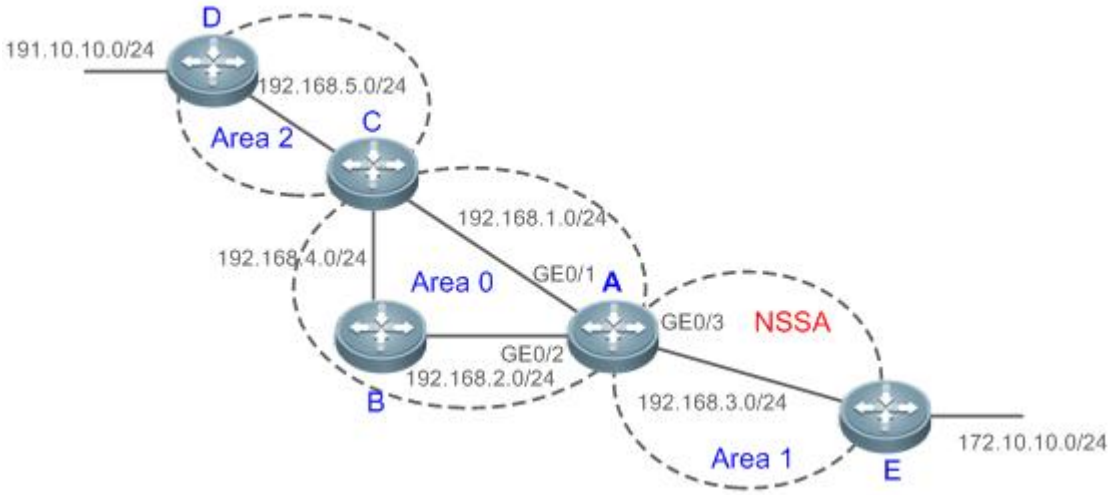
OSPF will be very quiet without changes in link costs or network addition or deletion. If any change takes place, the changed link states are advertised to quickly synchronize the LSDB.

SPT Computation → Formation of a Routing Table

After the complete LSDB is obtained from the router, the Dijkstra algorithm is run to generate an SPT from the local router to each destination network. The SPT records the destination networks, next-hop addresses, and costs. OSPF generates a routing table based on the SPT.

If changes in link costs or network addition or deletion take place, the LSDB will be updated. The router again runs the Dijkstra algorithm, generates a new SPT, and updates the routing table.

The Dijkstra algorithm is used to find a shortest path from a vertex to other vertices in a weighted directed graph.



OSPF Network Types

A router does not necessarily need to exchange LSAs with every neighbor and set up an adjacency with every neighbor. To improve efficiency, OSPF classifies networks that use various link layer protocols into five types so that LSAs are exchanged in different ways to set up an adjacency:

- Broadcast
  Neighbors are discovered, and the DR and BDR are elected.
  The DR (or BDR) exchanges LSAs with all other routers to set up an adjacency. Except the DR and BDR, all other routers do not exchange LSAs with each other, and the adjacency is not set up.
  Ethernet and fiber distributed data interface (FDDI) belong to the broadcast network type by default.
- Non-broadcast multiple access (NBMA)
  Neighbors are manually configured, and the DR and BDR are elected.
  The DR (or BDR) exchanges LSAs with all other routers to set up an adjacency. Except the DR and BDR, all other routers do not exchange LSAs with each other, and the adjacency is not set up.
  X.25, frame relay, and ATM belong to NBMA networks by default.
- Point-to-point (P2P)
  Neighbors are automatically discovered, and the DR or BDR is not elected.
  LSAs are exchanged between routers at both ends of the link, and the adjacency is set up.
  PPP,HDLC, and LAPB belongs to the P2P network type by default.
- Point-to-multipoint (P2MP)
  Neighbors are automatically discovered, and the DR or BDR is not elected.
  LSAs are exchanged between any two routers, and the adjacency is set up.
  Networks without any link layer protocol belong to the P2MP network type by default. P2MP broadcast
  Neighbors are manually configured, and the DR or BDR is not elected.
  LSAs are exchanged between any two routers, and the adjacency is set up.
  Networks without any link layer protocol belong to the P2MP network type by default.

OSPF Route Types

Figure 1-5

Display the OSPF routes (marked in red) in the routing table of Router A.

```
A#show ip route

Codes:  C - connected, S - static, R - RIP, B - BGP

O - OSPF, IA - OSPF inter area

N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2

E1 - OSPF external type 1, E2 - OSPF external type 2

i - IS-IS, su - IS-IS summary, L1 - IS-IS level-1, L2 - IS-IS level-2

ia - IS-IS inter area, * - candidate default

Gateway of last resort is no set

O N2 172.10.10.0/24 [110/20] via 192.168.3.2, 00:01:00,GigabitEthernet 0/3

O E2 191.10.10.0/24 [110/20] via 192.168.1.2, 01:11:26,GigabitEthernet 0/1

C    192.168.1.0/24 is directly connected,GigabitEthernet 0/1

C    192.168.1.1/32 is local host.

C    192.168.2.0/24 is directly connected,GigabitEthernet 0/2

C    192.168.2.1/32 is local host.

C    192.168.3.0/24 is directly connected,GigabitEthernet 0/3

C    192.168.3.1/32 is local host.

O    192.168.4.0/24 [110/2] via 192.168.2.2, 00:00:02,GigabitEthernet 0/2

O IA 192.168.5.0/24 [110/3] via 192.168.1.2, 00:01:02,GigabitEthernet 0/1
```

A mark is displayed in front of each OSPF route to indicate the type of the route. There are six types of OSPF routes:

- O: Intra-area route

  This type of route describes how to arrive at a destination network in the local area. The cost of this type of route is equal to the cost of the route from the local router to the destination network.

- IA: Inter-area route
  This type of route describes how to arrive at a destination network in another area. The cost of this type of route is equal to the cost of the route from the local router to the destination network.
- E1: Type 1 external route
  This type of route describes how to arrive at a destination network outside the AS. The cost of this type of route is equal to the cost of the route from the local router to the ASBR plus the cost of the route from the ASBR to the destination network. This type of route does not exist on routers in the stub or NSSA area.
- E2: Type 2 external route
  This type of route describes how to arrive at a destination network outside the AS. The cost of this type of route is equal to the cost of the route from the ASBR to the destination network. This type of route does not exist on routers in the stub or NSSA area.
- N1: Type 1 external route of the NSSA area
  This type of route describes how to arrive at a destination network outside the AS through the ASBR in the NSSA area. The cost of this type of route is equal to the cost of the route from the local router to the ASBR plus the cost of the route from the ASBR to the destination network. This type of route exists only on routers in the NSSA area.
- N2: Type 2 external route of the NSSA area
  This type of route describes how to arrive at a destination network outside the AS through the ASBR in the NSSA area. The cost of this type of route is equal to the cost of the route from the ASBR to the destination network. This type of route exists only on routers in the NSSA area.

Reliability of E2 and N2 routes is poor. OSPF believes that the cost of the route from the ASBR to a destination outside an AS is far greater than the cost of the route to the ASBR within the AS. Therefore, when the route cost is computed, only the cost of the route from the ASBR to a destination outside an AS is considered.

Related Configuration

Enabling OSPF

OSPF is disabled by default.

Run the **router ospf** command to create an OSPF process on the router.

Run the **network area** command to enable OSPF on the interface and specify the area ID.

Run the **area virtual-link** command to create a virtual link on the router. The virtual link can be treated as a logical interface.

Router ID

By default, the OSPF process elects the largest IP address among the IP addresses of all the loopback interfaces as the router ID. If the loopback interfaces configured with IP addresses are not available, the OSPF process elects the largest IP address among the IP addresses of all the loopback interfaces as the router ID.

Alternatively, you can run the **router-id** command to manually specify the router ID.

Protocol Control Parameters

Run the **ip ospf hello-interval** command to modify the Hello interval on the interface. The default value is 10s (or 30s for NBMA networks).

Run the **ip ospf dead-interval** command to modify the neighbor dead interval on the interface. The default value is four times the Hello interval.

Use the **poll-interval** parameter in the **neighbor** command to modify the neighbor polling interval on the NBMA interface. The default value is 120s.

Run the **ip ospf transmit-delay** command to modify the LSU packet transmission delay on the interface. The default value is 1s.

Run the **ip ospf retransmit-interval** command to modify the LSU packet retransmission interval on the interface. The default value is 5s.

Use the **hello-interval** parameter in the **area virtual-link** command to modify the Hello interval on the virtual link. The default value is 10s.

Use the **dead-interval** parameter in the **area virtual-link** command to modify the neighbor dead interval on the virtual link. The default value is four times the Hello interval.

Use the **transmit-delay** parameter in the **area virtual-link** command to modify the LSU packet transmission delay on the virtual link. The default value is 1s.

Use the **retransmit-interval** parameter in the **area virtual-link** command to modify the LSU packet retransmission interval on the virtual link. The default value is 5s.

Run the **timers throttle lsa all** command to modify parameters of the exponential backoff algorithm that generates LSAs. The default values of these parameters are 0 ms, 5000 ms, and 5000 ms.

Run the **timerspacinglsa-group** command to modify the LSA group update interval. The default value is 30s.

Run the **timers pacing lsa-transmit** command to modify the LS-UPD packet sending interval and the number of sent LS-UPD packets. The default values are 40 ms and 1.

Run the **timers lsa arrival** command to modify the delay after which the same LSA is received. The default value is 1000 ms.

Run the **timers throttle spf** command to modify the SPT computation delay, minimum interval between two SPT computations, and maximum interval between two SPT computations. The default values are 1000 ms, 5000 ms, and 10000 ms.

Run the **timers spf** command to modify the SPF computation delay and interval between two SPF computations. The default value is based on the **timers throttle spf** command configuration.

↘ OSPF Network Types

By default, Ethernet and FDDI belong to the broadcast type, X.25, frame relay, and ATM belong to the NBMA type, and PPP, HDLC, and LAPB belong to the P2P type.

Run the **ip ospf network** command to manually specify the network type of an interface.

Run the **neighbor** command to manually specify a neighbor. For the NBMA and P2MP non-broadcast types, you must manually specify neighbors.

Run the **ip ospf priority** command to adjust the priorities of interfaces, which are used for DR/BDR election. The DR/BDR election is required for the broadcast and NBMA types. The router with the highest priority wins in the election, and the router with the priority of 0 does not participate in the election. The default value is 1.

1.3.2 OSPF Route Management

Plan or optimize OSPF routes through manual configuration to implement management of OSPF routes.

Working Principle

(Totally) Stub Area and (Totally)NSSA Area

The (totally) stub and (totally)NSSA areas help reduce the protocol interaction load and the size of the routing table.

- If an appropriate area is configured as a (totally) stub or NSSA area, advertisement of a large number of Type 5 and Type 3 LSAs can be avoided within the area.

Area	Type1 and Type2 LSAs	Type 3 LSA	Type 4 LSA	Type 5 LSA	Type 7 LSA
Non (totally) stub area and NSSA area	Allowed	Allowed	Allowed	Allowed	Not allowed
Stub area	Allowed	Allowed (containing one default route)	Not allowed	Not allowed	Not allowed
Totally stub area	Allowed	Only one default route is allowed.	Not allowed	Not allowed	Not allowed
NSSA area	Allowed	Allowed (containing one default route)	Allowed	Not allowed	Allowed
Totally NSSA area	Allowed	Only one default route is allowed.	Allowed	Not allowed	Allowed

The ABR uses Type 3LSAs to advertise a default route to the (totally) stub or NSSA area.

The ABR converts Type 7 LSAs in the totally NSSA area to Type 5LSAs, and advertise Type5LSAs to the backbone area.

- If an area is appropriately configured as a (totally) stub area or an NSSA area, a large number of E1, E2, and IA routes will not be added to the routing table of a router in the area.

Area	Routes Available in the Routing Table of a Router Inside the Area
Non (totally) stub area and NSSA area	O: a route to a destination network in the local area IA: a route to a destination network in another area E1 or E2: a route or default route to a destination network segment outside the AS (via any ASBR in the AS)
Stub area	O: a route to a destination network in the local area IA: a route or a default route to a destination network in another area
Totally stub area	O: a route to a destination network in the local area IA: a default route
NSSA area	O: a route to a destination network in the local area IA: a route or a default route to a destination network in another area N1 or N2: a route or default route to a destination network segment outside the AS (via any ASBR in the local area)
Totally NSSA area	O: a route to a destination network in the local area IA: a default route N1 or N2: a route or default route to a destination network segment outside the AS (via any

	ASBR in the local area)

Route Redistribution

Route redistribution refers to the process of introducing routes of other routing protocols, routes of other OSPF processes, static routes, and direct routes that exist on the device to an OSPF process so that these routes can be advertised to neighbors using Type 5 and Type 7 LSAs. A default route cannot be introduced during route redistribution.

Route redistribution is often used for interworking between ASs. You can configure route redistribution on an ASBR to advertise routes outside an AS to the interior of the AS, or routes inside an AS to the exterior of the AS.

Default Route Introduction

By configuring a command on an ASBR, you can introduce a default route to an OSPF process so that the route can be advertised to neighbors using Type 5 and Type 7 LSAs.

Default route introduction is often used for interworking between ASs. One default route is used to replace all the routes outside an AS.

Route Summarization

Route summarization is a process of summarizing routing information with the same prefix into one route, and advertising the summarized route (replacing a large number of individual routes) to neighbors. Route summarization helps reduce the protocol interaction load and the size of the routing table.

By default, the ABR advertises inter-area routing information by using Type3 LSAs within a network segment, and advertises redistributed routing information by using Type 5 and Type 7 LSAs. If continuous network segments exist, it is recommended that you configure route summarization.

When configuring route summarization, the summarization range may exceed the actual network scope of routes. If data is sent to a network beyond the summarization range, a routing loop may be formed and the router processing load may increase. To prevent these problems, the ABR or ASBR automatically adds a discard route to the routing table. This route will not be advertised.

Route Filtering

OSPF supports route filtering to ensure security and facilitate control when the routing information is being learned, exchanged, or used.

Using configuration commands, you can configure route filtering for the following items:

- Interface: The interface is prevented from sending routing information (any LSAs) or exchanging routing information (any LSAs) with neighbors.
- Routing information advertised between areas: Only the routing information that meets the filtering conditions can be advertised to another area (Type 3 LSAs).
- Routing information outside an AS: Only the routing information that meets the filtering conditions can be redistributed to the OSPF process(Type 5 and Type 7 LSAs).
- LSAs received by a router: In the OSPF routing table, only the routes that are computed based on the LSAs meeting the filtering conditions can be advertised.

Route Cost

If redundancy links or devices exist on the network, multiple paths may exist from the local device to the destination network. OSPF selects the path with the minimum total cost to form an OSPF route. The total cost of a path is equal to the sum of the costs of individual links along the path. The total cost of a path can be minimized by modifying the costs of individual links along the path. In this way, OSPF selects this path to form a route.

Using configuration commands, you can modify the link costs:

- Cost from an interface to a directly connected network segment and cost from the interface to a neighbor
- Cost from an ABR to the inter-area summarization network segment and cost from the ABR to the default network segment
- Cost from an ASBR to an external network segment and cost from the ASBR to the default network segment

Both the cost and the metric indicate the cost and are not differentiated from each other.

OSPF Administrative Distance

The administrative distance (AD) evaluates reliability of a route, and the value is an integer ranging from 0 to 255. A smaller AD value indicates that the route is more trustworthy. If multiples exist to the same destination, the route preferentially selects a route with a smaller AD value. The route with a greater AD value becomes a floating route, that is, a standby route of the optimum route.

By default, the route coming from one source corresponds to an AD value. The AD value is a local concept. Modifying the AD value affects route selection only on the current router.

Route Source	Directly-Connected Network	Static Route	EBGP Route	OSPF Route	ISIS Route	RIP Route	IBGP Route	Unreachable Route
Default AD	0	1	20	110	115	120	200	255

Related Configuration

Stub Area and NSSA Area

No stub or NSSA area is configured by default.

Run the **area stub** command to configure a specified area as a stub area.

Run the **area nssa** command to configure a specified area as an NSSA area.

The backbone area cannot be configured as a stub or an NSSA area.

A transit area (with virtual links going through) cannot be configured as a stub or an NSSA area.

An area containing an ASBR cannot be configured as a stub area.

Route Redistribution and Default Route Introduction

By default, routes are not redistributed and the default route is not introduced.

Run the **redistribute** command to configure route redistribution.

Run the **default-information originate** command to introduce the default route.

After configuring route redistribution and default route introduction, the route automatically becomes an ASBR.

Route Summarization

By default, routes are not summarized. If route summarization is configured, a discard route will be automatically added.

Run the **arearange** command to summarize routes distributed between areas (Type 3 LSA) on the ABR.

Run the **summary-address** command to summarize redistributed routes (Type 5 and Type 7 LSAs) on the ASBR.

Run the **discard-route** command to add a discard route to the routing table.

Route Filtering

By default, routes are not filtered.

Run the **passive-interface** command to configure a passive interface. Routing information (any LSAs) cannot be exchanged on a passive interface.

Run the **ip ospf database-filter all out** command to prohibit an interface from sending routing information (any LSAs).

Run the **area filter-list** command to filter routing information advertised between areas on the ABR. Only the routing information that meets the filtering conditions can be advertised to another area (Type 3 LSAs).

Use the **route-map** parameter in the **redistribute** command, or use the **distribute-list out** command to filter the external routing information of the AS on the ASBR. Only the routing information that meets the filtering conditions can be redistributed to the OSPF process (Type 5 and Type 7 LSAs).

Run the **distribute-list in** command to filter LSAs received by the router. In the OSPF routing table, only the routes that are computed based on the LSAs meeting the filtering conditions can be advertised.

Route Cost

- Cost from the interface to the directly-connected network segment (cost on the interface)
  The default value is the auto cost. Auto cost = Reference bandwidth/Interface bandwidth
  Run the **auto-cost reference-bandwidth** command to set the reference bandwidth of auto cost. The default value is 100 Mbps.
  Run the **ip ospf cost** command to manually set the cost of the interface. The configuration priority of this item is higher than that of the auto cost.
- Cost from the interface to a specified neighbor (that is, cost from the local device to a specified neighbor)
  The default value is the auto cost.
  Use the **cost** parameter in the **neighbor** command to modify the cost from the interface to a specified neighbor. The configuration priority of this item is higher than that of the cost of the interface.
  This configuration item is applicable only to P2MP-type interfaces.
- Cost from the ABR to the inter-area summarization network segment (that is, the cost of the summarized inter-area route)
  If OSPF routing is compatible with RFC1583, the default value is the minimum cost among all costs of the summarized links; otherwise, the default value is the maximum cost among all costs of the summarized links.
  Run the **compatible rfc1583** command to make OSPF routing compatible with RFC1583. By default, OSPF routing is compatible with RFC1583.
  Use the **cost** parameter in the **area range** command to modify the cost of inter-area route summarization.
- Cost from the ABR to the default network segment (that is, the cost of the default route that is automatically advertised by the ABR to the stub or NSSA areas)
  The default value is 1.

Run the **area default-cost** command to modify the cost of the default route that the ABR automatically advertise to the stub or NSSA areas.

- Cost from the ASBR to an external network segment (that is, the metric of an external route)
  By default, the metric of the redistributed BGP route is 1, the metric of other redistributed routes is 20, and the route type is Type 2 External.
  Run the **default-metric** command to modify the default metric of the external route.
  Use the **metric**, **metric-type** and **route-map** parameters in the **redistribute** command to modify the metric and route type of the external route.
- Cost from the ASBR to the default network segment (that is, the metric of the default route that is manually introduced)
  By default, the metric is 1, and the route type is Type 2 External.
  Use the **metric**, **metric-type** and **route-map** parameters in the **default-information originate** command to modify the metric and route type of the default route that is manually introduced.
  Use the **metric** and **metric-type** parameters of **default-information originate** in the **area nssa** command to modify the metric and type of the default route that is manually introduced to the NSSA area.
- Run the **max-metric router-lsa** command to set metrics of all routes advertised on the router to the maximum value. In this way, the total cost of any path that passes through this router will become very large, and the path can hardly become the shortest path.

OSPF Administrative Distance

By default, the OSPF AD is 110.

Run the **distance** command to set the AD of an OSPF route.

1.3.3 Enhanced Security and Reliability

Use authentication, MTU verification and GR to enhance security, stability, and reliability of OSPF.

Working Principle

Authentication

Authentication prevents routers that illegally access the network and hosts that forge OSPF packet from participating in the OSPF process. OSPF packets received on the OSPF interface (or at both ends of the virtual link) are authenticated. If authentication fails, the packets are discarded and the adjacency cannot be set up.

Enabling authentication can avoid learning unauthenticated or invalid routes, thus preventing advertising valid routes to unauthenticated devices. In the broadcast-type network, authentication also prevents unauthenticated devices from becoming designated devices, ensuring stability of the routing system and protecting the routing system against intrusions.

MTU Verification

On receiving a DD packet, OSPF checks whether the MTU of the neighbor interface is the same as the MTU of the local interface. If the MTU of the interface specified in the received DD packet is greater than the MTU of the interface that receives the packet, the adjacency cannot be set up. Disabling MTU verification can avoid this problem.

Source Address Verification

Generally, the source address of a packet received by OSPF is in the same network segment as the receiving interface. The addresses at both ends of a P2P link are configured separately and are not necessarily in the same network segment. In this scenario, as the peer address information will be notified during the P2P link negotiation process, OSPF checks whether the source address of the packet is the address advertised by the peer during negotiation. If not, OSPF determines that the packet is invalid and discards this packet. In particular, for unnumbered interfaces, OSPF never performs address verification.

In some scenarios, the source address of a packet received by OSPF may not be in the same network segment as the receiving interface, and therefore OSPF address verification fails. For example, the negotiated peer address cannot be obtained on a P2P link. In this scenario, source address verification must be disabled to ensure that the OSPF adjacency can be properly set up.

Two-Way Maintenance

OSPF routers periodically send Hello packets to each other to maintain the adjacency. On a large network, a lot of packets may be sent or received, occupying too much CPU and memory. As a result, some packets are delayed or discarded. If the processing time of Hello packets exceeds the dead interval, the adjacency will be destroyed.

If the two-way maintenance function is enabled, in addition to the Hello packets, the DD, LSU, LSR, and LSAck packets can also be used to maintain the bidirectional communication between neighbors, which makes the adjacency more stable.

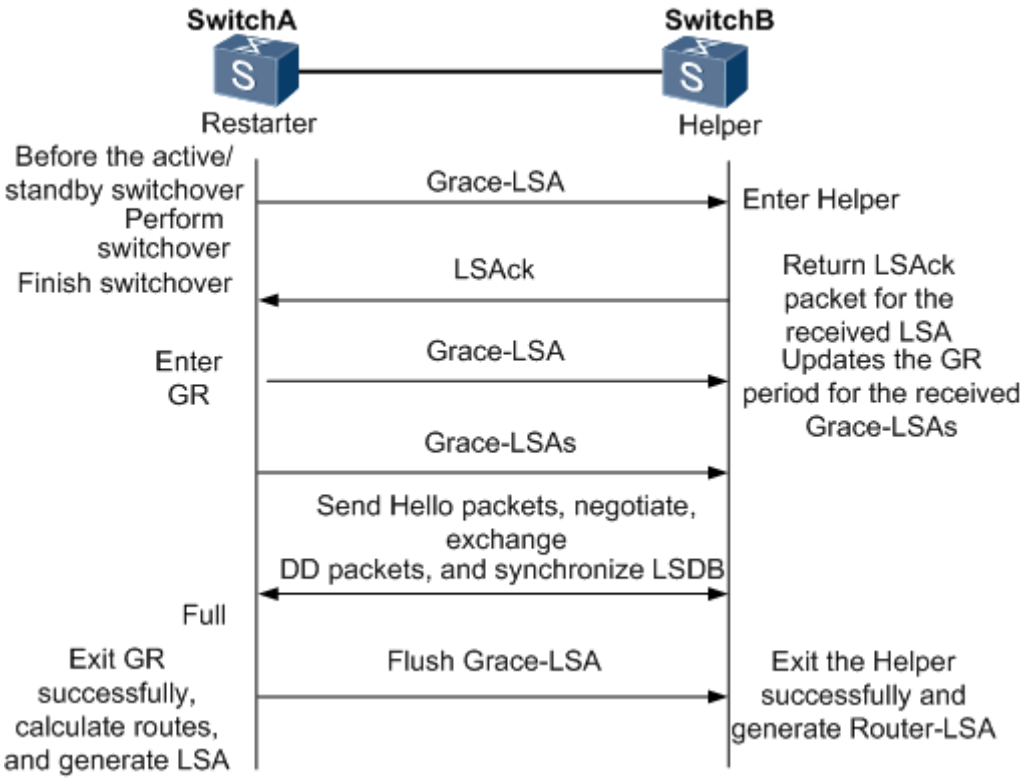
Concurrent Neighbor Interaction Restriction

When a router simultaneously exchanges data with multiple neighbors, its performance may be affected. If the maximum number of neighbors that concurrently initiate or accept interaction with the OSPF process, the router can interact with neighbors by batches, which ensures data forwarding and other key services.

Overflow

OSPF requires that routers in the same area store the same LSDB. The number of routers keeps increasing on the network. Some routers, however, cannot store so much routing information due to the limited system resources. The large amount of routing information may exhaust the system resources of routers, causing failures of the routers.

The overflow function limit the number of external routes in the LSDB to control the size of the LSDB.



When the number of external routes on a router exceeds the upper limit, the router enters the overflow state. The router deletes the external routes generated by itself from the LSDB, and does not generate new external routes. In addition, the router discards the newly received external routes. After the overflow state timer (5s) expires, if the number of external routes is lower than the upper limit, the normal state is restored.

GR

The control and forwarding separated technology is widely used among routers. On a relatively stable network topology, when a GR-enabled router is restarted on the control plane, data forwarding can continue on the forwarding plane. In addition, actions (such as adjacency re-forming and route computation) performed on the control plane do not affect functions of the forwarding plane. In this way, service interruption caused by route flapping can be avoided, thus enhancing reliability of the entire network.

Currently, the GR function is used only during active/standby switchover and system upgrade.

Figure 1-6 Normal OSPF GR Process

- The GR process requires collaboration between the restarter and the helper. The restarter is the router where GR occurs. The helper is a neighbor of the restarter.
- When entering or exiting the GR process, the restarter sends a Grace-LSA to the neighbor, notifying the neighbor to enter or exit the helper state.
- When the adjacency between the restarter and the helper reaches the Full state, the router can exit the GR process successfully.

Fast Hello

After a link failure occurs, OSPF takes some time (about 40s) to detect the death of a neighbor. Then it broadcasts this information and recalculates the SPT. During this period, the traffic may be interrupted.

When the Fast Hello function is enabled (that is, the neighbor dead time is set to 1s), OSPF can detect the death of a neighbor within 1s after a link failure occurs. This significantly accelerates route convergence and avoids traffic interruptions.

Related Configuration

OSPF Packet Authentication

By default, authentication is disabled.

- Run the **area authentication** command to enable the authentication function in the entire area so that the function takes effect on all interfaces in this area. If authentication is enabled in area 0, the function takes effect on the virtual link.

- Run the **ip ospf authentication** command to enable authentication on an interface. This configuration takes precedence over the area-based configuration.
- Run the **ip ospf authentication-key** command to set the text authentication key on an interface.
- Run the **ip ospf message-digest-key** command to set the message digest 5 (MD5) authentication key on an interface.
- Use the **authentication** parameter in the **area virtual-link** command to enable authentication at both ends of a virtual link. This configuration takes precedence over the area-based configuration.
- Use the **authentication-key** parameter in the **area virtual-link** command to set the text authentication key at both ends of a virtual link.
- Use the **message-digest-key** parameter in the **area virtual-link** command to set the MD5 authentication key at both ends of a virtual link.

MTU Verification

By default, MTU verification is disabled.

Run the **ip ospf mtu-ignore** command to disable MTU verification on an interface.

Source address verification

By default, source address verification is enabled on a P2P interface.

Run the **ip ospf source-check-ignore** command to disable source address verification on an interface.

Two-Way Maintenance

By default, bidirectional maintenance is enabled.

Run the **two-way-maintain** command to enable two-way maintenance.

Concurrent neighbor Interaction Restriction

Run the **max-concurrent-dd** command to modify the maximum number of neighbors that are concurrently interacting with the current OSPF process. The default value is 5.

Run the **ip router ospf max-concurrent-dd** command to modify the maximum number of neighbors that are concurrently interacting with all OSPF processes on the router. The default value is 10.

Overflow

Run the **overflow memory-lack** command to allow the router to enter the overflow state when the memory is insufficient. By default, the router is allowed to enter the overflow state when the memory is insufficient.

Run the **overflow database** command to allow the router to enter the overflow state when the number of LSAs is too large. By default, the router is not allowed to enter the overflow state when the number of LSAs is too large.

Run the **overflow database external** command to allow the router to enter the overflow state when the number of external LSAs is too large. By default, the router is not allowed to enter the overflow state when the number of external-LSAs is too large.

GR

By default, the restarter function is disabled, and the helper function is enabled.

Run the **graceful-restart** command to configure the restarter function.

Run the **graceful-restart helper** command to configure the helper function.

Fast Hello

By default, the neighbor dead time on an interface is 40s.

Run the **ip ospf dead-interval minimal hello-multiplier** command to enable the Fast Hello function (neighbor dead time is 1s) on an interface.

1.3.4 Network Management

Use functions such as the MIB and Syslog to facilitate OSPF management.

Working Principle

MIB

MIB is the device status information set maintained by a device. You can use the management program to view and set the MIB node.

Multiple OSPF processes can be simultaneously started on a router, but the OSPF MIB can be bound with only one OSPF process.

Trap

A Trap message is a notification generated when the system detects a fault. This message contains the related fault information.

If the Trap function is enabled, the router can proactively send the Trap messages to the network management device.

Syslog

The Syslog records the operations (such as command configuration) performed by users on routers and specific events (such as network connection failures).

If the Syslog is allowed to record the adjacency changes, the network administrator can view the logs to learn the entire process that the OSPF adjacency is set up and maintained.

Related Configuration

MIB

By default, the MIB is bound with the OSPF process with the smallest process ID.

Run the **enable mib-binding** command to bind the MIB with the current OSPF process.

Trap

By default, all traps are disabled, and the device is not allowed to send OSPF traps.

Run the **enable traps** command to enable a specified trap for an OSPF process.

Run the **snmp-server enable traps ospf** command to allow the device to send OSPF traps.

SYSLOG

By default, the Syslog is allowed to record the adjacency changes.

Run the **log-adj-changes** command to allow the Syslog to record the adjacency changes.

1.4 Configuration

Configuration	Description and Command	
Configuring OSPF Basic Functions	(Mandatory) It is used to build an OSPF routing domain.	
	routerospf	Creates an OSPF process.
	router-id	Configures a router ID.
	network area	Enables OSPF on an interface and specifies an area ID.
	area virtual-link	Creates a virtual link.
Setting the Network Type	(Optional) The configurations are mandatory if the physical network is the X.25, frame relay, or ATM network.	
	ip ospf network	Defines the network type.
	neighbor	Specifies a neighbor.
	ip ospf priority	Configures the DR priority.
Configuring Route Redistribution and Default Route	(Optional) The configurations are recommended if the OSPF routing domain is connected with an external network.	
	redistribute	Configures route redistribution.
	default-information originate	Introduces a default route.
Configuring Stub Area and NSSA Area	(Optional) It is used to reduce interaction of routing information and the size of routing table, and enhance stability of routes.	
	areastub	Configures a stub area.
	areanssa	Configures an NSSA area.
Configuring Route Summarization	(Optional) It is used to reduce interaction of routing information and the size of routing table, and enhance stability of routes.	
	arearange	Summarizes routes that are advertised between areas.
	summary-address	Summarizes routes that are introduced through redistribution.
	discard-route	Adds a discard route to the routing table.
Configuring Route Filtering	(Optional) It is used to manually control interaction of routing information and filter available OSPF routes.	
	passive-interface	Configures a passive interface.
	ip ospfdatabase-filter all out	Prohibits an interface from sending LSAs.
	area filter-list	Filters routes that are advertised between areas..

Configuration	Description and Command	
	distribute-list out	Filters routes that are introduced through redistribution.
	distribute-listin	Filters routes that are calculated based on the received LSAs.
Modifying Route Cost and AD	(Optional) It is used to manually control the shortest route computed by OSPF and determine whether to select an OSPF route preferentially.	
	auto-costreference-bandwidth	Modifies the reference bandwidth of the auto cost.
	ip ospf cost	Modifies the cost in the outbound direction of an interface.
	areadefault-cost	Modifies the cost of the default route in a stub or an NSSA area.
	default-metric	Modifies the default metric of a redistributed route.
	max-metric router-lsa	Configures the maximum metric.
	compatible rfc1583	Enables the routing rules to be compatible with RFC1583.
	distance	Modifies the OSPF AD.
Enabling Authentication	(Optional) It is used to prevent routers that illegally access the network and hosts that forge OSPF packets from participating in the OSPF protocol process.	
	areaauthentication	Enables authentication and sets the authentication mode in an area.
	ip ospf authentication	Enables authentication and sets the authentication mode on an interface.
	ip ospf authentication-key	Sets the text authentication key on an interface.
	ip ospfmessage-digest-keymd5	Sets the MD5 authentication key on an interface.
Enabling Overflow	(Optional) It is used to prevent the problem that OSPF processes stop running due to over-consumption of the memory.	
	overflow memory-lack	Allows the router to enter the overflow state when the memory is insufficient.
	overflow database	Allows the router to enter the overflow state when the number of LSAs exceeds the preset limit.
	overflow database external	Allows the router to enter the overflow state when the number of external LSAs exceeds the preset limit.
Modifying the Maximum Number of Concurrent	(Optional) It is used to prevent the problem of performance deterioration caused by over-consumption of the CPU.	

Configuration	Description and Command	
Neighbors	**max-concurrent-dd**	Modifies the maximum number of con current neighbors on the current OSPF process.
	router ospf max-concurrent-dd	Modifies the maximum number of con current neighbors on all OSPF processes.
Disabling Source Address Verification	⚠ (Optional) It is used to prevent the problem that the adjacency cannot be set up due to the failure to obtain the peer address.	
	ip ospf source-check-ignore	Disables source address verification on an interface.
Disabling MTU Verification	⚠ (Optional) It is used to prevent the problem that the adjacency cannot be set up due to MTU inconsistency on the neighbor interface.	
	ip ospf mtu-ignore	Disables MTU verification on an interface.
Enabling Two-Way Maintenance	⚠ (Optional) It is used to prevent termination of the adjacency due to the delay or loss of Hello packets.	
	two-way-maintain	Enables two-way maintenance.
Enabling GR	⚠ (Optional) It is used to maintain OSPF route forwarding and prevent traffic interruption during an OSPF process restart or active/standby switchover.	
	graceful-restart	Configures the Restarter function.
	graceful-restart helper	Configures the Helper function.
Configuring Fast Hello Function	⚠ (Optional) It is used to quickly detect neighbor death during link failure to avoid traffic interruption.	
	ip ospf dead-intervalminimal hello-multiplier	Enables the Fast Hello function on an interface.
Configuring the Network Management Function	⚠ (Optional) The configurations enable users to use the SNMP network management software to manage OSPF.	
	enable mib-binding	Binds the MIB with the current OSPF process.
	enable traps	Enables a specified trap for an OSPF process.
	snmp-server enable traps ospf	Allows the device to send OSPF traps.
	log-adj-changes	Allows the Syslog to record the adjacency changes.
Modifying Protocol Control Parameters	⚠ (Optional) You are advised not to modify protocol control parameters unless necessary.	
	ip ospf hello-interval	Modifies the Hello interval.
	ip ospf dead-interval	Modifies the neighbor death interval.
	timers throttle lsa all	Modifies parameters of the exponential backoff algorithm that generates LSAs.

Configuration	Description and Command	
	timers throttle route inter-area	Modifies the inter-area route computation delay.
	timers throttle route ase	Modifies the external route computation delay.
	timerspacinglsa-group	Modifies the LSA group update interval.
	timers pacing lsa-transmit	Modifies the LS-UPD packet sending interval.
	ip ospf transmit-delay	Modifies the LSU packet transmission delay.
	ip ospf retransmit-interval	Modifies the LSU packet retransmission interval.
	timers lsa arrival	Modifies the delay after which the same LSA is received.
	timers throttlespf	Modifies the SPT computation timer.

1.4.1 Configuring OSPF Basic Functions

Configuration Effect

- Set up an OSPF routing domain on the network to provide IPv4 unicast routing service for users on the network.

Notes

- Ensure that the IP unitcast routing function is enabled, that is, **ip routing** is not disabled; otherwise, OSPF cannot be enabled.
- It is strongly recommended that you manually configure the router ID.
- After **ip ospf disable all** is configured, the interface neither sends or receives any OSPF packet, nor participates in OSPF computation even if the interface belongs to the network.

Configuration Steps

Creating an OSPF Process

- Mandatory.
- The configuration is mandatory for every router.

Configuring a Router ID

- (Optional) It is strongly recommended that you manually configure the router ID.
- If the router ID is not configured, OSPF selects an interface IP address. If the IP address is not configured for any interface, or the configured IP addresses have been used by other OSPF instances, you must manually configure the router ID.

Adding Interface IPs to OSPF and Specifying an Area ID

- (Mandatory) If OSPF is enabled using the command under an interface, this configuration can be omitted.
- The configuration is mandatory for every router.

Enabling OSPF on an Interface and Specifying an Area ID

- (Mandatory) If an interface joins OSPF through the OSPF instance, this configuration can be omitted.
- The configuration is mandatory for every router.

Verification

- Run the **show ip route ospf** command to verify that the entries of the OSPF routing table are correctly loaded.
- Run the **ping** command to verify that the IPv4 unicast service is correctly configured.

Related Commands

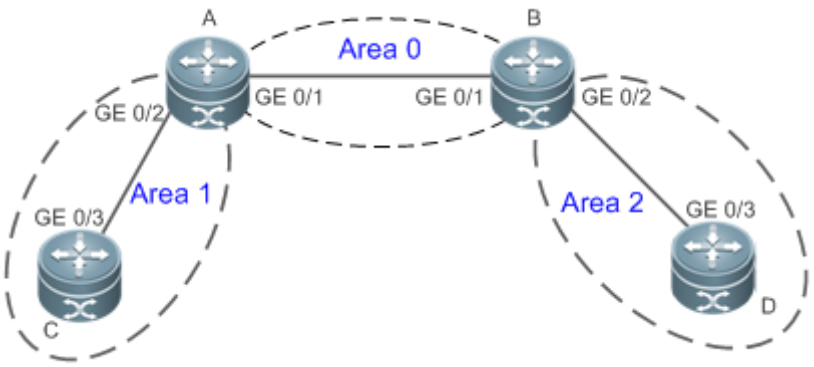
Creating an OSPF Process

Command	**router ospf** *process-id*
Parameter Description	*process-id:* Indicates the OSPF process ID. If the process ID is not specified, the process ID is 1.
Command Mode	Global configuration mode
Usage Guide	Different OSPF processes are independent of each other, and can be treated as different routing protocols that run independently.

Configuring a Router ID

Command	**router-id** *router-id*
Parameter Description	*router-id:* Indicates the router ID to be configured. It is expressed in the IP address.
Command Mode	OSPF routing process configuration mode
Usage Guide	Different OSPF processes are independent of each other, and can be treated as different routing protocols that run independently. Each OSPF process uses a unique router ID.

Enabling OSPF on an Interface and Specifying an Area ID



Command	**network** *ip-address wildcard* **area** *area-id*
Parameter Description	*ip-address*: Indicates the IP address of the interface. *wildcard:* Indicates the IP address comparison mode. **0** indicates accurate matching, and **1** indicates that no comparison is performed. *area-id:* Indicates the ID of an OSPF area. An OSPF area is always associated with an address range. To facilitate management, you can use a subnet as the ID of an OSPF area.
Command Mode	OSPF routing process configuration mode
Usage Guide	By defining *ip-address* and *wildcard*, you can use one command to associate multiple interfaces with one OSPF area. To run OSPF on one interface, you must include the primary IP address of the interface in the IP address range defined by **network area**. If the IP address range defined by **network area** contains only the secondary IP address of the interface, OSPF does not run on this interface. If the interface address matches the IP address ranges defined in the **network** commands of multiple OSPF processes, the OSPF process that the interface is associated with is determined based on the best match method.

Creating a Virtual Link

Command	**area** *area-id* **virtual-link** *router-id* [**authentication** [**message-digest** | **null**] | **dead-interval** { *seconds* | **minimal hello-multiplier** *multiplier* } | **hello-interval** *seconds* | **retransmit-interval** *seconds* | **transmit-delay** *seconds*] * [**authentication-key** [**0** | **7**] *key* | **message-digest-key** *key-id* **md5** [**0** | **7**] *key*]
Parameter Description	*area-id:* Indicates the ID of the OSPF transit area. The area ID can be a decimal integer or an IP address. *router-id:* Indicates the ID of a neighbor router on the virtual link. **authentication:** Sets the authentication type to plain text authentication. **message-digest:** Sets the authentication type to MD5 authentication. **null:** Indicates that authentication is disabled. **dead-interval** *seconds:* Indicates the time that the neighbor is declared lost. The unit is second. The value ranges from 0 to 2,147,483,647. The setting of this parameter must be consistent with that on a neighbor. **minimal**: Enables the Fast Hello function and sets the dead time to 1s. **hello-multiplier**: Indicates the multiplier of the dead interval to the hello interval in the Fast Hello function. *multiplier*: Indicates the number of Hello packets sent per second in the Fast Hello function. The value ranges from 3 to 20. **hello-interval** *seconds:* Indicates the interval at which OSPF sends the Hello packet to the virtual link. The unit is second. The value ranges from 1 to 65,535. The setting of this parameter must be consistent with that on a neighbor. **retransmit-interval** *seconds:* Indicates the OSPF LSA retransmission time. The unit is second. The value ranges from 1 to 65,535. **transmit-delay** *seconds:* Indicates the delay after which OSPF sends the LSA. The unit is second. The value ranges from 1 to 65,535. **authentication-key** [**0** | **7**]*key:* Defines the key for OSPF plain text authentication. **message-digest-key** *key-id***md5** [**0** | **7**]key: Defines the key ID and key for OSPF MD5 authentication.
Command Mode	OSPF routing process configuration mode
Usage Guide	In the OSPF routing domain, all areas must be connected to the backbone area. If the backbone area is disconnected, a virtual link must be configured to connect to the backbone area; otherwise, network communication problems will occur. A virtual link must be created between two ABRs, and the area to which both ABRs belong is the transit area. A stub area or an NSSA area cannot be used as a transit area. A virtual link can also be used to connect other non-backbone areas. **router-id** is the ID of an OSPF neighbor router. If you are sure about the value of **router-id**, run the **show ip ospf neighbor** command to confirm the value. You can configure the loopback address as the router ID. The **area virtual-link** command defines only the authentication key of the virtual link. To enable OSPF packet authentication in the areas connected to the virtual link, you must run the **area authentication** command. OSPF supports the Fast Hello function: Enabling the OSPF Fast Hello function accelerates neighbor discovery and rapid detection of neighbor failures in OSPF. The OSPF Fast Hello function is enabled by specifying the **minimal** and **hello-multiplier** keywords and the *multiplier* parameter. The **minimal** keyword sets the dead time to 1s, and the **hello-multiplier** value specifies the number of Hello packets sent per second, reducing the Hello packet

	interval to less than 1s. When a virtual link is configured with the Fast Hello function, the Hello interval field of the Hello packets advertised from that virtual link is set to 0, and the Hello interval field of the Hello packets received from that virtual link is ignored. The dead interval at both ends of a virtual link must be consistent regardless of whether Fast Hello is enabled or not. The hello-multiplier value does not need to be the same, as long as at least one Hello packet can be received within the dead interval. The **show ip ospf virtual-links** command can be used to monitor the dead interval and Fast Hello interval configured for virtual links. The **dead-interval minimal hello-multiplier** parameter and the **hello-interval** parameter introduced for Fast Hello function cannot be configured simultaneously.

Configuration Example

Scenario **Figure 1-7**	 **Remarks** The interface IP addresses are as follows: A: GE 0/1 192.168.1.1 GE 0/2 192.168.2.1 B: GE 0/1 192.168.1.2 GE 0/2 192.168.3.1 C: GE 0/3 192.168.2.2 D: GE 0/3 192.168.3.2
Configuration Steps	● Configure the interface IP addresses on all routers. ● Enable the IPv4 unicast routing function on all routers. (This function is enabled by default.) ● Configure the OSPF instances and router IDs on all routers. ● Enable OSPF on the interfaces configured on all routers.

A	`A#configure terminal`
	`A(config)#interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)#ip address 192.168.1.1 255.255.255.0`

	A(config-if-GigabitEthernet 0/1)#exit A(config)#interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)#ip address 192.168.2.1 255.255.255.0 A(config-if-GigabitEthernet 0/2)#exit A(config)#router ospf 1 A(config-router)#router-id192.168.1.1 A(config-router)#network 192.168.1.0 0.0.0.255 area 0 A(config-router)#network 192.168.2.0 0.0.0.255 area 1
B	B#configure terminal B(config)#interface GigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)#ip address 192.168.1.2 255.255.255.0 B(config-if-GigabitEthernet 0/1)#exit B(config)#interface GigabitEthernet 0/2 B(config-if-GigabitEthernet 0/2)#ip address 192.168.3.1 255.255.255.0 B(config-if-GigabitEthernet 0/2)#exit B(config)#router ospf 1 B(config-router)#router-id192.168.1.2 B(config-router)#network 192.168.1.0 0.0.0.255 area 0 B(config-router)#network 192.168.3.0 0.0.0.255 area 2
C	C#configure terminal C(config)#interface GigabitEthernet 0/3 C(config-if-GigabitEthernet 0/3)#ip address 192.168.2.2 255.255.255.0 C(config-if-GigabitEthernet 0/3)#exit C(config)#router ospf 1 C(config-router)#router-id192.168.2.2 C(config-router)#network 192.168.2.0 0.0.0.255 area 1
D	D#configure terminal D(config)#interface GigabitEthernet 0/3 D(config-if-GigabitEthernet 0/3)#ip address 192.168.3.2 255.255.255.0 D(config-if-GigabitEthernet 0/3)#exit D(config)#router ospf 1 D(config-router)#router-id192.168.3.2 D(config-router)#network 192.168.3.0 0.0.0.255 area 2

Verification	● Verify that the OSPF neighbors are correct on all routers. ● Verify that the routing table is correctly loaded on all routers. ● On Router D, verify that the IP address 192.168.2.2 can be pinged successfully.
A	A# show ip ospf neighbor OSPF process 1, 2 Neighbors, 2 is Full: Neighbor ID Pri State Dead Time Address Interface 192.168.1.2 1 Full/DR 00:00:40192.168.1.2 GigabitEthernet 0/1 192.168.2.2 1 Full/BDR00:00:34 192.168.2.2 GigabitEthernet 0/2 A# show ip route ospf O IA 192.168.3.0/24 [110/2] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1

D# ping 192.168.2.2
Sending 5, 100-byte ICMP Echoes to 192.168.2.2, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms.
```

Common Errors

- OSPF cannot be enabled because the IP unicast routing function is disabled.
- The network segment configured by the **network** command does not include the interface IP addresses.
- The area IDs enabled on adjacent interfaces are inconsistent.
- The same router ID is configured on multiple routers, resulting in a router ID conflict.
- The same interface IP address is configured on multiple routers, resulting in a running error of the OSPF network.

1.4.2 Setting the Network Type

Configuration Effect

- Run OSPF to provide the IPv4 unicast routing service if the physical network is X.25, frame relay, or ATM.

Notes

- The OSPF basic functions must be configured.
- The broadcast network sends OSPF packets in multicast mode. Neighbors are automatically discovered, and the DR/BDR election is required.
- The P2P network sends OSPF packets in multicast mode. Neighbors are automatically discovered.
- The NBMA network sends OSPF packets in unicast mode. Neighbors must be manually specified, and the DR/BDR election is required.
- The P2MP network (without the **non-broadcast** parameter) sends OSPF packets in multicast mode. Neighbors are automatically discovered.
- The P2MP network (with the **non-broadcast** parameter) sends OSPF packets in unicast mode. Neighbors must be manually specified.

Configuration Steps

↘ Configuring the Interface Network Type

- Optional.

- The configuration is required on routers at both ends of the link.

Configuring Neighbors

- (Optional) If the interface network type is set to NBMA or P2MP (with the **non-broadcast** parameter), neighbors must be configured.
- Neighbors are configured on routers at both ends of the NBMA or P2MP (with the **non-broadcast** parameter) network.

Configuring the Interface Priority

- (Optional) You must configure the interface priority if a router must be specified as a DR, or a router cannot be specified as a DR.
- Configure the interface priority on a router that must be specified as a DR, or cannot be specified as a DR.

Verification

- Run the **show ip ospf interface** command to verify that the network type of each interface is correct.

Related Commands

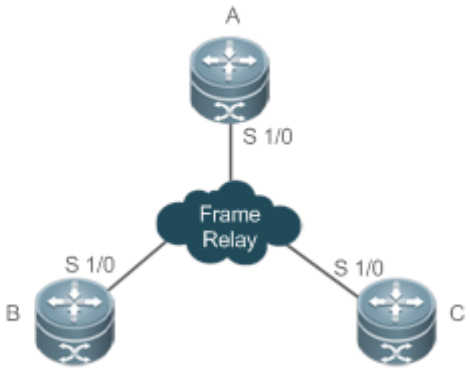
Configuring the Interface Network Type

Command	**ip ospf network** { **broadcast** | **non-broadcast**| **point-to-multipoint** [**non-broadcast**] | **point-to-point** }
Parameter Description	**broadcast**: Sets the interface network type to broadcast. **non-broadcast:** Sets the interface network type to non-broadcast. **point-to-multipoint** [**non-broadcast**]: Sets the interface network type to P2MP. If the interface does not have the broadcast capability, the **non-broadcast** parameter must be available. **point-to-point:** Sets the interface network type to P2P.
Command Mode	Interface configuration mode
Usage Guide	The broadcast type requires that the interface must have the broadcast capability. The P2P type requires that the interfaces are interconnected in one-to-one manner. The NBMA type requires full-meshed connections, and all interconnected routers can directly communicate with each other. The P2MP type does not raise any requirement.

Configuring Neighbors

Command	**neighbor** *ipv4-address* [**cost** *cost* | [**poll-interval** *poll-interval* | **priority** *priority*] *]
Parameter Description	*ipv4-address*: Indicates the IP address of the neighbor interface. **cost** *cost***:** Indicates the cost required to reach each neighbor. There is no default value. The value ranges from 0 to 65,535. This parameter is applicable only to the P2MP interface. **poll-interval** *poll-interval***:** Indicates the neighbor polling interval. The unit is second. The value ranges from 0 to 2,147,483,647. This parameter is applicable only to the NBMA interface. **priority** *priority*: Indicates the neighbor priority. The value ranges from 0 to 255. This parameter is applicable only to the NBMA interface.
Command Mode	OSPF routing process configuration mode

Usage Guide	Neighbors must be specified for the NBMA or P2MP (non-broadcast) interfaces. The neighbor IP address must be the primary IP address of this neighbor interface. If a neighbor router becomes inactive on the NBMA network, OSPF still sends Hello packets to this neighbor even if no Hello packet is received within the router death time. The interval at which the Hello packet is sent is called polling interval. When running for the first time, OSPF sends Hello packets only to neighbors whose priorities are not 0. In this way, neighbors with priorities set to 0 do not participate in the DR/BDR election. After a DR/BDR is elected, the DR/BDR sends the Hello packets to all neighbors to set up the adjacency. The P2MP (non-broadcast) network cannot dynamically discover neighbors because it does not have the broadcast capability. Therefore, you must use this command to manually configure neighbors for the P2MP (non-broadcast) network. In addition, you can use the **cost** parameter to specify the cost to reach each neighbor on the P2MP network.



Configuring the Interface Priority

Command	**ip ospf priority** *priority*
Parameter Description	*priority*: Indicates the OSPF priority of an interface. The value ranges from 0 to 255.
Command Mode	Interface configuration mode
Usage Guide	The OSPF interface priority is contained in the Hello packet. When the DR/BDR election occurs on the OSPF broadcast network, the router with the highest priority becomes the DR or BDR. If the priorities are the same, the router with the largest router ID becomes the DR or BDR. A router with the priority set to 0 does not participate in the DR/BDR election. This command is applicable only to the OSPF broadcast and NBMA interfaces.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Setting the Interface Network Type to P2MP

Scenario **Figure 1-8**	 **Remarks** The interface IP addresses are as follows: A: S1/0 192.168.1.2 B: S1/0 192.168.1.3 C: S1/0 192.168.1.4
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Set the interface network type to P2MP on all routers.

A	`A#configure terminal`
	`A(config)# interface Serial1/0`
	`A(config-Serial1/0)# encapsulation frame-relay`
	`A(config-Serial1/0)# ip ospf network point-to-multipoint`

B	`B#configure terminal`
	`B(config)# interface Serial1/0`
	`B(config-Serial1/0)# encapsulation frame-relay`
	`B(config-Serial1/0)# ip ospf network point-to-multipoint`

C	`C#configure terminal`
	`C(config)# interface Serial1/0`
	`C(config-Serial1/0)# encapsulation frame-relay`
	`C(config-Serial1/0)# ip ospf network point-to-multipoint`

Verification	Verify that the interface network type is P2MP.
	`A# show ip ospf interface Serial1/0`
	`Serial1/0 is up, line protocol is up`
	`Internet Address 192.168.1.2/24, Ifindex 2, Area 0.0.0.1, MTU 1500`
	`Matching network config: 192.168.1.0/24`
	`Process ID 1, Router ID 192.168.1.2, Network Type POINTOMULTIPOINT, Cost: 1`
	`Transmit Delay is 1 sec, State Point-To-Point`
	`Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5`
	`Hello due in 00:00:02`
	`Neighbor Count is 1, Adjacent neighbor count is 0`
	`Crypt Sequence Number is 4787`
	`Hello received 465 sent 466, DD received 8 sent 8`
	`LS-Req received 2 sent 2, LS-Upd received 8 sent 21`
	`LS-Ack received 14 sent 7, Discarded 3`

Common Errors

- The network types configured on interfaces at two ends are inconsistent, causing abnormal route learning.
- The network type is set to NBMA or P2MP (with the **non-broadcast** parameter), but neighbors are not specified.

1.4.3 Configuring Route Redistribution and Default Route

Configuration Effect

- In the OSPF domain, introduce a unicast route to other AS domains so that the unicast routing service to other AS domains can be provided for users in the OSPF domain.
- In the OSPF domain, inject a default route to other AS domains so that the unicast routing service to other AS domains can be provided for users in the OSPF domain.

Notes

- The OSPF basic functions must be configured.

Configuration Steps

↘ Configuring External Route Redistribution

- (Optional) This configuration is required if external routes of the OSPF domain should be introduced to an ASBR.
- This configuration is performed on an ASBR.

↘ Generating a Default Route

- (Optional) This configuration is required if the default route should be introduced to an ASBR so that other routers in the OSPF domain access other AS domains through this ASBR by default.

- This configuration is performed on an ASBR.

Verification

- On a router inside the OSPF domain, run the **show ip route** command to verify that the unicast routes to other AS domains are loaded.
- On a router inside the OSPF domain, run the **show ip route** command to verify that the default route to the ASBR is loaded.
- Run the **ping** command to verify that the IPv4 unicast service to other AS domains is correct.

Related Commands

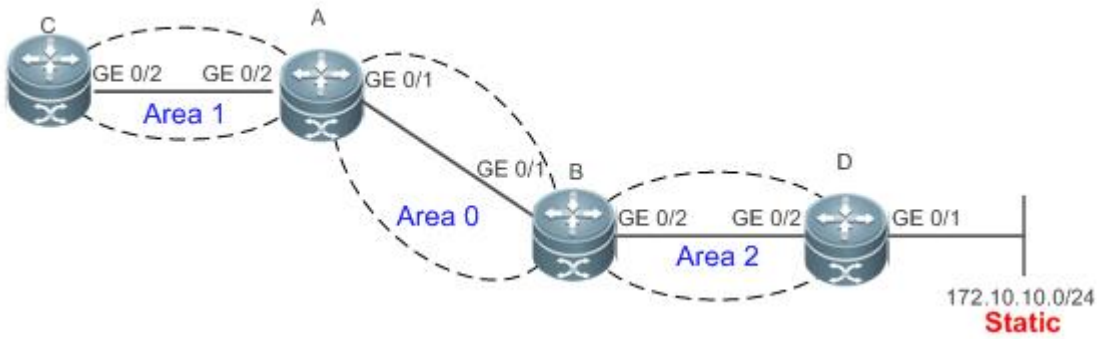
Configuring External Route Redistribution

Command	**redistribute** { **connected** | **ospf** *process-id* [**match** { **external** [**1** | **2**] | **internal** | **nssa-external** [**1 | 2**] } *] | **rip** | **static** } [**metric** *metric-value* | **metric-type** { **1** | **2** } | **route-map** *route-map-name* | **subnets** | **tag** *tag-value*] *
Parameter Description	**connected:** Indicates redistribution from direct routes. **ospf** *process-id:* Indicates redistribution from OSPF. *process-id* specifies an OSPF process. The value ranges from 1 to 65,535. **match:** Used only when OSPF routes are redistributed. Only the routes meeting the filtering conditions are redistributed. By default, all OSPF routes can be redistributed. **external [** 1 **|** 2 **]:** E1, E2, or all external routes. **internal**: Intra-area route and inter-area route. **nssa-external [1 | 2]:** N1, N2, or all external routes in the NSSA area. **rip:** Indicates redistribution from RIP. **static:** Indicates redistribution from static routes. **metric** *metric-value:* Specifies the metric of the OSPF external LSA. *metric-value* specifies the size of the metric. The value ranges from 0 to 16,777,214. **metric-type** { **1** | **2** }: Sets the external route type, which can be E-1 or E-2. **route-map** *route-map-name:* Sets the redistribution filtering rules. **subnets:** Specifies the non-standard networks for redistribution. **tag** *tag-value:* Specifies the tag value of the route that is redistributed into the OSPF routing domain. The value ranges from 0 to 4,294,967,295.
Command Mode	OSPF routing process configuration mode
Usage Guide	After this command is configured, the router becomes an ASBR, imports related routing information to the OSPF domain, and advertises the routing information as Type 5 LSAs to other OSPF routers in the domain. If you configure redistribution of OSPF routes without specifying the **match** parameter, OSPF routes of all sub-types can be distributed by default. The latest setting of the **match** parameter is used as the initial **match** parameter. Only routes that match the sub-types can be redistributed. You can use the **no** form of the command to restore the default value of **match**. For details, see the configuration example. If **route-map** is specified, the filtering rules specified in **route-map** are applicable to original parameters of redistribution. For redistribution of OSPF, the route map is used for filtering only when the redistributed routes meet criteria specified by **match**. The **set metric** value associated with **route-map** should fall into the range of 0 to 16,777,214. If the value

	exceeds this range, routes cannot be introduced. The configuration rules for the **no** form of the **redistribute** command are as follows: 1. If some parameters are specified in the **no** form of the command, default values of these parameters will be restored. 2. If no parameter is specified in the **no** form of the command, the entire command will be deleted.

Introducing a Default Route

Command	**default-information originate** [**always** | **metric** *metric* | **metric-type** *type* | **route-map** *map-name*] *
Parameter Description	**always:** Enables OSPF to generate a default route regardless of whether the local router has a default route. **metric** *metric:* Indicates the initial metric of the default route. The value ranges from 0 to 16,777,214. **metric-type** *type:* Indicates the type of the default route. OSPF external routes are classified into two types: Type 1: The metric varies with routers; Type 2: The metric is the same for all routers. Type 1 external routes are more trustworthy than Type 2 external routes. **route-map** *map-name:* Indicates the associated route-map name. By default, no route-map is associated.
Command Mode	OSPF routing process configuration mode
Usage Guide	When the **redistribute** or **default-information** command is executed, the OSPF router automatically becomes an ASBR. The ASBR, however, does not automatically generate or advertise a default route to all routers in the OSPF routing domain. To have the ASBR generates a default route, configure the **default-information originate** command. If **always** is specified, the OSPF routing process advertises an external default route to neighbors regardless of whether a default route exists. This default route, however, is not displayed on the local router. To confirm whether the default route is generated, run the **show ip ospf database** command to display the OSPF link status database. The external link with the ID 0.0.0.0 describes the default route. On an OSPF neighbor, you can run the **show ip route** command to see the default route. The metric of the external default route can only be defined in the **default-information originate** command, instead of the **default-metric** command. OSPF has two types of external routes. The metric of the Type 1 external route changes, but the metric of the Type 2 external route is fixed. If two parallel paths to the same destination have the same route metric, the priority of the Type 1 route is higher than that of the Type 2 route. Therefore, the **show ip route** command displays only the Type 1 route. A router in the stub area cannot generate an external default route. The **set metric** value associated with **route-map** should fall into the range of 0 to 16,777,214. If the value exceeds this range, routes cannot be introduced.



Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Configuring Static Route Redistribution

Scenario

Figure 1-9

Remarks	The interface IP addresses are as follows: A: GE 0/1 192.168.1.1 GE 0/2 192.168.2.1 B: GE 0/1 192.168.1.2 GE 0/2 192.168.3.1 C: GE 0/2 192.168.2.2 D: GE 0/1 192.168.6.2 GE 0/2 192.168.3.2

Configuration Steps

- Configure the interface IP addresses on all routers. (Omitted)
- Configure the OSPF basic functions on all routers. (Omitted)
- Introduce an external static route to Router D.

D

```
D# configure terminal
D(config)# ip route 172.10.10.0 255.255.255.0 192.168.6.3
D(config)#router ospf 1
D(config-router)# redistribute staticsubnets
```

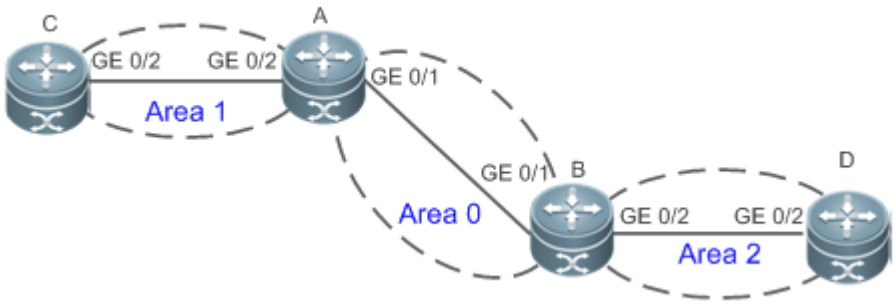
Verification

- On Router D, run the **show ip ospf database external brief** command to verify that an LSA corresponding to an external route is generated.
- On Router C, run the **show ip route ospf** command to verify that the external static route has been introduced.

D

```
D# show ip ospf database external brief
          OSPF Router with ID (192.168.22.30) (Process ID 1)
              AS External Link States

Link ID         ADV Router      Age  Seq#       CkSum  Route              Tag
172.10.10.0     192.168.22.30   11   0x80000001 0xa4bb E2 172.10.10.0/24    0
```



C

```
C# show ip route ospf
O E2 172.10.10.0/24 [110/20] via 192.168.2.1, 00:18:03, GigabitEthernet 0/2
```

Configuring the Default Route

Scenario

Figure 1-10

Remarks	The interface IP addresses are as follows: A: GE 0/1 192.168.1.1 GE 0/2 192.168.2.1 B: GE 0/1 192.168.1.2 GE 0/2 192.168.3.1 C: GE 0/2 192.168.2.2 D: GE 0/2 192.168.3.2

Configuration Steps

- Configure the interface IP addresses on all routers. (Omitted)
- Configure the OSPF basic functions on all routers. (Omitted)
- Configure the default route on Router D.

D

```
D# configure terminal
D(config)#router ospf 1
D(config-router)#default-information originate always
```

Verification

- On Router D, run the **show ip ospf database external brief** command to verify that an LSA corresponding to the default route is generated.
- On Router C, run the **show ip route ospf** command to verify that the OSPF default route exists.

D

```
D#show ip ospf database external brief

          OSPF Router with ID (192.168.22.30) (Process ID 1)

              AS External Link States

Link ID         ADV Router      Age  Seq#       CkSum  Route              Tag
0.0.0.0         192.168.22.30   565  0x80000002 0xa190 E2 0.0.0.0/0         1
```

C

```
C# show ip route ospf
O E20.0.0.0/0 [110/20] via 192.168.2.1, 00:18:03, GigabitEthernet 0/2
```

Common Errors

- The subnet route is not introduced because the **subnets** parameter in the **redistribute** command is not configured.
- A routing loop is formed because the **default-information originate always** command is configured on multiple routers.
- Routes cannot be introduced because route redistribution is configured on a router in the stub area.

1.4.4 Configuring Stub Area and NSSA Area

Configuration Effect

- Configure an area located on the stub as a stub area to reduce interaction of routing information and the size of routing table, and enhance stability of routes.

Notes

- The OSPF basic functions must be configured.
- A backbone or transit area cannot be configured as a stub or an NSSA area.
- A router in the stub area cannot introduce external routes, but a router in the NSSA area can introduce external routes.

Configuration Steps

↘ Configuring a Stub Area

- (Optional) This configuration is required if you wish to reduce the size of the routing table on routers in the area.
- The area must be configured as a stub area on all routers in this area.

↘ Configuring an NSSA Area

- (Optional) This configuration is required if you wish to reduce the size of the routing table on routers in the area and introduce OSPF external routes to the area.
- The area must be configured as an NSSA area on all routers in this area.

Verification

↘ Verifying the Stub Area

- On a router in the stub area, run the **show ip route** command to verify that the router is not loaded with any external routes.

↘ Verifying the NSSA Area

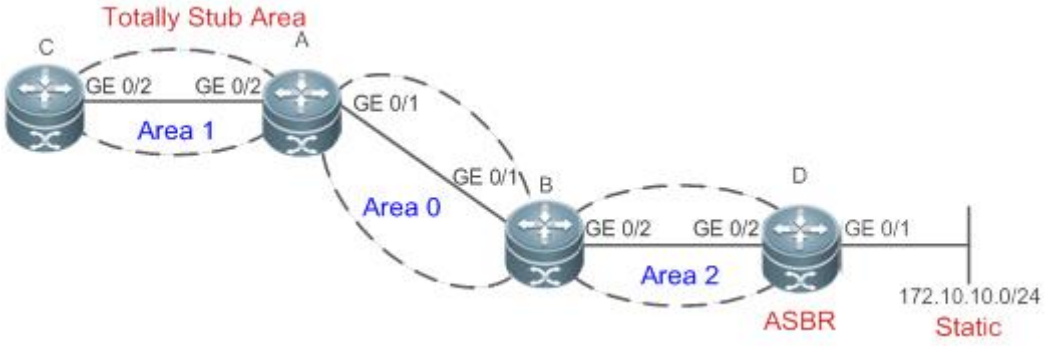
- On a router in the NSSA area, run the **show ip ospf database** command to verify that the introduced external route generates Type 7 LSAs.
- On a router in the backbone area, run the **show ip route** command to verify that the router is loaded with external routes introduced from the NSSA area.

Related Commands

Configuring a Stub Area

Command	**area** *area-id* **stub** [**no-summary**]
Parameter Description	*area-id:* Indicates the ID of the stub area. **no-summary:** Prohibits the ABR from sending network summary LSAs. At this time, the stub can be called totally stub area. This parameter is configured only when the router is an ABR.
Command Mode	OSPF routing process configuration mode
Usage Guide	You must run the **area stub** command on all routers in the OSPF stub area. The ABR sends only three types of LSAs to the stub area: (1) Type 1: Router LSA; (2) Type 2: Network LSA; (3) Type 3: Network Summary LSA. From the routing table point of view, a router in the stub area can learn only the internal routes of the OSPF routing domain, including the internal default route generated by an ABR. A router in the stub area cannot learn external routes of the OSPF routing domain. To configure a totally stub area, add the **no-summary** keyword when running the **area stub** command on the ABR. A router in the totally stub area can learn only the internal routes of the local area, including the internal default route generated by an ABR. You can run either the **area stub** or **area default-cost** command to configure an OSPF area as a stub area. If **area stub** is used, you must configure this command on all routers connected to the stub area. If **area default-cost** is used, run this command only on the ABR in the stub area. The **area default-cost** command defines the initial cost (metric) of the internal default route.

Configuring an NSSA Area



Command	**area** *area-id* **nssa** [**default-information-originate** [**metric** *metric* | **metric-type** *metric-type*] * | **no-redistribution** | **no-summary** | **translator** [**always** | **stability-interval** *stability-interval*] *] *
Parameter Description	*area-id:* Indicates the ID of the NSSA area. **default-information-originate:** Indicates that a default Type 7 LSA is generated and introduced to the NSSA area. This option takes effect only on an NSSA ABR or ASBR. **metric** *metric:* Specifies the metric of the generated default LSA. The value ranges from 0 to 16,777,214. The default value is 1. **metric-type** *metric-type e:* Specifies the route type of the generated default LSA. The values include 1 and 2. **1** represents N-1, and **2** represents N-2. The default value is 2. **no-redistribution:** Select this option if the router is an NSSA ABR and you want to use only the **no-summary:** Prohibits the ABR in the NSSA area from sending summary LSAs (Type-3 LSA). **translator:** Indicates that the NSSA ABR is a translator. **always:** Indicates that the current NSSA ABR always acts as a translator. The default value is the standby translator. **stability-interval** *seconds:* Indicates the stability interval after the NSSA ABR is changed from a translator to a non-translator. The unit is second. The default value is 40. The value ranges from 0 to 2,147,483,647.
Command Mode	OSPF routing process configuration mode
Usage Guide	The **default-information-originate** parameter is used to generate a default Type 7 LSA. This parameter has different functions on the ABR and the ASBR in the NSSA area. On the ABR, a Type 7 LSA default route is generated regardless of whether the default route exists in the routing table. On the ASBR (not an ABR), a Type 7 LSA default route is generated only when the default route exists in the routing table. If the **no-redistribution** parameter is configured on the ASBR, other external routes introduced by OSPF

	through the **redistribute** command cannot be advertised to the NSSA area. This parameter is generally used when a router in the NSSA area acts both as the ASBR and the ABR. It prevents external routing information from entering the NSSA area. To further reduce the number of LSAs sent to the NSSA area, you can configure the **no-summary** parameter on the ABR to prevent the ABR from sending the summary LSAs (Type 3 LSA) to the NSSA area. **area default-cost** is used on an ABR or ASBR connected to the NSSA area. This command configures the cost of the default route sent from the ABR/ASBR to the NSSA area. By default, the cost of the default route sent to the NSSA area is 1. If an NSSA area has two or more ABRs, the ABR with the largest router ID is elected by default as the translator for converting Type 7 LSAs into Type 5 LSAs. If the current device is always the translator ABR for converting Type 7 LSAs into Type 5 LSAs, use the **translator always** parameter. If the translator role of the current device is replaced by another ABR, the conversion capability is retained during the time specified by **stability-interval**. If the router does not become a translator again during **stability-interval**, LSAs that are converted from Type 7 to Type 5 will be deleted from the AS after **stability-interval** expires. To prevent a routing loop, LSAs that are converted from Type 7 to Type 5 will be deleted from the AS immediately after the current device loses the translator role even if **stability-interval** does not expire. In the same NSSA area, it is recommended that **translator always** be configured on only one ABR.

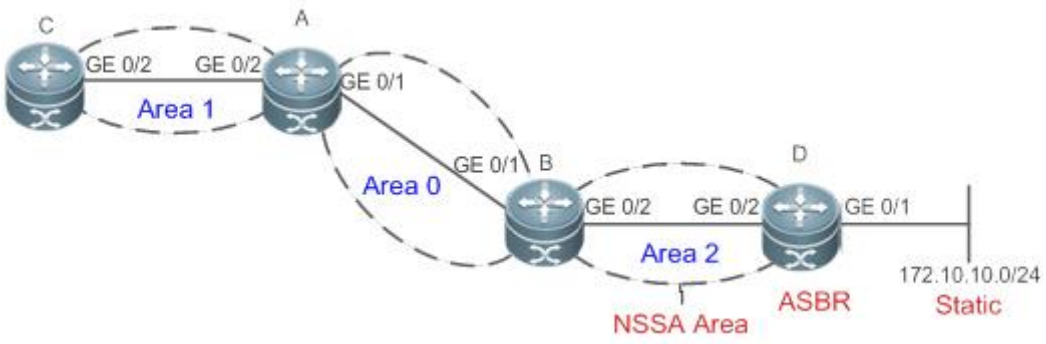
Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Configuring a Stub Area

Scenario **Figure 1-11**	
	Remarks The interface IP addresses are as follows: A: GE 0/1 192.168.1.1 GE 0/2 192.168.2.1 B: GE 0/1 192.168.1.2 GE 0/2 192.168.3.1 C: GE 0/2 192.168.2.2 D: GE 0/1 192.168.6.2 GE 0/2 192.168.3.2

Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Introduce an external static route to Router D. ● Configure area 1 as the stub area on Router A and Router C.



D	`D# configure terminal`
	`D(config)#router ospf 1`
	`D(config-router)# redistribute staticsubnets`

A	`A# configure terminal`
	`A(config)#router ospf 1`
	`A(config-router)#area 1 stubno-summary`

C	`C# configure terminal`
	`C(config)#router ospf 1`
	`C(config-router)#area 1 stub`

Verification	On Router C, run the **show ip route ospf** command to display the routing table. Verify that there is only one default inter-area route, and no external static route is introduced from Router D.
	`C#show ip route ospf` `O*IA 0.0.0.0/0 [110/2] via 192.168.2.1, 00:30:53, GigabitEthernet 0/2`

Configuring an NSSA Area

Scenario Figure 1-12	

Remarks	The interface IP addresses are as follows: A: GE 0/1 192.168.1.1 GE 0/2 192.168.2.1 B: GE 0/1 192.168.1.2 GE 0/2 192.168.3.1 C: GE 0/2 192.168.2.2 D: GE 0/1 192.168.6.2 GE 0/2 192.168.3.2

Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Introduce an external static route to Router D. ● Configure area 2 as the NSSA area on Router B and Router D.

B	`B# configure terminal`
	`B(config)#router ospf 1`
	`B(config-router)#area 2 nssa`

D	`D# configure terminal`
	`D(config)#ip route 172.10.10.0 255.255.255.0 192.168.6.2`
	`D(config)#router ospf 1`
	`D(config-router)#redistribute static subnets`
	`D(config-router)#area 2 nssa`

Verification	● On Router D, verify that the Type 7 LSA, 172.10.10.0/24, is generated. ● On Router B, verify that Type 5 and Type 7 LSAs coexist on 172.10.10.0/24. ● On Router B, verify that the N-2 route of 172.10.10.0/24 is generated.

D	`D# show ip ospf database nssa-external`
	`OSPF Router with ID (192.168.6.2) (Process ID 1)`
	`NSSA-external Link States (Area 0.0.0.1 [NSSA])`
	`LS age: 61`
	`Options: 0x8 (-|-|-|-|N/P|-|-|-)`
	`LS Type: AS-NSSA-LSA`
	`Link State ID: 172.10.10.0 (External Network Number For NSSA)`
	`Advertising Router: 192.168.6.2`
	`LS Seq Number: 80000001`
	`Checksum: 0xc8f8`
	`Length: 36`
	`Network Mask: /24`
	`Metric Type: 2 (Larger than any link state path)`
	`TOS: 0`
	`Metric: 20`
	`NSSA: Forward Address: 192.168.6.2`

```
      External Route Tag: 0
```

B

```
B# show ip ospf database nssa-external

          OSPF Router with ID (192.168.3.1) (Process ID 1)

              NSSA-external Link States (Area 0.0.0.1 [NSSA])

  LS age: 314

  Options: 0x8 (-|-|-|-|N/P|-|-|-)

              AS External Link States

  LS age: 875

  Options: 0x2 (-|-|-|-|-|-|E|-)

  LS Type: AS-external-LSA

  Link State ID: 172.10.10.0 (External Network Number)

  Advertising Router: 192.168.3.1

  LS Seq Number: 80000001

  Checksum: 0xd0d3

  Length: 36

  Network Mask: /24

       Metric Type: 2 (Larger than any link state path)

       TOS: 0

       Metric: 20

       Forward Address: 192.168.6.2
```

	External Route Tag: 0 B# show ip route ospf O N2 172.10.10.0/24 [110/20] via 192.168.3.2, 00:06:53, GigabitEthernet 0/2

Common Errors

- Configurations of the area type are inconsistent on routers in the same area.
- External routes cannot be introduced because route redistribution is configured on a router in the stub area.

1.4.5 Configuring Route Summarization

Configuration Effect

- Summarize routes to reduce interaction of routing information and the size of routing table, and enhance stability of routes.
- Shield or filter routes.

Notes

- The OSPF basic functions must be configured.
- The address range of summarized routes may exceed the actual network range in the routing table. If data is sent to a network beyond the summarization range, a routing loop may be formed and the router processing load may increase. To prevent these problems, a discard route must be added to the routing table or shield or filter routes.

Configuration Steps

↘ Configuring Inter-Area Route Summarization

- (Optional) This configuration is required when routes of the OSPF area need to be summarized.
- Unless otherwise required, this configuration should be performed on an ABR in the area where routes to be summarized are located.

↘ Configuring External Route Summarization

- (Optional) This configuration is required when routes external to the OSPF domain need to be summarized.
- Unless otherwise required, this configuration should be performed on an ASBR to which routes to be summarized are introduced.

Verification

Run the **show ip route ospf** command to verify that individual routes do not exist and only the summarized route exists.

Related Commands

↘ Configuring Inter-Area Route Summarization

Command	**area** *area-id* **range** *ipv4-address net-mask* [**advertise** | **not-advertise**] [**cost** *cost*]
Parameter	*area-id*: Specifies the ID of the OSPF area to which the summarized route should be injected. The area ID

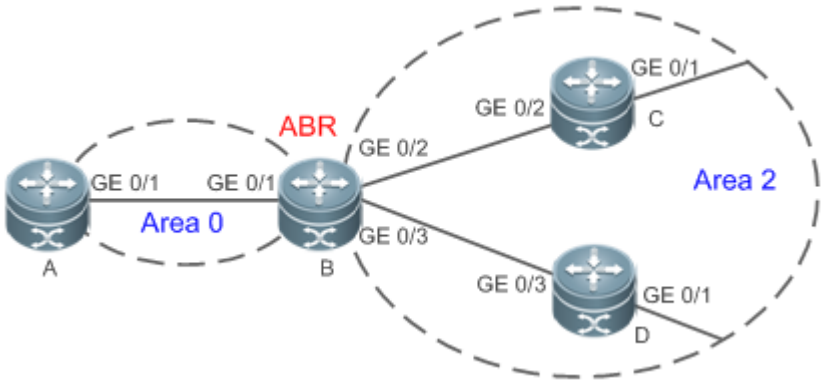
Description	can be a decimal integer or an IP address. *ipv4-address net-mask*: Defines the network segment of the summarized route. **advertise** | **not-advertise**: Specifies whether the summarized route should be advertised. **cost** *cost:* Indicates the metric of the summarized route. The value ranges from 0 to 16777215.
Command Mode	OSPF routing process configuration mode
Usage Guide	This command can be executed only on the ABR. It is used to combine or summarize multiple routes of an area into one route, and advertise the route to other areas. Combination of the routing information occurs only on the boundary of an area. Routers inside the area can learn specific routing information, whereas routers in other areas can learn only one summarized route. In addition, you can set **advertise** or **not-advertise** to determine whether to advertise the summarized route to shield and filter routes. By default, the summarized route is advertised. You can use the **cost** parameter to set the metric of the summarized route. You can configure route summarization commands for multiple areas. This simplifies routes in the entire OSPF routing domain, and improve the network forwarding performance, especially for a large-sized network. When multiple route summarization commands are configured and have the inclusive relationship with each other, the area range to be summarized is determined based on the maximum match principle.

Configuring External Route Summarization

Command	**summary-address** *ipv4-address net-mask* [[**cost** *cost* | **tag** *value*] * | **not-advertise**]
Parameter Description	*ipv4-addres*: Indicates the IP address of the summarized route. *net-mask*: Indicates the subnet mask of the summarized route. **cost** *cost*: Sets the cost value of the aggregation route. The value ranges from 0 to 16,777,214. **tag** *value:* Indicates the tag of the summarized route. The value ranges from 0 to 4,294,967,295. **not-advertise**: Indicates that the summarized route is not advertised. If this parameter is not specified, the summarized route is advertised.
Command Mode	OSPF routing process configuration mode
Usage Guide	When routes are redistributed from other routing processes and injected to the OSPF routing process, each route is advertised to the OSPF routers using an external LSA. If the injected routes are a continuous address space, the ABR can advertised only one summarized route to significantly reduce the size of the routing table. **area range** summarizesthe routes between OSPF routes, whereas **summary-address** summarizes external routes of the OSPF routing domain. When configured on the NSSA ABR translator, **summary-address** summarizes redistributed routes and routes obtained based on the LSAs that are converted from Type 7 to Type 5. When configured on the ASBR (not an NSSA ABR translator), **summary-address** summarizes only redistributed routes.

Configuring a Discard Route

Command	**discard-route** { **internal** | **external** }
Parameter Description	**internal:** Indicates that the discard route generated by the **area range** command can be added. **external:** Indicates that the discard route generated by the **summary-address** command can be added.



Command Mode	OSPF routing process configuration mode
Usage Guide	The address range of summarized routes may exceed the actual network range in the routing table. If data is sent to a network beyond the summarization range, a routing loop may be formed and the router processing load may increase. To prevent these problems, a discard route must be added to the routing table on the ABR or ASBR. This route is automatically generated, and is not advertised.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Scenario

Figure 1-13

Remarks	The interface IP addresses are as follows: A: GE0/1 192.168.1.1 B: GE0/1 192.168.1.2 GE0/2 172.16.2.1 GE0/3 172.16.3.1 C: GE0/2 172.16.2.2 GE0/1 172.16.4.2 D: GE0/2 172.16.3.2 GE0/1 172.16.5.2

Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Summarize routes of area 2 on Router B.

B	`B# configure terminal`
	`B(config)#router ospf 1`
	`B(config-router)#area 2 range 172.16.0.0 255.255.0.0`

Verification	On Router A, verify that the entry 172.16.0.0/16 is added to the routing table.
A	`A#show ip route ospf` `O IA 172.16.0.0/16 [110/2] via 192.168.1.2, 00:01:04, GigabitEthernet 0/1`

Common Errors

- Inter-area route summarization cannot be implemented because the **area range** command is configured on a non-ABR device.

1.4.6 Configuring Route Filtering

Configuration Effect

- Routes that do not meet filtering conditions cannot be loaded to the routing table, or advertised to neighbors. Network users cannot access specified destination network.

Notes

- The OSPF basic functions must be configured.
- Filtering routes by using the **distribute-list in** command affects forwarding of local routes, but does not affect route computation based on LSAs. Therefore, if route filtering is configured on the ABR, Type 3 LSAs will still be generated and advertised to other areas because routes can still be computed based on LSAs. As a result, black-hole routes are generated. In this case, you can run the **area filter-list** or **area range** (containing the **not-advertise** parameter) command on the ABR to prevent generation of black-hole routes.

Configuration Steps

↘ Configuring Inter-Area Route Filtering

- (Optional) This configuration is recommended if users should be restricted from accessing the network in a certain OSPF area.
- Unless otherwise required, this configuration should be performed on an ABR in the area where filtered routes are located.

↘ Configuring Redistributed Route Filtering

- (Optional) This configuration is required if external routes introduced by the ASBR need to be filtered.
- Unless otherwise required, this configuration should be performed on an ASBR to which filtered routes are introduced.

↘ Configuring Learned Route Filtering

- (Optional) This configuration is required if users should be restricted from accessing a specified destination network.
- Unless otherwise required, this configuration should be performed on a router that requires route filtering.

Verification

- Run the **show ip route** command to verify that the router is not loaded with routes that have been filtered out.
- Run the **ping** command to verify that the specified destination network cannot be accessed.

Related Commands

↘ Configuring a Passive Interface

Command	**passive-interface** { **default** | *interface-type interface-number* | *interface-type interface-number*

	ipv4-address}
Parameter Description	*interface-type interface-number*: Indicates the interface that should be configured as a passive interface. **default:** Indicates that all interface will be configured as passive interfaces. *interface-type interface-number ipv4-address:* Specifies an address of the interface as the passive address.
Command Mode	OSPF routing process configuration mode
Usage Guide	To prevent other routers on the network from learning the routing information of the local router, you can configure a specified network interface of the local router as the passive interface, or a specified IP address of a network interface as the passive address.

Configuring the LSA Update Packet Filtering

Command	**ip ospf database-filter all out**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Enable this function on an interface to prevent sending the LSA update packet on this interface. After this function is enabled, the local router does not advertise the LSA update packet to neighbors, but still sets up the adjacency with neighbors and receives LSAs from neighbors.

Configuring Inter-Area Route Filtering

Command	**area** *area-id* **filter-list** { **access** *acl-name* | **prefix** *prefix-name* } {**in** | **out**}
Parameter Description	*area-id*: Indicates the area ID. **access** *acl-name*: Indicates the associated ACL. **prefix** *prefix-name*: Indicates the associated prefix list. **in** | **out:** Filters routes that are received by or sent from the area.
Command Mode	OSPF routing process configuration mode
Usage Guide	This command can be configured only on an ABR. Use this command when it is required to configure filtering conditions for inter-area routes on the ABR.

Configuring Redistributed Route Filtering

Command	**distribute-list** { *acl-name* | *acl-number* | **prefix** *prefix-list-name* } **out** [**connected** | **ospf** *process-id* **| rip | static**]
Parameter Description	*acl-name* | *acl-number*: Uses the ACL for filtering. **prefix** *prefix-list-name*: Uses the prefixlist for filtering. **connected**: Filters directly connected routes. **ospf** *process-id*: Filters OSPF routes. **rip**: Filters RIP routes. **static**: Filters static routes.
Command Mode	OSPF routing process configuration mode
Usage Guide	**distribute-list out** is similar to **redistribute route-map**, and is used to filter routes that are redistributed from other protocols to OSPF. The **distribute-list out** command itself does not redistribute routes, and is

	generally used together with the **redistribute** command. The ACL and the prefixlist filtering rules are mutually exclusive in the configuration. That is, if the ACL is used for filtering routes coming from a certain source, the prefixlist cannot be configured to filter the same routes.

Configuring Learned Route Filtering

Command	**distribute-list** { *acl-name* | *acl-number* | [**prefix** *prefix-list-name*] [**gateway** *prefix-list-name*] } **in** [*interface-type interface-number*]
Parameter Description	*acl-name* | *acl-number*: Uses the ACL for filtering. **prefix** *prefix-list-name*: Uses the prefixlist for filtering. **gateway** *prefix-list-name*: Uses the gateway for filtering. **route-map** *route-map-name:* Uses the route map for filtering. *interface-type interface-number:* Specifies the interface for which LSA routes are filtered.
Command Mode	OSPF routing process configuration mode
Usage Guide	Filter routes that are computed based on received LSAs. Only routes meeting the filtering conditions can be forwarded. The command does not affect the LSDB or the routing tables of neighbors. The ACL, prefix list, and route map filtering rules are mutually exclusive in the configuration. That is, if the ACL is used for filtering routes of a specified interface, the prefix list or router map cannot be configured for filtering routes of the same interface.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Scenario **Figure 1-14**	 **Remarks**: The interface IP addresses are as follows: A: GE0/1 192.168.1.1 B: GE0/1 192.168.1.2 GE0/2 172.16.2.1 GE0/3 172.16.3.1 C: GE0/2 172.16.2.2 GE0/3 172.16.4.2 D: GE0/2 172.16.3.2 GE0/3 172.16.5.2
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted)

	● On Router A, configure route filtering.

A	`A# configure terminal`
	`A(config)#access-list 3 permit host 172.16.5.0`
	`A(config)#router ospf 1`
	`A(config-router)#distribute-list 3 in GigabitEthernet 0/1`

Verification	● On Router A, check the routing table. Verify that only the entry 172.16.5.0/24 is loaded.
A	`A# show ip route ospf` `O  172.16.5.0/24 [110/2] via 192.168.1.2, 10:39:40, GigabitEthernet 0/1`

Common Errors

- Filtering routes by using the **distribute-list in** command affects forwarding of local routes, but does not affect route computation based on LSAs. Therefore, if route filtering is configured on the ABR, Type 3 LSAs will still be generated and advertised to other areas because routes can still be computed based on LSAs. As a result, black-hole routes are generated.

1.4.7 Modifying Route Cost and AD

Configuration Effect

- Change the OSPF routes to enable the traffic pass through specified nodes or avoid passing through specified nodes.
- Change the sequence that a router selects routes so as to change the priorities of OSPF routes.

Notes

- The OSPF basic functions must be configured.
- If you run the **ip ospf cost** command to configure the cost of an interface, the configured cost will automatically overwrite the cost that is computed based on the auto cost.

Configuration Steps

↘ Configuring the Reference Bandwidth

- Optional.
- A router is connected with lines with different bandwidths. This configuration is recommended if you wish to preferentially select the line with a larger bandwidth.

↘ Configuring the Cost of an Interface

- Optional.
- A router is connected with multiple lines. This configuration is recommended if you wish to manually specify a preferential line.

Configuring the Default Metric for Redistribution

- Optional.
- This configuration is mandatory if the cost of external routes of the OSPF domain should be specified when external routes are introduced to an ASBR.

Configuring the Maximum Metric

- Optional.
- A router may be unstable during the restart process or a period of time after the router is restarted, and users do not want to forward data through this router. In this case, this configuration is recommended.

Configuring the AD

- Optional.
- This configuration is mandatory if you wish to change the priorities of OSPF routes on a router that runs multiple unicast routing protocols.

Verification

- Run the **show ip ospf interface** command to verify that the costs of interfaces are correct.
- Run the **show ip route** command to verify that the costs of external routes introduced to the ASBR are correct.
- Restart the router. Within a specified period of time, data is not forwarded through the restarted router.

Related Commands

Configuring the Reference Bandwidth

Command	**auto-cost reference-bandwidth** *ref-bw*
Parameter Description	*ref-bw*: Indicates the reference bandwidth. The unit is Mbps. The value ranges from 1 to 4,294,967.
Command Mode	OSPF routing process configuration mode
Usage Guide	By default, the cost of an OSPF interface is equal to the reference value of the auto cost divided by the interface bandwidth. Run the **auto-cost** command to obtain the reference value of the auto cost. The default value is 100 Mbps. Run the **bandwidth** command to set the interface bandwidth. The costs of OSPF interfaces on several typical lines are as follows: 64Kbps serial line: The cost is 1562. E1 line: The cost is 48. 10M Ethernet: The cost is 10. 100M Ethernet: The cost is 1. If you run the **ip ospf cost** command to configure the cost of an interface, the configured cost will automatically overwrite the cost that is computed based on the auto cost.

Configuring the Cost of an Interface

Command	**ip ospf cost** *cost*

Parameter Description	*cost*: Indicates the cost of an OSPF interface. The value ranges from 0 to 65,535.
Command Mode	Interface configuration mode
Usage Guide	By default, the cost of an OSPF interface is equal to the reference value of the auto cost divided by the interface bandwidth. Run the **auto-cost** command to obtain the reference value of the auto cost. The default value is 100 Mbps. Run the **bandwidth** command to set the interface bandwidth. The costs of OSPF interfaces on several typical lines are as follows: 64Kbps serial line: The cost is 1562. E1 line: The cost is 48. 10M Ethernet: The cost is 10. 100M Ethernet: The cost is 1. If you run the **ip ospf cost** command to configure the cost of an interface, the configured cost will automatically overwrite the cost that is computed based on the auto cost.

Configuring the Cost of the Default Route in a Stub or an NSSA Area

Command	**area** *area-id* **default-cost** *cost*
Parameter Description	*area-id*: Indicates the ID of the stub or NSSA area. *cost*: Indicates the cost of the default summarized route injected to the stub or NSSA area. The value ranges from 0 to 16,777,215.
Command Mode	OSPF routing process configuration mode
Usage Guide	This command takes effect only on an ABR in a stub area or an ABR/ASBR in an NSSA area. An ABR in a stub area or an ABR/ASBR in an NSSA area is allowed to advertise an LSA indicating the default route in the stub or NSSA area. You can run the **area default-cost** command to modify the cost of the advertised LSA.

Configuring the Default Metric for Redistribution

Command	**default-metric** *metric*
Parameter Description	*metric*: Indicates the default metric of the OSPF redistributed route. The value ranges from 1 to 16,777,214.
Command Mode	OSPF routing process configuration mode
Usage Guide	The **default-metric** command must be used together with the **redistribute** command to modify the initial metrics of all redistributed routes. The **default-metric**command does not take effect on external routes that are injected to the OSPF routing domain by the **default-information originate** command.

Configuring the Maximum Metric

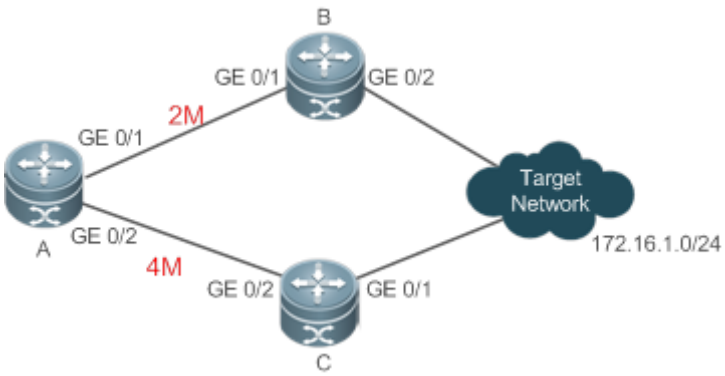
Command	**max-metric router-lsa** [**external-lsa** [*max-metric-value*] | **include-stub** | **on-startup** [*startup-interval-time*] | **summary-lsa** [*max-metric-value*]] *
Parameter Description	**router-lsa**: Sets the metrics of non-stub links in the Router LSA to the maximum value (0xFFFF). **external-lsa**: Allows a router to replace the metrics of external LSAs (including Type 5 and Type 7 LSAs)

	with the maximum metric. *max-metric-value*: Indicates the maximum metric of the external LSA. The default value is 16711680. The value ranges from 1 to 16,777,215. **include-stub:** Sets the metrics of stub links in the Router LSA advertised by the router to the maximum value. **on-startup:** Allows a router to advertise the maximum metric when started. *startup-interval-time:* Indicates the interval at which the maximum metric is advertised. The default value is 600s. The value ranges from 5 to 86,400. **summary-lsa:** Allows a router to replace the metrics of summary LSAs (including Type 3 and Type 4 LSAs) with the maximum metric. *max-metric-value*: Sets the maximum metric value for summary LSAs. The default value is 16,711,680. The value ranges from 1 to 16,777,215.
Command Mode	OSPF routing process configuration mode
Usage Guide	After the **max-metric router-lsa** command is executed, the metrics of the non-stub links in the Router LSAs generated by the router will be set to the maximum value (0xFFFF). If you cancel this configuration or the timer expires, the normal metrics of the links are restored. By default, if the **max-metric router-lsa** command is executed, the stub links still advertise common metrics, that is, the costs of outbound interfaces. If the **include-stub** parameter is configured, the stub links will advertise the maximum metric. If an ABR does not wish to transfer inter-area traffic, use the **summary-lsa** parameter to set the metric of the Summary LSA to the maximum metric. If an ASBR does not wish to transfer external traffic, use the **external-lsa** parameter to set the metric of the external LSA to the maximum metric. The **max-metric router-lsa** command is generally used in the following scenarios: Restart a device. After the device is restarted, IGP generally converges faster, and other devices attempt to forward traffic through the restarted device. If the current device is still building the BGP routing table and some BGP routes have not been learned yet, packets destined for these networks will be discarded. In this case, the **on-startup** parameter can be used to set a certain delay, so that transmission as a transit node will start after the timer expires. ● Add a device to the network but the device is not used to transfer traffic. The device is added to the network. If a candidate path exists, the current device is not used to transfer traffic. If a candidate path does not exist, the current device is still used to transfer traffic. ● Delete a device gracefully from the network. After the **max-metric router-lsa** command is executed, the current device advertises the maximum metric among all metrics of routes. In this way, other devices on the network can select the standby path for data transmission before the device is shut down. In the earlier OSPF version (RFC1247 or earlier), the links with the maximum metric (0xFFFF) in the LSAs do not participate in the SPF computation, that is, no traffic is sent to routers that generate these LSAs.

Configuring RFC1583Compatibility

Command	**compatible rfc1583**
Parameter	N/A

Description	
Command Mode	OSPF routing process configuration mode
Usage Guide	When there are multiple paths to an ASBR or the forwarding address of an external route, RFC1583 and RFC2328 define different routing rules. If RFC1583 compatibility is configured, a path in the backbone area or an inter-area path is preferentially selected. If RFC1583 compatibility is not configured, a path in a non-backbone area is preferentially selected.



Configuring the AD

Command	**distance** { *distance* | **ospf** { **external** *distance* | **inter-area** *distance* | **intra-area** *distance* } * }
Parameter Description	*distance*: Indicates the AD of a route. The value ranges from 1 to 255. **intra-area** *distance*: Indicates the AD of an intra-area route. The value ranges from 1 to 255. **inter-area** *distance*: Indicates the AD of an inter-area route. The value ranges from 1 to 255. **external** *distance:* Indicates the AD of an external route. The value ranges from 1 to 255.
Command Mode	OSPF routing process configuration mode
Usage Guide	N/A

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Configuring the Cost of an Interface

Scenario Figure 1-15	 **Remarks**: The interface IP addresses are as follows: A: GE0/1 192.168.1.1 GE0/2 192.168.2.1 B: GE0/1 192.168.1.2 GE0/2 192.168.3.2 C: GE0/1 192.168.4.2 GE0/2 192.168.2.2
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● On Router A, configure the cost of each interface.

A	A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip ospf cost 10 A(config)# interface GigabitEthernet 0/2 A(config-if-GigabitEthernet 0/2)# ip ospf cost 20
Verification	On Router A, check the routing table. The next hop of the optimum path to 172.16.1.0/24 is Router B.
A	A# show ip route ospf O E2172.16.1.0/0 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1

Common Errors

- If the cost of an interface is set to 0 in the **ip ospf cost** command, a route computation error may occur. For example, a routing loop is obtained.

1.4.8 Enabling Authentication

Configuration Effect

- All routers connected to the OSPF network must be authenticated to ensure stability of OSPF and protect OSPF against intrusions.

Notes

- The OSPF basic functions must be configured.
- If authentication is configured for an area, the configuration takes effect on all interfaces that belong to this area.
- If authentication is configured for both an interface and the area to which the interface belongs, the configuration for the interface takes effect preferentially.

Configuration Steps

↘ Configuring the Authentication Type of an Area

- (Optional) This configuration is recommended if the same authentication type should be used on all interfaces in the same area.
- This configuration is required if a router accesses a network that requires authentication.

↘ Configuring the Authentication Type of an Interface

- (Optional) This configuration is recommended if the different authentication types should be used on different interfaces in the same area.
- This configuration is required if a router accesses a network that requires authentication.

↘ Configuring a Plain Text Authentication Key for an Interface

- Optional.

- This configuration is required if a router accesses a network that requires plain text authentication.

Configuring an MD5 Authentication Key for an Interface

- (Optional) MD5 authentication features a high security, and therefore is recommended. You must configure either plain text authentication or MD5 authentication.
- This configuration is required if a router accesses a network that requires MD5 authentication.

Verification

- If routers are configured with different authentication keys, run the **show ip ospf neighbor** command to verify that there is no OSPF neighbor.
- If routers are configured with the same authentication key, run the **show ip ospf neighbor** command to verify that there are OSPF neighbors.

Related Commands

Configuring the Authentication Type of an Area

Command	**area** *area-id* **authentication** [**message-digest**]
Parameter Description	*area-id*: Indicates the ID of the area where OSPF authentication is enabled. The area ID can be a decimal integer or an IP address. **message-digest**: Enables MD5 authentication.
Command Mode	OSPF routing process configuration mode
Usage Guide	The RGOS supports three authentication types: (1) Type 0: No authentication is required. If this command is not configured to enable OSPF authentication, the authentication type in the OSPF data packet is 0. (2) Type 1: The authentication type is plain text authentication if this command is configured but does not contain the **message-digest** parameter. (3) Type 3: The authentication type is MD5 authentication if this command is configured and contains the **message-digest** parameter. All routers in the same OSPF area must use the same authentication type. If authentication is enabled, the authentication key must be configured on interfaces that are connected to neighbors. You can run the interface configuration command **ip ospf authentication-key** to configure the plain text authentication key, or **ip ospf message-digest-key** to configure the MD5 authentication key.

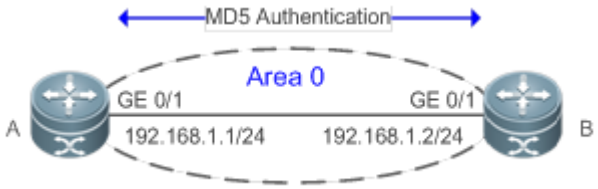
Configuring the Authentication Type of an Interface

Command	**ip ospf authentication** [**message-digest** | **null**]
Parameter Description	**message-digest**: Indicates that MD5 authentication is enabled on the current interface. **null**: Indicates that authentication is disabled.
Command Mode	Interface configuration mode
Usage Guide	If the **ip ospf authentication** command does not contain any option, it indicates that plain text authentication is enabled. If you use the **no** form of the command to restore the default authentication mode, whether authentication is enabled is determined by the authentication type that is configured in the area to which the interface belongs. If the authentication type is set to null, authentication is disabled forcibly. When

	authentication is configured for both an interface and the area to which the interface belongs, the authentication type configured for the interface is used preferentially.

Configuring a Plain Text Authentication Key for an Interface

Command	**ip ospf authentication-key** [**0** |**7**]*key*
Parameter Description	**0**: Indicates that the key is displayed in plain text. **7**: Indicates that the key is displayed in cipher text. *key*: Indicates the key. The key is a string of up to eight characters.
Command Mode	Interface configuration mode
Usage Guide	The key configured by the **ip ospf authentication-key** command will be inserted to the headers of all OSPF packets. If the keys are inconsistent, two directly connected devices cannot set up the OSPF adjacency and therefore cannot exchange the routing information. Different keys can be configured for different interface, but all routers connected to the same physical network segment must be configured with the same key. You can enable or disable authentication in an OSPF area by running the **areaauthentication** command in OSPF routing process configuration mode. You can also enable authentication on an individual interface by running the **ip ospf authentication** command in interface configuration mode. When authentication is configured for both an interface and the area to which the interface belongs, the authentication type configured for the interface is used preferentially.



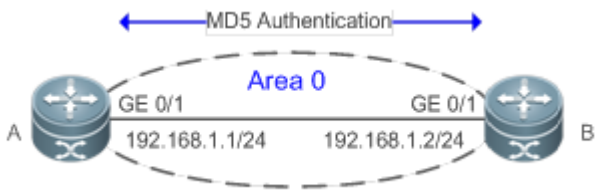
Configuring an MD5 Authentication Key for an Interface

Command	**ip ospf message-digest-key** *key-id* **md5** [**0** |**7**]*key*
Parameter Description	*key-id:* Indicates the key ID. The value ranges from 1 to 255. **0**: Indicates that the key is displayed in plain text. **7**: Indicates that the key is displayed in cipher text. *key:* Indicates the key. The key is a string of up to 16 characters.
Command Mode	Interface configuration mode
Usage Guide	The key configured by the **ip ospf message-digest-key** command will be inserted to the headers of all OSPF packets. If the keys are inconsistent, two directly connected devices cannot set up the OSPF adjacency and therefore cannot exchange the routing information. Different keys can be configured for different interface, but all routers connected to the same physical network segment must be configured with the same key. The same key ID on neighbor routers must correspond to the same key. You can enable or disable authentication in an OSPF area by running the **area authentication** command in OSPF routing process configuration mode. You can also enable authentication on an individual interface by running the **ip ospf authentication** command in interface configuration mode. When authentication is configured for both an interface and the area to which the interface belongs, the authentication type configured for the interface is used preferentially. The RGOS software supports smooth modification of the MD5 authentication key. A new MD5 authentication key must be first added before the old key can be deleted. When an OSPF MD5 authentication key is added to a router, the router determines that other routers do not use the new key yet and therefore uses different keys to send multiple OSPF packets until it confirms that the new key has been configured on neighbors.

	After configuring the new key all routers, you can delete the old key.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."



Scenario **Figure 1-16**	
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Configure the authentication type and MD5 authentication key on all routers.

A	`A# configure terminal`
	`A(config)#router ospf 1`
	`A(config-router)#area 0 authentication message-digest`
	`A(config-router)#exit`
	`A(config)#interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)#ip ospf message-digest-key 1 md5 hello`

B	`B# configure terminal`
	`B(config)#router ospf 1`
	`B(config-router)#area 0 authentication message-digest`
	`B(config-router)#exit`
	`B(config)#interface GigabitEthernet 0/3`
	`B(config-if-GigabitEthernet 0/3)#ip ospf message-digest-key 1 md5 hello`

Verification	On Router A and Router B, verify that the OSPF neighbor status is correct.

A	`A#show ip ospf neighbor`
	`OSPF process 1, 1 Neighbors, 1 is Full:`
	`Neighbor ID Pri State Dead Time Address Interface`
	`192.168.1.2 1 Full/DR 00:00:32 192.168.1.2 GigabitEthernet 0/1`

Scenario **Figure 1-16**	
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Configure the authentication type and MD5 authentication key on all routers.

A	`A# configure terminal`
	`A(config)#router ospf 1`
	`A(config-router)#area 0 authentication message-digest`
	`A(config-router)#exit`
	`A(config)#interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)#ip ospf message-digest-key 1 md5 hello`

B	`B# configure terminal`
	`B(config)#router ospf 1`
	`B(config-router)#area 0 authentication message-digest`
	`B(config-router)#exit`
	`B(config)#interface GigabitEthernet 0/3`
	`B(config-if-GigabitEthernet 0/3)#ip ospf message-digest-key 1 md5 hello`

Verification	On Router A and Router B, verify that the OSPF neighbor status is correct.

B	`A#show ip ospf neighbor`
	`OSPF process 1, 1 Neighbors, 1 is Full:`
	`Neighbor ID Pri State Dead Time Address Interface`
	`192.168.1.1 1 Full/DR 00:00:32 192.168.1.1 GigabitEthernet 0/1`

Common Errors

- The authentication modes configured on routers are inconsistent.
- The authentication keys configured on routers are inconsistent.

1.4.9 Enabling Overflow

Configuration Effect

- New routes are not loaded to routers when the router memory is insufficient.
- New routes are not loaded to routers when the usage of the database space reaches the upper limit.

Notes

- The OSPF basic functions must be configured.
- After a router enters the overflow state, you can run the **clear ip ospf process** command, or stop and then restart the OSPF to exit the overflow state.

Configuration Steps

Configuring the Memory Overflow Function

- Optional.
- This configuration is recommended if a large number of routes exist in the domain and may cause insufficiency of the router memory.

Configuring the Database Overflow Function

- Optional.
- This configuration is recommended if a large number of routes exist in the domain and may cause insufficiency of the router memory.

Configuring the External LSA Database Overflow Function

- Optional.
- This configuration is recommended if the ASBR introduces a large number of external routes and the router memory may be insufficient.

Verification

- After the memory becomes insufficient, add new routers to the network, and run the **show ip route** command to verify that new routes are not loaded.
- After the usage of the database space reaches the upper limit, add new routers to the network, and run the **show ip route** command to verify that new routes are not loaded.

Related Commands

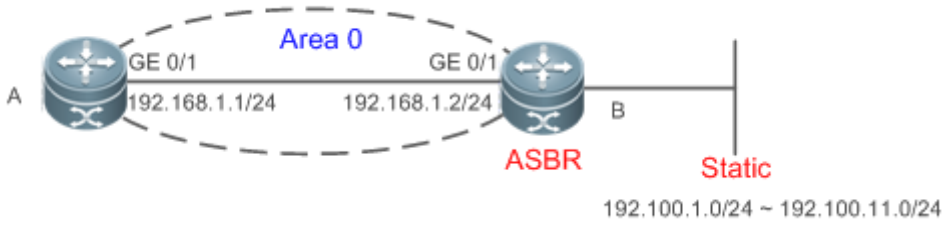
Configuring the Memory Overflow Function

Command	**overflow memory-lack**
Parameter Description	N/A
Command Mode	OSPF routing process configuration mode
Usage Guide	The OSPF process enters the overflow state to discard newly-learned external routes. This behavior can effectively ensure that the memory usage does not increase. After the overflow function is enabled, the OSPF process enters the overflow state and discards newly-learned external routes, which may cause a routing loop on the entire network. To reduce the

	occurrence probability of this problem, OSPF generates a default route to the null interface, and this route always exists in the overflow state. You can run the **clear ip ospf process** command to reset the OSPF process so that the OSPF process can exit the overflow state. You can use the **no** form of the command to prevent the OSPF process from entering the overflow state when the memory is insufficient. This, however, may lead to over-consumption of the memory resource, after which the OSPF process will stop and delete all the learned routes.

Configuring the Database Overflow Function

Command	**overflow database** *number* [**hard | soft**]
Parameter Description	*number*: Indicates the maximum number of LSAs. The value ranges from 1 to 4,294,967,294. **hard**: Indicates that the OSPF process will be stopped if the number of LSAs exceeds the limit. **soft:** Indicates that a warning will be generated if the number of LSAs exceeds the limit.
Command Mode	OSPF routing process configuration mode
Usage Guide	If the number of LSAs exceeds the limit, use the **hard** parameter if the OSPF process should be stopped, and use the **soft** parameter if a warning should be generated without stopping the OSPF process.



Configuring the External LSA Database Overflow Function

Command	**overflow database external** *max-dbsize wait-time*
Parameter Description	*max-dbsize*: Indicates the maximum number of external LSAs. This value must be the same on all routers in the same AS. The value ranges from 0 to 2,147,483,647. *wait-time*: Indicates the waiting time after a router in overflow state attempts to restore the normal state. The value ranges from 0 to 2,147,483,647.
Command Mode	OSPF routing process configuration mode
Usage Guide	When the number of external LSAs of a router exceeds the configured **max-dbsize**, the router enters the overflow state. In this state, the router no longer loads external LSAs and deletes external LSAs that are generated locally. After *wait-time* elapses, the device restores the normal state, and loads external LSAs again. When using the overflow function, ensure that the same **max-dbsize** is configured on all routers in the OSPF backbone area and common areas; otherwise, the following problems may occur: Inconsistent LSDBs throughout network are inconsistent, and the failure to achieve the full adjacency Incorrect routes, including routing loops Frequent retransmission of AS external LSAs

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Configuring the External LSA Database Overflow Function

Scenario **Figure 1-17**	
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● On Router B, configure redistribution and introduce external static routes. ● On Router B, configure the maximum number of external LSAs.

B	`B# configure terminal`
	`B(config)# router ospf 1`
	`B(config-router)# redistribute static subnets`

A	`A# configure terminal`
	`A(config)# router ospf 1`
	`A(config-router)# overflow database external 10 3`

Verification	On Router B, configure 11 static routes (192.100.1.0/24 to 192.100.11.0/24). On Router A, verify that only 10 static routes are loaded.

A	`A# show ip route ospf`
	`O E2 192.100.1.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.2.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.3.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.4.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.5.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.6.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.7.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.8.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.9.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`
	`O E2 192.100.10.0/24 [110/20] via 192.168.1.2, 00:18:03, GigabitEthernet 0/1`

Common Errors

- The OSPF adjacency is abnormal because the maximum number of LSAs is inconsistent on different routers.

1.4.10 Modifying the Maximum Number of Concurrent Neighbors

Configuration Effect

- Control the maximum number of concurrent neighbors on the OSPF process to ease the pressure on the device.

Notes

- The OSPF basic functions must be configured.

Configuration Steps

↘ Configuring the Maximum Number of Concurrent Neighbors on the OSPF Process

- (Optional) This configuration is recommended if you wish to set up the OSPF adjacency more quickly when a router is connected with a lot of other routers.
- This configuration is performed on a core router.

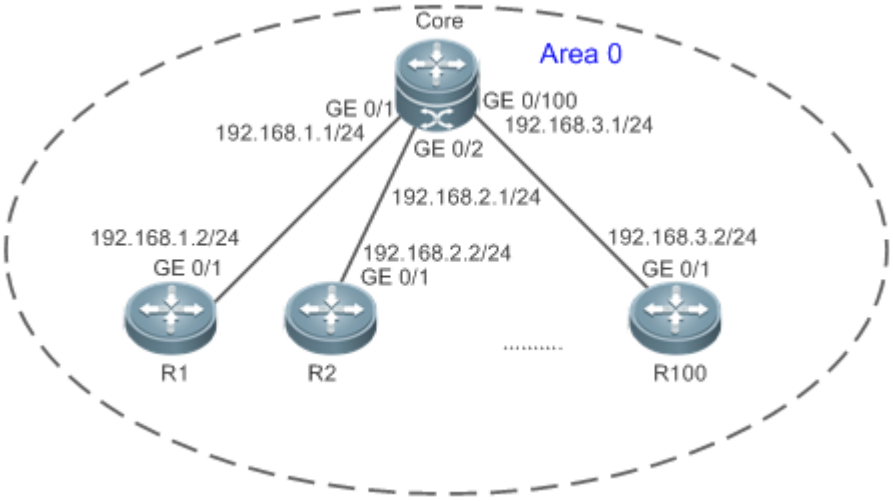
Verification

- Run the **show ip ospf neighbor** command to display the number of neighbors that are concurrently interacting with the OSPF process.

Related Commands

↘ Configuring the Maximum Number of Concurrent Neighbors on the Current Process

Command	**max-concurrent-dd** *number*
Parameter Description	*number:* Specifies the maximum number of neighbors that are concurrently interacting with the OSPF process. The value ranges from 1 to 65,535.
Command Mode	OSPF routing process configuration mode
Usage Guide	When the performance of a router is affected because the router exchanges data with multiple neighbors, you can configure this command to restrict the maximum of neighbors with which one OSPF process can concurrently initiates or accepts interaction.



↘ Configuring the Maximum Number of Concurrent Neighbors on All Processes

Command	**router ospf max-concurrent-dd** *number*
Parameter Description	*number:* Specifies the maximum number of neighbors that are concurrently interacting with the OSPF process. The value ranges from 1 to 65,535.
Command Mode	Global configuration mode
Usage Guide	When the performance of a router is affected because the router exchanges data with multiple neighbors, you can configure this command to restrict the maximum of neighbors with which all OSPF processes can concurrently initiate or accept interaction.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Configuring the Maximum Number of Concurrent Neighbors on the OSPF Process

Scenario **Figure 1-18**	
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● On the router Core, set the maximum number of concurrent neighbors to 4.
Core	`Core# configure terminal` `Core(config)# router ospf max-concurrent-dd 4`
Verification	On the router Core, check the neighbor status and verify that at most eight neighbors concurrently interact with the OSPF process.

1.4.11 Disabling Source Address Verification

Configuration Effect

- The unicast routing service can be provided even if the interface IP addresses of neighbor routers are not in the same network segment.

Notes

- The OSPF basic functions must be configured.
- Source address verification cannot be disabled on a broadcast or NBMA network.

Configuration Steps

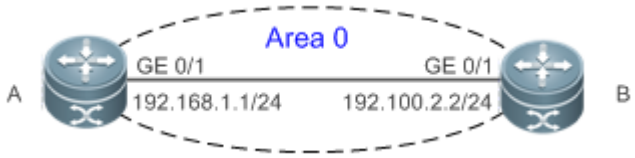
Disabling Source Address Verification

- (Optional) This configuration is mandatory if an adjacency should be set up between routers with interface IP addresses in different network segments.
- This configuration is performed on routers with interface IP addresses in different network segments.

Verification

- An adjacency can be set up between routers in different network segments.

Related Commands



Disabling Source Address Verification

Command	ip ospf source-check-ignore
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	Generally, the source address of a packet received by OSPF is in the same network segment as the receiving interface. The addresses at both ends of a P2P link are configured separately and are not necessarily in the same network segment. In this scenario, as the peer address information will be notified during the P2P link negotiation process, OSPF checks whether the source address of the packet is the address advertised by the peer during negotiation. If not, OSPF determines that the packet is invalid and discards this packet. In some scenarios, the source address may not meet the preceding requirement, and therefore OSPF address verification fails. For example, the negotiated peer address cannot be obtained on a P2P link. In this scenario, source address verification must be disabled to ensure that the OSPF adjacency can be properly set up.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Disabling Source Address Verification

Scenario	
Figure 1-19	
Configuration Steps	• Configure the interface IP addresses on all routers. (Omitted) • Configure the OSPF basic functions on all routers. (Omitted) • Set the network types of interfaces on all routers to P2P. • Disable source address verification on all routers.

A	A# configure terminal A(config)# interface GigabitEthernet 0/1 A(config-if-GigabitEthernet 0/1)# ip ospf network point-to-point A(config-if-GigabitEthernet 0/1)# ip ospf source-check-ignore
B	B# configure terminal B(config)# interface GigabitEthernet 0/1 B(config-if-GigabitEthernet 0/1)# ip ospf network point-to-point B(config-if-GigabitEthernet 0/1)# ip ospf source-check-ignore
Verification	On Router A, verify that the OSPF neighbor information is correct.
A	A# show ip ospfneighbor OSPF process 1, 1 Neighbors, 1 is Full: Neighbor ID Pri State Dead Time Address Interface 192.100.2.2 1 Full/- 00:00:34 192.100.2.2 GigabitEthernet 0/1

1.4.12 Disabling MTU Verification

Configuration Effect

- The unicast routing service can be provided even if the MTUs of interfaces on neighbor routers are different.

Notes

- The OSPF basic functions must be configured.

Configuration Steps

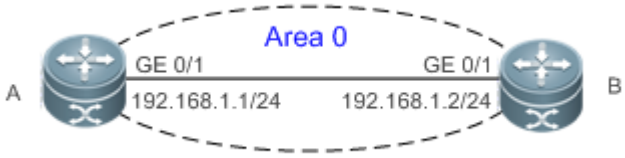
Disabling MTU Verification

- (Optional) MTU verification is disabled by default. You are advised to retain the default configuration.
- This configuration is performed on two routers with different interface MTUs.

Verification

The adjacency can be set up between routers with different MTUs.

Related Commands



Disabling MTU Verification

Command	**ip ospf mtu-ignore**
Parameter Description	N/A
Command	Interface configuration mode

Mode	
Usage Guide	On receiving the database description packet, OSPF checks whether the MTU of the interface on the neighbor is the same as the MTU of its own interface. If the interface MTU specified in the received database description packet is greater than the MTU of the local interface, the adjacency cannot be set up. To resolve this problem, you can disable MTU verification.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Scenario Figure 1-20	
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Configure different MTUs for interfaces on two routers. ● Disable MTU verification on all routers. (By default, the function of disabling MTU verification is enabled.)

A	`A# configure terminal`
	`A(config)# interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip mtu 1400`
	`A(config-if-GigabitEthernet 0/1)# ip ospf mtu-ignore`

B	`B# configure terminal`
	`B(config)# interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip mtu 1600`
	`B(config-if-GigabitEthernet 0/1)# ip ospf mtu-ignore`

Verification	● On Router A, verify that the OSPF neighbor information is correct.

A	`A# show ip ospfneighbor`
	`OSPF process 1, 1 Neighbors, 1 is Full:`
	`Neighbor ID Pri State Dead Time Address Interface`
	`192.168.1.2 1 Full/DR 00:00:34 192.168.1.2 GigabitEthernet 0/1`

1.4.13 Enabling Two-Way Maintenance

Configuration Effect

- Non-Hello packets can also be used to maintain the adjacency.

Notes

- The OSPF basic functions must be configured.

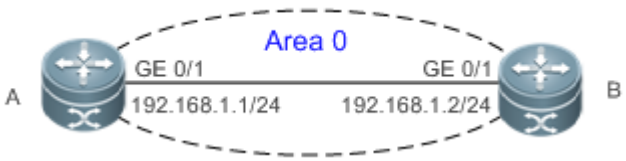
Configuration Steps

Enabling Two-Way Maintenance

- (Optional) This function is enabled by default. You are advised to retain the default configuration.
- This configuration is performed on all routers.

Verification

Non-Hello packets can also be used to maintain the adjacency.



Related Commands

Enabling Two-Way Maintenance

Command	two-way-maintain
Parameter Description	N/A
Command Mode	OSPF routing process configuration mode
Usage Guide	On a large network, a lot of packets may be sent or received, occupying too much CPU and memory. As a result, some packets are delayed or discarded. If the processing time of Hello packets exceeds the dead interval, the adjacency will be destroyed due to timeout. If the two-way maintenance function is enabled, in addition to the Hello packets, the DD, LSU, LSR, and LSAck packets can also be used to maintain the bidirectional communication between neighbors when a large number of packets exist on the network. This prevents termination of the adjacency caused by delayed or discarded Hello packets.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Scenario Figure 1-21	

Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● On Router A, enable the two-way maintenance function. (This function is enabled by default.)

A	`A# configure terminal`
	`A(config)#routerospf 1`
	`A(config-router)#two-way-maintain`

Verification	When the adjacency is being set up, Router A checks the neighbor dead interval and updates the dead interval without waiting for Router B to send a Hello packet.

A	`A# show ip ospfneighbor`
	`OSPF process 1, 1 Neighbors, 1 is Full:`
	`Neighbor ID Pri State Dead Time Address Interface`
	`192.168.1.2 1 Full/BDR 00:00:40 192.168.1.2 GigabitEthernet 0/1`

1.4.14 Enabling GR

Configuration Effect

- When a distributed router switches services from the active board to the standby board, data forwarding continues and is not interrupted.
- When the OSPF process is being restarted, data forwarding continues and is not interrupted.

Notes

- The OSPF basic functions must be configured.
- The neighbor router must support the GR helper function.
- The grace period cannot be shorter than the neighbor dead time of the neighbor router.

Configuration Steps

↘ Enabling Opaque LSA Processing Capability

- This function is enabled by default. You are advised to retain the default configuration..
- This configuration is performed on all routers..

↘ Configuring the OSPF GR Function

- (Optional) This function is enabled by default. You are advised to retain the default configuration.
- This configuration is performed on all routers.

↘ Configuring the OSPF GR Helper Function

- (Optional) This function is enabled by default. You are advised to retain the default configuration.
- This configuration is performed on all routers.

Verification

- When a distributed router switches services from the active board to the standby board, data forwarding continues and is not interrupted.
- When the OSPF process is being restarted, data forwarding continues and is not interrupted.

Related Commands

Enabling Opaque LSA Processing Capability

Command	**capability opaque**
Parameter Description	-
Command Mode	OSPF routing process configuration mode
Usage Guide	Opaque LSA processing capability is supported by default.

Configuring the OSPF GR Function

Command	**graceful-restart** [**grace-period** *grace-period* | **inconsistent-lsa-checking**]
Parameter Description	**grace-period** *grace-period*: Indicates the grace period, which is the maximum time from occurrence of an OSPF failure to completion of the OSPF GR. The value of the grace period varies from 1s to 1800s. The default value is 120s. **inconsistent-lsa-checking**: Enables topological change detection. If any topological change is detected, OSPF exits the GR process to complete convergence. After GR is enabled, topological change detection is enabled by default.
Command Mode	OSPF routing process configuration mode
Usage Guide	The GR function is configured based on the OSPF process. You can configure different parameters for different OSPF processes based on the actual conditions. This command is used to configure the GR restarter capability of a device. The grace period is the maximum time of the entire GR process, during which link status is rebuilt so that the original state of the OSPF process is restored. After the grace period expires, OSPF exits the GR state and performs common OSPF operations. Run the **graceful-restart** command to set the grace period to 120s. The **graceful-restart grace-period** command allows you to modify the grace period explicitly. The precondition for successful execution of GR and uninterrupted forwarding is that the topology remains stable. If the topology changes, OSPF quickly converges without waiting for further execution of GR, thus avoiding long-time forwarding black-hole. Disabling topology detection: If OSPF cannot converge in time when the topology changes during the hot standby process, forwarding black-hole may appear in a long time. Enabling topology detection: Forwarding may be interrupted when topology detection is enabled, but the interruption time is far shorter than that when topology detection is disabled. In most cases, it is recommended that topology detection be enabled. In special scenarios, topology detection can be disabled if the topology changes after the hot standby process, but it can be ensured that

	the forwarding black-hole will not appear in a long time. This can minimize the forwarding interruption time during the hot standby process. Under the Fast Hello function, graceful restart is not supported.

Configuring the OSPF GR Helper Function

Command	**graceful-restart helper** { **disable | strict-lsa-checking | internal-lsa-checking**}
Parameter Description	**disable**: Prohibits a device from acting as a GR helper for another device. **strict-lsa-checking**: Indicates that changes in Type 1 to Type 5 and Type 7 LSAs will be checked during the period that the device acts as a GR helper to determine whether the network changes. If the network changes, the device will stop acting as the GR helper. **internal-lsa-checking:** Indicates that changes in Type 1 to Type 3 LSAs will be checked during the period that the device acts as a GR helper to determine whether the network changes. If the network changes, the device will stop acting as the GR helper.
Command Mode	OSPF routing process configuration mode
Usage Guide	This command is used to configure the GR helper capability of a router. When a neighbor router implements GR, it sends a Grace-LSA to notify all neighbor routers. If the GR helper function is enabled on the local router, the local router becomes the GR helper on receiving the Grace-LSA, and helps the neighbor to complete GR. The **disable** option indicates that GR helper is not provided for any device that implements GR. After a device becomes the GR helper, the network changes are not detected by default. If any change takes place on the network, the network topology converges after GR is completed. If you wish that network changes can be quickly detected during the GR process, you can configure **strict-lsa-checking** to check Type 1 to 5 and Type 7 LSAs that indicate the network information or **internal-lsa-checking** to check Type 1 to 3 LSAs that indicate internal routes of the AS domain. When the network scale is large, it is recommended that you disable the LSA checking options (**strict-lsa-checking** and **internal-lsa-checking**) because regional network changes may trigger termination of GR and consequently reduce the convergence of the entire network.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Scenario **Figure 1-22**	 **Remarks**: The interface IP addresses are as follows: A: GE 0/1 192.168.1.1 B: GE 0/1 192.168.1.1 GE 0/2 192.168.2.1 GE 0/3 192.168.3.1 C: GE 0/1 192.168.4.2 GE 0/3 192.168.3.2 D: GE 0/1 192.168.5.2 GE 0/2 192.168.2.2
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● On Router A, Router C, and Router D, enable the GR helper function. (This function is enabled by default.) ● On Router B, enable the GR function.

B	`B# configure terminal`
	`B(config)# router ospf1`
	`B(config-router)# graceful-restart`

Verification	● Trigger a hot standby switchover on Router B, and verify that the routing tables of destination networks 1 and 2 remain unchanged on Router A during the switchover. ● Trigger a hot standby switchover on Router B, ping destination network 1 from Router A, and verify that data forwarding is not interrupted during the switchover.

Common Errors

- Traffic forwarding is interrupted during the GR process because the configured grace period is shorter than the neighbor dead time of the neighbor router.

1.4.15 Configuring Fast Hello Function

Configuration Effect

- Discovery of OSPF neighbor is accelerated and quick detection of neighbor failure can be realized.

Notes

- The OSPF basic functions must be configured.
- Dead interval must be consistent within the same network segment.
- The **dead-interval minimal hello-multiplier** parameter and the **hello-interval** parameter cannot be configured simultaneously on the interface.

Configuration Steps

↘ Configuring Fast Hello Function

- (Optional) This function is disabled by default.
- Configure it on router interfaces.

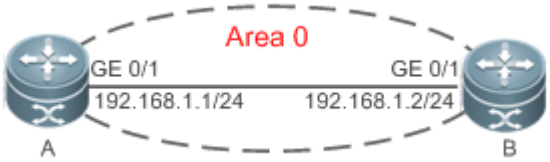
Verification

- Run the **show ip ospf interface** command to check the correct number of Hello packets sent per second on the interface and the correct neighbor dead time.

Related Commands

↘ Configuring Fast Hello Function

Command	**ip ospf dead-interval minimal hello-multiplier** *multiplier*
Parameter Description	**minimal**: Enables the Fast Hello function and sets the dead time to 1s. **hello-multiplier** *multiplier*: Indicates the number of Hello packets sent per second in the Fast Hello function. The value ranges from 3 to 20.
Command Mode	OSPF route configuration mode
Usage Guide	Enabling the OSPF Fast Hello function accelerates neighbor discovery and rapid detection of neighbor failures in OSPF. The OSPF Fast Hello function is enabled by specifying the **minimal** and **hello-multiplier** keywords and the *multiplier* parameter. The minimal keyword sets the dead time to 1s, and the hello-multiplier value specifies the number of Hello packets sent per second, reducing the Hello packet interval to less than 1s. When an interface is configured with the Fast Hello function, the Hello interval field of the Hello packets advertised from that interface is set to 0, and the Hello interval field of the Hello packets received from that interface is ignored. The dead interval must always remain consistent within the same network segment regardless of whether Fast Hello is enabled or not. The hello-multiplier value does not need to be the same, as long as at least one Hello packet can be received within the dead interval. The **show ip ospf interface** command can be used to monitor the dead interval and Fast Hello interval configured for interfaces. The **dead-interval minimal hello-multiplier** parameter and the **hello-interval** parameter introduced for Fast Hello function cannot be configured simultaneously. Under the Fast Hello function, graceful restart is not supported.



Configuration Example

The following configuration example is performed based on OSPF basic functions. For details about OSPF basic functions, see preceding descriptions.

Configuring Fast Hello Function

Scenario

Figure 1-23

Configuration Steps

- Configure IP addresses on all routers' interfaces. Omitted.
- Configure OSPF basic functions for all routers. Omitted.
- Enable the Fast Hello function on an interface of router A.

A

```
A# configure terminal
A(config)# interface GigabitEthernet 0/1
A(config-if-GigabitEthernet 0/1)# ip ospf dead-interval minimal hello-multiplier
10
```

Verification

Router A checks the interface parameters: The neighbor dead time is 1s, and the sending interval of Hello packets is 100 ms.

A

```
A# show ip ospf interface GigabitEthernet 0/1
GigabitEthernet 0/1 is up, line protocol is up
  Internet Address 192.168.1.1/24, Ifindex 2, Area 0.0.0.0, MTU 1500
  Matching network config: 192.168.1.0/24
  Process ID 1, Router ID 192.168.1.2, Network Type POINTOMULTIPOINT, Cost: 1
  Transmit Delay is 1 sec, State Point-To-Point
  No designated router on this network
  No backup designated router on this network
  Timer intervals configured, Hello 100 msec, Dead 1, Wait 1, Retransmit 5
```

Common Errors

- Configured at the same time as the **ip ospf hello-interval** command.

1.4.16 Configuring the Network Management Function

Configuration Effect

- Use the network management software to manage OSPF parameters and monitor the OSPF running status.

Notes

- The OSPF basic functions must be configured.
- You must enable the MIB function of the SNMP-Server before enabling the OSPF MIB function.
- You must enable the Trap function of the SNMP-Server before enabling the OSPF Trap function.
- You must enable the logging function of the device before outputting the OSPF logs.

Configuration Steps

Binding the MIB with the OSPF Process

- (Optional) This configuration is required if you want to use the network management software to manage parameters of a specified OSPF process.
- This configuration is performed on all routers.

Enabling the Trap Function

- (Optional) This configuration is required if you want to use the network management software to monitor the OSPF running status.
- This configuration is performed on all routers.

Configuring the Logging Function

- (Optional) This function is enabled by default. You are advised to retain the default configuration. If you want to reduce the log output, disable this function.
- This configuration is performed on all routers.

Verification

- Use the network management software to manage the OSPF parameters.
- Use the network management software to monitor the OSPF running status.

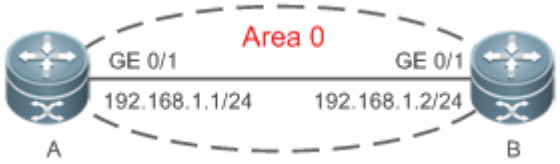
Related Commands

Binding the MIB with the OSPF Process

Command	**enable mib-binding**
Parameter Description	N/A
Command Mode	OSPF routing process configuration mode
Usage Guide	The OSPFv2 MIB does not have the OSPFv2 process information. Therefore, you must perform operations on a single OSPFv2 process through SNMP. By default, the OSPFv2 MIB is bound with the OSPFv2 process with the smallest process ID, and all user operations take effect on this process. If you wish to perform operations on a specified OSPFv2 through SNMP, run this command to bind the MIB with the process.

Enabling the Trap Function

Command	**enable traps** [**error** [**IfAuthFailure | IfConfigError | IfRxBadPacket | VirtIfAuthFailure | VirtIfConfigError | VirtIfRxBadPacket**] * | **lsa** [**LsdbApproachOverflow | LsdbOverflow | MaxAgeLsa | OriginateLsa**] * | **retransmit** [**IfTxRetransmit | VirtIfTxRetransmit**] * | **state-change** [**IfStateChange | NbrRestartHelperStatusChange | NbrStateChange | NssaTranslatorStatusChange | RestartStatusChange | VirtIfStateChange | VirtNbrRestartHelperStatusChange | VirtNbrStateChange**] *]
Parameter	**error**: Configures all trap switches related to error. This parameter can also be used to configure the



Description	following specific error trap switches: **IfAuthFailure**: Indicates that an interface authentication failure occurs. **IfConfigError:** Indicates that an interface parameter configuration error occurs. **IfRxBadPacket:** Indicates that the interface receives a bad packet. **IfRxBadPacket:** Indicates that the interface receives a bad packet. **VirtIfAuthFailure:** Indicates that a virtual interface authentication failure occurs. **VirtIfConfigError:** Indicates that a virtual interface parameter configuration error occurs. **VirtIfRxBadPacket:** Indicates that the virtual interface receives a bad packet. **lsa**: Configures all trap switches related to LSA. This parameter can also be used to configure the following specific LSA trap switches: **LsdbApproachOverflow:** Indicates that the number of external LSAs has reached 90% of the upper limit. **LsdbOverflow:** Indicates that the number of external LSAs has reached the upper limit. **MaxAgeLsa:** Indicates that the LSA aging timer expires. **OriginateLsa:** Indicates that a new LSA is generated. **retransmit**: Configures all trap switches related to retransmit. This parameter can also be used to configure the following specific retransmit trap switches: **IfTxRetransmit:** Indicates that a packet is retransmitted on the interface. **VirtIfTxRetransmit:** Indicates that a packet is retransmitted on the virtual interface. **state-change**: Configures all trap switches related to state-change. This parameter can also be used to configure the following specific state-change trap switches: **IfStateChange:** Indicates that interface state changes. **NbrRestartHelperStatusChange:** Indicates that the state of the neighbor GR process changes. **NbrStateChange:** Indicates that the neighbor state changes. **NssaTranslatorStatusChange:** Indicates that the NSSA translation state changes. **RestartStatusChange:** Indicates that the GR state of the local device changes. **VirtIfStateChange:** Indicates that the virtual interface state changes. **VirtNbrRestartHelperStatusChange:** Indicates that the GR state of the virtual neighbor changes. **VirtNbrStateChange:** Indicates that the virtual neighbor state changes.
Command Mode	OSPF routing process configuration mode
Usage Guide	The function configured by this command is restricted by the **snmp-server** command. You can configure **snmp-server enable traps ospf** and then **enable traps** command before the corresponding OSPF traps can be correctly sent out. This command is not restricted by the MIB bound with the process. The trap function can be enabled concurrently for different processes.

Configuring the Logging Function

Command	**log-adj-changes**[**detail**]
Parameter Description	**detail**: Records all status change information.
Command Mode	OSPF routing process configuration mode
Usage Guide	N/A

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Scenario **Figure 1-24**	
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Bind the MIB with the OSPF process on Router A. ● Enable the trap function on Router A.

A	`A# configure terminal`
	`A(config)# snmp-server host 192.168.2.2 traps version 2c public`
	`A(config)# snmp-server community public rw`
	`A(config)# snmp-server enable traps`
	`A(config)# router ospf 10`
	`A(config-router)# enable mib-binding`
	`A(config-router)# enable traps`

Verification	Use the MIB tool to read and set the OSPF parameters and display the OSPF running status.

Common Errors

Configurations on the SNMP-Server are incorrect. For example, the MIB or trap function is not enabled.

1.4.17 Modifying Protocol Control Parameters

Configuration Effect

Modify protocol control parameters to change the protocol running status.

Notes

- The OSPF basic functions must be configured.
- The neighbor dead time cannot be shorter than the Hello interval.

Configuration Steps

Configuring the Hello Interval

- (Optional) You are advised to retain the default configuration.
- This configuration is performed on routers at both end of a link.

Configuring the Dead Interval

- (Optional) You are advised to retain the default configuration. This configuration can be adjusted if you wish to accelerate OSPF convergence when a link fails.
- This configuration is performed on routers at both end of a link.

Configuring LSU Retransmission Interval

- (Optional) You are advised to adjust this configuration if a lot of routes exist in the user environment and network congestion is serious.

Configuring the LSA Generation Time

- (Optional) You are advised to retain the default configuration.

Configuring the LSA Group Refresh Time

- (Optional) You are advised to retain the default configuration. This configuration can be adjusted if a lot of routes exist in the user environment.
- This configuration is performed on an ASBR or ABR.

Configuring LSA Repeated Receiving Delay

- (Optional) You are advised to retain the default configuration.

Configuring the SPF Computation Delay

- (Optional) This configuration can be adjusted if network flapping frequently occurs.

Configuring the Inter-Area Route Computation Delay

- (Optional) You are advised to retain the default configuration.
- This configuration is performed on all routers.

Configuring the External Route Computation Delay

- (Optional) You are advised to retain the default configuration.
- This configuration is performed on all routers.

Configuring Route Computation Suppression Time on an Interface

- (Optional) It is used with **max-metric**.
- Configure it on interfaces.

Verification

Run the **show ip ospf** and **show ip ospf neighbor** commands to display the protocol running parameters and status.

Related Commands

Configuring the Hello Interval

Command	**ip ospf hello-interval** *seconds*
Parameter Description	*seconds*: Indicates the interval at which OSPF sends the Hello packet. The unit is second. The value ranges from 1 to 65,535.
Command Mode	Interface configuration mode
Usage Guide	The Hello interval is contained in the Hello packet. A shorter Hello interval indicates that OSPF can detect topological changes more quickly, but the network traffic increases. The Hello interval must be the same on all routers in the same network segment. If you want to manually modify the neighbor dead interval, ensure that the neighbor dead interval is longer than the Hello interval.

Configuring the Dead Interval

Command	**ip ospf dead-interval** *seconds*
Parameter Description	*seconds*: Indicates the time that the neighbor is declared lost. The unit is second. The value ranges from 0 to 2,147,483,647.
Command Mode	Interface configuration mode
Usage Guide	The OSPF dead interval is contained in the Hello packet. If OSPF does not receive a Hello packet from a neighbor within the dead interval, it declares that the neighbor is invalid and deletes this neighbor record form the neighbor list. By default, the dead interval is four times the Hello interval. If the Hello interval is modified, the dead interval is modified automatically. When using this command to manually modify the dead interval, pay attention to the following issues: 1. The dead interval cannot be shorter than the Hello interval. 2. The dead interval must be the same on all routers in the same network segment.

Configuring the LSU Transmission Delay

Command	**ip ospf transmit-delay** *seconds*
Parameter Description	*seconds*: Indicates the LSU transmission delay on the OSPF interface. The unit is second. The value ranges from 0 to 65,535.
Command Mode	Interface configuration mode
Usage Guide	Before an LSU packet is transmitted, the Age fields in all LSAs in this packet will increase based on the amount specified by the **ip ospf transmit-delay** command. Considering the transmit and line propagation delays on the interface, you need to set the LSU transmission delay to a greater value for a low-speed line or interface. The LSU transmission delay of a virtual link is defined by the **transmit-delay** parameter in the **area virtual-link** command. If the value of the Age field of an LSA reaches 3600, the packet will be retransmitted or a retransmission will be requested. If the LSA is not updated in time, the expired LSA will be deleted from the LSDB.

Configuring LSU Retransmission Interval

Command	**ip ospf retransmit-interval** *seconds*
Parameter Description	*seconds*: Indicates the LSU retransmission interval. The unit is second. The value ranges from 0 to 65,535. This interval must be longer than the round-trip transmission delay of data packets between two neighbors.

Command Mode	Interface configuration mode
Usage Guide	After a router finishes sending an LSU packet, this packet is still kept in the transmit buffer queue. If an acknowledgment from the neighbor is not received within the time defined by the **ip ospf retransmit-interval** command, the router retransmits the LSU packet. The retransmission delay can be set to a greater value on a serial line or virtual link to prevent unnecessary retransmission. The LSU retransmission delay of a virtual link is defined by the **retransmit-interval** parameter in the **area virtual-link** command.

Configuring the LSA Generation Time

Command	**timers throttle lsa all** *delay-time hold-time max-wait-time*
Parameter Description	*delay-time*: Indicates the minimum delay for LSA generation. The first LSA in the database is always generated instantly. The value ranges from 0 to 600,000. The unit is ms. *hold-time*: Indicates the minimum interval between the first LSA update and the second LSA update. The value ranges from 1 to 600,000. The unit is ms. *max-wait-time*: Indicates the maximum interval between two LSA updates when the LSA is updated continuously. This interval is also used to determine whether the LSA is updated continuously. The value ranges from 1 to 600,000. The unit is ms.
Command Mode	OSPF routing process configuration mode
Usage Guide	If a high convergence requirement is raised when a link changes, you can set **delay-time** to a smaller value. You can also appropriately increase values of the preceding parameters to reduce the CPU usage. When configuring this command, the value of **hold-time** cannot be smaller than the value of **delay-time,** and the value of **max-wait-time** cannot be smaller than the value of **hold-time**.

Configuring the LSA Group Refresh Time

Command	**timers pacing lsa-group** *seconds*
Parameter Description	*seconds*: Indicates the LSA group pacing interval. The value ranges from 10 to 1,800. The unit is second.
Command Mode	OSPF routing process configuration mode
Usage Guide	Every LSA has a time to live (LSA age). When the LSA age reaches 1800s, a refreshment is needed to prevent LSAs from being cleared because their ages reaching the maximum. If LSA update and aging computation are performed for every LSA, the device will consume a lot of CPU resources. In order to use CPU resources effectively, you can refresh LSAs by group on the device. The interval of group refreshment is called group pacing interval. The group refreshment operation is to organize the LSAs generated within a group pacing interval into a group and refresh the group as a whole. If the total number of LSAs does not change, a larger group pacing interval indicates that more LSAs need to be processed after timeout. To maintain the CPU stability, the number of LSAs processes upon each timeout cannot be too large. If the number of LSAs is large, you are advised to reduce the group pacing interval. For example, if there are 1000 LSAs in the database, you can reduce the pacing interval; if there are 40 to 100 LSAs, you can set the pacing interval to 10-20 minutes.

Configuring the LSA Group Refresh Interval

Command	**timers pacing lsa-transmit** *transmit-time transmit-count*
Parameter Description	*transmit-time*: Indicates the LSA group transmission interval. The value ranges from 10 to 1,000. The unit is ms. *transmit-count*: Indicates the number of LS-UPD packets in a group. The value ranges from 1 to 200.
Command Mode	OSPF routing process configuration mode
Usage Guide	If the number of LSAs is large and the device load is heavy in an environment, properly configuring **transimit-time** and **transimit-count** can limit the number of LS-UPD packets flooded on a network. If the CPU usage is not high and the network bandwidth load is not heavy, reducing the value of **transimit-time** and increasing the value of **transimit-count** can accelerate the environment convergence.

Configuring LSA Repeated Receiving Delay

Command	**timers lsa arrival** *arrival-time*
Parameter Description	*arrival-time*: Indicates the delay after which the same LSA is received. The value ranges from 0 to 600,000. The unit is ms.
Command Mode	OSPF routing process configuration mode
Usage Guide	No processing is performed if the same LSA is received within the specified time.

Configuring the Inter-Area Route Computation Delay

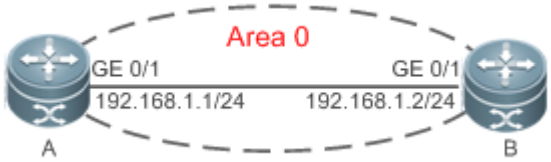
Command	**timers throttle route inter-area** *ia-delay*
Parameter Description	*ia-delay*: Indicates the inter-area route computation delay. The unit is ms. The value ranges from 0 to 600,000.
Command Mode	OSPF routing process configuration mode
Usage Guide	This delay cannot be modified if strict requirements are raised for the network convergence time.

Configuring the External Route Computation Delay

Command	**timers throttle route ase** *ase-delay*
Parameter Description	*ase-delay*: Indicates the external route computation delay. The unit is ms. The value ranges from 0 to 600,000.
Command Mode	OSPF routing process configuration mode
Usage Guide	This delay cannot be modified if strict requirements are raised for the network convergence time.

Configuring the SPF Computation Delay

Command	**timers spf** *spf-delay spf-holdtime*
Parameter Description	*spf-delay*: Defines the waiting time for the SPF computation, in seconds. The value ranges from 0 to 2,147,483,647. The OSPF routing process must wait for the specified time after receiving a topology change before performing SPF computation. *spf-holdtime*: Defines the time interval between two consecutive SPF computations, in seconds. The value ranges from 0 to 2,147,483,647. The SPF computation cannot be performed until the time interval between two consecutive computations has passed, even if the waiting time has elapsed.
Command	OSPF routing process configuration mode



Mode	
Usage Guide	The smaller the spf-delay and spf-holdtime values, the shorter the time OSPF takes to adapt to topology changes, which means faster network convergence, but it also consumes more CPU time on the routing device. The **timers spf** configuration and the **timers throttle spf** configuration will override each other.

Command	**timers throttle spf** *spf-delay spf-holdtime spf-max-waittime*
Parameter Description	*spf-delay*: Indicates the SPF computation delay. The unit is ms. The value ranges from 1 to 600,000. When detecting a topological change, the OSPF routing process triggers the SPF computation at least after **spf-delay** elapses. *spf-holdtime*: Indicates the minimum interval between two SPF computations. The unit is ms. The value ranges from 1 to 600,000. *spf-max-waittime*: Indicates the maximum interval between two SPF computations. The unit is ms. The value ranges from 1 to 600,000. *number*: indicates the metric of the summarized route.
Command Mode	OSPF routing process configuration mode
Usage Guide	**spf-delay** indicates the minimum time between the occurrence of the topological change and the start of SPF computation. **spf-holdtime** indicates the minimum interval between the first SPF computation and the second SPF computation. After that, the interval between two SPF computations must be at least twice of the previous interval. When the interval reaches **spf-max-waittime**, the interval cannot increase again. If the interval between two SPF computations already exceeds the required minimum value, the interval is computed by starting from **spf-holdtime**. You can set **spf-dela**y and **spf-holdtime** to smaller values to accelerate topology convergence, and set **spf-max-waittime** to a larger value to reduce SPF computation. Flexible settings can be used based on stability of the network topology. Compared with the **timers spf** command, this command supports more flexible settings to accelerate the convergence speed of SPF computation and further reduce the system resources consumed by SPF computation when the topology continuously changes. Therefore, you are advised to use the **timers throttle spf** command for configuration. 1. The value of **spf-holdtime** cannot be smaller than the value of **spf-delay**; otherwise, **spf-holdtime** will be automatically set to the value of **spf-delay**. 2. The value of **spf-max-waittime** cannot be smaller than the value of **spf-holdtime**; otherwise, **spf-max-waittime** will be automatically set to the value of **spf-holdtime**. 3. The configurations of **timers throttle spf** and **timers spf** are mutually overwritten. 4. When both **timers throttle spf** and **timers spf** are not configured, the default values of **timers throttle spf** prevail.

Configuration Example

The following configuration examples assume that the OSPF basic functions have been configured. For details about the OSPF basic functions, see section 1.4.1 "Configuring OSPF Basic Functions."

Configuring the Hello Interval and Dead Interval

Scenario **Figure 1-25**	
Configuration Steps	● Configure the interface IP addresses on all routers. (Omitted) ● Configure the OSPF basic functions on all routers. (Omitted) ● Configure the Hello interval and dead interval on all routers.

A	`A# configure terminal`
	`A(config)# interface GigabitEthernet 0/1`
	`A(config-if-GigabitEthernet 0/1)# ip ospf hello-interval 15`
	`A(config-if-GigabitEthernet 0/1)# ip ospf dead-interval 50`

B	`B# configure terminal`
	`B(config)# interface GigabitEthernet 0/1`
	`B(config-if-GigabitEthernet 0/1)# ip ospf hello-interval 15`
	`A(config-if-GigabitEthernet 0/1)# ip ospf dead-interval 50`

Verification	Check the interface parameters on Router A. Verify that the Hello interval is 10s and the dead interval is 50s.

A	`A# show ip ospf interface`
	`GigabitEthernet 0/1 is up, line protocol is up`
	`  Internet Address 192.168.1.1/24, Ifindex 2, Area 0.0.0.0, MTU 1500`
	`  Matching network config: 192.168.1.0/24`
	`  Process ID 1, Router ID 192.168.1.2, Network Type POINTOMULTIPOINT, Cost: 1`
	`  Transmit Delay is 1 sec, State Point-To-Point`
	`  Timer intervals configured, Hello 15, Dead 50, Wait 40, Retransmit 5`
	`    Hello due in 00:00:02`
	`  Neighbor Count is 1, Adjacent neighbor count is 0`
	`  Crypt Sequence Number is 4787`
	`  Hello received 465 sent 466, DD received 8 sent 8`
	`  LS-Req received 2 sent 2, LS-Upd received 8 sent 21`
	`  LS-Ack received 14 sent 7, Discarded 3`

Common Errors

- The configured neighbor dead time is shorter than the Hello interval.

1.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears and resets an OSPF process.	**clear ip ospf** [*process-id*] **process**

Displaying

Description	Command
Displays the OSPF process configurations.	**show ip ospf** [*process-id*]
Displays the OSPF internal routing table, including routes to ABRs and ASBRs.	**show ip ospf**[*process-id*] **border-routers**
Displays information about the OSPF LSDB.	**show ip ospf** [*process-id* [*area-id* | *ipv4-address*]] **database** [{ **asbr-summary** | **external** | **network** | **nssa-external** | **opaque-area** | **opaque-as** | **opaque-link** | **router** | **summary** }] [{ **adv-router** *ipv4-address* | **self-originate** } | *link-state-id* | **brief**] [**database-summary** | **max-age** | **detail**]
Displays OSPF-enabled interfaces.	**show ip ospf** [*process-id*] **interface** [*interface-type interface-number* | **brief**]
Displays the OSPF neighbor list.	**show ip ospf** [*process-id*] **neighbor** [**statistics** | [*interface-type interface-number* | *neighbor-id* | **detail**] *]
Displays the OSPF routing table.	**show ip ospf** [*process-id*] **route**[**count |** *ipv4-address mask*]
Displays the number of times SPT is computed in the OSPF area.	**show ip ospf** [*process-id*] **spf**
Displays the summarized route of OSPF redistributed routes.	**show ip ospf**[*process-id*] **summary-address**
Displays OSPF virtual links.	**show ip ospf** [*process-id*] **virtual-links** [*ipv4-address*]

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs OSPF events.	**debug ip ospf events** [**abr**|**asbr**|**lsa**|**nssa**|**os**|**restart**| **router**|**slink**| **vlink**]
Debugs OSPF interfaces.	**debug ip ospf ifsm** [**events**|**status**|**timers**]
Debugs OSPF neighbors.	**debug ip ospf nfsm** [**events** | **status** | **timers**]
Debugs the OSPF NSM.	**debug ip ospf nsm** [**interface** | **redistribute** | **route**]
Debugs OSPF LSAs.	**debug ip ospf lsa** [**flooding** | **generate** | **install** | **maxage** | **refresh**]
Debugs OSPF packets.	**debug ip ospf packet** [**dd**|**detail**|**hello**|**ls-ack**|**ls-request**|**ls-update**|**recv**|**send**]
Debugs OSPF routes.	**debug ip ospf route** [**ase** | **ia** | **install** | **spf** | **time**]

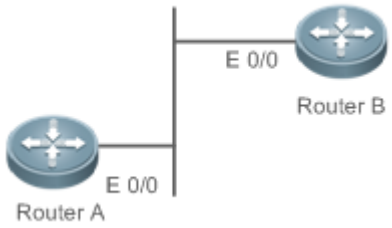
1 Configuring Routing Policies

1.1 Overview

Routing policies are used to modify packet forwarding path or routing information and are typically implemented through filtering lists and route maps. They are flexibly and widely applied in various ways, including:

- Use a filtering list in a routing protocol to filter or modify routing information.
- Use a route map in a routing protocol to filter or modify routing information. The route map can reference a filtering list.
- Use a route map in Policy-based Routing (PBR) to control packet forwarding or modify packet fields.

1.2 Applications



Application	Description
Route Filtering	Use a filtering list in a routing protocol to filter routing information sent or received by this protocol.
Route Redistribution	Use a route map in a routing protocol to filter or modify routing information and redistribute RIP routes to OSPF. Only RIP routes with four hops can be redistributed.
PBR	Use a route map in PBR to control packet forwarding or modify packet fields and specify optimal outbound interfaces for packets from different subnets.

1.2.1 Route Filtering

By default, a routing protocol advertises and learns all routing information. When a filtering list is used, the routing protocol advertises only required routes or receives only required routing information.

Scenario

Figure 1-1

As shown in Figure 1-1, Router A has routes to three networks: 10.0.0.0, 20.0.0.0, and 30.0.0.0.

Configure a filtering list on the routers to achieve the following purposes:

- Filter the sent routing information on Router A to filter routes that Router A does not need to send.
- Filter the received routing information on Router B to filter routes that Router B does not need to learn.

Deployment

- Filter the sent routing information 30.0.0.0 on Router A.
- Filter the received routing information 20.0.0.0 on Router B to ensure that Router B learns only routing information 10.0.0.0.

1.2.2 Route Redistribution

By default, route redistribution allows the device to redistribute all routing information in a routing protocol to another routing protocol. All routing attributes will also be inherited. You can use a route map to control redistribution of specific routing information between two routing protocols, including:

- Specify the route redistribution range and redistribute only routing information that meets certain rules.
- Set attributes of routes to be redistributed.

Scenario

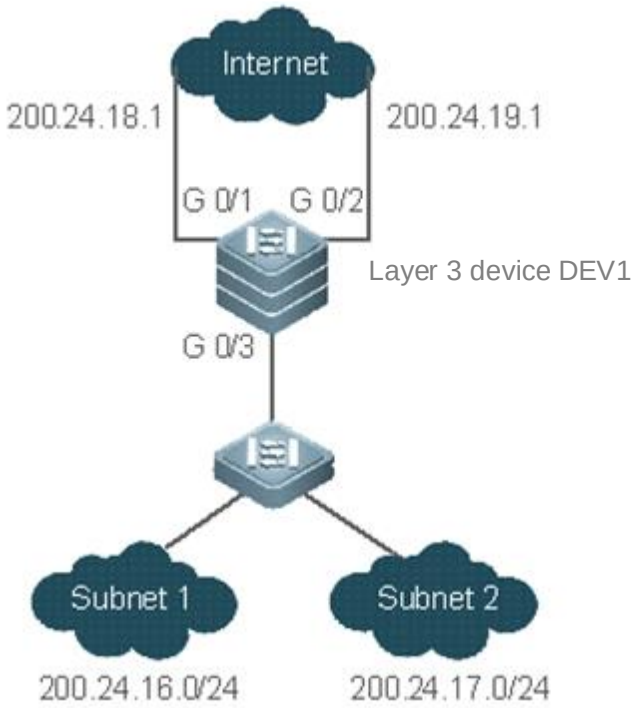
Figure 1-2

As shown in Figure 1-2, configure route redistribution on the devices to achieve the following purposes:

- Redistribute only RIP routes with four hops to OSPF.
- In the OSPF routing domain, the initial metric of this route is 40, the route type is Type-1 external route and the route tag value is set to 40.

Deployment

- In the route map **rip_to_ospf**, match a route with four hops, and set the initial metric of this route to 40, the route type to Type-1 external route and the route tag value to 40.
- Configure route redistribution to enable the device to redistribute RIP routes to OSPF by referencing the route map **rip_to_ospf**.



1.2.3 PBR

PBR is implemented by applying a route map including policies to interfaces and devices.

Similar to static routing, PBR is also manually configured. Recursive routes can also be automatically updated with network changes. Compared with static and dynamic routing, PBR is more flexible. Static and dynamic routing can be used to forward packets only based on destination addresses. PBR can forward packets based on the source and destination addresses, packet length, and inbound interface.

Scenario

Figure 1-3

Configure PBR on the Layer 3 device DEV1 to achieve the following purposes:

- Packets from subnet 1 (200.24.16.0/24) are sent from GE0/1 first.
- Packets from subnet 2 (200.24.17.0/24) are sent from GE0/2 first.

Deployment

- Configure two different access control lists (ACLs) to match packets from subnets 1 and 2 respectively.
- Configure the route map **RM_FOR_PBR**: policy 10 is used to ensure that packets from subnet 1 are sent from GE0/1 first; policy 20 is used to ensure that packets from subnet 2 are sent from GE0/2 first.
- Perform PBR for packets received from GE0/3 and reference the route map **RM_FOR_PBR**.

1.3 Features

Overview

Feature	Description
Filtering List	Defines a group of lists based on route attributes, which can be used by a routing protocol for route filtering.
Route Map	Takes actions when conditions are met.

1.3.1 Filtering List

Filtering lists are a group of lists defined based on route attributes for filtering routing policies. Independent filtering lists are invalid and can be used to filter routes only when being applied to routing protocols.

Working Principle

Based on different route attributes, filtering lists are classified into the following types.

ACL

ACLs comprise IPv4 and IPv6 ACLs. When defining ACLs, you can specify IPv4/IPv6 addresses and masks to match the destination network segment or next-hop addresses of routing information.

For description about ACLs, see *Configuring ACL*.

Address Prefix List

Similar to ACLs, address prefix lists (prefix-lists), including IPv4 and IPv6 prefix-lists, are used to match destination network segments of routing information during route filtering.

Related Configuration

Creating an ACL

By default, no ACL is configured and no policy is set.

In global configuration mode, run the **ip access-list** { **extended** | **standard** } { *id* | *name* } command to create an IPv4 ACL.

You can set multiple policies in an ACL, which are sorted by sequence number. Policies have two working modes: permit and deny.

Creating a Prefix-List

By default, no prefix-list is configured and no entry is set.

In global configuration mode, run the **ip prefix-list** *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ip-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*] command to create an IPv4 prefix-list and add a prefix entry to the list.

You can set multiple entries in the prefix-list, which are sorted by sequence number. Entries have two working modes: permit and deny.

Run the **ip prefix-list** *prefix-list-name* **description** *description-text* command to add the description to the prefix-list.

Run the **ip prefix-list sequence-number** command to enable the sorting function for the prefix-list.

1.3.2 Route Map

A route map uses the "match …, set…" statement, indicating that processing actions are taken if certain conditions are met.

Working Principle

Enforcing Policies

A route map may contain multiple policies, which are identified by sequence number. A smaller sequence number means a higher priority. Policies are executed based on their sequence numbers. Once the matching condition of a policy is met, the processing action for this policy needs to be taken and the route map exits. If no matching condition of any policy is met, no processing action will be taken.

Working Modes of Policies

Policies have two working modes:

- permit: When the matching condition of a policy is met, the processing action for this policy will be performed and the route map will exit.
- deny: When the matching condition of a policy is met, the processing action for this policy will not be performed and the route map will exit.

Matching Conditions of Policies

The matching condition of a policy may contain no match rule, one match rule, or more match rules.

- If the matching condition contains no match rule, packets are matched.
- If the matching condition contains one or more match rules, packets must match all rules.

Processing Action for a Policy

The processing action of a policy may contain no set rule, one set rule, or more set rules.

- If the processing action contains no set rule, no processing action will be performed and the route map will directly exit.
- If the processing action contains one or more set rules, all processing actions will be performed and then the route map will exit.

⚠ If set rules have different priorities, the set rule with the highest priority will take effect.

Related Configuration

Creating a Route Map (Policy)

By default, no route map is configured and no policy is set.

In global configuration mode, you can run the **route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*] command to create a route map and add a policy to the route map.

You can set multiple policies in a route map. Each policy uses different sequence numbers.

Setting Matching Conditions of a Policy

By default, no match rule is set (that is, the matching condition of a policy contains no match rule).

In route map mode, run the **match** command to set match rules. One **match** command is mapped to one match rule.

RGOS provides abundant **match** commands for setting flexible matching conditions.

Command	Description
match interface	Uses the outbound interface of a route as the matching condition.
match ip address	Uses the destination IPv4 address of a route as the matching condition.
match ip next-hop	Uses the next-hop IPv4 address of a route as the matching condition.
match ip route-source	Uses the source IPv4 address of a route as the matching condition.
match ipv6 address	Uses the destination IPv6 address of a route as the matching condition.
match ipv6 next-hop	Uses the next-hop IPv6 address of a route as the matching condition.
match ipv6 route-source	Uses the source IPv6 address of a route as the matching condition.

Command	Description
match mac-address	Uses the MAC address of a route as the matching condition.
match metric	Uses the metric of a route as the matching condition.
match route-type	Uses the type of a route as the matching condition.
match tag	Uses the tag value of a route as the matching condition.

Setting the Processing Actions of a Policy

By default, no set rule is configured (that is, the processing action of a policy contains no set rule).

In the route map mode, run the **set** command to configure set rules. One **set** command is mapped to one set rule.

RGOS provides abundant **set** commands for setting flexible processing actions.

Command	Description
set level	Sets the destination area type to which a route will be directed.
set metric	Changes the metric value of a route.
set metric-type	Sets the metric type of a route.
set next-hop	Sets the next-hop IP address of a route.
set tag	Sets the tag value of a route.

1.4 Configuration

Configuration	Description and Command	
Configuring a Route Map	(Optional) It is used to define a policy.	
	route-map	Creates a policy (route map).
	match	Sets matching conditions of the policy.
	set	Sets processing actions of the policy.
Configuring a Filtering List	(Optional) It is used to define a filtering list.	
	ip prefix-list	Creates a prefix-list.
	ip prefix-list description	Adds the description to a prefix-list.
	ip prefix-list sequence-number	Enables the sorting function for a prefix-list.
	ipv6 prefix-list	Creates an IPv6 prefix-list.
	ipv6 prefix-list description	Adds the description to an IPv6 prefix-list.
	ipv6 prefix-list sequence-number	Enables the sorting function for an IPv6 prefix-list.
Configuring the Exit Policy for Routing Protocols	**memory-lack exit-policy**	Specifies the exit policy for upper-layer routing protocols after the memory reaches the lower threshold.

1.4.1 Configuring a Route Map

Configuration Effect

- Define a set of routing policies to be used by routing protocols or PBR.

Notes

- If the **match** command uses an ACL to define matching conditions of packets, the ACL must have been configured.
- The following **match** commands in the left and right columns cannot be configured simultaneously.

Command	Conflicting Command
match ipv6 address	**match ipv6 prefix-list**
match ip next-hop	**match ip next-hop prefix-list**
match ipv6 next-hop	**match ipv6 next-hop prefix-list**
match ip route-source	**match ip route-source prefix-list**
match ipv6 route-source	**match ipv6 route-source prefix-list**

Configuration Step

Creating a Policy (Route Map)

- Mandatory.
- Perform this configuration on a device to which a policy needs to be applied.

Setting Matching Conditions of a Policy

- Optional.
- If no match rule is configured, packets are matched.
- If multiple match rules are configured, packets must match all the match rules.
- Perform this configuration on a device to which a policy needs to be applied.

Setting Processing Actions of a Policy

- Optional.
- If no set rule is configured, no processing action will be performed.
- If multiple set rules are configured, all set rules must be executed (if the set rules have different priorities, the set rule with the highest priority takes effect).
- Perform this configuration on a device to which a policy needs to be applied.

Verification

- Check the route map configuration.

Related Commands

Creating a Policy (Route Map)

Command	**route-map** *route-map-name* [{ **permit** | **deny** } *sequence*]
Parameter Description	*route-map-name*: Indicates the name of a route map. It has no more than 32 characters (limited to 200 characters in some versions). permit: Specifies the working mode of this policy as permit, which is the default mode. deny: Specifies the working mode of this policy as deny.

	sequence: Specifies the sequence number of this policy. A smaller value means a higher priority. The default value is 10.
Command Mode	Global configuration mode
Usage Guide	If this route map is unavailable, this command will create a route map and add a policy to the route map. If this route map is available, this command will add a policy to the route map.

Setting Matching Conditions of a Policy

Command	**match interface** *interface-type interface-number* [*…interface-type interface-number*]
Parameter Description	*interface-type interface-number*: Indicates the interface type and interface number.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the next-hop outbound interface of a route or a packet.

Command	**match ip address** { *access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...*| *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*] }
Parameter Description	*access-list-number*: Indicates the number of an ACL. For a standard ACL, the value range is from 1 to 99 and 1300 to 1999. For an extended ACL, the value range is from 100 to 199 and 2000 to 2699. For an expert-level extended ACL, the value range is from 2700 to 2899. *access-list-name*: Indicates the name of an ACL. **prefix-list** *prefix-list-name*: Indicates the name of a prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the destination IPv4 address of a packet or route by using an ACL or a prefix-list.

Command	**match ip next-hop** { *access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name* [*prefix-list-name...*] }
Parameter Description	*access-list-number*: Indicates the number of an ACL. For a standard ACL, the value range is from 1 to 99 and 1300 to 1999. For an extended ACL, the value range is from 100 to 199 and 2000 to 2699. *access-list-name*: Indicates the name of an ACL. **prefix-list** *prefix-list-name*: Indicates the name of a prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the next-hop IPv4 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured simultaneously.

Command	**match ip route-source** { *access-list-number* [*access-list-number...* | *access-list-name...*] | *access-list-name* [*access-list-number...* | *access-list-name*] | **prefix-list** *prefix-list-name*

	[*prefix-list-name...*] }
Parameter Description	*access-list-number*: Indicates the number of an ACL. For a standard ACL, the value range is from 1 to 99 and 1300 to 1999. For an extended ACL, the value range is from 100 to 199 and 2000 to 2699. *access-list-name*: Indicates the name of an ACL **prefix-list** *prefix-list-name*: Indicates the name of a prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the source IPv4 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured simultaneously.

Command	**match ipv6 address** { *access-list-name* | **prefix-list** *prefix-list-name* }
Parameter Description	*access-list-name*: Indicates the access list name. **prefix-list** *prefix-list-name*: Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the destination IPv6 address of a packet or route by using an ACL or a prefix-list. An ACL and a prefix list cannot be configured simultaneously.

Command	**match ipv6 next-hop** { *access-list-name* | **prefix-list** *prefix-list-name* }
Parameter Description	*access-list-name*: Indicates the access list name. **prefix-list** *prefix-list-name*: Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the next-hop IPv6 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured simultaneously.

Command	**match ipv6 route-source** { *access-list-name* | **prefix-list** *prefix-list-name* }
Parameter Description	*access-list-name*: Indicates the access list name. **prefix-list** *prefix-list-name*: Indicates the name of an IPv6 prefix-list to be matched.
Command Mode	Route map configuration mode
Usage Guide	This match rule matches the source IPv6 address of a route by using an ACL or a prefix-list. An ACL and a prefix-list cannot be configured simultaneously.

Command	**match metric** *metric*
Parameter Description	*metric*: Indicates the metric value of a route. The value range is from 0 to 4294967295.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the metric value of a route.

Command	**match route-type** { **internal | external** [**type-1 | type-2**] | **nssa-external** [**type-1** | **type-2**] }
Parameter	**Internal**: Indicates the internal route of OSPF.

Description	**external**: Indicates the external route of OSPF. **type-1 | type-2**: Indicates the Type-1 or Type-2 external route of OSPF. **nssa-external**: Indicates the OSPF NSSA external route.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the type of a route.

Command	**match tag** *tag* [*…tag*]
Parameter Description	*tag*: Indicates the tag value of a route.
Command Mode	Route map configuration mode
Usage Guide	This match rule is used to match the tag value of a route.

Setting the Processing Actions of a Policy

Command	**set level** {**stub-area** | **backbone** }
Parameter Description	**stub-area**: Indicates that the redistributed route is advertised to OSPF stub area. **backbone**: Indicates that the redistributed route is advertised to the OSPF backbone area.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the type of the destination area to which a route will be redirected.

Command	**set metric** [+ *metric-value* | **-** *metric-value* | *metric-value*]
Parameter Description	+: Indicates the value increased based on the metric value of the original route. -: Indicates the value decreased based on the metric value of the original route. *metric-value*: Sets the metric value of a redistributed route. A larger value means a lower priority.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to modify the metric value of a route.

Command	**set metric-type** *type*
Parameter Description	*type*: Sets the type of a redistributed route.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the metric type.

Command	**set next-hop** *ip-address*
Parameter Description	*ip-address*: Indicates the next-hop IP address.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the next-hop IP address.

Command	**set tag** *tag*
Parameter Description	*tag*: Sets the tag of a redistributed route.
Command Mode	Route map configuration mode
Usage Guide	This set rule is used to set the tag value of a route.

Displaying the Route Map Configuration

Command	**show route-map** [*name*]
Parameter Description	***name***: Specifies a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Run the **show route-map** command to display the route map configuration. If an ACL is used when a route map is configured, you can run the **show access-list** command to display the ACL configuration.

Configuration Example

Using a Route Map in Route Redistribution to Filter and Modify Routing Information

Scenario Figure 1-4	As shown in Figure 1-4, a device is connected to both the OSPF routing domain and RIP routing domain. 
	● Redistribute only RIP routes with four hops to OSPF. In the OSPF routing domain, if the route type is Type-1 external route, set the tag value of the route to 40. ● Redistribute only OSPF routes with the tag value 10 to RIP. In the RIP routing domain, set the initial metric value of this route to 10.
Configuration Steps	● Configure the route map **redrip**: match a route with four hops, set the initial metric value of the route to 40, set the route type to Type-1 external route, and set the tag value of the route to 40. ● Configure the route map **redospf**: match a route with the tag value 10 and set the initial metric value of the route to 10. ● Configure redistribution of the RIP route to OSPF and apply the route map **redrip**. ● Configure redistribution of the OSPF route to RIP and apply the route map **redospf**.

	`Hostname(config)# route-map redrip permit 10`
	`Hostname(config-route-map)# match metric 4`
	`Hostname(config-route-map)# set metric-type type-1`
	`Hostname(config-route-map)# set tag 40`
	`Hostname(config-route-map)# exit`
	`Hostname(config)# route-map redospf permit 10`
	`Hostname(config-route-map)# match tag 10`
	`Hostname(config-route-map)# set metric 10`
	`Hostname(config-route-map)# exit`

	Hostname(config)# router ospf 1 Hostname(config-router)# redistribute rip subnets route-map redrip Hostname(config-router)# exit Hostname(config)# router rip Hostname(config-router)# redistribute ospf 1 route-map redospf Hostname(config-router)# exit
Verification	● Check the route map configuration to verify policy rules. ● Check the OSPF routing information library to verify that the rules matching the policy rules are redistributed.

	Hostname# show route-map
	route-map redrip, permit, sequence 10
	  Match clauses:
	  metric 4
	  Set clauses:
	  metric 40
	  metric-type type-1
	  tag 40
	route-map redospf, permit, sequence 10
	  Match clauses:
	  tag 10
	  Set clauses:
	  metric 10

	Hostname# show ip ospf database external
	
	  OSPF Router with ID (192.100.1.9) (Process ID 1)
	
	  AS External Link States
	
	  LS age: 5
	  Options: 0x2 (-|-|-|-|-|-|E|-)
	  LS Type: AS-external-LSA
	  Link State ID: 192.168.199.0 (External Network Number)
	  Advertising Router: 192.100.1.9
	  LS Seq Number: 80000001
	  Checksum: 0x554d
	  Length: 36
	  Network Mask: /24
	  Metric Type: 1
	  TOS: 0
	  Metric: 4
	  Forward Address: 0.0.0.0
	  External Route Tag: 40

1.4.2 Configuring a Filtering List

Configuration Effect

- Define a set of route filtering rules to be used by routing protocols.

Notes

- A configured filtering list can take effect only when being associated with a routing protocol.

Configuration Step

Configuring a Prefix-List

- To filter address prefixes, you should perform this configuration.
- Unless otherwise required, perform this configuration on devices for which filtering based on a prefix-list needs to be performed.

Verification

- Check whether the filtering list is correctly configured.
- Check the routing table to verify that routes can be correctly filtered.

Related Commands

Creating a Prefix-List

Command	**ip prefix-list** *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ip-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]
Parameter Description	***prefix-list-name***: Indicates the prefix-list name. *seq-number*: Assigns a sequence number to an prefix-list entry. The value range is from 1 to 2147483647. If this command does not contain the sequence number, the system will assign a default sequence number to the prefix-list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each entry not assigned with a value is the first multiple of 5 greater than the previous sequence number. **deny**: Denies access when certain conditions are matched. **permit**: Permits access when certain conditions are matched. ***ip-prefix***: Configures the IP address and mask. The value has 0 to 32 digits. ***minimum-prefix-length***: Specifies the minimum range, namely, start length of a range. ***maximum-prefix-length***: Specifies the maximum range, namely, end length of a range.
Command Mode	Global configuration mode
Usage Guide	N/A

Adding the Description to a Prefix-List

Command	**ip prefix-list** *prefix-list-name* **description** *description-text*
Parameter Description	***prefix-list-name***: Indicates the prefix-list name. *description-text*: Indicates the description of the prefix-list.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Enabling the Sorting Function for a Prefix-List

Command	**ip prefix-list sequence-number**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Creating an IPv6 Prefix-List

Command	**ipv6 prefix-list** *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]
Parameter Description	***prefix-list-name***: Indicates the prefix-list name. *seq-number*: Assigns a sequence number to an prefix-list entry. The value range is from 1 to 2147483647. If this command does not contain the sequence number, the system will assign a default sequence number to the prefix-list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each entry not assigned with a value is the first multiple of 5 greater than the previous sequence number. **deny**: Denies access when certain conditions are matched. **permit**: Permits access when certain conditions are matched. ***ipv6-prefix***: Configures the IP address and mask. The value has 0 to 128 digits. ***minimum-prefix-length***: Specifies the minimum range, namely, start length of a range. ***maximum-prefix-length***: Specifies the maximum range, namely, end length of a range.
Command Mode	Global configuration mode
Usage Guide	N/A

Adding Description to an IPv6 Prefix List

Command	**ipv6 prefix-list** *prefix-list-name* **description** *description-text*
Parameter Description	***prefix-list-name***: Indicates the prefix-list name. *description-text*: Indicates the description of the prefix-list.
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling the Sorting Function for an IPv6 Prefix-List

Command	**ipv6 prefix-list sequence-number**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Common Errors

- A filtering list is configured but is incorrectly applied in a routing protocol, which causes that the filtering list to take ineffective.

1.4.3 Configuring the Exit Policy for Routing Protocols

Configuration Effect

- When the memory reaches the lower threshold, to ensure running of other protocols in the system, one routing protocol will be disabled to release memory resources.

Related Commands

Configuring the Exit Policy for Routing Protocols

Command	**memory-lack exit-policy** { **ospf** | **rip** }
Parameter Description	**ospf**: Specifies the OSPF protocol as the first to exit when memory is insufficient. **rip**: Specifies the RIP protocol as the first to exit when memory is insufficient.
Command Mode	Global configuration mode
Usage Guide	You must learn main network services supported by corresponding routing protocols. In case of insufficient memory, the least important protocol should be disabled to ensure running of main services in extreme situations. For routing protocols that are disabled, specifying them as the first to exit will not help the system obtain sufficient memory resources. Specifying this policy only partially protects important network services in case of insufficient memory. If the memory is further consumed, all routing protocols will exit and stop running.

1.5 Monitoring

Displaying

Command	Description
show route-map [*route-map-name*]	Displays the route map configuration.
show ip prefix-list [*prefix-name*]	Displays the IPv4 prefix-list configuration.
show ipv6 prefix-list [*prefix-name*]	Displays the IPv6 prefix-list configuration.
show ip protocols { **ospf | rip** }	Displays information about the status of running IPv4 routing protocols.

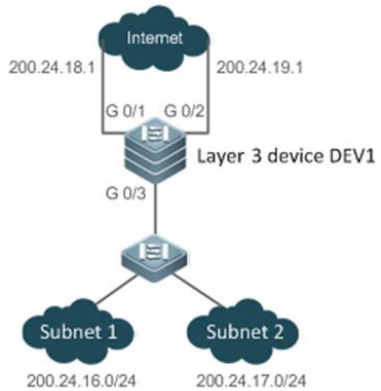
1 Configuring PBR

1.1 Overview

Policy-based Routing (PBR) is implemented by applying a route map including policies to interfaces and devices.

Similar to static routing, PBR is also manually configured and cannot automatically adapt to network changes. In addition, PBR is effective only for packets sent from local interfaces and devices. Compared with static and dynamic routing, PBR is more flexible. Static and dynamic routing can forward packets only based on destination addresses. PBR can forward packets based on destination addresses and inbound interfaces.

1.2 Applications



Application	Description
Selecting an ISP by Using PBR	Specify preferential outbound interfaces for packets from different subnets.

1.2.1 Selecting an ISP by Using PBR

An existing user network often uses resources of multiple internet server providers (ISPs). PBR is necessary because different bandwidths may be requested from different ISPs or the network resources for key users need to be protected. By controlling forwarding of specific data packets, you can optimize ISP resource usage and accomodate flexible and diversified application requirements.

Scenario

Figure 3-1

A LAN has two outbound interfaces connected to the Internet. PBR is configured on the Layer 3 device DEV1 to enable the two outbound interfaces to implement load balancing and mutual backup.

The specific requirements are as follows:

- Data streams from subnet 1 are sent from GE 0/1.
- Data streams from subnet 2 are sent from GE 0/2.

- If the link of GE 0/1 is disconnected, data streams on GE 0/1 are switched to GE 0/2. The same applies in reverse.

Deployment

- Configure two different Access Control Lists (ACLs) on DEV1:

ACL1: Source addresses belong to subnet 1.

ACL2: Source addresses belong to subnet 2.

- Configure two policies in the route map on DEV1:

Policy 1: Sets the next hops for packets matching ACL1 to GE0/1 and GE0/2. Based on the configuration sequence, GE0/1 takes effect first and GE0/2 works in backup mode.

Policy 2: Sets the next hops for packets matching ACL2 to GE0/2 and GE0/1. Based on the configuration sequence, GE0/2 takes effect first and GE0/1 works in backup mode.

- Configure PBR on GE0/3 by using a route map. Then, packets received on this interface are forwarded based on policies.

1.3 Features

Feature	Description
Configuring a Policy	Configures policies in a route map before configuring PBR.
Configuring PBR	Applies a route map including policies to interfaces and devices to implement PBR.

1.3.1 Configuring a Policy

A policy uses the "match …, set…" statement, indicating that processing actions are taken if certain conditions are met.

For details about policies, see *Configuring Routing Policies*.

Executing Policies

In global configuration mode, run the **route-map** *route-map-name* [**permit** | **deny**] [*sequence-number*] command to create a policy in a route map.

A route map may contain multiple policies, which are identified by sequence number. A smaller sequence number means a higher priority. Policies are executed based on their sequence numbers. Once the matching condition of a policy is met, the processing action for this policy needs to be taken and the route map exits. If no matching condition of any policy is met, no processing action will be taken.

Policies have two working modes:

- permit: When the matching condition of a policy is met, perform the processing action for this policy and exit the route map.
- deny: When the matching condition of a policy is met, do not perform the processing action for this policy and exit the route map.

Matching Conditions of Policies

The matching condition of a policy may contain no match rule, one match rule, or more match rules.

- If the matching condition contains no match rule, packets are matched.
- If the matching condition contains one or more match rules, packets must match all rules.

In route map configuration mode, run the **match** command to configure match rules. One **match** command is mapped to one match rule.

PBR supports the following **match** commands.

PBR	Command	Description
IPv4 PBR	**match ip address**	The source IPv4 address (and the destination IPv4 address) is used as the matching condition. Multiple **match ip address** commands can be configured in a policy.
IPv6 PBR	**match ipv6 address**	The source IPv6 address (and the destination IPv6 address) is used as the matching condition. Only one **match ipv6 policy** command can be configured in a policy.

IPv4 PBR defines the source IP address (and destination IP address) ranges of packets by using the standard or extended IP ACLs. IPv6 PBR defines the source IPv6 address (and destination IPv6 address) ranges of packets by using the extended IPv6 ACLs.

Packet forwarding based on policies of IPv4 PBR interfaces supports expert and MAC ACLs. Packet forwarding based on local policies does not support expert and MAC ACLs.

When PBR references a nonexistent ACL, the route sub-map will not be matched and the next route sub-map will be matched instead. If no route sub-map is matched, a common route will be selected for forwarding. If only ACLs are configured but no ACE is configured, the PBR forwarding behavior is the same as that in a scenario where an ACL does not exist.

Processing Action for a Policy

The processing action of a policy may contain no set rule, one set rule, or more set rules.

- If the processing action contains no set rule, no processing action will be performed and the route map will directly exit.
- If the processing action contains one or more set rules, all processing actions will be performed and then the route map will exit.

If set rules have different priorities, the set rule with the highest priority will take effect.

In route map configuration mode, run the **set** command to configure set rules. One **set** command is mapped to one set rule.

PBR supports the following **set** commands.

PBR	Command	Description
IPv4 PBR	**set ip next-hop**	Configures the next hop of IPv4 packet forwarding. The next hop must be directly connected; otherwise, this command is invalid. A packet matching the match rules will be forwarded to the next hop

PBR	Command	Description
		specified by **set ip next-hop first**, regardless of whether the route selected for the packet in the routing table is consistent with the next hop specified by PBR. On a switch, the outbound interfaces for next hops supported by PBR include the SVI, routed interface, and Layer 3 aggregate interface.
	set ip default next-hop	Configures the default next hop of IPv4 packet forwarding. A packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table.
IPv6 PBR	**set ipv6 next-hop**	Configures the next hop of IPv6 packet forwarding. An IPv6 packet matching the match rules will be forwarded to the next hop specified by **set ipv6 next-hop** first, regardless of whether the route selected for the IPv6 packet in the routing table is consistent with the next hop specified by PBR. The next hop must be directly connected; otherwise, this command is invalid.
	set ipv6 default next-hop	Configures the default next hop of IPv6 packet forwarding. An IPv6 packet matching the match rules will be forwarded to the default next hop specified by this command if a route fails to be selected or the default route is selected for this packet in the routing table. The next hop must be directly connected; otherwise, this command is invalid.

The following commands and routes are in descending order of priority: **set ip next-hop**, common route, **set ip default next-hop**, and default route. The preceding **set** commands can be configured simultaneously, but only the command with the highest priority takes effect.

The following commands and routes are in descending order of priority: **set ipv6 next-hop**, common route, **set ipv6 default next-hop**, and default route. The preceding **set** commands can be configured at the same time but only the command with the highest priority takes effect.

The **set ipv6 default next-hop** command is invalid for IPv6 addresses with the mask length longer than 64.

1.3.2 Configuring PBR

PBR

Apply a route map including policies to interfaces or devices to implement PBR.

- Apply a route map to an interface so that packets received by the interface are routed based on the policy.
  PBR is often used to control user packets received by a device. This command is effective only for forwarded packets but not for packets initiated locally.

- Apply a route map to a device so that packets initiated locally are routed based on the policy.
  PBR is often used to control protocol packets exchanged between devices (such as ping packets sent locally).
  This command is effective only for locally initiated packets, but not for forwarded packets.

By default, PBR is unavailable on a device and packets are forwarded based on a routing table.

Redundant Backup or Load Balancing

You can set multiple next hops in a policy. Either redundant backup or load balancing can be implemented among multiple next hops. Redundant backup is implemented by default.

Redundant backup or load balancing is only effective for next hops configured in the **set ip next-hop**, **set ip next-hop recursive**, **set ip default next-hop**, **set ipv6 next-hop**, and **set ipv6 default next-hop** commands, and for multiple next hops in the same set rule.

- Redundant backup

  Based on the configuration sequence, the first accessible next hop takes effect. When the currently effective next hop (R1) is faulty, traffic automatically switches to the next accessible next hop (R2). When R1 becomes accessible again, traffic automatically switches back to R1.

  A newly added next hop is arranged at the end of the sequence. Assume that the original sequence of multiple next hops is R1 > R2 > R3. After R1 is deleted and added again, the sequence changes to R2 > R3 > R1.
  If no next hop is accessible, packets will be discarded.

- Load balancing
  When multiple accessible next hops take effect simultaneously, the Weighted Cost Multiple Path (WCMP) and Equal Cost Multiple Path (ECMP) are supported. After an accessible next hop becomes unavailable, traffic will be load balanced among the other accessible next hops.

Correlation with BFD

Correlation between PBR and BFD is effective only for next hops configured by the **set ip next-hop** or **set ipv6 next-hop** command.

Correlation between PBR and BFD helps enhance the capability to detect network changes. When BFD detects that the current next hop is inaccessible, BFD will immediately notify PBR to switch the traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

For details on how to configure correlation between PBR and BFD, see *Configuring BFD*.

Correlation with Track

Correlation between PBR and track is effective only for next hops configured by the **set ip next-hop** command.

The **set ip next-hop** command carries **verify-availability** and **track** *track-obj-number* parameters, which can be used to configure correlation between PBR and a track session and monitor reachability of next hops.

Correlation between PBR and track helps enhance the capability to detect network changes. When track detects that the current next hop is inaccessible, track will immediately notify PBR to switch traffic to another accessible next hop (to implement redundant backup) or all the other accessible next hops (to implement load balancing).

Only IPv4 PBR supports correlation with track.

For details on how to configure correlation between PBR and track, see *Configuring RNS*.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of PBR	(Mandatory) It is used to apply PBR to forward packets.	
	ip policy route-map	Applies PBR to IPv4 packets received by an interface.
	ipv6 policy route-map	Applies PBR to IPv6 packets received by an interface.
	ip local policy route-map	Applies PBR to IPv4 packets initiated locally.
	ipv6 local policy route-map	Applies PBR to r IPv6 packets initiated locally.
Configuring Redundant Backup or Load Balancing	(Optional) It is used to set whether PBR implements redundant backup or load balancing among multiple next hops.	
	ip policy { **redundance** | **load-balance** }	Sets whether IPv4 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.
	ipv6 policy { **redundance** | **load-balance** }	Sets whether IPv6 PBR implements redundant backup or load balancing among multiple next hops. The default setting is redundant backup.

1.4.1 Configuring Basic Functions of PBR

Configuration Effect

Perform personalized routing management for user data streams by configuring flexible policies.

Perform personalized management for protocol interaction and network topologies by configuring flexible policies.

Notes

- A route map must be used when PBR is configured; therefore, you must configure a route map on a device.
- If an ACL is used when the route map is configured, you must first configure the ACL on the device.

Configuration Step

Applying PBR to IPv4 Packets Received by an Interface

- To perform personalized routing management for IPv4 user data streams passing a device, perform this configuration.
- Perform this configuration on the inbound interface for user data streams.
- Run the **ip policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv4 packets received on this interface.

Command	**ip policy route-map** *route-map-name*
Parameter Description	*route-map-name*: Indicates the name of a route map.
Defaults	By default, PBR is not configured on a device and packets are forwarded based on a routing table.
Command Mode	Interface configuration mode
Usage Guide	Only one **ip policy route-map** command can be configured for an interface. If multiple **ip policy route-map** commands are configured for an interface, only the latest configuration takes effect. If the route map used in PBR does not exist, PBR does not take effect.

Applying PBR to IPv6 Packets Received by an Interface

- To perform personalized routing management for IPv6 user data streams passing a device, perform this configuration.
- Perform this configuration on the inbound interface for user data streams.
- Run the **ipv6 policy route-map** command to apply a route map to an interface. Then, PBR is executed for IPv6 packets received on this interface.

Command	**ipv6 policy route-map** *route-map-name*
Parameter Description	*route-map-name*: Indicates the name of a route map.
Defaults	By default, PBR is not configured on a device and packets are forwarded based on a routing table.
Command Mode	Interface configuration mode
Usage Guide	Only one **ipv6 policy route-map** command can be configured for an interface. If multiple **ipv6 policy route-map** commands are configured for an interface, only the latest configuration takes effect. If the route map used in PBR does not exist, PBR does not take effect.

Applying PBR to IPv4 Packets Initiated Locally

- To perform personalized management for IPv4 protocol interaction and IPv4 network topologies, perform this configuration.
- Run the **ip local policy route-map** command to apply a route map to a device. Then PBR is executed for IPv4 packets initiated locally.

Command	**ip local policy route-map** *route-map-name*
Parameter Description	*route-map-name*: Indicates the name of a route map.
Defaults	By default, PBR is not configured on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one **ip local policy route-map** command can be configured for a device. If the route map used in PBR does not exist, PBR does not take effect.

Applying PBR to IPv6 Packets Initiated Locally

- To perform personalized management for IPv6 protocol interaction and IPv6 network topologies, perform this configuration.

- Run the **ipv6 local policy route-map** command to apply a route map to a device. Then, PBR is executed for IPv6 packets initiated locally.

Command	**ipv6 local policy route-map** *route-map-name*
Parameter Description	*route-map-name*: Indicates the name of a route map.
Defaults	By default, PBR is not configured on a device and packets are forwarded based on a routing table.
Command Mode	Global configuration mode
Usage Guide	Only one **ipv6 local policy route-map** command can be configured for a device. If the route map used in PBR does not exist, PBR does not take effect.

Verification

- Check the PBR configuration.
- Check the configuration of the route map used by PBR.
- If an ACL is used when the route map is configured, you should check the ACL configuration.

Displaying the IPv4 PBR Configuration

Command	**show ip policy** [*route-map-name*]
Parameter Description	*route-map-name*: Indicates the name of a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	Check the interfaces configured with IPv4 PBR according to the output information and the name of the used route map.
	`Hostname# show ip policy`
	`Banlance mode: redundance`
	`Interface Route map`
	`local RM_for_PBR_1`
	`GigabitEthernet 0/1 RM_for_PBR_2`
	Local indicates that PBR is applied to IPv4 packets initiated locally.

Displaying the IPv6 PBR Configuration

Command	**show ipv6 policy** [*route-map-name*]
Parameter Description	*route-map-name*: Indicates the name of a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	Check the interfaces configured with IPv6 PBR according to the output information and the name of the used route map.
	`Hostname#show ipv6 policy`
	`Banlance mode: redundance`
	`Interface Route map`
	`local RM_for_PBR_1`

	`VLAN 1 RM_for_PBR_2` **Local** indicates that PBR is applied to IPv6 packets initiated locally.

Displaying the Route Map Configuration

Command	**show route-map** [*route-map-name*]
Parameter Description	*route-map-name*: Indicates the name of a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	Multiple route maps may be available on a device. Focus on the route map used in PBR and check its policy settings.
	`Hostname# show route-map`
	`route-map RM_FOR_PBR, permit, sequence 10`
	`  Match clauses:`
	`    ip address acl1`
	`  Set clauses:`
	`ip next-hop 200.24.18.1`
	`route-map RM_FOR_PBR, permit, sequence 20`
	`  Match clauses:`
	`    ip address acl2`
	`  Set clauses:`
	`ip next-hop 200.24.19.1`

Displaying the ACL Configuration

Command	**show access-lists** [*acl-id* | *acl-name*]
Parameter Description	*acl-id*: Indicates the number of an ACL. *acl-name*: Indicates the name of an ACL.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	Multiple ACLs may be available on a device. Focus on the ACL used by a route map and check its configuration.
	`Hostname# show access-lists 1`
	`ip access-list standard 1`
	`  10 permit 200.24.16.0 0.0.0.255`
	`ip access-list standard 2`
	`  10 permit 200.24.17.0 0.0.0.255`

Displaying Routing Information About IPv4 PBR

Command	**show ip pbr route** [**interface** *if-name* | **local**]
Parameter Description	*if-name*: Indicates an interface name. **local**: Indicates that PBR is applied to packets initiated locally.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Specify a local interface or device and check routing information about IPv4 PBR.

```
Hostname# show ip pbr route
PBR IPv4 Route Summay : 1
Interface        : GigabitEthernet 0/1
  Sequence       : 10
  VRF ID         : 0
  Route Flags    :
   Route Type    : PBR
   Direct        : Permit
   Priority      : High
   Precedence    : None
  Precedence     : 0
  Mode           : redundance
  Nexthop Count  : 1
   Nexthop[0]    : 192.168.8.100
   Weight[0]     : 1
   Ifindex[0]    : 2
```

Displaying Routing Information About IPv6 PBR

Command	**show ipv6 pbr route** [**interface** *if-name* | **local**]
Parameter Description	*if-name*: Indicates an interface name. **local**: Indicates that PBR is applied to packets initiated locally.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	Specify a local interface or device and check routing information about IPv6 PBR.

```
Hostname# show ipv6 pbr route
PBR IPv6 Route Summary : 1
Interface        : GigabitEthernet 0/1
  Sequence       : 10
  ACL[0]         : 2900
  ACL_CLS[0]     : 5
  VRF ID         : 0
  Route Flags    :
   Route Type    : PBR
   Direct        : Permit
   Priority      : High
   Precedence    : None
  Precedence     : 0
  Mode           : redundance
  Nexthop Count  : 1
   Nexthop[0]    : 10::2
   Weight[0]     : 1
   Ifindex[0]    : 2
```

Displaying the Route Map Used by IPv4 PBR

Command	**show ip pbr route-map** *rmap-name*
Parameter Description	*rmap-name*: Indicates the name of a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	Specify a route map and check the route map used by IPv4 PBR.
	`Hostname# show ip pbr route-map rm`
	`PBR VRF: GLOBAL, ID: 0`
	` Forward Mode: redundance`
	` Forwarding: On`
	
	`Route-map rm`
	`  Route-map index: Sequence 10, permit`
	`    Match rule:`
	`      ACL ID :   2900, CLS: 1, Name: acl1`
	`    Set rule:`
	`      IPv4 nexthop: 192.168.8.100, (VRF name: , ID: 0), Weight: 0`
	`        PBR state info ifx: 2, Connected: True, Track state: Up`

Displaying the Route Map Used by IPv6 PBR

Command	**show ipv6 pbr route-map** *rmap-name*
Parameter Description	*rmap-name*: Indicates the name of a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

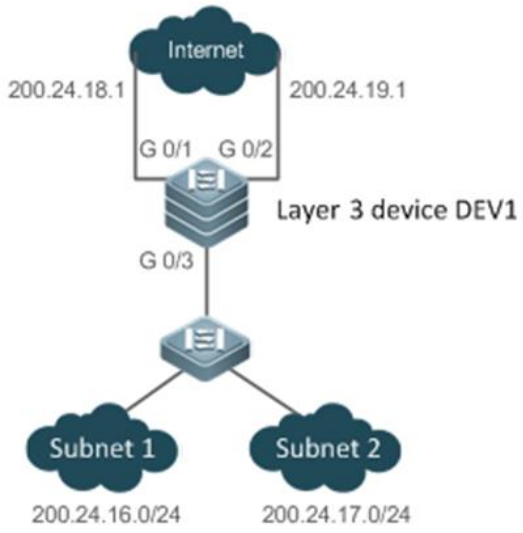
Usage Guide	Specify a route map and check the route map used by IPv6 PBR.
	`Hostname# show ipv6 pbr route-map rm6`
	`PBR VRF: GLOBAL, ID: 0`
	` Forward Mode: redundance`
	` Forwarding: On`
	
	`Route-map rm6`
	`  Route-map index: Sequence 10, permit`
	`    Match rule:`
	`      ACL ID :   2901, CLS: 5, Name: acl6`
	`    Set rule:`
	`      IPv6 nexthop: 10::2, (VRF name: , ID: 0), Weight: 0`
	`        PBR state info ifx: 2, Connected: True, Track state: Up`

Displaying Statistics About Packets Forwarded by IPv4 PBR

Command	**show ip pbr statistics** [**interface** *if-name* | **local**]
Parameter Description	*if-name*: Indicates an interface name. **local**: Indicates that PBR is applied to packets initiated locally.
Command	Privileged EXEC mode, global configuration mode, or interface configuration mode

Mode	

Usage Guide	`Hostname# show ip pbr statistics`
	`IPv4 Policy-based route statistic`
	`gigabitEthernet 0/1`
	`  statistics : 10`

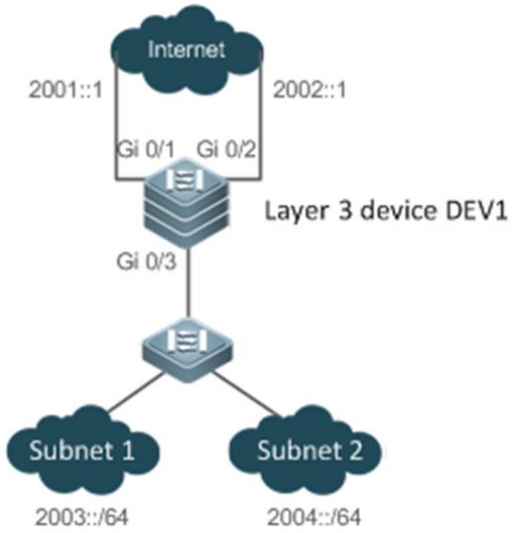


Displaying Statistics About Packets Forwarded by IPv6 PBR

Command	**show ipv6 pbr statistics** [**interface** *if-name* | **local**]
Parameter Description	*if-name*: Indicates an interface name. **local**: Indicates that PBR is applied to packets initiated locally.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	`Hostname# show ipv6 pbr statistics`
	`IPv6 Policy-based route statistic`
	`gigabitEthernet 0/1`
	`  statistics : 20`

Configuration Example



Configuring IPv4 PBR and Selecting an Egress Link Based on Source Addresses of Packets

Scenario **Figure 3-2**	
	● The Layer 3 device DEV1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24, whereas the network segment where subnet 2 resides is 200.24.17.0/24. ● DEV1 is connected to the Internet through GE0/1 and GE0/2, and their next hops are 200.24.18.1 and 200.24.19.1.
	This LAN has two outbound interfaces connected to the Internet. The requirements are as follows: ● Data streams from subnet 1 for accessing the Internet should pass GE 0/1. ● Data streams from subnet 2 for accessing the Internet should pass GE 0/2. ● If the link of GE 0/1 link is disconnected, data streams on GE 0/1 are switched to GE 0/2. The same applies in reverse.
Configuration	● Configure two ACLs to match packets from subnets 1 and 2 respectively. ● Set a policy and configure next hops for packets from subnet 1 to GE0/1 and GE0/2. (Pay

Steps	attention to the configuration sequence.) ● Set a policy and configure next hops for packets from subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.) ● Apply the policy to GE 0/3. ● Configure redundant backup among multiple next hops. (Redundant backup is used by default.) During redundant backup, based on the configuration sequence, the first next hop takes effect first.
	DEV1(config)# access-list 1 permit 200.24.16.0 0.0.0.255 DEV1(config)# access-list 2 permit 200.24.17.0 0.0.0.255 DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 1 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 20 DEV1(config-route-map)# match ip address 2 DEV1(config-route-map)# set ip next-hop 200.24.19.1 DEV1(config-route-map)# set ip next-hop 200.24.18.1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundance
Verification	● Check the IPv4 PBR configuration. ● Check the route map configuration. ● Check the ACL configuration.
	DEV1# show ip policy Interface Route map GigabitEthernet 0/3 RM_FOR_PBR
	DEV1# show route-map route-map RM_FOR_PBR, permit, sequence 10 Match clauses: ip address 1 Set clauses: ip next-hop 200.24.18.1 200.24.19.1 route-map RM_FOR_PBR, permit, sequence 20 Match clauses: ip address 2 Set clauses: ip next-hop 200.24.19.1 200.24.18.1
	DEV1# show access-lists ip access-list standard 1 10 permit 200.24.16.0 0.0.0.255

	ip access-list standard 2 10 permit 200.24.17.0 0.0.0.255

Configuring IPv6 PBR and Selecting an Egress Link Based on Source Addresses of Packets

Scenario **Figure 3-3**	
	● DEV1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 2003::/64, whereas the network segment where subnet 2 resides is 2004::/64. ● DEV1 is connected to the Internet through GE0/1 and GE0/2, and their next hops are 2001::1/64 and 2002::1/64.
	This LAN has two outbound interfaces connected to the Internet. The requirements are as follows: ● Data streams from subnet 1 for accessing the Internet should pass GE 0/1. ● Data streams from subnet 2 for accessing the Internet should pass GE 0/2. ● If the link of GE 0/1 link is disconnected, data streams on GE 0/1 are switched to GE 0/2. The same applies in reverse.
Configuration Steps	● Configure two ACLs to match packets from subnets 1 and 2 respectively. ● Set a policy and configure next hops for packets from subnet 1 to GE0/1 and GE0/2. (Pay attention to the configuration sequence.) ● Set a policy and configure next hops for packets from subnet 2 to GE0/2 and GE0/1. (Pay attention to the configuration sequence.) ● Apply the policy to GE 0/3. ● Configure redundant backup among multiple next hops. During redundant backup, based on the configuration sequence, the first next hop takes effect first.
	DEV1(config)# ipv6 access-list net1 DEV1(config-ipv6-acl)# permit ipv6 2003::/64 any DEV1(config-ipv6-acl)# exit DEV1(config)# ipv6 access-list net2 DEV1(config-ipv6-acl)# permit ipv6 2004::/64 any DEV1(config-ipv6-acl)# exit DEV1(config)# route-map RM_FOR_PBR 30 DEV1(config-route-map)# match ipv6 address net1

	DEV1(config-route-map)# set ipv6 next-hop 2001::1 DEV1(config-route-map)# set ipv6 next-hop 2002::1 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 40 DEV1(config-route-map)# match ipv6 address net2 DEV1(config-route-map)# set ipv6 next-hop 2002::1 DEV1(config-route-map)# set ipv6 next-hop 2001::1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ipv6 policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ipv6 policy redundance
Verification	● Check the IPv6 PBR configuration. ● Check the route map configuration. ● Check the ACL configuration.
	DEV1# show ipv6 policy Interface Route map GigabitEthernet 0/3 RM_FOR_PBR
	DEV1# show route-map route-map RM_FOR_PBR, permit, sequence 11 Match clauses: ipv6 address net1 Set clauses: ipv6 next-hop 2001::1 2002::1 route-map RM_FOR_PBR, permit, sequence 21 Match clauses: ipv6 address net2 Set clauses: ipv6 next-hop 2002::1 2001::1
	DEV1# show access-lists ipv6 access-list net1 10 permit ipv6 2003::/64 any (0 packets matched) ipv6 access-list net2 10 permit ipv6 2004::/64 any (0 packets matched)

Configuring Correlation Between IPv4 PBR and Track

Scenario **Figure 3-4**	
	● The Layer 3 device DEV1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24, whereas the network segment where subnet 2 resides is 200.24.17.0/24. ● DEV1 is connected to the Internet through GE0/1 and GE0/2 and their next hops are 200.24.18.1 and 200.24.19.1.
	● DEV1 can fast detect a faulty egress link and switch to a backup link.
Configuration Steps	When configuring IPv4 PBR and selecting an egress link based on source addresses of the packets, add or modify the following configurations: ● Set two track objects to track reachability of the next hops of the two outbound interfaces. ● When configuring a policy, configure correlation between the next hops and track objects.
DEV1	DEV1(config)# ip access-list extended 101 DEV1(config-ip-acl)# permit ip 200.24.16.0 0.0.0.255 any DEV1(config-ip-acl)# exit DEV1(config)# ip access-list extended 102 DEV1(config-ip-acl)# permit ip 200.24.17.0 0.0.0.255 any DEV1(config-ip-acl)# exit DEV1(config)#ip rns 1 DEV1(config-ip-rns)#icmp-echo 200.24.18.1 DEV1(config)#ip rns schedule 1 start-time now life forever DEV1(config)#track 1 rns 1 DEV1(config)#ip rns 2 DEV1(config-ip-rns)#icmp-echo 200.24.19.1 DEV1(config)#ip rns schedule 2 start-time now life forever DEV1(config)#track 2 rns 2 DEV1(config)# route-map RM_FOR_PBR 10 DEV1(config-route-map)# match ip address 101 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.18.1 track 1 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.19.1

	track 2 DEV1(config-route-map)# exit DEV1(config)# route-map RM_FOR_PBR 20 DEV1(config-route-map)# match ip address 102 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.19.1 track 2 DEV1(config-route-map)# set ip next-hop verify-availability 200.24.18.1 track 1 DEV1(config-route-map)# exit DEV1(config)# interface GigabitEthernet 0/3 DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_FOR_PBR DEV1(config-if-GigabitEthernet 0/3)# exit DEV1(config)# ip policy redundance
Verification	● Check whether the track objects are Up.

DEV1	DEV1#show track
	Track 1
	  Reliable Network Service 1
	  The state is Up
	  1 change, current state last: 120 secs
	  Delay up 30 secs, down 50 secs
	Track 2
	  Reliable Network Service 2
	  The state is Up
	  1 change, current state last: 130 secs
	  Delay up 30 secs, down 50 secs

Common Errors

- A route map is used when PBR is configured but the route map does not exist.
- An ACL is used when a route map is configured but the ACL does not exist.

1.4.2 Configuring Redundant Backup or Load Balancing

Configuration Effect

- Using multiple next hops in backup mode can enhance network reliability.
- Implementing load balancing among multiple next hops can increase the network bandwidth.

Notes

- Basic functions of PBR must be configured.
- Redundant backup and load balancing are effective only for the next hops configured by the following **set** commands.

Command	Description
set ip next-hop	Configures the next hop of IPv4 packets. This command carries the *weight* parameter, which is used to set the weight of WCMP. The default value is 1.

set ip default next-hop	Configures the default next hop of IPv4 packets. This command carries the *weight* parameter, which is used to set the weight of WCMP. The default value is 1.
set ipv6 next-hop	Configures the next hop of IPv6 packets. This command carries the *weight* parameter, which is used to set the weight of WCMP. The default value is 1.
set ipv6 default next-hop	Configures the default next hop of IPv6 packets. This command carries the *weight* parameter, which is used to set the weight of WCMP. The default value is 1.

Up to eight next hops can be set for WCMP, whereas up to 32 next hops can be set for ECMP.

Configuration Step

Configuring Whether IPv4 PBR Implements Redundant Backup or Load Balancing Among Multiple Next Hops

- If load balancing needs to be implemented among multiple next hops, perform this configuration.
- If load balancing is configured, perform this configuration to restore redundant backup.
- This configuration is effective for all PBR-based routes configured on a device.

Command	**ip policy** { **redundance** | **load-balance** }
Parameter Description	redundance: Indicates redundant backup. load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect simultaneously and share traffic by weight.

Configuring Whether IPv6 PBR Implements Redundant Backup or Load Balancing Among Multiple Next Hops

- If load balancing needs to be implemented among multiple next hops, perform this configuration.
- If load balancing is configured, perform this configuration to restore redundant backup.
- This configuration is effective for all PBR-based routes configured on a device.

Command	**ipv6 policy** { **redundance** | **load-balance** }
Parameter Description	redundance: Indicates redundant backup. load-balance: Indicates load balancing.
Defaults	Redundant backup is configured by default.
Command Mode	Global configuration mode
Usage Guide	If redundant backup is selected, the first next hop takes effect based on the configuration sequence. If load balancing is selected, all next hops take effect simultaneously and share traffic by weight.

Verification

- Check whether redundant backup or load balancing is implemented among multiple next hops.

Displaying Whether IPv4 PBR Implements Redundant Backup or Load Balancing Among Multiple Next Hops

Command	**show ip policy** [*route-map-name*]
Parameter Description	***route-map-name***: Specifies a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

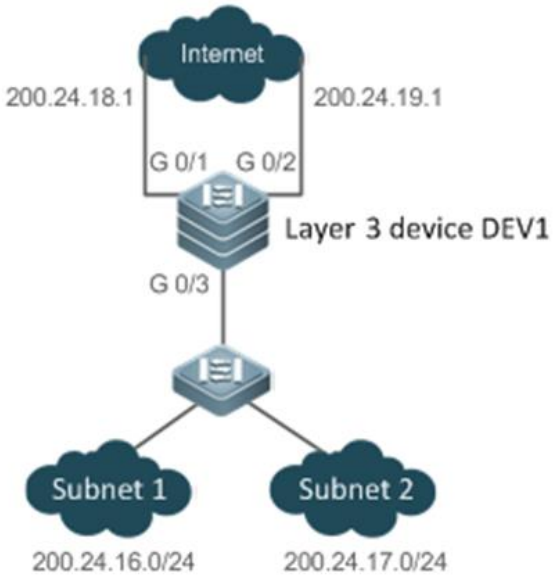
Usage Guide	See the following example and focus on the red field.
	`Hostname# show ip policy`
	`Banlance mode: redundance`
	`Interface Route map`
	`local test`
	`GigabitEthernet 0/3 test`

Checking whether IPv6 PBR implements redundant backup or load balancing among multiple next hops

Command	**show ipv6 policy** [*route-map-name*]
Parameter Description	***route-map-name***: Specifies a route map.
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	See the following example and focus on the red field.
	`Hostname#show ipv6 policy`
	`Banlance mode: redundance`
	`Interface Route map`
	`VLAN 1 RM_for_Vlan_1`
	`VLAN 2 RM_for_Vlan_2`

Configuration Example



Configuring IPv4 PBR to implement redundant backup among multiple next hops

See Configuring IPv4 PBR and Selecting an Egress Link Based on Source Addresses of Packets.

Configuring IPv6 PBR to implement redundant backup among multiple next hops

See Configuring IPv6 PBR and Selecting an Egress Link Based on Source Addresses of Packets.

Configuring IPv4 PBR to Implement Load Balancing Among Multiple Next Hops

Scenario **Figure 3-5**	
	● The Layer 3 device DEV1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 200.24.16.0/24, whereas the network segment where subnet 2 resides is 200.24.17.0/24. ● DEV1 is connected to the Internet through GE0/1 and GE0/2, and their next hops are 200.24.18.1 and 200.24.19.1.
	This LAN has two outbound interfaces connected to the Internet. The requirements are as follows: ● Traffic is equally shared by GE0/1 and GE0/2.
Configuration Steps	● Configure basic functions of PBR. Specify multiple next hops. ● Set the load balancing mode.

	`DEV1(config)# route-map RM_LOAD_PBR 10`
	`DEV1(config-route-map)# set ip next-hop 200.24.18.1`
	`DEV1(config-route-map)# set ip next-hop 200.24.19.1`
	`DEV1(config-route-map)# exit`
	`DEV1(config)# interface GigabitEthernet 0/3`
	`DEV1(config-if-GigabitEthernet 0/3)# ip policy route-map RM_LOAD_PBR`
	`DEV1(config-if-GigabitEthernet 0/3)# exit`
	`DEV1(config)# ip policy load-balance`

Verification	● Check the IPv4 PBR configuration. ● Check the route map configuration.

	`DEV1# show ip policy`
	`Balance mode: load-balance`
	`Interface Route map`
	`GigabitEthernet 0/3 RM_LOAD_PBR`

	`DEV1# show route-map`
	`route-map PBR-VRF-Selection, permit, sequence 10`
	`Match clauses:`
	`Set clauses:`
	`ip next-hop 200.24.18.1 8`
	`ip next-hop 200.24.19.1 8`

Configuring IPv6 PBR to Implement Load Balancing Among Multiple Next Hops

Scenario **Figure 3-6**	
	● DEV1 is connected to subnet 1 and subnet 2 through GE0/3. The network segment where subnet 1 resides is 2003::/64, whereas the network segment where subnet 2 resides is 2004::/64. ● DEV1 is connected to the Internet through GE0/1 and GE0/2, and their next hops are 2001::1/64 and 2002::1/64.
	This LAN has two outbound interfaces connected to the Internet. The requirements are as follows: ● Traffic is equally shared by GE0/1 and GE0/2.
Configuration Steps	● Configure basic functions of PBR. Specify multiple next hops. ● Set the load balancing mode.

	`DEV1(config)# route-map RM_LOAD_PBR 20`
	`DEV1(config-route-map)# set ipv6 next-hop 2001::1`
	`DEV1(config-route-map)# set ipv6 next-hop 2002::1`
	`DEV1(config-route-map)# exit`
	`DEV1(config)# interface GigabitEthernet 0/3`
	`DEV1(config-if-GigabitEthernet 0/3)# ipv6 policy route-map RM_LOAD_PBR`
	`DEV1(config-if-GigabitEthernet 0/3)# exit`
	`DEV1(config)# ipv6 policy load-balance`

Verification	● Check the IPv6 PBR configuration. ● Check the route map configuration.

	`DEV1# show ipv6 policy`
	`Balance mode: load-balance`
	`Interface Route map`
	`GigabitEthernet 0/3 RM_LOAD_PBR`
	`DEV1# show route-map`
	`route-map PBR-VRF-Selection, permit, sequence 10`
	`Match clauses:`
	`Set clauses:`

	ipv6 next-hop 2001::1 ipv6 next-hop 2002::1

1.5 Monitoring

Clearing

During device operation, running the **clear** command may cause service interruption due to key information loss.

Command	Description
clear ip pbr statistics [**interface** *if-name* | **local**]	Clears statistics about packets forwarded by IPv4 PBR.
clear ipv6 pbr statistics [**interface** *if-name* | **local**]	Clear statistics about packets forwarded by IPv6 PBR.

Displaying

Command	Description
show ip policy	Displays the IPv4 PBR configuration.
show ipv6 policy	Displays the IPv6 PBR configuration.
show route-map [*name*]	Displays the route map configuration.
show access-list	Displays the ACL configuration.
show ip pbr bfd	Displays correlation between IPv4 PBR and BFD.
show ipv6 pbr bfd	Displays correlation between IPv6 PBR and BFD.
show ip pbr route [**interface** *if-name* | **local**]	Displays routing information about IPv4 PBR.
show ipv6 pbr route [**interface** *if-name* | **local**]	Displays routing information about IPv6 PBR.
show ip pbr route-map *rmap-name*	Displays a route map used by IPv4 PBR.
show ipv6 pbr route-map *rmap-name*	Displays a route map used by IPv6 PBR.
show ip pbr statistics [**interface** *if-name* | **local**]	Displays statistics about IPv4 PBR.
show ipv6 pbr statistics [**interface** *if-name* | **local**]	Displays statistics about IPv6 PBR.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug pbr error	Debugs PBR errors.
debug pbr events	Debugs PBR events.
debug pbr ms	Debugs multiple service cards supported by PBR.
debug pbr msg	Debugs PBR message communication.
debug pbr nsm	Debugs interaction between PBR and NSM.
debug pbr packet	Debugs packet forwarding of PBR.
debug pbr restart	Debugs PBR GR.

1 Configuring Keys

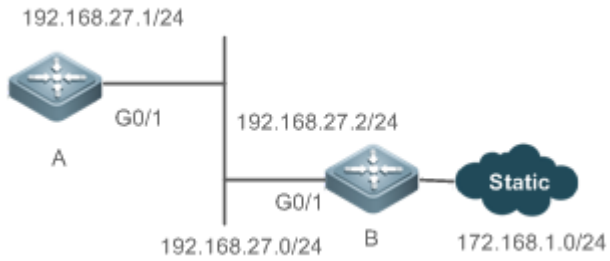
1.1 Overview

Keys are used in algorithms for conversion from cleartext to cipher text or from cipher text to cleartext.

Cleartext and cipher text authentication are supported for packet authentication in a routing protocol, during which keys need to be used.

Keys are used only for RIP packet authentication.

1.2 Applications



Application	Description
RIP Authentication	RIP uses keys for packet authentication.

1.2.1 RIP Authentication

Scenario

Network devices run RIP and use the MD5 authentication mode to improve protocol security.

Figure 1-1

Deployment

- Configure a keychain on A. Configure RIP to enable packet authentication and use the keychain.
- Configure a keychain on B. Configure RIP to enable packet authentication and use the keychain.

1.3 Features

Overview

Feature	Description
Keychain	Provides authentication in a routing protocol.

1.3.1 Keychain

Working Principle

A keychain may contain multiple different keys. Each key contains the following attributes:

- Key ID: Identifies a key. In the keychain, keys and IDs are mapped in one-to-one manner.
- Authentication string: Indicates a set of key characters used for verifying consistency of authentication strings in a routing protocol.
- Lifetime: Specifies the lifetime of the key for sending or receiving packets. Different authentication keys can be used in different periods.

Related Configuration

Creating a Keychain and a Key

In global configuration mode, run the **key chain** *key-chain-name* command to define a keychain and enter the keychain configuration mode.

In keychain configuration mode, run the **key** *key-id* command to define a key and enter the keychain key configuration mode.

Configuring an Authentication String

In keychain key configuration mode, run the **key-string** [**0** | **7**] *text* command to specify an authentication string.

- A cleartext authentication string is configured by default. The value 0 indicates that a cleartext authentication key is configured.
- The value 7 indicates that a cipher text authentication string is configured.
- The encryption authentication service is disabled by default. You can run the **service password-encryption** command to enable the encryption service to forcibly convert cleartext authentication into cipher text.

Configuring Lifetime

In the keychain key configuration mode, you can configure the lifetime of a keychain in receiving and sending directions.

- **accept-lifetime** *start-time* { **infinite |** *end-time* **| duration** *seconds* }: Configures the lifetime of a keychain in the receiving direction.
- **send-lifetime** *start-time* { **infinite |** *end-time* **| duration** *seconds* }: Configures the lifetime of a keychain in the sending direction.

1.4 Configuration

Configuration	Description and Command	
Configuring a Keychain	(Mandatory) It is used to create a key.	
	key chain	Creates a keychain.
	key	Configures a key ID.
	key-string	Configures a key string.
	accept-lifetime	Configures the lifetime in the receiving direction.

Configuration	Description and Command	
	send-lifetime	Configures the lifetime in the sending direction.

1.4.1 Configuring a Keychain

Configuration Effect

- Define a keychain to be used by a routing protocol.

Notes

- A keychain can take effect only when being associated with a routing protocol.

Configuration Step

Creating a Key Chain

- This configuration is mandatory if a keychain needs to be used.
- Unless otherwise required, perform this configuration on all routers for which routing protocol authentication needs to be performed.

Configuring a Key ID

- This configuration is mandatory if a keychain needs to be used.
- Unless otherwise required, perform this configuration on all routers for which routing protocol authentication needs to be performed.

Configuring a Key String

- This configuration is mandatory if a keychain needs to be used.
- Unless otherwise required, perform this configuration on all routers for which routing protocol authentication needs to be performed.

Configure the Lifetime in the Receiving Direction

- Optional.
- If the lifetime in the sending direction is not configured, the keychain will be always effective.

Configure the Lifetime in the Sending Direction

- Optional.
- If the lifetime in the sending direction is not configured, the keychain will be always effective.

Verification

- Use keys in a routing protocol and observe the neighbor relationship established by the routing protocol. If the keys are inconsistent, the neighbor relationship fails to be established.

Related Commands

Configuring a Key Chain

Command	**key chain** *key-chain-name*
Parameter Description	*key-chain-name*: Indicates the name of a keychain.
Command Mode	Global configuration mode
Usage Guide	To make a keychain take effect, you must configure at least one key.

Configuring a Key ID

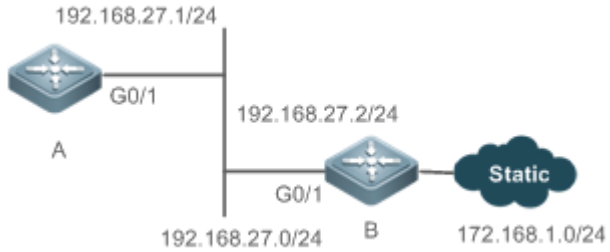
Command	**key** *key-id*
Parameter Description	*key-id*: Indicates the authentication key ID in a keychain. The value range is from 0 to 2147483647.
Command Mode	Keychain configuration mode.
Usage Guide	-

Configuring a Key Authentication String

Command	**key-string** [**0** | **7**] *text*
Parameter Description	**0**: Specifies that the key is displayed in cleartext. **7**: Specifies that the key is displayed in cipher text. *text*: Specifies the authentication character string.
Command Mode	Keychain key configuration mode.
Usage Guide	-

Configuring the Lifetime in the Sending Direction

Command	**send-lifetime** *start-time* {**infinite** | *end-time* | **duration** *seconds*}
Parameter Description	***start-time***: Indicates the start time of the lifetime. **infinite**: Indicates that the key is always effective. ***end-time***: Indicates the end time of the lifetime, which must be later than the start time. **duration *seconds***: Specifies the duration from the start time to the end time. The value range is from 1 to 2147483646.
Command Mode	Keychain key configuration mode.
Usage Guide	Run this command to define the lifetime of the key in the sending direction.



Configuring the Lifetime in the Receiving Direction

Command	**accept-lifetime** *start-time* **{infinite |** *end-time* **| duration** *seconds***}**
Parameter Description	***start-time***: Indicates the start time of the lifetime. **infinite**: Indicates that the key is always effective. ***end-time***: Indicates the end time of the lifetime, which must be later than the start time. **duration *seconds***: Specifies the duration from the start time to the end time. The value range is from 1 to 2147483646.
Command Mode	Keychain key configuration mode.

Usage Guide	Run this command to define the lifetime of the key in the receiving direction.

Configuration Example

Configuring a Keychain and Using the Keychain in RIP Packet Authentication

Scenario Figure 1-2	
Configuration Steps	● Configure a key on all routers. ● Configure RIP on all routers. ● Enable RIP authentication on all routers.
A	A>enable A#configure terminal A(config)#key chain ripchain A(config-keychain)#key 1 A(config-keychain-key)#key-string Hello A(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2013 duration 43200 A(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2013 duration 43200 A(config-keychain-key)#exit A(config-keychain)#key 2 A(config-keychain-key)#key-string World A(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 2013 infinite A(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2013 infinite A(config-keychain-key)#exit A(config)#interface gigabitEthernet 0/1 A(config-if)#ip address 192.168.27.1 255.255.255.0 A(config-if)#ip rip authentication key-chain ripchain A(config-if)#ip rip authentication mode md5 A(config-if)#exit A(config)#router rip A(config-router)#version 2 A(config-router)#network 192.168.27.0
B	B>enable B#configure terminal B(config)#key chain ripchain B(config-keychain)#key 1 B(config-keychain-key)#key-string Hello B(config-keychain-key)#accept-lifetime 16:30:00 Oct 1 2013 duration 43200 B(config-keychain-key)#send-lifetime 16:30:00 Oct 1 2013 duration 43200 B(config-keychain-key)#exit

	B(config-keychain)#key 2 B(config-keychain-key)#key-string World B(config-keychain-key)#accept-lifetime 04:00:00 Oct 2 2013 infinite B(config-keychain-key)#send-lifetime 04:00:00 Oct 2 2013 infinite B(config-keychain-key)#exit B(config)#interface gigabitEthernet 0/1 B(config-if)#ip address 192.168.27.2 255.255.255.0 B(config-if)#ip rip authentication key-chain ripchain B(config-if)#ip rip authentication mode md5 B(config-if)#exit B(config)#router rip B(config-router)#version 2 B(config-router)#network 192.168.27.0 B(config-router)#redistribute static
Verification	● Run the **show ip route rip** command to check whether router A can receive an RIP route from router B.
A	A(config)#show ip route rip R 172.168.0.0/16 [120/1] via 192.168.27.2, 00:05:16, GigabitEthernet 0/1

Common Errors

- A key is not correctly associated with a routing protocol, which causes an authentication failure.
- The keys configured on multiple routers are inconsistent, which causes an authentication failure.

1.5 Monitoring

Displaying

Command	Description
show key chain [*key-chain-name*]	Displays the configurations of a keychain.

Configuring Multicast

1. Configuring IPv4 Multicast Routing Configuration
2. Configuring IGMP Snooping

1 Configuring IPv4 Multicast Routing Configuration

1.1 Overview

IP multicasting is abstracted hardware multicasting and an extended multicast routing protocol on the standard IP network layer.

In traditional IP transmission, only one host can send packets to a single host (unicast communication) or all hosts (broadcast communication). However, the multicast technology provides the third choice: a host can send packets to certain specified hosts.

IP multicasting is applicable to one-to-many multimedia applications.

1.2 Monitoring

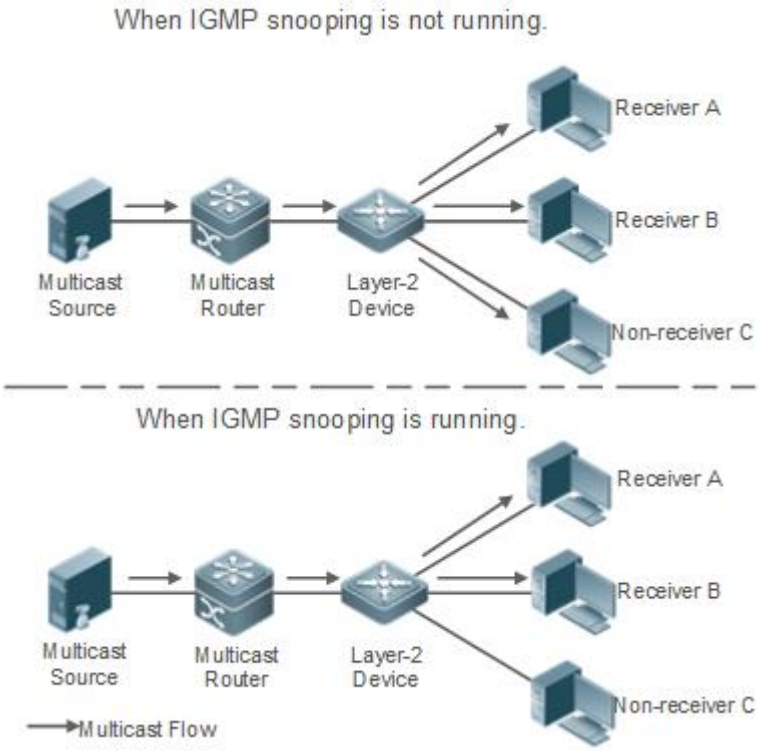
Displaying

Description	Command
Displays the IPv4 multicast non-stop forwarding configuration.	**show msf nsf**
Displays the IPv4 multi-layer multicast forwarding table.	**show msf msc**

Debugging

⚠ System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

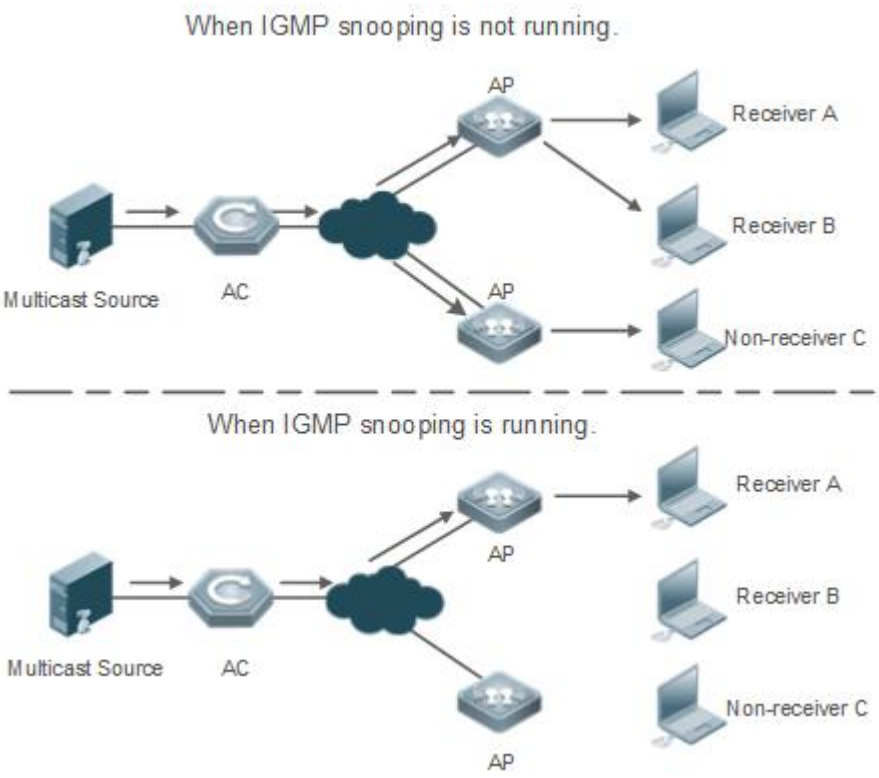
Description	Command
Debugs the processing of IPv4 multi-layer multicast packet forwarding.	**debug msf forwarding**
Debugs the operation on multi-layer multicast forwarding entries on an IPv4 network.	**debug msf mfc**
Debugs the bottom-layer hardware processing of IPv4 multi-layer multicast packet forwarding.	**debug msf ssp**
Debugs the invocation of API interfaces provided by IPv4 multi-layer multicast forwarding.	**debug msf api**
Debugs the processing of multi-layer multicast forwarding events on an IPv4 network.	**debug msf events**



1 Configuring IGMP Snooping

1.1 Overview

Internet Group Management Protocol (IGMP) snooping is a mechanism of listening to IP multicast. It is used to manage and control the forwarding of IP multicast traffic within VLANs, realizing Layer-2 multicasting.



As shown in the following figure, when a Layer-2 device is not running IGMP snooping, IP multicast packets are broadcasted within the VLAN; when the Layer-2 device is running IGMP snooping, IP multicast packets are transmitted only to profile members.

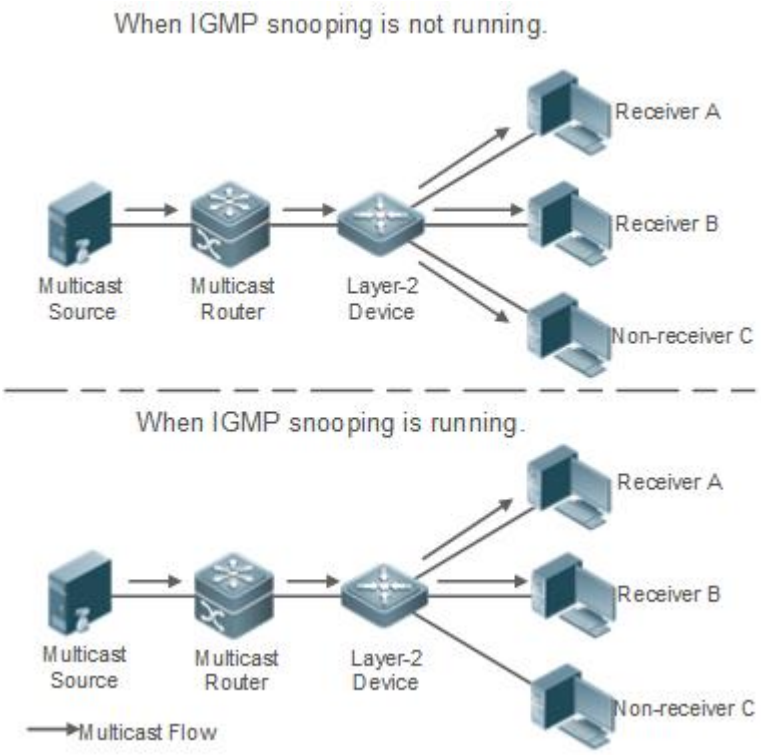
Figure 13-1 Networking Topology of IP Multicast Forwarding within the VLAN Before and After IGMP Snooping Is Run on the Layer-2 Device

As shown in the following figure, when IGMP Snooping does not run on the AC and AP in wireless multicast environment, multicast packets are broadcasted within the VLAN of the AC and are broadcasted by the AP to all wireless ports. When IGMP Snooping runs on both the AC and AP, multicast packets of a known multicast profile are not broadcasted but forwarded to specific receivers.

Figure 13-2 Forwarding of IP Multicast Streams in a VLAN Before and After IGMP Snooping Is Enabled on the AC and AP

Protocols and Standards

- RFC4541: Considerations for Internet Group Management Protocol (IGMP) and Multicast Listener Discovery (MLD) Snooping Switches



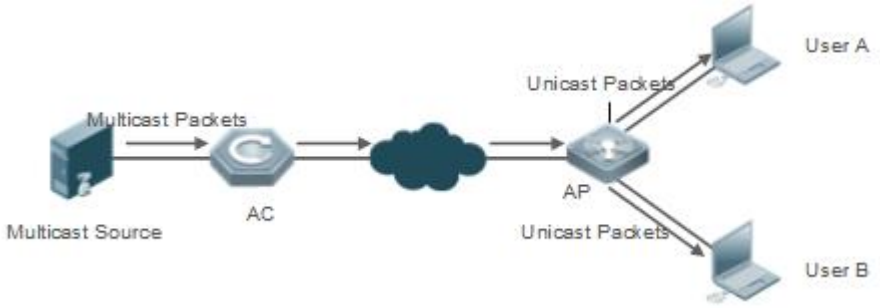
1.2 Applications

Application	Description
Layer-2 Multicast Control	Enables precise forwarding of Layer-2 multicast packets to avoid flooding at this layer.
Multicast-to-Unicast Conversion	Implements transmission of multicast packets between the AP and STAs in unicast mode.

1.2.1 Layer-2 Multicast Control

Scenario

- As shown in the following figure, multicast packets are transmitted to users through a Layer-2 switch. When Layer-2 multicast control is not performed, namely, when IGMP snooping is not implemented, multicast packets are flooded to all the users including those who are not expected to receive these packets. After IGMP snooping is implemented, the multicast packets from an IP multicast profile will no longer be broadcast within the VLAN but transmitted to designated receivers.
- Figure 13-3 Networking Topology of Implementing Layer-2 Multicast Control (Multicast VLAN)



Deployment

- Configure basic IGMP snooping functions.

1.2.2 Multicast-to-Unicast Conversion

Scenario

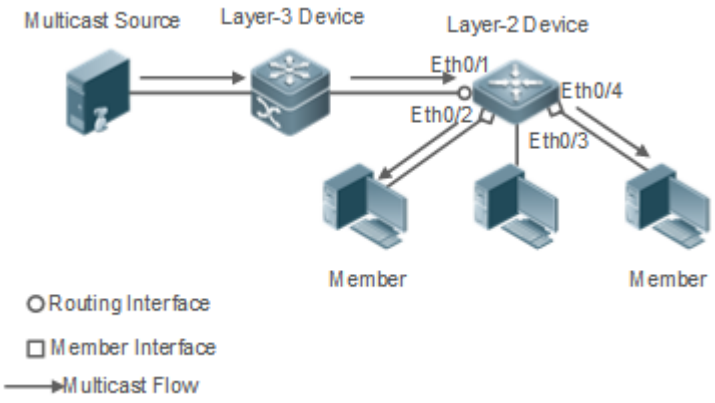
- When multicast-to-unicast conversion is not configured, packets are transmitted from the AP to STAs in multicast mode. There is no acknowledgement and retransmission mechanism for multicast packets in wireless networks. As a result, severe packet loss occurs, which affect experience of wireless multicast services in video on demand and other applications. Wireless multicast packets between the AP and STAs can be configured to be transmitted in multicast-to-unicast conversion mode in order to reduce the packet loss rate and enhance user experience.
- Figure 13-4 Multicast-to-Unicast Conversion

Deployment

- Configure the multicast-to-unicast conversion function.

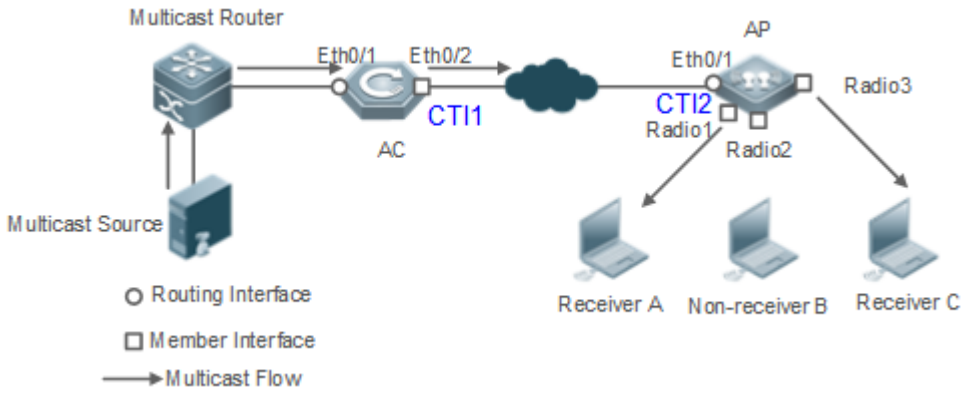
The function is available only in wireless multicast scenarios.

1.3 Features



Basic Concepts

Multicast Router Ports and Member Ports



IGMP snooping is VLAN-based. The ports involved refer to the member ports within the VLAN.

The device running IGMP snooping identifies the ports within the VLAN as a multicast router port or member port so as to manage and control the forwarding of IP multicast traffic within the VLAN. As shown in the following figure, when IGMP snooping is run on a Layer-2 device, multicast traffic enters the multicast router port and exits from the member ports.

Figure 13-5 Networking Topology of Two IGMP Snooping Ports

- Multicast router port: The location of the multicast source is directed by the port on the Layer-2 multicast device which is connected to the multicast router (Layer-3 multicast device): By listening to IGMP packets, the Layer-2 multicast device can automatically detect the multicast router port and maintain the port dynamically. It also allows users to configure a static router port.
- Member port: The port is on a Layer-2 multicast device and is connected to member hosts. It directs the profile members. It is also called the Listener Port. By listening to IGMP packets, the Layer-2 multicast device can automatically detect the member port and maintain the port dynamically. It also allows users to configure a static member port.
- Figure 13-6 Two Types of Ports in Wireless Environment

- Multicast router port: When the AC receives the PIM Hello or IGMP Query packet from the upstream multicast router (Layer-3 multicast device), the multicast router port Ethq/1 forms. When the AP receives the PIM Hello or IGMP Query packet forwarded by the AC, the multicast router port CTI2 also forms.
- Member port: also called listener port, that is, the port on a device for connecting to a multicast member. When Ports Radio1 and Radio3 on the AP receive Report packets from a wireless user receiver, they learn the wireless port as a member port. When the virtual interface CTI1 receives Report packets forwarded by the AP, it also learns the relevant wireless port as a member port.

IGMP Snooping Forwarding Entry

The device running IGMP snooping forwards IP multicast packets in accordance with the IGMP snooping forwarding entry.

An IGMP snooping forwarding entry includes the following items: source address (S), profile address (G), VLAN ID (VLAN_ID), multicast router port, and member port. It indicates that packets of required features (including S, G, and VLAN_ID) should enter the multicast router port and exit from a member port. An IGMP snooping forwarding entry is identified using a group of S, G, and VLAN_ID.

To display the IGMP snooping forwarding entry, run the **show ip igmp snooping gda-table** command.

```
Hostname# show ip igmp snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC  //Dynamic member port
  S: STATIC   //Static member port
  M: MROUTE   //Multicast router port (dynamic or static)
(*, 233.3.6.29, 1):   //(S: any; G: 233.3.6.29; VLAN_ID: VLAN 1)
  VLAN(1) 3 OPORTS:
    GigabitEthernet 0/3(S)

```

Overview

Feature	Description
Listening to IGMP Packets	Discovers and identifies the router port and member port to establish and maintain the IGMP snooping forwarding entries. :
IGMP Snooping Working Modes	Provides independent or shared multicast services to the user VLAN.
IGMP Querier	On a network without a Layer-3 multicast device, the Layer-2 multicast device acts as an IGMP querier.
Multicast-to-Unicast Conversion	Implements transmission of multicast packets between the AP and STAs in unicast mode.
Optimizing the Multicast Wireless Environment Configuration	Ignores port timer resetting for query packets.

1.3.1 Listening to IGMP Packets

A device running IGMP snooping analyzes IGMP packets received, and finds and identifies the router port and member port using these packets, thereby creating and maintaining an IGMP snooping entry.

Working Principle

A device running IGMP snooping can identify and handle the following types of IGMP packets:

Query Packets

An IGMP querier periodically sends General Query packets. When the IGMP querier receives Leave packets, it sends Group-Specific Query packets.

When the device running IGMP snooping receives the Query packets, it performs the following operations within the VLAN:

- Forward the IGMP Query packets to all the ports (except the receiving port of these packets).
- If the receiving port is a dynamic router port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- If the receiving port is not a dynamic router port, use it as a dynamic router port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic router port.
- If dynamic router port learning is disabled, IGMP snooping will not learn the dynamic router port.

Report Packets

When a member host receives a query, it responds to the query with a Report packet. If a host requests to join a profile, it will also send a report.

By default, IGMP Snooping is capable of processing IGMPv1 and IGMPv2 packets. For IGMPv3 Report packets, it processes profile information but does not process carried source information. IGMP Snooping v3 can be configured to process all information in IGMPv1, IGMPv2, and IGMPv3 packets.

When the device running IGMP snooping receives the Report packets, it performs the following operations within the VLAN:

- Forward the Report packets from all the router ports. After the **ip igmp snooping suppression enable** command is run in one IGMP query cycle, only the first report received by each profile will be forwarded.
- If the port on which Report packets are received is a dynamic member port, reset the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.
- If the port on which Report packets are received is not a dynamic member port, use it as a dynamic member port and enable the aging timer. If the timer expires, the port will no longer be used as the dynamic member port of the designated profile.

Leave Packets

If a host requests to leave a profile, it will send a Leave packet.

When the device running IGMP snooping receives the Leave packets, it performs the following operations within the VLAN:

- Forward the leave packets from all the router ports.
- If the port on which leave packets are received is a dynamic member port and the Leave function is enabled, the port will be immediately deleted from the IGMP snooping forwarding entry of the designated profile and will no longer be used as the dynamic member port.
- If the port on which the leave packets are received is a dynamic member port and the Leave function is disabled, the port state should be maintained.

Related Configuration

Configuring a Static Router Port

Run the **ip igmp snooping vlan mrouter interface** command to configure a static router port.

Configuring a Static Member Port

Run the **ip igmp snooping vlan static interface** command to configure a static member port.

Enabling Report Suppression

Report suppression is disabled by default.

Run the **ip igmp snooping suppression enable** command to enable report suppression.

After report suppression is enabled, in one IGMP query cycle, only the first Report packet received by each profile will be forwarded. The source media access control (MAC) address of the forwarded report will be changed to the MAC address of the device.

Enabling Immediate Leave

Immediate leave is disabled by default.

Run the **ip igmp snooping fast-leave enable** command to enable immediate leave.

Enabling Dynamic Router Port Learning

Dynamic router port learning is enabled by default.

Run the **no ip igmp snooping mrouter learn pim-dvmrp** command to disable dynamic router port learning.

Run the **no ip igmp snooping vlan** *vid* **mrouter learn pim-dvmrp** command to disable dynamic router port learning for designated VLANs.

Configuring the Aging Time of a Dynamic Member Port

The default aging time is 260s.

When a dynamic member port receives a Report packet, the aging timer of the port is enabled or reset, and the aging time is the maximum response time of the dynamic member port.

Run **ip igmp snooping host-aging-time** to configure the aging time of the dynamic member port.

Configuring the Maximum Response Time of a Query Packet

The maximum response time of a query packet is not configured by default and the maximum response time carries by the query packet is used.

Run **ip igmp snooping query-max-response-time** to configure the maximum response time of a query packet.

1.3.2 IGMP Snooping Working Modes

A device running in the IVGL mode of IGMP snooping can provide independent multicast services to the user VLAN.

Working Principle

IVGL

In IVGL mode, a device running IGMP snooping can provide independent multicast services to each user VLAN.

Independent multicast services indicate that multicast traffic can be forwarded only within the VLAN it belongs to, and a user host can subscribe to the multicast traffic within the VLAN that the host belongs to.

Related Configuration

Enabling IGMP Snooping and Selecting a Working Mode

IGMP snooping is disabled by default.

Run the **ip igmp snooping** command to enable IGMP snooping in IVGL mode.

1.3.3 IGMP Querier

On a network with a Layer-3 multicast device, the Layer-3 multicast device acts as an IGMP querier. In this case, a Layer-2 device needs only to listen to IGMP packets to establish and maintain the forwarding entry, realizing Layer-2 multicast.

On a network without a Layer-3 multicast device, the Layer-2 multicast device must be configured with the IGMP querier function so that the device can listen to IGMP packets. In this case, a Layer-2 device needs to act as an IGMP querier as well as listen to IGMP packets to establish and maintain the forwarding entry to realize Layer-2 multicast.

Working Principle

A Layer-2 device acts as an IGMP querier to periodically send IGMP Query packets, listen to and maintain the IGMP Report packets replied by a user, and create a Layer-2 multicast forwarding entry. You can adjust relevant parameters of the Query packets sent by the IGMP querier through configuration.

When the device receives a Protocol-Independent Multicast (PIM) or Distance Vector Multicast Routing Protocol (DVMRP) packet, it considers that a multicast router, which will act as an IGMP querier, exists on the network and disables the querier function. In this way, IGMP routing will not be affected.

When the device receives the IGMP Query packets from other devices, it will compete with other devices for the IGMP querier.

Enabling the Querier Function

You can enable the querier for a specific VLAN or all VLANs.

Only when the global querier function is enabled can the queriers for specific VLANs take effect.

Specifying the IGMP Version for a Querier

The version of IGMP used for sending Query packets can be configured as IGMPv1, IGMPv2, or IGMPv3.

Configuring the Source IP Address of a Querier

You can configure the source IP address of a query packet sent by the querier based on VLANs.

When the source IP address of the querier is not configured, the querier will not take effect.

Configuring the Query Interval of a Querier

You can configure the intervals for sending global Query packets based on different queriers on different VLANs.

Configuring the Maximum Response Time of a Query Packet

You can configure the maximum response time carried by a Query packet that is sent by a querier. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1. You can configure different maximum response time for queriers on different VLANs.

Configuring the Aging Time of a Querier

When other IGMP queriers exist on a network, the existing device will compete with other queriers. If the existing device fails to be elected and is in the non-querier state, the aging timer of a querier will be enabled. After the timer expires, other queriers on the network are considered as expired and the existing device will be resumed as the querier.

Related Configuration

Enabling the Querier Function

By default, the querier function of a device is disabled.

Run the **ip igmp snooping querier** command to enable the global querier function.

Run the **ip igmp snooping vlan** *num* **querier** command to enable the querier function for specific VLANs.

Specifying the IGMP Version for a Querier

By default, a querier runs IGMPv2.

Run the **ip igmp snooping querier version** command to configure the global querier version.

Run the **ip igmp snooping vlan querier version** command to specify the querier version for specific VLANs.

Configuring the Source IP Address of a Querier

By default, the source IP address of a querier is 0.

Run the ip igmp snooping querier address command to enable global source IP addresses of queriers.

Run the ip igmp snooping vlan querier address command to specify the source IP addresses of the queriers on specific VLANs.

Configuring the Query Interval of a Querier

By default, the query interval of a querier is 60s.

Run the **ip igmp snooping querier query-interval** command to enable the global query interval of queriers.

Run **ip igmp snooping vlan** *vid* **querier query-interval** to specify the global query interval of the queriers on specific VLANs.

Configuring the Maximum Response Time of a Query Packet

By default, the maximum response time of a query packet is 10s.

Run the **ip igmp snooping querier timer expiry** command to configure the maximum response time of the query packets sent by global queriers.

Run the **ip igmp snooping vlan queriertimer expiry** command to specify the maximum response time of the query packets sent by the queriers on specific VLANs.

Configuring the Aging Time of a Querier

By default, the aging time of a querier is 125s.

Run the **ip igmp snooping querier max-response-time** command to configure the aging time of global queriers.

Run the **ip igmp snooping vlan** *vid* **querier max-response-time** command to configure the aging time of queriers on specific VLANs.

1.3.4 Multicast-to-Unicast Conversion

The multicast-to-unicast conversion function is available only in wireless environment. After the function is configured on a wireless device, multicast packets between an AP and STAs are transmitted in unicast mode. The multicast-to-unicast conversion function runs on the AP.

Working Principle

The following describes the working principle of multicast-to-unicast conversion from several scenarios in wireless environment.

In fit AP centralized forwarding mode, an AC, according to recorded user information, queries the WLAN ID and RADIO ID of an STA for packets, conducts CAPWAP encapsulation on the packets, and then sends the packets to an AP. If the multicast-to-unicast conversion is enabled, packets sent to the AP are delivered to the wireless multicast fast forwarding module, which queries the interface of the multicast-to-unicast conversion module to learn about the users who need multicast-to-unicast conversion. Then, the AP transmits multicast packets in unicast mode.

In fit AP local forwarding mode, after packets are forwarded to an AP, if multicast-to-unicast conversion is enabled, the AP delivers the packets to the wireless multicast fast forwarding module, which transmit multicasts the packets in unicast mode.

Related Configuration

Enabling the Global Multicast Function

By default, the global multicast function is disabled. Run the **ip multicast wlan** command to enable the global multicast function. After global multicast is enabled, when an AC receives multicast packets, it conducts CAPWAP encapsulation on the multicast packets and sends the packets to the AP associated with the AC in CAPWAP unicast mode.

Run the **no ip multicast wlan** command to restore default configuration. After global multicast is disabled, an AC directly discards the received multicast packets.

Enabling Multicast-to-Unicast Conversion

By default, multicast-to-unicast conversion is disabled.

In ap-config mode on an AC, run the **igmp snooping mcast-to-unicast enable** command to enable multicast-to-unicast conversion.

In ap-config mode on an AC, run the **no igmp snooping mcast-to-unicast enable** command to disable multicast-to-unicast conversion, or on a fat AP.

Configuring the Multicast Range for Multicast-to-Unicast Conversion

By default, multicast-to-unicast conversion is available to all multicast profiles.

Use AC as an example. In ap-config mode, run the **igmp snooping mcast-to-unicast group-range** command to configure the profile address range for multicast-to-unicast conversion.

In ap-config mode, run the **no igmp snooping mcast-to-unicast group-range** command to restore the default configuration.

Configuring the Maximum Number of Profiles That Are Allowed to Use Multicast-to-Unicast Conversion

By default, multicast-to-unicast conversion can be configured for a maximum of 64 multicast profiles.

Use AC as an example. In ap-config mode, run the **igmp snooping mcast-to-unicast max-group** command to configure the maximum number of multicast profiles that are allowed to use multicast-to-unicast conversion.

In ap-config mode, run the **no igmp snooping mcast-to-unicast max-group** command to restore the default configuration.

1.3.5 Optimizing the Multicast Wireless Environment Configuration

Ignoring port timer resetting for query packets refers to not resetting the port aging timer when a device receives query packets.

When multiple STAs are configured in a congested wireless network, after an AP sends out a query packet, the IGMP report packet responded by STAs may be discarded or the STAs fail to receive the query packet, and as a result, the AP fails to receive responses from the STAs. Traffic interruption may occur on the STAs. In this case, this function can be configured, in combination with aging time configuration of member ports, to ensure that an STA does not age within multiple query intervals. If an IGMP report packet from the STA is received within the query intervals, the port timer time is reset as the port aging time.

The configuration takes effect when query packets are received next time. A port timer that has been reset on a port will not be cancelled. The configuration prolongs aging time. Use it in appropriate scenarios.

The function is disabled by default.

Use AC as an example. In ap-config mode, run the **igmp snooping ignore-query-timer** command to ignore the port aging timer resetting for query packets.

In ap-config mode, run the **no igmp snooping ignore-query-timer** command to restore the default configuration.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic IGMP Snooping Functions	⚠ It is used to enable IGMP snooping in IVGL mode.	
	ip igmp snooping	Enables global IGMP snooping on a Fat AP.
	no ip igmp snooping vlan *num*	Disables IGMP snooping for a VLAN.
Configuring the Packet Processing	⚠ (Optional) It is used to adjust relevant configurations for processing protocol packets.	
	ip igmp snooping vlan *vlan-id* **mrouter interface** *interface-type interface-number*	Configures a static router port.
	ip igmp snooping vlan *vid* **static** *group-address* **interface** *interface-type interface-number*	Configures a static member port.
	ip igmp snooping host-aging-time *time*	Configures the aging time of a dynamic member port.
	igmp snooping host-aging-time *time*	Configures the aging time of a dynamic member port.
	ip igmp snooping fast-leave enable	Enables the immediate-leave function for a dynamic member port.
	igmp snooping query-max-response-time *time*	Configures the maximum response time of an IGMP query packet.
	ip igmp snooping query-max-response-time *time*	Configures the maximum response time of an IGMP query packet.

	ip igmp snooping suppression enable	Enables IGMP Report packet suppression.
Configuring an IGMP Querier	⚠ (Optional) It is used to enable IGMP querier function on a network without a Layer-3 multicast device.	
	ip igmp snooping querier	Enables global querier function.
	ip igmp snooping vlan *vid* **querier**	Enables the querier for a VLAN.
	ip igmp snooping querier version *num*	Specifies the IGMP version for queriers globally.
	ip igmp snooping vlan *vid* **querier version** *num*	Specifies the IGMP version for a querier of a VLAN.
	ip igmp snooping querier address *ip-address*	Configures the source IP address of queriers globally.
	ip igmp snooping vlan *vid* **querier address** *ip-address*	Configures the source IP address for a querier of a VLAN.
	ip igmp snooping querier query-interval *num*	Configures the query interval of queriers globally.
	ip igmp snooping vlan *vid* **querier query-interval** *num*	Configures the query interval for a querier of a VLAN.
	ip igmp snooping querier max-response-time *num*	Configures the maximum response time for query packets globally.
	ip igmp snooping vlan *vid* **querier max-response-time** *num*	Configures the maximum response time of query packets for a VLAN.
	ip igmp snooping querier timer expiry *num*	Configures the aging timer for queriers globally.
	ip igmp snooping vlan *vid* **querier timer expiry** *num*	Configures the aging timer for a querier of a VLAN.
Configuring Multicast-to-Unicast Conversion	**igmp snooping mcast-to-unicast enable**	Enables multicast-to-unicast conversion.
	ip igmp snooping mcast-to-unicast enable	Enables multicast-to-unicast conversion.
	igmp snooping mcast-to-unicast group-range *ip-addr ip-addr*	Configures an AP's maximum multicast range for multicast-to-unicast conversion.
	ip igmp snooping mcast-to-unicast group-range *ip-address ip-address*	Configures an AP's maximum multicast range for multicast-to-unicast conversion.
	igmp snooping mcast-to-unicast max-group *group-num*	Configures an AP's maximum number of multicast profiles that are allowed to use multicast-to-unicast conversion.
	ip igmp snooping mcast-to-unicast max-group *group-num*	Configures an AP's maximum number of multicast profiles that are allowed to use multicast-to-unicast conversion.
Optimizing the Wireless Multicast Environment	**igmp snooping ignore-query-timer**	Configures the function of ignoring port aging timer resetting for query packets.

	ip igmp snooping ignore-query-timer	Configures the function of ignoring port aging timer resetting for query packets.

1.4.1 Configuring Basic IGMP Snooping Functions

Configuration Effect

- Enable IGMP snooping to realize Layer-2 multicast.
- Provide independent multicast services to each VLAN.

Configuration Steps

↘ Enabling Global IGMP Snooping in IVGL Mode

Mandatory.

After IGMP snooping is enabled globally, this function will be enabled for all VLANs.

↘ Disabling IGMP Snooping for a VLAN

(Optional) You can use this function if you wish to disable IGMP snooping on specified VLANs.

Only when global IGMP snooping is enabled can it be disabled on specified VLANs.

In IVGL mode, each VLAN can enjoy independent multicast services. Disabling any VLAN multicast services will not interfere in the services provided to the others.

Verification

- Run the **show ip igmp snooping gda-table** command to display the IGMP snooping forwarding table and verify that the member ports include only those connecting member hosts.
- Run the **show ip igmp snooping** command to display the basic IGMP snooping information and verify that IGMP snooping is working in IVGL mode.

Related Commands

↘ Enabling Global IGMP Snooping on a Fat AP

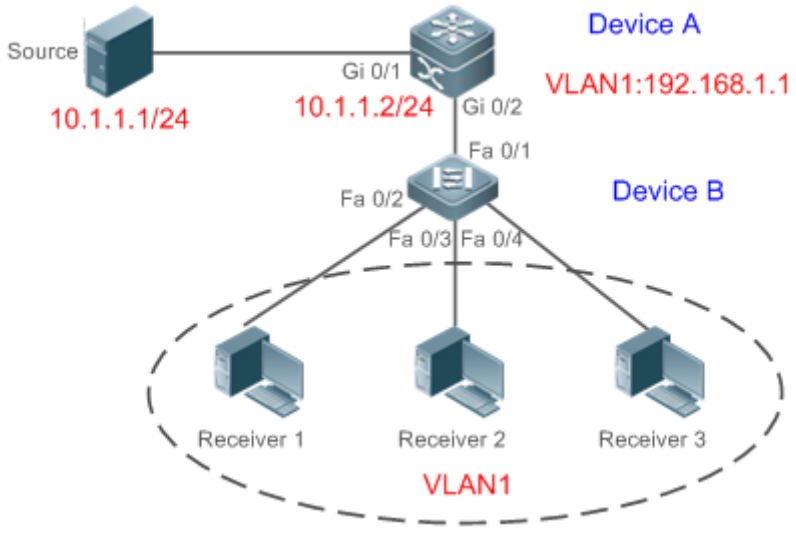
Command	**ip igmp snooping**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	After this command is executed, IGMP snooping will be run on all VLANs. By default, IGMP snooping is disabled.

↘ Disabling IGMP Snooping for a VLAN

Command	**no ip igmp snooping vlan** *num*
Parameter Description	N/A
Command	Global configuration mode

Mode	
Usage Guide	Only when global IGMP snooping is enabled can it be disabled on specified VLANs. In IVGL mode, you can disable IGMP snooping on any VLAN.

Displaying the IGMP Snooping Entry



Command	**show ip igmp snooping gda-table**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	This command is used to verify that the ports include only those connecting member hosts.

Displaying the IGMP Snooping Working Mode

Command	**show ip igmp snooping**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If a device is running in IVGL mode, the following information is displayed: `IGMP Snooping running mode: IVGL`

Configuration Example

Providing Layer-2 Multicast Services for the Subnet Hosts

Scenario **Figure 1-7**	
	A is the multicast router and is connected directly to the multicast source. B is the Layer-2 device and is connected directly to the user host. Receiver 1, Receiver 2, and Receiver 3 belong to VLAN 1.
Configuration Steps	● Configure the IP address and VLAN. ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1

	and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode.
A	A# configure terminal A(config)# ip multicast-routing A(config)# interface gigabitethernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit
B	B# configure terminal B(config)# ip igmp snooping
Verification	Send packets from the source (10.1.1.1) to G (229.1.1.1) to add Receiver 1 to G. ● Confirm that the packets (10.1.1.1 and 229.1.1.1) are received by Receiver 1. ● Display the IGMP snooping forwarding entry on B and ensure that the port (10.1.1.1, 229.1.1.1, 1) includes only Fa0/2. ● Check whether the IGMP snooping working mode is IVGL.
B	B# show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*,224.1.1.1, 1): VLAN(1) 2 OPORTS: FastEthernet 0/1(M) FastEthernet 0/2(D) B# show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Global Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds) vlan 1 ------------- IGMP Snooping state: Enable

	Multicast router learning mode: pim-dvmrp IGMP Fast-Leave: Disabled IGMP VLAN querier: Disable IGMP VLAN Mode: STATIC

Common Errors

- The working mode of IGMP snooping is improper.

1.4.2 Configuring the Packet Processing

Configuration Effect

- Configure specified ports as the static router ports to receive the multicast traffic from all profiles.
- Configure specified ports as the static member ports to receive the multicast traffic from specified profiles
- Enable Report packets suppression to forward only the first Report packet from a specified VLAN or profile to the router port within a query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network.
- Configure the immediate-leave function to delete a port from the entry of member ports when a leave packet is received by the port.
- Disable dynamic router port learning to disable the learning of any router port.
- Based on network load and configuration of a multicast device, you can adjust the aging time of a router port and member port as well as the maximum response time of a query packet.

Notes

- Only when basic IGMP snooping is configured can relevant configurations take effect.

Configuration Steps

↘ Configuring a Static Router Port

- Optional.
- You can perform this configuration if you want to specify a static port to receive all the multicast traffic within the VLAN.

↘ Configuring a Static Member Port

- Optional.
- You can perform this configuration if you want to specify a static port to receive specific multicast traffic within the VLAN.

↘ Enabling Report Packet Suppression

- Optional.
- When there are numerous receivers to receive the packets from the same multicast profile, you can enable Report packets suppression to suppress the number of Report packets to be sent.

Enabling the Immediate-Leave Function

- Optional.
- When there is only one receiver on a port, you can enable Leave to speed up the convergence of protocol upon leave.

Configuring the Aging Time of a Dynamic Member Port

- Optional.
- The aging time can be adjusted according to the IGMP query packet sending interval of the connected multicast routing device, which is generally set as the IGMP query packet sending interval *2 + IGMP last query response time of the multicast routing device.

Configuring the Maximum Response Time of a Query Packet

- Optional.
- You can configure the aging time based on network load.

Verification

- Run the **show ip igmp snooping mrouter** command to check whether the configured static router port has an "S" in the displayed configuration information.
- Run the **show ip igmp snooping gda** command to check whether the configured static member port is marked with an S.
- Run the **show ip igmp snooping** command to check whether Report packets suppression, immediate leave, router port learning, router port aging time, member port aging time, and the maximum response time of the Query packet take effect.

Related Commands

Configuring a Static Router Port

Command	**ip igmp snooping vlan** *vid* **mrouter interface** *interface-type interface-number*
Parameter Description	*vid*: Indicates a VLAN. The value ranges from 1 to 4,094. *interface-type interface-number*: Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	In IVGL mode, the configurations for the static router ports within all the VLANs can take effect.

Configuring a Static Member Port

Command	**ip igmp snooping vlan** *vid* **static** *group-address* **interface** *interface-type interface-number*
Parameter Description	*vid*: Indicates a VLAN. The value ranges from 1 to 4,094. *group-address*: Indicates a profile address. *interface-type interface-number*: Indicates an interface name.
Command Mode	Global configuration mode
Usage Guide	By default, no static member port is configured.

Enabling Report Packet Suppression

Command	**ip igmp snooping suppression enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When Report packets suppression is enabled, only the first Report packet from a specified VLAN or profile is forwarded to the router port within a Query interval, and the following Report packets will not be forwarded to the router port, thereby reducing the quantity of packets on the network. Only the IGMPv1 and IGMPv2 Report packets can be suppressed, and the IGMPv3 Report packets cannot be suppressed.

Enabling the Immediate-Leave Function

Command	**ip igmp snooping fast-leave enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	When this function is enabled, a port will be deleted from the entry of the member port when the port receives a leave packet. After that, the packets will no longer be forwarded to this port when it receives the query packets of specified profiles. Leave packets include the IGMPv2 Leave packets as well as the IGMPv3 Report packets that include types but carry no source address. The immediate-leave function applies only to the scenario where only one host is connected to a device port. It is used to conserve bandwidth and resources.

Configuring the Aging Time of a Dynamic Member Port

Command	**ip igmp snooping host-aging-time** *seconds*
Parameter Description	*seconds*: Indicates the aging time.
Command Mode	Global configuration mode
Usage Guide	The aging time of a dynamic member port indicates the time when a device port receives the IGMP join packet sent from host for subscribing to an IP multicast profile. When the IGMP join packet is received, the aging time of the dynamic member port will be reset. The value of the timer time is host-aging-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. After the aging time is configured, the aging time of following received IGMP join packets will be host-aging-time. This configuration takes effect after the next IGMP join packet is received, and the timer of the port in use will not be refreshed.

Configuring the Maximum Response Time of a Query Packet

Command	**ip igmp snooping query-max-response-time** *seconds*
Parameter	*seconds*: Indicates the maximum response time.

Description	
Command Mode	Global configuration mode
Usage Guide	When an IGMP general Query packet is received, the multicast device will reset the aging time of all the dynamic member ports, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. When an IGMP profile-specific Query packet is received, the multicast device will reset the aging time of all the dynamic member ports of the specific profile, which is query-max-response-time. If the timer expires, the multicast device deems that no user host for receiving the multicast packet exists under the port, and will delete the port from the entry of IGMP snooping member port. This configuration takes effect after the next Query packet is received, and the timer in use will not be refreshed. The timer of an IGMPv3 profile-specific Query packet is not refreshed.

Displaying Router Ports

Command	**show ip igmp snooping mroute**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	If the router port is successfully configured, an "S" will be displayed in the port information.
	`Hostname(config)#show ip igmp snooping mrouter`
	`Multicast Switching Mroute Port`
	`  D: DYNAMIC`
	`  S: STATIC`
	`(*, *, 1):`
	`  VLAN(1)  1 MROUTES:`
	`    GigabitEthernet 0/1(S)`

Displaying the Information of Dynamic Router Port Learning

Command	**show ip igmp snooping**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	Run the **show ip igmp snooping** command to display the aging time and learning status of the dynamic router port.
	`Dynamic Mroute Aging Time : 300(Seconds)`
	`Multicast router learning mode: pim-dvmrp`

Displaying the Information of a Member Port

Command	**show ip igmp snooping gda-table**
Parameter Description	N/A

Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	If the member port is successfully configured, an "S" will be displayed in the port information.
	`Hostname(config)#show ip igmp snooping gda-table`
	`Multicast Switching Cache Table`
	`D: DYNAMIC`
	`S: STATIC`
	`M: MROUTE`
	`(*, 224.1.1.1, 1):`
	`VLAN(1) 1 OPORTS:`
	`GigabitEthernet 0/1(S`

Displaying Other Parameters

Command	**show ip igmp snooping**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode

Usage Guide	Run the **show ip igmp snooping** command to display the aging time of the router port, aging time of the dynamic member port, response time of the query packet, and Report packets suppression, and immediate leave.
	`IGMP Fast-Leave: Enable`
	`IGMP Report suppress: Enable`
	`Query Max Response Time: 20(Seconds)`
	`Dynamic Mroute Aging Time : 300(Seconds)`
	`Dynamic Host Aging Time : 260(Seconds)`

Configuration Example

Configuring a Static Router Port and Static Member Port

Configuration Steps	● Configure basic IGMP snooping functions. ● Configure a static router port and static member port.

	`Hostname# configure terminal`
	`Hostname(config)# ip igmp snooping vlan 1 mrouter interface gigabitethernet 0/0`
	`Hostname(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface gigabitethernet 0/0`
	`Hostname(config)# end`

Verification	Run the **show ip igmp snooping mrouter** and **show ip igmp snooping gda-table** commands to check whether the configuration takes effect.

	`Hostname#show ip igmp snooping mrouter`
	`Multicast Switching Mroute Port`
	`D: DYNAMIC`
	`S: STATIC`

Configuration Steps	● Configure basic IGMP snooping functions. ● Configure a static router port and static member port.
	Hostname# configure terminal Hostname(config)# ip igmp snooping vlan 1 mrouter interface gigabitethernet 0/0 Hostname(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface gigabitethernet 0/0 Hostname(config)# end
Verification	Run the **show ip igmp snooping mrouter** and **show ip igmp snooping gda-table** commands to check whether the configuration takes effect.
	(*, *, 1): VLAN(1) 1 MROUTES: GigabitEthernet 0/0(S) Hostname#show ip igmp snooping gda-table Multicast Switching Cache Table D: DYNAMIC S: STATIC M: MROUTE (*, 224.1.1.1, 1): VLAN(1) 1 OPORTS: GigabitEthernet 0/0(SM)

Enabling Report Packet Suppression

Scenario **Figure 1-8**	
	A is the multicast router and is connected directly to multicast Source 1. B is a Layer-2 device and is connected directly to the user host and multicast Source 2. Receiver 1, Receiver 2, and Receiver 3 are connected to VLAN 1.
Configuration Steps	● Configure the IP address and VLAN. (Omitted) ● Enable multicast routing on A and enable the multicast routing protocol on Layer-3 interface (Gi0/1 and VLAN 1). ● Enable IGMP snooping on B and select IVGL mode.

	● Enable Report packets suppression on B.
A	A# configure terminal A(config)# ip multicast-routing A(config)# interface gigabitethernet 0/1 A(config-if-GigabitEthernet 0/1)# ip pim sparse-mode A(config-if-GigabitEthernet 0/1)# exit A(config)# interface vlan 1 A(config-if-VLAN 1)# ip pim sparse-mode A(config-if-VLAN 1)# exit
B	B# configure terminal B(config)#ip igmp snooping ivgl B(config)# ip igmp snooping suppression enable
Verification	Check whether Receiver 1 and Receiver 2 are added to profile 239.1.1.1, and only the IGMP Report packets of profile 239.1.1.1 are forwarded from interface Gi0/1 of B.
B	B# show ip igmp snooping IGMP Snooping running mode: IVGL IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Enable IGMP Globle Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Snooping version: 2 IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)

↘ Configuring Other Parameters

Configuration Steps	● Configure basic IGMP snooping functions. ● Enable Immediate-leave function. ● Disable router port learning. ● Configure the aging time of a router port. ● Configuring the aging time of a member port. ● Configure the response time of a Query packet.
	Hostname# configure terminal Hostname(config)# ip igmp snooping fast-leave enable Hostname(config)#ip igmp snooping dyn-mr-aging-time 200 Hostname(config)#ip igmp snooping host-aging-time 100 Hostname(config)#ip igmp snooping query-max-response-time 60 Hostname(config)# end
Verification	Run the **show ip igmp snooping** command to check whether the configuration is successful.
	Hostname#show ip igmp snooping

```
IGMP Snooping running mode: IVGL
IGMP Snooping L2-entry-limit: 65536
Source port check: Disable
Source ip check: Disable
IGMP Fast-Leave: Enable
IGMP Report suppress: Enable
IGMP Globle Querier: Disable
IGMP Preview: Disable
IGMP Tunnel: Disable
IGMP Snooping version: 2 Query Max Response Time: 60(Seconds)
IGMP Preview group aging time : 60(Seconds)
Dynamic Mroute Aging Time : 200(Seconds)
Dynamic Host Aging Time : 100(Seconds)
```

Common Errors

- Basic IGMP snooping functions are not configured or the configuration is not successful.

1.4.3 Configuring an IGMP Querier

Configuration Effect

- Configure the device as an IGMP querier, which will send IGMP Query packets periodically and collect user demanding information.

Notes

- Basic IGMP snooping functions must be configured.

Configuration Steps

↘ Enabling the Querier Function

- (Optional) Enable IGMP querier function globally or for a specified VLAN.
- (Optional) Disable the IGMP querier function for a specified VLAN.

↘ Configuring the Source IP Address of a Querier

- (Optional) You can configure the source IP address of a Query packet sent by the querier based on VLANs.
- After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect.

↘ Configuring the Maximum Response Time of a Query Packet

- (Optional) Adjust the maximum response time carried by an IGMP Query packet. As IGMPv1 does not support the carrying of maximum response time by a Query packet, this configuration does not take effect when the querier is running IGMPv1.

↘ Configuring the Query Interval of a Querier

- (Optional) Adjust the interval of the IGMP querier for sending query packets.

Configuring the Aging Timer of a Querier

- (Optional) Configure the aging timer of other IGMP queriers on the network.

Specifying the IGMP Version for a Querier

- (Optional) Specify the IGMP version for a querier (IGMPv2 by default).

Verification

- Run the **show ip igmp snooping querier detail** command to check whether the configuration takes effect.

Related Commands

Enabling the IGMP Querier Function

Command	**ip igmp snooping** [**vlan** *vid*] **querier**
Parameter Description	**vlan** *vid*: Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	IGMP querier for a specified VLAN will take effect only after global IGMP querier is enabled. If global IGMP querier is disabled, IGMP querier for all the VLANs will be disabled.

Configuring the Source IP Address of a Querier

Command	**ip igmp snooping** [**vlan** *vid*] **querier address** *ip-address*
Parameter Description	**vlan** *vid*: Specifies a VLAN. This configuration applies to all VLANs by default. *ip-address*: Indicates the source IP address.
Command Mode	Global configuration mode
Usage Guide	After a querier is enabled, a source IP address must be specified for the querier; otherwise, the configuration will not take effect. If the source IP address is specified by a VLAN, the address will be used preferentially.

Configuring the Maximum Response Time of a Querier

Command	**ip igmp snooping** [**vlan** *vid*] **querier max-response-time** *seconds*
Parameter Description	**vlan** *vid*: Specifies a VLAN. This configuration applies to all VLANs by default. *seconds*: Indicates the maximum response time. in the unit of seconds. The value ranges from 1 to 25.
Command Mode	Global configuration mode
Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

Configuring the Query Interval of a Querier

Command	**ip igmp snooping** [**vlan** *vid*] **querier query-interval** *seconds*
Parameter Description	**vlan** *vid*: Specifies a VLAN. This configuration applies to all VLANs by default. *seconds*: Indicates the query interval in the unit of seconds. The value ranges from 1 to 18,000.
Command Mode	Global configuration mode

Usage Guide	If the query interval is specified by a VLAN, the value will be used preferentially.

Configuring the Aging Timer of a Querier

Command	**ip igmp snooping** [**vlan** *vid*] **querier timer expiry** *seconds*
Parameter Description	**vlan** *vid*: Specifies a VLAN. This configuration applies to all VLANs by default. *seconds*: Indicates the timeout time in the unit of seconds. The value ranges from 60 to 300.
Command Mode	Global configuration mode
Usage Guide	A device may fail to be elected as the querier even when its querier function is enabled. If a device that fails to be elected does not receive the Query packet sent by the querier in the aging time, the querier in use is considered as expired, and a new round of election will be raised. If the aging time is specified by a VLAN, the value will be used preferentially.

Specifying the IGMP Version for a Querier

Command	**ip igmp snooping** [**vlan** *vid*] **querier version** { **1** | **2** }
Parameter Description	**vlan** *vid*: Specifies a VLAN. This configuration applies to all VLANs by default.
Command Mode	Global configuration mode
Usage Guide	A querier can be run in IGMPv1 and IGMPv2 (IGMPv2 by default). You can also run a command to configure the version to IGMPv1. If the IGMP version for a querier is specified by a VLAN, the version will be used preferentially.

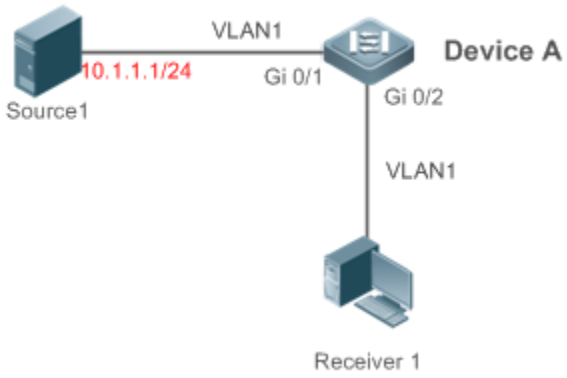
Displaying the IGMP Querier Configuration

Command	**show ip igmp snooping querier detail**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, or interface configuration mode
Usage Guide	If QinQ is enabled, the following content is displayed.

```
Hostname#show ip igmp snooping querier detail
Vlan     IP Address          IGMP Version          Port
-----------------------------------------------------------

Global IGMP switch querier status
-----------------------------------------------------------
admin state                 : Enable
admin version               : 2
source IP address           : 1.1.1.1
query-interval (sec)        : 60
max-response-time (sec)     : 10
querier-timeout (sec)       : 125

Vlan 1:   IGMP switch querier status
```



```
-----------------------------------------------------
admin state                 : Disable
admin version               : 2
source IP address           : 1.1.1.1
query-interval (sec)        : 60
max-response-time (sec)     : 10
querier-timeout (sec)       : 125
operational state           : Disable
operational version         : 2
```

Configuration Example

↘ Enabling the IGMP Querier Function

Scenario

Figure 13-9

In the scenario without Layer-3 multicast equipment, the multicast traffic can be forwarded only on the Layer-2 network.

A acts as a Layer-2 device to connect to the multicast source and receiver.

Configuration Steps

- Enable global IGMP snooping on A in IVGL mode.
- Enable IGMP querier for VLAN 1 on A.

A

```
A(config)#ip igmp snooping ivgl
A(config)#ip igmp snooping querier
A(config)#ip igmp snooping querier address 10.1.1.1
A(config)#ip igmp snooping vlan 1 querier
```

Verification

Run the **show ip igmp snooping querier** command to check whether the querier of VLAN 1 takes effect.

A

```
A(config)#show ip igmp snooping querier
Vlan     IP Address          IGMP Version          Port
-----------------------------------------------------------
1        10.1.1.1              2                 switch

A(config)#show ip igmp snooping querier vlan 1

Vlan 1:   IGMP switch querier status
```

```
-------------------------------------------------------
elected querier is 10.1.1.1        (this switch querier)
-------------------------------------------------------
admin state                  : Enable
admin version                : 2
source IP address            : 10.1.1.1
query-interval (sec)         : 60
max-response-time (sec)      : 10
querier-timeout (sec)        : 125
operational state            : Querier
operational version          : 2
```

Common Errors

- The source IP address is not configured for the querier and the querier does not take effect.

1.4.4 Configuring Multicast-to-Unicast Conversion

Configuration Effect

- Enable the multicast-to-unicast conversion on the AP, which transmits multicast packets to STAs in unicast mode.

Notes

- IGMP Snooping basic functions must be configured.

Configuration Steps

Enabling Global Multicast

- (Mandatory) Enable global multicast in global mode.
- If global multicast is disabled in global mode, a device directly discards received packets.

Enabling Multicast-to-Unicast Conversion

- (Optional) Configure whether to enable multicast-to-unicast conversion. After multicast-to-unicast conversion is enabled, after packets reach the AP, the AP judges the multicast packets that need to be transmitted in unicast mode and transmits such packets in unicast mode.

Configuring the Multicast Range for Multicast-to-Unicast Conversion

- (Optional) Multicast-to-unicast conversion is available to all multicast groups by default. A multicast range can be configured to allow multicast packets to be transmitted in unicast mode, so as to utilize AP resources to the maximum extent.

Configuring the Maximum Number of Multicast Profiles that Are Allowed to Use Multicast-to-Unicast Conversion

- (Optional) The maximum number of multicast profiles that are allowed to use multicast-to-unicast conversion can be adjusted.
- It is used in combination with the multicast range of multicast-to-unicast conversion.

Verification

- Run the show ip igmp snooping command to check whether the configuration takes effect.

Related Commands

Configuring Global Multicast

Command	**ip multicast wlan**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	If global multicast is enabled, multicast packets are processed only after they reach the AC. If global multicast is disabled, the AC directly discards the received multicast packets.

Configuring Multicast-to-Unicast Conversion

Command	**igmp snooping mcast-to-unicast enable**
Parameter Description	N/A
Command Mode	ap-config mode
Usage Guide	After multicast-to-unicast conversion is enabled, when multicast packets reach the AP, the AP judges the multicast packets that need to be transmitted in unicast mode according to the multicast-to-unicast conversion policy.

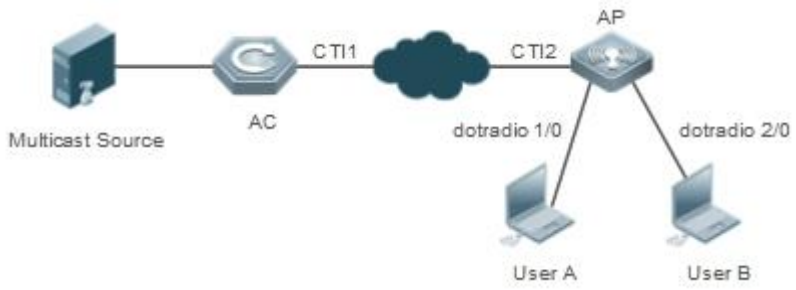
Configuring the Maximum Multicast Range for Multicast-to-Unicast Conversion

Command	**igmp snooping mcast-to-unicast group-range** *ip-address ip-address*
Parameter Description	*ip-address:* Indicates the multicast profile range. The value must be valid multicast addresses and ranges from 224.0.1.0 to 239.255.255.255.
Command Mode	Ap-config mode on the AC or global configuration mode on the fat AP
Usage Guide	If the multicast range of multicast-to-unicast conversion is not configured, multicast-to-unicast conversion is available to all multicast profiles by default.

Configuring the Maximum Number of Multicast Profiles That Are Allowed to Use Multicast-to-Unicast Conversion

Command	**igmp snooping mcast-to-unicast max-group** *number*
Parameter Description	number: Indicates the maximum number of multicast profiles that are allowed to use multicast-to-unicast conversion. The value ranges from 1 to 64. The default value is 64.
Command Mode	ap-config mode on the AC or global configuration mode on the fat AP
Usage Guide	It can be used in combination with the maximum multicast range of multicast-to-unicast conversion so as to properly allocate bandwidth and effectively control AP resources.

Displaying Multicast-to-Unicast Conversion Configuration



Command	show ip igmp snooping
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode

Usage Guide	If multicast-to-unicast conversion is configured successfully, the following information is displayed:
	`Hostname# sh ip igmp snooping`
	`WLAN Multicast: Enable`
	`IGMP Snooping running mode: IVGL`
	`IGMP Snooping M2U-Forward: Enable`
	`IGMP Snooping Support M2U Max-Group Num: 64`
	`IGMP Snooping M2U Group range: 233.3.3.1-233.3.3.64`
	`IGMP Snooping L2-entry-limit: 65536`
	`Source port check: Disable`
	`Source ip check: Disable`
	`IGMP Fast-Leave: Disable`
	`IGMP Report suppress: Disable`
	`IGMP Global Querier: Disable`
	`IGMP Preview: Disable`
	`IGMP Tunnel: Disable`
	`IGMP Preview group aging time : 60(Seconds)`
	`Dynamic Mroute Aging Time : 300(Seconds)`
	`Dynamic Host Aging Time : 260(Seconds)`

Configuration Example

The following configuration example describes only configurations related to IGMP Snooping.

Enabling the IGMP Querier

Scenario Figure 1-10	
	Multicast streams only need to be forwarded at Layer 2 in network deployment and there is no device supporting the Layer-3 multicast function in the network. User A and User B are multicast receivers.
Configuration Steps	● Enable IGMP Snooping on the AC. ● Enable global multicast on the AC. ● Enable IGMP Snooping in global configuration mode.

	● Enable multicast-to-unicast conversion in ap-config mode. ● Configure the maximum multicast range for multicast-to-unicast conversion in ap-config mode. ● Configure the maximum number of multicast profiles that are allowed to support multicast-to-unicast conversion in ap-config mode.
A	A(config)# ip igmp snooping A(config)# ip multicast wlan A(config)# ip igmp snooping A(config)# ap-confing all A(config-ap)# igmp snooping mcast-to-unicast enable A(config-ap)# igmp snooping mcast-to-unicast group-range 233.1.1.1 233.255.255.255 A(config-ap)# igmp snooping mcast-to-unicast max-group 10
Verification	Run the **show ip igmp snooping** command to check whether the configuration takes effect.
A	A# sh ip igmp snooping WLAN Multicast: Enable IGMP Snooping running mode: IVGL IGMP Snooping M2U-Forward: Enable IGMP Snooping Support M2U Max-Group Num: 64 IGMP Snooping M2U Group range: 233.3.3.1-233.3.3.64 IGMP Snooping L2-entry-limit: 65536 Source port check: Disable Source ip check: Disable IGMP Fast-Leave: Disable IGMP Report suppress: Disable IGMP Global Querier: Disable IGMP Preview: Disable IGMP Tunnel: Disable IGMP Preview group aging time : 60(Seconds) Dynamic Mroute Aging Time : 300(Seconds) Dynamic Host Aging Time : 260(Seconds)

Common Errors

- Multicast packets are not processed because global multicast is not configured.

1.4.5 Optimizing the Wireless Multicast Environment

Configuration Effect

- Configure the function of ignoring port timer resetting for query packets on the device.

Notes

- IGMP Snooping basic functions must be configured.

Configuration Steps

↘ **Configuring the Function of Ignoring Port Aging Timer Resetting for Query Packets**

- (Optional) Configure the function of ignoring port aging timer resetting for query packets so that the port does not age within multiple query intervals.

Verification

- Run the **show ip igmp snooping** command to check whether the configuration takes effect.

Related Commands

Configuring the Function of Ignoring Port Aging Timer Resetting for Query Packets

Command	Ip igmp snooping ignore-query-timer
Parameter Description	N/A
Command Mode	Global configuration mode or ap-config mode
Usage Guide	After the function of ignoring port aging timer for query packets is configured, the port does not age within multiple query intervals. When the port receives a Report request, the port aging timer resets.

1.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Description	Command
Clears the dynamic router ports and member ports.	**clear ip igmp snooping gda-table**

Displaying

Description	Command
Displays basic IGMP snooping configurations.	**show ip igmp snooping** [**vlan** *vlan-id*]
Displays the router ports.	**show ip igmp snooping mrouter**
Displays the IGMP snooping entries.	**show ip igmp snooping gda-table**
Displays the IGMP querier.	**show ip igmp snooping querier** [**detail**]
Displays user information.	**show ip igmp snooping user-info**
Displays the global switch of wireless multicast.	**show ip multicast wlan**

Debugging

System resources are occupied when debugging information is output. Therefore, disable debugging immediately after use.

Description	Command
Debugs all IGMP Snooping functions.	**debug igmp-snp**

Debugs the IGMP snooping events.	**debug igmp-snp event**
Debugs the IGMP snooping packets.	**debug igmp-snp packet**
Debugs the communications between IGMP snooping and MSF.	**debug igmp-snp msf**
Debugs the IGMP snooping alarms.	**debug igmp-snp warning**

Configuring AP Management

1. Configuring CAPWAP

1 Configuring CAPWAP

1.1 Overview

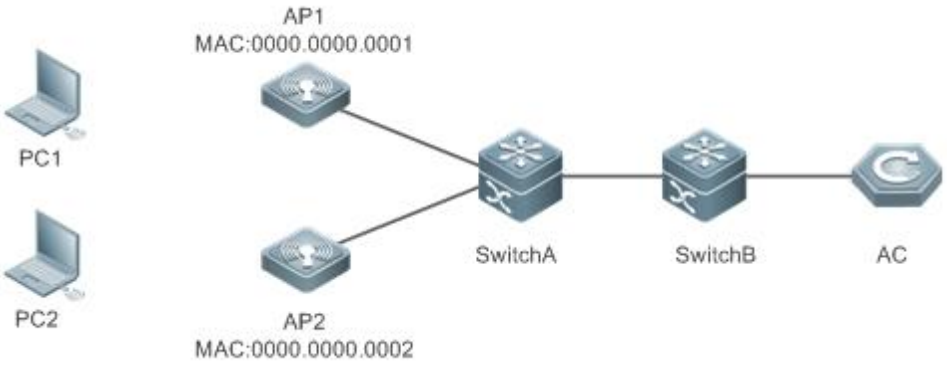
Control And Provisioning of Wireless Access Points (CAPWAP) is a protocol proposed to address the issue of large-scale access point (AP) deployment on the wireless local area network (WLAN).

On a fit AP network, the access controller (AC) manages all APs in a unified manner through CAPWAP. The AC delivers control polices to specified APs, eliminating the need to configure APs separately. CAPWAP is used to set up the control tunnel and the data tunnel between an AP and an AC. The control tunnel is used by ACs to configure APs, or by APs to send event notifications to ACs. The data tunnel is used to exchange data packets between APs and ACs.

Protocols and Standards

- RFC5415: Control And Provisioning of Wireless Access Points (CAPWAP) Protocol Specification
- RFC5416: Control and Provisioning of Wireless Access Points (CAPWAP) Protocol Binding for IEEE 802.11
- RFC5417: Control And Provisioning of Wireless Access Points (CAPWAP) Access Controller DHCP Option

1.2 Applications



Application	Description
Dynamic CAPWAP Tunnel Setup	An AP accesses an AC through switches. The DCHP server is deployed on the switch connected to APs. The AP obtains the AC address dynamically through DHCP to set up a CAPWAP tunnel with the AC.
Static CAPWAP Tunnel Setup	An AP accesses an AC through switches. The static IP address of the AC is configured on the AP. The AP sets up a CAPWAP tunnel with the AC based on the configured static IP address of the AC.
AP Upgrade	After a CAPWAP tunnel is set up between an AC and each AP, the AC upgrades APs in batches through CAPWAP.
Smart Upgrade	Smart upgrade is mainly applied in scenarios where high-reliability network is needed, such as warehouses and production networks that usually require uninterrupted services.

1.2.1 Dynamic CAPWAP Tunnel Setup

Scenario

APs access the AC through switches. The DCHP server is deployed on the switch connected to APs. The DHCP server is configured with a DHCP address pool and Option 138 that defines the IP address of the AC. The AP obtains the AC address and sets up a CAPWAP tunnel with the AC. As shown in Figure 1-1, the AC, switches (Switch A and Switch B), and APs (AP1 and AP2) are connected with each other through the trunk ports. PC1 is connected to AP1, and PC2 is connected to AP2.

Figure 1-1

Remarks	Switch: Indicates a switch. AC: Indicates a wireless access controller.

Deployment

- APs do not need to be configured one by one on a fit AP network. When an AP is powered on, the IP address must be obtained first. Therefore, a DHCP server must be deployed on the network. If the DHCP server is not deployed, the DHCP function of the AC is used to implement functions of the DHCP server.
- The AC communicates with the AP through the Layer 3 switch and the DHCP server must be configured with Option 138 that defines the IP address of the AC. After obtaining the IP address of the AC, the AP sets up a CAPWAP communication tunnel with the AC.
- On the AC, configure a loopback interface address, or run the **capwap ctrl-ip** *ip-address* command to configure the source address for setting up a CAPWAP tunnel.
- Configure a route to implement interconnection between the AC and the IP address obtained by the AP.

1.2.2 Static CAPWAP Tunnel Setup

Scenario

The AP sets up a CAPWAP tunnels with the AC based on the configured static IP address of the AC. An AP accesses an AC through switches. The topology is the same as that shown in Figure 1-1.

Deployment

- Configure the static IP addresses of ACs. The AP will send a Discover Request messages to these static IP addresses to check whether ACs are valid. Upon receiving a Discover Response message, the AP selects an AC and sets up a CAPWAP tunnel with the AC.
- On the AC, configure a loopback interface address as the source address for setting up a CAPWAP tunnel.
- Configure a route to implement interconnection between the AC and the IP address obtained by the AP.

1.2.3 AP Upgrade

Scenario

The AP obtains the AC address based on the configured static IP address of the AC or from the DHCP server, and sets up a CAPWAP tunnel with the AC. The AP accesses the AC through switches. The topology is the same as that shown in Figure 1-1.

Deployment

- On the AC, configure an IP interface address as the source address for setting up a CAPWAP tunnel.
- Configure a route to implement interconnection between the AC and the IP address obtained by the AP.
- On the AC, activate the AP software that is stored locally.

1.2.4 Smart Upgrade

Scenario

Smart upgrade is mainly applied in scenarios where high-reliability network is needed, such as warehouses and production networks that usually require uninterrupted services.

Deployment

- Activate the .bin file to be upgraded on the AC.
- Configure the upgrade mode in AP group configuration mode on the AC.
- Configure scheduled upgrade time and upgrade mode in AP group configuration mode on the AC.

1.3 Features

Basic Concepts

↘ STA, AP, and AC

STA: It is a wireless workstation that is equipped with the wireless network interface card (NIC), such as a laptop computer or a mobile phone.

AP: It is a wireless access point that provides radio signals so that the STA can access the wireless network.

AC: It is a wireless access controller that provides wireless connection and related service functions.

↘ Control Tunnel and Data Tunnel

Control tunnel: It is used by ACs to configure APs, or by APs to send event notifications to ACs.

Data tunnel: It is used to exchange data packets between APs and ACs.

↘ AC Discovery

An AP can send a Discover Request message by means of broadcast, multicast, DHCP, DNS, or static configuration to discover ACs. Upon receiving a Discover Response message, the AP selects the optimal AC and sets up a CAPWAP tunnel with the AC.

↘ Datagram Transport Layer Security (DTLS)

The CAPWAP control tunnel uses the DTLS protocol for key negotiation and encryption.

Options

The option field sent by the DHCP server can carry the IPv4 or IPv6 address of an AC. The AP obtains the AC address from the option field sent by the DHCP server.

The AP can obtain the IP address of an AC using Option 138 or Option 43, or obtain the IPv6 address of an AC using Option 52. When configuring the DHCP server of the AP, configure the related options that defines the IP address of the AC. Otherwise, the AP cannot discover the AC through DHCP discovery.

Option 138 and Option 52 are standard formats defined in RFC5417. Option 43 is defined by vendors. Currently, Option 43 in the following formats can be parsed:

Format 1: Assume that the IP address of a specified AC is 1.1.1.1. The corresponding configuration is Option 43 hex f10401010101.

```
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|   option-code   | option-length | Sub-opt Type   |   Sub-opt Len   |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|          Server   Address                       |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

option-code: Indicates the option code. In this example, the option code is 43 in decimal format.

option-length: Indicates the length of the option data, excluding option-code and option-length.

Sub-opt Type: Indicates the sub-option type. In this example, the sub-option type is 0xF1, that is, 241 in decimal format.

Sub-opt Len: Indicates the length of the sub-option, which is equal to (number of addresses x 4).

Server Address: Indicates the server address.

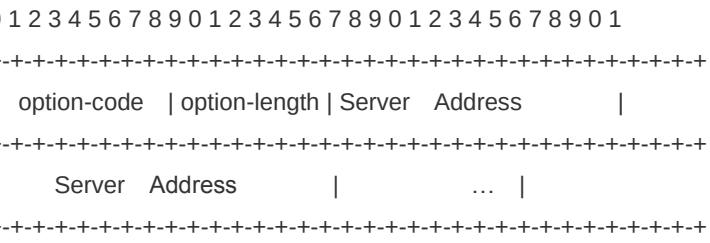
Format 2: Assume that the IP address of a specified AC is 1.1.1.1. The corresponding configuration is option 43 hex 8007000001010101.

```
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|   option-code   | option-length | Sub-opt Type   |   Sub-opt Len   |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
|            PXE Server Type            | PXE Server Num|                 |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
         PXE Server   Address                          |       …          |
+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+-+
```

option-code: Indicates the option code. In this example, the option code is 43 in decimal format.

option-length: Indicates the length of the option data, excluding option-code and option-length.

Sub-opt Type: Indicates the sub-option type. In this example, the sub-option type is 0x80, that is, 128 in decimal format.



Sub-opt Len: Indicates the length of the sub-option, which is equal to (number of addresses x 4 +3).

Server Type: Indicates the server type. The value is 0x0000.

Server Num: Indicates the number of server addresses.

Server Address: Indicates the server address.

Format 3: Assume that the IP address of a specified AC is 1.1.1.1. The corresponding configuration is option 43 hex 01010101.

option-code: Indicates the option code. In this example, the option code is 43 in decimal format.

option-length: Indicates the length of the option data, excluding option-code and option-length.

Server Address: Indicates the server address.

Overview

Feature	Description
AC Discovery	The AP discovers potential ACs.
CAPWAP Tunnel Setup	The AP selects the optimal AC and sets up a CAPWAP tunnel with the AC.
AP Upgrade	After a CAPWAP tunnel is set up between an AC and each AP, the AC upgrades APs in batches.
Data Data Forwarding over the Tunnel	After a CAPWAP tunnel is set up between an AC and each AP, data packets can be exchanged over the data tunnel.
Self-balancing Based on VAC	When a switch fails to balance load, self-balancing based on virtual AC (VAC) can be enabled to allow APs and STAs to evenly access the member ACs on the VAC network.

1.3.1 AC Discovery

An AP discovers potential ACs by sending a Discovery Request message.

Working Principle

As soon as an AP is connected to the network, the AP starts to discover ACs. The AP sends a Discovery Request message by means of broadcast, multicast, or unicast. If the AP unicasts a Discovery Request message, the AP obtains the IP address list of the AC through the DHCP server, DNS, or static IP configuration.

1.3.2 CAPWAP Tunnel Setup

The AP selects the optimal AC and sets up a CAPWAP tunnel with the AC.

Working Principle

The AP sends a Discovery Request message to ACs. ACs that receive the Discovery Request message reply a Discovery Response message to the AP respectively. The AP selects the optimal AC and sets up a DTLS connection with this AC.

After the DTLS connection is successfully set up, the AP sends a Join Request message. The AC replies a Join Response message to confirm that the AP is connected and starts to provide services for this AP.

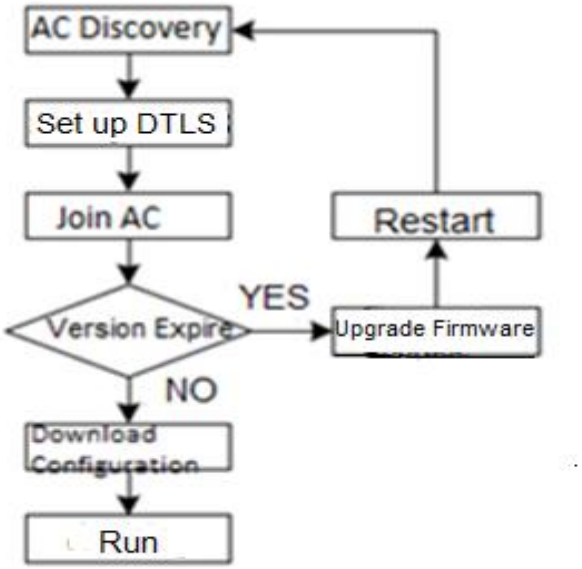
1.3.3 AP Upgrade

After a CAPWAP tunnel is set up between an AC and each AP, the AC upgrades APs in batches.

Working Principle

After an AP joins an AC, if the AP firmware version expires, the firmware needs to be upgraded. The AP downloads the latest firmware version from the AC, restarts after upgrade, and reinitiates an AC discovery process. If the AP firmware is the latest version, the AP downloads configuration parameters from the AC and starts running. Figure 1-2 shows the flowchart of the working principle.

Figure 1-2



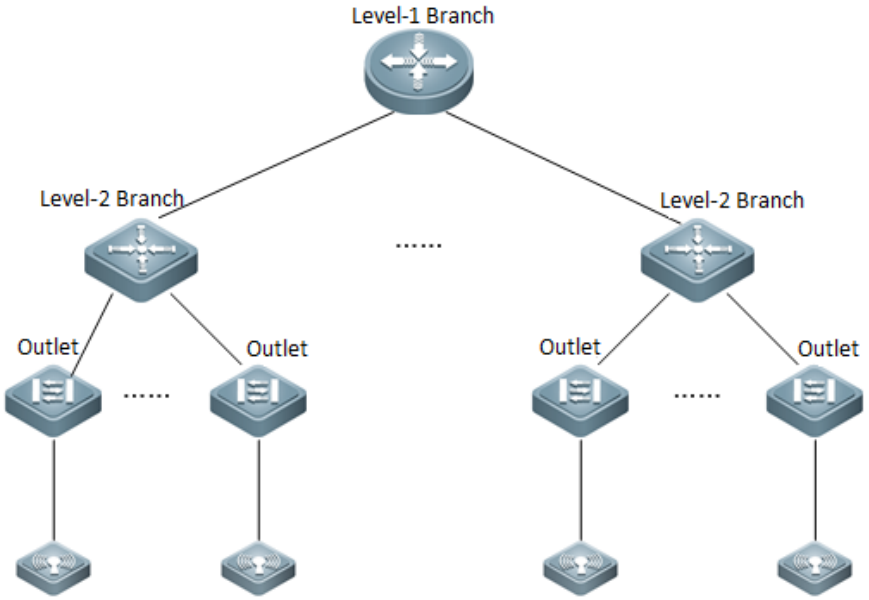


Figure 1-3 shows the typical scenario where the bandwidth is limited for upgrade.

Figure 1-3

The following explains the configuration method for upgrading APs in a bank. Assume that the bank consists of one level-1 branch and multiple level-2 branches, and each branch has hundreds of outlets. One AP is deployed in one outlet, and the AC is deployed in the level-1 branch. The bandwidth between the level-1 bank and the level-2 bank is 20 Mbps, and the bandwidth between the level-2 bank and the outlet is 2 Mbps. To avoid affecting normal services of the bank, the bandwidth occupied by the AP upgrade process cannot exceed 50% of the total available bandwidth. Assume that there are eight level-2 branches, eight upgrade groups are configured on the AC, and APs of outlets under each level-2 branches are added to the corresponding upgrade group. For each AP, the maximum available bandwidth is 1 Mbps. Therefore, a bandwidth of 128 kbps (1 Mbps = 1024 kbps) should be configured for each AP. Under each level-2 branch, up to 10 APs can be upgraded concurrently (bandwidth: 10 x 1 Mbps = 10 Mbps). In addition, you are advised to configure the maximum number of APs that can be concurrently upgraded by an AC as the number of upgrade groups multiplied by the number of APs that can be upgraded concurrently in an upgrade group, that is, 80.

1.3.4 Smart Upgrade

Smart upgrade is a solution to improve reliability during service upgrade. Users can set the upgrade time and mode as required, maximizing upgrade reliability.

Working Principle

The smart upgrade solution allows users to set a scheduled upgrade time and upgrade mode, improving reliability and reducing costs during upgrade. (1) Scheduled upgrade time: Users can schedule an off-peak time for upgrade to avoid automatic upgrades during service peak hours, reducing upgrade costs. (2) Upgrade mode: Forced upgrade and smart upgrade are provided. Forced upgrade mode is adopted to quickly upgrade APs. In smart upgrade mode, an optimal AP is selected from the AP group for upgrade. After the upgrade is completed, another optimal AP is further selected to continue upgrade, thereby avoiding service crash caused by simultaneous upgrades of multiple APs in the area.

1.3.5 Data Forwarding over the Tunnel

After a CAPWAP tunnel is set up between an AC and each AP, data packets can be exchanged over the data tunnel.

Working Principle

A control tunnel and a data tunnel between APs and ACs are set up through CAPWAP. The control tunnel is used by ACs to configure APs, or by APs to send event notifications to ACs. The control tunnel must be encrypted. The data tunnel is used to exchange the 802.11 or 802.3 frames between APs and ACs. When running on the IPv4 protocol stack, the CAPWAP uses the UDP for data transmission. When running on the IPv6 protocol stack, the CAPWAP uses the UDP over the control tunnel, and UDP or UDP-lite over the data tunnel for data transmission.

1.3.6 Self-balancing Based on VAC

Working Principle

To evenly distribute APs and STAs in a VAC scenario, configure load balancing policies on the switch directly connected to the AC for load balancing. However, when the switch fails to balance load, frequent AP migration may occur, which affects network use. In this case, self-balancing based on VAC can be enabled, so that APs and STAs can evenly access the member ACs on the VAC network.

1.4 Configuration

Configuration	Description and Command	
Configuring the AC Location	⚠ (Optional) It is used to configure the location of an AC.	
	location	Configures the location of an AC so that the physical location of the AC can be displayed.
Configuring the Version Number	⚠ (Optional) It is used to configure the version number.	
	set-version	Configures the version number,
Configuring the AP Location	⚠ (Optional) It is used to configure the location of an AP.	
	location	Configures the location of an AP so that the physical location of the AP can be displayed.
Configuring AP Time Synchronization	⚠ (Optional) It is used to enable the AP to synchronize the time with the AC.	
	timestamp	Enables the AP to synchronize the time with the AC.
Configuring an AP to Access an AC	⚠ (Optional) It is used to configure an AP to set up a CAPWAP tunnel with an AC.	
	ac-control disable	Configures an AP to access an AC.
	ac-domain-name	Configures the DNS domain name of the AP, which is used to obtain the address of the AC.
	acip ipv4	Configures the static IP address of the AC accessed by the AP.

	acip ipv6	Configures the static IPv6 address of the AC accessed by the AP.
	ip address	Configures the static IP address, subnet mask, and gateway.
	ipv6 address	Configures the static IPv6 address and gateway.
	ipv6 enable	Enables the CAPWAP IPv6 function on the AP.
Configuring an AP to Execute a Command	(Optional) It is used to configure an AP to set up a CAPWAP tunnel with an AC.	
	exec-cmd	Configures an AP or the entire AP group to execute the **ap-config** command.
Configuring AP Upgrade	(Optional) It is used to configure AP upgrade.	
	ap-serial	Creates the name of an AP product series and specifies the AP product models that belong to this series.
	ap-image	In AP configuration mode, configures the specified AP upgrade version. In AC configuration mode, configures the specified AP software version that should be used by a specified AP product series for the upgrade, or sets the adaptive upgrade mode.
	active-bin-file	Activates the AP software version file.
	capwap upgrade max-concurrent	Configures the maximum number of APs that can be concurrently upgraded by the AC.
	capwap upgrade group	In AC configuration mode, creates a bandwidth control upgrade group.
	ap-upgrade band-width	In AP configuration mode, configures the bandwidth for centralized AP upgrade.
	ap-upgrade group	In AP configuration mode, adds APs to the bandwidth control upgrade group.
Configuring Smart Upgrade	**ap-image upgrade-mode**	In AP group configuration mode, configures the upgrade mode as smart upgrade or forced upgrade.
	ap-image upgrade-appoint	In AP group configuration mode, configures scheduled upgrade time. You can start upgrade immediately, stop upgrade immediately, perform upgrade at scheduled time and periods, and execute a specified quantity of upgrade cycles in the scheduled time period.
Configuring a Micro AP	(Optional) It is used to configure a micro AP.	
	slot	Configures the name of a micro AP in a specified slot by running the **slot** command.

Configuring the CAPWAP Control Address Address	(Optional) It is used to configure the control IP address of the CAPWAP tunnel. When this address is not configured, the address of the loopback interface is used as the control IP address by default.	
	capwap ctrl-ip	Configures the control IP address of the CAPWAP tunnel.
Configuring CAPWAP Fragmentation	(Optional) It is used to configure CAPWAP fragmentation.	
	capwap mtu	Configures the path maximum transmission unit (MTU) transmitted over the data tunnel of a specified AP. This function can be enabled through the **capwap fragment enable** command.
	capwap ctrl-mtu	Configures the path MTU transmitted over a control tunnel of a specified AP. It is enabled by the software by default and cannot be disabled.
	capwap fragment enable	Enables CAPWAP data tunnel fragmentation for a specified AP.
Configuring CAPWAP Encryption	(Optional) It is used to configure CAPWAP encryption.	
	capwap data-tunnel encryption	Configures data tunnel encryption for a specified AP.
	capwap dtls enable	Enables encryption on the CAPWAP control tunnel.
Configuring CAPWAP Access Control	(Optional) It is used to control the maximum number of APs that can concurrently go online.	
	capwap max-concurrent	Configures the maximum number of APs that can concurrently go online.
Configuring the Heartbeat Keepalive Interval of the CAPWAP Tunnel	(Optional) It is used to configure the heartbeat keepalive interval of the CAPWAP tunnel.	
	echo-interval	Configures the heartbeat keepalive interval of the CAPWAP tunnel.
Configuring the Maximum Number of CAPWAP Packet Retransmission Attempts	(Optional) It is used to configure the maximum number of CAPWAP packet retransmission attempts.	
	capwap max-retransmit	Configures the maximum number of CAPWAP packet retransmission attempts.
Configuring the AC Discovery Mode	(Optional) It is used to configure the AC discovery mode.	
	capwap discovery-type ac-referral	Configures an AC to allow an AP to discover the AC by using discovery packets of the referral type.
	capwap discovery-type all	Configures an AC to allow an AP to discover the AC by using any type of discovery packets.
	capwap discovery-type dhcp	Configures an AC to allow an AP to discover the AC by using discovery packets of the DHCP type.

	capwap discovery-type dns	Configures an AC to allow an AP to discover the AC by using discovery packets of the DNS type.
	capwap discovery-type static-config	Configures an AC to allow an AP to discover the AC by using discovery packets containing a statically configured AC address.
	capwap discovery-type unknown	Configures an AC to allow an AP to discover the AC by using other types of discovery packets.
Enabling Self-Balancing Based on VAC	⚠ (Optional) It is used to enable self-balancing based on VAC.	
	virtual-ac self-balance enable	Enables self-balancing based on VAC.
Configuring the Command Set File Delivered by the AC to the AP	**auto-cfg**	Configures the command set file delivered by the AC to the AP.

1.4.1 Configuring the AC Location

Configuration Effect

- Configure the locations of ACs to conveniently check the locations of ACs on the WLAN.

Notes

- The location is a string of 1 to 255 characters and cannot contain any space.

Configuration Steps

- (Optional) Configure the locations of ACs to conveniently check the locations of ACs when a large number of ACs exist on the network.
- Enter the AC configuration mode and run the **location** command to configure the AC location on the AC.
- Use the **no** form of this command to restore the default setting.

Command	**location** *location-string*
Parameter Description	*location-string*: Indicates the location of an AC. The location is a string of 1 to 255 characters and cannot contain any space.
Defaults	Hostname_COM
Command Mode	AC configuration mode
Usage Guide	The AC location is **Hostname_COM** by default. You can configure the location for each AC as required to conveniently check the AC location on the WLAN.

Verification

- Run the **show ac-config** command to display the configuration.

Configuration Example

↘ **Configuring the AC Location as computer-layer2**

Configuration	● Enter the AC configuration mode.

Steps	● Configure the AC location.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)# locationcomputer-layer2`
	● Use the **no** form of this command to restore the default setting.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#no location`
Verification	Run the **show ac-config** command to display the current location of the AC.
AC	`Hostname#show ac-config` `ac location :Ac_COM`

Common Errors

- N/A

1.4.2 Configuring the Version Number

Configuration Effect

- Customize the firmware version.

Notes

- The customized version number contains a maximum of 63 characters.

Configuration Steps

- Optional.
- Run this command to configure the customized firmware version number.
- Use the **no** form of this command to restore the default setting.

Command	**set-version** *string*
Parameter Description	*string*: Indicates the customized version number.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	This command is used to configure the firmware version number of the AC and deliver the firmware version number to APs.

Verification

- Run the **show version** command to display the version number.

Configuration Example

Configuring the Customized Firmware Version Number as RGOS 10.4(2B17)-SP2

Configuration Steps	Enter the AC configuration mode. Configure the customized version number.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)# set-version RGOS 10.4(2B17)-SP2`
Verification	Run the **show version** command to display the version number.
AC	`Hostname#show version` `System software version : RGOS 10.4(2B17)-SP2`

Common Errors

- N/A

1.4.3 Configuring the AP Location

Configuration Effect

- Configure the location of an AP.

Notes

- The AP location is a string of 1 to 255 characters and cannot contain any space.

Configuration Steps

Configuring the AP Location

- Optional.
- Run the **location** command to configure the AP location.
- Enter the AP configuration mode and configure the AP location on the AC to conveniently check the physical location of the AP.

Command	**location** *location-string*
Parameter Description	*location-string*: Indicates the location of an AP. The location is a string of 1 to 255 characters and cannot contain any space
Defaults	Null
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** command to display the AP location.

Configuration Example

Configuring the Location of AP0001 as AP-company

Configuration Steps	● Enter the AP configuration mode on the AC. ● Configure the location of AP0001 as **AP-company**.
AC	`Hostname(config)# ap-config AP0001` `Hostname(config-ap)# location AP-company`
Verification	● Run the **show ap-config running** command to display the location of AP0001.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP0001`
	`location AP-company`
	`!`

Common Errors

- N/A

1.4.4 Configuring AP Time Synchronization

Configuration Effect

- Configure a specified AP or all APs in an AP group to synchronize the time with the AC.

Notes

- N/A

Configuration Steps

Configuring a Specified AP or All APs in an AP Group to Synchronize the Time with the AC

- Optional.
- To synchronize the time on the AP with that on the AC, enter the AP or AP group configuration mode on the AC and run the **timestamp** command.

Command	**timestamp**
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Check whether the time on the AC is the same as that on the AP.

Configuration Example

Configuring AP0001 to Synchronize the Time with the AC

Configuration Steps	● Enter the AP configuration mode on the AC. ● Configure AP0001 to synchronize the time with the AC.
AC	`Hostname(config)# ap-config AP0001` `Hostname(config-ap)# timestamp`
Verification	● Run the **show clock** command to display the time on the AP0001 and the AC.
AC	`Hostname#showclock` `16:41:05 UTC Thu, Oct 17, 2013`

Common Errors

- N/A

1.4.5 Configuring an AP to Access an AC

Configuration Effect

- Configure the static IP addresses of ACs. The AP will send a Discover Request messages to these static IP addresses to check whether ACs are valid. Upon receiving a Discover Response message, the AP select an AC and set up a CAPWAP tunnel with the AC.

Notes

- A fit AP is generally not configured. It can discover ACs by means of broadcast, unicast, DHCP, or DNS, or can join ACs based on the statically configured AC addresses.
- If the AP address is configured as the static address, the DHCP/DHCPv6 function will be disabled. In this case, the AC address cannot be obtained from the DHCP/DHCPv6 option. Therefore, before this command is configured, you need to configure the address of the connected AC in AP configuration mode so that the AP can discover and join the AC when the AP and the AC are not on the same subnet.
- If the current address of the AP is different from the address specified in the AC command, the AP static address will be updated and the CAPWAP tunnel will be re-established. If IPv6 is not enabled on the AP, the CAPWAP tunnel will not be re-established.
- If both IPv4 and IPv6 addresses of the AP are specified and IPv6 is enabled on the AP, the AP will discover the IPv4 and IPv6 ACs simultaneously.

Configuration Steps

Configuring the Static AC Address

- Optional.
- The AC address can be obtained through DHCP or DNS. Alternatively, the static AC address can be configured in AP configuration mode on the AC.
- When the AC address is obtained in static mode, run the **acip ipv4** or **acip ipv6** command to configure the static AC address.

Command	**acip ipv4***ip-address*[*ip-address*…]
Parameter Description	*ip-address*: Indicates the static IP address. Up to six static addresses can be configured.
Defaults	No static AC IP address is configured.
Command Mode	AP configuration mode on the AC
Usage Guide	N/A

Command	**acip ipv6** *ipv6-address*[*ipv6-address*…]
Parameter Description	*ipv6-address*: Indicates the static IP address. Up to six static addresses can be configured.
Defaults	N/A
Command Mode	AP configuration mode on the AC
Usage Guide	N/A

Configuring the Domain Name for the AP to Discover the AC

- (Optional) Run the **ac-domain-name** command to configure the domain name on the AC so that the AP can discover the AC based on the domain name.
- When the AC address is obtained in dynamic mode, configure the domain name on the AC. The IP address of the AC can be obtained based on the domain name.
- If the domain name is not configured, the AP cannot obtain the IP address of the AC through DNS.

Command	**ac-domain-name** *ac-domain-name*
Parameter Description	*ac-domain-name*: Indicates the domain name of the AC.
Defaults	ac. Hostname.com.cn
Command Mode	AP configuration mode or AP group configuration mode on the AC
Usage Guide	N/A

Configuring the Static IP Address of the AP

- Optional.
- On the AP, configure the static IPv4 or IPv6 address of the AP so that the AP can use the fixed IPv4 or IPv6 address to access the AC.

Command	**ip address** *ip-address network-mask gateway*
Parameter Description	*ip-address*: Indicates the IP address of the AP. *network-mask*: Indicates the subnet mask of the AP. *gateway*: Indicates the gateway of the AP.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	An AP can obtain an IP address through the static configuration or DHCP. If the static IP address is not

	configured on the AP, the AP obtains the address through DHCP and joins the AC. In this case, you can run this command to configure the static IP address of the AP so that the address can remain unchanged after the AP is restarted.

Configuring the Static IPv6 Address of a Specific AP

- Optional.

Command	**ipv6 address** *ipv6-address-with-mask gateway*
Parameter Description	*ipv6-address-with-mask*: Indicates the IPv6 address of the AP. The format is X:X:X:X::X/24. *gateway*: Indicates the IPv6 gateway of the AP.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	When IPv6 is enabled, the AP can obtain an IPv6 address through the static configuration or DHCPv6. If the static IPv6 address is not configured on the AP, the AP obtains the address through DHCPv6 and joins the AC. In this case, you can run this command to configure the static IPv6 address of the AP so that the address can remain unchanged after the AP is restarted.

Configuring the AP to Support IPv6 Access

- Optional.
- Run this command to control whether an AP sets up a CAPWAP IPv6 tunnel.
- If a CAPWAP IPv6 tunnel needs to be set up, run the **ipv6 enable** command in AP configuration mode on the AC to support establishment of an IPv6 tunnel.

Command	**ipv6 enable**
Parameter Description	N/A
Defaults	IPv6 is disabled on the AP.
Command Mode	AP configuration mode
Usage Guide	If the configuration causes a change in the IPv6 support status of the AP, the AP re-establishes the CAPWAP tunnel. When IPv6 is enabled on the AP and the AP is configured with both static IPv4 and IPv6 addresses, the AP attempts to discover the IPv4 and IPv6 ACs simultaneously during re-establishment of the CAPWAP tunnel. Among discovered ACs, the AP does not necessarily select and join an IPv6 AC. To ensure that the AP selects and joins an IPv6 AC, delete the static IPv4 address of the AP and retain only the static IPv6 address of the AP before IPv6 is enabled on the AP.

Configuring the Fit AP to Access an AC

- Optional.
- Enable an AC.

Command	**no ac-control disable**
Parameter Description	N/A
Defaults	Enabled.

Command Mode	AC configuration mode
Usage Guide	The device can serve only as a switch, a gateway, or an AC on the network. When the device serves only as a switch or gateway, the fit AP is expected to access the actual AC but not the device. This command can be used to control the access of the AP. When the AC function is disabled, the device disables the CAPWAP ports (such as ports 5246 and 5247) and stops listening to the corresponding ports.

Verification

- Run the **show ap-config running** command to display the configuration.

Configuration Example

Configuring the AP to Obtain the IP Address of the AC Based on the Static IPv4 Address

Configuration Steps	• Enter the AP configuration mode on the AC. • Set the static IP address of the AC accessed by the AP to 192.168.1.1. • Set the static IP address of the AP to 1.1.1.1, subnet mask to 255.255.255.0, and gateway to 1.1.1.2.

AC	`Hostname(config)# ap-config AP0001`
	`Hostname(config-ap)# acip ipv4 192.168.1.1`
	`Hostname(config-ap)# ip address 1.1.1.1 255.255.255.0 1.1.1.2`

Verification	• Display the AP configuration.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP0001`
	`acip ipv4 192.168.1.1`
	`ip address 1.1.1.1 255.255.255.0 1.1.1.2`
	`!`

Enabling the AP to Obtain the IP Address of the AC Based on the Domain Name

Configuration Steps	• Enter the AP configuration mode on the AC. • Set the domain name of the AC to **Hostname-ac**.
AC	`Hostname(config)# ap-config AP0001` `Hostname(config-ap)# ac-domain-name Hostname-ac`
Verification	• Display the AP configuration.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP0001`

Configuration Steps	● Enter the AP configuration mode on the AC. ● Set the domain name of the AC to **Hostname-ac**.
AC	`Hostname(config)# ap-config AP0001` `Hostname(config-ap)# ac-domain-name Hostname-ac`
Verification	● Display the AP configuration.
	`ac-domain-name Hostname.ac` `!`

Enabling IPv6 on the AP

Configuration Steps	● Enter the AP configuration mode on the AC. ● Enable IPv6 on the AP.
AC	`Hostname(config)# ap-config AP0001` `Hostname(config-ap)# ipv6 enable`
Verification	● Display the AP configuration.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP0001`
	`ipv6 enable`
	`!`

Configuring the Fit AP to Access the All-in-One AC

Configuration Steps	● Enter the AC configuration mode. ● Configure the fit AP to access the all-in-one AC.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#no ac-control disable`
Verification	● Display the AP configuration.

AC	`Hostname#show ap-config running`
	`!`
	`ac-controller`
	` no ac-control disable`

Common Errors

- N/A

1.4.6 Configuring an AP to Execute a Command

Configuration Effect

- (Optional) On the AC, configure an AP to execute a command.
- (Optional) On the AC, configure all APs in an AP group to execute a command.

Notes

- N/A

Configuration Steps

Configuring an AP to Execute a Command

- (Optional) Enter the AP configuration mode.
- On the AC, configure the AP to execute a command.

Command	**exec-cmd mode** *exec-mode* **cmd** *exec-cmd* [**slot** { *id* | **all** } | **once**]
Parameter Description	*exec-mode*: Indicates the mode in which a command is executed on the AP. *exec-cmd*: Indicates the command to be executed on the AP. *id* : Indicates the slot ID of the micro AP connected to the i-Share+ AP. **all**: Indicates all micro APs connected to the i-Share+ AP. **once**: Indicates that the command is executed only once and is not saved.
Defaults	N/A
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	Some commands are supported currently only on the AP and they are unavailable on the AC. To configure the commands for APs on the AC, run the **exec-cmd** command. To cancel or change the configuration of the **exec-cmd** command, run the **no exec-cmd** command to remove the configuration and then run the **exec-cmd** command to cancel or change the required configuration. If **ap-config all** and **ap-config** are configured simultaneously, for online APs, the later configuration will take effect; for offline APs, **ap-config** has a higher priority than **ap-config all**. The AC can deliver the corresponding command to a micro AP by expanding the **exec-cmd** command. After delivery, run the command on the micro AP. Note: If a dedicated command is used on an AC to deliver configurations to an AP, do not use this command to deliver the configurations. Otherwise, conflicts occur.

Verification

- Log in to the AP to check whether the configuration takes effect. On the AC, run the **show run** or **show ap-config run** command to check whether the configuration takes effect.

Configuring APs in an AP Group to Execute a Command

- (Optional) Enter the AP group configuration mode.

- Configure all APs in an AP group to execute a command.

Command	**exec-cmd** *exec-cmd*
Parameter Description	*exec-cmd*: Indicates the command to be executed on all APs in an AP group.
Defaults	N/A
Command Mode	AP group configuration mode.
Usage Guide	Some configuration commands are available only in AP configuration mode and they are unavailable in AP group configuration mode. To configure such a command for all APs in an AP group, run the **exec-cmd** command in the AP group. Note that the configuration is not saved in AP group configuration mode, that is, the command is executed only once on all APs in the current AP group. If the configuration already exists in AP configuration mode, the original configuration will be overridden when the command is executed in AP group configuration mode.

Verification

- Run the **show ap-config run** command to check whether the configuration of the APs in an AP group takes effect.

Configuration Example

↘ Disabling the Eweb Function for an AP on the AC and Configuring Bluetooth iBeacon for all APs in an AP Group

Configuration Steps	• On the AC, disable the Eweb function for APs. • On the AC, enable the Eweb function for APs. • Enable Bluetooth iBeacon for all APs in an AP group. • Disable the Eweb function for all APs in the AP group.
AC	Hostname(config)#ap-config AP1 Hostname(config-ap)# exec-cmd mode configure cmd "no enable service web-server all" Hostname(config-ap)# no exec-cmd mode configure cmd "no enable service web-server all" Hostname(config-ap)# exec-cmd mode configure cmd "enable service web-server all" Hostname(config)#ap-group default Hostname(config-group)#exec-cmd ibeacon uuid ffffffffffffffffffffffffffffffff major ffff minor ffff Hostname(config-group)#exec-cmd exec-cmd mode configure cmd "no enable service web-server all"
Verification	• On the AC, check whether the configuration takes effect.

AC	Hostname#show ap-config running ap-config AP1 exec-cmd mode configure cmd "no enable service web-server all" ibeacon uuid ffffffffffffffffffffffffffffffff major ffff minor ffff

Common Errors

- The configuration of the **exec-cmd** command is changed, the **no exec-cmd** command is not executed to delete original configuration, or the **exec-cmd** command is not re-executed to cancel the configuration.

1.4.7 Configuring AP Upgrade

Configuration Effect

- Upgrade the AP software version through configuration on the AC.

Notes

- Perform configuration to activate the AP software version file. This command loads the **.bin** file to the memory only when the AP needs to be upgraded. When no AP needs to be upgraded, the **.bin** file will be automatically removed from the memory.
- During the adaptive upgrade, the transitional version between RGOS 10 and RGOS 11 cannot be used to upgrade an AP equipped with the RGOS 10 system.
- When the bandwidth is limited, use the bandwidth control function for the upgrade.

Configuration Steps

Creating the AP Series

- (Optional) Run the **ap-serial** command to configure an AP product series on the AC.
- To upgrade the AP software version through the AC, you need to first configure the AP hardware version and product models for a specified product series on the AC.
- An AP software version is applicable to a series of APs. You can configure the AP hardware version and product models for a specified product series, and use the software version to upgrade specified AP models.

Command	**ap-serial** *serial-name ap-pid1* [*ap-pid2 ... ap-pidn*] [**hw-ver** *hardware-version*]
Parameter Description	*serial-name*: Indicates the name of the AP series to be created. *ap-pid1* [*ap-pid2 ... ap-pidn*]: Lists the product models to be added to the AP series. *hardware-version*: Specifies the AP hardware version.
Defaults	No AP series is configured.
Command Mode	AC configuration mode
Usage Guide	N/A

Activating the AP Software Version File

- (Optional) Run the **active-bin-file** command to activate an AP software version on the AC.

- To upgrade the AP software version through the AC, you need to activate the AP software version on the AC first.
- Only an activated AP software version can be used for the upgrade.

Command	**active-bin-file** *filename*[**rgos10**]
Parameter Description	*filename*:Specifies the name of a software version. The name may contain a path prefix (**flash:**,**tmp:**, or**usb0:**), followed by a real file name. The maximum length of a file name is 64 bytes. **rgos10:** Indicates that a transitional version between 10.X and 11.X is activated. It is applicable only to the AP software version.
Defaults	The AP software version is not activated.
Command Mode	AC configuration mode
Usage Guide	1. To download a software version from the AC to upgrade an AP, you need to activate the version file first. The RGOS 10 system differs a lot from the RGOS 11 system. Therefore, when using a transitional version between RGOS 10 and RGOS 11 for the upgrade, you need to add the RGOS 10 keyword. 2. The **.bin** file is loaded to the memory only when an AP needs to be upgraded. When no AP needs to be upgraded, the **.bin** file will be automatically removed from the memory. 3. Before configuring this command, ensure that the software version file already exists in the AC system files.

Upgrading the Version of Specified APs

- (Optional) Run the **ap-image** command to use a specified file to upgrade a specified AP series on the AC. This command takes effect on all APs connected to the AC.
- To upgrade the AP software version through the AC, you need to first specify the upgrade file used by the AP.
- To upgrade a specified AP series, you need to first activate the AP software version, specify the AP series, and specify a file for upgrading the specified AP series.

Command	**ap-image** *filename*
Parameter Description	*filename*: Specifies the software version name.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring Adaptive Upgrade

- (Optional) Run the **ap-image auto-upgrade** command so that the AC can automatically identify applicable AP products based on the AP upgrade file and upgrade all applicable APs.
- The command automatically matches the AP models to which the software version is applicable and upgrades these APs.

Command	**ap-image**{ **auto-upgrade** | *filename serial-name*}
Parameter Description	**auto-upgrade:** Indicates that the product model is automatically matched for the upgrade. *filename*: Specifies the software version name. This file name must be the same as that specified by the **active-bin-file** command. *serial-name*: Indicates the name of the AP series to be upgraded.

Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	You can use the **auto-upgrade** option to automatically match the software version and upgrade APs without configuring the mapping between the AP models and software version. You can also use a specified file to upgrade a specified AP series. When both the automatic upgrade mode and the specified series upgrade mode exist, the specified series upgrade mode is used preferentially. To enable the AC to upgrade the version of a specified AP series, you need to create the AP series, configure the software version corresponding to the specified APs, and activate the software version. The three steps are mandatory.

Configuring AP Upgrade Function in Hierarchical AC Scenarios

- Optional.
- Enable the AP upgrade function on the center AC or a branch AC in hierarchical AC scenarios.

Command	**capwap upgrade center enable**
Parameter Description	N/A
Defaults	The AP upgrade function is enabled on the center AC (disabled on branch ACs).
Command Mode	AC configuration mode
Usage Guide	1. This command applies only to hierarchical AC scenarios. 2. When the AP upgrade function on an AC is disabled, upgrade configurations (activated **.bin** file, automatic upgrade, sequential upgrade, and single AP upgrade) on the AC are automatically cleared. 3. After a branch AC is connected to the center AC, the configurations on the center AC are automatically synchronized to the branch AC. 4. When a branch AC is in the connection state, the configurations on the branch AC cannot be modified. The configurations can only be modified on the center AC and automatically synchronized to the branch AC. 5. When the branch AC is in the standalone state, the configurations on the branch AC can be modified.

Configuring the Maximum Number of APs That Can Be Concurrently Upgraded by the AC

- Optional.
- Limit the maximum number of APs that can be concurrently upgraded by the AC.

Command	**capwap upgrade max-concurrent** *num*
Parameter Description	*num*: Indicates the maximum number of APs that can be concurrently upgraded by the AC. The default value is 15. The value ranges from 1 to 200.
Defaults	15
Command Mode	AC configuration mode
Usage Guide	N/A

Creating an Upgrade Group

- Optional.

- Create an upgrade group. The AC can evenly distribute the centralized upgrade quota to the upgrade group through balanced scheduling to limit the bandwidth and avoid wasting the bandwidth.

Command	**capwap upgrade group** *group-name* [**max-concurrent** *num*]
Parameter Description	*group-name*: Indicates the name of an upgrade group. The upgrade group name cannot be set to **default**. *num*: Indicates maximum number of APs that can be concurrently upgraded in the group. The default value is 5. The value ranges from 0 to 200.
Defaults	No upgrade group is configured and the AP upgrade is not limited by the bandwidth. When an upgrade group is configured, the maximum number of APs that can be concurrently upgraded in the group is 5.
Command Mode	AC configuration mode
Usage Guide	N/A

Adding APs to an Upgrade Group

- Optional.
- Add APs to an upgrade group. Limit the number of APs that are upgraded in a centralized manner in this group through scheduling and configuration to control the bandwidth by upgrade group.

Command	**ap-upgrade group** *group-name*
Parameter Description	*group-name*: Indicates the name of the upgrade group. Before adding APs to an upgrade group, you need to run the **capwap upgrade group** command to create an upgrade group.
Defaults	APs are not added to any upgrade group.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the Bandwidth Used for AP Upgrade

- Optional.
- Configure the bandwidth used for AP upgrade.

Command	**ap-upgrade band-width** *num*
Parameter Description	*num*: Indicates the bandwidth used for AP upgrade. The unit is 1 kbps. The value ranges from 8 to 10,240.
Defaults	The bandwidth is not limited.
Command Mode	AP configuration mode
Usage Guide	The **capwap upgrade group** *group-name* [**max-concurrent***num*], **ap-upgrade group** *group-name*, and **ap-upgrade band-width** *num* commands are used to limit the bandwidth for AP upgrade.

Verification

- Check whether the AP version is successfully upgraded.
- Check the upgrade status of the bandwidth-limit upgrade group and APs in the group.

Configuration Example

Configuring AP Upgrade

Configuration Steps	● Enter the AC configuration mode on the AC. ● Create an AP series on the AC. ● Activate the specified AP software version used for the upgrade on the AC. ● Configure the AP upgrade version file on the AC.

AC	`Hostname(config-ac)# ap-serial serial1 AP220-E AP220-SE AP620-H hw-ver 1.0`
	`Hostname(config-ac)# active-bin-file ap.bin`
	`Hostname(config-ac)# ap-image ap.bin serial1`
	`Hostname(config-ac)# exit`

Verification	● Display the list of files activated on the AC.

AC	`Hostname#show ac-config active-file`
	`Cnt File Name Version Used Cnt Ready`
	`------ ---------- ---------- ---------- --------`
	`1 ap.bin RGOS 10.4(1t7)(1T7), Release(88888) 1 1`

Configuring the Bandwidth Used for AP Upgrade

Configuration Steps	● Enter the AC configuration mode on the AC. ● Create an AP upgrade group on the AC. ● Exit from the AC configuration mode. ● Enter the AP configuration mode. ● Configure the specified AP upgrade group on the AC. ● Activate the bandwidth used for AP upgrade on the AC.

AC	`Hostname(config-ac)# capwap upgrade group UPGRADE-GROUP1 max-concurrent 10`
	`Hostname(config-ac)# exit`
	`Hostname(config)#ap-config 8832.0000.1111`
	`Hostname(config-ap)# ap-upgrade group UPGRADE-GROUP1`
	`Hostname(config-ap)# ap-upgrade band-width 128`
	`Hostname(config-ap)# exit`

Verification	● Display the upgrade group and APs in the group on the AC. ● Display the APs and their bandwidths in an upgrade group on the AC.

AC	Hostname#show ac-config upgrade-group Cnt Group-Name Max-Concurrent Token cnt Upgrading cnt ------ ---------- ---------- ---------- 1 UPGRADE-GROUP1 10 2 1 Hostname#show ac-config upgrade-groupUPGRADE-GROUP1 Group have 2 ap, online 1 offline 1 Cnt Ap-Name Ap-Mac Online Upgrade Band-width ------- ---------- ---------- ------- ---------- ---------- 1 ap220e 8832.0000.1111 true true 128 2 ap330 - false false 128 Hostname#show ap-config wtp-info 8832.0000.1111 Hostname#show ap-config wtp-info ap220e Upgrade-banfwidth : 128 Upgrade group : UPGRADE-GROUP1

Configuring AP Upgrade Function in Hierarchical AC Scenarios

Configuration Steps	1. Enable the AP upgrade function on the center AC (and disable it on branch ACs).
	`Hostname(config-ac)# capwap upgrade center enable`
	2. Enable the AP upgrade function on a branch AC (and disable it on the center AC).
	`Hostname(config-ac)# no capwap upgrade center enable`
	3. Cancel the configuration.
	`Hostname(config-ac)# default capwap upgrade center enable`

Verification	Run the **show running-config** command to display the configuration.

Common Errors

- AP upgrade is configured, but the software version file used for the upgrade does not exist in the AC system files.

1.4.8 Configuring Smart Upgrade

Configuration Effect

- Upgrade is performed based on the upgrade time and upgrade mode that are specified by the user.

Notes

- In an AP group, if upgrade time is scheduled but no upgrade mode is configured, no upgrade is performed at scheduled time.
- After smart upgrade is configured, if an AP fails the upgrade, the remaining APs no longer perform the upgrade, even in the next scheduled cycle.
- Before the upgrade, you need to activate the **.bin** file. The automatic upgrade function is enabled during the **.bin** file activation. If an AP to be upgraded is in the group for scheduled upgrade, the AP will not be automatically upgraded, whereas an AP not in the group for scheduled upgrade is automatically upgraded.

Configuration Steps

Configuring an Upgrade Mode

- Configure the upgrade mode of an AP group as smart upgrade or forced upgrade.

Command	**ap-image upgrade-mode { force | smart }**
Parameter Description	**force**: Indicates forced upgrade. **smart**: Indicates smart upgrade.
Defaults	No upgrade mode is configured.
Command Mode	AP group configuration mode
Usage Guide	N/A

Configuring a Scheduled Time for Upgrade

- Configure a scheduled time for the upgrade.

Command	**ap-image upgrade-appoint {start | stop |** *period* **[date-start** *date***] {once | cycle}}**
Parameter Description	**start**: Starts the upgrade immediately. **Stop**: Stops the upgrade immediately. *period*: Schedules the time period for the upgrade, in the format of *HH:MM HH:MM*. **date-start**: Schedules the start date of the upgrade. The default value is the day when the upgrade is performed. *date*: Indicates the date when the upgrade starts, in the format of *yyyy-mm-dd.* **once**: Indicates that the upgrade is only performed at the scheduled time on the scheduled date. **cycle**: Indicates that the upgrade takes effect at the scheduled time on the scheduled date and every day thereafter.
Defaults	No scheduled time is configured for the upgrade.
Command Mode	AP group configuration mode
Usage Guide	• The **once** parameter takes effect only at the scheduled time on the scheduled date. If the current time is later than the start time of the scheduled time range, the configuration fails and the error message "Appoint time is before current time" is displayed. In addition, if the configuration restoration time is later than the start time of the scheduled time range when the device restarts, the configuration cannot be restored. • The **upgrade-appoint** command takes effect only after the **upgrade-mode** command is configured. Therefore, automatic upgrade cannot be implemented when only the **upgrade-appoint** command is configured. In an AP group, if a scheduled time is configured for upgrade but no

	upgrade mode is configured, the upgrade cannot performed at the scheduled time. ● Before the upgrade, activate the bin file. If you activate the bin file after the automatic upgrade function is enabled, and the AP to be upgraded is in the AP group configured for scheduled upgrade, the AP cannot be upgraded automatically. If the AP to be upgraded is not in the AP group configured for scheduled upgrade, the AP will be upgraded automatically. ● After the smart upgrade mode is configured, if an AP fails to be upgraded for more than three times, the AP will not be upgraded again, and the upgrade will be performed on other APs to be upgraded. ● The automatic upgrade function is enabled on an AP by default. To use the smart upgrade and scheduled upgrade functions, you need to configure the upgrade mode and activate the version upgrade file. ● After the **ap-image upgrade-appoint start** command is configured, the AP will perform the upgrade immediately, regardless of the scheduled time. After the **ap-image upgrade-appoint stop** command is configured, the upgrade will be stopped regardless of the scheduled time. However, the upgrade of an AP that is already in the upgrade process cannot be stopped. ● The **start** and **stop** parameters are parameters of an action command. The parameters take effect only once and are not saved.

Verification

- Run the **show upgrade-appoint summary** command to display the scheduled upgrade configuration of groups.
- Run the **show upgrade-appoint ap-group** *apg-name* command to display the scheduled upgrade configuration of a single group.

Configuration Example

Configuring an Upgrade Mode

Configuration Steps	● On an AP group of an AC, separately configure the forced upgrade mode and smart upgrade mode, and delete the upgrade modes.
AC	Forced upgrade mode: Hostname(config-group)#ap-image upgrade-mode force Smart upgrade mode: Hostname(config-group)#ap-image upgrade-mode smart Delete the upgrade mode: Hostname(config-group)#no ap-image upgrade-mode smart
Verification	● On the AC, display the upgrade mode configured for the current AP group.
AC	Hostname(config-group)#show this Building configuration... ! ap-image upgrade-mode force !

	end

Configuring a Scheduled Time

Configuration Steps	● Separately configure a scheduled time for the upgrade, configure the upgrade to start immediately, configure the upgrade to stop immediately, configure a single upgrade cycle in the scheduled time period, and configure multiple upgrade cycles in the scheduled time period.
AC	Configure the upgrade to start immediately. Hostname(config-group)#ap-image upgrade-appoint start Configure the upgrade to stop immediately. Hostname(config-group)#ap-image upgrade-appoint stop Set the time period for the upgrade to 12:00-13:00, the date to the current day, and the number of times to execute the upgrade in the scheduled time period to 1. Hostname(config-group)#ap-image upgrade-appoint 12:00 13:00 once Set the time period for the upgrade to 12:00-13:00, the date to 2021-09-10, and the number of times to execute the upgrade in the scheduled time period to multiple times. Hostname(config-group)#ap-image upgrade-appoint 12:00 13:00 start-date 2021-09-10 cycle
Verification	● Display the scheduled upgrade configuration of all groups on the AC. ● Display the scheduled upgrade configuration and AP status of a single group. ● Run the **show this** command to display the scheduled upgrade configuration of the current group.
AC	Hostname#show upgrade-appoint summary APG MODE TIME DATE PERIOD ---------- ----- ----- ---------- ---------- test force cycle 2021-09-10 12:00 13:00 Hostname#show upgrade-appoint ap-group test The upgrade mode: force The appoint date: 2021-09-10 12:00 13:00 Achieve appoint time: no AP-PID AP-MAC VERSION NEED ---------- ---------- ---------- ----- AP840-I 0074.9cbd.af08 AP_RGOS 11.9(0)B0, Release(08200100) NO AP710-A 8005.886b.599e AP_RGOS 11.1(9)B1P25 NO Hostname(config-group)#show this Building configuration... ! ap-image upgrade-mode force

	ap-image upgrade-appoint 12:00 13:00 start-date 2021-09-10 cycle !

1.4.9 Configuring a Micro AP

Configuration Effect

- An i-Share+ master AP can be connected to multiple micro APs. To facilitate micro AP management, perform some operations such as configuring the names of micro APs and displaying the installation status.

Notes

- N/A

Configuration Steps

Configuring the Name of a Micro AP

- (Optional) Run the **slot** command to name a micro AP in a specified slot.
- This configuration takes effect only for i-Share APs. The corresponding radio frequency (RF) card can be named to determine the position of this card.

Command	**slot** *slot-id* {*slot-name* [**secondary**] | **mac** *mac-address slot-name* }
Parameter Description	*slot-id*: Indicates the slot ID. The slot ID ranges from 1 to 24. *slot-name*: Indicates the name of an AP card. The name is a string of 1 to 63 characters and cannot contain any space. **secondary**: Applies to the secondary AP. *mac-address*: Indicates the MAC address of the micro AP.
Defaults	An AP card is not named.
Command Mode	AP configuration mode
Usage Guide	This command takes effect only for i-Share+ APs and cannot be configured for all APs. If you want to name a secondary micro AP, add the **secondary** parameter. Micro AP names are configured based on MAC addresses, allowing for offline configuration during installation. Each slot can be configured with two MAC addresses. When the micro AP with the corresponding MAC address goes online, the micro AP can automatically switch port-based configuration based on the cascading relationships.

Updating the Installation Status of a Micro AP

- (Optional) Run the **install update** or **uninstall** command to update the installation status of a micro APs.
- If the state of a removed micro AP is displayed as offline, you can update its installation status.

Command	**install update**

Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	If a micro AP is installed in a specified slot on the i-Share+ AP but is later manually removed, the system determines that this micro AP is offline. This command is executed to query an i-Share+ AP that is currently online, and update the installation status of the online micro AP to **installed**. Configurations of this command are not saved.

Command	**uninstall** *slot-id* [**secondary**]
Parameter Description	*slot-id*: Indicates the slot ID. The slot ID ranges from 1 to 24. **secondary**: Applies to the secondary AP.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	If a micro AP is installed in a specified slot on the i-Share+ AP but is later manually removed, the system determines that this micro AP is offline. You can use this command to remove a micro AP from the corresponding slot. If the micro AP in this slot is online, this command does not take effect. Configurations of this command are not saved. In addition, the command cannot be used in all AP configuration mode. If you want to name a secondary micro AP, add the **secondary** parameter.

Restarting a Micro AP

- (Optional) Run the **reset slot** *slot-id* command to restart a micro AP in a specified slot.
- To reset a micro AP, you can use this command to power off the micro AP and then power it on again.
- This command applies to two micro APs of a slot in a cascading scenario.

Command	**reset slot** *slot-id*
Parameter Description	*slot-id*: Indicates the slot ID. The slot ID ranges from 1 to 24.
Defaults	N/A
Command Mode	AP configuration mode

Usage Guide	This command takes effect only for i-Share+ APs and cannot be used in all-AP configuration mode. Configurations of this command are not saved.

Verification

- Check the installation information of micro APs, including the names and online status.

Configuration Example

Configuring the Name of a Micro AP

Configuration Steps	• Enter the AP configuration mode on the AC. • Configure the name of a micro AP in a specified slot.

AC	The following example sets the name of micro AP1 to **1#101**.
	`Hostname(config)# ap-config AP0001`
	`Hostname(config-ap)# slot 1 Dormitory 1#101`
	The following example sets the name of AP0001, secondary micro AP1 in slot 1, to **1#102**.
	`Hostname(config)# ap-config AP0001`
	`Hostname(config-ap)# slot 1 1#102 secondary`
	The following example sets the name of the micro AP (MAC address: 0001.0001.0001) in slot 1 to **1#101** and the name of the micro AP (MAC address: 0001.0001.0002) of slot 1 to **1#102**.
	`Hostname(config)# ap-config AP0001`
	`Hostname(config-ap)# slot 1 mac 0001.0001.0001 1#101`
	`Hostname(config-ap)# slot 1 mac 0001.0001.0002 1#102`

Verification	• Display the name of the micro AP on the AC.

AC	Hostname#show ap-config summary slot Total Install Number: 2 Total Online Number: 1 Total Offline Number: 1 AP(AP0001)'s Slots Information Install Number: 2 Online Number: 1 Offline Number: 1 AP mac Slot ID Role Slot Name Model Slot Mac Radio Radio Up/Off time State -------------- ------- --------- ---------- --------- -------------- -------------------- ------------------- ----------- ------- 00d0.f822.3418 1 master Dormitory 1#101 MAP552 5869.6c36.e268 1 E 0 6* 100 2 E 0 157* 100 1:03:39:38 online 00d0.f822.3418 2 slave Dormitory 1#102 MAP552 5869.6c36.e269 3 N 4 N 1:03:39:38 offline

Common Errors

- N/A

1.4.10 Configuring the CAPWAP Control Address

Configuration Effect

- Configure an IP address for the AC to set up a CAPWAP tunnel with an AP.

Notes

- When the IP address used by the AC to set up the CAPWAP tunnel is changed, online APs may be disconnected.
- If the configured IP address does not exist on the AC, the CAPWAP tunnel cannot be set up.
- If the gateway of the AP is not located on the AC (indicating a Layer 3 topology between the AC and AP), the option field of the AP's address pool needs to be configured with the address specified in the **capwap ctrl-ip** command (if available).
- In an AC hot standby environment, if this command is used to configure the control address of the CAPWAP tunnel, the peer backup AC must configure this control address as the peer control IP address in hot standby configuration mode. The command is **peer-ip** *A.B.C.D*.

Configuration Steps

↘ **Configuring the Maximum Number of APs That Can Concurrently Go Online**

- Optional. Run this command when a non-lookback IP address needs to be configured as the CAWAP control address.
- On the AC, configure the maximum number of APs that can concurrently go online to prevent an excessively high CPU usage caused by a large number of CAPWAP control packets.
- Run the **capwap ctrl-ip** *ip-address* command to specify an IP address on the AC to set up a CAPWAP tunnel with an AP. *ip-address* indicates the IP address of an interface on the AC.

Command	**capwap ctrl-ip** *ip-address*
Parameter Description	*ip-address*: Indicates the IP address of an interface on the AC to set up a CAPWAP tunnel with an AP. The IP address of Lookback 0 interface is used by default.
Defaults	The IPv4 address of the first lookback interface on the AC is used.
Command Mode	AC configuration mode
Usage Guide	By default, the AC establishes a CAPWAP tunnel with an AP using the IP address of the first loopback interface. This command allows users to manually specify the IP address for the AC to establish a CAPWAP tunnel with an AP.

Verification

- Run the **show running-config** command to display the configuration.

Configuration Example

Configuring the Control IP Address of the AC to 10.0.0.1

Configuration Steps	● Enter the AC configuration mode. ● Configure the control IP address of the AC to 10.0.0.1.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#capwap ctrl-ip 10.0.0.1`
Verification	● On the AC, run the **show running-config** command to display the configuration.

AC	`Hostname#show current-config`
	`!`
	`ac-controller`
	`capwap ctrl-ip 10.0.0.1`
	`!`

Common Errors

- N/A

1.4.11 Configuring CAPWAP Fragmentation

Configuration Effect

- After a data packet or control packet is encapsulated on the CAPWAP tunnel, the packet length may exceed the IP MTU, and will be fragmented at the IP layer. When the IP MTUs of multiple nodes on the link are inconsistent, the

packet may be fragmented and reassembled for several times, which reduces the packet forwarding performance. After CAPWAP fragmentation is enabled, the packet will be fragmented when encapsulated on the CAPWAP tunnel. The CAPWAP packet length is specified as the minimum IP MTU on the link, thereby avoiding fragmentation at the IP layer.

Notes

- If the configured MTU is too small, a lot of fragmented packets will be generated, affecting the packet forwarding performance. Even worse, large packets may fail to be transmitted. Therefore, it is important to determine the size of the MTU.
- The configured CAPWAP MTU must be smaller than or equal to the IP MTU at the egress of the device. Otherwise, IP fragmentation will be performed after CAPWAP fragmentation. The minimum IPv6 MTU is 1280 bytes, that is, the minimum path MTU is 1280 bytes. Therefore, the CAPWAP MTU must be greater than or equal to 1280 bytes.
- Fragmentation on a control tunnel is enabled by default and cannot be disabled. Fragmentation on a data tunnel is disabled by default, and you can run the **capwap fragment enable** to enable this function.

Configuration Steps

Configuring the Path MTU of the CAPWAP Data Tunnel

- (Optional) Enter the AP or AP group configuration mode, and run the **capwap mtu** command to configure the path MTU of the CAPWAP data tunnel.
- When the length of a data packet exceeds the path MTU of the CAPWAP tunnel after the data packet is encapsulated on the CAPWAP tunnel, the data packet will be fragmented on the CAPWAP tunnel. Set the path MTU of the data tunnel on the AC to the minimum IP MTU. Otherwise, IP fragmentation and reassembly are performed again during packet forwarding, reducing the forwarding performance.

Command	**capwap mtu** *num*
Parameter Description	*num*: Indicates the size of the path MTU of the CAPWAP data tunnel, in bytes. The value ranges from 110 to 1,500.
Defaults	1500 bytes
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Configuring the Path MTU of the CAPWAP Control Tunnel

- (Optional) After entering the AP configuration mode or AP group configuration mode, run the **capwap ctrl-mtu** command to configure the path MTU of the CAPWAP control tunnel.
- When the length of a control packet exceeds the path MTU of the CAPWAP tunnel after the control packet is encapsulated on the CAPWAP tunnel, the control packet will be fragmented on the CAPWAP tunnel. Set the path MTU of the control tunnel on the AC to the minimum IP MTU. Otherwise, IP fragmentation and reassembly are performed again during packet forwarding, reducing the forwarding performance.

Command	**capwap ctrl-mtu** *num*
Parameter Description	*num*: Indicates the size of the path MTU of the CAPWAP control tunnel, in bytes. The value ranges from 256 to 1,500.
Defaults	1500 bytes

Command Mode	AC configuration mode, AP configuration mode, or AP group configuration mode
Usage Guide	N/A

Enabling CAPWAP Fragmentation on the Data Tunnel

- Optional.
- When multiple IP MTU nodes exist on the transmission network, it is recommended that CAPWAP fragmentation be enabled on the AC and the CAPWAP MTU be set to the path MTU.
- After a packet is encapsulated on the CAPWAP tunnel, the packet length may exceed the IP MTU, and will be fragmented at the IP layer. When the IP MTUs of multiple nodes on the link are inconsistent, the packet may be fragmented and reassembled for several times, which reduces the packet forwarding performance. You can run this command to enable CAPWAP fragmentation. After this function is enabled, the packet will be fragmented when encapsulated on the CAPWAP tunnel. The CAPWAP packet length can be specified in the **capwap mtu** command as the minimum IP MTU on the link, thereby avoiding fragmentation at the IP layer.

Command	**capwap fragment enable**
Parameter Description	N/A
Defaults	CAPWAP fragmentation is disabled.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Check the detailed information about the CAPWAP tunnel such as the MTU and check whether CAPWAP fragmentation is enabled.
- Alternatively, run the **show ap-config running** command to display the configuration.

Configuration Example

Configuring the MTU of AP1 and Enabling CAPWAP Fragmentation

Configuration Steps	• Set the path MTU of AP1 to 1200 bytes on the AC. • Enable CAPWAP fragmentation of AP1 on the AC.

AC	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# capwap mtu 1200`
	`Hostname(config-ap)# capwap fragment enable`

Verification	Use the **show ap-config running** command to display the configuration.

AC	Hostname#show ap-config running ! capwap fragment enable capwap mtu 1200 !

Common Errors

- N/A

1.4.12 Configuring CAPWAP Encryption

Configuration Effect

- Enable the encryption function on the CAPWAP data tunnel to enhance WLAN security.
- Disable the encryption function on the CAPWAP control tunnel to perform packet analysis when network faults occur.

Notes

- Changing the encryption mode on the data tunnel triggers re-establishment of the CAPWAP tunnel.

Configuration Steps

Configuring CAPWAP Data Tunnel Encryption

- (Optional) After entering the AP configuration mode or AP group configuration mode, run the **capwap data-tunnel encryption** command to configure CAPWAP data tunnel encryption.
- The CAPWAP data tunnel is not encrypted by default. When the transmission link between the AC and AP is deployed on a public transport network, data may be intercepted or tampered with. On the AC, configure CAPWAP data tunnel encryption to ensure the transmission security of user data packets.
- Configure data tunnel encryption to ensure the security of package exchange between the AC and AP.

Command	**capwap data-tunnel encryption** { **bf** | **des** } *key*
Parameter Description	*key*: Indicates a shared key ended with a space. The value can contain a maximum of 255 characters.
Defaults	The CAPWAP data tunnel is not encrypted.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Configuring CAPWAP Control Tunnel Encryption

- Optional.
- On the AC, disable the encryption function on the CAPWAP control tunnel when network faults occur, allowing network engineers to locate faults through packet analysis.

Command	capwap dtls enable
Parameter Description	N/A
Defaults	DTLS encryption is enabled for the CAPWAP control tunnel.
Command Mode	AC configuration mode
Usage Guide	By default, DTLS encryption is enabled for the CAPWAP control tunnel to ensure security of packet exchange between the AC and the AP. In special cases, you can disable the encryption function on the CAPWAP control tunnel to facilitate tests.

Verification

- Check the detailed information about the CAPWAP tunnel to determine the encryption policies of the control tunnel and the data tunnel.
- Run the **show running-config** command to check whether encryption is enabled on the control tunnel.

Configuration Example

Enabling Encryption on the Data Tunnel and Disabling Encryption on the Control Tunnel

Configuration Steps	• On the AC, configure the AP to encrypt the data tunnel by using the DES encryption algorithm. The key is **Hostname**. • On the AC, disable the encryption function on the AP control tunnel.
AC	`Hostname(config-ap)# no capwap dtls enable`
Verification	• Check the information about the CAPWAP tunnel on the AC. • On the AC, run the **show running-config** command to check whether encryption is disabled on the control tunnel

AC	`Hostname# show capwap detail`
	`CAPWAP process "capwap 1" with state [ Run ]`
	`Process uptime is 0 days 0 hours 0 minutes 43 seconds`
	`Echo interval is 30 secs, Dead interval is 81 secs`
	`Current timers echo interval`
	`Peer address is 10.10.10.2`
	`Peer address6 is ::`
	`Peer control port is 10000, data port is 10001`
	`My address is 1.1.1.1`
	`My address6 is ::`
	`The MAC of AP is 001a.a94e.de9d`
	`The Session ID of AP is 001aa94e.de9d8ab5.11818ab5.11818ab5`
	`Capwap fragment is disable`
	`The Path MTU is 1500`

	Recent received request's sequence number 7 Recent received response's sequence number 3 Recent send request's sequence number 3 Retransmit Count 0, Discovery Count 0, Failed DTLS Session Count 0 Sending queue length 0, Receive queue length 0 Data crypt capacity BF and DES Data crypt type plain Hostname# show running-config ! no capwap dtls enable

Common Errors

- N/A

1.4.13 Configuring CAPWAP Access Control

Configuration Effect

- Configure the maximum number of concurrent APs.

Notes

- If the configured value is too small, the total online duration of all APs connected to the AC will be relatively long.

Configuration Steps

Configuring the Maximum Number of Concurrent APs

- Optional.
- On the AC, configure the maximum number of concurrent APs to prevent high CPU usage caused by a large number of CAPWAP control packets.

Command	**capwap max-concurrent** *num*
Parameter Description	*num*: Indicates the maximum number of concurrent APs. The number ranges from 1 to 65535.
Defaults	50
Command Mode	AC configuration mode
Usage Guide	If a large number of APs go online concurrently, the CPU usage of the AC may increase or even reach 100%. Consequently, tunnels of APs that are already online will be disconnected due to keepalive failures. You can use this command to configure the maximum number of concurrent APs.

Configuring the Number of CAPWAP Discovery Packets That Can Be Processed by an AC

- Optional.

- Configure the maximum number of discovery packets that can be processed by an AC on the AC to prevent high CPU usage caused by considerable CAPWAP control packets.
- Run the **capwap disc-concurrent** *num* command to configure the number of discovery packets that can be processed.

Command	**capwap disc-concurrent** *num*
Parameter Description	*num*: Indicates the number of discovery packets that can be processed per second depends on the product capacity.
Defaults	The default value varies with the product capacities, for example, the default value is 256 for the WS7800.
Command Mode	AC configuration mode
Usage Guide	The CAPWAP module needs to restrict the number of discovery packets based on the AC capacity to prevent discovery packet attacks.

Verification

- Run the **show running-config** command to display the configuration.

Configuration Example

Configuring the Maximum Number of Concurrent APs

Configuration Steps	● On the AC, configure the maximum number of APs that can concurrently go online.
AC	`Hostname(config-ac)#capwap max-concurrent 100`
Verification	● On the AC, run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config`
	`!`
	`ac-controller`
	`capwap max-concurrent 100`
	`!`

Common Errors

- N/A

1.4.14 Configuring the Heartbeat Keepalive Interval of the CAPWAP Tunnel

Configuration Effect

- (Optional) Configure the interval at which a keepalive packet is sent.

Notes

- During deployment of the wireless network, the heartbeat keepalive interval of the CAPWAP tunnel can be adjusted according to the network scale to properly plan the network convergence performance. Before configuring the

heartbeat keepalive interval, ensure that you have a good understanding about the network scale and confirm that the convergence is necessary. If the heartbeat keepalive interval is set to a small value on a wireless network where a large number of APs are deployed, the network environment will be affected.

Configuration Steps

- (Optional) Enter the AP or AP group configuration mode.
- Configure the heartbeat keepalive interval of the CAPWAP tunnel on the AC to control the keepalive period of the CAPWAP tunnel.

Command	**echo-interval** *seconds*
Parameter Description	*seconds*: Indicates the heartbeat keepalive interval of the CAPWAP tunnel, in seconds. The value ranges from 5 to 255.
Defaults	30s
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	On a fit AP network, an AC is interconnected with an AP through the CAPWAP tunnel. The Echo Request and Echo Response packets are exchanged between the AP and the AC to maintain the validity of links. If other request packets are not transmitted, the AP sends an Echo Request packet to the AC at the interval specified by **echo-interval** to keep the CAPWAP tunnel alive. If the AP does not receive any Echo Response packet, the Echo Request packet will be retransmitted. The transmission interval starts at the initial transmission interval (3s or half of **echo-interval**, whichever the smaller), and then is doubled upon next retransmission. The maximum retransmission interval cannot exceed the half of **echo-interval** or 60s, whichever the smaller. If the AP does not receive the Echo Response packet when **max-retransmit (**the maximum number of retransmission attempts) is reached, it is determined that the CAPWAP tunnel is disconnected. That is, the keepalive failure time of the tunnel is equal to the keepalive time plus the retransmission interval. This command takes effect only when the tunnel is in Run state. By default, **echo-interval** is 30s, and **max-retransmit** is 5. If the Echo Response packet is not received 0s after the Echo Request packet is sent, the Echo Request packet will be retransmitted at the interval of 3s, 6s, 12s, 15s, and 15s, respectively. The same rule is observed to calculate the packet timeout time if **echo-interval** and **max-retransmit** are set to other values.

Verification

- Check the detailed information about the CAPWAP tunnel, including the modified interval at which the keepalive packet is sent.

Configuration Example

Configuring the Heartbeat Keepalive Interval of the CAPWAP Tunnel

Configuration Steps	● On the AC, set the heartbeat keepalive interval of the CAPWAP tunnel to 50s.
AC	`Hostname(config)#ap-config AP0001` `Hostname(config-ap)# echo-interval 50`
Verification	● On the AC, check the detailed information about the CAPWAP tunnel.

AC	Hostname#show capwap 1.1.1.1 detail Echo interval is 50 secs, Dead interval is 119 secs

Common Errors

- N/A

1.4.15 Configuring the Maximum Number of CAPWAP Packet Retransmission Attempts

Configuration Effect

- (Optional) Configure the maximum number of retransmission attempts for a CAPWAP packet to adjust the keepalive interval of the CAPWAP tunnel.

Notes

N/A

Configuration Steps

- (Optional) Enter the AP or AP group configuration mode.
- Configure the maximum number of retransmission attempts for a CAPWAP packet to adjust the keepalive interval of the CAPWAP tunnel.

Command	**capwap max-retransmit** *num*
Parameter Description	*num*: Indicates the maximum number of retransmission attempts for a CAPWAP packet.
Defaults	5
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	If the AP does not receive any Echo Response packet after sending an Echo Request packet, the Echo Request packet will be retransmitted. The transmission interval starts at the initial transmission interval (3s or half of **echo-interval**, whichever the smaller), and then is doubled upon next retransmission. The maximum retransmission interval cannot exceed the half of **echo-interval** or 60s, whichever the smaller. If the AP does not receive the Echo Response packet when **max-retransmit (**the maximum number of retransmission attempts) is reached, it is determined that the CAPWAP tunnel is disconnected. You can configure the maximum number of retransmission attempts for a CAPWAP packet to adjust the keepalive interval of the CAPWAP tunnel. This command takes effect only when the tunnel is in Run state.

Verification

- Check the detailed information about the CAPWAP tunnel, including the modified interval at which the keepalive packet is sent.

Configuration Example

Configuring the Maximum Number of CAPWAP Packet Retransmission Attempts

Configuration Steps	● Set the maximum retransmission attempts of AP1 to 20.
AC	`Hostname(config)#ap-config AP1` `Hostname(config-ap)# capwap max-retransmit 20`
Verification	● On the AC, check the detailed information about the CAPWAP tunnel.
AC	`Hostname#show capwap 1.1.1.1 detail` `Config maxretransmit 20`

Common Errors

- N/A

1.4.16 Configuring the AC Discovery Mode

Configuration Effect

- An AP can discover an AC in recommended mode, DHCP mode, DNS mode, static mode, or other modes (such as broadcast or multicast mode). An AC can be configured to respond only to Discovery Request packets of specific types. Only after receiving Discovery Response packets from ACs, the AP can determine whether ACs are valid and then select an AC to set up a CAPWAP tunnel.

Notes

- If all AC discovery modes are not supported, an AP cannot access an AC by sending Discovery Request packets.

Configuration Steps

Discovering an AC in Recommended Mode

- Optional.

Command	**capwap discovery-type ac-referral { allow | forbidden}**
Parameter Description	**allow**: Indicates that this type of discovery request packets can be used to discover an AC. **forbidden**: Indicates that this type of discovery request packets cannot be used to discover an AC.
Defaults	An AP can send Discovery Request packets of a recommended type to discover an AC.
Command Mode	AC configuration mode
Usage Guide	N/A

Discovering an AC Through Discovery Request Packets

- Optional.
- After this command is configured, configurations of other discovery types will be overwritten.

Command	**capwap discovery-type all { allow | forbidden}**
Parameter Description	**allow**: Indicates that Discovery Request packets can be used to discover an AC. **forbidden**: Indicates that Discovery Request packets cannot be used to discover an AC.

Defaults	An AP can send Discovery Request packets to discover an AC.
Command Mode	AC configuration mode
Usage Guide	N/A

Discovering an AC in DHCP Mode

- Optional.

Command	**capwap discovery-type dhcp { allow | forbidden}**
Parameter Description	**allow**: Indicates that DHCP packets can be used to discover an AC. **forbidden**: Indicates that DHCP packets cannot be used to discover an AC.
Defaults	An AP can send DHCP packets to obtain the AC IP address and discover the AC.
Command Mode	AC configuration mode
Usage Guide	N/A

Discovering an AC in DNS Mode

- Optional.

Command	**capwap discovery-type dns { allow | forbidden}**
Parameter Description	**allow**: Indicates that DNS packets can be used to discover an AC. **forbidden**: Indicates that DNS packets cannot be used to discover an AC.
Defaults	An AP can send DNS packets to obtain the AC IP address and discover the AC.
Command Mode	AC configuration mode
Usage Guide	N/A

Discovering an AC in Static Mode

- Optional.
- Configure static AC IP addresses and clusters.

Command	**capwap discovery-type static-config { allow | forbidden}**
Parameter Description	**allow**: Indicates that packets carrying the configured AC IP address can be used to discover an AC. **forbidden**: Indicates that packets carrying the configured AC IP address cannot be used to discover an AC.
Defaults	An AP can send Discovery Request packets to discover the AC whose IP address is manually configured.
Command Mode	AC configuration mode
Usage Guide	N/A

Discovering an AC in Other Modes

- Optional.
- Configure other AC discovery modes, such as the broadcast or multicast mode.

Command	**capwap discovery-type unknown { allow | forbidden}**

Parameter Description	**allow**: Indicates that broadcast or multicast discovery packets can be used to discover an AC. **forbidden**: Indicates that broadcast or multicast discovery packets cannot be used to discover an AC.
Defaults	An AP can send broadcast or multicast packets to discover an AC.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to display the configuration.

Configuration Example

Forbidding an AP to Send Discovery Request Packets of a Recommended Type to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send Discovery Request packets of a recommended type to discover an AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type ac-referral forbidden`
Verification	● Display the AC configuration.

AC	`Hostname#show running-config`
	`!`
	`ac-controller`
	`capwap discovery-type ac-referral forbidden`
	`!`

Forbidding an AP to Send Discovery Request Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send Discovery Request packets to discover an AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type all forbidden`
Verification	● Display the AC configuration.

AC	`Hostname#show running-config`
	`!`
	`ac-controller`
	`capwap discovery-type all forbidden`
	`!`

Forbidding an AP to Send DHCP Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send DHCP packets to obtain the AC address and discover the AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type dhcp forbidden`
Verification	● Display the AC configuration.
AC	`Hostname#show running-config`

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send DHCP packets to obtain the AC address and discover the AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type dhcp forbidden`
Verification	● Display the AC configuration.

	`!`
	`ac-controller`
	`capwap discovery-type dhcp forbidden`
	`!`

Forbidding an AP to Send DNS Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send DNS packets to obtain the AC address and discover the AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type dns forbidden`
Verification	● Display the AC configuration.

AC	`Hostname#show running-config`
	`!`
	`ac-controller`
	`capwap discovery-type dns forbidden`
	`!`

Forbidding an AP to Send Packets Carrying the Statically Configured AC IP Address to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send packets carrying the statically configured AC IP address to discover the AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type static-config forbidden`
Verification	● Display the AC configuration.

AC	`Hostname#show running-config`
	`!`
	`ac-controller`
	`capwap discovery-type static-config forbidden`
	`!`

Forbidding an AP to Send Other Types of Discovery Request Packets to Discover an AC

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send other types of Discovery Request packets to discover the AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type unknown forbidden`
Verification	● Display the AC configuration.

Configuration Steps	● Enter the AC configuration mode. ● Forbid an AP to send other types of Discovery Request packets to discover the AC.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# capwap discovery-type unknown forbidden`
Verification	● Display the AC configuration.

AC	`Hostname#show running-config`
	`!`
	`ac-controller`
	`capwap discovery-type unknown forbidden`
	`!`

Common Errors

- N/A

1.4.17 Enabling Self-Balancing Based on VAC

Configuration Effect

- When self-balancing based on VAC is enabled on a VAC network, newly added APs will be evenly distributed to each member AC. In this way, frequent migration of APs between member ACs will be avoided when the switch directly connected to the AC fails to balance the load.

Notes

- If centralized forwarding mode is adopted on the VAC network, enabling self-balancing based on VAC will affect the forwarding performance of the device. Therefore, this function is suitable for VAC networks where local forwarding mode is adopted.

Configuration Steps

- (Optional) Enter the AC configuration mode to configure this function.

Command	**virtual-ac self-balance enable**
Parameter Description	N/A
Defaults	Disabled.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to display the configuration.
- Run the **show virtual-ac balance-info** command to display the AP load balancing information.

Configuration Example

Enabling Self-Balancing on the VAC Network

Configuration Steps	● Enable self-balancing on the VAC network.
	`Hostname(config)# ac-controller` `Hostname(config-ac)# virtual-ac self-balance enable`
Verification	● On the AC, run the **show running** command to display the configuration.
	`Hostname#show running` ` virtual-ac self-balance enable`

Common Errors

- N/A

1.4.18 Configuring the Command Set File Delivered by the AC to the AP

Configuration Effect

- On the AC, the commands to be executed by the AP are written to a specified file. The AC delivers the CLI command file to the AP in batches. After receiving the file, the AP executes the commands in the file in batches.

Notes

- N/A

Configuration Steps

Configuring the Command Set File Delivered by the AC to the AP

- Optional.
- Enter the AP configuration mode, AP group configuration mode, or all-AP configuration mode on the AC, run the **auto-cfg** command to perform configuration.

Command	**auto-cfg** [**save**] **file flash:***file-name* [**force** | **once**]
Parameter Description	**save**: Indicates that the file is retained on the AP after the AP executes the commands in the file. *file-name*: Indicates the name of the file delivered to the AP, which contains commands to be executed by the AP. **force**: Forcibly sends the command set file without checking whether the file name already exists, and the AC can send the files with the same file name to the AP. **once**: Forcibly sends the command set file without checking whether the file name already exists, and the AC does not save the file delivery record.
Defaults	N/A
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	1. The size of the CLI command set file cannot exceed 2000 KB, and the size of each command cannot exceed 128 bytes. 2. After the CLI command set file is delivered, the AP automatically executes all commands in the file.

	Ensure that the commands are correct and the AP version supports the commands in the file. 3. If the **save** parameter is not specified, the AP automatically deletes the file after executing the commands in the file. In AP configuration mode, the **save** parameter is mandatory. 4. If the configuration delivery mode is **once**, the AC does not save the delivery record of the command set file, and the command set file is not delivered again after the AP is disconnected and then reconnected. If the delivery mode is **force** or this parameter is not configured, the AC will save the command set delivery record and deliver the command set file again after the AP is reconnected.

Verification

- Run the **show running-config** command to check whether the commands in the file take effect.

Configuration Examples

Configuring the Command Set file Delivered by the AC to the AP

Configuration Steps	● Configure the AC to deliver the **ap001.txt** command set file to AP-0001.
AC	`Hostname(config)# ap-config AP-0001` `Hostname(config-ap)#auto-cfg save file flash:ap001.txt force`
Verification	● Run the **show running-config** command to check whether the commands in the file take effect.

Common Errors

Displaying

Command	Description
show ac-config active-file	Displays the list of files activated on the AC.
show ac-config serial-product	Displays the mapping between AP series configured on the AC and product models, and files used to upgrade the product series.
show ac-config upgrade-group [*group-name*]	Displays the information about the upgrade group configured on the AC.
show ap-config board-data *ap-name*	Displays the data on the master board of the AP.
show ap-config link-latency { **all** | **single** *ap-name* }	Displays the state of links between ACs and APs.
show ap-config inventory *ap-name*	Displays the AP vendor information.
show ap-config reboot *ap-name*	Displays the AP restart statistics.

Command	Description
show ap-config slot	Displays the information about micro APs connected to a specified AP.
show ap-config summary slot interface	Displays the information about downlink ports of all i-Share+ APs.
show ap-config summary group	Displays the information about i-Share+ APs in an AP group.
show ap-config static-ip{ **all** | **single** *ap-name* }	Displays the static IP address of an AP.
show ap-config summary location	Displays the AP location.
show ap-config summary slot	Displays the information about micro APs connected to all APs.
show ap-config updating-list	Displays the AP upgrade status.
show ap-config wtp-descriptor *ap-name*	Displays the AP status descriptions.
show ap-config wtp-info *ap-name*	Displays the AP status.
show capwap [index | [ip-address [port]]] **detail**	Displays the details of the CAPWAP tunnel.
show capwap state	Displays the status of the CAPWAP tunnel.
show capwap [index | [ip-address [port]]] **statistics**	Displays the statistics of the CAPWAP tunnel.
show version { **all** | *ap-name* }	Displays the AP version information.
show upgrade-appoint {summary | ap-group *apg-name***}**	Displays the scheduled time and AP upgrade status of an AP group.
tran-data-start *ap-name* {**exception** | **memory** | **tech-support** | **tech-package**} **tran-data-show** *ap-name* {**exception** | **cpuinfo** | **memory** | **syslog**| **tech-support**}	Collects and displays various logs on an AP.

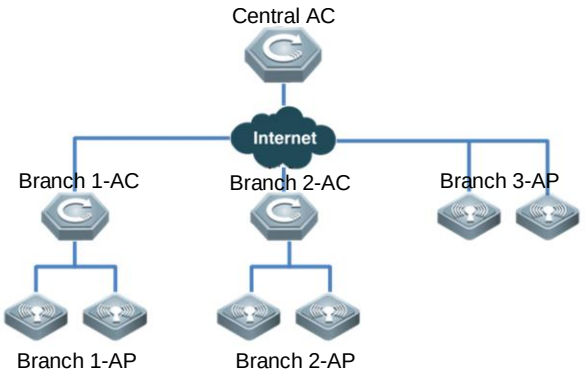
1 Configuring Basic Configuration Management Service



Supported functions vary depending on the product version.

1.1 Overview

In specific scenarios on a wireless network such as hierarchical access controller (AC) and all-optical i-Share+ master access point (AP) management, the identical configuration between two devices ensures better network running stability. Manual configuring the same commands on different devices is time-consuming and labor-intensive. The configuration management (CFGMG) function saves configuration information to a configuration template and allows administrators to add commands to and delete, modify, and query commands in the configuration template, providing the basic configuration service for different services. CFGMG improves the wireless network deployment efficiency and reduces the labor investment.

Protocols and Standards

1.2 Applications

Deployment

- Configure the AC at the headquarters as the central AC of the hierarchical AC networking.
- Configure the ACs in the branches as the branch ACs of the hierarchical AC networking.
- On the central AC and branch ACs, enable the wireless local area network (WLAN) hot standby function.
- On the central AC, add the hot standby peers for branch 1-AC and branch 2-AC.
- On branch 1-AC and branch 2-AC, add the hot standby peer for the central AC.
- On the central AC and branch ACs, add the AP groups to which branch 1-AP and branch 2-AP belong to the hot standby instances of the corresponding branches.
- On the central AC, create two configuration templates named **template1** and **template2**.
- Add the commands that are delivered to branch 1-AC to template1. On branch 1-AC, request template1.

- Add the commands that are delivered to branch 2-AC to template2. On branch 2-AC, request template2.

1.3 Features

Basic Concepts

A configuration template is used to store commands. Users can maintain commands in a configuration template through addition, deletion, modification, and query. Devices can associate with a configuration template to ensure batch delivery of commands in the configuration template to these devices.

Overview

Feature	Description
Creating a Configuration Template	Creates a configuration template.
Maintaining Commands in a Configuration Template	Adds commands to or deletes or modifies commands in a configuration template.

1.3.1 Creating a Configuration Template

To store commands in a configuration template, create a configuration template first. To modify commands in an existing configuration template, enter the configuration mode of the configuration template first.

Working Principle

Create a configuration template or enter the configuration mode of an existing configuration template. If you choose the former, you will enter the configuration mode after a configuration template is created.

1.3.2 Maintaining Commands in a Configuration Template

To meet command operation requirements of different services, you can add commands to and delete and modify commands in a configuration template. In addition, to add commands quickly, commands can be imported from a file in a specific format to a configuration template.

Working Principle

After a configuration template is created, a linked list is created in the memory to store commands in the configuration template. A line ID is required for each stored command to uniquely identify the command and determine the location of the command in the linked list. In this case, users can add, modify, and delete specific commands by line ID. To prevent command loss due to a process restart or device restart, commands in a configuration template are stored in file format, and command changes in the template will be synchronized to the file.

1.4 Configuration

Configuration	Description and Command	
Creating a Configuration Template	⚠ (Optional) It is used to create a configuration template.	
	cfgmg template	Creates a configuration template.

Maintaining Commands in a Configuration Template	(Optional) It is used to maintain commands in a configuration template.	
	import	Imports commands from a file to a configuration template.
	append	Appends commands to the end of a configuration template.
	insert	Inserts a command into a specific location of a configuration template.
	line	Modifies a command in a specific location of a configuration template.

1.4.1 Creating a Configuration Template

Configuration Effect

- Create a configuration template.

Notes

N/A

Creating a Configuration Template

- In AC global configuration mode, create a configuration template.

Command	**cfgmg template** *temp-name*
Parameter Description	*temp-name*: Indicates the name of a configuration template. The value is a string of 1 to 31 characters. Up to 512 configuration templates can be configured for each device.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running** or **show cfgmg template summary** command to check whether the configuration template is configured successfully.

Configuration Example

Creating a Configuration Template

Configuration Steps	• Create a configuration template in global configuration mode.
AC	`Hostname(config)#cfgmg template wlan-temp1` `Hostname(config-temp)#`
	• Check whether the configuration template is configured successfully.

AC	`Hostname#show cfgmg template summary`
	`Cfgmg Template Name`
	`1. wlan-temp1`

Common Errors

N/A

1.4.2 Maintaining Commands in a Configuration Template

Configuration Effect

- Add commands to or delete or modify commands in a configuration template.

Notes

A configuration template supports a maximum of 128 commands.

Appending Commands to a Configuration Template

- Append commands to a configuration template.

Command	**append** *command-string*
Parameter Description	*command-string*: Indicates the command line character string to be added to a configuration template. The value is a string of 0 to 255 characters. The command format is the same as that in the **show running** command output.
Defaults	N/A
Command Mode	Template configuration mode
Usage Guide	1. This command is used to append commands to the end of a configuration template. The line ID of an added command is the current maximum command line ID in the template plus 1. 2. The command format is the same as that in the **show running** command output. For example, if the format of the **wlan-config** command in the **show running** command output is **wlan-config** 1 Hostname, the command format in the configuration template is also **wlan-config** 1 Hostname. 3. This command does not have the **no** or **default** form. To delete a command in the specified line, use the **no line** command.

Inserting Commands into a Configuration Template

- Insert a command into the specified line of a configuration template.

Command	**insert** *line command-string*
Parameter Description	*line*: Indicates the ID of the line into which a command is to be inserted. The value range is from 1 to 65,536. *command-string*: Indicates the command character string to be inserted into the configuration template. The value is a string of 1 to 255 characters. The command format is the same as that in the **show running** command output.
Defaults	N/A
Command Mode	Template configuration mode
Usage Guide	1. This command is used to insert a command into the specified line of a configuration template. If a command already exists in the line, the existing command is moved to the next line after the new command is inserted. Subsequent lines with commands are moved to the next lines accordingly. 2. The command format is the same as that in the **show running** command output. For example, if the format of the **wlan-config** command in the **show running** command output is **wlan-config** 1

	Hostname, the command format in the configuration template is also **wlan-config** 1 Hostname. 3. This command does not have the **no** or **default** form. To delete a command in the specified line, use the **no line** command. 4. A configuration template supports a maximum of 128 commands.

Modifying Commands in a Configuration Template

- Add a command to or modify the command in the specified line of a configuration template.

Command	**line** *command-string*
Parameter Description	*line*: Indicates the ID of the line where a command to be added or the command to be modified resides. The value range is from 1 to 65,536. *command-string*: Indicates the command character string to be modified or inserted. The value is a string of 1 to 255 characters. The command format is the same as that in the **show running** command output.
Defaults	N/A
Command Mode	Template configuration mode
Usage Guide	1. This command is used to add a command to or modify the command in the specified line of a configuration template. If a command already exists in the line, the existing command is overwritten. If no command exists in the line, a command is added to the line. 2. The command format is the same as that in the **show running** command output. For example, if the format of the **wlan-config** command in the **show running** command output is **wlan-config** 1 Hostname, the command format in the configuration template is also **wlan-config** 1 Hostname. 3. The **no line** command is used to delete the command in the specified line.

Importing Commands to a Configuration Template

- Import commands from a file to a configuration template.

Command	**import** *filename*
Parameter Description	*filename*: Indicates the name of the file that stores the commands to be imported to a configuration template. The value is a string of 1 to 57 characters. The command line length in the file is a string of 1 to 255 characters, and each command occupies one line. The *filename* parameter is written in **path/file name** format. The file path can be the flash directory or data directory. If the flash directory is used, path in the *filename* parameter can be omitted.
Defaults	The file in the flash directory is imported.
Command Mode	Global configuration mode
Usage Guide	1. This command is used to import commands from the specified file to a configuration template. The command lines are added to the end of the configuration template and numbered by the current maximum command line ID in the template plus 1 accordingly. 2. The command format is the same as that in the **show running** command output. For example, if the format of the **wlan-config** command in the **show running** command output is **wlan-config** 1 Hostname, the command format in the configuration template is also **wlan-config** 1 Hostname. 3. This command does not have the **no** or **default** form. To delete a command in the specified line, use

	the **no line** command. 4. Windows or Unix file formats are supported, and the UTF-8 or GBK coded character set is supported. The coded character set can be selected based on actual requirements. If a coded character set is configured for the device system, the coded character set of the device system is used. Otherwise, it is recommended that the GBK coded character set be used, which is the default coded character set of the device system in a Chinese version and can prevent abnormal display during Web page access. In addition, the coded character set must be the same as that of the terminal simulation program to prevent abnormal display. 5. Each line in the file is a command, which is the same as the **append** command. *command-string* is a string of up to 255 characters. If the number of character strings of a command exceeds the limit, the command fails to be imported and all subsequent commands are stopped to be imported.

Verification

- Run the **show this** or **show cfgmg template name** command to check whether the commands are appended to the configuration template successfully.

Configuration Example

↘ Appending, Inserting, or Importing Commands to or Modifying Commands in a Configuration Template

Configuration Steps	Append, insert, or import commands to or modify commands in a configuration template.
	● Append commands to a configuration template in template configuration mode.

AC	`Hostname(config)#cfgmg template wlan-temp1`
	`Hostname(config-temp)#append wlan-config 1 Hostname`
	`Hostname(config-temp)#append tunnel local`

	● Check whether the commands are appended to the configuration template successfully.

AC	`Hostname(config-temp)#show this`
	`Building configuration...`
	`!`
	`line 1 wlan-config 1 Hostname`
	` line 2 tunnel local`
	`!`
	`end`

	● Import commands to a configuration template in template configuration mode.

AC	`Hostname(config)#cfgmg template wlan-temp2`
	`Hostname(config-temp)#import new-branch-cfg.txt`
	
	`For example, the content of the new-branch-cfg.txt file is as follows:`
	`wlan-config 2 Hostname2`
	`tunnel local`
	`wlan-config 3 Hostname3`
	`tunnel local`

	● Check whether the commands are imported to the configuration template successfully.

AC	Hostname(config-temp)#show this Building configuration... ! cfgmg template wlan-temp2 line 1 wlan-config 2 Hostname2 line 2 tunnel local line 3 wlan-config 3 Hostname3 line 4 tunnel local ! end
	● Insert commands into a configuration template in template configuration mode.
AC	Hostname(config)#cfgmg template wlan-temp3 Hostname(config-temp)#insert 10 wlan-config 100 Hostname Hostname(config-temp)#insert 10 wlan-config 22 Hostname
	● Check whether the commands are inserted into the configuration template successfully.
AC	Hostname(config-temp)#show this Building configuration... ! line 10 wlan-config 22 Hostname line 11 wlan-config 100 Hostname ! end
	● Add commands to or modify commands in a configuration template in template configuration mode.
AC	1: Add a command to the specified line. Hostname(config)#cfgmg template wlan-temp4 Hostname(config-temp)#line 10 wlan-config 22 Hostname Hostname(config-temp)#line 50 wlan-config 50 Hostname 2: Modify the command in the specified line. Hostname(config)#cfgmg template wlan-temp4 Hostname(config-temp)#line 10 wlan-config 10 Hostname 3: Delete the command in the specified line. Hostname(config)#cfgmg template wlan-temp4 Hostname(config-temp)#no line 50
	● Check whether the commands are added or modified successfully.

```
1: Check whether a command is added to the specified line successfully.
Hostname(config-temp)#show this
Building configuration...
!
line 10 wlan-config 22 Hostname
 line 50 wlan-config 50 Hostname
!
end
2: Check whether the command in the specified line is modified successfully.
Hostname(config-temp)#show this
Building configuration...
!
line 10 wlan-config 10 Hostname
 line 50 wlan-config 50 Hostname
!
end
3: Check whether the command in the specified line is deleted successfully.
Hostname(config-temp)#show this
Building configuration...
!
line 10 wlan-config 10 Hostname
!
end
```

Common Errors

1. The imported file is not in .txt format.
2. Commands in the imported file are not written based on the rule of one line for one command.

1 Configuring APMG

1.1 Overview

Tailored for the wireless network architecture that supports centralized management, AP Management (APMG) implements centralized management and configuration of access points (APs).

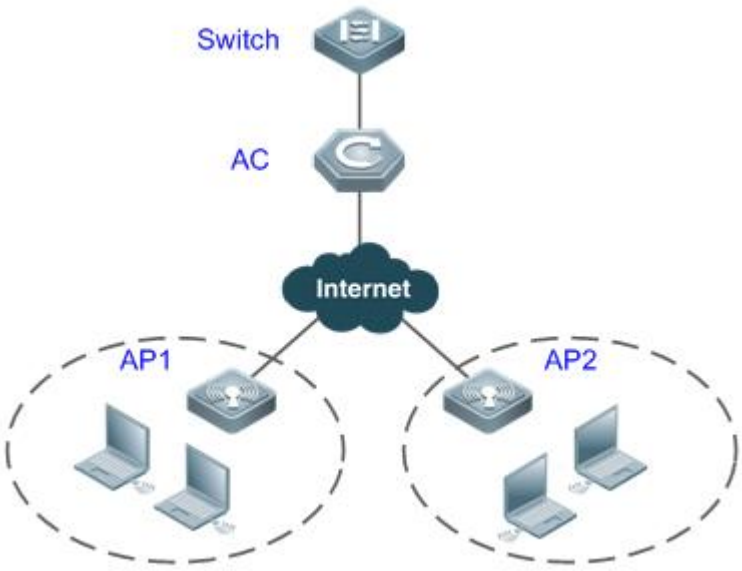
A Wireless Local Area Network (WLAN) refers to a network system that allows different PCs to communicate and share resources with each other by interconnecting different PCs through wireless communications technologies. The essence of a WLAN is that PCs are interconnected with each other in wireless rather than wired mode, thus constructing a network and allowing clients to move more flexibly.

A traditional WLAN adopts the fat AP network architecture in which APs work independently. On the traditional WLAN, each AP must be separately configured and managed, which increases the complexity of network management and O&M workload. In addition, problems, such as radio interference between APs and roaming of wireless users, cannot be effectively resolved due to poor collaboration between APs. To address these issues, a wireless network architecture that supports centralized management emerges. This network architecture consists of access controllers (ACs) and fit APs, and is also called fit AP network architecture. In this network architecture, APs are connected to ACs through the Control and Provisioning of Wireless Access Points (CAPWAP) tunnels, and ACs perform centralized management on APs.

Protocols and Standards

- RFC5415: Control And Provisioning of Wireless Access Points (CAPWAP) Protocol Specification
- RFC5416: Control and Provisioning of Wireless Access Points (CAPWAP) Protocol Binding for IEEE 802.11

1.2 Application



Application	Description
Fit AP Network	The network architecture consists of switches, ACs, and fit APs.

1.2.1 Fit AP Network Architecture

Scenario

A fit AP network consists of switches, ACs, and fit APs. In the fit AP network structure, APs serve as the wireless access points only and do not have the management or control function. The AC manages all the APs in a centralized manner, and delivers control policies to APs, eliminating the need to configure APs separately. As shown in Figure 1-1, the AC is connected to multiple APs through the CAPWAP tunnels. Users only need to perform configuration management on all the connected APs through the AC.

Figure 1-1 Fit AP Network Topology

Remarks	AP1 and AP2 are fit APs.

Deployment

- Configure an indicative name for each AP so that the AP can be configured based on the name.
- Create a WLAN and configure WLAN-related attributes.
- Create an AP group and add APs to a specified AP group so that all the APs in this AP group can be configured in a centralized manner.
- Deploy the WLAN on all the APs in the AP group through configuration of the AP group, after which the APs can provide the WLAN access service for wireless users.

1.3 Features

Basic Concepts

AP

AP is an access point used by wireless clients to access a wired network. It is equivalent to a bridge for communication between wireless clients and a wired network.

AC

AC is a wireless access controller. It is interconnected with APs over the wired network to manage and control APs in a centralized manner.

AC Cluster

AC cluster is also called AC redundancy. With this function, multiple ACs with different priorities are designated for an AP. When the connection between the AP and a high-priority AC is down, the AP is connected to a low-priority AC (standby

AC). When the connection to the high-priority AC is recovered, the AP disconnects the CAPWAP tunnel with the low-priority AC, and sets up a CAPWAP tunnel with the high-priority AC again.

Overview

Feature	Description
Configuration of AC Authorization Key	Configures the license activation/deactivation key of an old version system.
Configuration of AC Parameters	Configures parameters, such as the AC name and Trap message control.
Configuration of AP Parameters	Configure parameters, such as the AP name, Telnet user name and password, and periodical statistics report interval.
Configuration of AP Behaviors	Configures AP behaviors, including daily scheduled restart of an AP, restoration of AP factory settings, and AP reset.
AP Group Management	Manages APs through the AP group to reduce the workload incurred by configuring APs one by one.
AP Quantity Limit	Limits the maximum number of APs that can be connected to the AC.
AP Compliance Check	Implements the AP access control based on the bound MAC address.
AP Access Authentication	Authenticates the AP access.
AP Priority	Implements the AP access control based on the priority.
AC Cluster	Implements AC redundancy by using the AC cluster to reduce the AC single-point failure and improve availability of the wireless network.
AC Hot	Sets up the hot standby connection to ensure that the AP can set up two CAPWAP tunnels.
WLAN Configuration	Configures a WLAN and deploys the WLAN on APs to provide WLAN services for wireless users.
AP Backup	Configures the AP backup function to improve availability of the wireless network.
Hierarchical Permission-based AC Management	Virtualizes one AC into multiple ACs through permission control.
AP Virtualization	Virtualizes an AP into multiple APs to be managed by different ACs.
Default SSID Configuration	Configures the default SSID of an AP. When no tunnel is available, the AP uses the default SSID to provide the WLAN access service.
Automatic AP Grouping	Assigns an AP to a specified AP group according to the matching rules after the AP goes online.
AC/AP Version Access Control	Configures the AC version features to specify the AP software version features that can access the AP.

1.3.1 Configuration of AC Authorization Key

The AC authorization key is a license activation key of an earlier version system, and used to control the upper limit of APs supported by an AC.

Working Principle

The license activation key is used to control the upper limit of APs supported by an AC. You can use a command to configure or add a valid license. The input license must be valid, effective, and applicable to the local device. If the upper limit of APs supported by the AC is reached, no new license can be configured or added. You can also inactivate a license using the **no set license** *activation-key* command.

1.3.2 Configuration of AC Parameters

AC parameters include the AC name, Trap message control, and AC network access server (NAS) ID.

Working Principle

Configuration of AC parameters does not involve any working principle.

1.3.3 Configuration of AP Parameters

AP parameters include the AP name, Telnet user name and password, and periodical statistics report interval.

Working Principle

The AC configures AP parameters by sending CAPWAP packets to an AP.

1.3.4 Configuration of AP Behaviors

AP behaviors include daily scheduled restart of an AP, restoration of AP factory settings, and AP reset.

Working Principle

Configuration of AP behaviors is implemented by delivering CAPWAP packets to an AP. The AP performs the related behaviors based on the configuration delivered by the AC.

1.3.5 AP Group Management

The AC manages APs through the AP group. All APs in an AP group can be configured through the AP group, which reduces the configuration workload. Configurations of the AP group take effect on all the APs in the group. For the same configuration, if both the AP-based configurations and the AP-group-based configurations exist, the AP-based configurations prevail.

Working Principle

The system automatically creates a default AP group, which is named **default**. By default, APs are added to the **default** group. You can create AP groups and add APs to these groups to manage APs by group.

1.3.6 AP Quantity Limit

The maximum number of APs that can be connected to an AC is configured to limit the maximum AP load of the AC, thus avoiding overload of the AC.

Working Principle

When the number of APs connected to the AC reaches the maximum number, no more APs can access the AC.

Each wall-plate AP is treated as 0.5 device when the maximum number of APs that can be connected to an AC is calculated. That is, the maximum number of wall-plate APs that can be connected to an AC is twice the number of APs supported by the AC.

1.3.7 AP Compliance Check

The AP compliance check is also called AP access control based on the bound MAC address. If the AP compliance check is enabled, only APs with some specified MAC addresses are allowed to access the AC. This prevents access of unwanted APs and enhances security of the wireless network.

Working Principle

An AP is allowed to access the AC only when the AP configuration that is bound with the MAC address of this AP exists on the AC; otherwise, access of the AP to the AC is denied. To prevent binding MAC addresses with a large number of AP configurations, the MAC addresses of currently online APs are automatically bound when the AP compliance check is enabled. In addition, MAC addresses can be bound with specified AP configurations.

1.3.8 AP Access Authentication

AP access authentication can be implemented based on the serial number, password, or certificate. With the AP access authentication function, only authorized APs can access the AC.

Working Principle

When an AP sends an access request to the AC and uploads the authentication information, the AC verifies the authentication information. Only the AP that is successfully authenticated can access the AC.

1.3.9 AP Priority

The AP priority function is an advanced version of the AP quantity limit function. With this function, when the current number of APs connected to the AC reaches the upper limit, if a high-priority AP sends an access request, the AC proactively forces a low-priority AP to go offline and allows the access of the high-priority AP.

Working Principle

When an AP sends an access request, the current number of APs connected to the AC reaches the upper limit, and the AP priority function is enabled, the AC first compares the priorities. If the priority of an online AP is lower than the requesting AP, the AC forces a low-priority AP to go offline and allows the access of the high-priority AP.

1.3.10 AC Cluster

On the one hand, the AC cluster function enhances reliability of the AC cluster. On the other hand, this function controls the home AC of APs in stable conditions based on the priority to facilitate AP management.

Working Principle

See the CAPWAP protocol in RFC5415.

1.3.11 AC Hot Standby

The AC hot standby function enables millisecond-level switchover of the CAPWAP tunnels between ACs and APs when an AC is unreachable or faulty, thus ensuring uninterrupted services for associated STAs to the maximum extent.

Working Principle

Two tunnels are set up between an AP and two ACs, and one tunnel works in active mode, and the other works in standby mode. The AC corresponding to the active tunnel serves as the active device that processes all services and transfers the service status information to the standby device for backup purpose. The standby device does not process services, and only backs up the service data. If the active AC is faulty, the standby AC takes over all services.

For details about AC hot standby, see Configuring WLAN Hot Standby.

1.3.12 WLAN Configuration

Create and deploy a WLAN on an AP so that the AP can provide the WLAN access service for wireless users.

Working Principle

The WLAN created on the AC is used for WLAN parameter configuration. The WLAN deployment information and parameters are delivered through the packets defined in the CAPWAP protocol.

1.3.13 AP Backup

The AP backup function is used to back up radio signals transmitted by APs that are physically adjacent with each other, have overlapped coverage, and transmit different radio signals. When an AP that transmits important radio signals is faulty, one or more standby APs transmit radio signals of the faulty AP to replace the faulty AP, thus ensuring stability of radio signals. This function is generally used in special scenarios. For example, in the seamless roaming scenario of the medial industry, the AP4210 with a wide coverage is an active AP, and the APD-M connected to the AP4210 serves as a standby AP of the AP4210.

Working Principle

An AP backup group is created on the AC. In this AP backup group, one AP is selected as the active AP, and other APs are standby APs. When the active AP is faulty and goes offline, the WLAN configuration of the active AP is sent to all the standby APs in the group so that the standby APs can transmit radio signals of the active AP.

1.3.14 Hierarchical Permission-based AC Management

Hierarchical permission-based AC management virtualizes one AC into multiple ACs through permission control. Currently, the hierarchical permission-based AC management function is available only on the web management system. Users can log in to the web management page by using different administrator accounts and query and configure different WLANs, AP groups, and APs. In addition, administrators can back up information of each other. When multiple administrators share the same role, these administrators have the same permissions. When one administrator cannot perform operations due to absence or other causes, another administrator can log in to the web management page by using his or her own account and perform the operations. This ensures account security.

Working Principle

A super administrator can create different roles on the AC or by logging in to the web management page, associate administrators with different roles, and assign WLANs, AP groups, and APs to the roles. When an administrator logs in to the web management page, the administrator can only query and configure the corresponding WLANs, AP groups, and APs (STAs). This ensures that different roles manage the same AC simultaneously but do not interfere with each other, achieving the effect of virtualizing one AC into multiple ACs.

1.3.15 AP Virtualization

The AP virtualization function virtualizes one AP into multiple APs. Each virtual AP establishes a connection to an AC (not in the hot standby state), and these virtual APs share physical resources of the AP. Each AC can deliver its own configurations and configure its own wireless signals to manage the AP. When an STA receives signals broadcast by an AC, the AP serving the STA reports the corresponding data to the AC. As the data channels used by the virtual APs to report data to the ACs are different and the virtual APs are not accessible to each other, the data security is improved. In addition, as the APs are controlled by multiple ACs, the AC single point of failure (SPOF) will not occur and the AP stability is improved.

Working Principle

Create an AP virtualization template on the active AC and apply the template to an AP, an AP group, or all APs. In this case, the AP establishes connections to other ACs according to configurations of the AP virtualization template and the connected ACs can deliver their own configurations to the AP.

1.3.16 Default SSID Configuration

Configure an SSID for a fit AP to provide the WLAN access service when no CAPWAP tunnel is established.

Working Principle

The AC configures a default SSID for the AP. When the AP restarts or the tunnel is disconnected, the AP uses the SSID to provide the WLAN access service.

1.3.17 Automatic AP Grouping

On a fit AP network where many APs are deployed, plan different AP groups to manage the connected APs in a diversified and unified manner to reduce repetitive configuration workload. When APs are initially connected to an AC, the APs belong to the default AP group and you need to add each AP to a specified AP group one by one, which is cumbersome. The automatic AP grouping function provides a method for grouping APs in batches according to the preconfigured network segment matching rule in the AP group, which reduces the configuration workload of administrators.

Working Principle

Configure matching rules in the AP group, such as the source IP network segment (the IP addresses of APs). After an AP goes online, the AP is automatically assigned to the AP group if the configured rules are matched.

1.3.18 AC/AP Version Access Control

When deploying APs on a thin AP network, different software feature values of APs may cause incompatibility between APs and ACs. This issue can be resolved through version access control for the AC/AP software feature values.

Working Principle

When APs are brought online on ACs, they check the software feature values of each other. APs can access ACs only when they determine that they support each other's software feature values.

1.4 Configuration

Configuration	Description and Command	
Configuring the AC Authorization Key	(Optional) To increase the number of APs supported by an AC, purchase and install a new license.	
	set license	Configures the license activation key.
	license-idle-timeout	Configures the shared aging time of a license.
Configuring an AC Name	(Optional) It is used to configure an indicative name for the AC to facilitate management.	
	ac-name	Configures the name of the local AC.
Configuring the Trap Message Control Function	(Optional) It is used to enable sending of Trap messages. Network operation and maintenance (O&M) can be implemented based on the received Trap messages.	
	acctrl-trap	Configures whether the AC sends specified Trap messages.
Configuring the NAS ID of an AC	(Optional) By default, the NAS ID is the MAC address of the AC in dotted decimal notation.	
	nas-id	Configures the NAS ID of the AC in AC configuration mode.
Creating an AP Configuration	(Optional) It is used to create an AP configuration to configure a specified AP.	
	ap-config	Adds an AP configuration, or enters the AP configuration mode.
Creating an AP Group	(Optional) In AP group configuration mode, this command takes effect on all the online APs in the AP group.	
	ap-group	Adds an AP group configuration, or enters the AP group configuration mode.
Configuring the AP Group of an AP	(Optional) It is used to configure the AP group of a specified AP in AP configuration mode. By default, an AP belongs to the default group.	
	ap-group	Configures the AP group of an AP.
Configuring an AP Name	(Optional) It is used to configure a new name for an AP as required.	
	ap-name	Configures an AP name.
Binding an MAC Address to an AP Configuration	(Optional) It is used to bind an MAC address to an AP configuration so that the AP configuration can take effect on the AP with the MAC address.	
	ap-mac	Binds an MAC address to an AP configuration.

Configuration	Description and Command	
Configuring the User Name and Password of an AP	⚠ (Optional) It is used to modify the Telnet user name and password of an AP as required.	
	credential	Configures the user name and password of an AP.
Configuring the Interval at Which the AP Reports Statistics	⚠ (Optional) It is used to configure the interval at which the AP reports statistics as required. The default interval is 120s.	
	statistics-timer	Configures the interval at which the AP reports statistics.
Configuring the Daily Scheduled Restart Time for an AP	⚠ (Optional) It is used to configure the daily scheduled restart function for an AP to prevent the AP from working for a long time.	
	reload at	Configures the AP restart time.
Restoring Factory Settings of a Specified AP	⚠ (Optional) It is used to restore factory settings of an AP.	
	factory-reset	Restores factory settings of a specified AP.
Resetting an AP	⚠ (Optional) It is used to reset an AP.	
	reset	Resets an AP.
Configuring the AP Quantity Limit	⚠ (Optional) It is used to configure the maximum number of APs connected to the AC on demand to reduce the maximum load of the AC.	
	wtp-limit	Configures the maximum number of APs that can be connected to the AC.
Configuring the AP Compliance Check	⚠ (Optional) It is used to configure the AP compliance check to allow the access of only APs with the bound MAC addresses, thus effectively controlling the access of APs.	
	bind-ap-mac	Enables or disables the AP compliance check in AC configuration mode.
Configuring AP Access Authentication	⚠ (Optional) It is used to configure AP access authentication so that only authorized APs can access the AC, which enhances security of the wireless network.	
	ap-auth enable	Enables or disables the AP access authentication function of the AC in AC configuration mode.
	ap-auth serial-update	Updates authentication serial numbers for all online APs in AC configuration mode.
	ap-auth	Configures the access authentication information of a specified AP in AP configuration mode.
Configuring the AP Priority	⚠ (Optional) This command is available in both the AC and AP configuration modes.	
	ap-priority	Enables or disables the AP access priority function of the AC in AC configuration mode.
	priority	Configures the failover priority of a specified AP in AP configuration mode.

Configuration	Description and Command	
Configuring the AC Cluster Function	(Optional) It is used to configure the redundancy ACs of a specified AP or all APs in AP configuration mode.	
	primary-base	Configures the primary AC of an AP.
	secondary-base	Configures the secondary AC of an AP.
	tertiary-base	Configures the tertiary AC of an AP.
	backup-controller-primary	Configures the fourth AC of an AP.
	backup-controller-secondary	Configures the fifth AC of an AP.
	backup-controller-tertiary	Configures the sixth AC of an AP.
Configuring the AC Hot Standby Function	(Optional) It is used to adjust the hot standby connection parameters.	
	ap-group	Binds an AP group.
	peer-ip	Configures the peer IP address.
	peer-ipv6	Configures the peer IPv6 address.
	peer-ipv6 enable	Enables the peer IPv6.
Configuring the AP System Log Information	(Optional) It is used to configure the log information of a specified AP or all APs in AP configuration mode.	
	logging on	Enables or disables the function of displaying system logs.
	logging server	Configures the address of the system logging server.
Creating a WLAN	(Optional) A WLAN must be created before it can be deployed.	
	wlan-config	Creates a WLAN, or enters the WLAN configuration mode.
Deploying a WLAN	(Optional) It is used to configure the WLAN-VLAN mapping of a specified AP group and deploy the WLAN on all the APs in the AP group.	
	interface-mapping	Configures the WLAN-VLAN mapping of a specified AP group in AP group configuration mode.
Configuring WLAN SSID Broadcasting	(Optional) It is used to configure SSID broadcasting as required. SSID broadcasting is disabled by default.	
	enable-broad-ssid	Enables or disables SSID broadcasting of a specified WLAN in WLAN configuration mode.
Configuring the NAS ID of a WLAN User	(Optional) It is used to configure the NAS ID of a specified WLAN user. The NAS ID is a null string by default.	
	nas-id	Configures the NAS ID of a specified WLAN user.
Configuring the Fit or Fat AP Mode	(Optional) It is used to configure the fit or fat AP mode. The AP mode can be switched between the fit AP mode and the fat AP mode as required.	
	switch2fat	Switches the mode of a specified AP to the fat AP mode in AC configuration mode on the AC.

Configuration	Description and Command	
Configuring the WLAN SSID	(Optional) It is used to configure a new SSID for the WLAN as required.	
	ssid	Changes the SSID of the WLAN in WLAN configuration mode.
	ssid-code	Configures the coded character set for the SSID.
Configuring the AP Backup Function	(Optional) It is used to improve availability of the wireless network.	
	ap-backup group	Creates an AP backup group in AC configuration mode.
	ap-backup-group	Binds an AP backup group.
Configuring Hierarchical Permission-based AC Management	(Optional) It is used to assign wireless permissions and virtualize one AC into multiple ACs.	
	permit enable	Configures the local AC to enable or disable hierarchical permission-based AC management in AC configuration mode.
	master-group	Adds a role and enters the role configuration mode.
	master-group (AP configuration mode)	Assigns an AP to a specific role in AP configuration mode.
	master-group (AP group configuration mode)	Assigns an AP group to a specific role in AP group configuration mode.
	master-group (WLAN configuration mode)	Assigns a WLAN to a specific role in WLAN configuration mode.
	webmaster (role configuration mode)	Adds or deletes an administrator in role configuration mode.
Configuring the AP Virtualization Function	(Optional) It is used to enable multiple ACs to manage the same AP.	
	virtual-ap	Creates an AP virtualization template in global configuration mode.
	ac-ip	Configures the IP address of the AC to which a virtual AP is to be connected.
	wlan-capacity	Configures the number of WLANs supported by a virtual AP.
	sta-capacity	Configures the number of STAs supported by a virtual AP.
	link-interface	Configures the uplink interface used by a virtual AP to connect to an AC.
	virtual-ap	Configures a virtual AP in single AP, AP group, and all-AP configuration modes.
	ap-idle-timeout	Configures the duration for a virtual AP to provide services after the connection between the AP and active AC is down.
Configuring the Default SSID	**offline-ssid**	Configures the WLAN access signal provided when an AP is offline.

Configuration	Description and Command	
Configuring Automatic AP Grouping	(Optional) It is used to simplify the AP grouping configuration.	
	auto-join-group match src-ip	Configures the IP matching rules for automatic AP grouping in AP group configuration mode.
Configuring the AC Software Features	(Optional) By default, the AC software feature value is configured.	
	wlan-features	Configures the software feature value of the AC.

1.4.1 Configuring the AC Authorization Key

Configuration Effect

- Increase the number of APs supported by an AC.

Notes

- A configured license takes effect permanently. That is, the license never expires. Once you configure the license, you are assigned to use the function permanently.
- The license takes effect as soon as it is configured on a device, and restart of the device is not necessary.
- Multiple licenses can be configured on the same AC. That is, the maximum number of APs supported by an AC is equal to the sum of the AP quantities authorized by the licenses, but cannot exceed the capacity of the AC.
- After being deactivated, the license cannot be installed on the device again. But you can apply for a new license for another device using this license, the old SN, the deactivation key and a new SN.
- After you deactivate a license, the number of APs allowed to go online reduces immediately. The APs that are already online are not affected.
- This command is used to import the activation key of the earlier-version license system. A new license is installed by using the license file installation command. For details, see *Software Authorization Management*.

Configuration Steps

- Optional. To increase the number of APs supported by an AC, purchase and install a new license.
- The license activation key is not installed by default.
- You can run the **set license** *activation-key* command in global configuration mode to import the activation key of the earlier-version license system.

Command	**set license** *activation-key*
Parameter Description	*activation-key*: Indicates the license activation key to be configured. The format of the license key depends on the actual situations, for example, AAAA-BBBB-CCCC-DDDD-EEEE-FFFF-GGGG-HHHH.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	A license is applicable to only the device that you specify when applying for a license, and does not take effect on other devices. The same license cannot be configured for multiple times on one device.

Command	**license-idle-timeout** *timeout*
Parameter Description	*timeout*: Indicates the aging time (in hours) of the license sharing on a license sharing network after the AC stops using the license. The value ranges from 1 to 336 (14 days).
Defaults	168 (7 days)
Command Mode	AC configuration mode
Usage Guide	This command is applicable to the license sharing scenarios, such as AC virtualization scenarios.

Verification

- Run the **show license all-license** command to display the license information and check whether the configuration is successful.
- **show license unbind-code command** to check the deactivated license.

Configuration Example

Configuring the License Activation Key

Configuration Steps	• Add a license.
AC	`Hostname#config terminal` `Hostname(config)#set license4A3F-16AB-330C-B254-42C4-E18A-24F3-15CA`
Verification	• Run the **show license all-license** command to display the license.

AC	`Hostname(config)#show license all-license`
	`Searching license in the system...`
	`There's no license installed in the system.`
	
	`-----------------------------------------`
	`There are some old version licenses:`
	
	`1. 4A3F-16AB-330C-B254-42C4-E18A-24F3-15CA 128`

Common Errors

- N/A

1.4.2 Configuring an AC Name

Configuration Effect

- Set the name of an AC to a specified string.

Notes

- The AC name is a string of 1 to 63 characters, and cannot contain any space.

Configuration Steps

- Optional. Run the **ac-name** *ac-name* command in AC configuration mode to configure a new name for an AC.
- Run the **ac-controller** command to enter the AC configuration mode.

- Run the **ac-name** command to configure an AC name in AC configuration mode on an AC.

Command	**ac-controller**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**ac-name** *ac-name* **no ac-name**
Defaults	The default AC name is Hostname_Ac_*Last six digits of MAC address*. For example, if the MAC address of an AC is 001a.a916.e7b8, the default name of this AC is Hostname_Ac_16e7b8.
Parameter Description	*ac-name*: Indicates the name of an AC. The name is a string of 1 to 63 characters, and cannot contain any space.
Command Mode	AC configuration mode
Usage Guide	Different names can be configured for different ACs to facilitate management. The default AC name is Hostname_Ac_*Last six digits of MAC address*. For example, if the MAC address of an AC is 001a.a916.e7b8, the default name of this AC is Hostname_Ac_16e7b8.

Verification

- Run the **show ac-config** command to check the current AC name and determine whether the configuration is successful.

Configuration Example

Configuring the Name of an AC as Hostname-AC1

Configuration Steps	• Enter the AC configuration mode. • Configure an AC name.

AC	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#`
	`Hostname(config-ac)#ac-name Hostname-AC1`

Verification	• Run the **show ac-config** command to display the AC name.

AC	`Hostname#show ac-config`
	
	`ac_name :Hostname-AC1`

Common Errors

- N/A

1.4.3 Configuring the Trap Message Control Function

Configuration Effect

- The AC sends the following types of Trap messages: CAPWAP tunnel up/down information, failures to add APs to the AC, CAPWAP tunnel packet decryption failures, upgrade failures, time synchronization failures, and STA online/offline information.
- By default, all the preceding Trap messages are not sent. You can run the **acctrl-trap** command in AC configuration mode to enable the AC to send specified Trap messages.

Notes

- N/A

Configuration Steps

- Optional. On the AC, enter the AC configuration mode and run the **acctrl-trap** command to configure the Trap message control function.
- The AC sends the following types of Trap messages: CAPWAP tunnel up/down information, failures to add APs to the AC, CAPWAP tunnel packet decryption failures, upgrade failures, time synchronization failures, and STA online/offline information.

Command	**acctrl-trap** [**acap-updown-ctrl** | **acap-joinfail-ctrl** | **acap-decryeroreport-ctrl** | **acap-imageupdt-ctrl** | **acap-microap-ctrl** | **acap-snmpcache-ctrl** | **acap-timestamp-ctrl** | **acsta-oper-ctrl**]
Parameter Description	**acap-updown-ctrl**: Determines whether to send the Trap messages that contain the CAPWAP tunnel up/down information. **acap-joinfail-ctrl**: Determines whether to send the Trap messages that contain information about failures of adding APs to the AC. **acap-decryeroreport-ctrl**: Determines whether to send the Trap messages that contain information about CAPWAP tunnel packet decryption failures. **acap-imageupdt-ctrl**: Determines whether to send the Trap messages that contain information about the .bin file upgrade failures of the AP. **acap-microap-ctrl**: Controls forwarding of trap messages about status of micro APs. **acap-snmpcache-ctrl**: Controls forwarding of trap messages about cache for SNMP trap message updates. **acap-timestamp-ctrl**: Determines whether to send the Trap messages that contain the time synchronization information. **acsta-oper-ctrl**: Determines whether to send the Trap messages that contain the STA online/offline information.
Defaults	All types of Trap messages are not sent. You can run the **acctrl-trap** command in AC configuration mode to enable the AC to send these messages.
Command Mode	AC configuration mode
Usage Guide	This command is used to control sending of Trap messages on the AC.

Verification

- Run the **show ac-config** command to display the sending status of various Trap messages.

Configuration Example

Enabling the AC to Send the Trap Messages That Contain Information About Failures to Add APs to the AC

Configuration Steps	• Enter the AC configuration mode. • Enable the AC to send the Trap messages that contain information about failures to add APs to the AC. • Use the **no** form of this command to restore the default setting.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#acctrl-trap acap-joinfail-ctrl`
Verification	• Run the **show ac-config** command to display the sending status of various Trap messages.

AC	`Hostname#show ac-config`
	`acctrl-trap acap-updown-ctrl :Disable`
	`acctrl-trap acap-joinfail-ctrl :Enable`
	`acctrl-trap acap-decryeroreport-ctrl :Disable`
	`acctrl-trap acap-imageupdt-ctrl :Disable`
	`acctrl-trap acap-timestamp-ctrl :Disable`
	`acctrl-trap acsta-oper-ctrl :Disable`

Common Errors

- N/A

1.4.4 Configuring the NAS ID of an AC

Configuration Effect

- On the WLAN, the NAS IDs identify different hot spot areas. By default, the NAS ID of an AC is the MAC address of the AC in dotted decimal notation.

Notes

- N/A

Configuration Steps

- Optional.
- On the AC, enter the AC configuration mode and run the **nas-id** command to configure the NAS ID.

Command	**nas-id** *ac-nas-id*
Parameter Description	N/A
Defaults	MAC address of the AC in dotted decimal notation.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to display the AC configuration.

Configuration Example

Setting the NAS ID of the AC to 123456789

Configuration Steps	• Enter the AC configuration mode. • Configure the NAS ID.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)#nas-id123456789`
Verification	• Run the **show running** command to display the AC configuration.

AC	`Hostname#show running`
	`!`
	`ac-controller`
	`nas-id 123456789`
	`!`

Common Errors

- N/A

1.4.5 Creating an AP Configuration

Configuration Effect

- Create an AP configuration with the specified name, and enter the AP configuration mode.
- If the AP configuration corresponding to a name already exists, you can directly enter the AP configuration mode after the command is executed.
- The *ap-name* parameter indicates the name of the AP configuration. When an AP goes online, the AP name uploaded by the AP matches with the AP configuration name to determine the mapping between the AP and AP configuration.

Notes

- N/A

Configuration Steps

- Optional.
- On the AC, enter the global configuration mode and run the **ap-config** *ap-name* command to create an AP configuration.

Command	**ap-config** *ap-name*
Parameter Description	*ap-name*: Indicates the name of the AP configuration.
Defaults	No AP configuration is created.
Command Mode	Global configuration mode
Usage Guide	1. You can run the **ap-config all** command to enter the all-AP configuration mode. Configurations

	made in this mode take effect on all APs associated with the current AC. Configurations made in AP configuration mode take precedence over configurations made in all-AP configuration mode. If configurations (non-default settings) exist in AP configuration mode (entered by running the **ap-config** *ap-name* command), such configurations are preferentially used; otherwise, configurations made in all-AP configuration mode (entered by running the **ap-config all** command) are used.

Verification

- Run the **show ap-config running** *ap-name* command to display the configuration of the AP.

Configuration Example

Creating an AP Configuration Named Hostname_AP

Configuration Steps	● Create an AP configuration named **Hostname_AP**.

AC	`Hostname(config)#ap-config Hostname_AP`
	`You are going to config AP(Hostname_AP), which is not on line now.`
	`Hostname(config-ap)#`

Verification	● Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname#show ap-config running Hostname_AP`
	`!`
	`ap-config Hostname_AP`
	`!`

Common Errors

- N/A

1.4.6 Creating an AP Group

Configuration Effect

- The AC manages APs through the AP group. All the APs in an AP group can be configured through the AP group, which reduces the configuration workload. Configurations of the AP group take effect on all the APs in the group.

Notes

- The default group is created automatically by the system, and cannot be deleted.
- When an AP group is deleted, APs of this group are automatically moved to the default group.
- Configurations made in different configuration modes take effect in descending order: ap-config ap-name > ap-group > ap-config all.

Configuration Steps

- Optional.
- On the AC, enter the global configuration mode, and run the **ap-group** *ap-group-name* command to create an AP group.

Command	**ap-group** *ap-group-name*

Parameter Description	***ap-group-name***: Indicates the name of an AP group.
Defaults	An AP group named **default** is automatically created by default after the system is started. This group can neither be created nor deleted.
Command Mode	Global configuration mode
Usage Guide	When the **no** form of the command is used to delete an AP group, APs of this group are automatically moved to the default group.

Verification

- Run the **show running** command to display configurations of all AP groups.

Configuration Example

↘ Creating an AP Group Named APG-1

Configuration Steps	● In global configuration mode, run the **ap-group** command to create an AP group.
AC	`Hostname(config)#ap-group APG-1` `Hostname(config-ap-group)#`
Verification	● Run the **show running** command to check whether the AP group named **APG-1** exists.

AC	`Hostname#show running`
	`!`
	`ap-group APG-1`
	`!`

Common Errors

- N/A

1.4.7 Configuring the AP Group of an AP

Configuration Effect

- An AP group must already exist if you want to add an AP to this group.
- By default, APs belong to the default AP group, that is, the AP group named **default**.
- APs inherit all configurations of the AP group to which APs belong. If the same configuration exists in the specified AP configurations (**ap-config** *ap-name*), all AP configurations (**ap-config all**), and AP group configurations, the configurations take effect in descending order: specified AP configurations > AP group configurations > all AP configurations. Therefore, if the AP group of an AP changes, AP group configurations inherited by this AP change as well.

Notes

- N/A

Configuration Steps

- Optional.

- Run the **ap-config** command to create an AP group or enter the AP configuration mode.
- On the AC, enter the AP configuration mode and run the **ap-group** command to configure the AP group of an AP.

Command	**ap-config** *ap-name*
Parameter Description	*ap-name*: Indicates the name of the AP configuration.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**ap-group** *ap-group-name*
Parameter Description	*ap-group-name*: Indicates the name of an AP group.
Defaults	APs are automatically added to the default group.
Command Mode	AP configuration mode
Usage Guide	When an AP group is deleted, APs of this group are automatically moved to the default group.

Verification

- Run the **show ap-config running** command to display the configuration of the AP.

Configuration Example

Configuring the AP Group to Which Hostname-AP1 Belongs

Configuration Steps	• Create an AP group named **apg-1**. • Enter the AP configuration mode. • Use the **no** form of this command to restore the default AP group, that is, the AP group named **default**.

AC	`Hostname(config)#ap-group apg1`
	`Hostname(config-ap-group)#`
	`Hostname(config)#ap-config Hostname-AP1`
	`Hostname(config-ap)#`
	`Hostname(config-ap)#ap-group apg-1`

Verification	• Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname(config)#show ap-config running Hostname-AP1`
	`!`
	`ap-config Hostname-AP1`
	`ap-group apg-1`
	`!`

Common Errors

- N/A

1.4.8 Configuring an AP Name

Configuration Effect

Configure an AP name on the AC.

- If the AP is online, the configuration of the AP name takes effect immediately. In addition, the AP name in the AP configuration mode (that is, the string next to **ap-config**) is immediately replaced by the new name.
- If the AP is offline, the configuration of the AP name takes effect after the AP goes online, and the AP name in the AP configuration mode is not replaced by the new name until the AP goes online.
- After the AP name is configured, you can continue to configure this AP without exiting from the AP configuration mode.
- If the corresponding AP is online, the **no** form of the command is not supported.
- If the corresponding AP is offline, the **no** form of the command can be used to delete the AP name configuration that is not effective.
- If the new name is already in use, the configuration fails.

Configure an AP name on the AP.

- If the CAPWAP tunnel is not set up, the AP name is configured directly.
- If the CAPWAP tunnel is set up, the AP name is configured first. Then the CAPWAP tunnel will be disconnected and set up again. If the AP name is already configured on the AC or configured offline, this AP name prevails.

Notes

- The AP name is a string of up to 64 characters, and cannot contain any space.
- The AP name cannot be configured as **all** or **AP**.
- Avoid configuring the same AP name for different offline APs. If the same AP name is configured for different offline APs, the new name takes effect on the AP that goes online first, and the APs that go online later still use the original names.
- Configuring the AP name on the AP only takes effect in fit AP mode.

Configuration Steps

- Optional. You can run the **ap-name** *ap-name* command in AP configuration mode to configure an AP name. You are advised to configure an indicative AP name to facilitate management.
- On the AC, enter the AP configuration mode and run the **ap-group** command to configure an AP name.

Command	**ap-name** *name*
Parameter Description	*name*: Indicates the name of an AP. The name cannot contain any space.
Defaults	The AC uses the name uploaded by the AP as the AP name. In the factory settings, the MAC address is often used as the name of an AP.
Command Mode	AP configuration mode
Usage Guide	1. Do not configure the AP name as **all** or **AP**. 2. After the command is executed, the command mode of an online AP is the command mode of the

	AP with the new name, and you can continue to configure other attributes of the AP without existing from the command mode. The command mode of an offline AP remains unchanged.

Verification

- Run the **show ap-config running** command to display the configuration of the AP.
- Run the **show ap-config summary** command to check whether the name of the online AP is the new name.

Configuration Example

Changing the Name of an Online AP from Hostname-AC1 to Hostname-AC2

Configuration Steps	• Enter the AP configuration mode. • Configure the name of an AP.
AC	`Hostname(config)#ap-config Hostname-AC1` `Hostname(config-ap)#ap-name Hostname-AC2`
Verification	• Run the **show ap-config running** command to display the configuration of the AP. • Run the **show ap-config summary** command to query the name of the online AP.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config Hostname-AC2`
	`!`
	`Hostname#show ap-config summary`
	`========= show ap status =========`
	`Radio: Radio ID or Band: 2.4G = 1#, 5G = 2#, 6G = 3#`
	`E = enabled, D = disabled, N = Not exist`
	`Current Sta number/Max Sta number supported`
	`Channel: * = Global`
	`Power Level = Percent`
	
	`Online AP number: 0`
	`Offline AP number: 1`
	
	`AP Name IP Address Mac Address Radio 1`
	`Radio 2 Up/Off time State`
	`---------- ---------- ----------`
	`---------- ---------- ---------- -----`
	`ap1 10.0.20.15 00d0.f822.33b0 1 E 0`
	`1*/2.4G 100 N -/- - - 0:00:16:03 Quit`

Changing the Name of an Offline AP from Hostname-AC1 to Hostname-AC2

Configuration Steps	• Enter the AP configuration mode. • Configure the name of an AP.
AC	`Hostname(config)#ap-config Hostname-AC1` `Hostname(config-ap)#ap-name Hostname-AC2`
Verification	• Run the **show ap-config running** command to display the configuration of the AP.

AC	Hostname#show ap-config running ! ap-config Hostname-AC1 ap-name Hostname-AC2 !

Common Errors

- N/A

1.4.9 Binding an MAC Address to an AP Configuration

Configuration Effect

- In AP configuration mode, run the **ap-mac** command to bind an MAC address to an AP configuration so that the AP configuration takes effect only on the AP with the MAC address.
- Generally, when an AP goes online, it determines the configuration to be used based on the mapping between the AP name and the AP configuration name. MAC address binding is a stronger binding relationship than name mapping, and takes precedence over name mapping. Therefore, when an AP goes online, the AP uses the configuration so far as the MAC address bound to the AP configuration is the same as the MAC address of the AP.
- If no MAC address is bound to an AP configuration, the MAC address is automatically bound when the corresponding AP goes online. This binding still takes effect when the AP goes offline. That is, the binding configuration will be automatically generated when the AP goes online.
- MAC address binding is also used for the AC access control function configured by using the **bind-ap-mac** command. For details, see the configuration description of this command.
- You can bind a specified MAC address only to the configuration of an offline AP.
- In the hot standby environment, you can ensure consistency of configurations between two ACs by binding the MAC addresses with AP configurations.

Notes

- You can bind a specified MAC address only to the configuration of an offline AP.

Configuration Steps

- Optional.
- On the AC, enter the AP configuration mode and run the **ap-mac** command to bind an MAC Address to an AP configuration.

Command	**ap-mac** *ap-mac-address*
Parameter Description	*ap-mac-address*: Indicates the MAC address that is bound.
Defaults	No AP configuration is bound to the MAC address by default. You can bind the MAC address of an AP to the AP configuration to forcibly apply this AP configuration to the AP with the MAC address.
Command Mode	AP configuration mode

Usage Guide	The **ap-mac** *ap-mac-address* command is applicable to configurations of offline APs. You can use this command to specify the MAC address of an offline AP so that the AP configuration can be located directly based on the MAC address after the AP goes online.

Verification

- Run the **show ap-config running** command to display the MAC address binding of the AP.

Configuration Example

Binding the Offline AP Hostname-AP1 to the MAC Address 001a.a979.1234

Configuration Steps	● Enter the AP configuration mode. ● The **no** form of the command is used to delete the MAC address binding.
AC	`Hostname(config)#ap-config Hostname-AP1` `Hostname(config-ap)#ap-mac 001a.a979.1234`
Verification	● Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname(config)#show ap-config running Hostname-AP1`
	`!`
	`ap-config Hostname-AP1`
	`ap-mac 001a.a979.1234`
	`!`

Common Errors

- N/A

1.4.10 Configuring the User Name and Password of an AP

Configuration Effect

- Unauthorized users may directly login to an AP and modify the AP configuration through Telnet, which affects normal running of the WLAN. To prevent this problem, you can configure the Telnet user name and password of a specified AP.
- The **credential** command can be used in **ap-config** *ap-name*, **ap-group**, or **ap-config all** configuration mode. Configurations made by using the **credential** command take effect in descending order: **ap-config** *ap-name* > **ap-group** > **ap-config all**.

Notes

- N/A

Configuration Steps

Configuring the Username and Password for an AP

- Optional. You can run the **credential** *user-name password* command to configure a new Telnet user name and password in AP configuration mode to enhance security.
- On the AC, enter the AP or AP group configuration mode and run the **credential** command for configuration.

Command	**credential** *user-name password*
Parameter Description	*user-name*: Indicates the user name. A user name cannot contain any space. *password*: Indicates the password. A password cannot contain any space.
Defaults	The AC uses factory settings of the Telnet user name and password of an AP. You can change the Telnet user name and password of an AP as required to facilitate management.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Configuring the Username and Security Password

- (Optional) You can run the **credential username** *user-name* **password** { **0** | **7** } *password* command to configure a username and a security password for secure Telnet connection.
- A password contains at least eight characters and must be a combination of at least three types of the following: lowercase letters, uppercase letters, special characters, and numbers.
- On the AC, enter the AP configuration mode or AP group configuration mode and run the **credential** command.

Command	**credential username** *user-name* **password** { **0**	**7** } *password*
Parameter Description	*user-name*: Indicates the username without spaces. **0**: Utilizes the cleartext password. It contains at least eight characters and must be a combination of at least three types of the following: lowercase letters, uppercase letters, special characters, and numbers. **7**: Utilizes the ciphertext password that complies with the encryption standard. *password*: Indicates the password without spaces. It contains at least eight characters and must be a combination of at least three types of the following: lowercase letters, uppercase letters, special characters, and numbers.
Defaults	N/A
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	To configure a cyphertext password, you can copy one from the existing configuration.

Verification

- Run the **show ap-config running** or **show running** command to display the configuration.

Configuration Example

Configuring the User Name and Password of Hostname-AP1

Configuration Steps	● Configure the user name and password of Hostname-AP1.
AC	`Hostname(config)#ap-config Hostname-AP1` `Hostname(config-ap)#credential user pass`
Verification	● Run the **show ap-config running** command to display the configuration of the AP.
AC	`Hostname(config)#show ap-config running Hostname-AP1` `!`

	ap-config Hostname-AP1 credential user pass !

Configuring a Username and a Security Password

Configuration Steps	● Configure the username as **admin1** and set the password to **ruijie@123** on AP1. ● Configure the username as **admin2** and set the password to **1007072e0f1b4f2d704078** on AP2.
AC	Hostname(config)#ap-config AP1 Hostname(config-ap)#credential username admin1 password 0 ruijie@123 Hostname(config-ap)#exit Hostname(config)# ap-config AP2 Hostname(config-ap)#credential username admin2 password 7 1007072e0f1b4f2d704078 Hostname(config-ap)#exit
Verification	Run the **show ap-config running** command to display the AP configuration.
AC	Hostname(config)#show ap-config running ! ap-config AP1 credential username admin1 password 7 1007072e0f1b4f2d704078 ! ap-config AP2 credential username admin2 password 7 1007072e0f1b4f2d704078 !

Common Errors

- N/A

1.4.11 Configuring the Interval at Which the AP Reports Statistics

Configuration Effect

- Run the **statistics-timer** command to configure the interval at which the AP reports statistics.

Notes

- N/A

Configuration Steps

- Optional. You can adjust the interval based on the statistics accuracy requirement and loads on the AC and AP.
- On the AC, enter the AP or AP group configuration mode and run the **statistics-timer** command for configuration.

Command	**statistics-timer** *timer-interval*
Parameter Description	*timer-interval*: Indicates the interval that the AP reports statistics, in seconds.
Defaults	120s

Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** command to display the configuration.

Configuration Example

Setting the Interval at Which Hostname-AP1 Reports Statistics to 300s

Configuration Steps	● Set the interval at which Hostname-AP1 reports statistics to 300s. ● Use the **no** form of the command to restore the default interval at which Hostname-AP1 reports statistics.
AC	`Hostname(config)#ap-config Hostname-AP1` `Hostname(config-ap)#statistics-timer 300`
Verification	● Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname(config)#show ap-config running Hostname-AP1`
	`!`
	`ap-config Hostname-AP1`
	`statistics-timer 300`
	`!`

Common Errors

- N/A

1.4.12 Configuring the AP System Log Information

Configuration Effect

- Configure the function of displaying the AP system logs, and set the IP address of the server that records the AP system logs.

Notes

- N/A

Configuration Steps

- Optional.
- Run the **logging on** command to display system logs of a specified AP.
- Run the **logging server** *ip-address* **[udp-port** *num***]** command to configure the IP address of the system log server of a specified AP.

Command	**loggingon**
Parameter Description	N/A
Defaults	The system logs are displayed.

Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Command	**logging server** *ip-address*[**udp-port** *num*]
Parameter Description	*ip-address*: Indicates the IP address of the host that receives the log information. num: Indicates the port number of the host that receives the log information. This parameter is optional.
Defaults	N/A
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	You can configure at most five log server addresses. The log information will be sent simultaneously to all the configured log servers.

Verification

- Run the **show ap-config running** command to display the configuration.

Configuration Example

Disabling the Function of Displaying System Logs on Hostname-AP1

Configuration Steps	• Enter the AP configuration mode. • Disable the function of displaying system logs.
AC	`Hostname(config)#ap-config Hostname-AP1` `Hostname(config-ap)#no logging on`
Verification	• Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname(config)#show ap-config running Hostname-AP1`
	`!`
	`ap-config Hostname-AP1`
	`no logging on`
	`!`

Configuring the Log Server Address of Hostname-AP1

Configuration Steps	• Enter the AP configuration mode. • Set the log server address to 1.1.1.1.
AC	`Hostname(config)#ap-config Hostname-AP1` `Hostname(config-ap)#logging server 1.1.1.1`
Verification	• Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname(config)#show ap-config running Hostname-AP1`
	`!`
	`ap-config Hostname-AP1`
	`logging server 1.1.1.1`
	`!`

Common Errors

- N/A

1.4.13 Configuring the Daily Scheduled Restart Time for an AP

Configuration Effect

- If APs work for a long time, the load may be too heavy, affecting the network access quality of users. To prevent this problem, you can configure the daily scheduled restart time for an AP so that the network access quality of users can be ensured every day.

Notes

- N/A

Configuration Steps

- Optional. You can enable the daily scheduled restart function based on the AP load.
- Configure the daily scheduled restart time to prevent APs from working for a long time, enhancing availability of the network.

Command	**reload at** [**everyday** | **everyweek** *day* | **everymonth date** *num* | **month** *month* **date** *num*] *time*
Parameter Description	**everyday**: Indicates that the AP restarts every day at the specified time. **everyweek**: Indicates that the AP restarts every week at the specified time. *day*: Indicates the day of each week on which the AP restarts. The options are **Mon**, **Tues**, **Wed**, **Thur**, **Fri**, **Sat**, and **Sun**. **everymonth**: Indicates that the AP restarts every month at the specified time. **date** *num*: Indicates the day of each month on which the AP restarts. The value range is from 1 to 31. **month** *month*: Indicates the month in which the AP restarts. The options are **Jan**, **Feb**, **Mar**, **Apr**, **May**, **Jun**, **Jul**, **Aug**, **Sept**, **Oct**, **Nov**, and **Dec**. *time*: Indicates the restart time in the hh:mm:ss format. Do not set this parameter to **00:00:00**.
Defaults	The daily scheduled restart function of an AP is disabled.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	● The **reload at** commands can be used in AP configuration mode, AP group configuration mode, and all-AP configuration mode and takes effect based on the configuration mode priority (AP configuration mode > AP group configuration mode > all-AP configuration mode). For example, if you configure the AP to restart every month in all-AP configuration mode and every day in AP configuration mode, the AP restarts every day. ● Only one AP restart rule can be configured in one configuration mode. When a new rule is configured, the original configuration is replaced.

Verification

- Run the **show ap-config running** and **show running-config** command to display the configuration.

Configuration Example

↘ Configuring Hostname-AP1 to Restart at 1:00:00 Every Day

Configuration	● Configure Hostname-AP1 to restart at 1:00:00 every day.

Steps	• Use the **no** form of the command to cancel the scheduled restart configuration.
AC	`Hostname(config)#ap-config Hostname-AP1` `Hostname(config-ap)#reload at everyday 1:00:00`
Verification	• Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname(config)#show ap-config running Hostname-AP1`
	`!`
	`ap-config Hostname-AP1`
	`reload at everyday 1:00:00`
	`!`

Configuring All APs in the Ruijie-APG1 Group to Restart at 1:00:00 Every Day

Configuration Steps Configure all APs in the Ruijie-APG1 group to restart at 1:00:00 every day.

AC

```
Hostname(config)#ap-group Ruijie-APG1
Hostname(config-group)#reload at everyday 1:00:00
```

Verification Run the **show running-config** command to display the AP group configuration.

AC

```
Hostname(config)#show running-config
!
ap-group Ruijie-APG1
reload at everyday 1:00:00
!
```

Configuring All APs to Restart at 1:00:00 Every Day

Configuration Steps Configure all APs to restart at 1:00:00 every day.

AC

```
Hostname(config)#ap-config all
Hostname(config-ap)#reload at everyday 1:00:00
```

Verification Run the **show running-config** command to display the configuration.

AC

```
Hostname(config)#show running-config
!
ap-config all
reload at everyday 1:00:00
!
```

Common Errors

- N/A

1.4.14 Restoring Factory Settings of a Specified AP

Configuration Effect

- Restore factory settings of a specified AP.
- The configuration takes effect only on an online AP.

Notes

- This operation will cause disconnection and reset of the AP.

Configuration Steps

- Optional. You can restore factory settings of a specified AP on demand.
- Restoring AP factory settings is an instant behavior of an AP. This command can restore factory settings of the AP and will trigger reset of the AP.

Command	**factory-reset** *ap-name*
Parameter Description	*ap-name*: Indicates the name of an AP.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	This command is used to restore factory settings of a specified AP. This operation will cause reset of the AP.

Verification

- After this command is executed for an online AP, this AP will go offline. After the AP goes online again, run the **show ap-config running** command to check whether factory settings of the AP are restored.

Configuration Example

Restoring Factory Settings of the Online AP Hostname-AP1

Configuration Steps	• Enter the AC configuration mode. • Restore factory settings of the online AP Hostname-AP1.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#factory-reset Hostname-AP1`
Verification	• After this command is executed for an online AP, this AP will go offline. After the AP goes online again, run the **show ap-config running** command to check whether factory settings (null settings) of the AP are restored.

Common Errors

- N/A

1.4.15 Resetting an AP

Configuration Effect

- Reset an online AP.
- Reset all online APs.

Notes

- N/A

Configuration Steps

- Optional. You can reset one or more APs as required.
- If you configure AP reset on the AC, the corresponding AP will reset. You can configure reset of a specified AP or all online APs.

Command	**reset**{ **all** |**single** *ap-name*}
Parameter Description	**all**: Indicates that all online APs are reset. **single *ap-name***: Indicates that a specified AP is reset.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- After the configuration is completed, you can view the syslog record on the AC, indicating that the corresponding AP goes offline, and the AP will be reset.

Configuration Example

↘ Resetting Hostname-AP1

Configuration Steps	• Enter the AC configuration mode. • Reset Hostname-AP1.

AC	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#`
	`Hostname(config-ac)#reset Hostname-AP1`

Verification	• Check whether Hostname-AP1 is reset, and whether the following syslog record indicating the offline event of the AP can be viewed on the AC.
AC	`%APMG-6-RX_CTRL_MSG: AP(AP_20#3F_S:001a.a912.3456) leave AC.`

Common Errors

- N/A

1.4.16 Configuring the AP Quantity Limit

Configuration Effect

- The number of online APs connected to the AP does not exceed the configured maximum number of APs supported by the AC.

Notes

- The weight of an AP varies according to the AP model. For example, the weight of one wall-plate is 0.5 and two wall-plate APs are treated as one AP. When APs are connected to an AC, the weighted number of APs is calculated based on the weight. This command and the license control the weighted number of APs, instead of the actual number of APs.

Configuration Steps

- Optional. You can configure the AP quantity limit within the capacity range as required.

Command	**wtp-limit** *max-num*
Parameter Description	*max-num*: Indicates the maximum number of APs that can be connected to an AC.
Defaults	The quantity limit is equal to the number of APs supported by an AC.
Command Mode	AC configuration mode
Usage Guide	This command is used to configure the maximum number of APs connected to an AC. This number cannot exceed the maximum number of APs supported by the AC or the maximum number of APs allowed by the license.

Verification

- Run the **show ac-config** command to check the current AC name and determine whether the configuration is successful.

Configuration Example

↘ Setting the Maximum Number of APs Connected to the AC to 512

Configuration Steps	● Enter the AC configuration mode. ● Set the maximum number of APs connected to the AC to 512.

AC	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#wtp-limit 512`
	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#no wtp-limit`

Verification	● Run the **show ac-config** command to display the configured maximum number of APs that can be connected to the AC.

AC	`Hostname#show ac-config`
	`…`
	`max_wtp :512`
	`…`

Common Errors

- N/A

1.4.17 Configuring the AP Compliance Check

Configuration Effect

- The AP compliance check is also called AP access control based on the bound MAC address, or bind-ap-mac function. If AP compliance check is enabled, only APs that have offline configurations bound to their MAC addresses are allowed to associate with the AC.

Notes

- N/A

Configuration Steps

- Optional. You can enable the AP compliance check to allow only APs with specified MAC addresses to go online, thus implementing strict control on access of APs.
- When the AP compliance check is enabled, all online APs are automatically bound to MAC addresses. Therefore, you are advised to disable this function during network deployment and enable the function after all planned APs go online.
- When the **bind-ap-mac** function is enabled, MAC addresses automatically bound to all online APs are converted to the formal MAC address bindings, which are not automatically deleted when APs go offline.
- On the AC, you can run the **ap-mac** *X.Y.Z* command in AP configuration mode to configure the MAC address binding of an AP configuration.

Command	**bind-ap-mac**
Parameter Description	N/A
Defaults	The AP compliance check is disabled.
Command Mode	AC configuration mode
Usage Guide	This command is used to enable the AP compliance check.

Command	**ap-mac** *ap-mac-address*
Parameter Description	*ap-mac-address*: Indicates the MAC address that is bound.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	The **ap-mac** *ap-mac-address* command is applicable to offline APs. You can use this command to specify the MAC address of an offline AP so that the AP configuration can be located directly based on the MAC address after the AP goes online.

Verification

- Run the **show running** command to check whether the **bind-ap-mac** function is enabled.
- Run the **show ap-config running** command to display the MAC address binding information of AP configurations.

Configuration Example

Enabling the AP Compliance Check on an AC

Configuration Steps	● After all authorized APs go online, enter the AC configuration mode and run the **bind-ap-mac** command to enable the AP compliance check function.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#bind-ap-mac`
Verification	● Run the **show running** command to check whether the AP compliance check function is

	enabled.

AC	`Hostname#show running`
	`!`
	`ac-controller`
	`  bind-ap-mac`
	`!`

Common Errors

- N/A

1.4.18 Configuring AP Access Authentication

Configuration Effect

- AP access authentication can be implemented based on the serial number, password, or certificate.

Notes

- If you run the **ap-auth** { **serial** | **password** | **certificate** } **enable** command in AC configuration mode to enable the access authentication function, but do not run the **ap-auth** { **serial** *serial-string* |**password** *password* |**ac-cert** *ac-cert-name* |**ap-cert** *ap-cert-name* } command in AP configuration mode to configure related authentication parameters, AP access authentication will fail and the AP cannot go online.

Configuration Steps

- Optional.
- Run the **ap-auth serial-update** command to update the authentication serial numbers for all online APs.
- Run the **ap-auth enable** command in AC configuration mode to enable a specified type of AP access authentication.
- Run the **ap-auth** { **serial** *serial-string* | **password** *password* | **ac-cert** *ac-cert-name* | **ap-cert** *ap-cert-name* } command to configure the related AP access authentication parameters.

Command	**ap-auth serial-update**
Parameter Description	N/A
Defaults	This function is disabled.
Command Mode	AC configuration mode
Usage Guide	All online APs use the current AP serial numbers for authentication.

Command	**ap-auth** { **serial**	**password**	**certificate** } **enable**
Parameter Description	**serial**: Indicates the authentication function based on the AP access serial number. **password**: Indicates the authentication function based on the AP access password. **certificate**: Indicates the authentication function based on the AP certificate.
Defaults	The authentication function is disabled.
Command Mode	AC configuration mode

Usage Guide	N/A

Command	**ap-auth** { **serial** *serial-string* | **password** *password* | **ac-cert** *ac-cert-name* | **ap-cert** *ap-cert-name* }
Parameter Description	*serial-string*: Specifies the AP access serial number. *password*: Specifies the AP access password. *ac-cert-name*: Specifies the AC certificate file name. *ap-cert-name*: Specifies the AP certificate file name.
Defaults	This function is disabled.
Command Mode	AP configuration mode
Usage Guide	The AP access authentication configuration takes effect only when the AP makes an access attempt. If the AP is already online, the configuration takes effect next time when the AP goes online. The **ap-auth serial** command cannot be used in all-AP configuration mode because the serial number varies according to the AP. The certificate file issued by the **ap-auth ap-cert** command will be stored as **cert.crt** on the AP, and the file name cannot be changed.

Verification

- Run the **show ap-config running** command to check whether the configuration is successful.

Configuration Example

Configuring the AP Access Authentication Based on the Serial Number

Configuration Steps	• After all authorized APs go online, update the authentication serial numbers for all online APs. • Enable the AP access authentication function based on the serial number. • Configure the authentication serial number of a specified AP.

AC	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#ap-auth serial-update`
	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#ap-auth serial enable`
	`Hostname(config)#ap-config Hostname-AP1`
	`Hostname(config-ap)#ap-auth serial G1GD10U000456`

Verification	• Run the **show running** or **show ap-config running** command to display the AP access authentication configuration.

AC	`Hostname(config)#show run`
	`!`
	`ac-controller`
	`  ap-auth serial enable`
	`!`
	`Hostname(config)#show ap-config running Hostname-AP1`
	`!`
	`ap-config Hostname-AP1`
	`ap-auth serial G1GD10U000456`

	!

Updating the Access Authentication Certificate of an AP

Configuration Steps	● Update the access authentication certificate of an AP.
AC	Hostname(config)#ap-config Hostname-AP1 Hostname(config-ap)#ap-auth ap-cret ap1_cret.crt
Verification	● Run the **show ap-config running** command to display the name of the current AC. If the corresponding AP is online, the **ap1_cret.crt** certificate file is updated to the AP instantly; otherwise, the file is updated to the AP after the AP goes online.
AC	Hostname(config)#show ap-config running Hostname-AP1 ! ap-config Hostname-AP1 ap-auth ap-cret ap1_cret.crt !

Common Errors

- N/A

1.4.19 Configuring the AP Priority

Configuration Effect

- By default, the AC allows the access of APs based on the sequence of AP association requests received by the AC. You can set the failover priorities of APs and enable the AC to support the failover priorities of APs so that the AC can allow the access of APs based on the AP priorities. The AP priority ranges from 1 to 4, where 1 is the lowest priority.

Notes

- N/A

Configuration Steps

- Optional. You can enable the AP priority function as required and configure the priority of a specified AP.
- On the AC, enter the AC configuration mode and run the **ap-priority** { **enable** | **disable** } command to enable or disable the AP priority function.
- On the AC, enter the AP configuration mode and run the **priority** *priority-value* command to configure the priority of a specified AP.

Command	**ap-priority** { **enable**	**disable**}
