Parameter Description	**enable**: Enables the AP to support the failover priority. **disable**: Disables the AP to support the failover priority.
Defaults	Disabled.
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**priority** *priority-value*
Parameter Description	priority-value: Indicates the AP priority. The value ranges from 1 to 4, where 1 is the lowest priority.
Defaults	The default priority of an AP is 1. The priority can be set to a value from 1 to 4, where 1 is the lowest priority and 4 is the highest priority. You can run the **priority** command in AP configuration mode to configure the AP priority.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show running** or **show ap-config running** command to display the configuration.

Configuration Example

↘ Setting the Priority of Hostname-AP1 to 2 and Enabling the AP Priority Function

Configuration Steps	• Enter the AP configuration mode. • Configure the AP priority. • Enter the AC configuration mode. • Enable the AP priority function.

AC	`Hostname(config)#ap-config Hostname-AP1`
	`Hostname(config-ap)#priority 2`
	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#ap-priority enable`

Verification	• Run the **show running** command to check whether the **ap-priority enable** command is configured in AC configuration mode. • Run the **show ap-config running** command to display the AP configuration.

AC	`Hostname(config)#show running`
	`!`
	`ac-controller`
	`  ap-priority enable`
	`!`
	`Hostname#show ap-config running`
	`!`
	`ap-config Hostname-AP1`
	`  priority 2`
	`!`

Common Errors

- N/A

1.4.20 Configuring the AC Cluster Function

Configuration Effect

- AC cluster is also called AC redundancy. With this function, multiple ACs with different priorities are designated for an AP. When the connection between the AP and a high-priority AC is down, the AP is connected to a low-priority AC (standby AC). When the connection with the high-priority AC is recovered, the AP disconnects the CAPWAP tunnel with the low-priority AC, and sets up a CAPWAP tunnel with the high-priority AC again.
- On the one hand, the AC cluster function enhances reliability of the AC cluster. On the other hand, this function controls the home AC of APs in stable conditions based on the priority to facilitate AP management.

Notes

- For a specified AP, the same priority must be configured for this AP on each AC that belongs to the cluster. For example, on AC1, AC2 is configured as the primary AC for AP1, and AC1 is configured as the secondary AC for AP1. On AC2, AC1 is configured as the primary AC for AP1, and AC2 is configured as the secondary AC for AP1. That is, on both AC1 and AC2, the peer AC is configured as the high-priority AC for AP1. In this way, an endless loop is formed because the AP keeps switching between tunnels with two ACs.
- The redundancy AC configuration supports both the ap-config ap-name and ap-config all configuration modes. The redundancy AC configuration made in ap-config ap-name configuration mode takes precedence over that made in ap-config all configuration mode.
- Except the **primary-base** command, commands of other priorities do not support switchback to prevent network interruption caused by the switchback. The administrator can re-configure the priorities for a manual switchover, or configure the **switch-back** parameter for an automatic switchback.

Configuration Steps

- Optional. The redundancy AC configuration does not exist on an AP by default. You can configure redundancy ACs with different priorities for an AP based on the number of ACs deployed on the wireless network.
- Run the **primary-base** *ac-name* { *ip-address* | *ipv6-address* } command to configure the primary AC for a specified AP.
- Run the **secondary-base** *ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the secondary AC for a specified AP.
- Run the **tertiary-base** *ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the tertiary AC for a specified AP.
- Run the **backup-controller-primary** *ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the fourth AC for a specified AP.
- Run the **backup-controller-secondary** *ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the fifth AC for a specified AP.
- Run the **backup-controller-tertiary** *ac-name* { *ip-address* | *ipv6-address* } [**switch-back**] command to configure the sixth AC for a specified AP.

Command	**primary-base** *ac-name* { *ip-address*	*ipv6-address* }
Parameter Description	*ac-name*: Indicates the name of the AC to be configured. *ip-address*: Indicates the IP address of the primary AC. The format is A.B.C.D. *ipv6-address*: Indicates the IPv6 address of the primary AC. The format is X;Y::Z.
Defaults	N/A
Command	AP configuration mode (supporting the **ap-config all** configuration mode)

Mode	
Usage Guide	N/A

Command	**secondary-base** *ac-name* {*ip-address* | *ipv6-address* }[**switch-back**]
Parameter Description	*ac-name*: Indicates the name of the AC to be configured. *ip-address*: Indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: Indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: Indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**tertiary-base** *ac-name* {*ip-address* | *ipv6-address*}[**switch-back**]
Parameter Description	*ac-name*: Indicates the name of the AC to be configured. *ip-address*: Indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: Indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: Indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**backup-controller-primary** *ac-name* {*ip-address* | *ipv6-address*}[**switch-back**]
Parameter Description	*ac-name*: Indicates the name of the AC to be configured. *ip-address*: Indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: Indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: Indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**backup-controller-secondary** *ac-name* { *ip-address* | *ipv6-address*}[**switch-back**]
Parameter Description	*ac-name*: Indicates the name of the AC to be configured. *ip-address*: Indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: Indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: Indicates the switchback function. Switchback is disabled by default.
Defaults	N/A

Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Command	**backup-controller-tertiary** *ac-name* { *ip-address* | *ipv6-address* }[**switch-back**]
Parameter Description	*ac-name*: Indicates the name of the AC to be configured. *ip-address*: Indicates the IP address of the AC. The format is A.B.C.D. *ipv6-address*: Indicates the IPv6 address of the AC. The format is X;Y::Z. **switch-back**: Indicates the switchback function. Switchback is disabled by default.
Defaults	N/A
Command Mode	AP configuration mode (supporting the **ap-config all** configuration mode)
Usage Guide	N/A

Verification

- Run the **show ac-config** command to display the current AC name and check whether the configuration is successful.

Configuration Example

Configuring Hostname-AC1 as the Primary AC of Hostname-AP1, and Hostname-AC2 as the Secondary AC

Configuration Steps	• Enter the AP configuration mode. • Configure the primary AC and secondary AC of the AP.

Hostname-AC1	`Hostname(config)#ap-config Hostname-AP1`
	`Hostname(config-ap)#primary-base Hostname-AC1 5.5.5.5`
	`Hostname(config-ap)#secondary-base Hostname-AC2 6.6.6.6`

Hostname-AC2	`Hostname(config)#ap-config Hostname-AP1`
	`Hostname(config-ap)#primary-base Hostname-AC1 5.5.5.5`
	`Hostname(config-ap)#secondary-base Hostname-AC2 6.6.6.6`

Verification	• Run the **show ap-config running** command to display the AP configuration.

Hostname-AC1	`Hostname#show ap-config running`
	`!`
	`ap-config Hostname-AP1`
	`  primary-base Hostname-AC1 5.5.5.5`
	`secondary-base Hostname-AC2 6.6.6.6`
	`!`

Hostname-AC2	`Hostname#show ap-config running`
	`!`
	`ap-config Hostname-AP1`
	`  primary-base Hostname-AC1 5.5.5.5`
	`secondary-base Hostname-AC2 6.6.6.6`
	`!`

Common Errors

- N/A

1.4.21 Configuring the AC Hot Standby Function

Configuration Effect

- Set up the hot standby connection to ensure that the AP can establish two CAPWAP tunnels.

Notes

- N/A

Configuration Steps

- Optional. If an AP does not use the hot standby IP address of the AC to set up a tunnel, the AC address of the first tunnel must be specified. When the IPv6 address must be used to set up the second tunnel, the IPv6 hot standby tunnel function must be enabled.
- Run the **peer-ip** command to configure the IP address for setting up a CAPWAP tunnel with the hot standby neighbor. This IP address will be delivered to the AP, and the AP will set up the second CAPWAP tunnel with the hot standby neighbor based on the peer IP address. If the AP does not use the default hot standby IP address of the AC to set up a tunnel, you need to configure the peer IP address.
- Run the **peer-ipv6** command to configure the IPv6 address for setting up a CAPWAP tunnel with the hot standby neighbor. This IPv6 address will be delivered to the AP, and the AP will set up the second CAPWAP IPv6 tunnel with the hot standby neighbor based on the peer IPv6 address. When an AP and an AC use the IPv6 address to set up a tunnel, you need to configure the peer IPv6 address to set up the second CAPWAP IPv6 tunnel because currently the IPv6 address cannot be used for setting a hot standby connection between ACs.
- After the **peer-ipv6 enable** command is executed, the AP sets up the second CAPWAP IPv6 tunnel with the hot standby neighbor. To set up a CAPWAP IPv6 tunnel between an AP and an AC, you need to enable peer-ipv6 so that the second CAPWAP IPv6 tunnel can be set up between the AP and the AC.
- Run the **ap-group** command to bind an AP group to the hot standby instance. After the AP group is bound to the hot standby instance, data of STAs associated with APs in the AP group can be synchronized from the active AC to the standby AC.

Command	**peer-ip** *ipv4-address*
Parameter Description	*ipv4-address*: Indicates the IP address used by the hot standby neighbor to set up a CAPWAP tunnel.
Defaults	Source address used by CAPWAP.
Command Mode	Hot standby instance mode
Usage Guide	In the non-NAT environment, use the default setting, that is, the source IP address used by CAPWAP. In the NAT environment, configure the IPv6 address based on the environment where the AC and AP are located. When the AC is located inside the NAT, its address is a private network address, which is not accessible by the AP. Therefore, the AP must be notified of the configured public network address. ● If both the AP and the AC are on the same NAT intranet, use the default setting.

	● If the AP is on the NAT external network, use the IP address configured by the user as the peer AC address.

Command	**peer-ipv6***ipv6-address*
Parameter Description	*ipv6-address*: Indicates the IPv6 address used by the hot standby neighbor to set up a CAPWAP tunnel.
Defaults	Source IP address used by CAPWAP
Command Mode	Hot standby instance mode
Usage Guide	In the non-NAT environment, use the default setting, that is, the source address used by CAPWAP. In the NAT environment, configure the IPv6 address based on the environment where the AC and AP are located. When the AC is located inside the NAT, its address is a private network address, which is not accessible by the AP. Therefore, the AP must be notified of the configured public network address. ● If both the AP and the AC are on the same NAT intranet, use the default setting. ● If the AP is on the NAT external network, use the IP address configured by the user as the peer AC address. You need to run the **peer-ipv6 enable** command to enable the function of using CAPWAP to set up the dual IPv6 hot standby tunnels.

Command	**peer-ipv6 enable**
Parameter Description	N/A
Defaults	Disabled.
Command Mode	Hot standby instance mode
Usage Guide	The peer-ipv6 must be enabled when CAPWAP is used to set up an IPv6 tunnel between the AP and a hot standby AC so that the AP can use CAPWAP to set up an IPv6 tunnel with another hot standby AC.

Command	**ap-group** *ap-group*
Parameter Description	*ap-group*: Indicates the name of an AP group.
Defaults	N/A
Command Mode	Hot standby instance mode
Usage Guide	After the AP group is bound to the hot standby instance, data of STAs associated with APs in the AP group can be synchronized from the active AC to the standby AC.

Verification

- Run the **show running** command to display the configuration.

Configuration Example

For details about the AC hot standby deployment solution, see WLAN Hot Backup.

Configuring the AC to Use the Public Network Address as the AC Address

Configuration Steps	● Configure the hot standby address and enter the hot standby configuration mode. ● Configure the hot standby instance. ● In the hot standby instance configuration mode, configure the peer IP address.
AC	`Hostname(config-hotbackup)# context 10` `Hostname(config-hotbackup-ctx)# peer-ip 1.1.1.1`
Verification	● Run the **show running** command to display the configuration.

AC	`Hostname(config)#show running`
	`wlan hot-backup 1.1.1.1`
	`!`
	`context 10`
	`peer-ip 1.1.1.1`

Common Errors

- N/A

1.4.22 Creating a WLAN

Configuration Effect

- You can create multiple WLANs on an AC and enter the configuration mode of a specified WLAN to configure related functions and attributes of the WLAN according to the actual network requirements.
- The WLAN service template that is generated based on the following configurations can take effect only after the WLAN is deployed on a specified AP group. Wireless users can access related APs to access the WLAN.
- On the wireless network, you can divide the network into multiple WLAN subnets by creating WLANs. In addition, you can configure the functions and attributes of a specified WLAN in WLAN configuration mode to provide different network services for wireless users.
- When creating a WLAN, you need to associate the WLAN with an SSID, which is the name of a network service zone. One SSID can be mapped to one or multiple WLANs.

Notes

- N/A

Configuration Steps

- Optional. No WLAN is configured by default. You need to create a WLAN before deploying the WLAN.
- Run the **wlan-config** command to create a WLAN, and use the **no** form of the command to delete the WLAN.

Command	**wlan-config** *wlan-id* [*profile –string*][*ssid-string*]
Parameter Description	*wlan-id*: Indicates the ID of a WLAN. The value ranges from 1 to 4094. *profile -string*: Indicates the profile of the WLAN. This parameter is optional. The maximum length is 32 bytes.

	ssid-string: Indicates the SSID. The maximum length is 32 bytes. When creating a WLAN, you need to specify the SSID associated with the WLAN. Use the **no** form of the command to delete a specified WLAN.
Defaults	No WLAN is created.
Command Mode	Global configuration mode
Usage Guide	One SSID can be mapped to one or multiple WLANs, but one WLAN can be associated with only one SSID.

Verification

- Run the **show running** command to display the WLAN configurations.

Configuration Example

Creating a WLAN

Configuration Steps	● Create WLAN 1. The SSID of WLAN 1 is Hostname-wireless.
AC	`Hostname(config)#wlan-config 1 Hostname-wireless` `Hostname(config-wlan)#`
Verification	● Run the **show running** command to display the WLAN configurations.

AC	`Hostname#show running`
	`!`
	`wlan-config 1 Hostname-wireless`
	`!`

Common Errors

- N/A

1.4.23 Deploying a WLAN

Configuration Effect

- The WLAN configuration takes effect only after the WLAN is deployed on a specified AP group. Wireless users can access the WLAN through the related APs. Run the **interface-mapping** command in AP group configuration mode to deploy the WLAN on a specified AP group. This command supports three mapping modes between the WLAN and VLANs, that is, single VLAN ID, VLAN group, and VLAN list, to map a specified WLAN to a corresponding VLAN of a wired network.

Notes

- When the WLAN forwarding mode is set to local forwarding, if the VLAN ID assigned to a STA by running the **interface-mapping** command is the same as the VLAN ID specified by the **ap-vlan** command, the service VLAN used by the STA for data forwarding is determined by the access switch of the AP, and is not the VLAN assigned by running the **interface-mapping** command. In particular, if the VLAN ID configured by running the **interface-mapping** command is 1, the VLAN of the STA in local forwarding mode is determined by the access switch. If no **ap-vlan** command is configured, the default VLAN ID in the **ap-vlan** command is 1.

- When using the **interface-mapping** command to configure the **list** mapping mode, you can add a single VLAN ID, but cannot remove a specified VLAN ID from the VLAN list.
- When using the **interface-mapping** command to configure the **list** mapping mode, the corresponding VLANs of the VLAN members in the VLAN list must be configured on the AC; otherwise, the IEEE 802.1X authenticated STAs cannot access the VLANs.

Configuration Steps

- Optional. You can run the **interface-mapping** command in AP group configuration mode to configure a WLAN and deploy the WLAN on all APs in the AP group.
- On the AC, enter the AP configuration mode and run the **interface-mapping** command for configuration.

Command	**interface-mapping** *wlan-id* [*vlan-id* I **group** *vlan-group-id* I **list** *vlan-list* [**def-vlan** *def-vlan-id*]] [**radio** { *radio-id* | **802.11b** | **6GHz** }] [**ap-wlan-id** *ap-wlan-id*]
Parameter Description	*wlan-id*: Indicates the ID of the specified WLAN. This WLAN must have been created. The WLAN ID ranges from 1 to 4094. *vlan-id*: Indicates the ID of the specified VLAN. The VLAN ID ranges from 1 to 4094. vlan-group-id: Indicates the ID of the specified VLAN group. The VLAN group ID ranges from 1 to 128. *vlan-list*: Indicates the specified VLAN list. The value ranges from 1 to 4094. The number of VLANs allowed in the list is 1 to 32. *def-vlan-id*: Indicates the default VLAN in the VLAN list. The value ranges from 1 to 4094. r*adio-id*: Indicates the ID of the radio of a specified AP. If radio-id is not specified, the mapping is applied to all radios of all APs in the AP group. The radio ID ranges from 1 to 96. **802.11b**: Indicates that the mapping is applied to all 2.4 GHz radios of all APs in the AP group. **802.11a**: Indicates that the mapping is applied to all 5.8 GHz radios of all APs in the AP group. **6GHz**: Indicates that the mapping is applied to all 6 GHz radios of all APs in the AP group. *ap-wlan-id*: Specifies the wlan-id that is used on the AP through interface-mapping. The value ranges from 1 to 64.
Defaults	The WLAN is not deployed on any AP.
Command Mode	AP group configuration mode
Usage Guide	● If the **ap-wlan-id** parameter is not specified, the mapping automatically selects and uses an idle ap-wlan-id. ● If the **ap-wlan-id** parameter is not specified, the first VLAN in the VLAN list is automatically selected and used for the mapping.

Verification

- Run the **show running** command to display the AP group configurations.

Configuration Example

Deploying a WLAN on a Specified AP Group

Configuration Steps	Hostname-AP1 belongs to the AP group APG-1. Create a WLAN, and deploy the WLAN on Hostname-AP1.

	● Create WLAN 1. The SSID of WLAN 1 is Hostname-wireless. ● Create VLAN 1. ● Configure the WLAN-VLAN mapping in AP group configuration mode.

AC	`Hostname(config)#wlan-config 1 Hostname-wireless`
	`Hostname(config-wlan)#exit`
	`Hostname(config)#vlan 1`
	`Hostname(config-vlan)#exit`
	`Hostname(config)#ap-group APG-1`
	`Hostname(config-ap-group)#interface-mapping 1 1`

Verification	● Run the **show running** command to check the AP group configurations.

	`Hostname#show running`
	`!`
	`wlan-config 1 Hostname-wireless`
	`!`
	`!`
	`ap-group APG-1`
	`  interface-mapping 1 1`
	`!`

Common Errors

- N/A

1.4.24 Configuring WLAN SSID Broadcasting

Configuration Effect

- On the WLAN, the AP periodically broadcasts the SSID information to notify the existence of the wireless network. Wireless users use the wireless network interface cards (NICs) to search SSIDs and detect the wireless network. The SSID broadcasting function can be enabled to prevent the wireless network from being searched and connected by unauthorized users based on the SSID.

Notes

- N/A

Configuration Steps

- Optional. WLAN SSID broadcasting is enabled by default. If the WLAN SSID needs to be hidden to prevent the wireless network from being searched and connected by unauthorized users based on the SSID, you can disable the WLAN SSID broadcasting function.
- On the AC, enter the WLAN configuration mode and run the **enable-broad-ssid** command for configuration.

Command	**enable-broad-ssid**
Parameter Description	N/A
Defaults	WLAN SSID broadcasting is enabled.
Command	WLAN configuration mode

Mode	
Usage Guide	WLAN SSID broadcasting is enabled by default. You can use the **no** form of the command to disable this function. If the SSID broadcasting configuration of the WLAN changes, users associated with the WLAN will go offline.

Verification

- Run the **show running** command to display the WLAN configuration.

Configuration Example

Disabling SSID Broadcasting of WLAN 1

Configuration Steps	• Enter the WLAN configuration mode. • Disable SSID broadcasting.
AC	`Hostname(config)#wlan-config 1` `Hostname(config-wlan)#no enable-broad-ssid`
Verification	• Run the **show running** command to display the WLAN configuration.

AC	`Hostname#show running`
	`!`
	`wlan-config 1 Hostname-wireless`
	`  no enable-broad-ssid`
	`!`

Common Errors

- N/A

1.4.25 Configuring the NAS ID of a WLAN User

Configuration Effect

- On the WLAN, the NAS IDs of WLAN users identify different hot spot areas. By default, the NAS ID of a WLAN user is a null string.

Notes

- N/A

Configuration Steps

- Optional.
- On the AC, enter the WLAN configuration mode and run the **nas-id** command to configure the NAS ID.

Command	**nas-id** *wlan-nas-id*
Parameter Description	N/A
Defaults	Null string
Command	WLAN configuration mode

Mode	
Usage Guide	N/A

Verification

- Run the **show running** command to display the WLAN configuration.

Configuration Example

Configuring the NAS ID of a WLAN User

Configuration Steps	• Enter the WLAN configuration mode. • Configure the NAS ID of a WLAN user.
AC	`Hostname(config)#wlan-config 1` `Hostname(config-wlan)#nas-id0000059159100460`
Verification	• Run the **show running** command to display the WLAN configuration.

AC	`Hostname#show running`
	`!`
	`wlan-config 1 Hostname-wireless`
	`nas-id0000059159100460`
	`!`

Common Errors

- N/A

1.4.26 Configuring the Fit or Fat AP Mode

Configuration Effect

- On the AC, run the **switch2fat** command in AC configuration mode to switch the mode of an online AP to the fat AP mode.

Notes

- If the **switch2fat** command is executed on the AC in AP configuration mode to switch the mode of an online AP to the fat AP mode, the AP will be disconnected from the AC. After that, you cannot configure the AP on the AC.

Configuration Steps

- Optional. For an AC, an online AP definitely works in fit AP mode. You can run the **switch2fat** command if you need to switch the mode of the AP to the fat AP mode.
- On the AC, run the **switch2fat** command in AC configuration mode to switch the mode of an online AP to the fat AP mode.

Command	**switch2fat** *ap-name*
Parameter Description	*ap-name*: Indicates the name of a specified AP.
Defaults	All fit APs are controlled by the associated AC. A fit AP can be switched to a fat AP to implement self-control.

Command Mode	AC configuration mode
Usage Guide	This command takes effect only on an online AP.

Verification

- N/A

Configuration Example

Switching the Mode of the Online AP Hostname-AP1 to the Fat AP Mode on the AC

Configuration Steps	• Enter the AC configuration mode. • Run the **switch2fat** command.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#switch2fat Hostname-AP1`
Verification	N/A

Common Errors

- N/A

1.4.27 Configuring the WLAN SSID

Configuration Effect

- Configure a new SSID for the WLAN. If this WLAN has been deployed, all users associated with this WLAN will go offline.
- Configure the coded character set for the SSID. If the WLAN has been deployed, all users of this WLAN will go offline.

Notes

- N/A

Configuration Steps

- Optional.
- On the AC, enter the WLAN configuration mode and run the **ssid** command to configure the new SSID.

Command	**ssid** *ssid-string*
Parameter Description	N/A
Defaults	N/A
Command Mode	WLAN configuration mode
Usage Guide	N/A

- On the AC, enter the WLAN configuration mode and run the **ssid-code** command to configure the encoding character set for the SSID.

Command	**ssid-code** { **gbk** | **utf-8** }
Parameter Description	**gbk**: Sets the character set to GBK. **utf-8**: Sets the character set to UTF-8.
Defaults	N/A. The system character set is used.
Command Mode	WLAN configuration mode
Usage Guide	1. If the WLAN has been deployed, all users of this WLAN will go offline. 2. Some wireless clients may only support UTF-8 or GBK. When the SSID is set in Chinese, these clients may fail to associate. In this case, you can use the **ssid-code** command to change the SSID to UTF-8 or GBK, thereby making it adaptive to the wireless clients.

Verification

- Run the **show running** command to display the WLAN configuration.

Configuration Example

Setting the New SSID of WLAN 1 to Hostname

Configuration Steps	• Enter the WLAN configuration mode. • Set the new SSID of WLAN 1 to Hostname.
AC	`Hostname(config)#wlan-config 1` `Hostname(config-wlan)#ssid Hostname`
Verification	• Run the **show running** command to display the WLAN configuration.

AC	`Hostname#show running`
	`!`
	`wlan-config 1 Hostname`
	`!`

Common Errors

- N/A

1.4.28 Configuring the AP Backup Function

Configuration Effect

- If the active AP in an AP backup group is faulty and disconnected, other standby APs in the group receive the WLAN configuration of the active AP and transmit radio signals of the active AP.

Notes

- In an AP backup group, if the active AP is not selected, the AP backup function does not take effect.

Configuration Steps

Configuring an AP Backup Group

- Optional. Create an AP backup group when the wireless network of an AP needs to be backed up.
- In AC configuration mode, run the **ap-backup group** command to create an AP backup group.

Command	**ap-backup group** *backup-group*
Parameter Description	*backup-group*: Indicates the name of the AP backup group.
Defaults	If only the AP backup group named **default** exists on the AC, the backup function of this group does not take effect.
Command Mode	AC configuration mode
Usage Guide	N/A

Adding APs to an AP Backup Group

- Optional. When the wireless network of an AP must be backed up by other APs, add the standby APs and the AP to be backed up to the AP backup group, and select the AP to be backed up as the active AP.
- In AP configuration mode, run the **ap-backup-group** command to add the AP to the AP backup group. When adding an AP to an AP backup group, you can specify whether the AP is the active AP.

Command	**ap-backup-group** *backup-group***[master]**
Parameter Description	*backup-group*: Indicates the name of the AP backup group.
Defaults	The AP is not added to the default group, and the backup function of the backup group does not take effect.
Command Mode	AP configuration mode
Usage Guide	This command does not support the ap-config all mode. The keyword master is optional. If the command contains this keyword, the AP is designated as the active AP of the group; otherwise, the AP is the standby AP. An AP backup group can have multiple standby APs but only one active AP. When the AP backup group starts to work, that is, the standby APs have inherited WLAN signals from the active AP, note that the following four operations change the WLAN configurations of the standby APs that should take effect, and the inherited WLAN signals will take effect again: 1. Modify the WLAN configurations of the AP group to which the standby APs belong. 2. Modify the WLAN configurations of the AP group to which the active AP belongs. 3. Change the AP group of the standby APs. 4. Change the AP group of the active AP. If online users already exist, these users will go offline.

Verification

- Run the **show ap-config running** and **show ac-config ap-backup-group** commands to display the configuration.

Configuration Example

Creating an AP Backup Group Named APBACK-APG-1

Configuration Steps	In AC configuration mode, run the **ap-backup group** command to create an AP backup group.
AC	`Hostname(ac-config)#ap-backup group APBACK-APG-1`
Verification	Run the **show ac-config ap-backup-group** command to check the configurations.
AC	`Hostname#show ac-config ap-backup-group` `Cnt Group-Name Master-AP cntStandby-AP cnt`

	Master-AP-Name Working ------ ---------- 1 APBACK-APG-1 1 2 AP4210-1 false

Adding AP4210-1 to the AP Backup Group Named APBACK-APG-1, and Configuring this AP as the Active AP of the Group

Configuration Steps	● In AP configuration mode, run the **backup-group** command to add the AP to the AP backup group.
AC	Hostname(ap-config)#ap-backup-group APBACK-APG-1 master
Verification	● Run the **show ac-config ap-backup-group** command to display the configuration.
AC	Hostname#show ac-config ap-backup-groupAPBACK-APG-1 Cnt Ap-Name Ap-Mac Online Is-Master Inherit-Wlan Cnt ------- ---------- ---------- ------- ---------- ---------- 1 AP4210-1 8832.0000.1111 true Yes 0

Common Errors

- N/A

1.4.29 Configuring Hierarchical Permission-based AC Management

Configuration Effect

- After an administrator logs in to the web management page, the administrator can only check and configure authorized WLANs, AP groups, and APs (STAs).

Notes

- N/A

Configuration Steps

Enabling Hierarchical Permission-based AC Management

- Optional. When multiple administrators are required in a wireless environment to manage different wireless networks and APs, enable hierarchical permission-based AC management.
- Run the **permit enable** command in AC configuration mode to enable hierarchical permission-based AC management.
- Run the **master-group** command in global configuration mode to create a role and enter the role configuration mode.
- Run the **master-group** command in AP configuration mode to assign an AP to a specific role.
- Run the **master-group** command in AP group configuration mode to assign an AP group to a specific role.
- Run the **master-group** command in WLAN configuration mode to assign a WLAN to a specific role.

- Run the **webmaster** command in role configuration mode to add or delete an administrator.

Command	**permit enable**
Parameter Description	N/A
Defaults	The AC virtualization function is disabled.
Command Mode	AC configuration mode
Usage Guide	Whether this configuration is supported depends on the actual product.

Command	**master-group** master-group-name
Parameter Description	*master-group-name*: Indicates the role name.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	When the **no** form of this command is used to delete a role, APs, AP groups, and WLANs assigned to the role are restored to the unassigned state and the administrator of this role is restored to the default role-free state. Whether this configuration is supported depends on the actual product.

Command	**master-group** master-group-name
Parameter Description	*master-group-name*: Indicates the role name.
Defaults	N/A
Command Mode	AP configuration mode, AP group configuration mode, or WLAN configuration mode
Usage Guide	After a role is deleted, APs, AP groups, and WLANs assigned to the role are restored to the default unassigned state. Whether this configuration is supported depends on the actual product.

Command	**webmaster** webmaster-name
Parameter Description	*webmaster-name*: Indicates the administrator name.
Defaults	N/A
Command Mode	Role configuration mode
Usage Guide	When a role is deleted, the administrator of the role is restored to the default role-free state. Whether this configuration is supported depends on the actual product.

Verification

- Run the **show running-config** and **show ap-config running** commands to display configurations.

Configuration Example

Enabling Hierarchical Permission-based AC Management

Configuration Steps	● Run the **permit enable** command in AC configuration mode to enable hierarchical permission-based AC management.
AC	`Hostname(ac-config)# permit enable`
Verification	● Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config | begin ac-controller`
	`ac-controller`
	` permit enable`
	` ac-name Hostname`
	` country CN`

Creating Role test-group and Adding Administrator test-admin-1 for the Role

Configuration Steps	● Run the **master-group** command in global configuration mode to create the role (test-group) and enter the role configuration mode. ● Run the **webmaster** command in role configuration mode to add the administrator (test-admin-1).
AC	`Hostname(config)# master-group test-group` `Hostname(config-master-group)# webmaster test-admin-1`
Verification	● Run the **show running-config** command to display configurations.

AC	`Hostname# show running-config | begin master-group`
	`master-group test-group`
	` webmaster test-admin-1`

Assigning AP (ap-1), AP Group (apg-1), and WLAN (1) to Role test-group

Configuration Steps	● Run the **master-group** command in AP configuration mode to assign the AP (ap-1) to the role (test-group). ● Run the **master-group** command in AP group configuration mode to assign the AP group (apg-1) to the role (test-group). ● Run the **master-group** command in WLAN configuration mode to assign the WLAN (1) to the role (test-group).

AC	`Hostname(config)# ap-config ap-1`
	`Hostname(config-ap)# master-group test-group`
	`Hostname(config-ap)# exit`
	`Hostname(config)# ap-group apg-1`
	`Hostname(config-group)# master-group test-group`
	`Hostname(config-group)# exit`
	`Hostname(config)# wlan-config 1`
	`Hostname(config-wlan)# master-group test-group`

Verification	● Run the **show running-config** and **show ap-config running** commands to display configurations.
AC	`Hostname# show running-config | begin wlan-config 1` `wlan-config 1 Hostname`

	master-group test-group ! Hostname# show running-config | begin ap-group apg-1 ap-group apg-1 master-group test-group ! Hostname# show ap-config running | begin ap-config ap-1 ap-config ap-1 master-group test-group !

Common Errors

- N/A

1.4.30 Configuring the AP Virtualization Function

Configuration Effect

- Multiple ACs can assign their own WLANs to the same AP, and the STAs connect to the virtual APs served by corresponding ACs.

Notes

- ACs cannot broadcast the same signal.

Configuration Steps

Configuring an AP Virtualization Template

- Optional. Configure an AP virtualization template when multiple ACs need to manage the same AP.
- In global configuration mode, run the **virtual-ap** command to create an AP virtualization template.

Command	**virtual-ap** *sub-ap-name*
Parameter Description	*sub-ap-name*: Indicates the name of an AP virtualization template.
Defaults	No AP virtualization template is created.
Command Mode	AC global configuration mode
Usage Guide	N/A

Configuring the IP Address of the AC to Which a Virtual AP is to Connect

- Optional. If the IP address of the AC to which a virtual AP is to connect is not configured, the virtual AP created on the AP using the AP virtualization template cannot connect to the AC.

Command	ac-ip *ip*
Parameter Description	*ip*: Indicates the IPv4 address of the AC to which a virtual AP is to connect.
Defaults	The virtual APs created on the AP using the AP virtualization template cannot connect to ACs.

Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. The AP disconnects all tunnels and reconnects them each time the configurations are changed. The configured IP address cannot be the IP address of the active AC, and can only be the IP address of the AC to be connected and the address of the loopback 0 interface or the CAPWAP control IP address if any.

Configuring the Number of WLANs Supported by a Virtual AP

- Optional. If the number of WLANs supported by a virtual AP is not configured, it is calculated as follows: (Total number of WLANs supported by the AP – Number of WLANs configured for virtual APs)/Number of virtual APs with the number of supported WLANs not configured

Command	**wlan-capacity** *wlan-cap*
Parameter Description	*wlan-cap*: Indicates the number of WLANs supported by a virtual AP.
Defaults	The number of WLANs supported by a virtual AP is not configured.
Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. In default configuration mode, if the remaining number of WLANs is 0, the virtual AP cannot broadcast wireless signals. The AP disconnects all tunnels and reconnects them each time the configurations are changed.

Configuring the Number of STAs Supported by a Virtual AP

- Optional. If the number of STAs supported by a virtual AP is not configured, it is calculated as follows: (Total number of STAs supported by the AP – Number of STAs configured for virtual APs)/Number of virtual APs with the number of supported STAs not configured

Command	**sta-capacity** *sta-cap*
Parameter Description	*sta-cap*: Indicates the number of STAs supported by a virtual AP.
Defaults	The number of STAs supported by a virtual AP is not configured.
Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. In default configuration mode, if the remaining number of STAs is 0, the virtual AP cannot broadcast wireless signals. The AP disconnects all tunnels and reconnects them each time the configurations are changed.

Configuring the Uplink Interface Used by a Virtual AP

- Optional. If the uplink interface used by a virtual AP is not configured, the virtual AP uses the uplink interface used by the active AC.

Command	**link-interface** { *other* | *num}*
Parameter Description	*other*: Indicates that a virtual AP uses an uplink interface different from that used by the active AC. This parameter is specified when there are two uplink interfaces and virtual AP and active AC use them for connection. *num*: Indicates the number of uplink interface used by a virtual AP.
Defaults	A virtual AP uses the uplink interface used by the active AC.
Command Mode	AP virtualization template configuration mode
Usage Guide	This command is configured in the AP virtualization template. In default configuration mode, a virtual AP uses the uplink interface used by the active AC to establish a CAPWAP tunnel. The other parameter is configured only when there are two uplink interfaces and the virtual AP and active AC use them for connection. Otherwise, the virtual AP cannot establish a CAPWAP tunnel with the corresponding AC. If the configured uplink interface number does not exist, the virtual AP cannot establish a connection to the corresponding AC. The AP disconnects all tunnels and reconnects them each time the configurations are changed. If multiple uplink interfaces exist and the **other** or **num** parameter is configured after the aggregation function is configured, the virtual AP cannot establish a CAPWAP tunnel to the corresponding AC.

Configuring Virtual APs for an AP

- Optional. If virtual APs are not configured for an AP, the AP does not create virtual APs.

Command	**virtual-ap** *sub-ap-name* {**id** *num*}
Parameter Description	*sub-ap-name*: Indicates the name of an AP virtualization template. *num*: (Optional) Indicates the number of a virtual AP on the AP, which starts from 1 by default.
Defaults	An AP does not create virtual APs.
Command Mode	AP, AP group, or all-AP configuration mode
Usage Guide	This command is configured in AP, AP group, or all-AP configuration modes. In a configuration mode, multiple virtual APs can be configured but the virtual APs cannot have the same AC IP address except the default one. The AP disconnects all tunnels and reconnects them each time the configurations are changed. Configurations of the **virtual-ap** command are delivered based on the priority in descending order: Configurations in AP configuration mode > Configurations in AP group configuration mode > Configurations in all-AP configuration mode.

Configuring the Duration for a Virtual AP to Provide Services After the AP is Disconnected from the Active AC

- Optional. If the duration for a virtual AP to provide services after the AP is disconnected from the active AC is not configured, the virtual AP continues to provide services for one day.

Command	**ap-idle-timeout** *num*
Parameter Description	*num*: Indicates the duration (in days) for a virtual AP to provide services after the AP is disconnected from the active AC. The value ranges from 0 to 14.
Defaults	A virtual AP continues to provide services for one day after the AP is disconnected from the active AC.
Command Mode	AP, AP group, or all-AP configuration mode
Usage Guide	This command is configured in AP, AP group, or all-AP configuration mode. If the **num** parameter is set to 0 to prevent tunnel instability, the tunnel between the virtual AP and corresponding AC is not disconnected immediately but retained for two minutes. After an AP is disconnected from the active AC and the time specified in **ap-idle-timeout** has not expired, a virtual AP does not associate with an AC if the tunnel between the virtual AP and corresponding AC is disconnected. Only when the connection between the AP and active AC is re-established, the virtual AP will associate with the corresponding AC.

Verification

- Run the **show running** command to display configurations.

Configuration Example

Creating an AP Virtualization Template Named VAP-1

Configuration Steps	Run the **virtual-ap** command in AC global configuration mode to create the AP virtualization template named VAP-1.

AC	`Hostname(config)#virtual-ap VAP-1`
	`Hostname(config-virtual-ap)# wlan-capacity 6`
	`Hostname(config-virtual-ap)# sta-capacity 6`
	`Hostname(config-virtual-ap)# ac-ip 1.1.1.1`
	`Hostname(config-virtual-ap)# link-interface 2`

Verification	Run the **show running-config** command to display configurations.

AC	`Hostname#show running-config`
	
	`Building configuration...`
	`Current configuration: 6069 bytes`
	
	`version AC_RGOS 11.1(5)B00, Release(04150906)`
	`!`
	`virtual-ap VAP-1`
	` ac-ip 1.1.1.1`
	` wlan-capacity 6`
	` sta-capacity 16`
	` link-interface 2`
	`!`

Applying AP Virtualization Template VAP-1 to AP1

Configuration Steps	● Run the **virtual-ap** command in AP configuration mode, AP group configuration mode, or all-AP configuration mode.

AC	`Hostname(config)#ap-config AP1`
	`You are going to config AP(AP1), which is not online now.`
	`Hostname(config-ap)#virtual-ap VAP-1`
	`Hostname(config-ap)#`

Verification	● Run the **show ap-config running** command to display configurations.

AC	`Hostname(config-ap)#show ap-c running`
	`!`
	`ap-config AP1`
	` virtual-ap VAP-1 id 1`
	`!`

Common Errors

- N/A

1.4.31 Configuring the Default SSID

Configuration Effect

- When a fit AP starts up or the CAPWAP tunnel of the AP is disconnected, the AP broadcasts a 2.4 GHz unencrypted SSID signal. When the CAPWAP tunnel is set up, the SSID is disabled.

Notes

- If RIPT is configured and the tunnel is disconnected, signals are not broadcast.
- The SSID in Chinese is not supported.
- When the AP is restarted, the configurations will be saved.

Configuration Steps

- Optional.
- On the AC, run the **offline-ssid** command in AP, AP group, or all-AP configuration mode to specify the SSID signal of the AP.

Command	**offline-ssid** *ssid* [**hide**]
Parameter Description	*ssid*: Indicates the SSID signal broadcasted when the AP starts up or the tunnel is disconnected. **hide**: Indicates that no SSID signal is broadcasted.
Defaults	No SSID is configured.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	N/A

Verification

- Run the **show running** or **show ap-config running** command to display the configuration.

Configuration Example

Setting the Default SSID of AP1 to my-def-ssid

Configuration Steps	● Set the default SSID of the default AP group to my-group-ssid.

AC	`Hostname(config)#ap-config AP1`
	`Hostname(config-ap)#offline-ssid my-def-ssid`
	`Hostname(config-ap)#exit`
	`Hostname(config)#ap-group default`
	`Hostname(config-ap-group)#offline-ssid my-group-ssid`

Verification	● Run the **show running** command to check whether the command is configured in all-AP and AP group configuration modes. ● Run the **show ap-config running** command to display the configuration of the AP.

AC	`Hostname(config)#show running`
	`!`
	`ap-group default`
	`  offline-ssid my-group-ssid`
	`!`
	`Hostname#show ap-config running`
	`!`
	`ap-config AP1`
	`  offline-ssid my-def-ssid`
	`!`

Common Errors

- N/A

1.4.32 Configuring Automatic AP Grouping

Configuration Effect

- Configure matching rules in the AP group, such as the source IP network segment (the IP addresses of APs). After an AP goes online, the AP is automatically assigned to the AP group if the configured rules are matched.

Notes

- Perform the configuration in the target AP groups for grouping. The default AP group cannot be configured.
- The configuration takes effect for the AP in the default AP group only after the AP goes online.

Configuration Steps

- Optional.
- On the AC, run the **auto-join-group match src-ip** command in AP group configuration mode to configure the network segment matching rule for automatic AP grouping.

Command	**auto-join-group match src-ip** *match-ip-address network-address-mask*
Parameter	*match-ip-address*: Specifies the IP address of the AP that meets the requirement for joining the AP

Description	group, in format of A.B.C.D. Only one IP address can be configured for a rule. A single AP group supports up to 16 rules. *network-address-mask*: Configures the subnet mask of the IP address of the AP that meets the requirement for joining the AP group, in format of A.B.C.D. **recover**: Reassign an online AP in an AP group to the default AP group when deleting the network segment matching rule in the AP group. An AP is not reassigned to the default AP group by default.
Defaults	This function is not configured.
Command Mode	AP group configuration mode
Usage Guide	● After an AP goes online, the AP is automatically added to an AP group that matches the IP rule. ● Perform the configuration in the target AP groups for grouping. The default AP group cannot be configured. ● The configuration takes effect for APs in the default AP group only. ● The automatic AP grouping function takes effect only when an AP goes online for the first time. Adding or modifying a network segment matching rule does not affect the grouping of APs that are already online. ● Reassigning an AP to the default AP group after a rule is deleted is only available for online APs in the AP group for which this command takes effect.

Verification

- Run the **show auto-join-group rule src-ip summary** command to display the configuration.

Configuration Example

↘ Configuring APs in the Network Segment 192.168.1.0 to Automatically Join Group apg1

Configuration Steps	● Configure APs in the network segment 192.168.1.0 to automatically join Group apg1.
AC	`Hostname(config)#ap-group apg1` `Hostname(config-group)#auto-join-group match src-ip 192.168.1.0 255.255.255.0`
Verification	● Run the **show auto-join-group rule src-ip summary** command to check whether the command is configured in AP group configuration mode.

AC	`Hostname #show auto-join-group rule src-ip summary`
	`RULE IP Ap Group Name`
	`------------------ ----------------------------------------`
	`192.168.1.0/24 apg1`

Common Errors

- N/A

1.4.33 Configuring the AC Software Features

Configuration Effect

- Configure the software features of the AC to a hexadecimal value.

Notes

- The maximum value is **0xFFFFFFFF**.

Configuration Steps

- Run the **ac-controller** command to enter the AC configuration mode.
- Run the **wlan-features** command in AC configuration mode on the AC to configure the software features.

Command	**ac-controller**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Command	**wlan-features** *features* **no wlan-features** **default wlan-features**
Defaults	The default value of AC software features is the engineering configuration value of the system.
Parameter Description	*features*: Indicates the software feature value of the AC. The maximum value is **0xFFFFFFFF**.
Command Mode	AC configuration mode
Usage Guide	You can configure software features that the AC does not support to temporarily bring the AP online.

Verification

- Run the **show running-config** command to display the software features of the AC and check whether the configuration is successful.

Configuration Example

Configuring the AC Software Feature Value to 0x02

Configuration Steps	• Enter the AC configuration mode. • Configure the software feature value of the AC, assuming that the current system value is 0x01.
AC	`Hostname(config)# ac-controller` `Hostname(config-ac)# wlan-features 0x02`

Verification	Run the **show running-config** command to display the software features of the AC.

AC	`Hostname# show running-config`
	`!`
	`ac-controller`
	` wlan-features 0x3`
	` capwap ctrl-ip 10.104.22.152`
	`!`

Resuming the AC Software Feature Value to the System Value

Configuration Steps
- Enter the AC configuration mode.
- Use the **no** form of this command to resume the AC software feature value to the system value.

AC

```
Hostname(config)# ac-controller
Hostname(config-ac)# no wlan-features
```

Verification

Run the **show running-config** command to display the software features of the AC.

AC

```
Hostname# show running-config
!
ac-controller
 wlan-features 0x1
 capwap ctrl-ip 10.104.22.152
!
```

Common Errors

Clearing

- N/A

Displaying

Command	Description
show ac-config	Displays the basic configurations of the current AC.
show ac-config ap-backup-group	Displays the AP backup group information.
show ac-device information	Displays the wireless AC hardware information.
show ap-device information [ap-name]	Displays the hardware information of the AP associated with the AC.
show ap-config bssid	Displays the BSSID list of all APs.
show ap-config bssid cb	Displays the BSSID information of an AP.
show ap-config cb	Displays the AP status information.
show ap-config inherit-wlan	Displays the WLAN information inherited by the AP.
show ap-config product	Displays the AP product list.
show ap-config summary	Displays the current status of all APs.
show ap-config summary ap-auth	Displays the authentication-related information of all APs.
show ap-config summary deny-ap	Displays APs that attempt to associate with the AC but are rejected by the AC.
show ap-config summary hot-backup	Displays the hot standby configuration and APs associated with the active AC.
show ap-config summary virtual-ap-role	Displays the virtual APs of all APs.
show ap-config virtual-ap detail	Displays the information about the virtual AP of an AP.

Command	Description
show ap-config virtual-ap summary	Displays the operating status of the virtual AP of an AP on the AC.
show ap-group aps	Displays the APs in a specified AP group.
show ap-group aps summary	Displays the APs in all AP groups.
show ap-group cb	Displays the basic information about a specified AP.
show ap-group intf-wlan-map	Displays the WLAN-VLAN mapping of a specified AP group.
show ap-group radios	Displays AP radio statistics of an AP group.
show ap-group summary	Displays all APs
show auto-join-group rule src-ip *ip-address ip-mask* **conflict**	Displays the configuration that conflicts with the input automatic grouping IP rule.
show auto-join-group rule src-ip summary	Displays the configured automatic grouping IP rule.
show license	Displays the supported APs after the license is installed on the AC.
show virtual-ap detail	Displays the information of a virtual AP template.
show virtual-ap summary	Displays the virtual AP template list on the AC.
show wlan hot-backup	Displays the instance list on the hot standby peer.
show wlan-config cb	Displays the basic information about a specified WLAN.
show wlan-config summary	Displays the WLAN configuration list on the AC.
show device-config map summary	Displays the information about an micro AP connected to the all-optical AM

Whether this configuration is supported depends on the actual product.

Debugging

- N/A

1 Configuring ETH-MNG

1.1 Overview

Access points (APs) provide Ethernet ports, including WAN ports, LAN ports, and cascade ports. The WAN ports are used to connect to the uplink access switches, and the LAN ports provided by some APs (wall-plate APs and i-Share+ APs) are used to access wired or other devices and forward data to WAN ports. The cascade ports provided by i-Share+ APs are used to connect to micro APs or other devices. In the fit AP network architecture, an AP obtains the IP address of an AC over the WAN port to establish a CAPWAP tunnel with the AC, and the AP cannot obtain the AC IP address through DHCP over the LAN port. Therefore, the LAN port cannot be used to establish a CAPWAP tunnel.

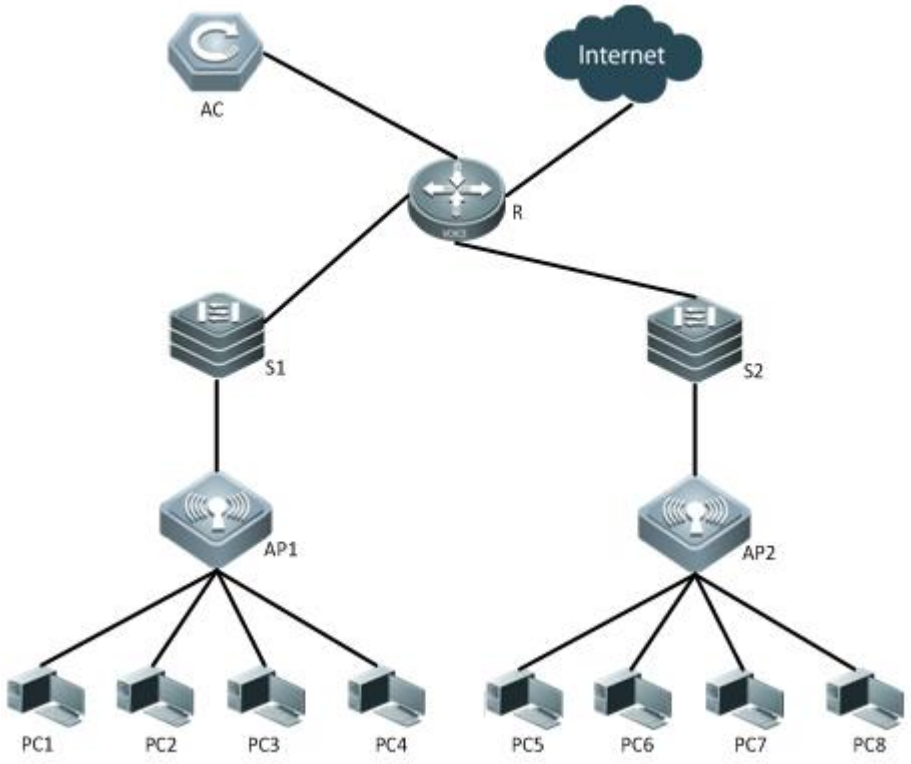
Protocols and Standards

N/A

1.2 Applications

Application	Description
Configuring VLANs on LAN Ports	Configure VLANs on LAN ports to separate APs and wired users.

1.2.1 Configuring VLANs on LAN Ports



Scenario

In the fit AP architecture, configure VLANs on LAN ports.

Take the following topology as an example:

- An AC is connected to the Internet through a router. Two APs (AP1 and AP2) are connected to the router through two switches, and are associated with the AC.
- PC1, PC2, PC3, and PC4 are associated with AP1; PC5, PC6, PC7, and PC8 are associated with AP2. These PCs access the Internet through the AC.

Figure 1-1

Remarks	R: Indicates a network egress router. S1 and S2: Indicates two Layer 2 switches that serve as the access devices of APs. AP1 and AP2: Indicates two wireless access points. STA1 and STA2: Indicates two client devices connected to S1 and S2 respectively.

Deployment

- Enable the Layer 2 switch to provide the access function for the APs.
- Connect the router R to the network formed by the AC and the APs. Connect the router R to the PCs and the Internet.
- Configure VLANs for LAN ports on APs through the AC.

1.3 Features

Basic Concepts

N/A

Overview

Feature	Description

Configuring the Configuring the VLANs of an AP	Configures the default VLAN of an AP, VLANs of Ethernet ports, and transmission VLANs of i-Share+ APs.
Configuring a Bandwidth Limit for a Configuring a Bandwidth Limit for a LAN Port	Configures the maximum bandwidth for the LAN ports of APs to avoid the slow Internet access of wireless users in a scenario where wireless and wired users coexist and wired users occupy a substantial bandwidth.
Configuring the LAN/WAN Attribute of an AP Port	Configures the WAN/LAN attribute of the port to change devices with the default port attribute of WAN+LAN into dual-WAN-port devices.

1.3.1 Configuring the VLANs of an AP

Working Principle

An AP automatically removes the tag from a frame that carries the native VLAN before forwarding the frame. That is, in local forwarding mode, if the VLAN of a STA is the same as the native VLAN, the frame of the STA does not carry the tag when forwarded, and the access switch determines the VLAN to which the STA belongs. The default VLAN of the AP is VLAN 1. The default VLAN of the AP, VLAN of wireless users, and VLAN of wired users can be planned flexibly to ensure that the STAs and AP are on the same VLAN or different VLANs.

i-Share+ APs can be deployed in cascading mode, and transmission VLANs can be configured to ensure that VLAN packets of downlink devices can be forwarded by uplink devices.

1.3.2 Configuring a Bandwidth Limit for a LAN Port

Working Principle

The bandwidth limiting function is used to configure the maximum bandwidth for LAN ports of APs to avoid the slow Internet access of wireless users in a scenario where wireless and wired users coexist and wired users occupy a substantial bandwidth.

1.3.3 Configuring the LAN/WAN Attribute of an AP Port

Working Principle

When the AP starts, determine whether to use the default port attribute or the changed port attribute as the WAN/LAN capability value of the port based on whether the WAN/LAN attribute of the port has been changed. This enables switching the WAN/LAN attribute of ports and meets the deployment requirements for different AP port attributes.

1.4 Configuration

Configuration	Description and Command	
Configuring the Default VLAN of an AP	⚠ (Optional) It is used to configure the native VLAN of an AP.	
	ap-vlan	Configures the default VLAN of an AP.
Configuring the Transmission VLAN of an AP	⚠ (Optional) It is used to configure the transmission VLAN of an AP.	
	pass-vlan	Configures the transmission VLAN of an AP.

Configuring a VLAN for	(Optional) It is used to configure a VLAN for an Ethernet port that provides wired access.	
	wired-vlan	Configures a VLAN for an Ethernet port.
Configuring a VLAN for a Cascade Port	(Optional) It is used to configure a VLAN for a connected non-micro AP.	
	wired-vlan connect	Configures a VLAN for a connected non-micro AP.
Configuring the Ethernet Port Status of an AP	(Optional) It is used to disable an Ethernet port of an AP that provides wired access.	
	wired-interface	Disables an Ethernet port of an AP.
Configuring the Sub-Interface of the WAN Interface on the AP	(Optional) It is used to configure the sub-interface of the WAN interface on the AP.	
	ap-subif	Configures the sub-interface of the WAN interface on the AP.
Configuring a Bandwidth Limit for an Ethernet Port of an AP	(Optional) It is used to configure the maximum bandwidth of LAN ports of APs.	
	wired-rate *value*	Configures bandwidth limits of LAN ports of APs.
Configuring the Specified AP Port As a WAN Port	(Optional) It is used to configure the port attribute.	
	wired-mode wan eth	Configures the specified AP port as a WAN port.
Configuring the Specified AP Port As a LAN Port	(Optional) It is used to configure the port attribute.	
	wired-mode lan eth	Configures the specified AP port as a LAN port.

1.4.1 Configuring the Default VLAN of an AP

Configuration Effect

- An AP automatically removes the tag from a frame that carries the native VLAN before forwarding the frame. That is, in local forwarding mode, if the VLAN of a STA is the same as the native VLAN, the frame of the STA does not carry the tag when forwarded, and the access switch determines the VLAN to which the STA belongs.

Notes

- After this command is executed, an online AP will be disconnected and then reconnected.
- When a wireless distribution system (WDS) is deployed, the same AP-VLAN must be planned for the root bridge and non-root bridge devices; otherwise, the non-root bridge devices cannot share the same address pool with root bridge devices or the non-root bridge devices cannot even forward packets properly.
- This command needs to be configured only in the following case: In local forwarding mode, STAs and an AP are on the same subnet and VLANs have been configured for the STAs and the AP. This command is not required in other cases.

- If the static DHCP address pool is configured, and the client ID is specified to use Bridge-Group Virtual Interface (BVI) 1, configuration of this command will change the BVI interface of the AP. In this case, the DHCP server configuration must be modified; otherwise, the address cannot be obtained.
- If the AP uses the PPPoE dial-up mode to obtain the address, the CAPWAP module on the AP will select dialer 1 as the source interface, and the STA traffic will be forwarded without carrying the tag. Therefore, this command is meaningless.

Configuration Steps

Configuring the Default VLAN of an AP

- Optional.
- When the native VLAN of a STA needs to be planned, set the default VLAN of an AP to the same as the VLAN of the STA. In this way, both the VLAN of the STAr and the VLAN of the AP are determined by the access switch.

Command	ap-vlan *vlan-id*
Parameter Description	*vlan-id*: Indicates a specified VLAN ID. The value ranges from 1 to 4094. The default value is 1.
Defaults	1
Command Mode	AP configuration mode or all AP (ap-config all) configuration mode
Usage Guide	An AP automatically removes the tag from a frame that carries the native VLAN before forwarding the frame. That is, in local forwarding mode, if the VLAN of a STA is the same as the native VLAN, the frame of the STA does not carry the tag when forwarded, and the access switch determines the VLAN to which the STA belongs.

Verification

- Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configuration of a specified AP.

Configuration Example

Setting the Native VLAN ID of AP1 to 20

Configuration Steps	• Enter the AP configuration mode on the AC. • Set the VLAN ID of the native VLAN of AP1 to **20**.
AC	`Hostname(config)# ap-config AP1` `Hostname(config-ap)# ap-vlan20`
Verification	Run the **show ap-config running** command to display the location information of AP1.

AC	Hostname#show ap-config running ! ap-config AP1 ap-vlan 20 !

Common Errors

For example, the native VLAN of the switch is VLAN 20, and all wireless/wired users and APs belong to VLAN 20. The following configurations are incorrect:

On the AC:

```
Hostname(config)# ap-configAP120
Hostname(config-ap)# wired-vlan20
Hostname(config-ap)# exit
Hostname(config)#wlan-config 1 ssid
Hostname(config-wlan)#tunnel local
Hostname(config-wlan)#exit
Hostname(config)#ap-group default
Hostname(config-ap-group)#interface-mapping 1 20 radio 1
```

On the switch:

```
Hostname(config)#interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport mode trunk
Hostname(config-if-GigabitEthernet 0/1)#switchport trunk native vlan 20
```

The configurations here are incorrect because the VLAN of users is different from the native VLAN of APs. Therefore, the uplink packets of APs carry tag 20 when forwarded, and the access switch transparently forwards VLAN 20 and assigns addresses to users. As the native VLAN of the switch is VLAN 20, the downlink packets do not carry the tag when forwarded. The Native VLAN of APs is 1 by default. Therefore, the packets cannot be forwarded to users, causing a failure for wireless and wired users to obtain IP addresses.

Either of the following methods can be used to modify the configurations:

Method 1: Change **wired-vlan 20** to **wired-vlan 1** and **interface-mapping 1 20 radio 1** to **interface-mapping 1 1 radio 1**, and the native VLAN of the switch remains unchanged.

Method 2: Add the native VLAN configurations for APs, and other configurations remain unchanged.

On the AC:

```
Hostname(config)# ap-configAP120
Hostname(config-ap)# ap-vlan 20
```

1.4.2 Configuring the Transmission VLAN of an AP

Configuration Effect

- When the i-Share+ APs are cascaded or a ring network is deployed, configure transmission VLANs for the master APs. This allows the uplink master APs to forward packets from STAs associated with different APs when STAs are deployed on different VLANs.

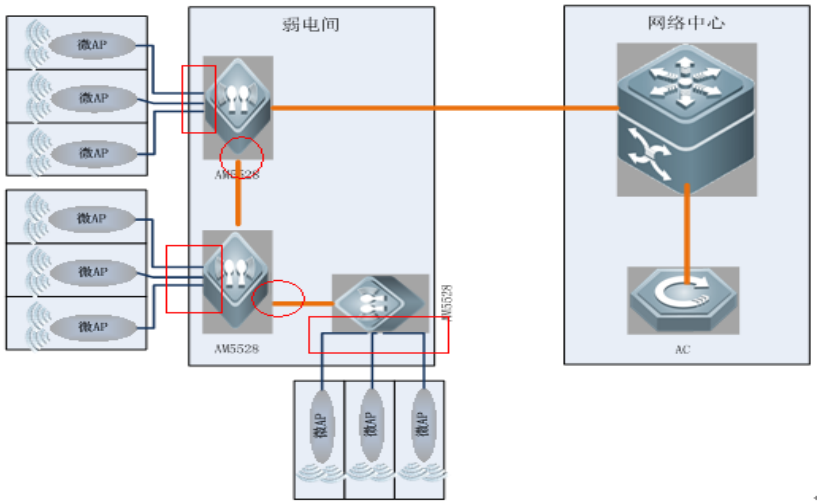
Notes

- The transmission VLAN cannot conflict with the VLANs specified by the **interface-mapping**, **ap-vlan**, and **wired-vlan** commands, and cannot be VLAN 2444.

Configuration Steps

Configuring the Transmission VLAN of an AP

- Optional.
- When the i-Share+ APs are cascaded or a ring network is deployed, run this command to configure the transmission VLAN. This allows the uplink master APs to forward packets from STAs associated with different APs when STAs are deployed on different VLANs.



Command	**pass-vlan** *vlan-range*
Parameter Description	*vlan-range*: Indicates the VLAN ID range. Multiple VLAN IDs can be specified. Separate two VLAN IDs by a comma (,) and separate two VLAN ID ranges by a hyphen (-).
Defaults	No VLAN is configured.
Command Mode	AP configuration mode
Usage Guide	1. This command can be configured for all APs but takes effect only on the i-Share+ master AP. 2. When this command is run, the transmission VLAN will be created on the i-Share+ master AP, enabling the master AP to forward packets based on the transmission VLAN. In addition, the transmission VLAN will be automatically pruned on the downlink port of the master AP, to prevent broadcast and multicast packets of other master APs from being flooded to micro APs connected to the master AP.

Verification

Run the **show ap-config running** command to display the AP configuration.

Configuration Example

↘ **Configuring the Transmission VLAN of an i-Share+ Master AP**

Scenario **Figure 1-3**	 As shown in the cascading deployment topology, provided that the VLANs for the three AM5528 master APs from top to bottom are set to VLAN 10, VLAN 20, and VLAN 30 respectively.
Configuration Steps	● Enter the AP configuration mode of the AC. ● Configure the transmission VLANs of AM-1 as VLAN 20 and VLAN 30 to enable interconnection with the VLANs of AM-2 and AM-3. ● Configure the transmission VLAN of AM-2 as VLAN 30 to enable interconnection with the VLAN of AM-3.

AC	`Hostname(config)#ap-config AM-1`
	`Hostname(config-ap)# pass-vlan 20,30 //VLAN 20 and VLAN 30 for interconnection with AM-2 and AM-3`
	`Hostname(config-ap)# exit`
	`Hostname(config)#ap-config AM-2`
	`Hostname(config-ap)# pass-vlan 30  // VLAN 30 for interconnection with AM-3`

Verification	Run the **show ap-config running** command to display the configuration.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AM-1`
	`pass-vlan 20,30`
	`!`
	`ap-config AM-2`
	`pass-vlan 30`
	`!`

Common Errors

N/A

1.4.3 Configuring a VLAN for an Ethernet Port of an AP

Configuration Effect

- Specify the VLAN of wired users when the AP provides Ethernet ports for access of wired users.

Notes

- This command can be configured on all APs, but the configuration take effect only on APs that provide Ethernet ports.
- If this command does not contain the **port** parameter, the same VLAN is configured for all Ethernet ports. When the same VLAN needs to be configured for all ports, the command is configured without the **port** parameter.
- In wireless AP mode, the AP implements only the wireless access function, but does not assign addresses to users. In this mode, if the VLAN used by the Ethernet port is configured the same as the VLAN of the AP, the VLAN of the packets sent over the Ethernet port will be determined by the access switch, instead of the VLAN specified in this command. If the packets sent over the Ethernet port must contain the tag when forwarded, the native VLAN of the access switch cannot be the same as the VLAN of the Ethernet port; otherwise, the packets cannot be forwarded to the Ethernet port.
- In wireless routing mode, the AP can assign addresses to users. In this mode, wired users obtain IP addresses from the DHCP address pool, and the VLAN corresponding to the address pool must be the same as the VLAN specified in this command.
- When the configuration of the Ethernet port is automatically saved on the AP and the VLAN of the Ethernet port is different from the native VLAN of the AP, and the IP address of the Ethernet port cannot be obtained after the AP is restarted, management cannot be implemented through the Ethernet port. In this case, press and hold the Reset button on the AP to restore the factory settings.

Configuration Steps

↘ Configuring the Access VLAN of an Ethernet Port of an AP

- Optional.
- To configure a different VLAN for the Ethernet port from the VLAN of the AP, run the **wired-vlan** command on the AC.

Command	**wired-vlan** *vlan-id* [**slot** *slot-id* [**secondary**]] [**port** *port-id*] **auto-save**
Parameter Description	*vlan-id*: Indicates the specified VLAN ID. The VLAN ID ranges from 1 to 4094. By default, the VLAN used by the Ethernet port is the same as the VLAN of the AP. *slot-id*: Indicates the slot to which a micro AP belongs. The value ranges from 1 to 24. **secondary**: Applies to the secondary device in the slot. *port-id:* Indicates the Ethernet port ID. The value ranges from 1 to 8. **auto-save**: Indicates that configuration is automatically saved on the AP. After the AP is restarted, the configuration can be restored.
Defaults	The VLAN of the Ethernet port is not configured, indicating that this VLAN is the same as the VLAN of the AP.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode

Usage Guide	The *slot* parameter takes effect only for i-Share+ APs. If no slot is specified, the configuration applies to all micro APs. If the secondary parameter is configured, the configuration applies to the secondary device in a cascading scenario. Otherwise, the configuration takes effect for the primary device in a non-cascading or cascading scenario. In wireless AP mode, the AP implements only the wireless access function, but does not assign addresses to users. In this mode, if the VLAN used by the Ethernet port is configured the same as the VLAN of the AP, the VLAN of the packets sent over the Ethernet port will be determined by the access switch, instead of the VLAN specified in this command. If the packets sent over the Ethernet port must contain the tag when forwarded, the native VLAN of the access switch cannot be the same as the VLAN of the Ethernet port; otherwise, the packets cannot be forwarded to the Ethernet port. In wireless routing mode, the AP can assign addresses to users. In this mode, wired users obtain IP addresses from the DHCP address pool, and the VLAN corresponding to the address pool must be the same as the VLAN specified in this command. The fit AP is started without being configured, and its configurations are delivered from the AC. The **auto-save** parameter can be configured to automatically save the Ethernet port configurations on the AP. In this way, when the AP is disconnected from the AC, the Ethernet port configurations can be restored after the AP is restarted, and users can still access the network through the Ethernet port.

Verification

Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

Configuring VLAN 20 for the Ethernet Port of AP1

Configuration Steps	Enter the AP configuration mode on the AC. Configure VLAN 20 for the Ethernet port of AP1.
AC	`Hostname(config)# ap-config AP1` `Hostname(config-ap)# wired-vlan20`
Verification	Run the **show ap-config running** command to display the configuration of AP1.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP1`
	`wired-vlan 20`
	`!`

Common Errors

N/A

1.4.4 Configuring a VLAN for a Cascade Port

Configuration Effect

- In i-Share+ scenarios, configure a VLAN for the connected non-micro APs (such as external IoT devices directly connected to the master AP or external IoT devices connected to micro APs). This VLAN is called a connect VLAN for differentiation from the VLAN of the Ethernet port.

Notes

- This command is available only for the i-Share+ APs.
- A connect VLAN is configured for a non-micro AP connected to a cascade port. If a connect VLAN is configured and then a micro AP is connected, a fault may occur. For example, the micro AP cannot access the master AP.
- Set the *slot* parameter to specify a port. Otherwise, the configuration takes effect on all ports.
- When the **secondary** parameter is not contained in this command, a connect VLAN is configured for the cascade port of the master AP. If this command carries the **secondary** parameter, a connect VLAN is configured for cascade ports of micro APs.

Configuration Steps

↘ Configuring a VLAN for a Cascade Port

- Optional.
- To configure a VLAN for a device connected to a cascade port, run this command on the AC.

Command	**wired-vlan** *vlan-id* [**slot** *slot-id*] **connect** [**secondary**]
Parameter Description	*vlan-id*: Specifies the connect VLAN ID. The value ranges from 1 to 4094. By default, the connect VLAN of a cascade port is the same as the default VLAN of a micro AP. *slot-id*: Specifies the slot to which a micro AP is connected. The value ranges from 1 to 24. **secondary**: Specifies the cascade device in the current slot.
Defaults	No VLAN is configured for a cascade port.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	This command is available only for the i-Share+ APs. A connect VLAN is configured for a non-micro AP connected to a cascade port. If a connect VLAN is configured and then a micro AP is connected, a fault may occur. For example, the micro AP cannot access the master AP. Set the *slot* parameter to specify a port. Otherwise, the configuration takes effect on all ports. When the **secondary** parameter is not contained in this command, a connect VLAN is configured for the cascade port of the master AP. If this command carries the **secondary** parameter, a connect VLAN is configured for cascade ports of micro APs.

Verification

- Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

Configuring Connect VLAN 20 for the Non-micro AP Connected to Slot 1 of the Master AP

Configuration Steps	• Enter the AP configuration mode on the AC. • Configure connect VLAN 20 for the non-micro AP.
AC	`Hostname(config)# ap-config AP1` `Hostname(config-ap)# wired-vlan 20 slot 1 connect`
Verification	• Run the **show ap-config running** command to display the configuration of AP1.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP1`
	`wired-vlan 20 slot 1 connect`
	`!`

Configuring Connect VLAN 30 for the Non-micro AP Connected to the Cascade Port of the Micro AP That Is Connected to Slot 2 of the Master AP

Configuration Steps	• Enter the AP configuration mode on the AC. • Configure connect VLAN 30 for the non-micro AP.
AC	`Hostname(config)# ap-config AP1` `Hostname(config-ap)# wired-vlan 30 slot 2 connect secondary`
Verification	• Run the **show ap-config running** command to display the configuration of AP1.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP1`
	`wired-vlan 30 slot 2 connect secondary`
	`!`

Common Errors

- N/A

1.4.5 Configuring the Ethernet Port Status of an AP

Configuration Effect

- Enable or disable an Ethernet port of an AP.

Notes

- This command can be configured on all APs, but the configuration takes effect only on APs that provide Ethernet ports.
- If this command does not contain the **port** parameter, the same configuration is applied to all Ethernet ports. When all ports needs to be disabled, the command without the **port** parameter is configured and displayed. The *slot* parameter takes effect only for i-Share+ APs. If no slot is specified, the configuration applies to all micro APs connected to 24 slots.
- When the Ethernet port is disabled, management cannot be implemented through the Ethernet port after the AP is restarted. In this case, you can press and hold the Reset button on the AP to restore factory settings.

Configuration Steps

Configuring the Status of an Ethernet Port of an AP

- Optional.
- To enable or disable an Ethernet port of an AP, run the **wired-interface** command on the AC.

Command	**wired-interface** [**slot** *slot-id* [**secondary**]] [**port** *port-id*] **enable**
Parameter Description	*slot-id*: Indicates the slot to which a micro AP is connected. The value ranges from 1 to 24. **secondary**: Applies to the secondary device in the slot. *port-id:* Indicates the Ethernet port ID. The value ranges from 1 to 8. **enable**: Enables the specified Ethernet port.
Defaults	All Ethernet ports are enabled.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	The Ethernet ports of APs can be disabled when APs provide the Ethernet ports for access of wired users, but the application scenario does not require access to the wired network or deployment of the wired network is not completed yet. The *slot* parameter takes effect only for i-Share+ APs. If no slot is specified, the configuration applies to all micro APs. If the **secondary** parameter is configured, the configuration applies to the secondary device in a cascading scenario. Otherwise, the configuration takes effect for the primary device in a non-cascading or cascading scenario.

Verification

Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

Disabling All Ethernet Ports of AP1

Configuration Steps	Enter the AP configuration mode on the AC. Disable all Ethernet ports of AP1.
AC	`Hostname(config)# ap-config AP1` `Hostname(config-ap)# no wired-interfaceenable`
Verification	Run the **show ap-config running** command to display the configuration of AP1.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP1`
	`no wired-interfaceenable`
	`!`

Common Errors

N/A

1.4.6 Configuring the Sub-Interface of the WAN Interface on the AP

Configuration Effect

- A wireless AP creates a sub-interface of the WAN interface by default to forward tagged packets sent from STAs. In wireless routing mode where the AP can assign addresses to STAs, the AP functions as the gateway for STAs, and the packets do not need to contain a tag when forwarded. You can run the **ap-subif enable** command to delete the sub-interface of the WAN interface on the AP to prevent an address conflict caused by the same gateway address of STAs.

Notes

- If the AP obtains the address in PPPoE dial-up mode, the sub-interface of the WAN interface on the AP will be automatically deleted. In dial-up mode, this command cannot be used to configure the sub-interface of the WAN interface on the AP.

Configuration Steps

↘ Configuring the Sub-Interface of the WAN Interface on the AP

- Optional.
- In wireless routing mode, delete the sub-interface of the WAN interface on the AP; otherwise, an address conflict occurs when a large number of packets are forwarded through the sub-interface because the gateway addresses of STAs are the same.

Command	**ap-subif enable**
Parameter Description	N/A

Defaults	A sub-interface of the WAN interface is created.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Verification

Run the **show running** command to display the configurations of all APs, or the **show ap-config running** command to display the configurations of a specified AP.

Configuration Example

Deleting the Sub Interface of the WAN Interface on AP1

Configuration Steps	Enter the AP configuration mode on the AC. Delete the sub-interface of the WAN interface on AP1.
AC	`Hostname(config)# ap-config AP1` `Hostname(config-ap)# no ap-subif enable`
Verification	Run the **show ap-config running** command to display the configuration of AP1.

AC	`Hostname#show ap-config running`
	`!`
	`ap-config AP1`
	` no ap-subif enable`
	`!`

Common Errors

N/A

1.4.7 Configuring a Bandwidth Limit for an Ethernet Port of an AP

Configuration Effect

- Configure a bandwidth limit for a LAN port.

Notes

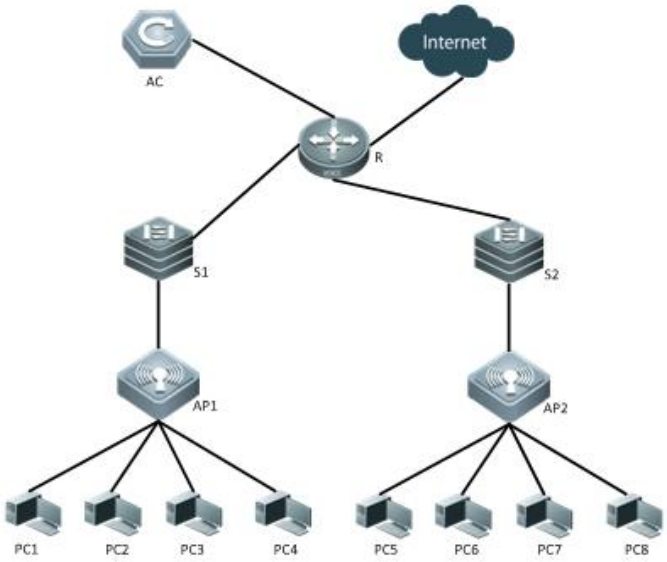
- N/A

Configuration Steps

Configuring a Bandwidth Limit for a LAN Port

- Optional.

- Perform this configuration on the AC.
- Run the **wired-rate** command to configure a bandwidth limit for a LAN port.



Command	**wired-rate** *value* [**port** *port-id*]
Parameter Description	If no port ID is specified, all ports are configured.
Defaults	The bandwidth of each LAN port is not limited. The maximum bandwidth for each LAN port is auto-negotiated.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	The bandwidth of each LAN port is not limited by default. The supported configuration may vary depending on the actual product.

Verification

- Run the **show running-config** command to display the bandwidth limit configuration of LAN ports.

Configuration Example

Configuring LAN Port Bandwidth Restriction

Scenario **Figure 1-4**	 Assume that the bandwidths of the LAN ports need to be limited on the fit AP network. • Configure the maximum bandwidth for LAN ports.
Configuration Steps	• On the AC, set the maximum bandwidth of port 3 on the AP to 30 Mbps.
AC	`Hostname(config)# ap-config [ap-name]` `Hostname(config-ap)# wired-rate 30 port 3`
	• On the AC, set the maximum bandwidth of port 3 in the AP group to 30 Mbps.
AC	`Hostname(config)# ap-group default`

	`Hostname(config-group)#wired-rate 30 port 3`
	● On the AC, set the maximum bandwidth of all LAN ports in the AP group to 30 Mbps.
AC	`Hostname(config)# ap-group default` `Hostname(config-group)#wired-rate 30`
	● On the AC, set the maximum bandwidth of port 3 on all APs to 30 Mbps.
AC	`Hostname(config)# ap-config all` `Hostname(config-ap)# wired-rate 30 port 3`
	● On the AC, set the maximum bandwidth of port 3 of slot 3 on the i-Share+ AP to 30 Mbps.
AC	`Hostname(config)# ap-config am5528` `Hostname(config-ap)# wired-rate 30 port 3 slot 3`
	● On the AC, set the maximum bandwidth of all LAN ports of slot 3 on the i-Share+ APs to 30 Mbps.
AC	`Hostname(config)# ap-config am5528` `Hostname(config-ap)# wired-rate 30 slot 3`
Verification	● On the AC, run the **show ap-config running-config** command to display the configuration.

AC	`Hostname(config)# show ap-config running-config`
	`ap-config ap120w-4`
	`wired-rate 30 port 3`

	● On the AC, run the **show running-config** command to display the configuration.

AC	`Hostname(config)# show running-config`
	`ap-group default`
	`wired-rate 30 port 3`

	● On the AC, run the **show running-config** command to display the configuration.

AC	`Hostname(config)# show running-config`
	`ap-group default`
	`wired-rate 30`

	● On the AC, run the **show running-config** command to display the configuration.

AC	`Hostname(config)# show running-config`
	`ap-config all`
	`…`
	`wired-rate 30 port 3`
	`…`
	
	`Hostname(config)# show running-config`

```
ap-config am5528
 …
 wired-rate 30 port 3 slot 3
 …
```

```
Hostname(config)# show running-config
ap-config am5528
 …
 wired-rate 30 slot 3
 …
```

Common Errors

- N/A

1.4.8 Configuring the Specified AP Port As a WAN Port

Configuration Effect

Configure the specified AP port as a WAN port.

Notes

- The configuration takes effect after the device is restarted if the specified port is a LAN port, and its default port attribute is LAN.
- This command is effective only for RG-AP880-AR, RG-AP880-A, RG-AP840-I(V2), RG-AP850-AR(V3), and RG-AP820-AR(V3) devices with the port attribute of WAN+LAN.

Configuration Steps

↘ Configuring the Specified AP Port As a WAN Port

Optional. Run the **wired-mode wan eth** *port_idx* command to configure the specified AP port as a WAN port.

Command	**wired-mode wan eth** *port_idx*
Parameter Description	*port_idx*: Indicates the number of the port to be configured as a WAN port. The value is an integer with a length of 1.
Defaults	By default, the port attribute is not configured.
Command Mode	AP configuration mode
Usage Guide	This command is used to change the attribute of the specified AP port to WAN. It does not take effect on WAN ports.

Verification

Run the **show ap-config running** *ap-name* command on the AC to check whether the configuration is successful.

Configuration Example

Configuring the Specified AP Port As a WAN Port

Configuration Steps The following example configures the attribute of the gigabitEthernet 0/2 port to WAN on the AC.

AC

```
Hostname(config)#ap-config 00d0.f822.3383
Hostname(config-ap)#wired-mode wan eth 2
```

Verification Run the **show ap-config running** *apname* command on the AC to display the AP information.

AC

```
Hostname#show ap-config running 00d0.f822.3383
Building configuration...
Current configuration: 199 bytes
!
ap-config 00d0.f822.3383
 ap-mac 00d0.f822.3383
 wired-mode wan eth 2
!
end
```

1.4.9 Configuring the Specified AP Port As a LAN Port

Configuration Effect

Configure the specified AP port as a LAN port.

Notes

- The configuration takes effect after the device is restarted if the specified port is a WAN port, and its default port attribute is LAN.
- This command is effective only for RG-AP880-AR, RG-AP880-A, RG-AP840-I(V2), RG-AP850-AR(V3), and RG-AP820-AR(V3) devices with the port attribute of WAN+LAN.

Configuration Steps

Configuring the Specified AP Port As a LAN Port

Optional. Run the **wired-mode lan eth** *port_idx* command to configure the specified AP port as a LAN port.

Command	**wired-mode lan eth** *port_idx*
Parameter Description	*port_idx*: Indicates the number of the port to be configured as a LAN port. The value is an integer with a length of 1.
Defaults	By default, the port attribute is not configured.
Command Mode	AP configuration mode
Usage Guide	This command is used to change the attribute of the specified AP port to LAN. It does not take effect on LAN ports and ports with the default attribute of WAN.

Verification

Run the **show ap-config running** *ap-name* command to check whether the **wired-mode wan eth** *port_idx* configuration is cleared.

Configuration Example

Configuring the Specified AP Port As a LAN Port

Configuration Steps

The following example configures the attribute of the gigabitEthernet 0/2 port to LAN on the AC.

AC

```
Hostname(config)#ap-config 00d0.f822.3383
Hostname(config-ap)#wired-mode lan eth 2
```

Verification

Run the **show ap-config running** *apname* command on the AC to display the AP information.

AC

```
Hostname#show ap-config running 00d0.f822.3383
Building configuration...
Current configuration: 199 bytes
!
ap-config 00d0.f822.3383
 ap-mac 00d0.f822.3383
!
end
```

1 Configuring AMMG

1.1 Overview

AM Management (AMMG) is used to manage all-optical i-Share master access points (all-optical AMs) and micro access points (APs).

Protocols and Standards

N/A

1.2 Features

Basic Concepts

MAP

Downlink micro APs connected to all-optical AMs are called MAPs.

MQTT

Message Queuing Telemetry Transport (MQTT) is a transmission protocol of the International Organization for Standardization (ISO) standard (ISO/IEC PRF 20922) and a lightweight message protocol in binary transmission mode.

On a simplified all-optical i-Share+ network, MQTT clients are all-optical AMs, and MQTT servers are access controllers (ACs). In the following sections, MQTT servers are referred to as ACs. An MQTT channel is a message channel established between an all-optical AM and an AC.

Four Power Output Ports

An all-optical AM provides four 56 V power output ports, achieving centralized power supply for downlink MAPs.

Overview

Feature	Description
Upgrading an All-Optical AM	Upgrades the software of an all-optical AM.
Configuring Basic Information of All-Optical AMs	Configures the name, command template, statuses of the four power output ports, and status description of the four power output ports of an all-optical AM.
Configuring the Working Mode of an All-Optical AM	Configures the working mode of an all-optical AM. An all-optical AM can work in i-Share mode that supports only MAPs and common mode that support any APs.

1.2.1 Upgrading an All-Optical AM

An AC can upgrade the software of all all-optical AMs or a specific all-optical AM.

Working Principle

After all-optical AM upgrade is initiated manually on an AC, the AC verifies the model, version, and other information of the all-optical AMs and upgrades the software of the all-optical AMs that meet the conditions. Currently, all-optical AMs can be upgraded using a File Transfer Protocol (FTP) channel. The detailed procedure is described as follows:

Upgrade through an FTP channel: The AC functions as the FTP server. The all-optical AMs that need to be upgraded function as the FTP clients, obtain the software version package from the AC using the FTP mode, and complete the upgrade.

1.2.2 Configuring Basic Information of All-Optical AMs

Configure basic information of all all-optical AMs, including their name, pre-configured template information, and statuses of the four power output ports on the AC in a unified manner, enabling administrators to perform quick network planning.

Working Principle

After an all-optical AM goes online, the AC delivers the pre-configured template information to the all-optical AM over an MQTT channel.

1.2.3 Configuring the Working Mode of an All-Optical AM

An all-optical AM can work in i-Share mode or common mode.

Working Principle

The two working modes differ in the type of APs allowed to connect to the downlink ports of an all-optical AM, the method for discovering an AC, and the MAP management method.

- i-Share mode

  Only MAPs are allowed to access an all-optical AM working in i-Share mode.

  The all-optical AM establishes an MQTT channel with an AC. After the channel is established, the all-optical AM advertises the AC IP address to an MAP. The MAP attempts to establish a Control and Provisioning of Wireless Access Points (CAPWAP) tunnel with the AC based on the IP address of the AC. When a non-MAP attempts to access a downlink port of the all-optical AM, the port is automatically shut down.

  After the MAP accesses the AC through the CAPWAP channel, the all-optical AM reports the port, media access control (MAC) address, and name of the MAP to the AC. The AC centrally manages MAPs through the all-optical AM.

- Common mode

  All APs are allowed to interconnect with an all-optical AM working in common mode.

  Functioning as a common switch, the all-optical AM establishes an MQTT channel with an AC. This channel is only used by the AC to manage the all-optical AM. When an AP accesses a downlink port of the all-optical AM, the AP discovers an AC through the DHCP or domain name system (DNS) mode and establishes a CAPWAP tunnel with the AC. After the AP accesses the AC through the CAPWAP tunnel, the AP reports its basic information to the AC. The AC manages APs connected to the all-optical AM and common APs in the same way.

1.3 Configuration

Configuration	Description and Command	
Upgrading an All-Optical AM Through an FTP Channel	(Optional) It is used to upgrade the software of an all-optical AM through an FTP channel.	
	device-upgrade	Upgrades the software of an all-optical AM through an FTP channel.
Configuring a Name for an All-Optical AM	(Optional) It is used to configure a name for an all-optical AM.	
	device-name	Configures a name for an all-optical AM.
Creating AM Configuration	(Optional) It is used to add the configuration of the specified all-optical AM based on the MAC address.	
	device-config	Adds AM configuration or enters the AM configuration mode.
Configuring Template Information for an All-Optical AM	(Optional) It is used to configure a template for an all-optical AM.	
	cfgmg template	Adds a configuration template for an all-optical AM.
Configuring Statuses of the Four Power Output Ports for an All-Optical AM	(Optional) It is used to configure the statuses of the four power output ports of the specified AM.	
	power-central enable	Configures the statuses of the four power output ports of the specified all-optical AM.
Configuring the Working Mode of an All-Optical AM	(Optional) It is used to configure the working mode of an all-optical AM.	
	am-mode	Configures the working mode of the specified AM.

1.3.1 Upgrading an All-Optical AM Through an FTP Channel

Configuration Effect

- The AC upgrades the software of an all-optical AM through an FTP channel, and the upgrade is successful.

Notes

This command applies to all-optical AMs only.

Running the Upgrade Command

- Run the upgrade command on the AC.

Command	**device-upgrade** [**mac** *am-mac*] **url** *url-addr*
Parameter Description	*am-mac*: Indicates the MAC address of the all-optical AM to be upgraded. *url-addr*: Indicates the URL of the software version to be upgraded, including the FTP server address, account and password used to log in to the FTP server, and software version. The parameter is in ftp://user:pass@ip/filename format. **ip** indicates the IP address of the AC used to communicate with the all-optical AM. **filename** indicates the software version uploaded to the AC.
Defaults	If no MAC address of an all-optical AM is configured, the upgrade command takes effect to all all-optical

	AMs.
Command Mode	Global configuration mode
Usage Guide	1. A maximum of five all-optical AMs can be upgraded concurrently. 2. If the upgrade command does not carry the **mac** parameter, all all-optical AMs are upgraded. When the command is run, the AC starts upgrade and circularly searches for all-optical AMs that can be upgraded. If an all-optical AM can be upgraded, the AC delivers the **url** parameter of the software version to the all-optical AM. The AC detects whether the download progress on all-optical AMs changes at intervals. If the download progress on an all-optical AM does not change in three detection intervals, the AC determines that the download fails and adds the all-optical AM to the failure list. To achieve upgrade success, ensure that the FTP server channel is not occupied by other processes during the upgrade. Otherwise, the upgrade may fail. 3. Before running the upgrade command, enable the FTP function on the AC and upload the AM software version to the AC in advance. 4. If an all-optical AM is restarted or disconnected from the AC during the upgrade process and is not reconnected within the keepalive period (30s by default), the AC stops to upgrade the AM. If an all-optical AM re-associates with the AC in the keepalive period after it is disconnected from the AC, the upgrade continues. 5. After the command is configured, AMs that match the upgrade package after they go online can be upgraded automatically. To disable automatic upgrade, run the **no device-upgrade** url url-addr command. 6. Pay attention to the AM and AC connection environment. If AMs are serially-connected, they are upgraded in sequence. If one AM is restarted, the other AM that depends on this AM to connect with the network may fail to be upgraded. 7. If the username or password used to log in to the FTP server carries special characters, such as the at sign (@), pound sign (#), colon (:), comma (,), and exclamation mark (!), use **%** and the hexadecimal ASICLL code of a special character to replace it during command configuration. For example, "username chy#wuxian!01! password 123.1!2" can be replaced with ftp://chy%23wuxian%2101%21:123%2E1%212@1.1.1.1/123.bin.

Verification

- Run the **show running-config** command on the AC to display the configuration.

Configuration Example

↘ Running the Upgrade Command

Configuration Steps	● Enable the FTP function on the AC.

AC	`Hostname# config terminal`
	`Hostname(config)#ftp-server enable`
	`Hostname(config)#ftp-server topdir flash`
	`Hostname(config)#ftp-server username acuser password acpasswd`

	● Display the FTP configuration.
AC	`Hostname(config)#show ftp-server` `ftp-server information`

	========== enable : Y topdir : flash:/ timeout: 10min username:acuser password:(PLAINT)acpasswd
	● Obtain the IP address for communicating with the all-optical AM on the AC.
AC	Hostname(config)#show ip interface brief Interface IP-Address(Pri) IP-Address(Sec) Status Protocol VLAN 1 172.30.103.158/24 no address up up
	● Upload the AM software version to the AC. ● Run the upgrade command.
AC	Hostname(config)#device-upgrade mac c0b8.e64b.9ee0 url ftp://acuser:acpasswd@172.30.103.158/filename.bin
	● Display the version information.
AM	AM5552-SF#show version System description : Hostname indoor AM5552-SF (802.11a/n/ac/ax and 802.11b/g/n/ax) By Hostname Networks. System start time : 2021-03-23 17:47:45 System uptime : 7:18:09:33 System hardware version : 1.00 System software version : AM_RGOS 11.9(0)B0, Release(08152214) System patch number : NA System serial number : G1P90PR00086A System boot version : 1.2.41 Module information: Slot 0 : AM5552-SF Cpu 0: Hardware version : 1.00 Boot version : 1.2 Software version : AM_RGOS 11.9(0)B0, Release(08152214) Serial number : G1P90PR00086A

Common Errors

N/A

1.3.2 Configuring a Name for an All-Optical AM

Configuration Effect

- Configure a name for an all-optical AM.

Notes

N/A

Configuration Steps

- Optional.
- Run the **device-name** command on the AC to configure a name for an all-optical AM in all-optical AM configuration mode.

Command	**device-name** *device-name*
Parameter Description	*device-name*: Indicates the name configured for an all-optical AM.
Defaults	N/A
Command Mode	All-optical AM configuration mode
Usage Guide	1. If the all-optical AM is online, the configured name takes effect immediately. 2. If the all-optical AM is offline, the configured name takes effect after the all-optical AM goes online. 3. After the name of the all-optical AM is configured, you can continue to configure the AM without exiting the all-optical AM configuration mode. 4. If the new name is already used by another all-optical AM, the configuration fails. 5. An all-optical AM name contains a maximum of 64 characters and cannot contain spaces. 6. Do not configure the same name for different offline all-optical AMs. The AM that goes online first uses the configured name, and AMs that go online later cannot use the configured name and will retain their original names.

Verification

- Run the **show running-config** command on the AC to display the configuration.

Configuration Example

↘ Configuring a Name for an All-Optical AM with MAC Address 00ff.ffff.1111

Configuration Steps	● Set the new name of the all-optical AM to **Hostname_DEVICE** on the AC.
	`Hostname(config)# device-config 00ff.ffff.1111`
	`Hostname(config-device)#device-name Hostname_DEVICE`

	● Delete the name configuration of the all-optical AM.
	`Hostname(config)# device-config 00ff.ffff.1111`
	`Hostname(config-device)#no device-name`

Verification	Run the **show running-config** command to display the configuration of the all-optical AM.

AC	`Hostname#show running-config`
	`!`
	`device-name Hostname_DEVICE`
	`!`

Common Errors

N/A

1.3.3 Creating AM Configuration

Configuration Effect

- After the configuration for the AM with the specified MAC address is created, enter the AM configuration mode.
- If the configuration of the AM with this MAC address already exists, enter the AM configuration mode directly.
- The *device-mac* parameter carried in the **device-configdevice-config** command is the MAC address of the AM. When the all-optical AM goes online, the MAC address uploaded by the AM matches with the MAC address in the AM configuration to determine the relationship between the AM and the AM configuration.

Notes

N/A

Configuration Steps

- Optional.
- Run the **device-config** *device-mac command* on the AC in global configuration mode to create AM configuration.

Command	**device-config** *device-mac*
Parameter Description	*device-mac*: Indicates the MAC address of the all-optical AM.
Defaults	No AM configuration is created.
Command Mode	Global configuration mode
Usage Guide	1. You can run the **device-config** *device-mac command* to create AM configuration or enter the configuration mode of the specified all-optical AM. 2. You can run the **no device-config** *device-mac* command to delete the configuration of the specified all-optical AM unless it is online. The supported configuration may vary depending on the actual product.

Verification

- Run the **show running-config** command on the AC to display the configuration.

Configuration Example

Creating the Configuration for the AM with the MAC Address 00ff.ffff.1111

Configuration Steps	● Create the configuration for the AM with the MAC address 00ff.ffff.1111.
AC	`Hostname(config)# device-config 00ff.ffff.1111` `Hostname(config-ap)#`
Verification	Run the **show running-config** command to display configuration of the all-optical AM.

AC	`Hostname#show running-config`
	`!`
	`device-config 00ff.ffff.1111`

	!

Common Errors

N/A

1.3.4 Configuring Template Information for an All-Optical AM

Configuration Effect

- When an all-optical AM accesses the AC for the first time, a configuration template is automatically synchronized. Based on the configuration of the all-optical AM, the network administrator determines whether commands in the configuration template are synchronized to the all-optical AM.
- Manually trigger configuration template synchronization on the AC. Based on the configuration of the all-optical AM, the network administrator determines whether commands in the configuration template are synchronized to the all-optical AM.

Notes

- A configuration template needs to be created before it is applied.
- An AC synchronizes the configuration template to an all-optical AM only when the all-optical AM accesses the AC for the first time.

Configuration Steps

- Optional.
- Configure template information on the AC in all-optical AM configuration mode.

Command	**cfgmg template** *temp-name*
Parameter Description	*temp-name*: Indicates the name of the configuration template specified for an all-optical AM on the AC. The configuration template needs to be created on the AC in advance.
Defaults	N/A
Command Mode	All-optical AM configuration mode
Usage Guide	1. A maximum of eight configuration templates can be applied. 2. When multiple configuration templates are applied, the sequence for synchronizing commands in these templates depends on the sequence when these templates are applied. 3. Applied configuration templates are delivered to an all-optical AM only when the all-optical AM associates with the AC for the first time. Subsequent template configuration changes are not proactively synchronized to the all-optical AM. 4. Applied configuration templates are not forcibly bound to configuration templates of the CFGMG module. A non-existent configuration template can be applied. However, no configuration can be synchronized. When configuration templates of the CFGMG module are deleted, applied configuration templates are not deleted. 5. When an all-optical AM goes online, it uploads the name, working mode, status of the power supplies, and status description to the AC. You do not need to configure the information in the configuration template. Otherwise, conflicts may occur, resulting in inconsistent configurations. A configuration template is delivered after the **device-config** command is run. Therefore, ensure

	consistent content at two ends to prevent misunderstandings caused by configuration changes after the configuration is overwritten. 6. When a configuration template is delivered to the AM, the AM updates the configuration based on the sequence of the commands in the template. If a command fails to be run, other commands in the template are not run. To address this issue, ensure that the AM supports all the commands in the template.

Verification

- Run the **show running-config** command on the AC to display the configuration.

Configuration Example

↘ Creating a Configuration Template for an All-Optical AM with the MAC Address 00ff.ffff.1111

Configuration Steps	● Create a configuration template named **wlan-temp1**.
AC	`Hostname(config)#cfgmg template wlan-temp1` `Hostname(config-temp)#`
	● Configure the all-optical AM whose MAC address is 00ff.ffff.1111 and associate it with the configuration template **wlan-temp1**.

	`Hostname(config)#device-config 00ff.ffff.1111`
	`Hostname(config-device)#cfgmg template wlan-temp1`
	`Hostname(config-device)#`

Verification	Run the **show running-config** command to display the configuration of the all-optical AM.

AC	`Hostname#show running-config`
	`!`
	`device-config 00ff.ffff.1111`
	` cfgmg template wlan-temp1`
	`!`
	`cfgmg template wlan-temp1`
	`!`

Common Errors

N/A

1.3.5 Configuring Statuses of the Four Power Output Ports for an All-Optical AM

Configuration Effect

- Configure the statuses of the four power output ports for the specified all-optical AM. The four power output ports can be controlled independently.

Notes

N/A

Configuration Steps

Configuring the Statuses of the Four Power Output Ports

- Optional.
- Configure the statuses of the four power output ports on the AC in all-optical AM configuration mode.

Command	**power-central enable** *power-supply-index*
Parameter Description	*power-supply-index*: Indicates the ID of a power output port. The value range is from 1 to 4.
Defaults	The four power output ports are enabled.
Command Mode	All-optical AM configuration mode
Usage Guide	1. If the configuration on an all-optical AM is inconsistent with that on the AC, the configuration on the AC prevails. When the all-optical AM goes online, the AC delivers the configuration to the all-optical AM and the all-optical AM modifies the configuration. 2. The default statuses of the four power output ports are **enable**, which can be viewed by running the **show running-config** command. The supported configuration may vary depending on the actual product.

Configuring Status Description of the Four Power Output Ports

- Optional.
- Configure status description of the four power output ports on the AC in all-optical AM configuration mode.

Command	**power-central description** *power-supply-index desc*
Parameter Description	*power-supply-index*: Indicates the ID of a power output port. The value range is from 1 to 4. *desc:* Indicates the status description of the four power output ports.
Defaults	N/A
Command Mode	All-optical AM configuration mode
Usage Guide	1. If the configuration on an all-optical AM is inconsistent with that on the AC, the configuration on the AC prevails. When the all-optical AM goes online, the AC delivers the configuration to the all-optical AM and the all-optical AM modifies the configuration. 2. Status description of the four power output ports is null by default. You can configure the status description as required. Status description of each power supply cannot exceed 128 bytes. 3. Status description cannot contain spaces and must be consecutive character strings. The supported configuration may vary depending on the actual product.

Verification

- Run the **show running-config** command on the AC to display the configuration.

Configuration Example

Disabling the Power Supply Function of the First Power Output Port on an All-optical AM

Configuration Steps	Disable the power supply function of the first power output port on an all-optical AM.
AC	`Hostname(config)# device-config 00ff.ffff.1111` `Hostname(config-device)# no power-central enable 1`
Verification	Run the **show running-config command** to display the configuration of the all-optical AM.

AC	`Hostname#show running-config`
	`!`
	`device-config 00ff.ffff.1111`
	`  no power-central enable 1`
	`!`

Common Errors

N/A

1.3.6 Configuring the Working Mode of an All-Optical AM

Configuration Effect

- Configure the working mode (i-Share mode or common mode) of an all-optical AM as required.

Notes

N/A

Configuration Steps

- Optional.
- Configure the i-share mode or common mode in all-optical AM configuration mode on the AC.

Command	**am-mode** { **normal** | **smart** }
Parameter Description	**normal**: Sets the working mode of an all-optical AM to the common mode. **smart**: Sets the working mode of an all-optical AM to the i-Share mode.
Defaults	The working mode of an all-optical AM is the i-Share mode.
Command Mode	All-optical AM configuration mode (AC)
Usage Guide	• When the working mode of an all-optical AM is changed on the AC and the all-optical AM is online, the working mode takes effect immediately. If the all-optical AM is offline, the working mode takes effect after the all-optical AM goes online. • After the working mode of an all-optical AM is changed, you can continue to configure the AM without exiting the all-optical AM configuration mode. • You are advised to change the working mode of an all-optical AM on the AC and the AC advertises the working mode configuration to the all-optical AM, ensuring consistent configurations at both ends. • If the working mode is changed on the all-optical AM, the all-optical AM needs to go offline and associate with the AC again. In this case, the devices at both ends automatically synchronize the working mode configuration. Principles for configuring automatic synchronization:

	1. If the working mode configuration exists on the AC or both ends, the AC delivers the working mode configuration to the AM to update the configuration on the AM. 2. If the working mode configuration exists only on the all-optical AM, the AC automatically saves the working mode configuration on the all-optical AM. ● When the all-optical AM is restored to factory settings, the default working mode is the i-Share mode. When the **no/default am-mode** command is run, the default working mode is the common mode. ● When the all-optical AM works in i-Share mode and the AP connected to the downlink port of the AM is not an MAP, the **shutdown/no shutdown** command is run to disconnect the AP.

Verification

- Run the **show running-config** command on the AC to display the configuration.

Configuration Example

↘ Configuring an All-Optical AM to Work in i-Share Mode

Configuration Steps	Configure an all-optical AM to work in i-Share mode.
AC	`Hostname(config)# device-config 00ff.ffff.1111` `Hostname(config-device)# am-mode smart`
Verification	Run the **show running-config** command to display the configuration of the all-optical AM.

AC	`Hostname#show running-config`
	`!`
	`device-config 00ff.ffff.1111`
	` am-mode smart`
	`!`

1.4 Monitoring

Clearing

N/A

Displaying

Command	Description
show device-config interfaces fiber-channel	Displays the optical channel information of an all-optical AM associated with an AC.
show device-config interfaces transceiver	Displays the optical module information of an all-optical AM associated with an AC.
show device-config map summary	Displays the downlink MAP list of all all-optical AMs associated with an AC.
show device-config summary	Displays the list of all all-optical AMs associated with an AC.

show device-config summary by-name	Displays the list of all all-optical AMs associated with an AC in the sequence of names.
show device-config upgrading-list	Displays the list of all-optical AMs that are being upgraded.
show device-config version summary	Displays the version list of all all-optical AMs associated with an AC.
show device-config power summary	Displays the statuses of the four power output ports of all all-optical AMs associated with an AC.

1 Configuring LED

1.1 Overview

Light Emitting Diode (LED) is a solid luminous semiconductor. It serves as an indicator light to display the working status of an access point (AP) in different colors.

The following part only introduces LED.

Protocols and Standards

N/A

1.2 Applications

N/A

1.3 Features

An AP provides one or multiple LEDs to display its working status. For example, the LED of an Ethernet interface blinks when a data flow exists on the Ethernet interface. The LED is controlled through a General Purpose Input/Output (GPIO) interface or Complex Programmable Logic Device (CPLD) to change the status and colors, such as solid green, blinking green, blinking red and so on. By observing the LED, you can easily tell AP's working status and faults.

1.4 Configuration

Configuration	Description and Command	
Configuring AP Location	(Optional) It is used to locate an AP.	
	led on	Turn on the LED to locate an AP.
Configuring Quiet Mode	(Optional). It is used to enable LED quiet mode.	
	quiet-mode session	Enable LED quiet mode.

1.4.1 Configuring AP Location

Configuration Effect

- Turn on the LED to locate an AP.

Notes

- Disable the configuration after location. Otherwise, the lighting of LEDs no longer changes.

Configuration Steps

Configuring AP Location

- Optional.
- Enable this configuration before location and disable it after location.

Command	**led on** [**slot** *slot-id* [**secondary**]]
Parameter Description	*slot-id*: Indicates the slot ID corresponding to the RF card. **secondary**: Applies to the secondary device in the slot.
Defaults	This function is disabled.
Configuration Mode	AP configuration mode
Usage Guide	Use this command to turn on the LED for locating an AP. For i-Share+ micro APs, specify the slot ID for each RF card. For non-i-Share+ micro APs, the *slot-id* parameter is invalid. The **secondary** parameter indicates that the command applies to the secondary device. If the **secondary** parameter is not configured, this command takes effect on the primary device.

Verification

- Check whether the location LED is on the AP.

Configuration Examples

Locating AP 00d0.f822.33bc

Scenario	N/A
Configuration Steps	Configure AP location on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config 00d0.f822.33bc`
	`Hostname(ap-config)# led on`

Verification	Check whether the location LED is on the AP.

Common Mistakes

N/A

1.4.2 Configuring Quiet Mode

Configuration Effect

- All LEDs on an AP are off when this command takes effect.

Notes

- The effective time for the quiet mode must be configured first.

Configuration Method

Creating a Session

- Optional.
- Create a session before configuring the quiet mode.
- Configure the effective time for the session.

Command	**schedule session** *sid* **time-range** *n* **period** *day1* [**to** *day2*] **time** *hh1:mm1* **to** *hh2:mm2*
Parameter Description	*sid*: Indicates the scheduling session ID. *n*: Indicates the scheduling session time period number. *day1*: Indicates the start date of the scheduling time period, in the range of { sun | mon | tue | wed | thu | fri | sat }. **to** *day2*: Indicates the scheduling time period is set to one day by default. *day 2* indicates the end date of the scheduling time period. **time** *hh1:mm1* **to** *hh2:mm2*: Indicates the scheduling time. *hh1:mm1* is the start time and *hh2:mm2* the end time in the range from 0 to 23 hours and 0 to 59 minutes.
Defaults	The scheduling time period is set to null.
Command Mode	Global configuration mode
Usage Guide	Create a session first.

Configuring Quiet Mode

- Optional.
- Configuring LED quiet mode.

Command	**quiet-mode session** *session-num*
Parameter Description	session-num: Specifies a session ID.
Defaults	This function is disabled.
Configuration Mode	AP configuration mode
Usage Guide	Configure the session first.

Verification

- All LEDs are off when the system time is within the session interval.

Configuration Examples

Enabling LED Quiet Mode from 11 PM on Monday to 7 AM on Tuesday Every Week

Configuration Steps	● Configure a session. ● Configure the session ID for the quiet mode.
	Hostname# configure terminal Hostname(config)#schedule session 1 Hostname(config)#schedule session 1 time-range 1 period Mon time 23:00 to 7:00 Hostname(config)#ap-config 00d0.f822.33bc Hostname(config-ap)#quiet-mode session 1
Verification	When the system time is within the session interval, all LEDs on the AP are off.

Common Errors

- The configured session ID does not exist.

Configuring iBeacon

1.1 Overview

iBeacon is a new function provided by Apple when Apple launched iOS 7 in September 2013. It is similar to the NFC technology but is different. iBeacon uses the Bluetooth Low Energy (BLE) technology, specifically, a broadcast frame named advertising in BLE. The advertising frame is sent periodically. Devices supporting BLE can receive the frame. iBeacon is implemented by embedding data in the format defined by a product in the payload of the advertising frame.

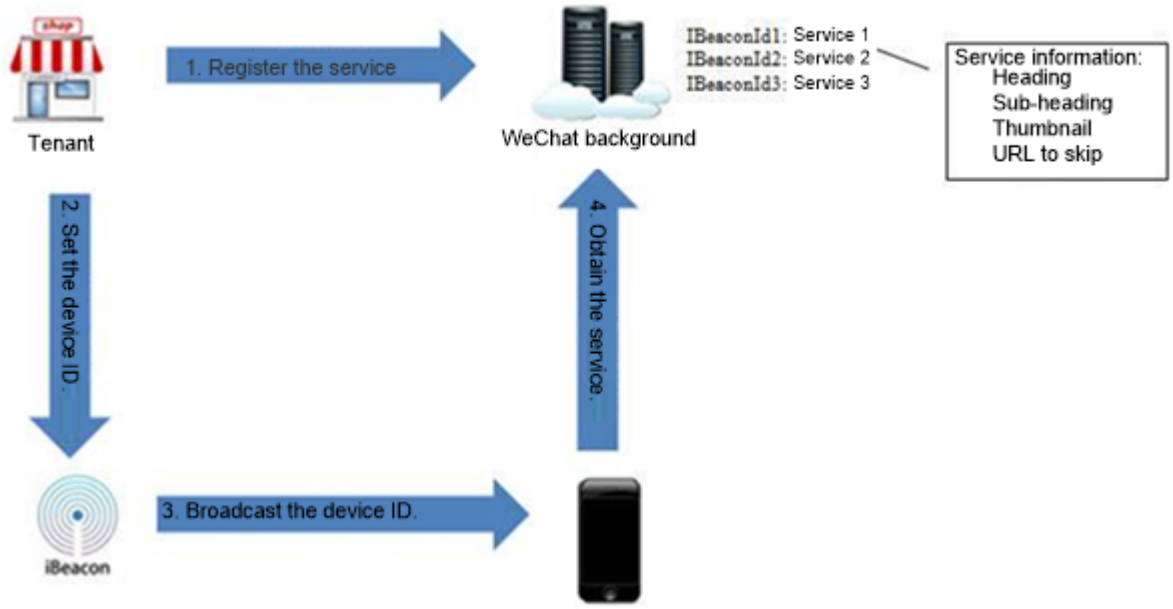
The iBeacon technology is implemented based on BLE and integration with an iBeacon base station to achieve connections. Noted that this does not require support of the Internet. For example, if you enter a store with an iPhone or an Android phone and the store has deployed an iBeacon base station, you have entered the coverage of the iBeacon base station. In this case, the store can send messages such as coupons or information about commodities in the store to your phone through the base station. You can consume and get discount in the store by using the received electronic coupons.

Protocols and Standards

N/A

1.2 Applications

Application	Description
WeChat Shake	iBeacon protocol and WeChat Shake are supported.



1.2.1 WeChat Shake

Scenario

The following figure shows the workflow:

1) The service provider (SP) applies to the WeChat backend for a service. The WeChat backend generates an iBeaconID, maps it to the service provided by the SP, and informs the SP of the iBeaconID.
2) The SP sets the iBeaconID on an iBeacon device and enables the iBeacon device to broadcast the iBeaconID.
3) After a user in the signal coverage of the iBeacon device enables the WeChat Shake function, the WeChat App obtains the iBeaconID.
4) Based on the obtained iBeaconID, the WeChat App pulls the corresponding service from the WeChat backend and shows the service in the result of shaking.
5) After the user clicks the result of shaking, together with the user information, the browser embedded in WeChat redirects to the URL filled in by the SP when the SP applies for the service in Step 1 and the application page is displayed.

Figure 1-1 WeChat Shake Workflow

Deployment

- The wireless access controller (AC) delivers related iBeacon configurations to APs.

1.3 Features

Basic Concepts

iBeacon Technology

- Beacon data consists of the following information: Unique General Identifier (UUID), Major, Minor, and Measured Power.
- **UUID** is a 128-bit identifier compliant with the ISO/IEC11578:1996 standard.
- **Major** and **Minor**, the hexadecimal identifiers, are set by the iBeacon publisher. For example, a chain store can write regional information in **Major** and IDs of individual stores in **Minor**. In addition, when the iBeacon function is embedded in household appliances, **Major** can be used to indicate the product model and **Minor** can be used to indicate the error code to notify a fault.
- **Measured Power** is the reference received signal strength indicator (RSSI) when the iBeacon module is 1m away from the receiver.

Overview

Feature	Description
iBeacon	iBeacon packets are sent through Bluetooth broadcast.

1.3.1 iBeacon

iBeacon is implemented through transmission of Bluetooth broadcast.

Working Principle

When the iBeacon configuration is modified on an AC, an iBeacon configuration packet is sent to the corresponding AP.

After the packet is received, the packet is sent in the specified format to the Bluetooth chip through I2C.

After receiving the packet, the CC2541 Bluetooth chip parses the configuration packet and updates the iBeacon packet.

1.4 Configuration

Configuration	Description and Command	
Configuring iBeacon	(Optional) It is used to configure the iBeacon function.	
	ibeacon uuid major minor	Configures the iBeacon function.
Configuring iBeacon Based on BT Radio	**ibeacon uuid major minor radio**	Configures the iBeacon function based on BT radio.

1.4.1 Configuring iBeacon

Configuration Effect

- Configure global (AP) iBeacon parameters.

Notes

- If the current device does not support Bluetooth, the configuration cannot take effect. Device models supporting iBeacon include: AP520(BT)v1.x, AP520 v1.x, AP4220, MA1220, AM5528 (EP).

Configuration Steps

Configuring iBeacon for the Specified AP

- (Optional) Run the **ibeacon uuid** *uuid* **major** *major* **minor** *minor* command to configure the iBeacon function in AP configuration mode.
- The iBeacon function can be configured on only APs supporting Bluetooth.

Command	**ibeacon uuid** *uuid* **major** *major* **minor** *minor*
Parameter Description	*uuid*: Indicates the **UUID** that is a string of 32 hexadecimal characters. *major*: Indicates the **Major** value that is a string of four hexadecimal characters. *minor*: Indicates the **Minor** value that is a string of four hexadecimal characters.
Defaults	iBeacon is not configured.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	Use this command to configure the iBeacon function for an AP. For devices that do not support Bluetooth, the configuration cannot take effect. The iBeacon function cannot be configured on all APs.

Verification

- Run the **show ap-config running** *ap-name* command on an AC to check whether the configuration is successful.

Configuration Examples

Configuring iBeacon for the Specified AP

Configuration Steps	• Configure iBeacon for the specified AP.
	Hostname# configure terminal Hostname(config)#ap-config ap520(bt) Hostname(config-ap)# ibeacon uuid FDA50693A4E24FB1AFCFC6EB07647825 major 2714 minor 3154
Verification	After configuring iBeacon for the specified AP, you can run the **show ap-config running** *ap-name* command on an AC to check the configuration.
	AC: Hostname(config)#show ap-config running ap520(bt) ! ap-config ap520(bt) ... ... ibeacon uuid FDA50693A4E24FB1AFCFC6EB07647825 major 2714 minor 3154... ... !

1.4.2 Configuring iBeacon Based on BT Radio

Configuration Effect

Configure iBeacon parameters based on BT radio.

Notes

If the device does not support Bluetooth, the configuration does not take effect. Device models supporting iBeacon based on BT radio include: AP520(BT)v1.x, AP520 v1.x, AP4220, MA1220, AM5528 (EP)

Configuration Steps

Configuring iBeacon Based on BT Radio

- (Optional) Run the **ibeacon uuid** *uuid* **major** *major* **minor** *minor* ***radio*** *radio-id* command to configure iBeacon based on BT radio in AP configuration mode.
- The configuration takes effect on only the APs supporting Bluetooth.

Command	**ibeacon uuid** *uuid* **major** *major* **minor** *minor* **radio** *radio-id*
Parameter Description	*uuid*: Indicates the **UUID** that is a string of 32 hexadecimal characters. *major*: Indicates the **Major** value that is a string of four hexadecimal characters. *minor*: Indicates the **Minor** value that is a string of four hexadecimal characters. *radio-id*: Indicates the radio value that is an integer ranging from 1 to 255. The number of supported radios varies with products.
Defaults	iBeacon is not configured.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	Use this command to configure iBeacon based on BT radio. The configuration takes effect on only the APs supporting Bluetooth. The iBeacon function cannot be configured on all APs.

Verification

- Run the **show ap-config running** *ap-name* command on an AC to check whether the configuration is successful.

Configuration Example

Configuring iBeacon Based on BT Radio

Configuration Steps	● Configure iBeacon based on BT radio on the specified AP.

	`Hostname# configure terminal`
	`Hostname(config)#ap-config ap520(bt)`
	`Hostname(config-ap)# ibeacon uuid FDA50693A4E24FB1AFCFC6EB07647825 major 2714 minor 3154 radio 13`

Verification	After configuring iBeacon based on BT radio, you can run the **show ap-config running** *ap-name* command on an AC to check the configuration.

	`AC:`
	`Hostname(config)#show ap-config running ap520(bt)`
	`!`
	`ap-config ap520(bt)`
	`...`
	`...`
	`ibeacon uuid  FDA50693A4E24FB1AFCFC6EB07647825 major 2714 minor 3154 radio 13`
	`...`
	`!`

Configuring STA Management

1. Configuring WLAN WBS-FWD
2. Configuring STA Management
3. Configuring VIP-FIRST
4. Configuring Hotspot 2.0
5. Configuring STA Identification
6. Configuring STA Connectivity Test

1 Configuring WLAN WBS-FWD

1.1 Overview

WLAN Basic Service-Forwarding Mode (WBS-FWD) is used to control the forwarding modes of packets on access points (APs). An Access controller (AC) communicate with an AP through the Control and Provisioning of Wireless Access Points (CAPWAP) tunnel. The AP forwards data packets in one of the following modes:

- Centralized forwarding mode: An AP encapsulates user data packets into 802.3 frames and sends them over a CAPWAP tunnel to an AC. The AC then forwards these packets to an upper-layer networks. When the AC receives the data packets, it sends the packets over the CAPWAP tunnel to the AP. Then the AP converts the packets into 802.11 frames and sends them to STAs.
- Local forwarding mode: An AP encapsulates user data packets into 802.3 frames and implements Layer 2 or Layer 3 forwarding. That is, the AP forwards the packets to an upper-layer network without transmitting them over a CAPWAP tunnel.
- Local authentication forwarding mode: An AP forwards user data packets locally and wireless users are authenticated on the AP.
- VLAN priority: In metro scenarios, the VLAN priority feature is enabled on specified APs. After configuring the priority VLAN, when the packets of the VLAN pass, the VLAN priority feature is activated, that is, only the packets with the configured priority VLAN ID can pass, and the packets with non-priority VLAN are discarded, and a multicast packet is sent in the priority VLAN. The multicast address of the multicast packet can be configured.

You can configure the forwarding mode for all APs on the wireless local area network (WLAN), or you can specify the forwarding mode for a specified virtual local area network (VLAN), IP address, or a packet of a certain type. You can configure the AP forwarding mode based on diverse requirements such as the AP load and centralized management in various scenarios so that packets of different types are forwarded as required.

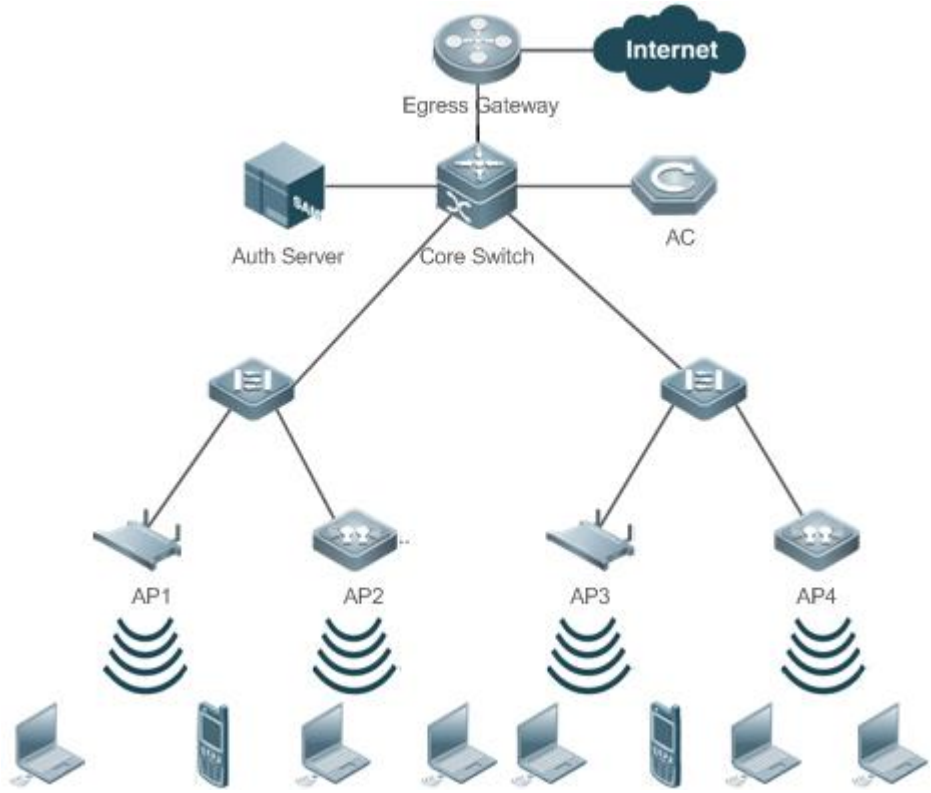
Protocols and Standards

N/A

1.2 Applications

Application	Description
Centralized Forwarding Mode	All branch APs are managed by an AC and all packets are forwarded by the AC.
Local Forwarding Mode	All branch APs are managed by an AC and the packets are forwarded by the AP locally.
VLAN Priority	An AP allocates different VLANs to customers of different priorities. When one AP-S3 is faulty, high-priority users automatically connect to the other AP-S3. In this case, to ensure the bandwidth of high-priority user, the common user network of the AP needs to be disabled, that is, only the packets of the priority VLANs can pass through the AP. When there is no packet of this priority VLAN passing

	through for more than 60s, the packets of normal VLANs are allowed to pass through.



1.2.1 Centralized Forwarding Mode

Scenario

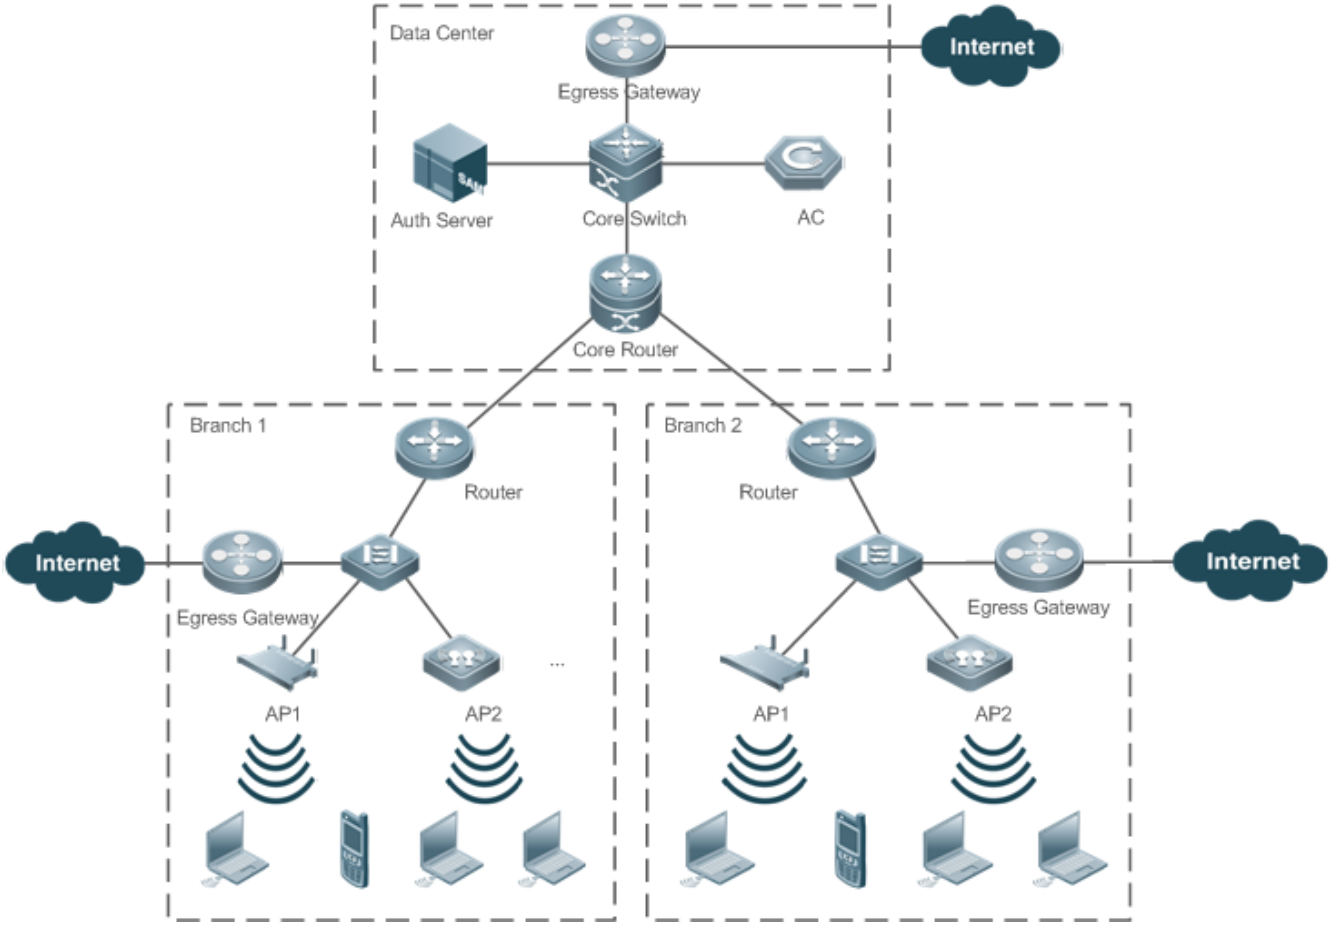
Centralized forwarding mode is applicable to the following scenarios:

- All APs and the AC are on the same LAN with sufficient bandwidth.
- The AC has high forwarding performance.
- The network egress is unified.

Figure 1-1

Deployment

On the AC, configure centralized forwarding mode for APs.



1.2.2 Local Forwarding Mode

Scenario

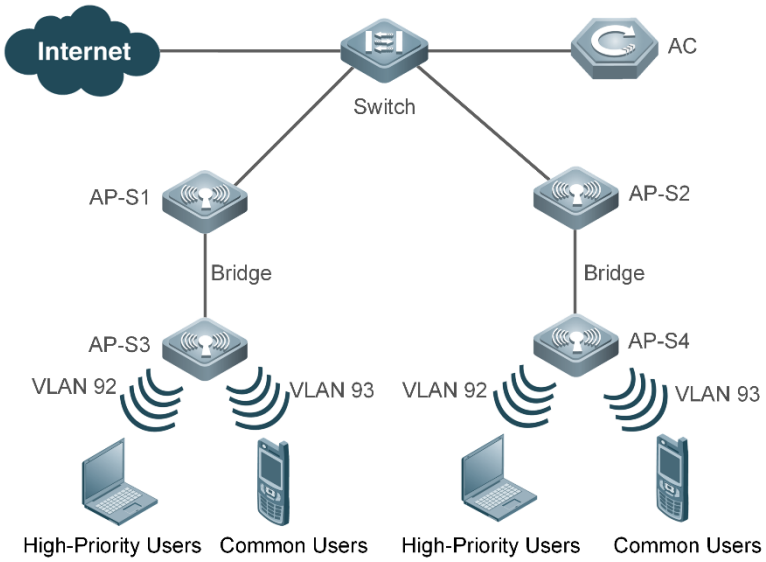
Local forwarding mode is applicable to the following scenarios:

- APs are deployed in different branches and are managed by the AC in the headquarters.
- The bandwidth of the links between branches and the headquarter is low.
- Each branch has an independent egress.

Figure 1-2

Deployment

- On the AC, configure local forwarding mode for APs.
- On the AC, configure centralized forwarding mode for Dynamic Host Configuration Protocol (DHCP).



1.2.3 VLAN Priority

Scenario

VLAN priority is applicable to the following scenarios:

An AP allocates different VLANs to users of different priorities. When one AP-S3 is faulty, high- priority users automatically connect to the other AP-S3. In this case, the network is disabled for common users on the AP to ensure the bandwidth of high-priority users. That is, only the packets of high-priority VLANs can be forwarded through the AP. When no packets of high-priority VLANs are forwarded for more than 60s, the packets of normal VLANs are allowed to be forwarded.

Figure 1-3

Deployment

Configure it on the AC: Enable the VLAN priority feature on specified APs.

1.3 Features

Basic Concepts

Centralized Forwarding Mode and Local Forwarding Mode

An AP communicates with an AC through the CAPWAP tunnel. The AP forwards data packets in one of the following modes:

- Centralized forwarding mode: An AP encapsulates user data packets into 802.3 frames and sends them over a CAPWAP tunnel to an AC. The AC then forwards these packets to an upper-layer networks. When the AC receives the data packets, it sends the packets over the CAPWAP tunnel to the AP. Then the AP converts the packets into 802.11 frames and sends them to STAs. In this case, packets are forwarded by an AC, facilitating centralized management and maintenance while increasing the load on the AC. Moreover, the AC need to provide high performance in centralized forwarding mode.
- Local forwarding mode: An AP encapsulates user data packets into 802.3 frames and implements Layer 2 or Layer 3 forwarding. That is, the AP forwards the packets to an upper-layer network without transmitting them over a CAPWAP tunnel, which reduces the load on the AC. However, centralized control, management, and maintenance cannot be achieved in this mode.
- Comparison of two forwarding modes:

Forwarding Mode	Advantage	Disadvantage	Scenario
Centralized forwarding mode	Centralized control, management, and maintenance on an AC; flexible scalability	High requirement for AC performance	High-performance AC, high bandwidth of links between APs and AC, a few APs managed by an AC, and service flexibility

Local forwarding mode	Low requirement for AC performance	No centralized control and maintenance	Low- performance AC, low bandwidth of links between APs and AC, and many APs managed by an AC

Overview

Feature	Description
Configuring the Forwarding Mode of an AP	Specifies the forwarding mode of different packets on an AP.
Configuring the Forwarding Mode of an AC	Specifies the forwarding mode of different packets on an AC.
Configuring Configuring VLAN Priority	Configures the VLAN priority for the specified AP.
Configuring WLAN Forwarding Acceleration	Enables WLAN forwarding acceleration for the specified AP.

1.3.1 Configuring the Forwarding Mode of an AP

You can configure the AP forwarding mode based on diverse requirements such as the AP load and centralized management in various scenarios so that packets of different types are forwarded as required.

Working Principle

Forwarding Mode

Two forwarding modes are available: centralized forwarding and local forwarding. When an AP receives a wireless packet, it forwards the packet based on the configured mode.

You can configure the packet forwarding mode for an AP on an AC.

Forwarding Mode Settings

Products support the following forwarding modes:

- WLAN-based forwarding mode: Forwards the packets on all APs based on the forwarding mode (centralized forwarding mode or local forwarding mode) specified for the WLAN.
- Forwarding mode based on AP group and WLAN: Specifies a forwarding mode for a WLAN of a specific AP group for forwarding and access authentication. The AC delivers the configuration to the AP for storage. Based on the WLAN associated with the STA, the AP determines whether STA access authentication is implemented on the AP or AC and whether data packets is forwarded locally or centrally.
- VLAN-based forwarding mode: Forwards the packets on a specified VLAN of a WLAN based on the forwarding mode (centralized forwarding mode or local forwarding mode) specified for the VLAN.
- IP-based forwarding mode: Forwards the packets of a specified destination IP address in local forwarding mode.

- DHCP-based centralized forwarding mode: Forwards all DHCP packets in centralized forwarding mode. If this mode is configured, all DHCP packets will be sent in centralized forwarding mode.

Priorities of Different Forwarding Modes

Products support the preceding five forwarding modes. These modes can be configured at the same time and their priorities are ranked as follows (in descending order):

1. DHCP-based centralized forwarding mode
2. IP-based forwarding mode
3. VLAN-based forwarding mode
4. Forwarding mode based on AP group and WLAN
5. WLAN-based forwarding mode

After a wireless packet is received by an AP, the packet will be forwarded based on the priority of the forwarding mode. If a high-priority mode is detected, the packet will be forwarded in this mode; if not, the packet will be forwarded in the default centralized forwarding mode. The forwarding mode setting based on the AP group and WLAN is ultimately reflected on the AP as the WLAN-based forwarding mode configuration.

For example:

1. If DHCP-based centralized forwarding mode is configured, all the DHCP packets will be forwarded in centralized mode.
2. For a non-DHCP packet, if its IP address is specified for local forwarding, the packet will be forwarded in local forwarding mode. If not, Step 3 will be performed.
3. If the VLAN where the packet belongs is configured with a forwarding mode, the packet will be forwarded in this mode. If not, Step 4 will be performed.
4. If the WLAN where the packet belongs is configured with a forwarding mode, the packet will be forwarded in this mode. If not, Step 5 will be performed.
5. The packet will be forwarded in the default centralized forwarding mode.

1.3.2 Configuring the Forwarding Mode of an AC

You can configure the forwarding mode for an AC based on the load of the entire wireless network, unified management requirement, and the actual service environment. The AC adjusts internal parameters to better adapt to the current service environment based on the configured forwarding mode,.

Working Principle

Forwarding Mode

Hybrid forwarding mode and local forwarding mode are available. When hybrid forwarding mode is configured for ACs, WLANs support both centralized forwarding and local forwarding. That is, some WLANs use centralized forwarding while other WLANs use local forwarding. When local forwarding mode is configured for ACs, WLANs support only local forwarding mode (including local authentication forwarding mode).

Forwarding Mode Settings

You can configure the forwarding mode for an AC.

1.3.3 Configuring VLAN Priority

You can configure the VLAN priority for specified APs as required.

Working Principle

Configuring the VLAN Priority

Configure the VLAN priority. When packets with the specified VLAN priority pass through, the feature takes effect, and subsequent packets with the same VLAN priority are allowed to pass through, while packets with other VLANs are directly discarded. The timer is enabled to detect packet timestamps. If no packets with the specified VLAN priority come in within 60 seconds, packets with other VLANs are allowed to pass through. By default, there is no specified VLAN priority, and packets from all VLANs are allowed to pass through.

Configuring the Multicast Address

After the VLAN priority configuration takes effect, a multicast packet will be sent once on the priority VLAN and the multicast address can be configured.

1.3.4 Configuring WLAN Forwarding Acceleration

You can configure WLAN forwarding acceleration as needed.

Working Principle

Forwarding Acceleration Mode

Forwarding acceleration differs from normal forwarding. Configuring forwarding acceleration will improve the overall forwarding performance of the AP, but may cause certain features to become unavailable (see the supported AP models and unsupported features below). The device supports the following forwarding acceleration mode:

Software: Software-based forwarding acceleration mode. Wireless data packets are not processed by the wireless driver, but are directly forwarded through the wired driver. Because the packet transmission path of the wired driver is much shorter than that of the wireless driver, this mode can improve the forwarding performance of wireless data packets.

After this function is configured, the support for some features of the device will change.

Series	Model	tware-based Forwarding	Hardware-based Forwarding
AP180 series	AP180-I AP180P-L	Supported Features not supported: 1. WIDS 2. Wireless location 3. WAPI 4. Dynamic EDCA 5. WIS	Not supported

1.4 Configuration

Configuration	Description and Command	
Configuring WLAN-based Forwarding Mode	⚠ (Mandatory) It is used to specify the forwarding mode for a WLAN.	
	tunnel	Specifies the forwarding mode for an AP on a WLAN.
Configuring Forwarding Mode Based on AP Group and WLAN	⚠ (Optional) It is used to set the forwarding mode for a specific WLAN of an AP group.	
	tunnel local-auth wlan	Sets the forwarding mode for a specific WLAN of an AP group to local authentication forwarding mode.
Configuring VLAN-based Forwarding Mode	⚠ (Optional) It is used to specify the forwarding mode for a specified VLAN of a WLAN.	
	tunnel local wlan	Specifies local forwarding as the forwarding mode for a specified VLAN of a WLAN.
	tunnel 8023 wlan	Specifies centralized forwarding as the forwarding mode for a specified VLAN of a WLAN.
Configuring IP-based Forwarding Mode	⚠ (Optional) It is used to specify local forwarding as the forwarding mode for a specified IP address.	
	local fw ip	Forwards all packets of a specified IP address in local forwarding mode.
	⚠ (Optional) It is used to specify centralized forwarding as the forwarding mode for DHCP packets.	

Configuration	Description and Command	
Configuring DHCP-based Centralized Forwarding Mode	**central dhcp enable**	Forwards all DHCP packets on a WLAN in centralized forwarding mode.
Configuring AC-based Forwarding Mode	(Optional) It is used to specify the forwarding mode for an AC.	
	tunnel-mode	Specifies the forwarding mode for an AC.
Configuring VLAN Priority	(Optional) It is used to configure VLAN priority for a specific AP.	
	vlan-first	Configures VLAN priority for a specified AP.
Configuring WLAN Forwarding Acceleration	(Optional) It is used to configure WLAN forwarding acceleration.	
	wlan forward acceleration software	Configures software-based forwarding acceleration for the AP.

1.4.1 Configuring WLAN-based Forwarding Mode

Configuration Effect

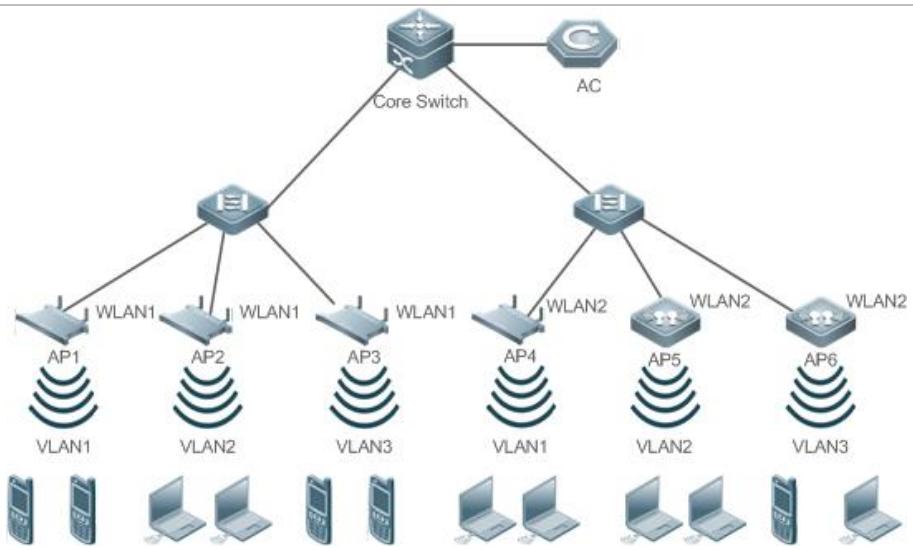
- Specify a forwarding mode for APs on a WLAN, including local forwarding mode, centralized forwarding mode, and local authentication forwarding mode.

Notes

- The **tunnel local-auth** command takes effect only when remote intelligent perception technology (RIPT) is enabled.

Configuration Steps

- Mandatory.
- In WLAN configuration mode on an AC, configure the forwarding mode for all APs on the WLAN as local forwarding mode, centralized forwarding mode, or local authentication forwarding mode.
- The default forwarding mode is centralized forwarding.
- Configure the forwarding mode before applying the WLAN template to a specified AP group. Otherwise, the configuration will not take effect.



Command	**tunnel** { **8023** | **local** }
Parameter Description	**8023**: An AP encapsulates received data packets into 802.3 frames and forwards the packets to an AC. **local**: An AP forwards packets locally.
Defaults	Centralized forwarding mode
Command Mode	WLAN configuration mode
Usage Guide	-

Verification

- Verify the WLAN configuration.

Configuration Example

Configuring the Forwarding Mode for All APs on a WLAN

Scenario **Figure 1-4**	 ● AP 1, AP 2, and AP 3 on WLAN 1 are used for mobile device connections. Centralized forwarding mode is configured due to lower traffic volume. ● AP 4, AP 5, and AP 6 on WLAN 2 are used for office PC connections. Local forwarding mode is configured due to higher traffic volume.
Configuration Steps	● Enter WLAN configuration mode. ● Configure the forwarding mode for a WLAN.
WLAN1	`Hostname(config)#wlan-config 1` `Hostname(config-wlan)#tunnel local`
WLAN2	`Hostname(config)#wlan-config 2` `Hostname(config-wlan)#tunnel 8023`
Verification	N/A

1.4.2 Forwarding Mode Based on AP Group and WLAN

Configuration Effect

- The forwarding mode for a specific WLAN of an AP group is set to local authentication forwarding mode.

Notes

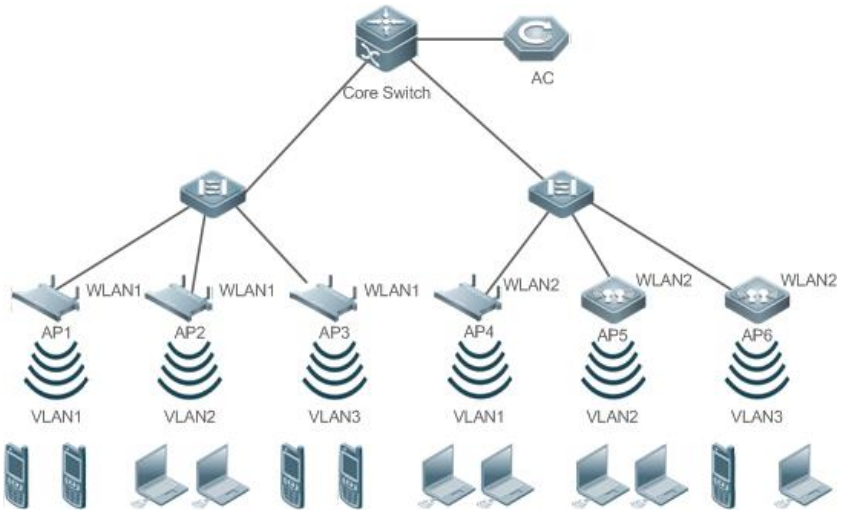
- In local authentication forwarding mode, an AP forwards the received data packets locally and STAs are authenticated for access on the AP.
- Local authentication forwarding mode can be configured on WLANs that support OPEN/PSK authentication. However, this mode is unavailable on WLANs that support 802.1X authentication, web-based authentication, and other authentication methods. If this mode is applied to WLANs that adopt 802.1X or web-based authentication, access authentication errors may occur on STAs.

- If the WLAN does not exist or is not mapped to the AP group, the configuration will be saved but not take effect. After the WLAN is added or is mapped to the AP group, the configuration automatically takes effect.

Configuration Steps

Configuring the Forwarding Mode Based on AP Group and WLAN

- Optional. If a WLAN requires a forwarding mode that differs from the overall WLAN configuration in a specific AP group, you can set it to the forwarding mode based on AP group and WLAN.
- If it is not configured, data packets are forwarded in the WLAN-based forwarding mode.
- In the AP group configuration mode on the AC, run the **tunnel local-auth wlan** *wlan-id* command to specify the local authentication forwarding mode for a specific WLAN of an AP group.



Command	**tunnel local-auth wlan** *wlan-id*
Parameter Description	*wlan-id*: Indicates the ID of the WLAN where local authentication forwarding mode is configured. The WLAN must be created first. The value ranges from 1 to 2,048.
Defaults	N/A
Command Mode	AP group configuration mode
Usage Guide	1. In local authentication forwarding mode, the AP forwards the received data packets locally and STAs are authenticated for access on the AP. 2. After the WLAN forwarding mode is configured through the **tunnel local-auth wlan** command, only OPEN/PSK authentication are supported for STA access. If 802.1X, web-based, or other authentication methods are used, access authentication errors may occur on STAs. 3. If the WLAN does not exist or is not mapped to the AP group, the configuration will be saved but not take effect. After the WLAN is added or is mapped to the AP group, the configuration automatically takes effect.

Verification

- N/A

Configuration Example

Configuring the Local Authentication Forwarding Mode for a WLAN of an AP Group

Scenario **Figure 1-5**	 ● AP1, AP2, and AP3 are on WLAN 1, where AP 1 belongs to APG1 group, AP2 belongs to APG2 group, and AP3 belongs to APG3 group. There is an unstable middle link between AP1 and the AC. Therefore, local authentication forwarding mode needs to be applied to APG1 group, and local forwarding mode to APG2 and APG3 groups.
Configuration Steps	● Enter WLAN configuration mode. ● Configure the forwarding mode for a WLAN. ● Specify the forwarding mode for a WLAN of an AP group.

WLAN1	`Hostname(config)#wlan-config 1`
	`Hostname(config-wlan)#tunnel local`
	`Hostname(config-wlan)#exit`
	`Hostname(config)#ap-group APG1`
	`Hostname(config-ap-group)#tunnel local-auth wlan 1`

1.4.3 Configuring VLAN-based Forwarding Mode

Configuration Effect

- Configure the forwarding mode for a specified VLAN on a WLAN: local or centralized forwarding.

Notes

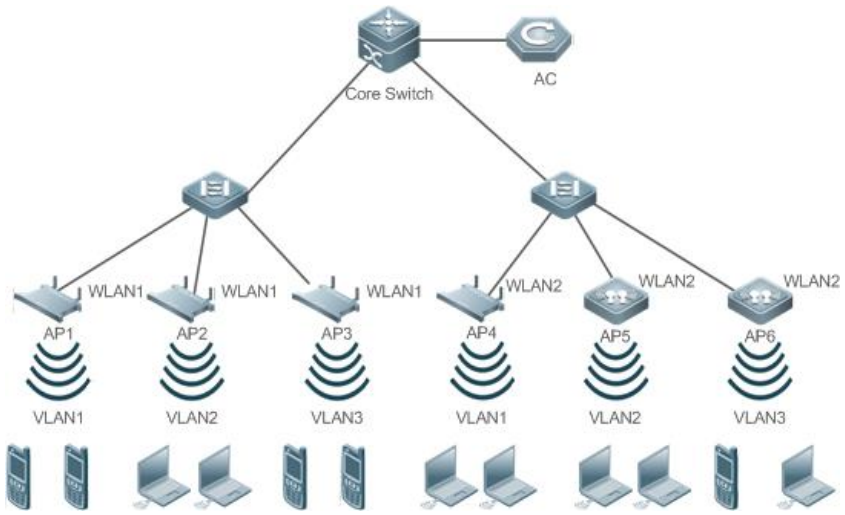
- You can configure the forwarding mode for the entire WLAN as WLAN-based forwarding mode, or you can set the forwarding mode for a specified VLAN on the WLAN to VLAN-based forwarding mode.
- As VLAN-based forwarding mode prevails over WLAN-based forwarding mode, if both of these modes are configured, the packets on the specified VLAN will be forwarded in VLAN-based forwarding mode and the others will be forwarded in WLAN-based forwarding mode.
- Configure either local forwarding or centralized forwarding for a VLAN.
- The VLAN can be a port-based VLAN, MAC-based VLAN, or authentication-based VLAN.

Configuration Steps

Configuring the Forwarding Mode for a VLAN

- (Optional) If a specified VLAN on a WLAN requires a different forwarding mode from that of the other VLANs, specify a forwarding mode for this VLAN.
- The default is WLAN-based forwarding mode.
- In AP group configuration mode on an AC, run **tunnel local wlan** *wlan-id* **vlan** *vlan-id* to specify local forwarding mode for a specified VLAN.
- In AP group configuration mode on an AC, run **tunnel 8023 wlan** *wlan-id* **vlan** *vlan-id* to specify centralized forwarding mode for a specified VLAN.

Command	**tunnel local wlan** *wlan-id* **vlan** *vlan-id*
Parameter Description	*wlan-id*: Indicates the WLAN ID. The WLAN must be created first. The value ranges from 1 to 2,048. *vlan-id*: Indicates the VLAN ID. The VLAN must be created first. The value ranges from 1 to 4,094.
Defaults	Local forwarding mode is not configured for a specified VLAN. The forwarding mode is the same as that configured by the **tunnel** command.
Command Mode	AP group configuration mode
Usage Guide	11. In WLAN configuration mode, you can run the **tunnel 8023** command to specify centralized forwarding mode for the entire WLAN, or you can run **tunnel local wlan** to specify local forwarding mode for a specified VLAN on the WLAN. 12. After the WLAN forwarding mode is configured through the **tunnel local wlan** command, only OPEN/PSK authentication is supported for STA access. If 802.1X, web-based, or other authentication methods are used, access authentication errors may occur on STAs.



Command	**tunnel 8023 wlan** *wlan-id* **vlan** *vlan-id*
Parameter Description	*wlan-id*: Indicates the ID of the WLAN where centralized forwarding mode is configured. The WLAN must be created first. The value ranges from 1 to 2,048. *vlan-id*: Indicates the ID of the VLAN where centralized forwarding mode is configured. The WLAN must be created first. The value ranges from 1 to 4,094.
Defaults	Centralized forwarding mode is not configured for a specified VLAN. The forwarding mode is the same as that configured by the tunnel command.
Command Mode	AP group configuration mode
Usage Guide	1. In WLAN configuration mode, you can run the **tunnel local** command to specify local forwarding mode for the entire WLAN, or you can run the **tunnel 8023 wlan** command to specify centralized forwarding mode for a specified VLAN. 2. After the WLAN forwarding mode is configured through the **tunnel 8023 wlan** command, only OPEN/PSK authentication is supported for STA access. If 802.1X, web-based, or other authentication methods are used, access authentication errors may occur on STAs.

Verification

- N/A

Configuration Example

Configuring the Forwarding Mode for a Specified VLAN on a WLAN

Scenario **Figure 1-6**	 ● AP1, AP2 and AP3 on WLAN1 belong to VLAN1, VLAN2 and VLAN3 respectively. VLAN1 and VLAN 3 are used for the access of mobile phones while VLAN 2 for PCs which require high bandwidth. Therefore, VLAN2 is configured with local forwarding mode. ● AP4, AP5 and AP6 on WLAN2 belong to VLAN 1, VLAN 2 and VLAN 3 respectively. VLAN1 and VLAN 2 are used for the access of PCs while VLAN 3 for mobile phones which require low bandwidth. Therefore, VLAN 3 is configured with centralized forwarding mode.
Configuration Steps	● Enter WLAN configuration mode. ● Configure the forwarding mode of a WLAN. ● Specify a forwarding mode for the specified VLAN on the WLAN.

WLAN1	`Hostname(config)#wlan-config 1`
	`Hostname(config-wlan)#tunnel 8023`
	`Hostname(config-wlan)#exit`
	`Hostname(config)#ap-group default`
	`Hostname(config-ap-group)#tunnel local wlan 1 vlan 2`

WLAN2	`Hostname(config)#wlan-config 2`
	`Hostname(config-wlan)#tunnel local`
	`Hostname(config-wlan)#exit`
	`Hostname(config)#ap-group default`
	`Hostname(config-ap-group)#tunnel 8023 wlan 2 vlan 3`

Verification	N/A

1.4.4 Configuring IP-based Forwarding Mode

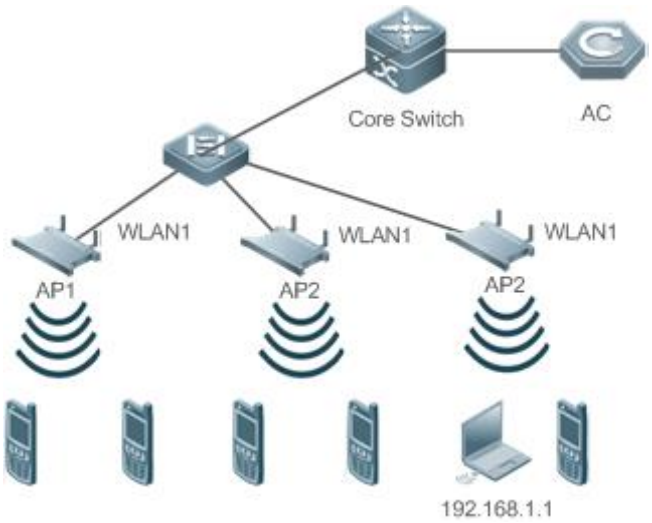
Configuration Effect

- Configure local forwarding mode for packets of a specified IP address.

Notes

- You can set the forwarding mode of an AP to WLAN-based forwarding mode and VLAN-based forwarding mode, or you can further configure local forwarding mode for packets of a specified IP address.
- As IP-based forwarding mode prevails over WLAN-based forwarding mode and VLAN-based forwarding mode, if all of these modes are configured, packets of a specified address will be forwarded locally, and the others will be forwarded in WLAN-based forwarding mode or VLAN-based forwarding mode.

Configuration Steps



Configuring IP-based Forwarding Mode

- (Optional) You can configure local forwarding mode for packets of a specified IP address.
- In AC configuration mode on an AC, configure local forwarding mode for a specified IP address.
- If IP-based forwarding is not configured, packets are forwarded based on WLAN or VLAN. If IP-based forwarding is configured, packets of a specified IP address are forwarded locally.

Command	**local fw ip** [*ip address*]
Parameter Description	*ip address*: Indicates the IP address of a STA.
Defaults	All IP packets are forwarded in WLAN-based forwarding mode.
Command Mode	AC configuration mode
Usage Guide	The AC can automatically identify data packets based on access conditions and determine whether to use local or centralized forwarding. Currently, the AC selects the forwarding mode based on the IP addresses of an STA.

Configuration Example

Configuring Local Forwarding for Packets of a Specified IP Address

Scenario **Figure 1-7**	 - AP1, AP2 and AP3 on WLAN1 are typically used for the access of mobile phones which require low bandwidth. Therefore, centralized forwarding mode is configured. When a PC with

	an IP address **192.168.1.1** is connected to AP2 and the PC requires high bandwidth, local forwarding is configured for **192.168.1.1**.
Configuration Steps	● Enter AC configuration mode. ● Configure local forwarding mode for a specified IP address.
AC	`Hostname(config)#ac-controller` `Hostname(config-ac)#local fwip 192.168.1.1`
Verification	N/A

1.4.5 Configuring DHCP-based Centralized Forwarding Mode

Configuration Effect

- Configure centralized forwarding mode for all DHCP packets.

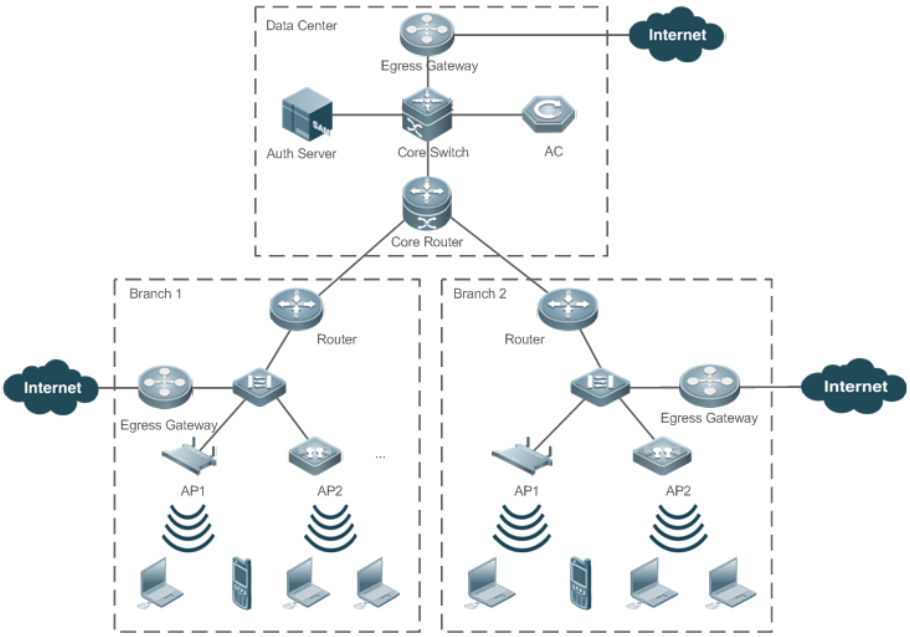
Notes

- DHCP-based centralized forwarding mode prevails over WLAN-based forwarding mode, VLAN-based forwarding mode, and IP-based forwarding mode. If DHCP-based centralized forwarding mode is configured, all DHCP packets on a specified WLAN will be forwarded in centralized mode.
- To facilitate management of the DHCP address pool and simplify the DHCP topology, you are advised to enable this function.

Configuration Steps

↘ Configuring DHCP-based Centralized Forwarding Mode

- (Optional) Perform the configuration when the AC assigns IP addresses to STAs uniformly.
- If DHCP centralized forwarding mode is not configured, DHCP packets will be forwarded in the same mode as other packets. If DHCP centralized forwarding mode is configured, all DHCP packets will be forwarded in centralized mode.
- Configure the forwarding mode before applying the WLAN template to a specified AP group. Otherwise, the configuration will not take effect.



Command	**central dhcp enable**
Parameter Description	N/A
Defaults	All packets are forwarded in WLAN-based forwarding mode.
Command Mode	WLAN configuration mode
Usage Guide	To facilitate management of the DHCP address pool and simplify the DHCP topology, you are advised to enable this function.

Verification

- Verify the WLAN configuration.

Configuration Example

↘ Configuring DHCP Services on an AC

Scenario **Figure 1-8**	 ● APs are deployed in different branches and are managed by the AC in the headquarters. ● The bandwidth of the links between branches and the headquarters is low. ● Each branch has an independent egress. ● IP addresses are assigned by the AC.
Configuration Steps	● Enter WLAN configuration mode. ● Configure the forwarding mode of the WLAN. ● Configure DHCP-based centralized forwarding mode.

AC	`Hostname(config)#wlan-config 100 Hostname_wlan`
	`Hostname(config-wlan)#tunnel local`
	`Hostname(config-wlan)#central dhcp enable`

Verification	N/A

1.4.6 Configuring AC-based Forwarding Mode

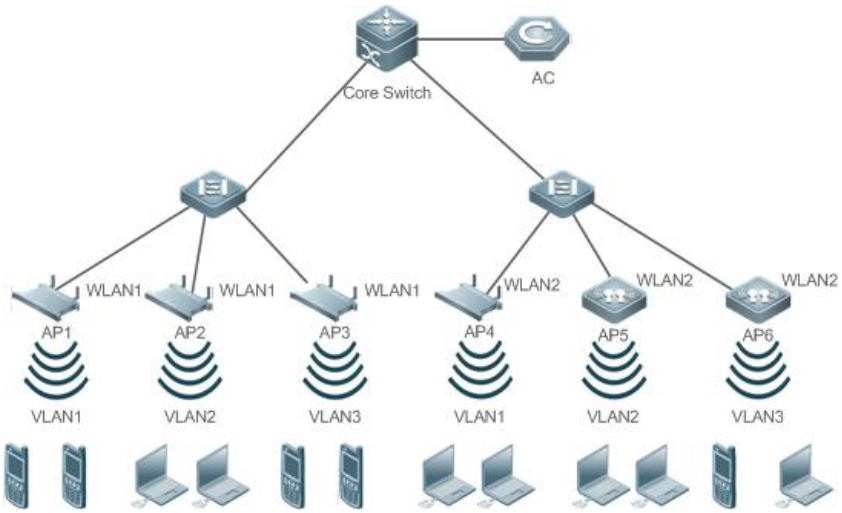
Configuration Effect

- Hybrid forwarding mode and local forwarding mode are available. When hybrid forwarding mode is configured for ACs, WLANs support both centralized forwarding and local forwarding. That is, some WLANs use centralized forwarding while other WLANs use local forwarding. When local forwarding mode is configured for ACs, WLANs support only local forwarding mode (including local authentication forwarding mode).

Configuration Steps

- Optional.
- In AC configuration mode on an AC, set the forwarding mode of the AC to hybrid forwarding or local forwarding.
- If no forwarding mode is configured for an AC, the AC uses the hybrid forwarding mode by default.
- Save the configuration and restart the device after configuration. Otherwise, the configuration does not take effect.

Command	**tunnel-mode** { **hybrid** | **local** }



Parameter Description	**hybrid**: Indicates hybrid forwarding mode. In this mode, WLANs support both centralized forwarding mode and local forwarding mode, that is, some WLANs use centralized forwarding while some WLANs adopt local forwarding. **local**: Indicates local forwarding mode. In this mode, WLANs support only local forwarding mode (including local authentication forwarding mode).
Defaults	Hybrid forwarding mode.
Command Mode	AC configuration mode
Usage Guide	1. The AC forwarding mode switching takes effect only after the configuration is saved and the device is restarted. Mode switching does not trigger device restart and you need to manually restart the device. 2. If the AC is restarted after the forwarding mode configuration is added to or modified in the **config.text** file, the configuration takes effect only after the AC is restarted again. It is invalid to delete the AC forwarding mode configuration from the **config.text** file. 3. The AC forwarding mode configuration is preconfigured in the system. That is, the configuration takes effect after the AC is restarted even if the **write** command is not executed. 4. If the tunnel mode is set to **hybrid** for an AC, the AC is explicitly configured to adopt the hybrid forwarding mode. After configuration, the tunnel mode remains unchanged when the default configuration is updated due to the AC version upgrade. 5. When an AC switches from hybrid forwarding mode to local forwarding mode, WLANs using centralized forwarding automatically switch to local forwarding mode after the AC is restarted. 6. When an AC switches from local forwarding mode to hybrid forwarding mode, the forwarding mode of WLANs does not change automatically after the AC is restarted. 7. In local forwarding mode, service configurations that need to be supported by centralized forwarding keep unchanged but their functions do not take effect. Such configurations include but are not limited to the broadcast forwarding proportion and token bucket configuration of the data plane, WQoS AC-based rate limit, WIDS AC-based/AC-SSID-based Layer 2 isolation, and application identification. 8. The maximum number of managed APs and STAs changes accordingly after the AC forwarding mode is changed. 9. The AC forwarding mode does not support default configuration restoration using the reset button.

Verification

- Check the AC configuration.
- Run the **show ac-config** command to display the current effective forwarding mode of the AC.

Configuration Example

Setting the Forwarding Mode of an AC to Local Forwarding

Scenario **Figure 1-9**	 ● The AC is deployed in bypass mode. All STA traffic does not need to pass through the AC. The AC is configured in local forwarding mode so as to manage more APs.
Configuration Steps	● Enter the AC configuration mode. ● Configure the forwarding mode for the AC, save the configuration, and restart the AC.

AC	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#tunnel-mode local`
	`Hostname(config-ac)#end`
	`Hostname#write`
	
	`Building configuration...`
	
	`[OK]`
	`Hostname#reload`
	`Reload system?(Y/N)y`

Verification	N/A

1.4.7 Configuring VLAN Priority

Configuration Effect

- Configure the VLAN priority feature for a specified AP to enable the priority VLAN and multicast address.

Notes

- N/A

Configuration Steps

↘ Enabling VLAN Priority

- Optional.
- This configuration can be performed if you need to enable the VLAN priority feature.
- Enable VLAN priority in AP configuration mode on the AC.

Command	**vlan-first global-enable**
Parameter Description	N/A
Defaults	Disabled
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the Priority VLAN

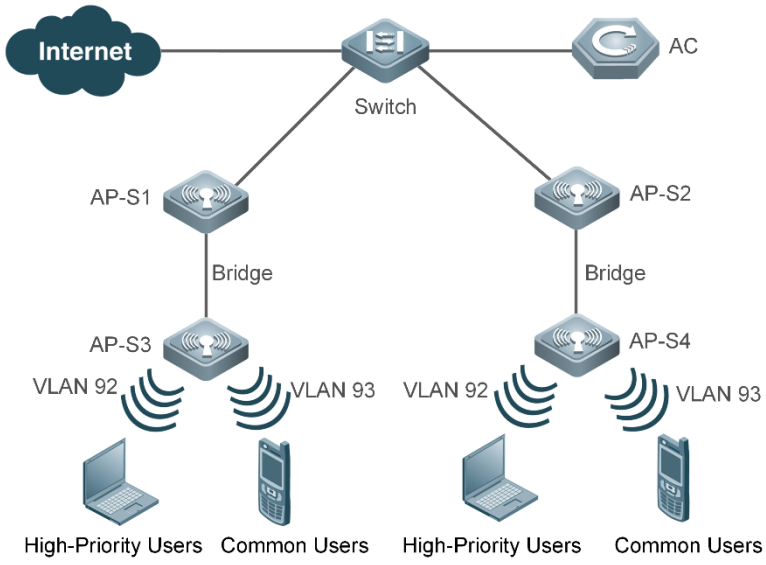
- Optional.
- You can configure priority VLAN for a specific AP.
- Configure the priority VLAN in AP configuration mode on the AC.

Command	**vlan-first vlan** *vian-id*
Parameter Description	*vian-id*: Specifies the priority VLAN. The value ranges from 1 to 4,094.
Defaults	All VLANs are non-priority VLANs.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the Multicast Address for the VLAN Priority Feature

- Optional.
- You can configure a multicast address for the VLAN priority feature of a specific AP.
- Configure the multicast address in AP configuration mode on the AC.

Command	**vlan-first ip** *sip dip*
Parameter Description	*sip*: Configures the source IP address of a multicast packet. *dip*: Configures the destination IP address of a multicast packet.
Defaults	No multicast address is configured.
Command Mode	AP configuration mode



Usage Guide	N/A

Verification

- Run the show **run** command to display the configuration.

Configuration Example

Configuring the Multicast Address for the VLAN Priority Feature

Scenario **Figure 1-10**	 **Note**: ● AP-S1 bridges with AP-S3, different VLANs are assigned to priority users and common users on AP-S3 and all APs are centrally managed by the AC. ● The multicast address for the VLAN priority feature on AP-S3 can be configured on the AC.
Configuration Steps	● Enter AP configuration mode on the AC. ● Configure the multicast address for the VLAN priority feature.
AC	`Hostname(config)#ap-config AP1` `Hostname(config-ap)# vlan-first ip 192.168.100.7 224.1.1.1`
Verification	Run the **show run** command to display the configuration.

1.4.8 Configuring WLAN Forwarding Acceleration

Configuration Effect

Configuring forwarding acceleration will improve the overall forwarding performance of the AP.

Notes

In the multi-user scenario where software-based forwarding acceleration is enabled, the recommended number of users is 32. If more than 32 users are configured, the performance will be lowered.

Configuration Steps

Configuring Software-based WLAN Forwarding Acceleration

Optional.

Command	**wlan forward acceleration software**
Parameter Description	N/A
Defaults	Software-based forwarding acceleration is disabled by default.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	• Configuring software-based forwarding acceleration will cause functions such as WIDS, dynamic EDCA, WIS, and wireless location to become unavailable. For details, see Configuring WLAN Forwarding Acceleration. • After software-based forwarding acceleration is configured on the AP, restart the AP to make the function to take effect. That is, after this command is configured, a confirmation prompt will appear. You need to input y, after which the AP will automatically restart, and WLAN forwarding acceleration will be activated.

Verification

Run the **show running-config** or **show wlan forward acceleration** command to display the configuration.

Configuration Example

Configuring Software-based WLAN Forwarding Acceleration

Configuration Steps	• Enter the AP configuration mode on the AC. • Configure software-based forwarding acceleration.
AC	`Hostname(config)#ap-config AP1` `Hostname(config-ap)# wlan forward acceleration software`
Verification	Run the **show running-config** or **show wlan forward acceleration** command to display the configuration.

Common Errors

N/A

1.5 Monitoring

Displaying

Command	Description
show wlan-config cb *wlan-id*	Displays the WLAN configuration.
show ac-config	Displays the AC forwarding mode.
show running-config	Displays the VLAN priority configuration.
show wlan forward acceleration	Displays the WLAN forwarding acceleration configuration of the AC or AP.

1 Configuring STA Management

1.1 Overview

STA Management (STAMG) implements station (STA) management, including STA access control management and STA event notification. Event notification is mainly used to serve other function modules. Applications of the STAMG functions are as follows:

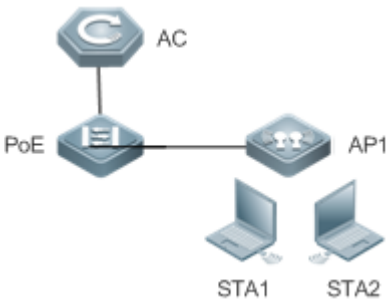
- The dynamic blocklist is used on a security-sensitive network to prevent user attacks.
- The STA limit is used when the number of STAs exceeds the AP capacity.
- Load balancing is used when STAs need to be evenly distributed to multiple APs.
- Association control is used in the e-bag scenario.

Protocols and Standards

- N/A

1.2 Applications

Application	Description
Fit AP Networking	In fit AP network mode, at least one AC and one AP are required.
Large Conference Room	In fit AP network mode, at least one AC and two APs are required.
E-	In fit AP network mode, at least one AC and two APs are required.



1.2.1 Fit AP Networking

Scenario

One AC is deployed on the wireless network, and dynamic blocklist and STA limit are enabled on the AC.

As shown in Figure 1-1, dynamic blocklist and STA limit are enabled on the AC.

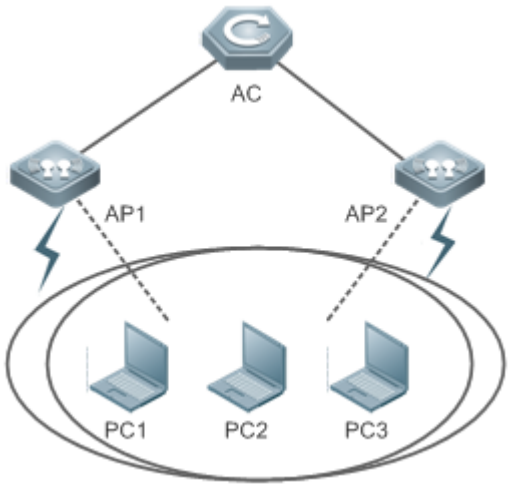
Figure 1-1

Remarks	AC: Indicates a wireless access controller. PoE: Indicates the switch that functions as the gateway of APs. AP: Indicates a wireless access point.

	STA1 and STA2: Indicates two client devices.

Deployment

- Enable dynamic blocklist and STA limit on the AC.



1.2.2 Large Conference Room

Scenario

In a large conference room, the number of STAs is generally large, and STAs must be evenly distributed to multiple APs. Otherwise, too many STAs are connected to some specific APs, resulting in a low network speed and a poor user experience.

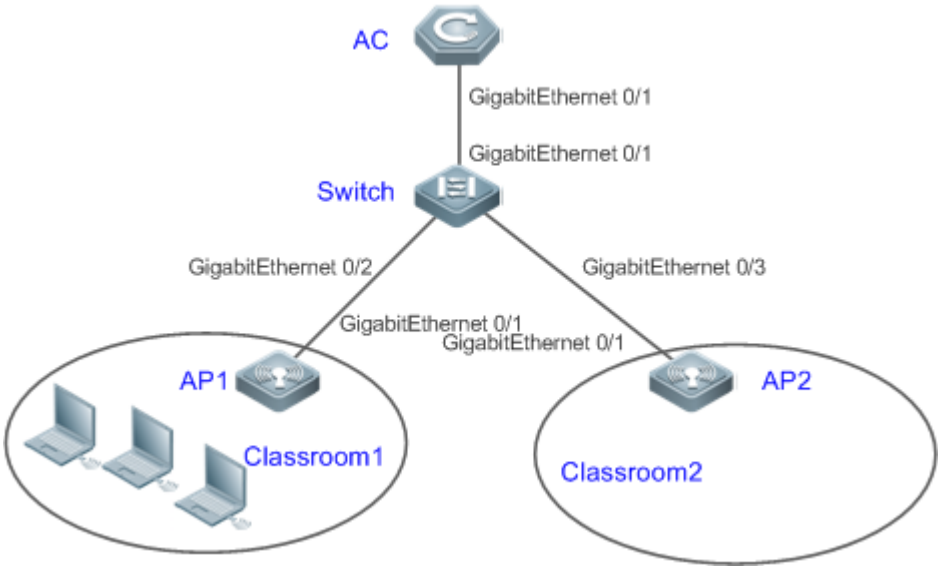
As shown in Figure 1-2, two APs (AP1 and AP2) are deployed in the conference room so that STAs can be evenly distributed to the two APs.

Figure 1-2

Remarks	AC: Indicates a wireless access controller. AP1 and AP2: Indicates two wireless access points. PC1, PC2, and PC3: Indicates three STAs.

Deployment

- Enable load balancing on the AC, and add AP1 and AP2 to the load balancing group.



1.2.3 E-bag

Scenario

One AC is deployed on the wireless network, and multiple APs are deployed in different classrooms. When the teacher's STA is associated with an AP, the students' STAs must also be associated with the same AP. This ensures the network transmission speed.

As shown in Figure 1-3, AP1 is deployed in Classroom1 and AP2 is deployed in Classroom2. When the teacher's STA is associated with AP1, the students' STAs must also be associated with AP1, instead of AP2. In this way, traffic destined for Classroom1 is only sent to AP1 without affecting users on AP2.

Figure 1-3

Remarks	AC: Indicates a wireless access controller. PoE: Indicates the switch that functions as the gateway of APs. AP1 and AP2: Indicates two wireless access points.

In an e-bag scenario, if the teacher uses the wired network connection, one of STAs used by students must be configured as the primary STA to implement association control. Who uses this primary STA is determined by users. For example, the primary STA can be used by the class monitor or the teacher so that secondary STAs can be associated properly. After proper association of the secondary STAs, the teacher can put this primary STA aside, and use the wired network connection during the class.

Deployment

- Enable association control on the AC, and add APs to a specified association control zone.

1.3 Features

Overview

Feature	Description
Dynamic	Detects association of unauthorized users.
STA Limit	Limits the number of STAs.
Load Balancing	Distributes STAs evenly to multiple APs.
Inter-Radio Load Balancing (by Number of STAs/Traffic/Ratio)	Distributes STAs evenly to multiple radios of the same AP.

Inter-Radio Load Balancing (by Bandwidth Resources)	Compares the weights of radio frequency band resources, hides SSID signals with few radio resources, and balances the access STAs among the radios.
Association Control	Associates secondary STAs with APs in the same control domain if the primary STA is associated with these APs.
STA Management	Disassociates STAs without traffic forcibly to recycle resources.
STA Informational Syslog Suppression	Suppresses the informational syslog output rate of STAs.
Intelligent SSID Hiding	Hides the SSID when the number of STAs on an AP or radio reaches the upper limit.
STA Jitter Prevention	Retains the STA entry for a period of time after the STA is disassociated from the WLAN.
Syslog Format Upon STA Association	Adds the syslog format for obtaining an IP address when a STA goes online.
Fast STA Association	Indicates that during the STA association process, the AC does not wait for the response packet that the STA is successfully added from the AP, improving STA access efficiency.
IP Address Detection	Indicates that the STA will be disconnected and reacquire IP address if it fails to obtain an IP address.
DHCP Proxy	Indicates the DHCP proxy request feature.

1.3.1 Dynamic Blocklist

The AC can use the dynamic blocklist to punish malicious or unauthorized STAs so that these STAs cannot be associated within a period of time. In addition, the dynamic blocklist can be used to disassociate these STAs.

Working Principle

The number of STA association failures (including failures caused by incorrect user names or passwords) is counted in a period of time. When the number of association failures of a STA exceeds a certain threshold, the STA is added to the blocklist. STAs in the blocklist cannot be associated within a period of time.

1.3.2 STA Limit

STA limit aims to limit the number of STAs that can be associated with an AP based on the load capacity. This prevents the risk of insufficient resources caused by overload of APs.

Working Principle

When STAs are associated, the AP checks whether the number of associated STAs exceeds the threshold. If so, STAs cannot be associated.

1.3.3 Load Balancing

Load balancing can balance the load among APs managed by an AC. The load here can be traffic or the number of associated STAs. Load balancing is used to address the problem that some APs are overloaded and some APs are in the idle state.

Working Principle

When a STA attempts to access an AP, if the load on the AP associated by the STA exceeds the preset threshold, the system checks whether the load difference between all the APs in the load balancing group of this AP exceeds the threshold. If so, the STA is not allowed to associate with this AP. The load difference can be configured as the number of STAs or the traffic.

To address the issue that the STA can receive signals from only one AP but fails to be associated due to load balancing, the maximum number of load balancing times can be configured. If two consecutive association failures occur due to load balancing, load balancing is not performed for the third time and the STA can be associated with the AP.

1.3.4 Inter-Radio Load Balancing (by Number of STAs/Traffic/Ratio)

Inter-radio load balancing can balance the load among radios of the same AP to prevent overload of a single radio. Similarly, the load here can be the traffic or the number of associated STAs.

Working Principle

The principle of inter-radio load balancing is similar to that of load balancing group except that you can configure the load balancing thresholds respectively for intra-frequency radios (2.4 GHz, 5 GHz) or inter-frequency radios. The load ratio, that is, the radio weight ratio, can be configured for radios. The default radio weight is 100. For example, if weight of radio 1 is set to 50 and that of radio 2 is set to 100, the load ratio between radio 1 and radio 2 is 1:2. When load balancing is performed, load is balanced to radio 1 and radio 2 according to this load ratio.

1.3.5 Inter-Radio Load Balancing (by Bandwidth Resources)

This feature balances the load among radios based on the bandwidth resources.

Working Principle

When automatic load balancing is configured among radios, the resource weight is calculated for radios based on the channel bandwidth, utilization, and number of STAs accessing the AP. A greater weight indicates that the radio uses more resources. The formula is as follows: Radio weight = (Channel idle rate × Channel bandwidth)/Number of STAs. The channel idle rate equals 100 minus channel utilization rate, which is an integer in the range from 0 to 100, for example, 50 indicates that the channel utilization rate is 50%. By comparing the resource weights of radios accessing the AP, SSID signals on radios with fewer resources are hidden, and inter-radio load balancing guidance is provided for STAs accessing the AP.

1.3.6 Association Control

Association control is a method for controlling association behaviors of wireless STAs. STAs are divided into two groups. In each group, only one STA is defined as the primary STA, and the other STAs are defined as secondary STAs. The secondary STAs must follow the association behaviors of the primary STA. That is, the primary and secondary STAs must be associated with the same wireless network. In this way, association behaviors of wireless STAs can be properly controlled.

Working Principle

The coverage area of a wireless network is divided into several association control domains. One or several APs are deployed in each domain, and wireless clients are divided into groups. The control domains that can be associated with the clients are strictly controlled. For example, a school has many classrooms, and a wireless AP is deployed in each

classroom. Radio signals travel in the space. When e-bags are used in two adjacent classrooms at the same time, the ideal condition is that all clients of the teachers and students are associated with the AP in their own classrooms respectively, avoiding mutual interference. In this case, a classroom must be defined as an association control domain and all clients of the teacher and students in a classroom must be associated with the AP in the classroom.

Association control aims to prevent clients from associating with a wireless network at random when multiple wireless networks are available for selection. The following are prerequisites for network configurations:

- Based on the pre-configured association control domains and package information, the AC delivers the information about primary STAs in all packages to all APs in the association control domains and generates an allowlist of primary STAs on these APs.
- The information about primary STAs in all packages is available in the AP allowlist. Therefore, before association control is enabled, the primary STA must associate itself with the corresponding SSID in the specified control domain. After that, the AC assigns all corresponding secondary STAs to all APs in the association control domain and generates an allowlist based on the configuration of the primary STA package to allow the secondary STAs to associate themselves with the control domain.
- When the primary STA is de-associated from the control domain, all the secondary STAs will also be de-associated and deleted from the AP allowlist.
- The above process can be summarized as follows: The secondary STAs must follow the primary STA to associate themselves with an AP in the same control domain, with which the primary STA is associated. Only the APs in this control domain have an allowlist of the corresponding secondary STAs. This ensures that STAs are not randomly associated with APs in other control domains.

1.3.7 STA Management

STA management is used to manage association and disassociation logic processing of STAs.

Working Principle

In normal cases, a STA sends a disassociation frame to inform the AC that the STA is disassociated. If the STA does not send a disassociation frame to the AC when it is disassociated abnormally (for example, because the user removes the network interface card (NIC)), the AC cannot learn the disassociation of the STA. In this case, the AC detects the STA traffic and finds that the STA has no traffic within a period of time, and concludes that the STA had been disassociated. Then, the AC performs disassociation processing on the STA.

1.3.8 STA Informational Syslog Suppression

STA informational syslog suppression prevents a high CPU usage caused by the large number of informational syslogs generated when STAs are frequently associated or disassociated.

Working Principle

The number of syslogs output per second is counted. When this number reaches the upper limit, no more syslog is output within the second, thereby suppressing the syslog. In the next second, the number of syslogs is counted again.

1.3.9 Intelligent SSID Hiding

When the number of STAs on an AP or a radio reaches the upper limit, new STAs are not allowed to go online but the STAs can still scan the SSID and attempt to perform association. After the intelligent SSID hiding feature is enabled, new STAs cannot detect the signal and will not attempt to perform association. This prevents STAs from performing association even when the STA quantity exceeds the upper limit.

Working Principle

When the number of STAs on an AP or a radio reaches the upper limit, the Beacon frame sent by the AP does not carry the SSID. When a new STA sends a probe request, the AP does not respond with a Probe response.

1.3.10 STA Jitter Prevention

STA jitter prevention is used to retain a STA entry on the AC for a period of time after a STA is disassociated. In this time period, if the STA goes online from the same WLAN of the AP again, it is regarded that the STA has never gone offline. If the STA goes online from the same WLAN of another AP, it is regarded that the STA roams to the AP with the same SSID. If the STA goes online from another WLAN, it is regarded that the STA is switched to another AP with a different SSID. If the AP or authentication server proactively forces a STA to go offline, the STA jitter prevention function does not take effect and the STA goes offline immediately.

STA jitter prevention enables a STA to perform Layer 3 roaming, preventing a roaming failure caused by a disassociation request proactively sent by the STA in the coverage hole.

Working Principle

After STA jitter prevention is enabled and a STA is disassociated, the AC adds the STA to the offline queue and starts a timer according to the expected deletion time specified based on the jitter prevention time. If the STA re-associates with an AP before the timer expires, the AC removes the STA from the offline queue and regards it as an online STA. Otherwise, the AC forces the STA to go offline when the timer expires.

1.3.11 Syslog Format Upon STA Association

The syslog format for obtaining an IP address is provided when a STA goes online, facilitating interconnection with log systems.

Working Principle

The device determines whether the format switching command is configured when the syslog format is output after the IP address is successfully obtained when the STA goes online. If not, output the default format; otherwise, output the configured format.

1.3.12 Fast STA Association

When a STA goes online, the AC does not wait for the response packet from AP indicating that the STA is added.

Working Principle

When this feature is disabled, during STA online interaction, the AC will process the next association request packet after the STA is associated with the AP. When this feature is enabled, the AC will no longer wait, improving concurrent STA access performance.

1.3.13 IP Address Detection

IP address detection is used to detect whether a STA has obtained an IP address.

Working Principle

The system detects the IP addresses of STAs. STAs without IP address will be disconnected to reacquire IP address. STAs disconnected by IP detection mechanism will not be checked again for a period of time.

1.3.14 DHCP Proxy

The STA management module notifies whether DHCP proxy is enabled or disabled.

Working Principle

The STA management module notifies the DHCP module to enable or disable DHCP proxy through the command. When DHCP proxy is enabled, the device will replace the STA to initiate DHCP discover packets, exchange packets with the DHCP server, and generate DHCP snooping entries on the AC, eliminating the need for STA to participate in this process.

1.4 Configuration

Configuration	Description and Command	
Configuring Dynamic	⚠ (Mandatory) It is used to enable the dynamic blocklist function.	
	sta-blacklist enable	Enables the dynamic blocklist function.
	⚠ (Optional) It is used to configure the parameters of the dynamic blocklist.	
	sta-blacklist lifetime	Configures the aging time of the dynamic blocklist.
	sta-blacklist detect-time	Configures the detection time of the dynamic blocklist.
	sta-blacklist fail-limit	Configures the maximum number of association failures.
Configuring STA Limit	⚠ (Optional) It is used to configure the maximum number of STAs.	
	sta-limit	Configures the maximum number of STAs.
	sta-limit per-ap	Configures the STA quantity limit for each AP on a WLAN.
	sta-limit radio	Configures the maximum number of STAs that can be associated with a radio of the AP.
Configuring Load Balancing	⚠ (Mandatory) It is used to configure load balancing.	
	num-balance-group enable	Enables the number-based balancing feature.

	num-balance-group create	Creates a number-based balancing group.
	num-balance-group add	Adds an AP to the number-based balancing group.
	num-balance-group del	Deletes an AP from the number-based balancing group.
	flow-balance-group enable	Enables the traffic balancing feature.
	flow-balance-group create	Creates a traffic-based balancing group.
	flow-balance-group add	Adds an AP to the traffic-based balancing group.
	flow-balance-group del	Deletes an AP from the traffic-based balancing group.
	(Optional) It is used to configure the load balancing parameters.	
	num-balance-group num	Configures the threshold of the number-based balancing group.
	num-balance-group mode	Configures the working mode of the number-based balancing group.
	flow-balance-group flow	Configures the threshold of the traffic-based balancing group.
	flow-balance-group radio-flow	Enables a specified traffic balancing group to use the traffic uploaded by APs.
	flow-balance-group base	Configures the traffic base value.
	sta-balance num-limit enable	Configures the number of the load balancing attempts.
Configuring Inter-Radio Load Balancing (by Number of STAs/Traffic/Ratio)	(Mandatory) It is used to enable inter-radio load balancing.	
	inter-radio-balance flow-balance enable	Enables inter-radio traffic-based balancing.
	inter-radio-balance num-balance enable	Enables inter-radio number-based balancing.
	(Optional) It is used to configure the load balancing parameters.	
	inter-radio-balance flow-balance dual-band	Configures parameters for traffic-based balancing among inter-frequency radios.
	inter-radio-balance flow-balance same-band	Configures parameters for traffic-based balancing among intra-frequency radios.
	inter-radio-balance num-balance dual-band	Configures parameters for number-based balancing among inter-frequency radios.

	inter-radio-balance num-balance same-band	Configures parameters for number-based balancing among intra-frequency radios.
Configuring Inter-Radio Load Balancing (by Bandwidth Resources)	(Mandatory) It is used to enable inter-radio load balancing.	
	ap-inter-balance enable	Enables inter-radio load balancing.
	(Optional) It is used to configure the load balancing parameters.	
	ap-inter-balance chan-wid-thrd	Configures the bandwidth resource threshold for triggering inter-radio load balancing guidance.
	ap-inter-balance weight-scale	Configures the amplification factor of the bandwidth resource weight of the STA-accessed radio.
	ap-inter-balance low-weight-scale	Configures the amplification factor of the bandwidth resource weight of the non-STA-accessed radio.
	ap-inter-balance hide-limit count	Configures the frequency limit of the AC sending messages to the hidden SSID.
Configuring Inter-Radio Load Balancing (by Bandwidth Resources) **Config**	(Mandatory) It is used to enable association control.	
	package	Configures a package.
	primary-sta	Configures the primary STA in the package.
	secondary-sta	Configures the secondary STA in the package.
	control-zone	Configures an association control domain.
	ap	Configures the AP information.

uration

Effect

Guide STAs to access radios with more bandwidth resources for inter-radio load balancing.

Notes

- When the inter-radio load balancing feature and the 5G first feature are both enabled, and the SSID signal is hidden by the load balancing feature because the 5 GHz radio has fewer resources, new STAs accessing the radio will be rejected by the 5G first feature if they support 5G.
- If the bandwidth resource weight of the radio that STAs access is still lower than other radios after the resource weight is amplified through the amplification factor, the SSID of the radio is hidden to prevent users from viewing it.

Configuring STA Management	(Optional) It is used to configure the time after which the STA is disassociated if no traffic is detected.	
	sta-idle-timeout	Configures the time after which the STA is disassociated if no traffic is detected.
Configuring STA Informational Syslog Suppression	(Optional) It is used to configure the maximum output rate of the STA informational syslogs.	
	sta-logging rate-limit	Configures the maximum output rate of the STA informational syslogs.
Configuring Configuring Intelligent SSID	**hide-ssid sta-reach-limit** [**radio** { **2.4g** | **5g** | **6g** }]	Configures intelligent SSID hiding.
Configuring STA Jitter Prevention	(Optional) It is used to set the jitter prevention time.	
	prevent-jitter enable	Enables STA jitter prevention.
	prevent-jitter time keep-time	Configures the STA jitter prevention time.
Configuring Configuring the Syslog Format upon STA Association STA Association	(Optional) It is used to set the format of the syslog output when a STA obtains an IP address online.	
	sta-logging mac-fmt-line	Configures the format of the syslog output when a STA goes online and obtains an IP address.
Enabling Enabling Fast STA Association	(Optional) It is used to enable fast association for STAs.	
	sta-behaviour fast-assoc	Configures fast association for STAs.
Enabling Enabling IP Address Detection	(Mandatory) It is used to enable or disable IP address detection for STAs.	
	sta-behaviour ip-check enable	Enables or disables IP address detection.
	(Optional) It is used to set the delay for IP address detection for STAs.	
	sta-behaviour ip-check delay *time*	Configures the delay for IP address detection, in seconds.
	(Optional) It is used to set the quiet period for IP address detection for STAs.	
	sta-behaviour ip-check sulk *time*	Configures the quiet period for IP address detection, in seconds.
Enabling Enabling DHCP Proxy	(Optional) It is used to enable DHCP proxy.	
	sta-behaviour dhcp-proxy enable	Enables or disables DHCP proxy.
	(Optional) It is used to configure the delay for DHCP proxy.	
	sta-behaviour dhcp-proxy delay *time*	Configures the delay for DHCP proxy, in seconds.
Configuring Configuring	(Optional) It is used to delete the MAC address of a specified wireless STA.	

Wireless STA Management	**client-kick**	Deletes the MAC address of a specified wireless STA.

1.4.1 Configuring Dynamic Blocklist

Configuration Effect

- When the number of association failures on a STA reaches the threshold within the specified time, this STA is added to the blocklist.

Notes

- The time period is not fixed and is between **detect-time** and (**detect-time** + 5), in seconds. This factor must be considered during configuration.
- If multiple authentication modes are applied, the number of STA association failures increases by 1 when one of the authentication modes fails. Combinations of authentication modes include, but are not limited to, PSK + Web, PSK + MAB + Web, PSK + MAB, MAB + Web, and 802.1X + Web.

Configuration Steps

Enabling Dynamic Blocklist

- (Mandatory) Enable dynamic blocklist on an AC.

Command	**sta-blacklist enable**
Parameter Description	N/A
Defaults	Dynamic blocklist is disabled.
Command Mode	AC configuration mode
Usage Guide	N/A

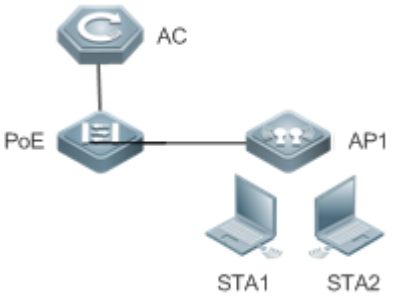
Configuring the Dynamic Blocklist Parameters

- (Optional) Configure the dynamic blocklist parameters on an AC.
- Configure the aging time for the blocklist. If the aging time of blocklist entries is set improperly, you can reconfigure the aging time.
- Run the **sta-blacklist lifetime** command to configure the aging time for the dynamic blocklist. A longer aging time indicates a longer period of time within which blocklisted STAs are not allowed for association.
- Run the **sta-blacklist detect-time** command to configure the detection time. As the detection time decreases, unauthorized STA detection becomes more sensitive and the number of false reports increases.
- Run the **sta-blacklist fail-limit** command to configure the upper limit of association failures. A larger upper limit indicates that a STA can make more association attempts.

Command	**sta-blacklist lifetime** *seconds*
Parameter Description	*seconds:* Indicates the aging time of STAs in the blocklist. The value ranges from 60s to 1200s.
Defaults	300s

Command Mode	AC configuration mode
Usage Guide	N/A

Command	**sta-blacklist detect-time** *seconds*
Parameter Description	*seconds:* Indicates the STA detection time. The value ranges from 5s to 60s.
Defaults	60s
Command Mode	AC configuration mode
Usage Guide	This command is used to configure the STA detection time. When a STA fails upon first association, the STA is listed as a suspected attacker. If the number of association failures on the STA reaches the upper limit (namely, the **fail-limit**) within the detection time, the STA is added to the blocklist.



Command	**sta-blacklist fail-limit** *number*
Parameter Description	*number*: Indicates the maximum number of association failures. The value ranges from 1 to 100.
Defaults	The maximum number of association failures is 5.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show sta-blacklist** command to display the STAs in the blocklist.

Configuration Example

↘ Configuring Dynamic Blocklist

Scenario **Figure 1-4**	
Configuration Steps	● Configure the dynamic blocklist function.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ac-controller AC(config-ac)# sta-blacklist enable

Verification	● After the CAPWAP tunnel is established between an AP and an AC, enter an incorrect password for several times to verify that the STA can be added to the blocklist.
AC	AC# show sta-blacklist Num STA MAC Add time ---------- -------------- -------------------- 1 0080.1111.1111 2013-07-02 13:56:22 2 0090.2222.3333 2013-07-02 13:56:35 3 0070.1111.2233 2013-07-02 13:57:08

Common Errors

- N/A

1.4.2 Configuring STA Limit

Configuration Effect

- Limit the maximum number of STAs that can be associated with an AC, a WLAN, an AP, or a radio of an AP on the wireless network.

Notes

- The STA limits configured for an AC, a WLAN, an AP, or a radio of an AP take effect simultaneously. That is, a STA can be associated only if all the STA limits are met.
- The STA limit configured on the AC is not under license control.

Configuration Steps

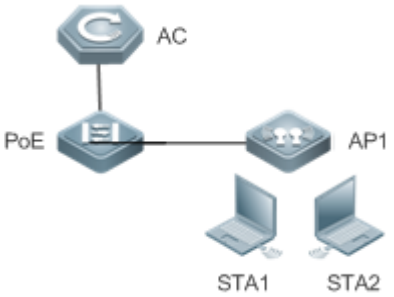
↘ Configuring STA Limit

- (Optional) Configure the STA limit an AC.
- If there a large number of STAs on the wireless network, configure the STA limit to allow more STAs to be associated, but the total bandwidth will decrease.
- Run the **sta-limit** command to configure the STA limit. A large STA limit indicates that more STAs can be associated.
- The default AC-based STA limit is the maximum number of STAs that can be associated with an AC. The default WLAN-based STA limit is not specified. By default, the AP-based STA limit is 32 for a disassociated AP or in AP group configuration mode and varies with models for an associated AP.
- Run the **sta-limit radio** command to configure the radio-based STA limit for an AP. A larger STA limit indicates that more STAs can be associated. No limit is set by default. Radio-based STA limit and AP-based STA limit are independent. The total number of radio-based STA limits cannot be considered as the AP-based STA limit.
- Run the **sta-limit per-ap** command to configure the maximum number of STAs supported on each AP on a WLAN. By default, the number of STAs on an AP is not limited. If the number of configured STAs exceeds the maximum number of STAs supported by an AP, no new STA can be associated with the AP.

Command	**sta-limit** *max-num*

Parameter Description	*max-num*: Indicates the maximum number of STAs. The value varies according to the configuration modes and devices.
Defaults	In AC configuration mode, the default value is the maximum number of STAs supported by an AC, not limited by the license. In AP group configuration mode, the default value is 64. In AP configuration mode, the default value is 64 for a disassociated AP or in the **ap-config all** configuration mode. The default value for an associated AP is determined by the AP model. In WLAN configuration mode, the STA limit is not specified.
Command Mode	AC configuration mode, WLAN configuration mode, AP configuration mode, or AP group configuration mode
Usage Guide	If the maximum number of STAs configured for a disassociated AP exceeds the actual capacity, the STA limit automatically changes to the actual maximum number of STAs supported after the AP is associated.

Command	**sta-limit** *max-num* **radio** *radio-id*
Parameter Description	*max-num*: Indicates the maximum number of STAs. The value ranges from 1 to 4,096. *radio-id*: Indicates the radio ID. The value ranges from 1 to 96.
Defaults	The STA limit is not specified.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	If the maximum number of STAs configured for a disassociated AP exceeds the actual capacity of the radio, the STA limit automatically changes to the actual maximum number of STAs supported after the AP is associated.



Command	**sta-limit per-ap** *max-num*
Parameter Description	*max-num*: Indicates the maximum number of STAs supported on an AP. The value ranges from 1 to 4,096.
Defaults	The number of STAs supported on an AP is not limited.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Verify that the number of STAs is limited.

Configuration Example

Configuring STA Limit

Scenario **Figure 1-5**	
Configuration Steps	● Configure the STA limit.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ap-config ap1 AC(config-ap)# sta-limit64
Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the AC running configuration.
AC	AC# show ap-config running ap-config ap1 sta-limit 64 !

Common Errors

- N/A

1.4.3 Configuring Load Balancing

Configuration Effect

- Enable even distribution of STAs on multiple APs in a load balancing group.

Notes

- Load balancing is applicable only to STAs that are associated, but not to STAs that are disassociated. Therefore, after STAs are disassociated, the traffic difference between APs or the STA quantity difference may exceed the threshold.
- Load balancing takes effect only on the same type of radios (2.4 GHz, 5 GHz, or 6 GHz). If the types of radios are different, load balancing is performed only when the AP reports that the STAs are capable of multi-band operation. Otherwise, the 2.4 GHz STAs may fail to be associated with 2.4 GHz radios when no STA is associated with 5 GHz radio. The same applies to other radios.
- After the traffic-based balancing group is configured to use the traffic information uploaded by APs, APs must upload the traffic information to the AC at a regular interval because the traffic only exists on APs and is not routed to the AC. During this interval, the traffic information on the AC does not change. At this time, if the traffic between APs is not

balanced, STAs cannot be associated with APs with heavy traffic until the APs upload the traffic information to the AC.

Configuration Steps

Creating a Number-based Balancing Group

- (Mandatory) Create a number-based balancing group on the AC.
- APs can be only added to a created load balancing group.

Command	**num-balance-group create** *group-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group.
Defaults	No number-based balancing group is created.
Command Mode	AC configuration mode
Usage Guide	N/A

Adding an AP to the Number-based Balancing Group

- (Mandatory) The configuration is performed on the AC.
- Load balancing only applies to the APs which are added to a load balancing group.

Command	**num-balance-group add** *group-name ap-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group. *ap-name*: Indicates the AP name.
Defaults	No AP is added to the number-based balancing group.
Command Mode	AC configuration mode
Usage Guide	N/A

Creating a Traffic-based Balancing Group

- (Mandatory) The configuration is performed on the AC.
- Load balancing only applies to the APs which are added to a created load balancing group.

Command	**flow-balance-group create** *group-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group.
Defaults	No traffic-based balancing group is created.
Command Mode	AC configuration mode
Usage Guide	N/A

Adding an AP to the Traffic-based Balancing Group

- (Mandatory) The configuration is performed on the AC.
- Load balancing only applies to the APs which are added to a load balancing group.

Command	**flow-balance-group add** *group-name ap-name*

Parameter Description	*group-name*: Indicates the name of a load balancing group. *ap-name*: Indicates the AP name.
Defaults	No AP is added to the traffic-based balancing group.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring Load Balancing Group Parameters

- (Optional) Configure the parameters of a load balancing group on the AC.
- Run the **num-balance-group num** command to configure the threshold of number-based balancing. A larger threshold indicates a greater difference in the number of STAs associated with two APs, and the less balanced load.
- Run the **num-balance-group mode** command to configure radio-based balancing. If radio-based balancing is enabled, the control on the distribution of STAs is more accurate, but the effect of balancing among APs is less satisfying.
- Run the **num-balance-group enable** command to configure the trigger threshold of the number-based balancing group. A higher trigger threshold indicates that load balancing is enabled only when the AP load is heavier.
- Run the **num-balance-group del** command to delete an AP from the number-based balancing group.
- Run the **flow-balance-group flow** command to configure the traffic-based balancing threshold. A higher traffic balancing threshold indicates that the traffic difference between two APs is greater and the traffic is less balanced.
- Run the **flow-balance-group radio-flow** command to enable the traffic balancing group to use the traffic information uploaded by APs. In local forwarding mode, data packets are not routed to the AC, and the AC cannot obtain the traffic information. Therefore, the traffic information uploaded by APs must be used to determine whether to enable load balancing.
- Run the **flow-balance-group enable** command to configure the trigger threshold of the traffic-based balancing group. A higher trigger threshold indicates that load balancing is enabled only when the AP load is heavier.
- Run the **flow-balance-group del** command to delete an AP from the traffic-based balancing group.
- Run the **flow-balance-group base** command to configure the baseline of traffic balancing in global configuration mode.
- Run the **sta-balance num-limit enable** command to configure the maximum number of times for enabling load balancing.

Command	**num-balance-group num** *group-name number*
Parameter Description	*group-name*: Indicates the name of a load balancing group. *number*: Indicates the trigger threshold. The default value is 3. The value ranges from 0 to 20. **0** indicates that number-based balancing is disabled for the load balancing group.
Defaults	3
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**num-balance-group mode** *group-name*{ **radio-mode**| **ap-mode** }

Parameter Description	*group-name:* Indicates the name of a load balancing group.
Defaults	AP-based number balancing
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**num-balance-group enable** *group-name number*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *number*: indicates the trigger threshold. The default value is 3. The value ranges from 0 to 10. **0** indicates that number-based balancing is disabled for the load balancing group.
Defaults	3
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**num-balance-group del** *group-name ap-name*
Parameter Description	*group-name*: Indicates the name of a load balancing group. *ap-name*: Indicates the AP name.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**flow-balance-group flow** *group-name number*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *number*: indicates the trigger threshold. The unit is %. The default value is 5%. The value ranges from 0 to 1,000. **0** indicates that load balancing is disabled for the load balancing group. The traffic baseline is 10 Mbps by default.
Defaults	5%
Command Mode	AC configuration mode
Usage Guide	N/A

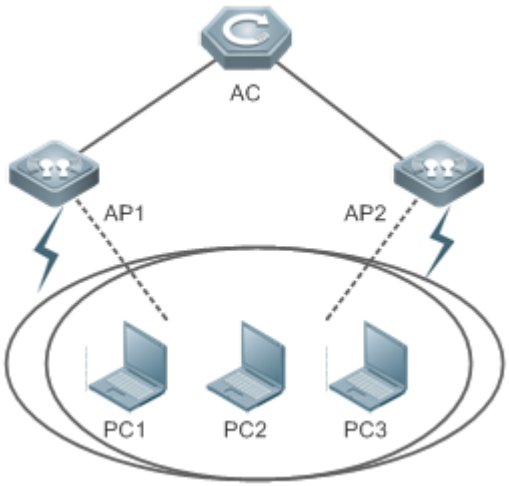
Command	**flow-balance-group radio-flow** *group-name*
Parameter Description	*group-name:* Indicates the name of a specified traffic balancing group that uses the traffic information uploaded by APs.
Defaults	Traffic information on the CAPWAP data channel is used on the AC.
Command Mode	AC configuration mode
Usage Guide	You can enable a traffic balancing group to use the traffic information uploaded by APs. In this way, the traffic

	balancing group can receive the traffic information periodically sent by APs for load balancing.

Command	**flow-balance-group enable** *group-name number*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *number*: Indicates the trigger threshold. The unit is %. The default value is 5%. The value ranges from 0 to 500. **0** indicates that load balancing is disabled for the load balancing group. The traffic baseline is 10 Mbps by default.
Defaults	5%
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**flow-balance-group del** *group-name ap-name*
Parameter Description	*group-name:* Indicates the name of a load balancing group. *ap-name:* Indicates the AP name.
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	N/A

Command	**flow-balance-group base** *number*
Parameter Description	*number*: Indicates that traffic baseline. The default value is 10 Mbps. The value ranges from 1 to 100.
Defaults	10 Mbps
Command Mode	AC configuration mode
Usage Guide	N/A



Command	**sta-balance num-limit enable**
Parameter Description	N/A
Defaults	The function is disabled.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Number balancing: Check whether the difference in the number of STAs associated with APs in the load balancing group is within the threshold.
- Traffic balancing: Check whether the difference in the traffic of APs in the load balancing group is within the threshold.

Configuration Example

Configuring Traffic-based Balancing

Scenario **Figure 1-6**	
Configuration Steps	● Create a load balancing group. ● Set the trigger threshold of this load balancing group to 1,000 Kbps. ● Add AP1 and AP2 to the load balancing group named **test-group.** (If two APs are added to the same load balancing group, PCs in this group can search the radio signals of both APs.)
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)#ac-controller AC(config-ac)#flow-balance-group create test-group AC(config-ac)#flow-balance-group flow test-group 10 AC(config-ac)#flow-balance-group add test-group AP1 AC(config-ac)#flow-balance-group add test-group AP2
Verification	● Check the configuration of the load balancing group.
AC	AC# show ac-config flow-balance summary Group State Enable Threshold Base mode AP NAME --- ----- --- --- ---- --- --- test-group UP 5*100kbps 10% 10 ap-mode(0) AP1, AP2

Common Errors

- N/A

1.4.4 Configuring Inter-Radio Load Balancing (by Number of STAs/Traffic/Ratio)

Configuration Effect

- Enable inter-radio load balancing on APs to balance the load among radios.
- Configure the load ratio of radios. Load is balanced among radios according to the ratio.

Notes

- This function is not applicable to the i-Share solution. Signals of different radios cover different areas. A STA may receive signals from one or several radios. In this case, the inter-radio load balancing function cannot be enabled.
- Load balancing is applicable only to STAs that are associated. Therefore, after STAs are disassociated, the traffic difference between APs or the STA quantity difference may exceed the threshold.
- If the radio that a STA attempts to associate with is different from the radio with the lowest load, load balancing is performed only when the AP reports that the STA is capable of multi-band operation. Otherwise, the 2.4 GHz STAs may fail to be associated with 2.4 GHz radios when no STA is associated with 5 GHz radio. The same applies to other radios.
- After the traffic balancing group is configured to use the traffic information uploaded by APs, APs must upload the traffic information to the AC at a regular interval because the traffic only exists on APs in local forwarding mode. During this interval, the traffic information on the AC does not change. At this time, if the traffic among APs is not balanced, STAs cannot be associated with APs with heavy traffic until the APs upload the traffic information to the AC.
- Configuration of load balancing parameters varies according to the inter-frequency and intra-frequency radios. When performing load balancing, the AC determines the load balancing parameter according to the target radio and the type of the radio associated with the STA and determines whether to associate the STA to the target radio
- For a specific AP, when load balancing is enabled in any of the **ap-config**, **ap-group**, and **ap-config** all modes, load balancing is enabled on this AP. If the load balancing configurations in the three modes are different, the configurations take effect in descending order: **ap-config** mode, **ap-group** mode, **ap-config all** mode.
- When inter-radio load balancing is enabled, the association attempt of the same STA will be denied for at most twice within five minutes. If the STA is still associated with a radio with a heavy load for the third time, the association is allowed. Therefore, the effect of inter-radio load balancing is related to the actual STA behaviors.

Configuration Steps

↘ Enabling Inter-radio Traffic Balancing

- (Mandatory). The configuration is performed on the AC. After the function is enabled, traffic is balanced whenever possible among different radios of the same AP.
- This function can be enabled for a single AP, all APs in an AP group, or all APs (configured in **ap-config all** mode).

Command	**inter-radio-balance flow-balance enable**
Parameter Description	N/A
Defaults	Inter-radio traffic balancing is disabled.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	N/A

↘ Enabling Inter-radio Number Balancing

- (Mandatory) The configuration is performed on the AC. After the function is enabled, the number of STAs is balanced whenever possible among different radios of the same AP.
- This function can be enabled for a single AP, all APs in an AP group, or all APs (configured **in ap-config all** mode).

Command	**inter-radio-balance num-balance enable**
Parameter Description	N/A
Defaults	Inter-radio number balancing is disabled.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	N/A

Configuring Inter-radio Load Balancing Parameters

- (Optional) The configuration is performed on the AC. The configuration of parameters can be changed based on actual requirements of network optimization.
- Run the **inter-radio-balance flow-balance dual-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for traffic balancing among inter-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.
- Run the **inter-radio-balance flow-balance same-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for traffic balancing among intra-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.
- Run the **inter-radio-balance num-balance dual-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for number balancing among inter-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.
- Run the **inter-radio-balance num-balance same-band enable-load** *en-num* **threshold** *thrs-num* command to configure the trigger threshold and the load threshold for number balancing among intra-frequency radios. A smaller trigger threshold indicates that it is easier to enable load balancing. A smaller load threshold indicates that the load is better balanced.

Command	**inter-radio-balance flow-balance dual-band enable-load** *en-num* **threshold** *thrs-num*
Parameter Description	*en-num*: Indicates the trigger threshold. The unit is kbps. The value ranges from 1 to 1,000. *thrs-num*: Indicates the load threshold. The unit is kbps. The value ranges from 1 to 1,000.
Defaults	Both the trigger threshold and the load threshold are 10.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	N/A

Command	**inter-radio-balance flow-balance same-band enable-load***e n-num* **threshold** *thrs-num*
Parameter Description	*en-num*: Indicates the trigger threshold. The unit is 100 kbps. The value ranges from 1 to 1,000. *thrs-num*: Indicates the load threshold. The unit is 100 kbps. The value ranges from 1 to 1,000.
Defaults	Both the trigger threshold and the load threshold are 5.

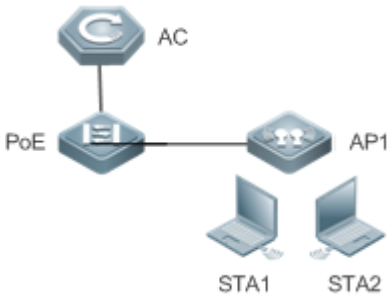
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	N/A

Command	**inter-radio-balance num-balance dual-band enable-load** *en-num* **threshold** *thrs-num*
Parameter Description	*en-num*: Indicates the trigger threshold. The value ranges from 1 to100. *thrs-num*: Indicates the load threshold. The value ranges from 1 to 100.
Defaults	The trigger threshold value is 20 and the load threshold is 8.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	N/A

Command	**inter-radio-balance num-balance same-band enable-load** *en-num* **threshold** *thrs-num*
Parameter Description	*en-num*: Indicates the trigger threshold. The value ranges from 1 to 100. *thrs-num*: Indicates the load threshold. The value ranges from 1 to 100.
Defaults	The trigger threshold and the load threshold are 20 and 6 respectively.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	N/A

Configuring the Load Ratio of Radios

- (Optional) The configuration is performed on the AC. After the load ratio is configured, load is balanced to different radios of the same AP based on the ratio.
- The load ratio can be configured for a single AP, all APs in an AP group, or all APs (configured in **ap-configure all** mode).



Command	**inter-radio-balance radio** *radio-id* **weight** *weight-num*
Parameter Description	N/A
Defaults	The radio weight is 100, and load is balanced between radios based on the 1:1 ratio by default.
Command Mode	AP configuration mode and AP group configuration mode
Usage Guide	N/A

Verification

- Number balancing: Run the **show ap-config summary** command to check whether the difference in the number of STAs between radios of the AP where load balancing is within the threshold.
- Traffic balancing: Run the **show ac-config client** command to check whether the traffic difference between radios of the AP where load balancing is enabled is within the threshold.

Configuration Example

Enabling Inter-radio Number Balancing on All APs in the Default AP Group

Scenario **Figure 1-7**	
Configuration Steps	● Enter the default AP group configuration mode. ● Enable inter-radio number balancing.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)#ap-group default AC(config-group)#inter-radio-balance num-balance enable
Verification	● Run the **show run** command to display the configuration.
AC	AC# show run | begin ap-group default ap-group default inter-radio-balance num-balance enable

Common Errors

- N/A

1.4.5 Configuring Inter-Radio Load Balancing (by Bandwidth Resources)

Configuration Effect

Guide STAs to access radios with more bandwidth resources for inter-radio load balancing.

Notes

- When the inter-radio load balancing feature and the 5G first feature are both enabled, and the SSID signal is hidden by the load balancing feature because the 5 GHz radio has fewer resources, new STAs accessing the radio will be rejected by the 5G first feature if they support 5G.
- If the bandwidth resource weight of the radio that STAs access is still lower than other radios after the resource weight is amplified through the amplification factor, the SSID of the radio is hidden to prevent users from viewing it.
- Only resource weights of radios on one AP can be compared.
- An SSID can be hidden based on the bandwidth resource weight only when the same SSID is configured on different radios, so that user services are not affected. For example, if SSID4 exists on radio 1 and not on radio 2, SSID4 will not be hidden even if the resource weight of radio 1 is far lower than that of radio 2, ensuring that users can always access SSID4 in the wireless environment.

Configuration Steps

Enabling Inter-Radio Load Balancing

- Optional

Command	**ap-inter-balance enable**
Parameter Description	N/A
Defaults	The feature is disabled.
Command Mode	AP group configuration mode, AP configuration mode, and all AP configuration mode
Usage Guide	N/A

Configuring the Bandwidth Resource Threshold for Triggering Inter-Radio Load Balancing Guidance

- Optional

Command	**ap-inter-balance chan-wid-thrd** { **20** | **40** | **80** | **160** } **thrd-hold** *thrd-num*
Parameter Description	**20**: Indicates the lower limit of average STA bandwidth resources if the radio bandwidth is 20 MHz. **40**: Indicates the lower limit of average STA bandwidth resources if the radio bandwidth is 40 MHz. **80**: Indicates the lower limit of average STA bandwidth resources if the radio bandwidth is 80 MHz. **160**: Indicates the lower limit of average STA bandwidth resources if the radio bandwidth is 160 MHz. *thrd-num*: Indicates the lower limit of average bandwidth resources occupied by each STA accessing the radio. If the occupied resources are lower than this threshold, inter-radio load balancing guidance is triggered. The value range is from 1 to 320.
Defaults	Default lower limit of average STA bandwidth resources, *thrd-num*, depends on the bandwidth configuration of the radio. ● If the default bandwidth is 20 MHz, the default lower limit of average STA bandwidth resources is 4. ● If the default bandwidth is 40 MHz, the default lower limit of average STA bandwidth resources is 8. ● If the default bandwidth is 80 MHz, the default lower limit of average STA bandwidth resources is 8. ● If the default bandwidth is 160 MHz, the default lower limit of average STA bandwidth resources is 16.
Command Mode	AP group configuration mode, AP configuration mode, and all AP configuration mode
Usage Guide	N/A

Configuring the Bandwidth Resource Weight Amplification Factor of the STA-Accessed Radio

- Optional
- When a STA accesses the AP, the radio where the SSID that the STA connects to is located is the STA-accessed radio, while other radios on the AP are non-STA-accessed radios.

Command	**ap-inter-balance weight-scale** *scale-num*
Parameter Description	*scale-num*: Indicates the factor based on which the resource weight of the STA-accessed radio is amplified during resource weight calculation. For example, 50 indicates that the weight is amplified by 50%. The value range is from 1 to 1000.
Defaults	The default value is 50, that is, weight × 1.5.
Command	AP group configuration mode, AP configuration mode, and all AP configuration mode

Mode	
Usage Guide	• Calculated resource weights of different radios may differ greatly. Therefore, resource weights of STA-accessed radios are amplified based on a specific ratio to reduce the differences, preventing frequent SSID hiding before the resource lower limit is reached. • The larger resource weight amplification factor, the less chance of SSID hiding and load balancing guidance.

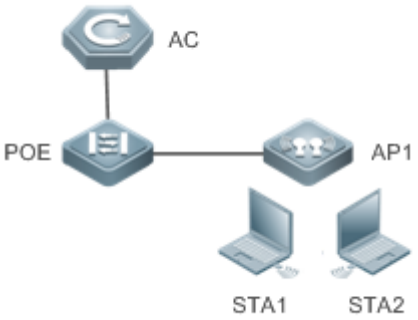
Configuring the Bandwidth Resource Weight Amplification Factor of Non-STA-Accessed Radios

- Optional
- When a STA accesses the AP, the radio where the SSID that the STA connects to is located is the STA-accessed radio, while other radios on the AP are non-STA-accessed radios.

Command	**ap-inter-balance low-weight-scale** *scale-num*
Parameter Description	*scale-num*: Indicates the factor based on which the resource weight of the non-STA-accessed radio is amplified during resource weight calculation. For example, 50 indicates that the weight is amplified by 50%. The value range is from 1 to 1000.
Defaults	The default value is 0.
Command Mode	AP group configuration mode, AP configuration mode, and all AP configuration mode
Usage Guide	Resource weights of radios are amplified based on this factor to reduce resource weight differences among radios, preventing frequent SSID hiding. If this factor is larger, hidden SSIDs are unhidden and wireless service is restored earlier.

Configuring the Frequency Limit of the AC Sending Messages to the Hidden SSID

- Optional
- Compare the resource weights of different radios on the AP. If the resource weight of the STA-accessed radio is still lower than those of other radios after the weight is amplified based on the amplification factor, the SSID is hidden.



Command	**ap-inter-balance hide-limit count** *count-num* **lifetime** *time*
Parameter Description	*count-num*: Indicates the maximum number of times that the AC sends messages to the hidden SSID within one cycle. The value range is from 1 to 300. *time*: Indicates the duration of one cycle, in seconds. The value range is from 3 to 300.
Defaults	The default value of *count-num* is 30, and the default value of *time* is 120.
Command Mode	AP group configuration mode, AP configuration mode, and all AP configuration mode
Usage Guide	N/A

Verification

Run the **show ap-config running** *ap-name* command to check whether the configuration is successful.

Configuration Example

Configuring Load Balancing

Scenario **Figure 1-1**	
Configuration Steps	5. Enable inter-radio load balancing for AP1. 6. Set the bandwidth of the radio to 80 MHz and the lower limit of average STA bandwidth resources to 10 MHz. 7. Set the resource weight amplification factor to 30 for STA-accessed radios and non-STA-accessed radios. 8. Configure the AC to send messages to the hidden SSID 30 times at maximum within 150s.

AC	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# ap-inter-balance enable`
	`Hostname(config-ap)# ap-inter-balance chan-wid-thrd 80 thrd-hold 10`
	`Hostname(config-ap)# ap-inter-balance weight-scale 30`
	`Hostname(config-ap)# ap-inter-balance low-weight-scale 30`
	`Hostname(config-ap)# ap-inter-balance hide-limit count 30 lifetime 150`

Verification	View the configuration.

AC	`Hostname# show ap-config running`
	` ap-inter-balance enable`
	` ap-inter-balance chan-wid-thrd 80 thrd-hold 10`
	` ap-inter-balance weight-scale 30`
	` ap-inter-balance low-weight-scale 30`
	` ap-inter-balance hide-limit count 30 lifetime 150`
	`!`

Common Errors

- N/A

1.4.6 Configuring Association Control

Configuration Effect

- Secondary STAs must be associated with APs in the same group as the primary STA when being associated.

Notes

- When a package is deleted, all its related configurations are deleted as well. If some STAs in this package are currently associated, all these STAs will be disassociated.
- A package can only be configured with one primary STA. If the information about the primary STA in the package is configured for multiple times, the latest configuration prevails.
- When a primary STA is deleted from a package, the primary STA and all secondary STAs in this package may be disassociated.
- When a secondary STA is deleted from a package, this secondary STA may be disassociated.
- The association control domain name cannot be duplicated. Otherwise, an error will be prompted. In addition, if an association control domain is deleted, all configurations related to this domain will be deleted. Consequently, STAs in the package associated with this control domain may be disassociated.
- When the AP information in an association control domain is deleted, STAs in the package associated with this AP be disassociated.

Configuration Steps

Configuring a Package

- (Mandatory) The configuration is performed on an AC.
- The primary and secondary STA information can be configured only after a package is configured.

Command	**package** *pkg-name*
Parameter Description	*pkg-name*: Indicates the name of a package. The package name is a string of 1 to 32 characters.
Defaults	No package is configured.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Primary and Secondary STAs in a Package

- (Mandatory) The configuration is performed on an AC.
- Run the **primary-sta** command to configure the primary STA. Only one primary STA can be configured. The secondary STAs will be associated with APs in the same group as the primary STA.
- Run the **secondary-sta** command to configure a secondary STA. After the secondary STA is configured, the secondary STA will be associated with an AP in the same group as the primary STA.

Command	**primary-sta** *mac-address*
Parameter Description	*mac-address*: Indicates the MAC address of the STA.
Defaults	No primary STA is configured.
Command Mode	Package configuration mode
Usage Guide	N/A

Command	**secondary-sta** *mac-address*

Parameter Description	*mac-address*: indicates the MAC address of the STA.
Defaults	No secondary STA is configured.
Command Mode	Package configuration mode
Usage Guide	N/A

Configuring an Association Control Domain

- (Mandatory) The configuration is performed on an AC.
- Configure an association control domain.
- APs can be added to an association control domain only after this association control domain is configured.

Command	**control-zone** *czone-name*
Parameter Description	*czone-name*: Indicates the name of an association control domain. The name is a string of 1 to 64 characters.
Defaults	No association control domain is configured.
Command Mode	Global configuration mode
Usage Guide	N/A

Adding an AP to an Association Control Domain

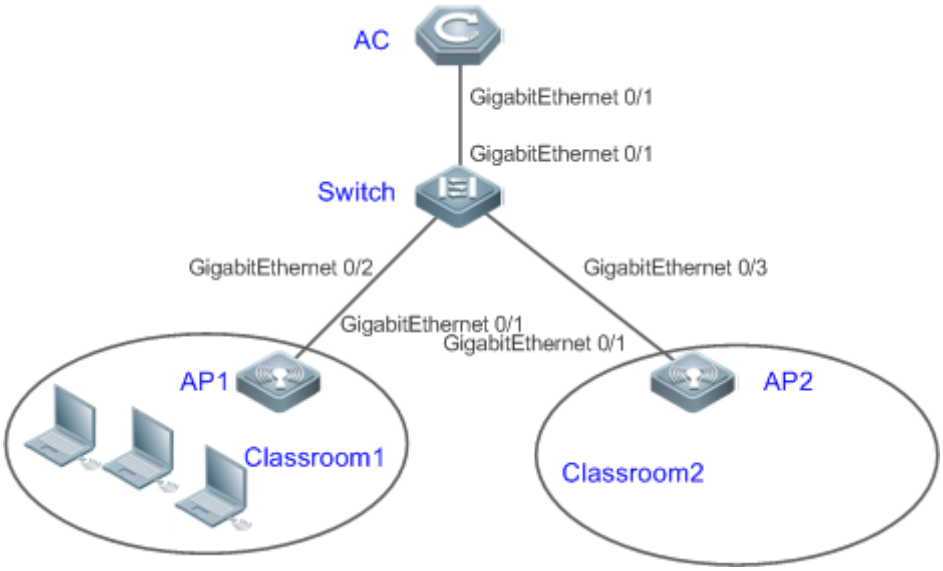
- (Mandatory) The configuration is performed on an AC.
- Add an AP to an association control domain.
- Association control can be performed on only APs that are added to the association control domain.

Command	**ap** *WORD*
Parameter Description	*WORD*: Indicates the name of an AP. The name is a string of 1 to 64 characters.
Defaults	No AP is added to an association control domain.
Command Mode	Association control domain configuration mode
Usage Guide	N/A

Enabling Association Control

- (Mandatory) The configuration is performed on an AC. The **assoc-control** command must be used to enable association control.
- Enable association control.

Command	**assoc-control**
Parameter Description	N/A
Defaults	Association control is disabled.



Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Verify that secondary STAs can be associated with APs in the same group as the primary STA.

Configuration Example

Configuring the E-bag in Fit AP Architecture.

Scenario **Figure 1-8**	
Configuration Steps	● Configure packages and related primary STAs and secondary STAs. ● Configure association control domains and related APs. ● Enable association control.
AC	AC#configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# package Cart 1 AC(config-package)#primary-sta 00d0.f800.0001 AC(config-package)#secondary-sta 00d0.f800.0002 AC(config-package)#secondary-sta 00d0.f800.0003 AC(config-package)#exit AC(config)# control-zone Classroom 1 AC(config-czone)#apAP1 AC(config-czone)#exit AC(config)# control-zone Classroom 2 AC(config-czone)# apAP2 AC(config-czone)#exit

	AC(config)#assoc-control
Verification	● Display the association control running state. ● Display the package configuration. ● Display the association control domain configuration.
AC	AC#show assoc-control Association control is enabled. AC# show package total package num : 1 ========= Cart 1 ========= primary STA : 00d0.f800.0001 secondary STA num : 2 00d0.f800.0002 00d0.f800.0003 AC# show control-zone control zone num : 2 control-zoneAP ------------ ---------- Classroom 1 AP1 00d0.f800.889e Classroom 2 AP2 00d0.f800.889f

Common Errors

- N/A

1.4.7 Configuring STA Management

Configuration Effect

- STAs are disassociated if no traffic is detected on the STAs within the specified time.

Notes

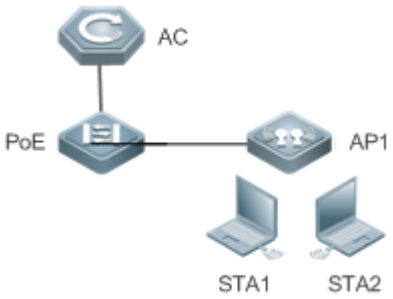
- N/A

Configuration Steps

↘ Configuring the STA Aging Time

- (Optional) The configuration is performed on an AC.
- A shorter aging time indicates that a STA without traffic can be detected and disassociated in a faster manner.

Command	**sta-idle-timeout** *timer-num*
Parameter Description	*timer-num*: Indicates the aging time, in seconds. The value ranges from 60 to 64,000.



Defaults	300s
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Check whether the STA aging time is successfully configured.

Configuration Example

Configuring the STA Aging Time

Scenario **Figure 1-9**	
Configuration Steps	● Configure the STA aging time.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ap-config ap1 AC(config-ap)# sta-idle-timeout 15
Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the configuration.
AC	AC# show ap-config running ap-config ap1 sta-idle-timeout 15 !

Common Errors

- N/A

1.4.8 Configuring STA Informational Syslog Suppression

Configuration Effect

- Even though STAs are frequently associated or disassociated, the number of informational syslogs output per second does not exceed the limit.

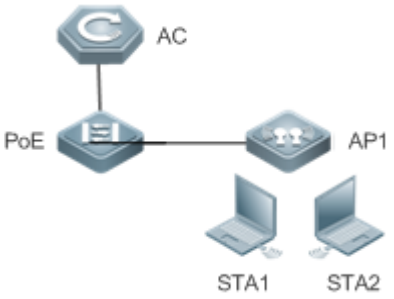
Notes

- N/A

Configuration Steps

Configuring the Syslog Suppression Rate

- (Optional) The configuration is performed on the AC.
- Configure the syslog suppression rate. A larger rate indicates that more syslogs can be output per second.



Command	**sta-logging rate-limit** *limit-num*
Parameter Description	*limit-num*: Indicates the rate, in entries per seconds. The value ranges from 0 to 10,000.
Defaults	Less than five syslogs are output per second, that is, the maximum syslog output rate is 5 entries per second.
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to check whether the syslog suppression rate is successfully configured.

Configuration Example

Configuring STA Informational Syslog Suppression

Scenario **Figure 1-10**	
Configuration Steps	● Configure STA informational syslog suppression.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ac-controller AC(config-ac)# sta-logging rate-limit 50
Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the configuration.
AC	AC# show running ac-controller sta-logging rate-limit 50 !

Common Errors

- N/A

1.4.9 Configuring Intelligent SSID Hiding

Configuration Effect

- When the number of STAs on an AP or a radio reaches the upper limit, new STAs cannot detect the SSID.

Notes

- This function takes effect only when both the AC and AP versions support this function.

Configuration Steps

↘ Enabling Intelligent SSID Hiding

- (Optional) The configuration is performed on an AC.
- Enable intelligent SSID hiding.

Command	**hide-ssid sta-reach-limit** [**radio** { **2.4g** | **5g** | **6g** }]
Parameter Description	**radio**: Indicates a specific radio on which intelligent SSID hiding is enabled. If this parameter is not specified, intelligent SSID hiding is enabled on all radios. **2.4g**: Indicates that intelligent SSID hiding is enabled on the 2.4 GHz radio.

	5g: Indicates that intelligent SSID hiding is enabled on the 5 GHz radio. **6g**: Indicates that intelligent SSID hiding is enabled on the 6 GHz radio.
Defaults	Intelligent SSID hiding is disabled.
Command Mode	AP configuration mode
Usage Guide	After intelligent SSID hiding is enabled and the numbers of STAs on all APs in an area reach the upper limit, new STAs cannot detect the SSID in this area. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Verification

- Run the **show running or show ap-config running** command to check the configuration.

Configuration Example

Enabling the Intelligent SSID Hiding Function

Scenario **Figure 1-2**	
Configuration Steps	● Enable intelligent SSID hiding.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# ap-config AP1`
	`AC(config-ap)# hide-ssid sta-reach-limit`

Verification	● After the CAPWAP tunnel is established between an AP and an AC, check the configuration.

AC	`AC# show ap-config running AP1`
	`ac-config AP1`
	` hide-ssid sta-reach-limit`
	`!`

Common Errors

The AC version supports the intelligent SSID hiding function but the AP version does not.

1.4.10 Configuring STA Jitter Prevention

Configuration Effect

- When STA jitter prevention is enabled for a WLAN and a STA is disassociated from the WLAN, the AC retains a STA entry for a period of time before forcing the STA to go offline.

Notes

- When an AC or authentication server proactively forces a STA to go offline, the STA jitter prevention function does not take effect.

Configuration Steps

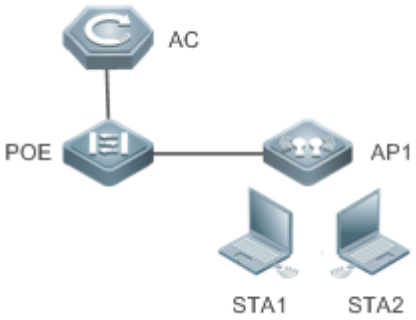
↘ Enabling STA Jitter Prevention

- (Mandatory) Enable STA jitter prevention on the AC.

Command	**prevent-jitter enable**
Parameter Description	N/A
Defaults	STA jitter prevention is disabled.
Command Mode	WLAN configuration mode
Usage Guide	When STA jitter prevention is enabled for a WLAN and a STA is disassociated from the WLAN, the AC retains a STA entry for a period of time (60s by default) before forcing the STA to go offline.

↘ Configuring the STA Jitter Prevention Time

- (Optional) Configure the STA jitter prevention time on the AC.



Command	**prevent-jitter time** *keep-time*
Parameter Description	*keep-time*: indicates the STA jitter prevention time, in seconds. The value ranges from 1 to 8,6400.
Defaults	60s
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run the **show running** or **show ap-config running** command to check the configuration.

Configuration Example

↘ Enabling STA Jitter Prevention

Scenario **Figure 1-11**	
Configuration Steps	● Enable STA jitter prevention.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# wlan-config 1`
	`AC(config-wlan)# prevent-jitter enable`

Verification	● Check the configuration.

AC	`AC# show running-config`
	`wlan-config 1 SSID`
	` prevent-jitter enable`
	`!`

Common Errors

- N/A

1.4.11 Configuring the Syslog Format upon STA Association

Configuration Effect

- When this command is configured, the syslog output will be in the configured format when a STA goes online and obtains an IP address.

Notes

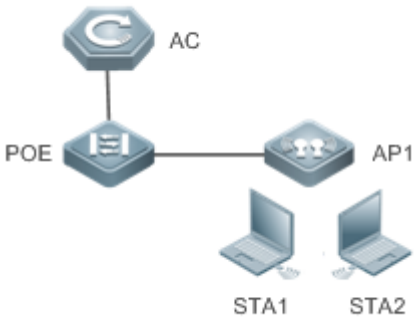
- N/A

Configuration Steps

↘ Configuring the Syslog Format

- (Mandatory) The configuration is performed on an AC.

Command	**sta-logging mac-fmt-line**



Parameter Description	N/A
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	The default syslog format for obtaining IP address when a STA comes online is: User Online, MAC Address 0001.2fe1.5022, AP Name *name,* base radio MAC: 0074.9c5b.288a, IP address 192.168.1.1, SSID: test. The syslog format after the command is configured is: CLIENT_ONLINE: UserIP=192.168.1.1, UserMAC=00-01-2F-E1-50-22, APMAC=00-74-9C-5B-28-85.

Verification

- Run the **show running** command to display the configuration.

Configuration Example

Configuring the Syslog Format upon STA Association

Scenario Figure 1-3	
Configuration Steps	● Configure the syslog format when a STA goes online.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ac-controller AC(config-ac)# sta-logging mac-fmt-line
Verification	● Display the configuration.
AC	AC# show running ac-controller sta-logging mac-fmt-line !

Common Errors

- N/A

1.4.12 Enabling Fast STA Association

Configuration Effect

- When the fast association feature is enabled for a STA, the AC does not need to wait for the AP to add the STA response and can directly process the next association request when the STA goes online.

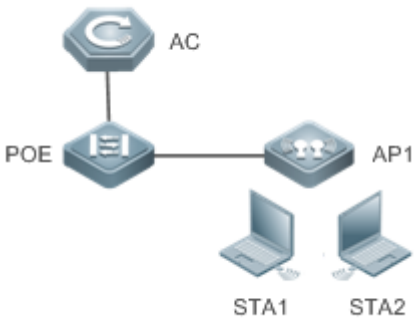
Notes

- N/A

Configuration Steps

Configuring Fast Association

- (Optional) The configuration is performed on the AC.



Command	**sta-behaviour fast-assoc**
Parameter Description	N/A
Defaults	Disabled
Command Mode	AC configuration mode
Usage Guide	By default, when STA goes online, the AC will wait for the response packet from AP before processing the next STA's association request packet. After this command is configured, there is no need to wait, avoiding message blocking in high-concurrency situations.

Verification

- Run the **show running** command to check the configuration.

Configuration Example

Enabling Fast Association

Scenario **Figure 1-4**	
Configuration Steps	● Enable fast association.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z.

	AC(config)# ac-controller AC(config-ac)# sta-behaviour fast-assoc
Verification	● Display the configuration.
AC	AC# show running ac-controller sta-behaviour fast-assoc !

Common Errors

- N/A

1.4.13 Enabling IP Address Detection

Configuration Effect

- When IP address detection is enabled, a STA will be disconnected if it fails to obtain an IP address.

Notes

- N/A

Configuration Steps

↘ Configuring IP Address Detection

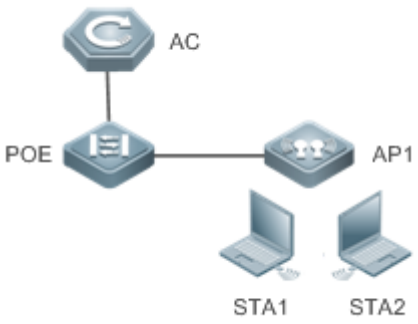
- (Mandatory) The configuration is performed on an AC.

Command	**sta-behaviour ip-check enable**
Parameter Description	N/A
Defaults	Enabled
Command Mode	AC configuration mode
Usage Guide	After configuration, IP address detection will be enabled. A STA will be disconnected if it doesn't have an IP address.

- (Optional) The configuration is performed on an AC.

Command	**sta-behaviour ip-check delay** *time*
Parameter Description	*time*: Indicates the delay, in seconds. The minimum value is 1s and the maximum value is 60s.
Defaults	30s
Command Mode	AC configuration mode
Usage Guide	After configuration, IP address detection will be delayed for the specified time. If the delay for IP address detection is set to 0, IP address detection is disabled.

- (Optional) The configuration is performed on an AC.



Command	**sta-behaviour ip-check sulk** *time*
Parameter Description	*time*: Indicates the quiet period, in seconds. The minimum value is 0s and the maximum value is 86,400s.
Defaults	600s
Command Mode	AC configuration mode
Usage Guide	If a STA is disconnected due to IP address detection, IP address detection will not be performed during the quiet period.

Verification

- Run the **show running** command to display the configuration.

Configuration Example

Enabling IP Address Detection

Scenario **Figure 1-5**	
Configuration Steps	● Enable IP address detection. Set the delay for IP address detection of STAs to 20s and the quiet period to 300s within which IP address detection is not performed for a STA after it is disconnected due to IP address detection.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ac-controller AC(config-ac)# sta-behaviour ip-check enable AC(config-ac)# sta-behaviour ip-check delay 20 AC(config-ac)# sta-behaviour ip-check sulk 300
Verification	● Display the configuration.
AC	AC# show running sta-behaviour ip-check delay 20 sta-behaviour ip-check sulk 300 !

Common Errors

- N/A

1.4.14 Enabling DHCP Proxy

Configuration Effect

- After this command is configured, the AC will initiate DHCP Discover packets, interact with the server, and generate snooping entries on the AC on behalf of a STA, eliminating the need for the STA to participate in this process.

Notes

- N/A

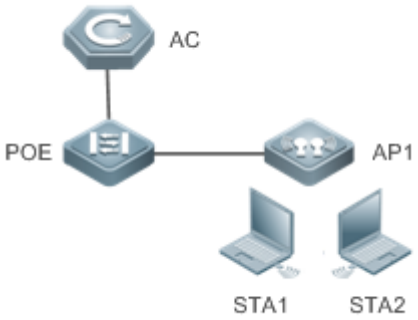
Configuration Steps

↘ Enabling DHCP Proxy

- (Optional) The configuration is performed on an AC.

Command	**sta-behaviour dhcp-proxy enable**
Parameter Description	N/A
Defaults	Disabled
Command Mode	AC configuration mode
Usage Guide	After this command is configured, DHCP proxy will be enabled.

- (Optional) The configuration is performed on an AC.



Command	**sta-behaviour dhcp-proxy delay** *time*
Parameter Description	*time*: Indicates the delay, in seconds. The minimum value is 1s and the maximum value is 60s.
Defaults	5s
Command Mode	AC configuration mode
Usage Guide	After this command is configured, DHCP proxy will be delayed for the specified time.

Verification

- Run the **show running** command to check the configuration.

Configuration Example

↘ Enabling DHCP Proxy

Scenario **Figure 1-6**	
Configuration Steps	● Enable DHCP proxy and set the delay to 20s.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# ac-controller AC(config-ac)# sta-behaviour dhcp-proxy enable AC(config-ac)# sta-behaviour dhcp-proxy delay 20
Verification	● Display the configuration.
AC	AC# show running sta-behaviour dhcp-proxy enable sta-behaviour dhcp-proxy delay 20 !

Common Errors

- N/A

1.4.15 Configuring Wireless STA Management

Configuration Effect

- Delete the MAC address of a specified wireless STA.

Notes

- N/A

Configuration Steps

↘ Deleting the MAC Address of a Specified Wireless STA

- (Optional) The configuration is performed on an AC.

Command	**client-kick** *sta-mac*
Parameter	*sta-mac*: Indicates the MAC address of a wireless STA.

Description	
Defaults	N/A
Command Mode	AC configuration mode
Usage Guide	N/A

Verification

N/A

Configuration Example

Deleting the MAC Address of a Specified Wireless STA

Configuration Steps	The following example deletes the wireless STA with the MAC address aaaa.bbbb.cccc.
	`Hostname(config)# ac-controller` `Hostname(config-ac)# client-kick aaaaa.bbbbb.ccccc`

Common Errors

- N/A

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show ac-config client [**by-ap-name** | **802.11a** | **802.11b** | **802.11n** | **802.11g** | **802.11ac** | **802.11ax** | **other**]	Displays the information about all STAs connected to the AC.
show ac-config client detail *mac-address*	Displays the detailed information about a specified STA.
show ac-config client statistic	Displays the statistics of all STAs.
show ac-config flow-balance summary	Displays the detailed configuration of the traffic-based balancing group.
show ac-config num-balance summary	Displays the detailed configuration of the number-based balancing group.
show assoc-control	Displays the status of the association control function.
show control-zone [**summary** | *czone-name*]	Displays the association control domain configuration.
show package [*pkt-name*]	Displays the package configuration.
show sta-blacklist	Displays the STAs in the blocklist.
show ac-config client hot-backup	Displays the backup information of a STA.

1 Configuring VIP-FIRST

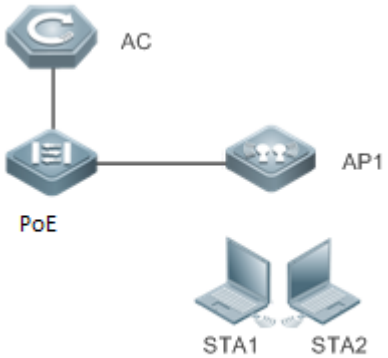
1.1 Overview

VIP-FIRST is a function used to improve the wireless user experience, including preferred access and independent rate limiting for VIP users.

Preferred access for VIP users ensures that VIP users can access the network at any time without being affected by the STA-LIMIT function. When a wireless user accesses the network, the MAC address of the wireless user is used to determine whether it is a VIP user.

Independent rate limiting for VIP users indicates that an independent rate limit can be configured for VIP users to prevent them being affected by the global rate limit.

1.2 Applications



Application	Description
VIP-FIRST in Fit AP Networking	Fit AP networking is adopted, including at least one AC and one AP.

1.2.1 VIP-FIRST in Fit AP Networking

Scenarios

On a wireless network, an AC is deployed with preferred access and independent rate limiting enabled for VIP users. The VIP user list is uploaded to a specific directory on the AC, and the **import** command is run to advertise the AC to parse the VIP user list.

Figure 1-1

Remarks	AC: Indicates a wireless access controller. PoE: Indicates a switch used as the gateway of the AP. AP: Indicates a wireless access point. STA1 and STA2: Indicates two wireless clients.

Deployment

- Enable the VIP-FIRST function on the AC.

1.3 Features

Basic Concepts

Preferred Access for VIP Users

In scenarios where a large number of users access the network, good user experience cannot be guaranteed for each user. If the number of users on the AC, WLAN, AP, or radio exceeds the limit specified by the STA-LIMIT function, preferred access for VIP users allows VIP users to access the network and disconnects non-VIP users with poor communication quality.

Independent Rate Limiting for VIP Users

In scenarios where a large number of users access the network, good user experience cannot be guaranteed for each user. In addition to the global rate limit, an independent rate limit is configured for VIP users to ensure that the bandwidth of VIP users is higher than that of non-AP users.

Overview

Feature	Description
Preferred Access for VIP Users	Ensures that VIP users can access the network at any time.
Independent Rate Limiting for VIP Users	Ensures that the bandwidth of VIP users is higher than that of non-VIP users.

1.3.1 Preferred Access for VIP Users

Preferred access for VIP users ensures that VIP users can access the network anytime without being affected by the STA-LIMIT function.

Working Principle

If the number of users on the AC, WLAN, AP, or radio exceeds the limit specified by the STA-LIMIT function, non-VIP users with poor communication quality will be disconnected to ensure that VIP users can access the network.

1.3.2 Independent Rate Limiting for VIP Users

In addition to the global rate limit, an independent rate limit is configured for VIP users to ensure that the bandwidth of VIP users is higher than that of non-VIP users.

Working Principle

When the global rate limit is configured, a higher independent rate limit is configured for VIP users.

1.4 Configuration

Configuration	Description and Command	
Configuring VIP User Parsing or Deletion	⚠ (Mandatory) It is used to advertise the AC to parse the VIP user list.	
	vip-first import	Advertises the AC to parse the VIP user list.
	⚠ (Optional) It is used to advertise the AC to delete the VIP user list.	
	vip-first clear	Clears the VIP user list from the AC.
Configuring Preferred Access for VIP Users	⚠ (Mandatory) It is used to enable preferred access for VIP users.	
	vip-first prior-assoc	Enables preferred access for VIP users on the AC.
Common Errors N/A	⚠ (Mandatory) It is used to enable independent rate limiting for VIP users.	
Configuring Independent Rate Limiting for VIP Users	**vip-first rate-limit**	Configures the uplink and downlink rate limits for VIP users on the AC.

1.4.1 Configuring VIP User Parsing or Deletion

Configuration Effect

- Advertise the AC to parse or delete the VIP user list.

Notes

- Upload the VIP user list file to the **flash** directory and then run the **import** command to advertise the AC to parse the VIP user list. It takes several to dozens of seconds for the AC to parse the VIP user list.
- The VIP user list file is named **vip_user_list.txt**.
- The **clear** command will delete VIP users and the VIP user list file cached on the AC.
- The VIP user parsing or deletion command is not saved.

Configuration Steps

↘ **Advertising the AC to Parse the VIP User List**

- Mandatory.

- Run the **vip-first import** command in global configuration mode on the AC.

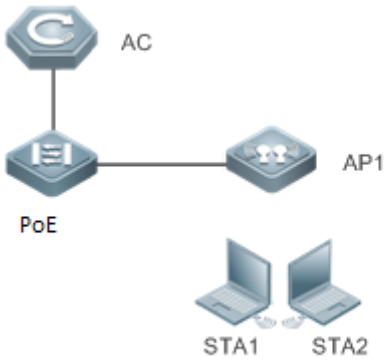
Command	vip-first import
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show vip-first user** command to check whether a user is a VIP user.

↘ Advertising the AC to Delete the VIP User List

- Optional.
- Run the **vip-first clear** command in global configuration mode on the AC.

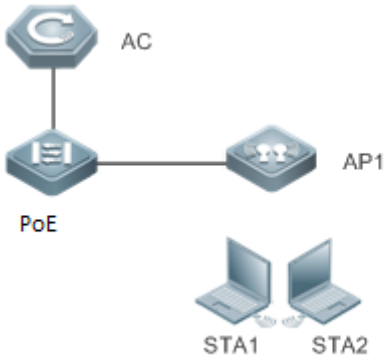


Command	vip-first clear
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **dir** command to check whether the **vip_user_list.txt** file exists.

Configuration Example



↘ Advertising the AC to Parse the VIP User List

Scenario **Figure 1-2**	
Configuration Steps	● Advertise the AC to parse the VIP user list in global configuration mode.
AC	`Hostname#configure terminal` `Hostname(config)# vip-first import`
Verification	Run the **show vip-first user** command to display configuration.

AC	`AC_20_3F#show vip-first user 0000.0000.0001`
	`STA_MAC YES/NO`
	`------------ ------`
	`0000.0000.0001 YES`

Configuration Example

Deleting the VIP User List

Scenario **Figure 1-3**	
Configuration Steps	● Advertise the AC to delete the VIP user list in global configuration mode.
AC	`Hostname#configure terminal` `Hostname(config)# vip-first clear`
Verification	Check whether the **vip_user_list.txt** file exists in the **flash** directory.

AC	AC_20_3F# dir Number Properties Size Time Name ------ ---------- ------ ------------------------ -------------------- 1 drwx 160B Tue Apr 25 08:39:38 2017 dev 2 drwx 160B Thu Nov 24 18:06:41 2016 rep 3 drwx 224B Thu Nov 24 18:06:42 2016 var

Common Errors

- The **vip-first import** command is run to advertise the AC to parse the VIP user list before the **vip_user_list.txt** file is uploaded to the AC.

1.4.2 Configuring Preferred Access for VIP Users

Configuration Effect

- Enable VIP users to access the network anytime without being affected by the STA-LIMIT function.

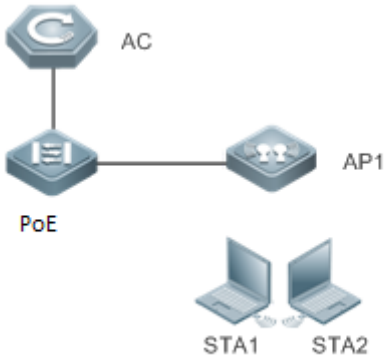
Notes

- The function can be configured only in global configuration mode on the AC.

Configuration Steps

↘ Enabling Preferred Access for VIP Users

- Mandatory.
- Run the **vip-first prior-assoc** command in global configuration mode on the AC.
- Enable preferred access for VIP users to ensure that VIP users can access the network anytime without being affected by the STA-LIMIT function.



Command	**vip-first prior-assoc**
Parameter Description	N/A
Defaults	Preferred access for VIP users is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running-config** command to display configuration.

Configuration Example

Enabling Preferred Access for VIP Users

Scenario **Figure 1-4**	
Configuration Steps	• Enable preferred access for VIP users in global configuration mode on the AC.
AC	Hostname#configure terminal Hostname(config)# vip-first prior-assoc
Verification	Run the **show running-config** command to display configuration.
AC	Hostname# show ap-config running ! vip-first prior-assoc!

Common Errors

- N/A

1.4.3 Configuring Independent Rate Limiting for VIP Users

Configuration Effect

- Ensure that the bandwidth of VIP users is higher than that of non-VIP users.

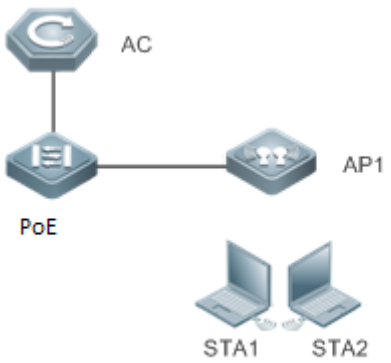
Notes

- An independent rate limit can be configured for VIP users only after a global rate limit is configured. The VIP user rate limit must be greater than the global rate limit. The global rate limit takes effect for all users on the AC.

Configuration Steps

↘ Enabling Independent Rate Limiting for VIP Users

- Mandatory.
- Enable independent rate limiting in the global configuration mode on the AC.
- Enable independent rate limiting for VIP users to increase the bandwidth of VIP users.



Command	**vip-first rate-limit** { **down-stream** | **up-stream** } **average-rate** *average-rate* **burst-rate** *burst-rate*
Parameter Description	**down-streams**: Sets the downlink rate limit of an AP. **up-streams**: Sets the uplink rate limit of an AP. *average-rate*: Sets the average rate limit. The unit is 8 kbps. The value range is **8** to **261,120**. *burst-rate*: Sets the burst rate limit. The unit is 8 kbps. The value range is **8** to **261,120**.
Defaults	Independent rate limiting for VIP users is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running-config** command to display configuration.

Configuration Example

↘ Enabling Independent Rate Limiting for VIP Users

Scenario **Figure 1-5**	
Configuration Steps	• Enable independent rate limiting for VIP users in global configuration mode on the AC.

AC	Hostname#configure terminal Hostname(config)# vip-first rate-limit up-stream average-rate 8 burst-rate 8 Hostname(config)# vip-first rate-limit down-stream average-rate 8 burst-rate 8
Verification	Run the **show ap-config running** command to display configuration.
AC	Hostname# showap-config running ! vip-first rate-limit up-stream average-rate 8 burst-rate 8 vip-first rate-limit down-stream average-rate 8 burst-rate 8 !

1 Configuring Hotspot 2.0

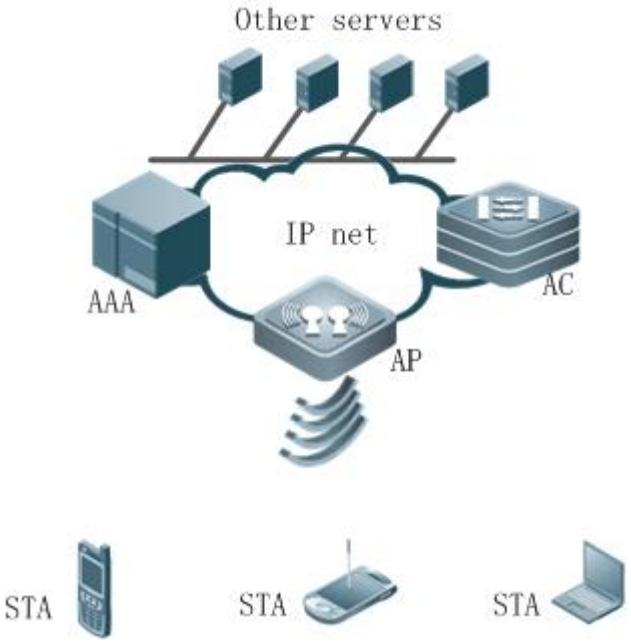
1.1 Overview

To implement automatic association and authentication on wireless local area networks (WLANs), automatic offloading of cellular network data, STA roaming between networks of different service providers, and effective management of authentication information, Wi-Fi Alliance releases the Hotspot 2.0 technical standard. Built on IEEE 802.11u standards, Hotspot 2.0 allows wireless STAs to perform automatic Wi-Fi identification and seamless handover without additional identity authentication, providing wireless users with cellular-like mobile experience.

Protocols and Standards

- IEEE 802.11u-2011
- Hotspot_2-0_(R2)_Technical_Specification_v1-1-0

1.2 Applications



Application	Description
Self-Built Hotspot 2.0 Network	The service scope of a Hotspot 2.0 network that is not deployed by a service provider is small.
Hotspot 2.0 Network Built by a Service Provider	The service scope of a Hotspot 2.0 network deployed by a service provider is limited to the network.
Roaming Hotspot 2.0 Network	The service scope of Hotspot 2.0 networks deployed by multiple service providers can be extended across the Hotspot 2.0 networks.

1.2.1 Self-Built Hotspot 2.0 Network

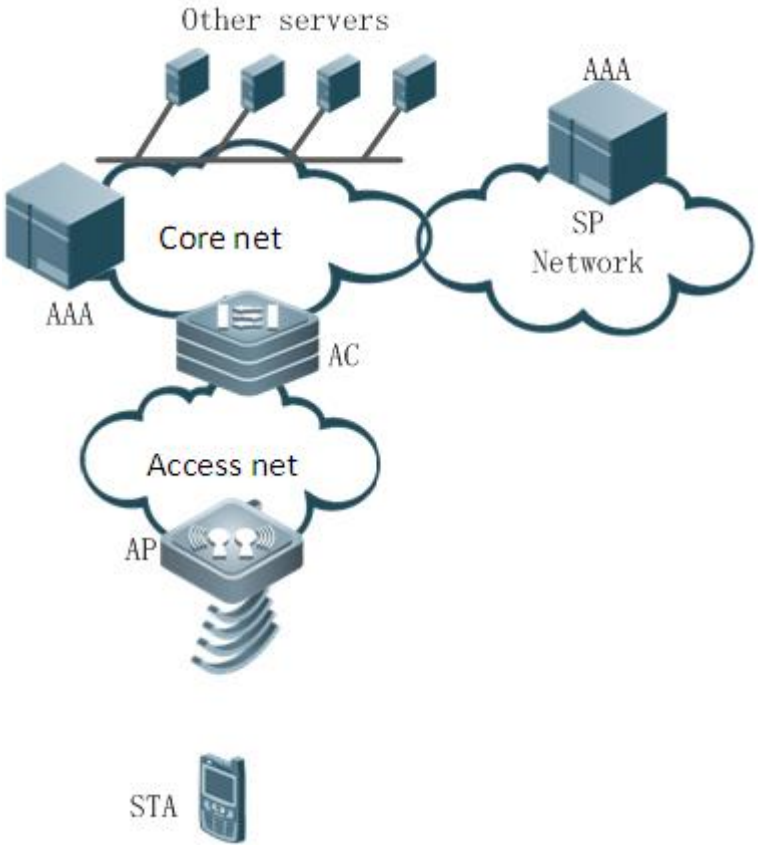
Scenario

Entities other than service providers (such as shopping malls, train stations, and airports) deploy Hotspot 2.0 access networks to provide the Hotspot 2.0 service for STAs. The Hotspot 2.0 authentication service is available only on the Hotspot 2.0 access network.

Figure 1-1 Topology of a Self-Built Hotspot 2.0 Network

Remarks	AAA: Indicates an authentication, authorization, and accounting (AAA) server. AC: Indicates a wireless access controller. AP: Indicates a wireless access point. STA: Indicates a wireless access client. Other servers: Indicates other servers, such as email server and domain name system (DNS) server.

Deployment



- Configure Hotspot 2.0 for the AP on the AC.
- Configure 802.1X authentication for the AP on the AC and configure the network-attached storage (NAS) device.
- Configure AAA authentication on the AAA server.
- Enable Hotspot 2.0 on STAs.

1.2.2 Hotspot 2.0 Network Built by a Service Provider

Scenario

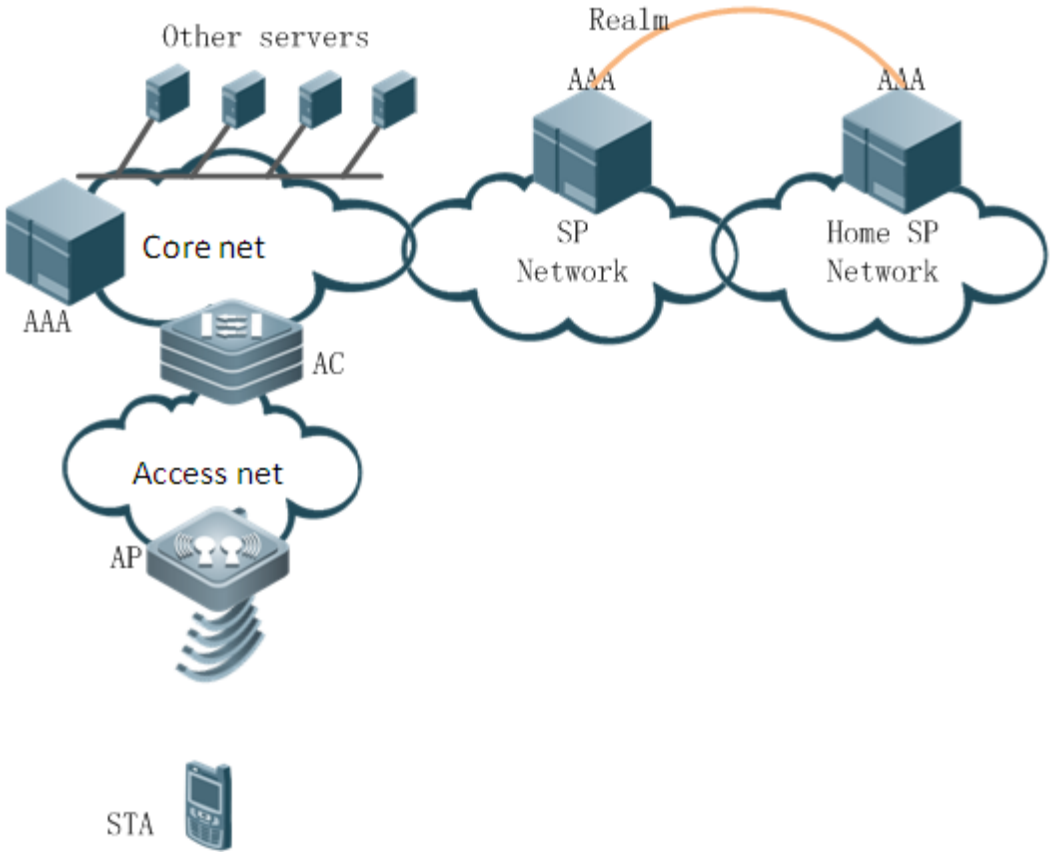
A service provider deploys a Hotspot 2.0 network in a site to provide WLAN services. On the network, the access STAs are subscribers of the service provider and access authentication needs to be implemented by the service provider. In general, an internal AAA server is deployed in a site to simplify and implement hierarchical deployment. The internal AAA server is interconnected with the AAA server of a service provider for authentication.

Figure 1-2 Topology of a Hotspot 2.0 Network Deployed by a Service Provider

Remarks	AAA: Indicates an AAA server. AC: Indicates a wireless access controller. AP: Indicates a wireless access point. STA: Indicates a wireless access client. Other servers: Indicates other servers, such as email server and DNS server. SP Network: Indicates the network of a service provider.

Deployment

- Configure Hotspot 2.0 for the AP on the AC.
- Configure 802.1X authentication for the AP on the AC and configure the NAS device.
- Configure proxy authentication on the local AAA server and local authentication on the service provider's AAA server.
- Enable Hotspot 2.0 on STAs.



1.2.3 Roaming Hotspot 2.0 Network

Scenario

Multiple service providers deploy Hotspot 2.0 networks in some sites to provide WLAN services. The subscribers of different service providers can access the Internet on the Hotspot 2.0 networks of different service providers. To achieve this goal, different service providers need to enable wireless clients to roam between networks. The service providers'

AAA servers are used for subscriber authentication as a proxy, and routing and proxy authentication are performed through the realm.

Figure 1-3 Topology of a Roaming Hotspot 2.0 Network

Remarks	AAA: Indicates AAA servers, including the local AAA server, the AAA server of a service provider, and the AAA server of the home service provider. AC: Indicates a wireless access controller. AP: Indicates a wireless access point. STA: Indicates a wireless access client. Other servers: Indicates other servers, such as email server and DNS server. SP Network: Indicates the network of a service provider. Home SP Network: Indicates the network of the home service provider, that is, the service provider network to which a user subscribes.

Deployment

- Configure Hotspot 2.0 for the AP on the AC.
- Configure 802.1X authentication for the AP on the AC and configure the NAS device.
- Configure proxy authentication on the local AAA server, local authentication and proxy authentication on the service provider's AAA server, and local authentication on the home service provider's AAA server.
- Enable Hotspot 2.0 on STAs.

1.3 Features

Basic Concepts

Network Entity

STA: Indicates wireless stations with wireless network interface cards (NICs) such as laptops and mobile phones.

AP: Indicates a wireless access point that provides wireless signals for STA access.

AC: Indicates a wireless access controller that provides wireless connection and relevant services.

AAA: Indicates an AAA server.

OSUS: Indicates an online sign-up server that provides online sign-up service for Hotspot 2.0 STAs.

HLR: Indicates the home location register.

CA: (Optional) indicates the digital certificate authentication center server used to issue certificates to servers.

GAS, ANQP, and OSU

Generic Advertisement Service (GAS) is a mechanism defined by 802.11u through which the STA obtains network information by exchanging Request and Response packets with the network side.

Access Network Query Protocol (ANQP) is a network information query protocol encapsulated in GAS packets. ANQP defines the network parameters that are used to identify networks.

Online sign-up (OSU) provides a mechanism for STAs with no authentication information available on the AAA server to sign up online and obtain authentication information.

Overview

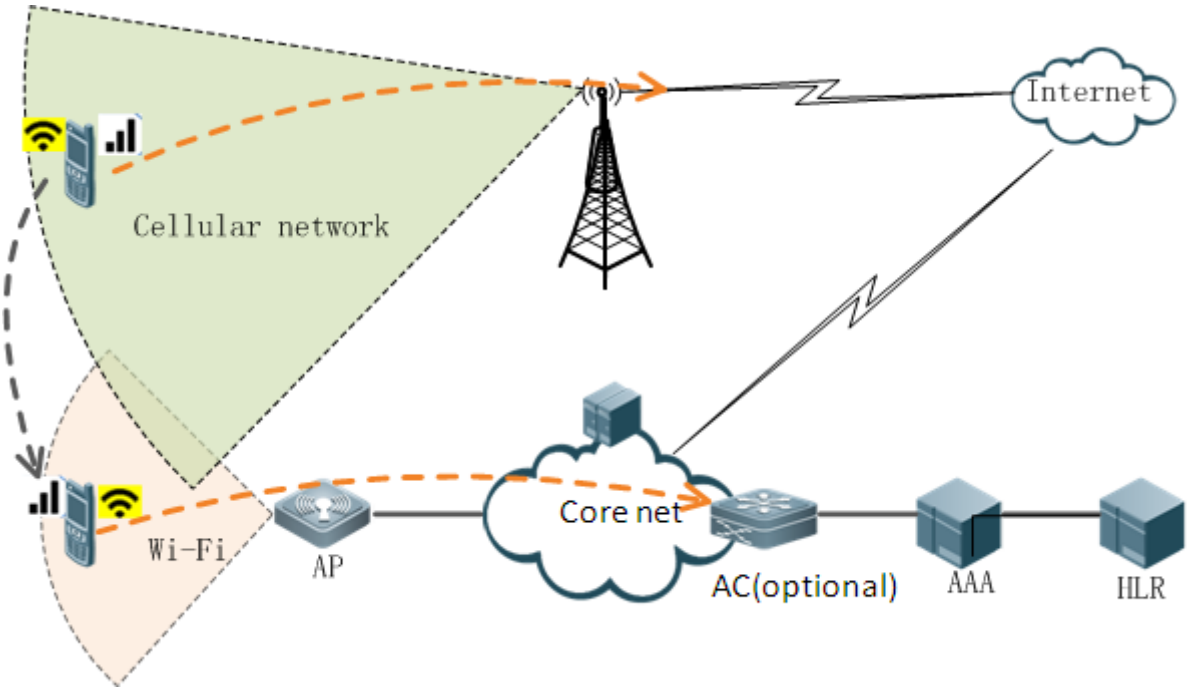
Feature	Description
Features of Hotspot 2.0	Hotspot 2.0 implements automatic WLAN association, online sign-up of users, automatic offloading of cellular traffic, and STA roaming between networks of different service providers.
Hotspot 2.0 Principle	Hotspot 2.0 network discovery, selection, and access process
GAS Principle	GAS principle and use
ANQP Principle	ANQP principle and use
Common Protocol Dictionary	Definitions of common dictionary used by protocols

1.3.1 Features of Hotspot 2.0

Hotspot 2.0 implements automatic STA access, online sign-up of users, automatic offloading of cellular traffic, and STA roaming between networks of different service providers.

Automatic Access

After the WLAN function is enabled on a STA, the STA automatically discovers and selects a Hotspot 2.0 network, connects to the network, and performs authentication for Internet access. Automatic access authentication eliminates the need for manual intervention, achieving cellular-like network access.



Online Sign-up

After a STA selects a Hotspot 2.0 WLAN, if the AAA server does not have the STA's access authentication information, you can choose online sign-up to submit identity information, obtain authentication information, and install identity information. After completion, the STA can be automatically authenticated for Internet access based on the installed identity information. The identity information sign-up and installation are completed by users independently and the process is simple.

Automatic Offloading of Cellular Traffic

A user initially accesses the Internet by using mobile data within the coverage of a cellular network. As the user moves to the coverage area of a Hotspot 2.0 WLAN, a STA automatically connects to the Hotspot 2.0 WLAN and accesses the Internet through the WLAN. If both mobile data and WLAN functions are enabled, the STA automatically selects WLAN first. You can also manually disable mobile data.

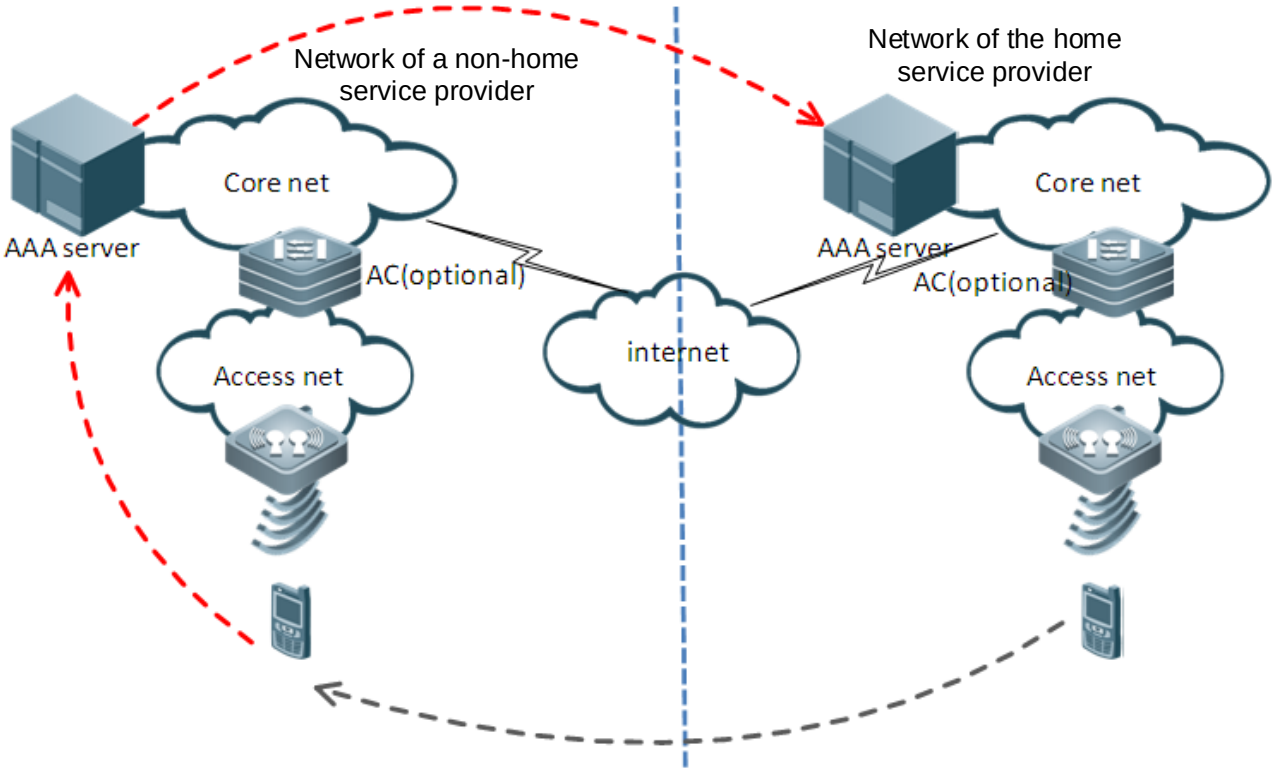


Figure 1-4 Automatic Offloading of Cellular Traffic

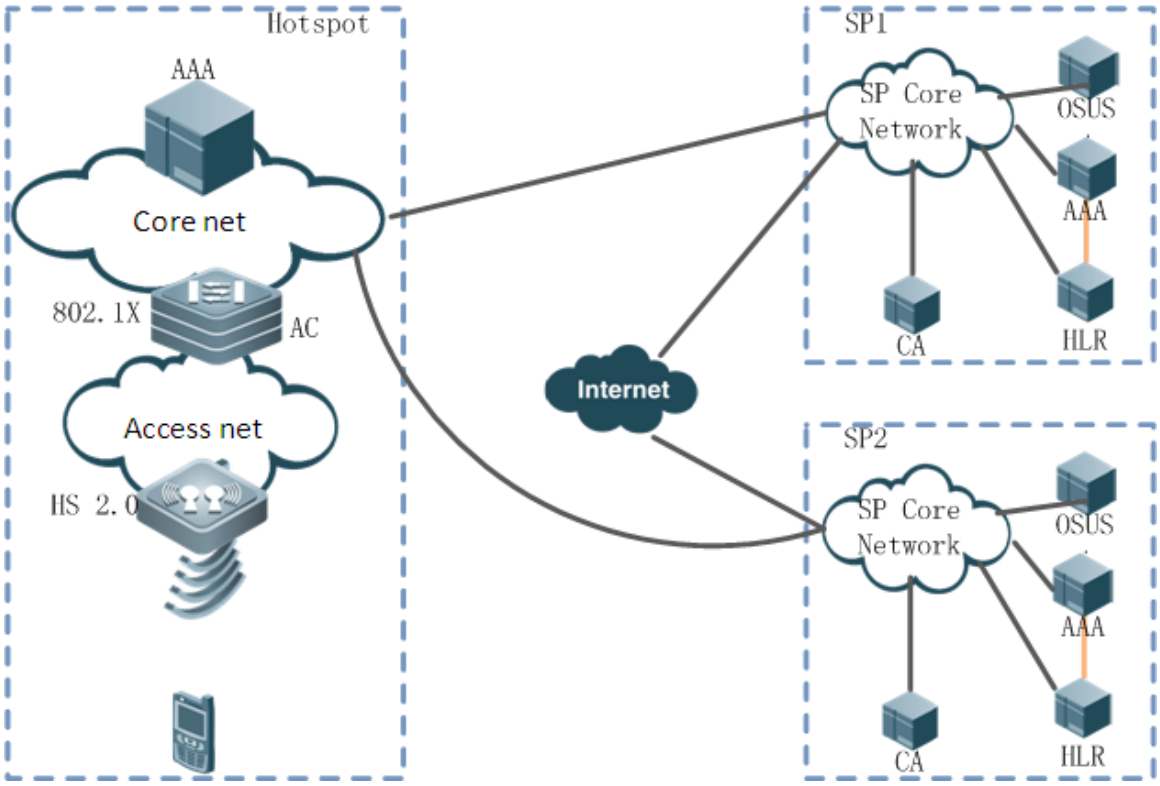
STA Roaming Between Networks of Different Service Providers

A user registers user information on the network of the home service provider and subscribes to the Hotspot 2.0 WLAN service. The user can connect to the Hotspot 2.0 WLAN for Internet access by using the registered authentication information. When the user moves to the Hotspot 2.0 WLAN of a non-home service provider, the user can still connect to the network for Internet access, eliminating the need to register identity information and obtain authentication credential.

Figure 1-5 STA Roaming Between Networks of Different Service Providers



1.3.2 Hotspot 2.0 Principle

Network Architecture

The Hotspot 2.0 WLAN architecture can be divided into the Hotspot 2.0 WLAN access network and server cluster of service providers.

Figure 1-6 Hotspot 2.0 Network Architecture

Access Network of a Hotspot 2.0 WLAN

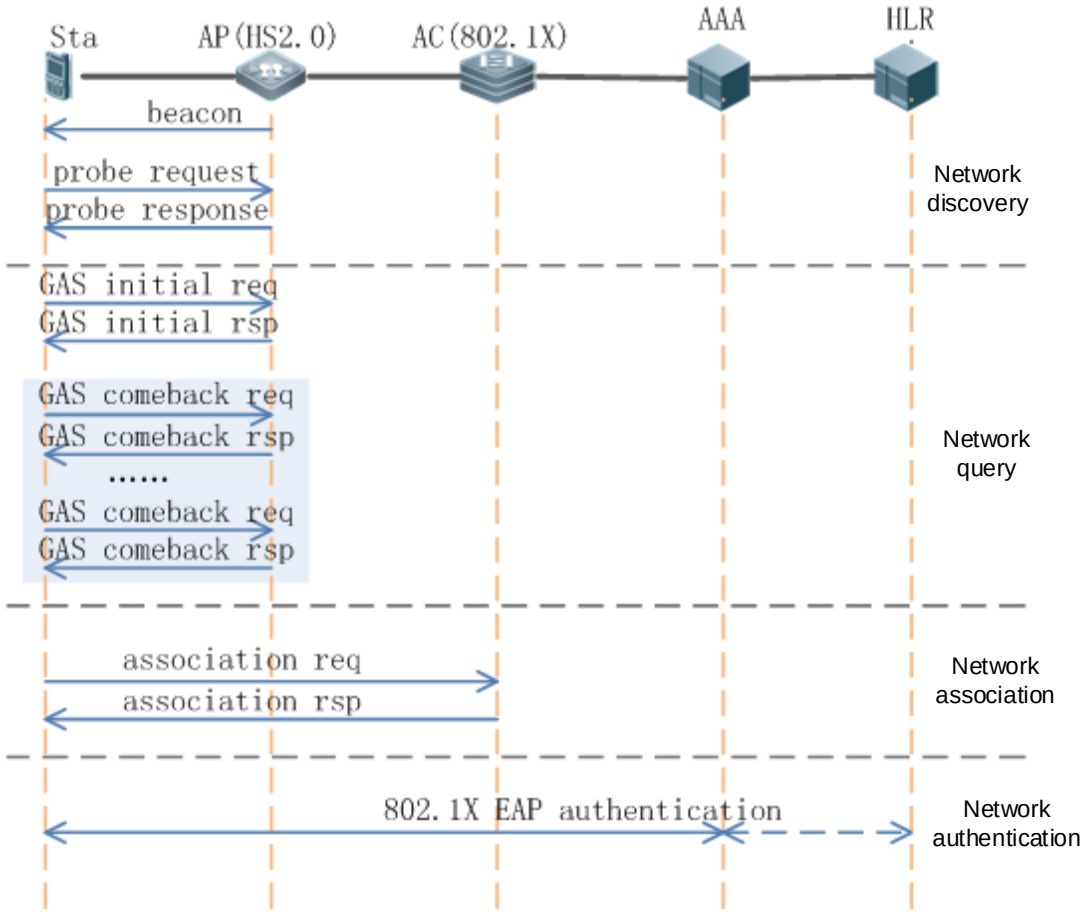
The AC manages APs in a unified manner and APs run Hotspot 2.0 for user access. The AC supports 802.1X authentication and interconnects with the AAA server on the Hotspot 2.0 network to implement user access authentication. The AAA server on the Hotspot 2.0 network serves as a proxy and interworks with service providers' AAA servers to complete the authentication. In the fat mode, APs are associated directly with the local AAA server for authentication.

Service Cluster of a Service Provider

Authentication on a service provider's network is managed by the service provider in a unified manner. After receiving authentication requests from a service provider's users, the AAA server on a Hotspot 2.0 network forwards the requests to the service provider's AAA server, and the service provider's AAA server returns authentication results to the AAA server on the Hotspot 2.0 network, which finally returns the results to access users to complete authentication.

If a user adopts SIM authentication, the service provider's AAA server interconnects with the service provider's HLR server to complete SIM authentication.

If an access user is not a subscriber of the current service provider but a subscriber of another service provider, roaming between networks of the service providers is required for authentication. The AAA server on the current network sends the authentication request of a user to the AAA server on the user's home network to implement authentication on the user. The AAA server on the user's home network returns the authentication result. If a user employs SIM authentication, the AAA server on the home network needs to interconnect with the HLR server on the home network to complete authentication.



For STAs that have no authentication information on the AAA server upon first access, service providers offer OSU service for online sign-up as well as authentication information downloading and installation. Then, the STAs can access the Hotspot 2.0 network by using the registered authentication information.

Network Access Process

Hotspot 2.0 is implemented based on IEEE 802.11u standards. IEEE 802.11u defines a mechanism for STAs to obtain WLAN information. In roaming or non-roaming scenarios, STAs can discover a Hotspot 2.0 WLAN through Beacon or Probe frames and obtain detailed WLAN information through GAS frames. Based on the received WLAN information, the STAs automatically select the optimal WLAN network to access, where the STAs will be automatically authenticated.

Network information exchange is achieved through GAS and ANQP packets on a Hotspot 2.0 WLAN.

Figure 1-7 Hotspot 2.0 Network Access

In general, the process of Hotspot 2.0 network access involves four phases: network discovery, network query, network association, and network authentication.

Network Discovery

A Hotspot 2.0 network can be discovered through passive or active scan, that is, by using Beacon frames and Probe frames. The principle is as follows: An AP sends a Beacon or Probe frame which contains the Hotspot 2.0 network

information elements to a STA. The STA parses information elements related to Hotspot 2.0 and then discovers a Hotspot 2.0 network.

Network Query

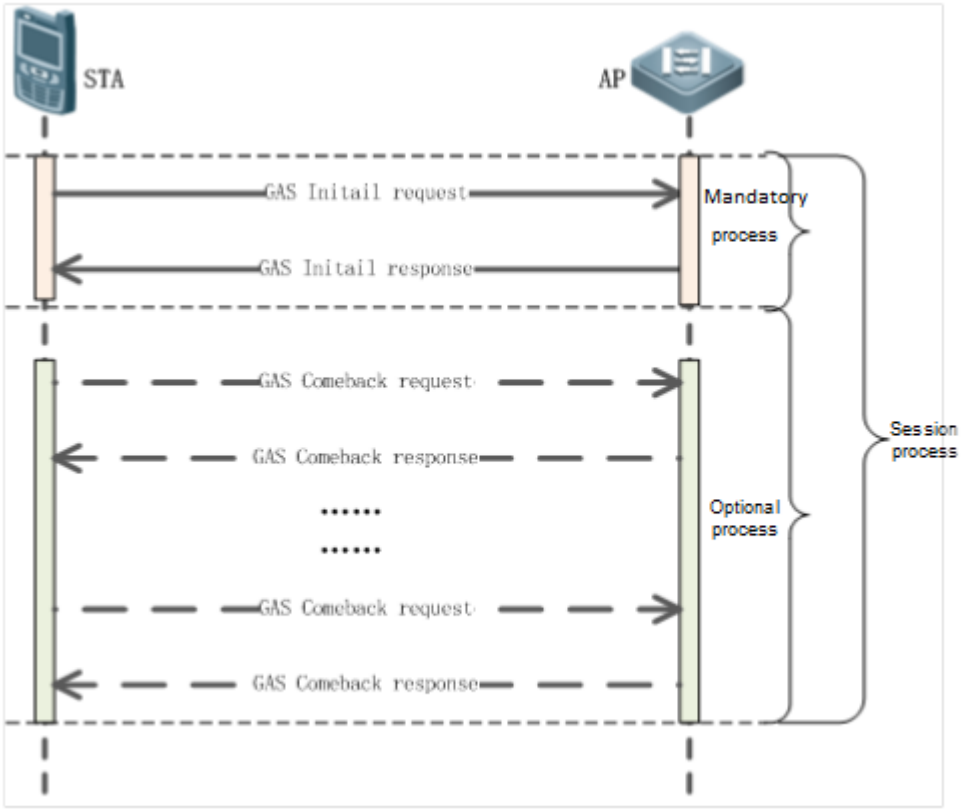
This phase is unique to Hotspot 2.0. After a STA discovers a Hotspot 2.0 network, it needs to obtain further information related to Hotspot 2.0 through GAS query. GAS Initial Request frame and GAS Initial Response frame are mandatory for GAS exchange between an AP and a STA. However, GAS Comeback Request and GAS Initial Response frame exchange are optional, which occur only when the requested response data needs to be fragmented or a response delay is set.

Network Association

The association process of a Hotspot 2.0 network is exactly the same as that of a traditional WLAN, except that the QoS MAP advertisement is added to the Association Response frame.

Network Authentication

Hotspot 2.0 networks adopt IEEE 802.1X authentication and the standard Extensible Authentication Protocol (EAP) method for STA authentication. Remote Authentication Dial-In User Service (RADIUS) options need to be extended to support Hotspot 2.0.



1.3.3 GAS Principle

Generic Advertisement Service (GAS) is a mechanism defined by 802.11u through which the STA obtains network information by exchanging Request and Response packets with the network side.

Protocol Exchange Process

GAS adopts the standard client/server mode, in which STAs serve as clients, an AP serves as the server, and the AP responds to STAs' requests. One GAS session exchange process includes the mandatory process and the optional process that is executed only when conditions are met. The mandatory process means the exchange between a STA and an AP through GAS Initial Request and GAS Initial Response frames, and this process is executed only once. The optional process is one or more exchanges using GAS Comeback Request and GAS Comeback Response frames. It is the continuation of the mandatory process. This process starts when the AP is required to delay obtaining response data or the response data exceeds the maximum data length of one-time response.

Figure 1-8 GAS Exchange Process

GAS Session Management

GAS session management includes session generation, session processing, and session termination.

Session Generation

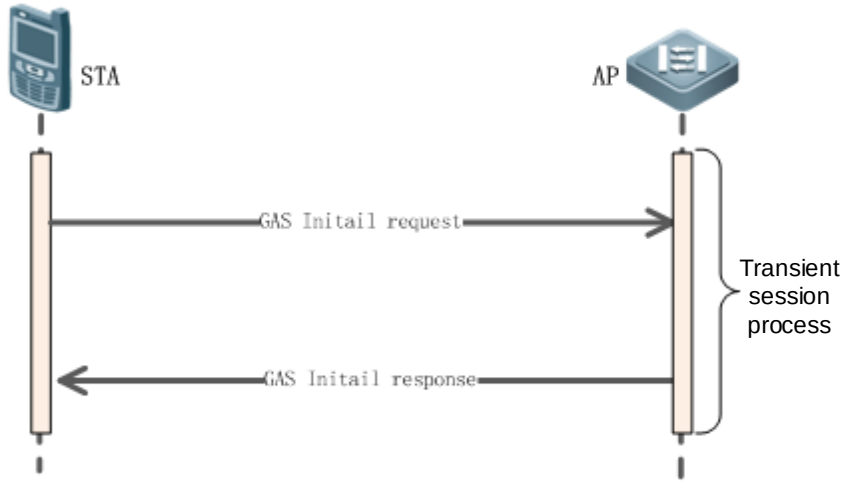
A GAS session is identified by a STA + Dialog Token. The STA refers to the STA's MAC address, and Dialog Token is the Dialog Token in a GAS Initial Request frame.

A GAS session is generated upon the receiving of a GAS Initial Request frame. There are transient sessions and persistent sessions.

A transient session refers to a session that ends after a GAS Initial Request frame is received, the request is parsed, and all the response data is encapsulated into the GAS Initial Response frame at a time. The transient session adopts the mode of only one response to one request with simple logic.

The difference between a persistent session and a transient session lies in whether response data is encapsulated into one GAS Initial Response frame. If it is impossible to encapsulate response data into one response frame, the session becomes a persistent session. It can be said that a persistent session includes the transient session process. The only difference is that the GAS Initial Response frame of a transient session contains complete response data while a persistent session responds with an empty GAS Initial Response frame, and the valid data is captured in subsequent GAS Comeback exchange.

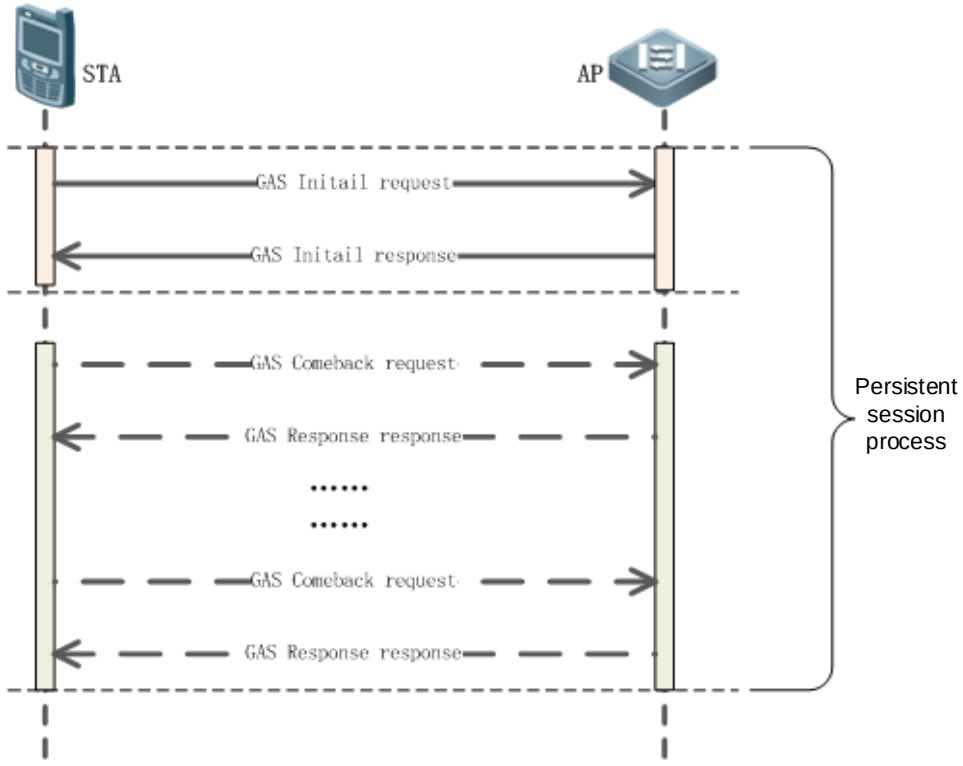
A GAS session enters the persistent session state when either of the following conditions is met:



- GAS response delay is configured.

- The response content exceeds the maximum data length of a one-time response.

Session Processing



A transient session is very simple. One GAS Initial Request frame maps to one GAS Initial Response frame, and the whole session ends after one response is returned to one request.

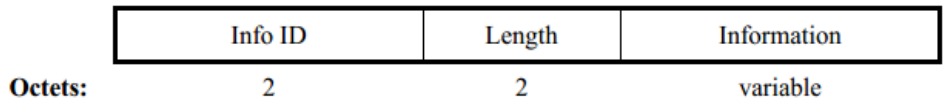
Figure 1-9 GAS Transient Session

Compared with transient sessions, persistent sessions have the GAS Comeback exchange process. Data is only generated in the GAS Initial process, and the valid data exchange occurs in the GAS Comeback process.

Figure 1-10 GAS Persistent Session

Session Termination

A transient session is terminated after an AP replies a GAS Initial Response.



A persistent session may be terminated in the event of the following cases:

- The session ends normally, that is, all data is exchanged. The session ends after the last GAS Comeback exchange is completed.
- The session ends due to timeout. If no GAS Comeback Request is received within the timeout duration of a session (5 seconds by default), the session is terminated. If a GAS Comeback Request is received within the timeout duration, the timeout countdown is re-counted.
- A session ends due to other exceptions, for example, a session is released due to insufficient resources.

1.3.4 ANQP Principle

ANQP is carried over GAS and GAS uses ANQP for information encapsulation. The GAS service is usually called the ANQP service and the GAS server is also called the ANQP server. ANQP encapsulates messages in the TLV (ID, length, and value) format.

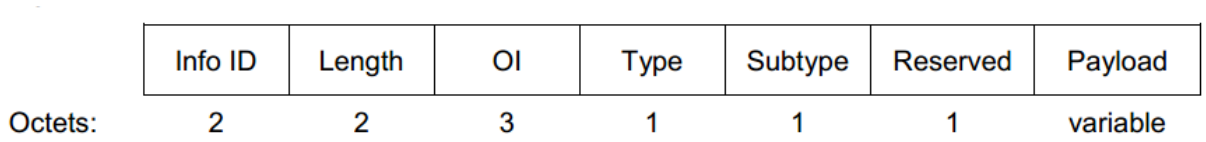


Figure 1-11 Standard Message Format of ANQP

	Info ID	Length	Information
Octets:	2	2	variable

The information element with info ID 56797 is an extended ANQP information element, which is used by Hotspot 2.0.

Figure 1-12 Extended ANQP Message Format of Hotspot 2.0

	Info ID	Length	OI	Type	Subtype	Reserved	Payload
Octets:	2	2	3	1	1	1	variable

The value of **Info ID** is fixed at **56797**. **Length** indicates the length of all data behind the element. **OI** indicates the organization ID and Wi-Fi Alliance uses 0x 506F9A. **Type** indicates the OI type and is set to **0x11**. **SubType** indicates the type of an extended information element. **Reserved** is a reserved field and the value is **0**. **Payload** indicates the content of the information element. It may contain sub-elements, which is also encapsulated in the TLV (ID, length, value) format.

Standard ANQP Options

Information Element	Info ID	Generated by	Description
ANQP Query list	256	STA	ANQP query list. A STA specifies the information to be queried in this information element and specifies the info ID to be queried in the request body.
ANQP Capability list	257	AP	ANQP capability list. It is a response to **ANQP Query list** and specifies the capability set of ANQP. It involves no specific parameter values.

Information Element	Info ID	Generated by	Description
Venue Name information	258	AP	Venue name. It is a response to **ANQP Query list**. There are zero or multiple names of BSS-related venues. If there is more than one venue name, they refer to the same venue name in different languages and the venue name information contains venue type information (venue group and venue type).
Network Authentication Type information	260	AP	Network authentication type. It is a response to **ANQP Query list**. The network authentication type here is actually the additional action required for users to access the network and can be set to the following: **0**: accepting the terms of use **1**: online registration **2**: HTTP/HTTPS redirection **3**: DNS redirection
Roaming Consortium list	261	AP	Roaming consortium list. It is a response to **ANQP Query list**. Each roaming member is represented by OI, which is arranged in the format of length, value.
IP Address Type Availability Information	262	AP	IP address type availability information. It is a response to **ANQP Query list** and indicates the availability of the IP service after a STA is associated with a WLAN. For IPv6 addresses, the values are as follows: **0**: unavailable; **1**: available; **2**: unknown. For IPv4 addresses, the values are as follows: **0**: unavailable; **1**: Public IPv4 addresses are available. **2**: Port-restricted IPv4 addresses are available. **3**: Single-NATed private IPv4 addresses are available. **4**: Double-NATed private IPv4 addresses are available. **5**: Single-NATed and port-restricted IPv4 addresses are available. **6**: Double-NATed and port-restricted IP addresses are available. **7**: unknown.
NAI Realm list	263	AP	NAI realm list. It is a response to **ANQP Query list** and contains the realm name and authentication mode.
3GPP Cellular Network information	264	AP	3GPP cellular network information. It is a response to **ANQP Query list**. It contains the cellular network ID to assist STAs in selecting an AP to access 3GPP networks. Cellular network information also includes a 3-bit mobile country code (MCC) and a 2-bit or 3-bit mobile network code (MNC).
Domain Name list element	268	AP	Operator domain name list. It is a response to **ANQP Query list**. It contains the domain name of a hotspot operator to assist STAs with network selection. A STA can obtain this information through ANQP query.

Extended ANQP Options of Hotspot 2.0

Information Element	Subtype	Generated by	Description
HS Query List element	1	STA	HS request list. A STA specifies the information to be queried in this information element and specifies the subtype ID to be queried in the request body.
NAI Home Realm Query element	6	STA	NAI home realm query. Through this information element, a STA requests an AP to query information about the home service provider network that has the STA's authentication information, to find out whether the STA has permission to access the local network. Multiple home service provider networks can be specified.
Icon Request element	10	STA	Sign-up icon request. Hotspot 2.0 supports the OSU service provider icon query by file name.
HS Capability List element	2	AP	HS capability list. It is a response to **HS Query List** and indicates the capability support. It involves no specific capability values.
Operator Friendly Name element	3	AP	Operator's friendly name. It is a response to **HS Query List**. If there are multiple pieces of operator information, it is information about the same operator in different languages.
WAN Metrics element	4	AP	WAN link status. It is a response to **HS Query List** and contains the following information: Status: down/up/test; symmetric or not; rate: uplink/downlink, symmetric link rate.
Connection Capability element	5	AP	IP protocol connection control. It is a response to **HS Query List**. It controls service ports and specifies whether to disallow or allow users to use IP services after access, including TCP, UDP, and ICMP.
OSU Providers List element	8	AP	OSU provider list. It is a response to **HS Query List** and provides online sign-up service for STAs, including OSU SSIDs. It can provide a list of OSU service providers and information about each provider includes the OSU provider name, description, OSU server URI, OSU method, OSU network access ID, and available icon file information.
Icon Binary File element	11	AP	Icon binary file content. It is a response to **Icon Request**.

1.3.5 Common Protocol Dictionary

Venue Type

1.4 Configuration

Configuration	Description and Command	
Configuring a Hotspot 2.0	(Mandatory) It is used to configure a Hotspot 2.0 profile.	
	hotspot2 template *template-name*	(Mandatory) Creates a Hotspot 2.0 profile.
	3gpp-cellular-network mcc *mcc* **mnc** *mnc*	(Optional) Configures a cellular network ID.
	network-auth-type {acceptance | online-enroll| http-https-redirection [redirect-url *url***] | dns-redirection }**	(Optional) Configures the network authentication type.
	osu-ssid *ssid*	(Optional) Configures an OSU SSID.
	venue-group *venue-group* **type** *venue-type*	(Optional) Configures the venue type.
	venue-name language-code *language-code* **name** *name*	(Optional) Configures the venue name.
	roam-consortium oi *oi* **[in-beacon]**	(Optional) Configures a roaming consortium.
	hessid *mac-address*	(Optional) Configures a homogeneous extended service set identifier (HESSID).
	domain-name *domain-name*	(Optional) Configures a hotspot operator domain name.
	network-type { emergency-service | personal-device | private | private-guest | public-chargeable | public-free | test | wildcard } [internet-access]	(Optional) Configures the network type.

	ipv4-address-available {not-available | public-available | port-restricted | single-nat | double-nat | port-restricted-single-nat | port-restricted-double–nat | unknown }	(Optional) Configures available IPv4 address types.
	ipv6-address-available { not-available | available | unknown }	(Optional) Configures available IPv6 address types.
	nai-realm realm-name *realm-name* **[eap-method-type [eap-ttls [auth-method** *auth-method-id* **auth-para** *auth-para-value* **] | eap-tls [auth-method** *auth-method-id* **auth-para** *auth-para-value* **] | eap-sim [auth-method** *auth-method-id* **auth-para** *auth-para-value* **] | eap-aka [auth-method** *auth-method-id* **auth-para** *auth-para-value* **] | eap-aka' [auth-method** *auth-method-id* **auth-para** *auth-para-value* **]]]**	(Optional) Configures a NAI realm member.
	connection-capability { esp | icmp | tcp-ftp | tcp-http | tcp-pptp-vpn | tcp-ssh | tcp-tls-vpn | tcp-voip | udp-ike2-4500 | udp-ike2-500| udp-voip } { enable | disable }	(Optional) Configures the IP protocol and port connection capability.
	dgaf {enable | disable }	(Optional) Enables or disables downstream group-addressed forwarding (DGAF).
	operator-name language-code *language-code* **name** *name*	(Optional) Configures an operator name.
	dls-tdls {enable | disable}	(Optional) Configures DLS connection control.
	osu-provider *template-name*	(Optional) Configures an OSU provider profile to be applied.
	gas-response delay {enable | disable}	(Optional) Enables GAS response delay.
	wan-metrics link-status {up | down | test} [asymmetric downlink-speed *downlink-speed* **uplink-speed** *uplink-speed* **| symmetric link-speed** *link-speed* **]**	(Optional) Configures the WAN port status.
Configuring an OSU Provider	⚠ (Optional) It is used to configure an OSU provider profile.	
	Hotspot2 osu-provider template *template-name*	(Mandatory) Creates an OSU provider profile.

	friendly-name language-code *language-code* **name** *name*	(Optional) Configures an OSU provider name.
	service-description language-code *language-code* **description** *description*	(Optional) Configures the OSU service description.
	server-uri *uri*	(Mandatory) Configures the OSU server URI.
	method {oma-dm | soap-xml-spp}	(Mandatory) Configures the OSU method.
	nai *nai*	(Optional) Configures the OSU network access ID.
	icon-name *name* **type {png | jpg | bmp | gif} language-code** *code* [**width** *width* **height** *height*]	(Optional) Configures an OSU icon.
Applying a Hotspot 2.0 Profile to a WLAN	⚠ (Mandatory) It is used to apply a Hotspot 2.0 profile to a WLAN.	
	Hotspot2 template *template-name*	Applies Hotspot 2.0 configuration in WLAN configuration mode of an AC.

1.4.1 Configuring a Hotspot 2.0 Profile

Configuration Effect

- Create a Hotspot profile and configure parameters in the profile. The configured Hotspot 2.0 profile can be applied and bound to a WLAN so that the WLAN supports the Hotspot 2.0 functions.

Notes

- Only existing Hotspot 2.0 profiles can be bound to a WLAN.

Configuration Steps

↘ Creating a Hotspot 2.0 Profile

- Mandatory.
- Create a Hotspot 2.0 profile and enter the Hotspot 2.0 configuration mode.

Command	**hotspot2 template** *template-name*
Parameter Description	*template-name*: Indicates the name of a profile. The value is a string of up to 32 case-sensitive visible characters excluding question marks (?) and spaces.
Defaults	No Hotspot 2.0 profile is configured.
Command Mode	Global configuration mode
Usage Guide	A maximum of 16 Hotspot 2.0 profiles can be configured and the profile names must be unique.

↘ Configuring a Cellular Network ID

- Optional.
- Configure a cellular network ID in the Hotspot 2.0 profile.

- A STA needs to obtain the 3GPP cellular public land mobile network (PLMN) ID from an AP so as to select the network for access. The cellular network ID is used to identify a cellular network and the cellular network information includes the 3-bit mobile country code (MCC) and 2-bit or 3-bit mobile network code (MNC).

Command	**3gpp-cellular-network mcc** *mcc* **mnc** *mnc*
Parameter Description	*mcc*: Indicates the 3-bit mobile country code. The value is a number in the range of 0 to 9. *mnc*: Indicates the 2-bit or 3-bit mobile network code. The value is a number in the range of 0 to 9.
Defaults	No cellular network ID is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of 16 cellular network IDs can be configured.

Configuring the Network Authentication Type

- Optional.
- Configure the network authentication type in the Hotspot 2.0 profile.
- A Hotspot 2.0-supported AP carries parameter information (additional steps required for access (ASRA)) in Beacon frames and Probe response frames to help STAs discover and select appropriate networks. If a network operator expects STAs to perform specified actions such as opening the specified web page for Portal authentication, the ASRA field needs to be set to **1** in the frames, indicating that additional authentication is required when STAs access the network. Then you can use this command to specify the network authentication mode. The network authentication type parameter exists only when ASRA is set to **1** in the **Interworking** field. The parameter must be set to **0** if RSNA is enabled.

Command	**network-auth-type {acceptance [redirect-url** *url***] | online-enroll | http-https-redirection [redirect-url** *url***] | dns-redirection }**
Parameter Description	*url*: Indicates the authentication redirection URL.
Defaults	No network authentication type is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of four authentication types can be configured.

Configuring an OSU SSID

- Optional.
- Configure an OSU SSID in the Hotspot 2.0 profile.
- When an OSU network access identifier (NAI) is provided, the OSU access network uses the OSEN mode. Otherwise, the OPEN mode is adopted. You are advised to hide OSU SSIDs to ensure security.

Command	**osu-ssid** *ssid*
Parameter Description	*ssid*: Indicates the OSU SSID. The value is a string of 1 to 32 characters.
Defaults	No OSU SSID is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	Up to one OSU SSID can be configured. The repeated configuration will overwrite the previous

	configuration. Another WLAN needs to be deployed to implement access to the OSU network. The SSID of the WLAN must be the same as the configured OSU SSID. If an OSU NAI is configured, the OSEN access mode needs to be configured for the WLAN. Otherwise, the OPEN access mode needs to be configured.

Configuring the Venue Type

- Optional.
- Configure the venue type in the Hotspot 2.0 profile.
- Specify venue information to indicate the site information of the Hotspot 2.0 network.

Command	**venue-group** *venue-group* **type** *venue-type*
Parameter Description	*venue-group*: See Section 1.3.5 Common Protocol Dictionary. *venue-type*: See Sections 1.3.5 Common Protocol Dictionary.
Defaults	The group is not specified (the value is **0**) and the type is not specified (the value is **0**).
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	One venue group and one venue type can be configured at most.

Configuring the Venue Name

- Optional.
- Configure the venue name in the Hotspot 2.0 profile.
- If there are multiple venue names, they refer to the same venue name in different languages.

Command	**venue-name language-code** *language-code* **name** *name*
Parameter Description	*language-code*: The value is a string of 2 to 3 characters. It supports both ISO-639-1 and ISO-639-2 standards. If ISO-639-1 is adopted, **0** is added to ensure that the value contains three characters. *name*: The value is a string of 1 to 252 case-sensitive visible characters excluding question marks (?) and spaces.
Defaults	No venue name is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of eight venue names can be configured.

Configuring a Roaming Consortium

- Optional.
- Configure a roaming consortium in the Hotspot 2.0 profile.
- An operator identifier (OI) uniquely identifies a roaming member. It consists of six or ten characters in hexadecimal notation. **in-beacon** indicates that the OI needs to be added to the Beacon frame. A maximum of three OIs can be added to the Beacon frame. If this parameter is not specified, the OI is not added to the Beacon frame.

Command	**roam-consortium oi** *oi* **[in-beacon]**
Parameter Description	*oi*: Indicates the OI. The value is in the format of HH-HH-HH or HH-HH-HH-HH-HH. **H** is a 1-bit character in hexadecimal notation.
Defaults	No roaming consortium is configured.

Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of 16 roaming consortium OIs can be configured.

(Optional) Configuring an HESSID

- Optional.
- Configure an HESSID in the Hotspot 2.0 profile.
- When multiple Hotspot 2.0 services exist on the network, a STA needs to identify the access service providers but SSIDs are not unique. Therefore, unique HESSIDs are used to identify APs of the same service provider. The HESSID is consistent with the BSSID of an AP. HESSID is an optional parameter in the Hotspot 2.0 profile. A Hotspot 2.0-supported AP carries parameter information in Beacon frames and Probe response frames to help STAs determine whether to obtain network parameters again.

Command	**hessid** *mac-address*
Parameter Description	*mac-address*: Indicates the HESSID in the format of HHHH.HHHH.HHHH. **H** is a 1-bit character in hexadecimal notation.
Defaults	No HESSID is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	Up to one HESSID can be configured

Configuring a Hotspot Operator Domain Name

- Optional.
- Configure a hotspot operator domain name in the Hotspot 2.0 profile.
- After a hotspot operator domain name is configured, a STA can obtain the information through ANQP query to facilitate network selection.

Command	**domain-name** *domain-name*
Parameter Description	*domain-name*: Indicates a hotspot operator domain name. The value is a string of 1–255 characters and complies with RFC1035. It cannot contain question marks (?) and spaces. The string cannot end with double quotation marks (").
Defaults	No hotspot operator domain name is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of eight hotspot operator domain names can be configured.

Configuring the Network Type

- Optional.
- Configure the network type in the Hotspot 2.0 profile.
- When multiple Hotspot 2.0 services exist on a network, a STA needs to obtain information about the Hotspot 2.0 networks to select a network for access. A Hotspot 2.0-supported AP carries parameter information in Beacon frames and Probe response frames to help STAs discover and select appropriate networks.

Command	**network-type { emergency-service | personal-device | private | private-guest | public-chargeable |**

	public-free | test | wildcard } [internet-access]
Parameter Description	N/A
Defaults	The **network-type wildcard internet-access** command is configured and STAs can access the Internet.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	Up to one network type can be configured.

Configuring an Available IPv4 Address Type

- Optional.
- Configure an available IPv4 address type in the Hotspot 2.0 profile.
- When a STA accesses the Hotspot 2.0 service, Hotspot 2.0 can transfer the available IPv4 address type on the network as an ANQP parameter to the STA through an AP. In this way, the STA can know the type of an IP address that can be obtained after accessing the network.

Command	**ipv4-address-available** { **not-available** | **public-available** | **port-restricted** | **single-nat** | **double-nat** | **port-restricted-single-nat** | **port-restricted-double–nat** | **unknown** }
Parameter Description	N/A
Defaults	The available type of IPv4 addresses is set to **unknown**.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	Up to one available IPv4 address type can be configured.

Configuring an Available IPv6 Address Type

- Optional.
- Configure an available IPv6 address type in the Hotspot 2.0 profile.
- When a STA accesses the Hotspot 2.0 network, Hotspot 2.0 can transfer the available IPv6 address type on the network as an ANQP parameter to the STA through an AP. In this way, the STA can know the type of an IP address that can be obtained after accessing the network.

Command	**ipv6-address-available { not-available | available | unknown }**
Parameter Description	N/A
Defaults	The available type of IPv6 addresses is set to **unknown**.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	Up to one available IPv6 address type can be configured at most.

Configuring a NAI Realm Member

- Optional.
- Configure a NAI realm member in the Hotspot 2.0 profile.
- After a NAI realm member is configured, a STA can access the configured operator network.

Command	**nai-realm realm-name** *realm-name* [**eap-method-type** [**eap-ttls** [**auth-method** *auth-method-id* **auth-para** *auth-para-value*] | **eap-tls** [**auth-method** *auth-method-id* **auth-para** *auth-para-value*] | **eap-sim** [**auth-method** *auth-method-id* **auth-para** *auth-para-value*] | **eap-aka** [**auth-method** *auth-method-id* **auth-para** *auth-para-value*] | **eap-aka'** [**auth-method** *auth-method-id* **auth-para** *auth-para-value*]]]
Parameter Description	*realm-name*: Indicates the realm name of a NAI realm member. The value is a string of 1–252 visible characters and complies with RFC4282. It cannot contain question marks (?) and spaces, and the string cannot end with double quotation marks ("). *auth-method-id*: Indicates the authentication method. 2: **Non-EAP Inner Authentication Type**; 5: **Credential Type**; 6: **Tunneled EAP Method Credential Type** *auth-para*: Indicates authentication parameters. When **auth-method-id** is set to **2**, authentication parameters that can be configured are as follows: 1: **PAP**; 2: **CHAP**; 3: **MSCHAP**; 4: **MSCHAPV2** When **auth-method-id** is set to **5**, authentication parameters that can be configured are as follows: 1: **SIM**; 2: **USIM**; 3: **NFC Secure Element**; 4: **Hardware Token**; 5: **Softoken**; 6: **Certificate**; 7: **Username/password**; 8: **None***(server-side authentication only) When **auth-method-id** is set to **6**, authentication parameters that can be configured are as follows: 1: **SIM**; 2: **USIM**; 3: **NFC Secure Element**; 4: **Hardware Token**; 5: **Softoken**; 6: **Certificate**; 7: **Username/password**; 9: **Anonymous**
Defaults	No NAI realm member is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of 16 NAI realm members can be configured. Authentication parameters need to be configured based on the current user scenario to ensure that the configuration is consistent with the authentication environment. If the authentication environment is not specified, you can skip the authentication parameter configuration.

Configuring the IP Protocol and Port Connection Capability

- Optional.
- Configure the connection capability in the Hotspot 2.0 profile, including allowed IP protocols and ports of the network.
- Configure whether a Hotspot 2.0 network supports common IP protocols and ports.

Command	**connection-capability** { **esp** | **icmp** | **tcp-ftp** | **tcp-http** | **tcp-pptp-vpn** | **tcp-ssh** | **tcp-tls-vpn** | **tcp-voip** | **udp-ike2-4500** | **udp-ike2-500** | **udp-voip** } { **enable** | **disable** }
Parameter Description	N/A
Defaults	A Hotspot 2.0 network supports all IP protocols and ports.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	N/A

Configuring DGAF

- Optional.

- Configure DGAF in the Hotspot 2.0 profile.
- After the DGAF function is enabled on an AP, the AP forwards all downstream wireless broadcast ARP packets and wireless multicast packets. After the DGAF function is disabled, the AP discards all downstream wireless broadcast ARP packets and wireless multicast packets. Disabling DGAF can prevent attackers from forging group address frames and attacking clients by utilizing the vulnerability that all clients in the same BSS use the same group temporal key (GTK). If wireless broadcast ARP packets or wireless multicast packets need to be forwarded, you can enable proxy ARP before disabling DGAF.

Command	**dgaf {enable | disable }**
Parameter Description	N/A
Defaults	DGAF is enabled.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	N/A

Configuring the Operator Name

- Optional.
- Configure the operator name in the Hotspot 2.0 profile.
- If there are multiple operator names, they refer to the same operator name in different languages.

Command	**operator-name language-code** *language-code* **name** *name*
Parameter Description	*language-code*: The value is a string of 2 to 3 characters. It supports both ISO-639-1 and ISO-639-2 standards. If ISO-639-1 is adopted, **0** is added to ensure that the value contains three characters. *name*: The value is a string of 1 to 252 case-sensitive visible characters excluding question marks (?) and spaces.
Defaults	No operator name is configured.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of eight operator names can be configured.

Configuring DLS Connection Control

- Optional.
- Configure DLS connection control in the Hotspot 2.0 profile.
- STAs in the same BSS cannot directly perform Layer 2 communication with each other, and Layer 2 packet detection and filtering are required for the communication. Hotspot 2.0 supports only DLS control and TDLS control.

Command	**dls-tdls {enable | disable}**
Parameter Description	N/A
Defaults	DLS and TDLS connections can be established between STAs.
Command Mode	Hotspot 2.0 configuration mode

Usage Guide	N/A

Configuring an OSU Provider Profile to Be Applied

- Optional.
- Configure an OSU provider profile to be applied in the Hotspot 2.0 profile.
- An OSU provider profile must be configured during online sign-up, and the OSU provider profile to be applied must exist.

Command	**osu-provider** *template-name*
Parameter Description	*template-name*: Indicates the name of a profile. The value is a string of up to 32 case-sensitive visible characters excluding question marks (?) and spaces.
Defaults	No OSU provider profile is applied.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	A maximum of 16 OSU provider profiles can be applied.

Enabling GAS Response Delay

- Optional.
- Enable GAS response delay in the Hotspot 2.0 profile.
- Enable GAS response delay to delay responding to GAS requests. You are advised not to enable this function.

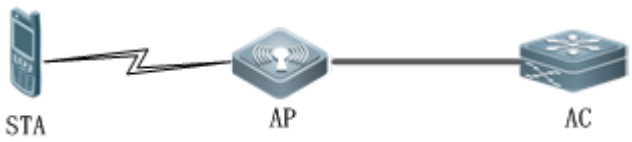
Command	**gas-response delay** { **enable** | **disable** }
Parameter Description	N/A
Defaults	GAS response delay is disabled.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	N/A

Configuring the WAN Port Status

- Optional.
- Configure the WAN port status of an AP in the Hotspot 2.0 profile.
- Perform the configuration to advertise the WAN port status of an AP to STAs so as to help STAs select appropriate Hotspot 2.0 networks.

Command	**wan-metrics link-status** { **up** | **down** | **test** } [**asymmetric downlink-speed** *downlink-speed* **uplink-speed** *uplink-speed* | **symmetric link-speed** *link-speed*]
Parameter Description	*down-speed*: Indicates the downlink speed, in kbps. The value range is from 1 to 4,194,304. *up-speed*: Indicates the uplink speed, in kbps. The value range is from 1 to 4,194,304.
Defaults	No WAN port status is configured. If no link speed is configured, the link speed is **0**, indicating unknown.
Command Mode	Hotspot 2.0 configuration mode
Usage Guide	The WAN port status includes the link work status, uplink speed, downlink speed, uplink usage, downlink usage, metrics period, whether upstream and downstream rates are the same, and whether user access

	is denied when the upper limit is reached. Currently, the uplink and downlink usage remains **0**, indicating unknown. The metrics period is set to **0**, indicating that the uplink and downlink loads cannot be calculated and are unknown. The parameter indicating whether user access is denied when the upper limit is reached is set to **0**, and whether access upper limit is reached is not detected here.



Verification

- Display the configuration of the Hotspot 2.0 profile to ensure the configuration correctness.

Configuration Example

Configuring a Hotspot 2.0 Profile in Fit AP Environment

- The configuration in the fat AP environment is completely the same as that in the fit AP environment.

Scenario **Figure 1-13**	

Configuration Steps	● Create and configure a Hotspot 2.0 profile.
	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# hotspot2 template test`
	`Hostname(config-hs20-tmplt)# 3gpp-cellular-network mcc 461 mnc 03`
	`Hostname(config-hs20-tmplt)# network-auth-type acceptance`
	`Hostname(config-hs20-tmplt)# osu-ssid osussid`
	`Hostname(config-hs20-tmplt)# vune-group 1 type 1`
	`Hostname(config-hs20-tmplt)# venue-name language-code eng name testvenue`
	`Hostname(config-hs20-tmplt)# roam-consortium oi 00-11-11 in-beacon`
	`Hostname(config-hs20-tmplt)# hessid 0141.1241.1124`
	`Hostname(config-hs20-tmplt)# domain-name www.org.com`
	`Hostname(config-hs20-tmplt)# network-type test`
	`Hostname(config-hs20-tmplt)# ipv4-address-availabe public-available`
	`Hostname(config-hs20-tmplt)# ipv6-address-availabe not-available`
	`Hostname(config-hs20-tmplt)# nai-realm realm-name testgg`
	`Hostname(config-hs20-tmplt)# connection-capability icmp enable`
	`Hostname(config-hs20-tmplt)# dgaf enable`
	`Hostname(config-hs20-tmplt)# operator-name language-code eng name mywifi`
	`Hostname(config-hs20-tmplt)# dls-tdls enable`
	`Hostname(config-hs20-tmplt)# osu-provider osu-test`
	`Hostname(config-hs20-tmplt)# gas-response delay enable`
	`Hostname(config-hs20-tmplt)# wan-metrics link-status up asymmetric`
	`downlink-speed 34 uplink-speed 56`

```
Hostname(config-hs20-tmplt)#exist

Common Errors

- N/A

1.4.2 Configuring an OSU Provider Profile

Configuration Effect

- Create a Hotspot 2.0 OSU provider profile and configure parameters in the profile. The configured Hotspot 2.0 OSU provider profile can be applied and bound to a Hotspot 2.0 profile and bound to the Hotspot 2.0 profile so that the Hotspot 2.0 profile supports the Hotspot 2.0 OSU function.

Notes

- N/A

Configuration Steps

Creating an OSU Provider Profile

- Mandatory.
- Create an OSU provider profile.
- An OSU provider profile must be configured during online sign-up.

Command	**hotspot2 osu-provider template** *template-name*
Parameter Description	*template-name*: Indicates the name of a profile. The value is a string of up to 32 case-sensitive visible characters excluding question marks (?) and spaces.
Defaults	No OSU provider profile is configured.
Command Mode	Global configuration mode
Usage Guide	A maximum of 16 OSU provider profiles can be configured.

Configuring an OSU Provider Name

- Optional.
- Configure an OSU provider name.
- If a provider has multiple names, they refer to the same provider in different languages.

Command	**friendly-name language-code** *language-code* **name** *name*
Parameter Description	*language-code*: The value is a string of 2 to 3 characters. It supports both ISO-639-1 and ISO-639-2 standards. If ISO-639-1 is adopted, **0**is added to ensure that the value contains three characters. *name*: The value is a string of 1 to 252 case-sensitive visible characters excluding question marks (?) and spaces.
Defaults	No OSU provider name is configured.
Command Mode	OSU configuration mode
Usage Guide	A maximum of eight OSU provider names can be configured.

Configuring the OSU Service Description

- Optional.
- Configure the OSU service description.
- If a provider has multiple descriptions, they refer to the same service description in different languages.

Command	**service-description language-code** *language-code* **description** *description*
Parameter Description	*language-code*: The value is a string of 2 to 3 characters. It supports both ISO-639-1 and ISO-639-2 standards. If ISO-639-1 is adopted, **0** is added to ensure that the value contains three characters.

	description: The value is a string of 1 to 252 case-sensitive visible characters excluding question marks (?).
Defaults	No OSU provider description is configured.
Command Mode	OSU configuration mode
Usage Guide	A maximum of eight OSU provider descriptions can be configured.

Configuring the OSU Server URI

- Mandatory.
- Configure the OSU server URI.
- A client accesses an OSU server through the URI of the OSU server and performs the OSU process.

Command	**server-uri** *uri*
Parameter Description	*uri*: The value is a string of 1–255 visible characters and complies with RFC4282. It cannot contain question marks (?) and spaces, and the string cannot end with double quotation marks (").
Defaults	No OSU server URI is configured.
Command Mode	OSU configuration mode
Usage Guide	Up to one OSU server URI can be configured. Repeated configuration will overwrite the previous configuration.

Configuring an OSU Method

- Mandatory.
- Configure an OSU method.
- OSU methods include the OMA DM method and SOAP XML SPP method.

Command	**method** { **oma-dm** | **soap-xml-spp** }
Parameter Description	**oma-dm**: Indicates the OMA DM method. See section 8.3 in the Hotspot 2.0 protocol. **soap-xml-spp**: Indicates the SOAP XML SPP method. See section 8.4 in the Hotspot 2.0 protocol.
Defaults	No OSU method is configured.
Command Mode	OSU configuration mode
Usage Guide	A maximum of two OSU methods can be configured at the same time.

Configuring the OSU Network Access ID

- Optional.
- Configure the OSU network access ID.
- An OSU network access ID serves as an identity for EAP authentication when a client accesses the encrypted OSU wireless service. When an encrypted OSU wireless service is provided for a client, an OSU network access ID (OSU_NAI) needs to be configured.

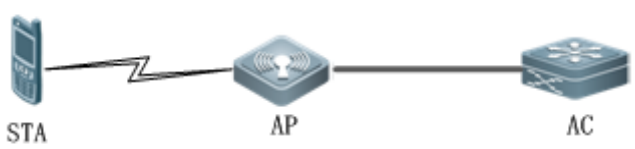
Command	**nai** *nai*
Parameter Description	*nai*: Indicates the network access ID of an OSU server. The value is a string of 1–252 case-sensitive characters.

Defaults	No network access identifier is configured for an OSU server.
Command Mode	OSU configuration mode
Usage Guide	Up to one network access identifier can be configured for an OSU server.

Configuring an OSU Icon

- Optional.
- Configure an OSU icon.
- This command only loads images to an OSU provider profile and specifies the attributes of the images. To upload and store images, you need to use other means such as FTP or TFTP. Icon images are stored in the **wlan_bs/hotspot2/icons** path.

Command	**icon-name** *name* **type** { **png| jpg**	**bmp**	**gif** } **language-code** *code* [**width** *width* **height** *height*]
Parameter Description	*name*: Indicates the name of an icon file. The value is a string of 1 to 64 case-sensitive visible characters excluding question marks (?) and spaces. *code*: The value contains 2–3 characters. It supports both ISO-639-1 and ISO-639-2 standards. If ISO-639-1 is adopted, **0** is added to ensure that the value contains three characters. *width:* Indicates the pixel width of the icon file. The value range is from 1 to 65,536. The actual value should be consistent with the real image. If it is not set, the pixel width is automatically calculated. *height***:** Indicates the pixel height of the icon file. The value range is from 1 to 65,536. The actual value should be consistent with the real image. If it is not set, the pixel height is automatically calculated.
Defaults	No OSU icon is configured.
Command Mode	OSU configuration mode
Usage Guide	A maximum of eight OSU icons can be configured and the size of each icon image cannot exceed 64 KB. One icon image can be configured only once in the same OSU provider profile, and one image cannot be used for more than one language.



Verification

- Display the configuration of the OSU provider profile to ensure the configuration correctness.

Configuration Example

Configuring an OSU Provider Profile in Fit AP Environment

- The configuration in the fat AP environment is completely the same as that in the fit AP environment.

Scenario **Figure 1-14**	
Configuration	● Create and configure an OSU provider profile.

1.4.3 Applying a Hotspot 2.0 Profile to a WLAN on an AC

Configuration Effect

- Apply Hotspot 2.0 configuration to a WLAN so that the WLAN can run the Hotspot 2.0 functions.

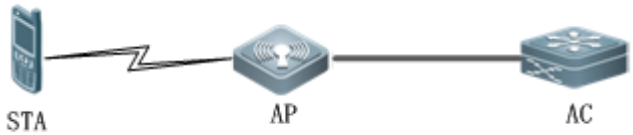
Notes

- N/A

Configuration Steps

Applying a Hotspot 2.0 Profile to a WLAN on an AC

- Mandatory.
- Apply a Hotspot 2.0 profile to a WLAN on an AP.
- Apply Hotspot 2.0 configuration to a WLAN.



Command	**hotspot2 template** *template-name*
Parameter Description	**template** *template-name*: Uses the WLAN as the Hotspot 2.0 WLAN and specifies the Hotspot 2.0 profile. The name of a Hotspot 2.0 profile is a string of up to 32 case-sensitive visible characters excluding question masks (?) and spaces.
Defaults	No Hotspot 2.0 profile is applied to a WLAN.
Command Mode	WLAN configuration mode
Usage Guide	The specified Hotspot 2.0 profile must exist. Only one Hotspot 2.0 profile can be applied to a WLAN. If Hotspot 2.0 profiles are configured for the same WLAN multiple times, the later configuration will overwrite the previous configuration.

Verification

- Display the configuration of the Hotspot 2.0 profile applied to a WLAN to ensure the configuration correctness.

Configuration Example

Applying a Hotspot 2.0 Profile to a WLAN in the AC Environment

Scenario **Figure 1-15**	
Configuration Steps	• Apply a Hotspot 2.0 profile to a WLAN.
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#wlan-config 1 test Hostname(config-wlan)#hotspot2 template testtmplt

	Hostname(config)#
Verification	Run the **show running-config** command to display the configuration.

1 Configuring STA Identification

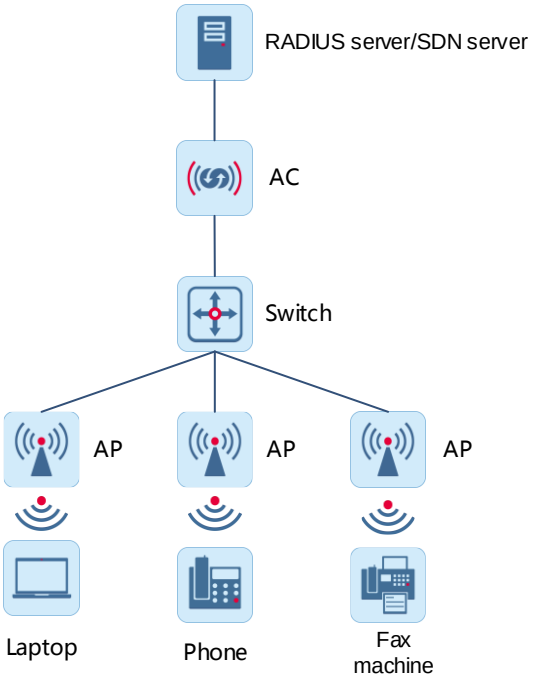
1.1 Overview

As the electronic industry develops, STAs are becoming increasingly diversified, requiring a method to identify and manage various STAs. Traditional STA management are inefficient and cannot meet the demands of modern network management.

The STA identification function analyzes and classifies STA information to identify STAs of different types. By comparing the STA information carried in different packets with the STA information feature library, it can identify the hardware information and software versions of the STAs. This method enables network administrators to perform efficient operation and maintenance (O&M), including visualized STA information, STA classification management, and authentication and accounting management.

1.2 Applications

Application	Description
Basic Scenarios of STA Identification	Users are connected to wireless devices over Layer 2 networks.



1.2.1 Basic Scenarios of STA Identification

Scenario

To facilitate monitoring and O&M, users require that wireless STAs accessing the network can be identified, and different management policies can be configured based on the STA type. In this case, a wireless access controller (AC) and an SDN controller or RADIUS server can work together to achieve effective management on STAs of different types.

- Enable STA identification on the AC or SDN controller. The AC can directly identify original data and report the identification result to the RADIUS server. Alternatively, the AC can send original data to the SDN controller for identification.
- The RADIUS server or SDN controller implements authentication control based on the identification result and delivers authorization information.

Figure 1-1 STA Identification

Deployment

- Enable global STA identification on the AC.

1.3 Features

Basic Concepts

STA Identification by an AC

The STA identification function is enabled on an AC to collect the packets of STAs and then identify the STA information, including STA types, operating systems, vendors, and models.

STA Identification by an SDN Controller

An AC collects original packets from STAs and send the packets to an SDN controller. Then the SDN controller identifies the STA information, including STA types, operating systems, vendors, and models.

Overview

Feature	Description
STA Identification by an AC	The STA identification function is enabled on an AC to collect the packets of STAs and then identify the STA information, including STA types, operating systems, vendors, and models.

STA Identification by an SDN Controller	A Ruijie SDN controller needs to be deployed on the network to identify the STA information, including STA types, operating systems, vendors, and models.

1.3.1 STA Identification by an AC

The STA identification function is enabled on an AC to collect the packets of STAs and then identify the STA information, including STA types, operating systems, vendors, and models.

Working Principle

- In a scenario where the IP address of a STA is automatically allocated by the DHCP server and the DHCP snooping function is enabled on the AC, the AC identifies the STA information such as the STA type and operating system based on DHCP options when the STA requests an IP address.
- When a STA adopts web-based authentication, the AC identifies information such as the product model and operating system version based on the User-Agent field sent by the browser.
- On an AC that supports STA identification profile configuration, you can configure the AC to collect specified types of packets such as DHCP, HTTP, DNS, mDNS, and SIP packets, and to extract key characteristics from the collected information for identifying STAs.

1.3.2 STA Identification by an Controller

Working Principle

By collecting specified types of packets such as DHCP, HTTP, DNS, mDNS, and SIP packets and extracting key characteristics from the collected information, the AC reports the characteristics to an SDN controller through gRPC. The SDN controller identifies the STA information, including STA types, operating systems, vendors, and models.

1.4 Configuration

Configuration	Description and Command	
Configuring STA Information Collection	(Mandatory) It is used to enable global STA identification.	
	terminal-identify enable	Enables global STA identification.
	(Mandatory) It is used to create a STA identification profile.	
	terminal-identify-template *template-name*	Creates a STA information collection profile.
	(Optional) It is used to configure basic parameters of a collection profile.	
	dhcp enable	Enables DHCP packet collection.
	dns enable	Enables DNS packet collection.
	mdns enable	Enables mDNS packet collection.
	http enable	Enables HTTP packet collection.

	sip enable *address port*	Configures SIP packet collection.
	notification enable	Enables data reporting through gRPC.
	terminal-identify template *template-name* **global**	Applies a STA identification profile globally
Configuring STA Identification Component UpgradeUpgrade	**terminal-identify upgrade feature flash**:*/url*	Upgrades the STA identification feature library.
	terminal-identify upgrade engine flash:*/url*	Upgrades the STA identification engine model.

1.4.1 Configuring STA Information Collection

Configuration Effect

- The AC collects STA packets of specified types and sends the packets to the SDN controller for identification of STA types, operating systems, vendors, and models.

Notes

- N/A

Configuration Steps

Enabling STA Identification

Command	**terminal-identify enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Creating a STA Information Collection Profile or Entering STA Information Collection Profile Configuration Mode

Command	**terminal-identify-template** *template-name*
Parameter Description	*template-name*: Indicates the profile name.
Command Mode	Global configuration mode
Usage Guide	1. If the profile name does not exist, create a collection profile and enter the collection profile configuration mode. 2. If the profile name already exists, enter the collection profile configuration mode. 3. Up to five templates can be created.

Enabling DHCP Packet Collection

Command	**dhcp enable**

Parameter Description	N/A
Command Mode	STA information collection profile configuration mode
Usage Guide	N/A

Enabling DNS Packet Collection

Command	**dns enable**
Parameter Description	N/A
Command Mode	STA information collection profile configuration mode
Usage Guide	N/A

Enabling mDNS Packet Collection

Command	**mdns enable**
Parameter Description	N/A
Command Mode	STA information collection profile configuration mode
Usage Guide	N/A

Enabling HTTP Packet Collection

Command	**http enable**
Parameter Description	N/A
Command Mode	STA information collection profile configuration mode
Usage Guide	N/A

Configuring SIP Packet Collection

Command	**sip enable** { *ipv4-address* | *ipv6-address* } *port*
Parameter Description	*ipv4-address*: Indicates the IPv4 address of the SIP server. *ipv6-address*: Indicates the IPv6 address of the SIP server. *port*: Indicates the port number of the SIP server.
Command Mode	STA information collection profile configuration mode
Usage Guide	After this function is enabled, SIP packets with specified destination addresses and ports are collected for STA identification. A maximum of five SIP server addresses can be configured in a profile. The SIP packet collection function can be configured only for unicast addresses.

Enabling Data Reporting through gRPC

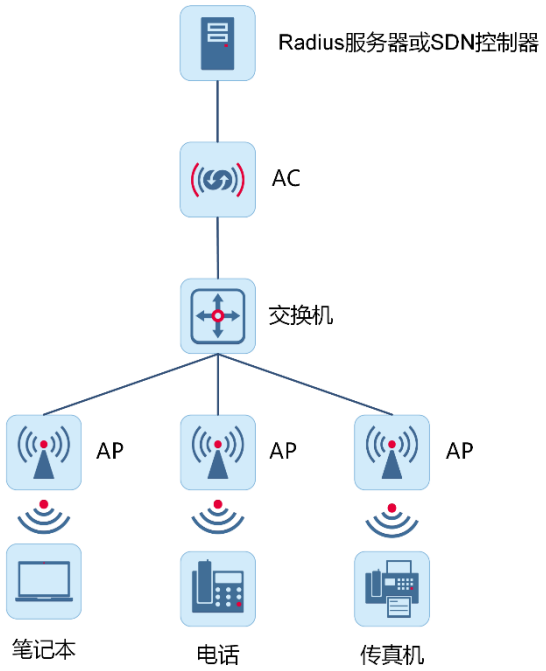
Command	**notification enable**
Parameter Description	N/A
Command Mode	STA information collection profile configuration mode
Usage Guide	N/A

Applying a STA Information Collection Profile Globally

Command	**terminal-identify template** *template-name* **global**
Parameter Description	*template-name*: Indicates the profile name.
Command Mode	Global configuration mode
Usage Guide	1. Only one STA information collection profile can be applied globally. 2. When a STA information collection profile is applied, it indicates that the STA information collection function is enabled.

Configuring the Uploading Mode of the Collected STA Information

Command	**terminal-identify hw-radius-attr option**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable this function, you need to run the **radius-server authentication vendor hw package** command first to configure the device to encapsulate a Huawei proprietary attribute in RADIUS authentication request packets. For details, see *Configuring RADIUS*.



Verification

- Run the **show running-config** command to check whether STA information collection is enabled and display information about the created profile as well as the application status of the global profile.
- Enter the STA information collection profile configuration mode and run the **show this** command to display the configuration of the profile.

Configuration Examples

The following configuration example only describes the configuration related to STA identification.

Configuring STA Identification

Scenario **Figure1-2**	
Configuration Steps	● Enable STA identification on the AC. ● Enter the default STA information collection profile named **default** and disable the collection of DNS and mDNS packets. ● Apply the STA information collection profile named **default** globally.
	Hostname# config Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#terminal-identify enable Hostname(config)#terminal-identify-template default Hostname(terminal-identify-template)#no dns enable Hostname(terminal-identify-template)#no mdns enable Hostname(terminal-identify-template)#exit Hostname(config)#terminal-identify template default global
Verification	● Display the configuration of the default STA information collection profile named **default**.
	Hostname#show terminal-identify template Template apply(default) Template default: Type Status -------- -------- DHCP Enable DNS Enable MDNS Enable HTTP Enable ● Display the application status of the STA information collection profile.

	Hostname#show running-config | include terminal-identify terminal-identify template default global

1.4.2 Configuring STA Identification Component Upgrade

Configuration Effect

- Upgrade the STA identification feature library and engine model to the latest version.

Notes

- N/A

Configuration Steps

Upgrading the STA Identification Feature Library

Command	**terminal-identify upgrade feature flash**:*/url*
Parameter Description	*url*: Indicates the path of the feature library file to be upgraded.
Command Mode	Global configuration mode
Usage Guide	The feature library stores the STA identification codes supported by the system. If STA identification codes in the feature library need to be updated, run this command to upgrade the feature library.

Upgrade the STA Identification Engine Model

Command	**terminal-identify upgrade engine flash**:*/url*
Parameter Description	*url*: Indicates the path of the engine model file to be upgraded.
Command Mode	Global configuration mode
Usage Guide	The command is used to upgrade the engine model on products supporting the STA identification engine.

Verification

Run the **show terminal-identify database upgrade history** command to display the upgrade records.

1.5 Monitoring

Displaying

Command	Description
show terminal-identify user	Displays the STA identification result.
show terminal-identify database version	Displays the feature library and engine model version on the device.

show terminal-identify database upgrade history	Displays the update records of the feature library and engine model on the device.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug terminal-identify	Debugs STA identification.

1 Configuring STA Connectivity Test

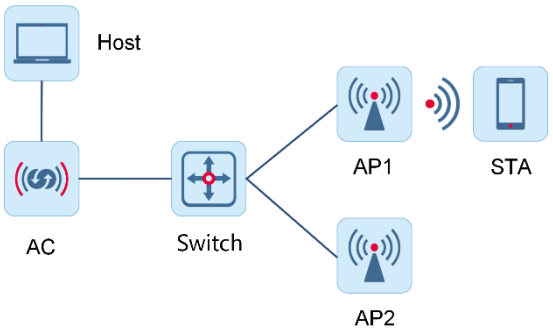
1.1 Overview

When a fault occurs on a network, it is necessary to quickly and accurately locate the fault and rectify it to restore network services. The connectivity test function is used to detect connectivity between stations (STAs) and different key nodes (such as air interface, gateway, and server). By configuring the target detection node for connectivity test, you can detect the delay and packet loss rate on the link between a STA and the corresponding node.

Protocols and Standards

N/A

1.2 Applications



Application	Description
Checking Checking Connectivity Between a STA and the Air Interface of an APthe Air Interface of an AP	In Fit AP mode, a wireless access point (AC) sends a VSP message to an access point (AP) based on the STA's MAC address to trigger link detection on the AP. The AC simulates packet exchange between the AP and STA to obtain the delay and packet loss rate.
Checking Checking Connectivity Between a STA and the Gateway/DHCP Server/DNS Server	In Fit AP mode, the AC sends a VSP message to the AP based on the STA's MAC addresses to trigger link detection on the AP. The AC simulates packet exchange between the AP and the gateway, DHCP server, or DNS server of the STA to obtain the delay and packet loss rate.

1.2.1 Checking Connectivity Between a STA and the Air Interface of an AP

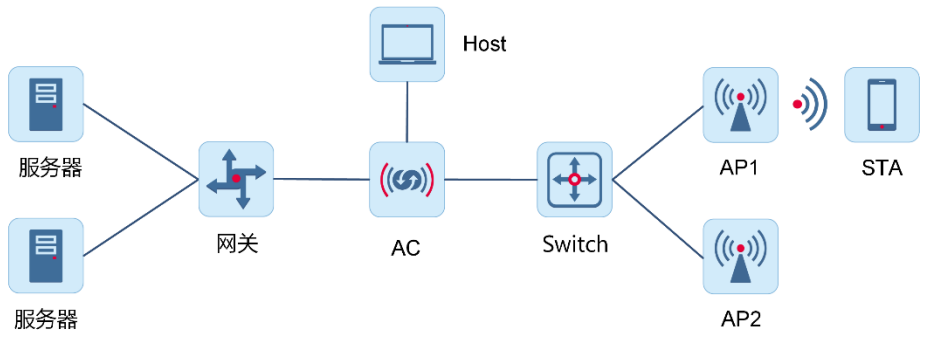
Scenario

In Fit AP mode, the AC sends a VSP message to the AP based on the MAC address of a STA to trigger link detection on the AP. The AC simulates packet exchange between the AP and STA to obtain the delay and packet loss rate.

Figure 1-1 Checking Connectivity Between a STA and the Air Interface of an AP

Remarks	Switch: A switch AC: A wireless access controller. AP1 and AP2: Two wireless access points. Host: A remote host. STA: A wireless access endpoint.

Deployment



- Enable STA connectivity test on a specified AP connected to the AC.
- Configure the VLAN of the STA to be detected on the AC.
- Configure the MAC address of the STA to be detected on the AC.
- Configure the AC to check the connectivity between the STA and the air interface of the AP.

1.2.2 Checking Connectivity Between a STA and the Gateway/DHCP Server/DNS Server

Scenario

In Fit AP mode, the AC sends a VSP message to the AP based on the MAC address of a STA to trigger link detection on the AP. The AC simulates packet exchange between the AP and the gateway, DHCP server, or DNS server of the STA to obtain the delay and packet loss rate.

Figure 1-2 Checking Connectivity Between a STA and the Gateway/DNS/DHCP Server

Deployment

- Enable STA connectivity test on a specified AP connected to the AC.
- Configure the VLAN of the STA to be detected on the AC.
- Configure the MAC address of the STA to be detected on the AC.
- Configure the AC to check the connectivity between the STA and the gateway, DHCP server, or DNS server.

1.3 Features

Basic Concepts

Packet Loss and Delay Statistics

The AC collects packet loss and delay statistics through Internet Control Message Protocol (ICMP).

CAPWAP Tunnel

In a fit AP network architecture, the AC uniformly manages all APs through a Control and Provisioning of Wireless Access Points (CAPWAP) tunnel, and delivers control policies to APs, eliminating the need to configure APs separately. The CAPWAP tunnel between an AP and the AC consists of a control tunnel and a data tunnel. The AC delivers configurations to the AP and the AP sends event notifications to the AC over the control tunnel, while data packets is transmitted over the data tunnel between the AC and AP.

Overview

Feature	Description
STA Connectivity Test	After the STA connectivity test function is enabled on a specified AP, the AP proactively generates ICMP packets for the STA to be detected and simulates the STA's ICMP communication to detect the link connectivity.

1.3.1 STA Connectivity Test

After the STA connectivity test function is enabled on a specified AP, the AP proactively generates ICMP packets for the STA to be detected and simulates the STA's ICMP communication to detect the link connectivity.

Working Principle

When a connectivity test is performed, the WLAN ID, radio ID, VLAN ID, and forwarding mode of the STA are collected. After link detection is enabled, the AP checks whether the STA is online based on the configuration of the STA connectivity test function. If the STA is online, the AP generates an ICMP packet based on the IP and MAC addresses of the STA. The DATA field in the ICMP packet records information such as the REQ_ID, generation time, and special flag, and stores the packet sending status. The AP simulates a normal STA to send the ICMP request packet, and records the delay and packet loss rate based on the ICMP response packet. Then, the AP sends the information collected at an interval to the AC for storage.

1.4 Configuration

Configuration	Description and Command	
Configuring STA Connectivity	(Mandatory) It is used to enable the STA connectivity test function.	
	sta-cv enable	Enables the STA connectivity test function.
	(Mandatory) It is used to configure the VLAN of the STA.	
	sta-cv vlan	Configures the VLAN of the STA.
	(Optional) It is used to configure the link detection interval for a STA.	
	sta-cv detect interval	Configures the link detection interval for a STA.
	(Mandatory) It is used to configure the MAC address of the STA to be detected.	
	sta-cv mode static	Configures the MAC address of the STA.
	(Mandatory) It is used to configure the target node for link detection.	
	sta-cv target	Configures the detection node type.

1.4.1 Configuring STA Connectivity Test

Configuration Effect

The network connectivity between the STA and the AP's air interface, gateway, DHCP server, or DNS server can be checked.

Notes

N/A

Configuration Steps

Enabling STA Connectivity Test

- Mandatory.
- Enable this function on a specified AP.

Command	**sta-cv enable**
Parameter Description	N/A
Defaults	The function is disabled.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	The configuration priority is listed in descending order: AP configuration mode > AP group configuration mode > all-AP configuration mode. In cases where there are overlapping configurations on the AP, the configuration with the highest priority takes precedence. For example, if connectivity test service is

	configured in both all-AP configuration mode and AP configuration mode, the configuration in AP configuration mode prevails.

Configuring the VLAN of a STA

- Mandatory.

Command	**sta-cv vlan** *vlan-id gateway-ip gateway-mac dns-ip dhcp-ip*
Parameter Description	*vlan-id*: Indicates the VLAN ID. The value range is from 1 to 4094, and the value is unique. *gateway-ip*: Indicates the IP address of the gateway. *dhcp-ip*: Indicates the IP address of the DHCP server. *dns-ip*: Indicates the IP address of the DNS server. *gateway-mac*: Indicates the MAC address of the gateway.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	• When you configure entries with the same VLAN ID but different IP and MAC addresses, the original VLAN configuration is updated. • The STA link detection function simulates a STA to initiate link detection. Therefore, you need to configure the VLAN table associated with the STA (to simulate the forwarding path of a real user, so as to calculate the link delay and packet loss rate).

Configuring the Link Detection Interval

- Optional.

Command	**sta-cv detect interval** *interval-time*
Parameter Description	*interval-time*: Indicates the detection interval, in seconds. The value range is from 2 to 10.
Defaults	2 seconds
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the MAC Address of a STA

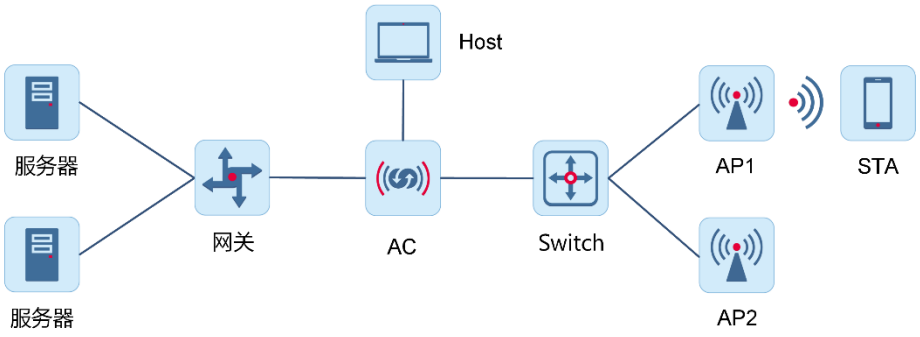
- Mandatory.

Command	**sta-cv mode static** *sta-mac*
Parameter Description	*sta-mac*: Configures the MAC address of a STA.
Defaults	N/A
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode

Usage Guide	● If you configure the MAC address of an offline STA, the configuration does not take effect until the STA goes online. ● You can configure multiple static STAs. Up to 16 static STA entries can be configured. If you configure static STA entries with the same MAC address but different IP address, the original configuration is updated.

Configuring the Detection Node Type

- Mandatory.
- To perfom link detection for a specified node, configure the type of the target node on the AC.



Command	**sta-cv target** { **air** | **gateway** | **server** { **dhcp** | **dns** | *server-ip* } }
Parameter Description	**air**: Configures the detection node as the air interface. **gateway**: Configures the detection node as the gateway. **server**: Configures the detection node as the server. **dhcp**: Specifies the DHCP server.. **dns**: Specifies the DNS server. *server-ip*: Specifies the server with a customized IP address.
Defaults	N/A
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	● If multiple detection node types are configured, the configurations take effect simultaneously. ● Up to 16 detection node entries can be configured (including the air interface, gateway, DHCP server, and DNS server).

Verification

Run the **show running-config** or **show sta-cv cur-cfg** command, or run the **show this** command in the current configuration mode, to display the configuration.

Configuration Examples

Configure STA connectivity Test on a Fit AP Network

Scenario **Figure1 -3**	
Configuration Steps	● Enter the global configuration mode. ● Configuring the VLAN of a STA.

	● Set the link detection interval to 4 seconds. ● Enter the all-AP configuration mode. ● Enable STA connectivity test on all APs. ● Configure the MAC address of a STA. ● Configure the detection nodes as the air interface, gateway, DHCP server, and DNS server.

AC	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# sta-cv vlan 101 192.168.101.1 00D0.F822.35FB 8.8.8.8 10.104.64.125`

Configuring WLAN Roaming

1. Configuring Roaming
2. Configuring MED
3. Configuring SFN

1 Configuring Roaming

Whether this function is supported depends on the actual product version.

1.1 Overview

Roaming allows stations (STAs) to be re-associated with access points (APs) when STAs move in coverage areas of different APs.

Roaming enables STAs to maintain ongoing IP communication and enjoy all application services when they move. The STAs do not detect occurrence of such a behavior during roaming.

Roaming is required when STAs move in different areas in a wireless environment. Roaming is classified into intra-AC and inter-AC roaming:

- Intra-AC roaming is applicable to a network with only one access controller (AC) deployed.
- Inter-AC roaming is applicable to a network with multiple ACs deployed.

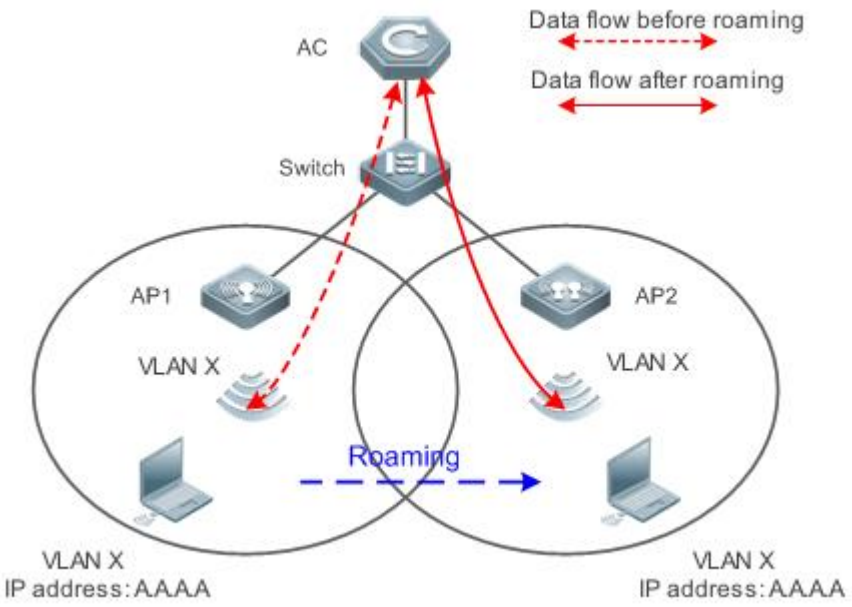
Protocols and Standards

N/A

1.2 Applications

Application	Description
Intra-AC Roaming	One STA is associated with AP1 connected to one AC, and then moves to the coverage area of AP2 connected to the same AC and is associated with AP2.
Inter-AC Roaming	One STA is associated with AP1 connected to AC1, and then moves to the coverage area of AP2 connected to AC2 and is associated with AP2.

1.2.1 Intra-AC Roaming



Scenario

One STA is associated with AP1 connected to one AC, and then moves to the coverage area of AP2 connected to the same AC and is associated with AP2. Depending on whether data is forwarded by the AC or AP, intra-AC roaming is further classified into intra-AC Layer 2 or Layer 3 roaming in centralized or local forwarding mode.

1.2.1.1 Intra-AC Layer 2 or Layer 3 Roaming in Centralized Forwarding Mode

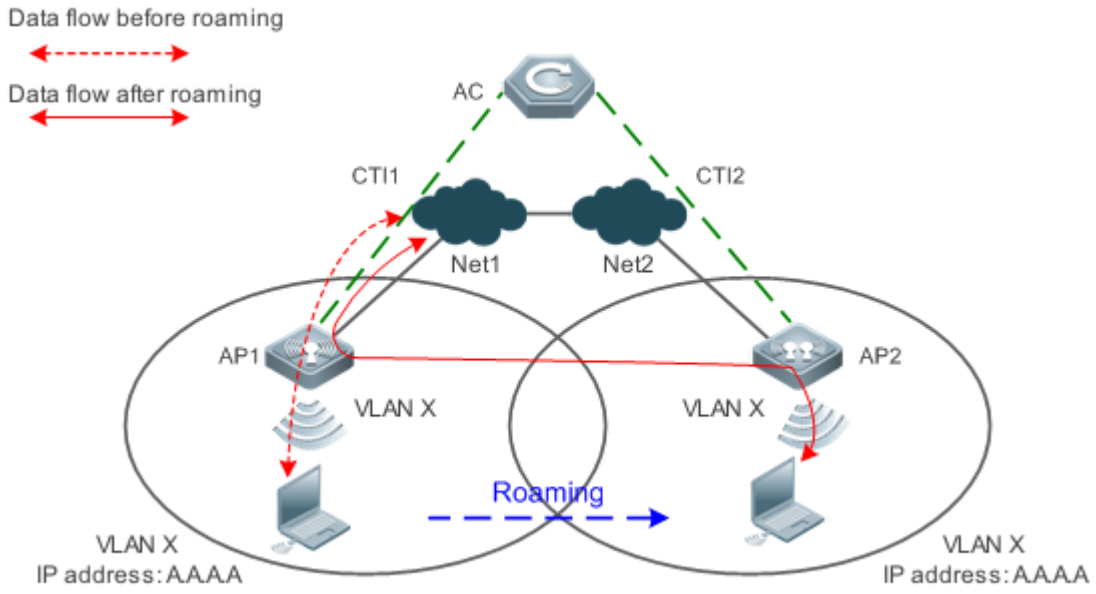
Figure 1-1 shows intra-AC Layer 2 or Layer 3 roaming in centralized forwarding mode.

Figure 1-1 Intra-AC Layer 2 or Layer 3 Roaming in Centralized Forwarding Mode

Remarks	VLAN X indicates the VLAN ID associated with the STA. (If VLAN X corresponding to AP2 is changed to VLAN Y, Layer 3 roaming occurs.)

The difference between Layer 2 and Layer 3 roaming depends on whether VLANs associated with a STA are different before and after roaming.

Deployment



- AP1 and AP2 are associated with the AC through an intermediate device and are assigned to the same WLAN.
- A STA is associated with AP1 and obtains the IP address A.A.A.A.
- Then the STA moves to the coverage area of AP2 and is associated with AP2. During this process, the IP address remains unchanged with service continuity.

A STA can roam only when the wireless service set identifiers (SSIDs) provided by AP1 and AP2 are the same.

1.2.1.2 Intra-AC Layer 2 or Layer 3 Roaming in Local Forwarding Mode

Figure 1-2 shows intra-AC Layer 2 or Layer 3 roaming in local forwarding mode.

Figure 1-2 Intra-AC Layer 2 or Layer 3 Roaming in Local Forwarding Mode

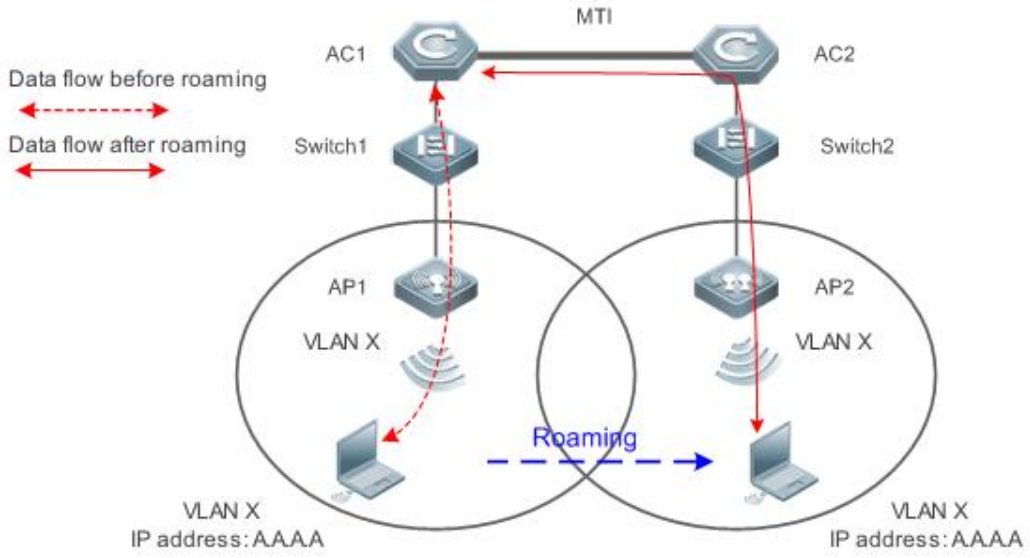
Remarks	The CTI is the communication tunnel between an AP and an AC. VLAN X indicates the VLAN ID associated with a STA.

Deployment

- AP1 and AP2 set up control channels with the AC, and are allocated to VLAN X on the same WLAN.
- AP1 and AP2 work in local forwarding mode. A STA is associated with AP1 and obtains the IP address A.A.A.A.
- Then the STA moves to the coverage area of AP2 and is associated with AP2. During this process, the IP address remains unchanged with service continuity.
- Before roaming, data is directly sent out by AP1. After roaming, data is forwarded from AP2 to AP1, and then sent out by AP1.

⚠ A STA can roam only when the SSIDs provided by AP1 and AP2 are the same.

1.2.2 Inter-AC Roaming



Scenario

One STA is associated with AP1 connected to AC1, and then moves to the coverage area of AP2 connected to AC2 and is associated with AP2. Depending on whether data is forwarded by the AC or AP, inter-AC roaming is further classified into inter-AC roaming in centralized or local forwarding mode.

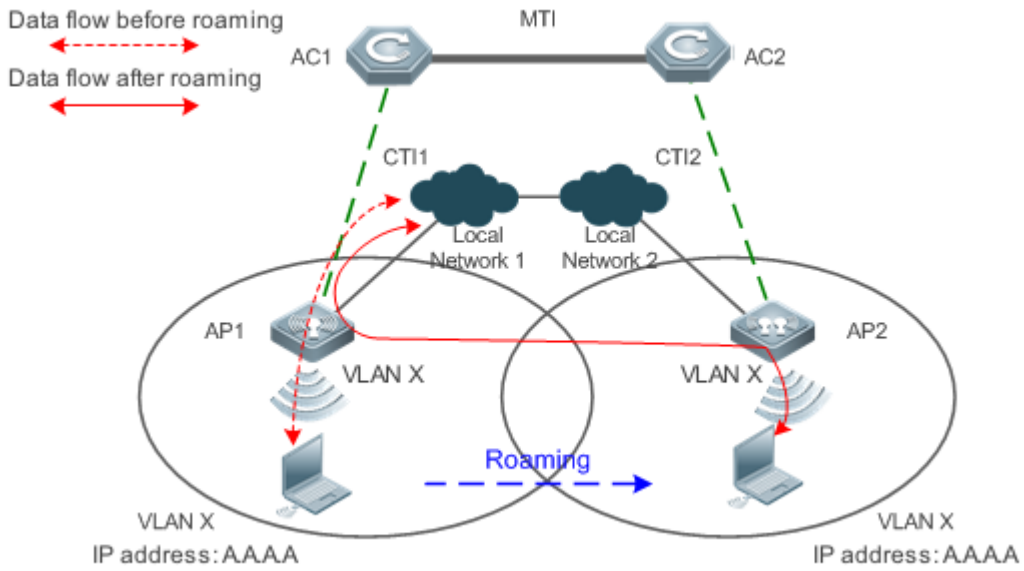
1.2.2.1 Inter-AC Layer 2 or Layer 3 Roaming in Centralized Forwarding Mode

Figure 1-3 shows inter-AC Layer 2 or Layer 3 roaming in centralized forwarding mode.

Figure 1-3 Inter-AC Layer 2 or Layer 3 Roaming in Centralized Forwarding Mode

Remarks	VLAN X indicates the VLAN ID associated with a STA. MTI is the communication tunnel between ACs.

Deployment



- AC 1 and AC 2 need to be configured as roaming members of each other and can communicate with each other.
- AP1 is connected to AC1 and AP2 is connected to AC2. Both AP1 and AP2 are assigned to VLAN X on the same WLAN.
- A STA is associated with AP1 and obtains the IP address A.A.A.A. Then the STA moves to the coverage area of AP2, and is associated with AP2. During this process, the IP address remains unchanged with service continuity.
- Before roaming, data is directly sent out by AC1. After roaming, data is forwarded from AC2 to AC1 through the MTI, and then sent out by AC1.

A STA can roam only when the SSIDs provided by AP1 and AP2 are the same.

1.2.2.2 Inter-AC Layer 2 or Layer 3 Roaming in Local Forwarding Mode

Figure 1-4 shows inter-AC Layer 2 or Layer 3 roaming in local forwarding mode.

Figure 1-4 Inter-AC Layer 2 or Layer 3 Roaming in Local Forwarding Mode

Remarks	VLAN X indicates the VLAN ID associated with the STA. The MTI is the communication tunnel between ACs, and the CTI is the communication tunnel between an AP and an AC.

Deployment

- AC 1 and AC 2 need to be configured as roaming members of each other in a roaming group.
- AP1 is connected to AC1 and AP2 is connected to AC2. Both AP1 and AP2 are assigned to VLAN X on the same WLAN. Both AP1 and AP2 work in local forwarding mode.
- A STA is associated with AP1 and obtains the IP address A.A.A.A. Then the STA moves to the coverage area of AP2, and is associated with AP2. During this process, the IP address remains unchanged with service continuity.
- Before roaming, data is directly sent out by AP1. After roaming, data is forwarded from AP2 to AP1, and then sent out by AP1.

⚠ A STA can roam only when the SSIDs provided by AP1 and AP2 are the same.

1.3 Features

Basic Concepts

Association and Re-Association

Association: A STA selects an extended service area, and sends the asso frame to set up a connection with this extended service area.

Re-association: A STA moves from a service area of an extended service area to another service area, and is associated with a new AP. In this case, the STA sends the reasso frame.

STA, AP, and AC

STA: Is a wireless workstation that is equipped with the wireless network interface card (NIC), such as a portable computer or a mobile phone.

AP: Is a wireless access point that provides radio signals for the associated STA to access a wireless network.

AC: Is a wireless access controller that provides wireless connections and related service functions.

L2 Roaming and L3 Roaming

L2 roaming: The VLAN to which a STA belongs remains unchanged before and after roaming.

L3 roaming: The VLAN to which a STA belongs changes after roaming.

Centralized Forwarding and Local Forwarding

Centralized forwarding: All packets of a STA are forwarded by an AC.

Local forwarding: Control packets of a STA are processed by an AC, whereas data packets are directly forwarded by an AP.

Intra-AC Roaming and Inter-AC Roaming

Intra-AC roaming: A STA roams from one AP connected to an AC to another AP connected to the same AC.

Inter-AC roaming: A STA roams from an AP connected to an AC to another AP connected to a different AC.

Home AC and Foreign AC

- Home AC (HA): When a STA is associated with an AC in the mobility group for the first time, this AC is called HA of the STA.
- Foreign AC (FA): A STA is connected to an AC that is not the HA. This AC is called FA of the STA.

For intra-AC roaming, the HA and FA are the same.

Overview

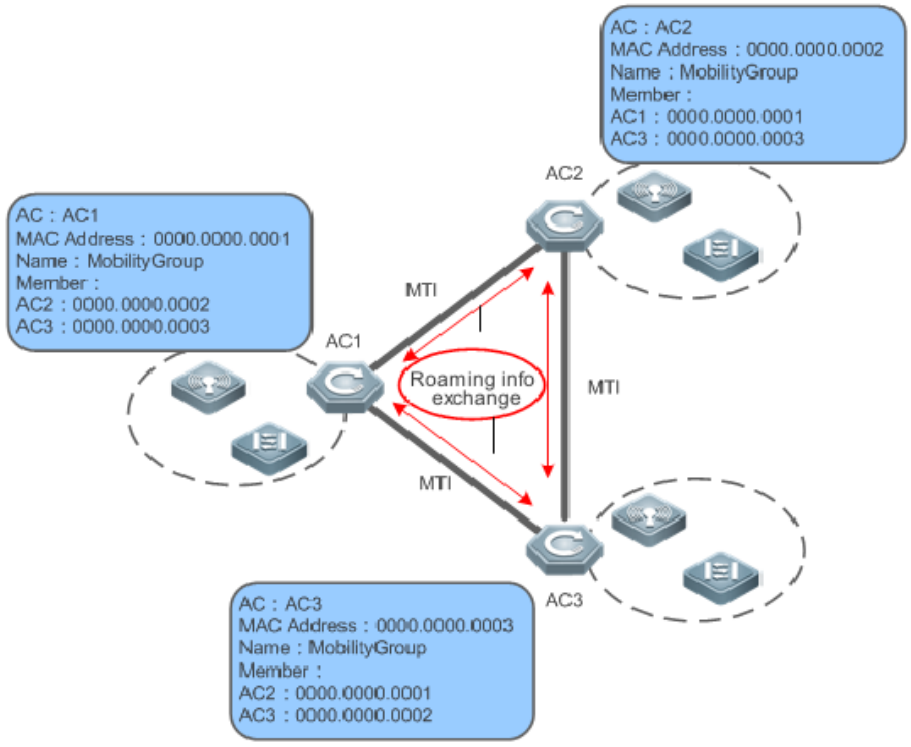
Feature	Description
Mobility Group	After a mobility group is configured, a STA can roam to different ACs in the same mobility group.

Mobility List	The mobility list is an extension of the mobility group. The number of AC members in the mobility group is limited. The mobility list is introduced to extend the roaming scope of STAs without affecting roaming of the mobility group.
Checking the STA Roaming Status and Roaming Tracks	The status of all roaming STAs on the local AC and the roaming track of a STA can be displayed.
Suppressing STA Roaming Syslogs	The output rate of STA roaming syslogs is suppressed.
Disabling Roaming Based on WLANs	When multiple WLANs have been planned with the same SSID, roaming can be disabled based on the WLAN ID so that resources on the WLAN can be allocated properly. This ensures that STAs accessing a WLAN ID do not roam to other WLAN IDs with the same SSID.
Disabling Roaming Based on the Device	STAs do not roam when they move between ACs by disabling the inter-AC roaming function.

1.3.1 Mobility Group

The roaming scope of STAs within a WLAN cannot be expanded without limit. To enable a STA to roam among APs connected to different ACs and manage the roaming scope of STAs, configure a mobility group to include a group of ACs within the roaming scope of STAs.

Working Principle



Each AC is configured with a list of other members of a mobility group. When a STA joins an AC, the AC sends out a message to all the other ACs in the mobility group. If it is the first time the STA accesses the mobility group, the initially connected AC (HA) will save information about the STA. When the STA roams to another AC (FA), the HA synchronizes the STA information to the FA. If this STA is roaming, the HA synchronizes the STA information to the FA after receiving a notification message.

Generally, the roaming STA information is exchanged only after roaming occurs. Before roaming occurs, the information synchronization function of the mobility group can be used to proactively share STA information among ACs in the mobility group. This saves time in STA roaming and improves the roaming efficiency.

↘ Topology of the Mobility Group

ACs in a mobility group encapsulate and transfer roaming information through the Controlling and Provisioning of Wireless Access Point (CAPWAP) tunnel. This technology reduces the re-authentication time on the RADIUS server after inter-AC roaming of STAs, and accelerates authentication of roaming STAs, facilitating seamless roaming. **Figure 1-5** shows the topology of the mobility group.

Figure 1-5 Topology of the Mobility Group

Remarks	The MTI is the communication tunnel between ACs. AC1, AC2, and AC3 are in the same mobility group. On each AC, another two ACs are configured as its mobility members.

1.3.2 Mobility List

A mobility list is an extension of a mobility group. The number of AC members in a mobility group is limited, so the mobility list is introduced to extend the roaming scope of STAs without affecting roaming of the mobility group.

Working Principle

↘ Comparison Between a Mobility List and a Mobility Group

Data exchange of roaming STAs in a mobility list is similar to that in a mobility group. The difference is as follows: Intra-group roaming adopts Proactive Key Caching (PKC), while inter-group roaming uses the mobility list that requires a roaming STA to complete the entire authentication process with the AAA/RADIUS server. Compared with intra-group roaming, inter-group roaming has lower efficiency. The similarity between them is that the roaming process is seamless and transparent for STAs.

When an AC is allocated to a specific mobility group, STAs connected to the AC are allowed to roam within the mobility group. If a mobility list is configured on the AC (with member ACs not in the same mobility group as the current AC), STAs on the current AC are allowed to roam across mobility groups.

1.3.3 Checking the STA Roaming Status and Roaming Tracks

To learn the roaming status and mobility of all STAs on an AC, you can check the status and roaming tracks of roaming STAs.

Working Principle

Information about roaming STAs is recorded on the HA, including the roaming type, connected WLAN, as well as VLANs, APs, and radios before and after roaming. Such information is stored, and deleted only when the STAs are deassociated.

The roaming track is recorded by default.

1.3.4 Suppressing STA Roaming Syslogs

STA roaming syslog suppression prevents a high CPU usage caused by a large amount of syslogs output during roaming of a large number of STAs.

Working Principle

The number of output syslogs per second is counted. When the number reaches the upper limit, no more syslog is output within the second. In the next second, the number of syslogs is counted again.

1.3.5 Disabling Roaming Based on WLANs

When multiple WLANs have been planned with the same SSID, roaming can be disabled based on the WLAN ID so that resources can be properly allocated on the WLAN. This ensures that users accessing a particular WLAN ID do not roam to other WLAN IDs with the same SSID.

Working Principle

When an AC receives a roaming request, it checks whether roaming is disabled for the incoming or outgoing WLAN. If so, roaming is not allowed, and the STA goes online normally.

1.3.6 Disabling Roaming Based on the Device

By default, after Layer 3 roaming occurs, a STA still uses the VLAN before roaming for communication on a network to ensure that the STA's IP address remains unchanged after roaming. However, in some special scenarios, STAs may need to use the VLAN assigned after roaming to communicate. This can be achieved by disabling roaming.

After roaming is disabled, moving a STA from one AP to another is referred to as migration. After migration, the STA uses the VLAN assigned after migration to communicate. Migration with the same VLAN before and after migration is called Layer 2 migration, while migration with different VLANs before and after migration is called Layer 3 migration.

For roaming on the entire network, ensure that the STA's IP address can be used for communication in a VLAN before and after roaming. Otherwise, the STA may fail to access the network after roaming.

By disabling the inter-AC roaming function, STAs can be prevented from roaming between ACs.

Working Principle

Roaming can be disabled based on centralized forwarding and local forwarding.

When roaming is disabled based on centralized forwarding, STAs associated with WLANs in centralized forwarding mode will use the VLAN mapped by the AP after Layer 3 roaming for communication.

Local forwarding works in the same manner. When roaming is disabled based on local forwarding, STAs associated with WLANs in local forwarding mode will use the VLAN mapped by the AP after Layer 3 roaming for communication.

For Layer 3 migration, the device checks whether the IP address of a STA is changed by default. If the IP address remains unchanged, the STA does not r-apply for an IP address and cannot access the Internet. The STA is disconnected to trigger the STA to go online and obtain the IP address again. If the IP address of the STA can be used for Internet access before and after Layer 3 migration, detecting IP address changes can be disabled.

Inter-AC roaming requires the use of the roaming tunnel, that is, the MTI tunnel to exchange packets. MTI tunnels fall into data and control channels, which use UDP as the transport-layer protocol. The data channel uses UDP port 5249, and the control channel uses UDP port 5248. The inter-AC roaming function can be used to control whether the roaming module monitors the corresponding port, thereby disabling the inter-AC roaming function.

1.4 Configuration

Configuration	Description and Command	
Configuring a Mobility Group	⚠ (Optional) It is used to implement the inter-AC roaming function.	
	mobility-group	Configures a mobility group.
	member	Adds or deletes a mobility member to or from the mobility group.
Configuring Proactive Information Exchange within the Mobility Group	⚠ (Optional) It is used to exchange STA information within the mobility group.	
	mobility-fast	Enables proactive information exchange within a mobility group.
Configuring a Mobility List	⚠ (Optional) It is used to add members to a mobility list.	
	list	Adds or deletes member ACs to or from the mobility list.
Configuring the Number of Times a Keepalive Packet Can Be Transmitted	⚠ (Optional) It is used to configure the maximum number of times a keepalive packet can be transmitted. If the value is exceeded, the keepalive attempt fails.	
	keepalive-count	Configures the maximum number of times a keepalive packet can be transmitted
Configuring the Interval at Which a Keepalive Packet Is Sent	⚠ (Optional) It is used to configure the interval at which a keepalive packet is sent.	
	keepalive-interval	Configures the interval at which a keepalive packet is sent.
	⚠ (Optional) It is used to test whether ACs in a mobility group are interconnected properly.	

Testing Roaming Connectivity_Starting_a_Roaming	mti-ping	Tests connectivity of tunnels between ACs in a mobility group.
Suppressing STA Roaming Syslogs	(Optional) It is used to suppress the output rate of STA roaming syslogs.	
	roaming logging rate-limit	Sets the output rate of STA roaming syslogs.
Preventing STA Roaming	(Optional) It is used to disable roaming on a specified WLAN.	
	roaming support wlan	Configures whether roaming is allowed within a specified WLAN.
Disabling Roaming Based on the Device	(Optional) It is used to disable roaming in some scenarios.	
	roaming central-unroam	Disables roaming in centralized forwarding.
	roaming local-unroam	Disables roaming in local forwarding.
	roaming disable	Disables inter-AC roaming.
	roaming local-layer2 direct	Configures migration for roaming in local forwarding mode.

1.4.1 Configuring a Mobility Group

Configuration Effect

- Configure a mobility group and add a mobility member to implement inter-AC roaming.
- The centralized forwarding mode is configured in the same way as the local forwarding mode.

Notes

To implement inter-AC roaming, ensure that the two ACs can communicate with each other normally.

Configuration Steps

Creating a Mobility Group

- (Optional) The configuration is mandatory if inter-AC roaming needs to be implemented. Run the **mobility-group** *group-name* command to create a mobility group.
- Configure at least one mobility group on each AC that involves inter-AC roaming.

Up to eight mobility groups can be created on an AC.

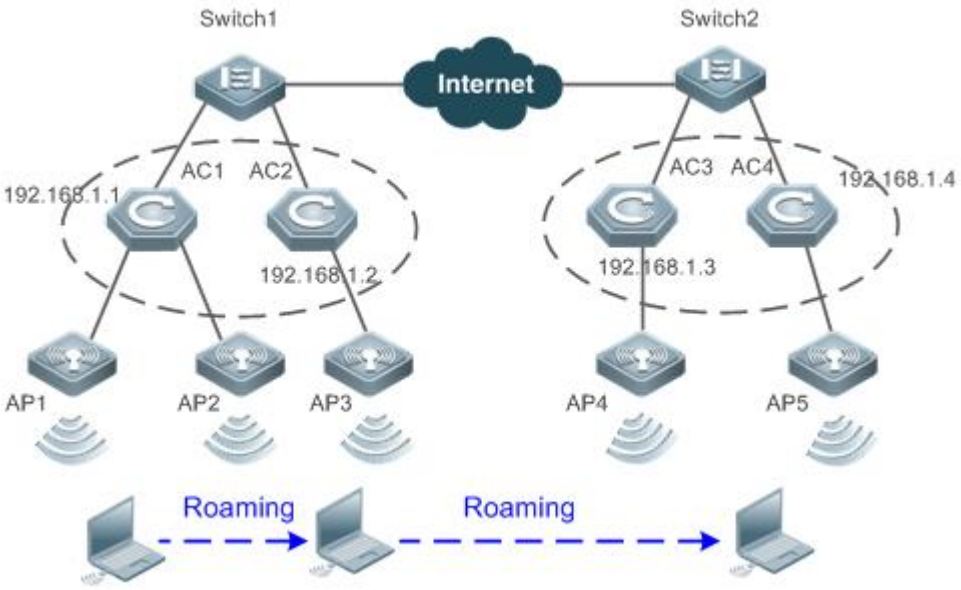
Command	**mobility-group** *group-name*
Parameter Description	*group-name*: Specifies the name of a mobility group.
Defaults	No mobility group is configured by default.
Command Mode	Global configuration mode

Usage Guide	N/A

Adding Mobility Members

- (Optional) The configuration is mandatory if inter-AC roaming needs to be implemented.
- Add at least one member to a mobility group on each AC that involves inter-AC roaming.
- After a mobility group is created, there is no mobility member in the group. Therefore, you need to add one or more mobility members.
- To ensure that information is efficiently and reliably synchronized between ACs within a mobility group, you must limit the number of members in the mobility group. A mobility group supports up to 24 mobility members.

Command	**member** {ip-address|ipv6-address}
Parameter Description	*ip-address:* Indicates the IPv4 address of a mobility member. *ipv6-address:* Indicates the IPv6 address of a mobility member.
Defaults	A new mobility group does not contain any member.
Command Mode	Mobility group configuration mode
Usage Guide	N/A



Verification

Check mobility group information to determine whether members are successfully added and whether connections are normal.

Configuration Example

All the configuration examples in this document are provided for the scenario of inter-AC roaming in centralized forwarding mode.

Configuring a Mobility Group and Adding a Member to this Group

Scenario **Figure 1-6**	 ● Inter-AC or intra-AC Roaming Scenario
Configuration Steps	● Set loopback addresses of AC1 and AC2 to 192.168.1.1 and 192.168.1.2 respectively, and ensure that one AC can be pinged successfully from another AC. ● Add a mobility group. ● Add a mobility member.

AC1	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#mobility-groupmgroup_name`
	`Hostname(config-mobility)#member 192.168.1.1`

AC2	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#mobility-groupmgroup_name`
	`Hostname(config-mobility)#member 192.168.1.2`

Verification	● Check mobility group information to determine whether the configurations are successful. ● Run the **show mobility status** *mgroup_name* command on each AC.

AC1	`Hostname# show mobility status mgroup_name`
	`Mobility Group mgroup_name`
	`Mobility Keepalive Interval..... 10`

	Mobility Keepalive Count..... 3 Mobility Group Status..... normal Mobility Members: IP Address Client/Server Data Tunnel Ctrl Tunnel 192.168.1.1Client OK Mobility List Members:
AC2	Hostname# show mobility status mgroup_name Mobility Group mgroup_name Mobility Keepalive Interval..... 10 Mobility Keepalive Count..... 3 Mobility Group Status..... normal Mobility Members: IP Address Client/Server Data Tunnel Ctrl Tunnel 192.168.1.2Client OK Mobility List Members:

Common Errors

- Mobility AC members fail to ping each other.
- The mobility group or members are not configured on an AC.
- The mobility group names are inconsistent.

1.4.2 Configuring Proactive Information Exchange within the Mobility Group

Configuration Effect

When roaming does not occur, an AC also shares STA information with other AC members in the mobility group.

Notes

A mobility group must be configured.

Configuration Steps

- (Optional) After configuring a mobility group on ACs, enter the mobility group configuration mode and enable proactive information exchange.
- (Optional) Configure fast roaming as required.

Command	mobility-fast
Parameter Description	N/A
Defaults	Proactive information exchange is disabled by default.
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

Check mobility group information. If the mobility group status is Fast Mode, the configuration is successful.

Configuration Example

Configuring Proactive Information Exchange within the Mobility Group

Configuration Steps	• Configure a mobility group. The configurations are omitted here. • Enable proactive information exchange within the mobility group.

AC	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#mobility-groupmgroup_name`
	`Hostname(config-mobility)# mobility-fast`

Verification	Check mobility group information.

AC	`Hostname# show mobility status mgroup_name`
	`Mobility Group mgroup_name`
	`Mobility Keepalive Interval..... 10`
	`Mobility Keepalive Count..... 3`
	`Mobility Group Status..... Fast Mode`
	`……b`

Common Errors

N/A

1.4.3 Configuring a Mobility List

Configuration Effect

When no more members can be added to a mobility group, configure a mobility list to implement roaming.

Notes

A mobility group must be configured.

Configuration Steps

- (Optional) Add members to the mobility list after a mobility group is configured on the AC. Run the **list** { *ip-address* | *ipv6-address* } command to add a member to the mobility list.
- If the number of mobility members exceeds the maximum value of the mobility group, you can add members to the mobility list as an alternative.

A mobility list supports up to 72 members.

Command	**list** {ip-address| ipv6-address}
Parameter Description	*ip-address*: Indicates the IPv4 address of a mobility member. *ipv6-address:* Indicates the IPv6 address of a mobility member.
Defaults	No mobility list is configured by default.
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

Check mobility group information to determine whether added members exist.

Configuration Example

Configuring a Mobility List

Configuration Steps	● Configure a mobility group. The configurations are omitted here. ● Add members to the mobility list.

AC	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#mobility-groupmgroup_name`
	`Hostname(config-mobility)# list 192.168.1.1`
	`Hostname(config-mobility)# list 192.168.1.2`

Verification	Check mobility list information.

AC	Hostname# show mobility status mgroup_name Mobility Group mgroup_name Mobility Keepalive Interval..... 10 Mobility Keepalive Count..... 3 Mobility Group Status..... Fast Mode Mobility Members: IP Address Client/Server Data Tunnel Ctrl Tunnel Mobility List Members: IP Address Client/Server Data Tunnel Ctrl Tunnel 192.168.1.2 Client OK OK 192.168.1.1 Client OK OK

Common Errors

N/A

1.4.4 Configuring the Number of Times a Keepalive Packet Can Be Transmitted

Configuration Effect

(Optional) Configure the number of times a keepalive packet can be transmitted. If the value is exceeded, the keepalive attempt fails.

Notes

A mobility group must be configured and has at least one mobility member.

Configuration Steps

- (Optional) Configure a mobility group on the AC and enter the mobility group configuration mode.
- The maximum number of times a keepalive packet can be transmitted does not need to be changed by default. If the network is unstable, you can increase this value.

Command	**keepalive-count** *counts*
Parameter Description	*counts*: Indicates the number of times a keepalive packet can be transmitted. The value ranges from 2 to 30.
Defaults	The default value is 4 after a mobility group is created.
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

Check mobility group information. The maximum number of times a keepalive packet can be transmitted should be displayed.

Configuration Example

Configuring the Number of Times a Keepalive Packet Can Be Transmitted

Configuration Steps	● Configure a mobility group. The configurations are omitted here. ● Set the number of times a keepalive packet can be transmitted to 5.
AC	`Hostname(config)#mobility-group mgroup_name` `Hostname(config-mobility)# keepalive-count 5`
Verification	Check the mobility group configuration.

AC	`Hostname# show mobility status mgroup_name`
	`Mobility Group mgroup_name`
	`Mobility Keepalive Interval..... 10`
	`Mobility Keepalive Count..... 5`
	`Mobility Group Status..... normal`

Common Errors

N/A

1.4.5 Configuring the Interval at Which a Keepalive Packet Is Sent

Configuration Effect

(Optional) Configure the interval at which a keepalive packet is sent.

Notes

A mobility group must be configured and has at least one mobility member.

Configuration Steps

- (Optional) Configure a mobility group on the AC and enter the mobility group configuration mode.
- The interval at which a keepalive packet is sent is 10s by default. If the network is unstable, you can increase the interval.

Command	**keepalive-interval** *seconds*

Parameter Description	*seconds*: Indicates the interval at which a keepalive packet is sent, in seconds. The value ranges from 1 to 30.
Defaults	The default value is 10s after a mobility group is created.
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

Check mobility group information. The interval at which a keepalive packet is sent should be displayed.

Configuration Example

Configuring the Interval at Which a Keepalive Packet Is Sent

Configuration Steps	● Configure a mobility group. The configurations are omitted here. ● Set the interval at which a keepalive packet is sent to 20s.
AC	`Hostname(config)#mobility-group mgroup_name` `Hostname(config-mobility)# keepalive-interval20`
Verification	Check the mobility group configuration.

AC	`Hostname# show mobility status mgroup_name`
	`Mobility Group mgroup_name`
	`Mobility Keepalive Interval..... 20`
	`Mobility Keepalive Count..... 4`
	`Mobility Group Status..... normal`

Common Errors

N/A

1.4.6 Testing Roaming Connectivity

Configuration Effect

(Optional) Start a connectivity test to check whether member ACs are connected to each other normally.

Notes

A mobility group must be configured and has at least one mobility member.

Configuration Steps

- (Optional) After configuring a mobility group on an AC, enter the mobility group configuration mode to start a connectivity test.
- Start a connectivity test to check whether member ACs in the mobility group communicate with each other normally.

Command	**mti-ping** {ip-address|ipv6-address}
Parameter Description	*ip-address*: Indicates the IPv4 address of a mobility member. *ipv6-address:* Indicates the IPv6 address of a mobility member.
Defaults	N/A
Command Mode	Mobility group configuration mode
Usage Guide	N/A

Verification

Check the test result.

Configuration Example

Starting a Roaming Connectivity Test

Configuration Steps	• Configure a mobility group and add mobility members. The configurations are omitted here. • Start a roaming connectivity test.

AC	`Hostname(config)#mobility-group my_group_name`
	`Hostname(config-mobility)#mti-ping 192.168.1.2`
	`Sending 4, MTI packet to  192.168.1.1, timeout is 2 seconds:`
	`!!!!`
	`Success rate is 100 percent (4/4)`

Verification	Check the test result.

AC	`Sending 4, MTI packet to  192.168.1.1, timeout is 2 seconds:`
	`!!!!`
	`Success rate is 100 percent (4/4)`

Common Errors

The **mti-ping** command is different from the **ping** command, that is, successful execution of the **ping** command does not mean that execution of the **mti-ping** command is also successful. The **mti-ping** command is applicable to mobility group members.

1.4.7 Suppressing STA Roaming Syslogs

Configuration Effect

Even if STAs roam frequently, the number of roaming syslogs output per second does not exceed the limit.

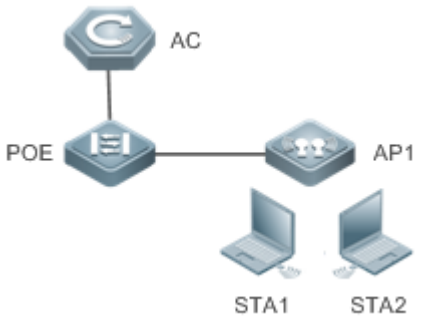
Notes

N/A

Configuration Steps

Configuring the Syslog Suppression Rate

- (Optional) The configuration is performed on an AC. Run the **roaming logging rate-limit** command to configure the syslog suppression rate.
- Configure the syslog suppression rate. A larger rate configured indicates that more syslogs can be output per second.



Command	**roaming logging rate-limit** *limit-num*
Parameter Description	*limit-num*: Indicates the syslog suppression rate, which is expressed in records per seconds. The value range is from 1 to 10000.
Defaults	Less than five syslog records are output per second by default, that is, the maximum syslog output rate is 5 records per second.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running** command to check whether the syslog suppression rate is successfully configured.

Configuration Example

Suppressing STA Roaming Syslogs

Scenario **Figure 1-7**	
Configuration Steps	Configure the STA syslog suppression rate.

AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# roaming logging rate-limit 30
Verification	After the CAPWAP tunnel is established between an AP and an AC, check the configuration.
AC	AC# show running roaming logging rate-limit 30 !

Common Errors

N/A

1.4.8 Preventing STA Roaming

Configuration Effect

STAs are prevented from roaming within a WLAN.

Notes

N/A

Configuration Steps

↘ Preventing STA Roaming within a WLAN

- (Optional) The configuration is performed on an AC. Run the **roaming support wlan** command to configure the device to permit STA roaming within a specified WLAN.
- Roaming is permitted by default. Run the **no roaming support wlan** command to prevent STA roaming.

Command	**roaming support wlan** *wlan-id*
Parameter Description	*wlan-id*: Specifies the ID a WLAN where roaming is disabled.
Defaults	Roaming is permitted by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running** command to check whether roaming is prevented.

Configuration Example

Preventing STA Roaming

Configuration Steps	Configure roaming prevention within WLAN 100.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# no roaming support wlan 100`

Verification	After the CAPWAP tunnel is established between an AP and an AC, check the configuration.

AC	`AC# show running`
	`no roaming support wlan 100`
	`!`

Common Errors

N/A

1.4.9 Disabling Roaming Based on the Device

Configuration Effect

STAs can communicate using the VLAN mapped to the AP after Layer 3 roaming.

Notes

Some STAs do not initiate a new DHCP process after roaming and directly use the IP address before roaming for communication, so the STA's IP address needs to be used for forwarding in both VLANs before and after roaming, which requires collaboration on the entire network. If the STA's IP address cannot be used for forwarding in the VLAN after roaming, the STA will fail to access the network after roaming.

Configuration Steps

Disabling Roaming in Centralized Forwarding Mode

- (Optional) This configuration does not affect the STAs who have already roamed, and new STAs who experience roaming in centralized forwarding mode will communicate using the VLAN after roaming.
- The device does not check whether the IP address of the STA is changed during Layer 3 migration.
- If there are no special requirements, this configuration is not required.

Command	**roaming central-unroam**

Parameter Description	N/A
Defaults	In centralized forwarding mode, STAs still communicate using the VLAN before roaming.
Command Mode	Global configuration mode
Usage Guide	N/A

Disabling Inter-AC Roaming

- If there are no special requirements, this configuration is not required.

Command	**roaming disable**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Disabling Roaming in Local Forwarding Mode

- (Optional) This configuration does not affect the STAs who have already roamed, and new STAs who experience roaming in local forwarding mode will communicate using the VLAN after roaming.
- The device does not check whether the IP address of the STA is changed during Layer 3 migration.
- If there are no special requirements, this configuration is not required.

Command	**roaming local-unroam**
Parameter Description	N/A
Defaults	In local forwarding mode, STAs still communicate using the VLAN before roaming.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Migration for Roaming in Local Forwarding Mode

Whether this configuration is supported depends on the actual product version.

- (Optional) This configuration does not affect the STAs who have already roamed, and new STAs who experience roaming in local forwarding mode adopt migration.
- This function is the same as the function of the **roaming local-unroam** command. The difference is that the device checks whether the STA's IP address is changed after roaming by default.

- If there are no special requirements, this configuration is not required.

Command	roaming local-layer2 direct
Parameter Description	N/A
Defaults	In local forwarding mode, Layer 2 roaming uses migration and Layer 3 roaming does not use migration.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running** command to check whether the configuration is successful.

Configuration Example

Disabling Roaming in Local Forwarding Mode

Configuration Steps	Disable roaming in local forwarding mode.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# roaming local-unroam
Verification	Run the **show run** command to check the configuration.
AC	AC# show running roaming local-unroam !

Disabling Inter-AC Roaming

Configuration Steps	Disable the inter-AC roaming function.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# roaming disable
Verification	Run the **show run** command to display the configuration.
AC	AC# show running roaming disable

	!

Common Errors

N/A

1.5 Monitoring

Displaying

Command	Description
show mobility summary	Displays the configuration of all mobility groups.
show mobility status *group-name*	Displays the configuration of a specified mobility group.
show mobility statistics	Displays roaming statistics.
show mobility user [*mac-address*]	Displays roaming STA information.
show mobility user roam-track *mac-address*	Displays roaming tracks of roaming STAs.

1 Configuring Zero Roaming

Whether this function is supported depends on the actual product version.

1.1 Overview

With the development of medical information technology, mobile healthcare services have become increasingly important. The WLAN responsible for supporting the mobile healthcare services has strict requirements on the latency, packet loss, and bandwidth.

Medical staff needs to carry handheld devices frequently and process tasks at any time. During the entire process, quick response is required without client connection latency and data transmission delay. The mobile medical service range must cover all patients, even those in the innermost of wards, with requirements including picture archiving and communication system (PACS) image calling and medical condition update. The handheld clients used for mobile healthcare services generally require high wireless signal quality, where the signal strength in the ward needs to be above –60 dBm. Additionally, they are also highly sensitive to packet loss during roaming, which may cause service interruptions.

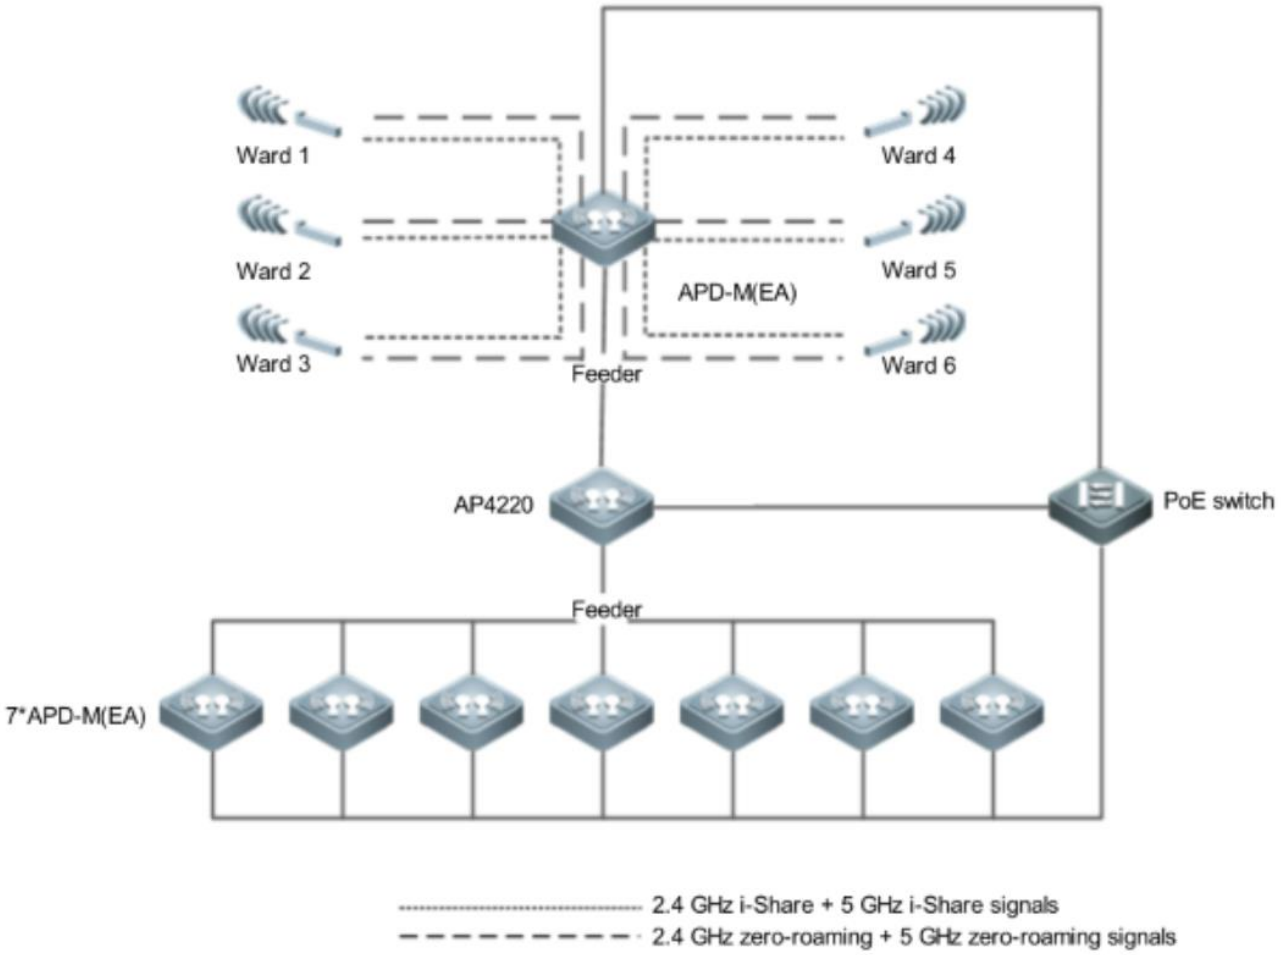
Zero roaming is targeted for healthcare scenarios. It can prevent problems caused by roaming and signal overlapping, such as mobile medical service delay, packet loss, and poor performance.

1.2 Applications

Application	Description
Zero Roaming	Applies to the wireless medical scenario.
PoE	Applies to the Internet of Things (IoT) scenario.
Zero Roaming+	Applies to the wireless medical scenario.

1.2.1 Zero Roaming

Scenario



The application scenario of the third-generation zero-roaming medical i-Share solution is as follows:

1. The network is composed of one zero-roaming AP (RG-AP4220) and multiple i-Share units (RG-APD-M(EA)).
2. The zero-roaming AP provides eight channels of signals to an i-Share unit through a feeder.
3. An i-Share unit provides six channels of signals. Therefore, each i-Share cell can cover 6 wards, and all 48 wards are covered in this scenario.
4. The third-generation zero-roaming medical i-Share solution provides the following two operating modes:

- Mode 1: The 5G zero-roaming function is enabled by default. In this case, the zero-roaming AP works in dual-band mode, while the i-Share unit works in single-stream mode on 5G.

- Mode 2: The 5G zero-roaming function is disabled. The zero-roaming AP works in the single 2.4 G band, while the i-Share unit works in the dual-stream 802.11ac mode on 5G.

1.2.1.1.1 Medical Deployment

Deployment

Configure the devices as follows:

1. The 5G zero-roaming function is enabled by default. Both the zero-roaming AP and the i-Share unit work in single-stream mode on 5G, and the 5G signal of the zero-roaming AP serves as the 5G zero-roaming access signal.
2. When the 5G zero-roaming function is disabled, the 5G signal of the zero-roaming AP is disabled in wards covered by the designated i-Share unit, and the 5G signal of the i-Share cell works in dual-stream mode.

1.2.2 PoE on a Wired Port

Scenario

The i-Share unit is connected to the HPoE switch, and the common AP is connected to the second downlink port of the i-Share unit.

1.2.2.1.1 HPoE Scenario

Deployment

The i-Share unit must be connected to an HPoE-powered device. Enable the PoE function on the second downlink port of the i-Share unit, and power on a common AP for startup.

1.2.3 Zero Roaming+

Scenario

The scenario of zero roaming+ is similar to that of the third-generation zero-roaming medical i-Share solution. The zero roaming AP is HAP4720 and the i-Share unit is HAP-APD that does not support access to an extranet.

1. The network is composed of one zero-roaming AP (RG-HAP4720) and multiple i-Share units (RG-HAP-APD).
2. The zero-roaming AP evenly distributes the zero-roaming signals into 8 channels, and connects the i-Share units through feeders.
3. An i-Share unit splits the signals into 6 channels. Each i-Share unit can cover 6 wards, and all together 48 wards can be covered in this scenario.

Deployment

1. If the zero-roaming AP is powered by an HPoE switch, it can work in dual-band (2.4 GHz and 5 GHz) mode.
2. If the zero-roaming AP is powered by a common PoE device or an i-Share+ host, it only supports the single-band mode. By default, the RG-HAP4720 works in 5 GHz band. You can use a command to switch to the 2.4 GHz band.

1.3 Features

Basic Concepts

↘ Zero Roaming

When there are multiple APs on a network and signal coverage ranges among APs overlap, a wireless STA can move within the coverage area of the entire wireless local area network (WLAN). The wireless network interface card (NIC) can automatically discover an AP with the stronger signal around and send and receive data through this AP, ensuring a nonstop network connection. This is called wireless roaming.

A wireless STA is both the decision maker and the initiator of a roaming action, and the roaming decision may vary for different NICs and STAs. In the medical industry, PDAs used by wireless STAs may not support roaming or may have

poor roaming performance, which can affect user experience. The zero-roaming function can effectively solve the roaming issues for PDAs in this scenario.

The zero roaming function ensures that the same wireless SSID signal always exists within the range covered by the zero-roaming AP. Therefore, the wireless client will not encounter packet loss or roaming during moving.

Overview

Feature	Description
Zero Roaming	Enables the 5 GHz zero roaming function.
Wired-Port PoE	Enables the wired-port PoE function.
Zero Roaming+	Bounds the i-Share unit and zero-roaming AP.

1.3.1 Zero Roaming

Working Principle

The zero-roaming AP feeds signals into multiple i-Share units through a feeder, which then control the signals to be fed into multiple coverage areas through the feeder. When wireless STAs move within the signal coverage area of the zero-roaming AP, the signal is provided by the zero-roaming AP. In this case, roaming will not occur.

1.3.2 Wired-Port PoE

Working Principle

Power over Ethernet (PoE) is a technology for supplying direct current (DC) power to IP-based clients (such as the IP phone, WLAN AP, and webcam) while transmitting data signals of these devices without changing the existing Ethernet category 5 cabling infrastructure. PoE is also referred to as Power over LAN (PoL) or Active Ethernet or Ethernet power supply that complies with 802.3af/at/bt standards.

1.3.3 Zero Roaming+

Working Principle

A zero-roaming AP feeds signals into multiple i-Share cells through a feeder, which then control the signals to be fed into multiple coverage areas through the feeder. When wireless STAs move within the signal coverage area of the zero-roaming AP, the signal is provided by the zero-roaming AP. In this case, roaming will not occur.

The zero-roaming AP feeds signals into i-Share units, but the AC cannot detect the relationship between the i-Share units and the zero-roaming AP. To better manage the network, take the following measures:

- Add a binding relationship between the i-Share units and zero-roaming AP.
- Rename the connected i-Share units and bind MAC addresses to them based on the feeder ports R1 to R8 of the zero-roaming AP.
- Rename the connected antennas based on the feeder ports R1 to R6 of i-Share units.

Therefore, the AC can intuitively obtain the number of i-Share units connected to each zero-roaming AP, feeder port information, and antenna port information for each i-Share unit.

1.4 Configuration

Configuration	Description and Command	
Configuring Zero Roaming	(Optional) It is used to configure the zero roaming function.	
	zero-roaming enable	Configures the 5 GHz zero roaming function.
Configuring PoE	(Optional) It is used to configure the PoE function on a wired port.	
	wired-poe enable port *num*	Configures the PoE function on a wired port.
Configuring Zero Roaming+	(Optional) It is used to bind an HAPD to an AP.	
	hapd *num name*	Configures the name of the i-Share unit (HAP-APD).
	hapd mac *H.H.H*	Configures the MAC address of the i-Share unit (HAP-APD).
	hapd *num* **antenna-id** *ant-id ant-name*	Configures the name of the antenna connected to the i-Share unit (HAP-APD).

1.4.1 Configuring Zero Roaming

Note

Whether this function is supported depends on the actual product version.

This function is supported on all wireless ACs and is supported only on APs with the model of RG-APD-M(EA).

Configuration Effect

Enable the 5 GHz zero roaming function.

Notes

If the device does not support the 5 GHz zero roaming function, the configuration does not take effect. Only RG-APD-M(EA) supports the 5 GHz zero roaming function.

Configuration Steps

Enabling Zero Roaming on a Designated AP

- Optional. Run the **zero-roaming** command in AP configuration mode to enable the zero roaming function.
- You can only enable the 5 GHz zero roaming function only on APs that support this function.

Command	**zero-roaming enable**
Parameter Description	**enable**: Enables the zero roaming function.

Defaults	The zero roaming function is enabled by default.
Command Mode	AP configuration mode
Usage Guide	Run this command to enable the 5 GHz zero roaming function on an AP. The configuration does not take effect on devices that do not support zero roaming.

Verification

Run the **show ap-config running** *ap-name* command on the AC to check whether the configuration is successful. Run the **show run** command on the AP to check whether the configuration is successful.

Configuration Example

Enabling Zero Roaming on a Designated AP

Configuration Steps	Enable the 5 GHz zero roaming function on a designated AP.

	`Hostname# configure terminal`
	`Hostname(config)#ap-config apd-ea`
	`Hostname(config-ap)#no zero-roaming enable`
	`Hostname(config-ap)#zero-roaming enable`

Verification	● Run the following commands to check the configuration status of the 5 GHz zero roaming function after it is enabled on the AP. ● Run the **show ap-config running** *ap-name* command on the AC to display the configuration status.

	Configuration on the AC
	`Ruijie(config)#show ap-config running apd-ea`
	`!`
	`ap-config apd-ea`
	`...`
	`no zero-roaming enable`
	`...`
	`...`
	`!`

1.4.2 Configuring PoE on a Wired Port

Configuration Effect

Enable PoE on a wired port.

Notes

- If the device does not support the wired port, the configuration does not take effect. The i-Share unit supports the wired port.
- If Port 1 of the device is not powered through HPoE, the configuration does not take effect.

- i-Share units support PoE only on LAN 2 ports.

Configuration Steps

Enabling Wired-Port PoE on Designated AP

- Optional. Run the following command in AP configuration mode to enable the PoE function on a wired port.
- You can enable this function only on APs that support PoE on a wired port.

Command	**wired-poe enable port** *num*
Parameter Description	*num*: Indicates the number of a wired port.
Defaults	The PoE function on a wired port is disabled by default.
Command Mode	AP configuration mode on the AC
Usage Guide	This command can be used to enable the PoE function on a wired port of an AP. The configuration does not take effect on devices that do not this function.

Verification

Run the **show ap-config running** *ap-name* command on the AC to check whether the configuration is successful.

Configuration Example

Enabling Zero Roaming on a Designated AP

Configuration Steps	Enable the PoE function on a wired port of a designated AP.

	`Ruijie# configure terminal`
	`Ruijie(config)#ap-config apd-ea`
	`Ruijie(config-ap)#wired-poe enable port 2`

Verification	● Run the following commands to check the configuration after it is enabled on the AP. ● Run the **show ap-config running** *ap-name* command on the AC to display the configuration.

	Configuration on the AC
	`Ruijie(config)#show ap-config running apd-ea`
	`!`
	`ap-config apd-ea`
	`...`
	`wired-poe enable port 2`
	`...`
	`...`
	`!`

1.4.3 Configuring Zero Roaming+

Configuration Effect

After i-Share units are bound to a zero-roaming AP, the antenna and feeder information of i-Share units can be uploaded to the AC through the zero-roaming AP. The AC can display the RG-HAP-APD's feeder status and the relationship between antennas, i-Share units, and RG-HAP4720.

Notes

None

Configuration Steps

Configuring the Name of a i-Share Unit

- (Optional) Configure the name of an HAP-APD connected to a feeder port on the HAP4720.

Command	**hapd** *num name*
Parameter Description	*num*: Indicates the number of a feeder port of the zero-roaming AP that is connected to the i-Share unit. The value range is from 1 to 8. *name*: Indicates the new name the i-Share unit.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the MAC Address of the i-Share Unit

- (Optional) Pre-configure the MAC address for the i-Share unit connected to the zero-roaming AP.

Command	**hapd** *num* **mac** *mac-address*
Parameter Description	*num*: Indicates the number of a feeder port of the zero-roaming AP that is connected to the i-Share unit. The value range is from 1 to 8. *mac-address*: Indicates the MAC address of the i-Share unit.
Defaults	
Command Mode	AP configuration mode
Usage Guide	

Configuring the Name of an Antenna of an HAP-APD

- Optional. Name the antenna connected to a feeder port on an HAP-APD.

Command	**hapd** *num antenna-id ant-id ant-name*
Parameter Description	*num*: Indicates the number of a feeder port corresponding to R1 to R8 on the zero-roaming AP (APHAP4720) that is connected to the i-Share unit. The value range is from 1 to 8. *ant-id*: Indicates the number of an antenna (R1 to R6) connected to the i-Share unit (HAP-APD). The value range is from 1 to 6. *ant-name*: Indicates the name of the antenna connected to the i-Share unit.
Defaults	No antenna name is configured by default.
Command Mode	AP configuration mode
Usage Guide	The configuration takes effect only on devices that support HAP-APD binding.

Verification

Run the **show ap-config running** *ap-name* command on the AC to display the configuration.

Configuration Example

Binding a Specified HAP-APD to an AP

Configuration Steps	Bind a specified HAP-APD to an AP.
	Ruijie# configure terminal Ruijie(config)#ap-config HAP4720 Ruijie(config-ap)#hapd 1 Hallway on floor 1 Ruijie(config-ap)#hapd 1 mac 0800.1111.2222 Ruijie(config-ap)#hapd 1 antenna-id 1 Ward 101 Ruijie(config-ap)#hapd 1 antenna-id 2 Ward 102 Ruijie(config-ap)#hapd 1 antenna-id 3 Ward 103 Ruijie(config-ap)#hapd 1 antenna-id 4 Ward 104 Ruijie(config-ap)#hapd 1 antenna-id 5 Ward 105 Ruijie(config-ap)#hapd 1 antenna-id 6 Ward 106
Verification	Run the following commands to display the configuration after the specified HAP-APD is bound to an AP: ● Run the **show ap-config running** *ap-name* command on the AC to display the configuration. ● Run the **show run** command on the AP to display the configuration.
	AC: Ruijie(config)#show ap-config running HAP4720 ! ap-config HAP4720 ... hapd 1 Hallway on floor 1 hapd 1 mac 0800.1111.2222 hapd 1 antenna-id 1 Ward 101 hapd 1 antenna-id 2 Ward 102 hapd 1 antenna-id 3 Ward 103 hapd 1 antenna-id 4 Ward 104 hapd 1 antenna-id 5 Ward 105 hapd 1 antenna-id 6 Ward 106 ... ... !

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show hapd antenna { **all** | **single** *ant-name* }	Displays the antenna and feeder status of the i-Share unit.
show hapd antenna summary	Displays the configuration of the i-Share unit.
show hapd information	Displays the status of the i-Share unit connected to the zero-roaming AP.

Debugging

N/A

1 Configuring SFN

1.1 Overview

Same Frequency Net (SFN) is a wireless solution that virtualizes multiple access points (APs) into a single AP within a wireless local area network (WLAN).

In industries such as healthcare, handheld devices such as personal digital assistants (PDAs) often lack support for roaming or have poor roaming performance, resulting in a suboptimal user experience with APs. SFN technology effectively addresses these roaming issues. SFN operates on a single channel to deploy the network, enabling zero roaming. By deploying multiple layers of independent intra-frequency networks, it supports high-density deployment while simplifying both installation and maintenance. However, one downside of using a single channel for deployment is that, in dense environments, co-frequency interference can become significant, which may negatively impact overall network throughput.

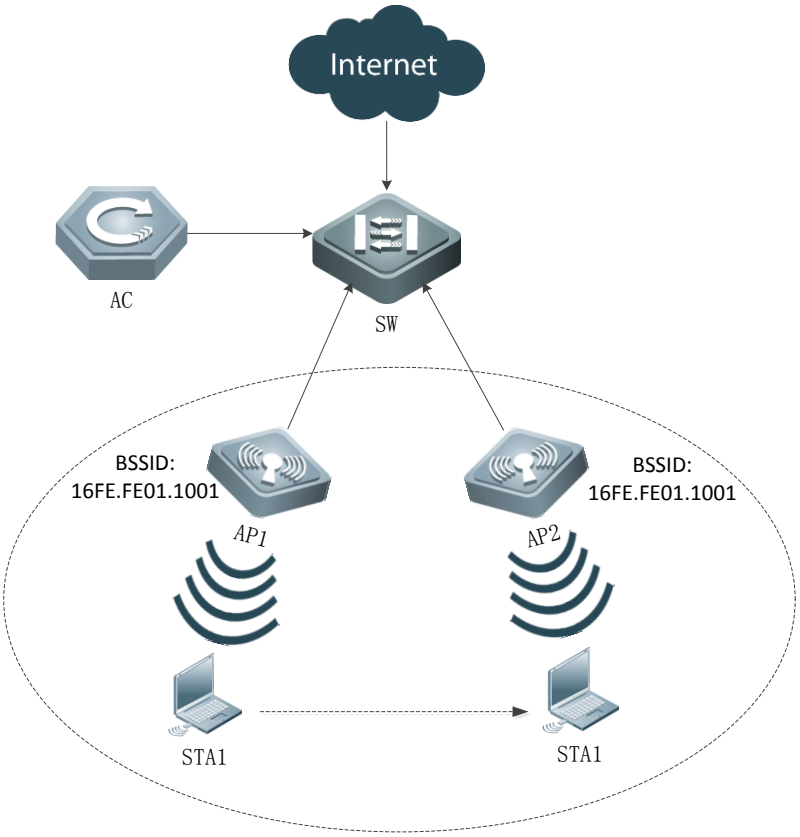
Based on the preceding analysis, you are advised to use SFN in the following scenarios:

- Scenarios where APs are densely deployed, with low wireless throughput requirements but high roaming requirements, such as in healthcare, logistics, and similar industries
- Scenarios with less dense AP deployment but involving high-speed moving wireless terminals

Protocols and Standards

IEEE 802.11

1.2 Applications



Application	Description
SFN Application	SFN is applicable to thin AP topologies and the following scenarios: ● Scenarios where APs are densely deployed, with low wireless throughput requirements but high roaming requirements, such as in healthcare, logistics, and similar industries ● Scenarios with less dense AP deployment but involving high-speed moving wireless terminals

1.2.1 SFN Application

Scenario

Stations (STAs) are associated with the SFN network. Initially, AP1 provides the strongest signal and the wireless link service. As a STA moves, the signal from AP2 becomes stronger, and SFN technology automatically switches the service to AP2, which then takes over as the wireless link service provider for the STA.

Figure 1-1SFN Application Scenario

Deployment

SFN Network Implementation

1. Deploy the fit AP environment as needed.
2. Create an SFN group and add the specified AP group to the SFN group. Then all APs in the AP group form a large virtual AP to provide services for STAs.
3. Ensure that all physical APs that constitute the virtual AP provide full coverage for STAs' active area to achieve seamless roaming of STAs.
4. Ensure that the physical AP providing the wireless service for STAs will switch accordingly when a STA moves within the coverage area of the virtual AP. No packet loss occurs during handover, resulting in seamless roaming.

Notes

The configuration points on the device are as follows:

1. Create an SFN group.
2. Enable SFN for the specified radio.
3. For the SFN group, configure the channel and RSSI threshold for STA handover.
4. Add the specified AP group to the SFN group.

1.3 Features

Basic Concepts

BSSID

The Base Service Set Identifier (BSSID) is a 48-bit locally managed IEEE MAC address. Each Base Service Set (BSS) is assigned a BSSID to identify itself. In an SFN group, each STA is assigned a unique BSSID, which is automatically generated by the access controller (AC) and assigned to the AP.

SFN Group

An SFN group refers to configuring all APs within a specified AP group to operate on the same frequency, with consistent configuration across all APs in the group.

Overview

Feature	Description
SFN Group	Creates an SFN network and configures network parameters.

1.3.1 SFN Group

Working Principle

AC Control Mode Intra-frequency Handover

The basic principle of SFN is that all specified APs within a network operate on the same channel and broadcast the same SSID. When a STA associates with an AP, a unique BSS is created based on the STA's Association Identifier (AID). The AP providing this BSS is determined by the AC, based on the STA's location. From the STA's perspective, all APs broadcasting the same SSID within the network can be viewed as a single virtual AP. This virtual AP can consist of hundreds or even thousands of physical APs, enabling coverage across areas such as hospital wards or dormitories. As the STA moves within this coverage area, it will appear to stay connected to the same AP, without experiencing roaming. In practice, the STA may be connected to different physical APs. The specific AP that the STA connects to is determined by the AC, which considers factors such as the STA's Received Signal Strength Indicator (RSSI) on the AP and AP's load. The handover between APs is managed by the AC, and the STA is unaware of the transition.

AP Control Mode Intra-frequency Handover

The basic principle is similar to that in "AC Control Mode Intra-frequency Handover." The difference is that the specific AP associated with a STA is determined by the neighboring AP and associated AP when the STA moves within the coverage area of the SFN network. If the neighboring AP has sufficient capacity and the STA's RSSI is stronger than the RSSI threshold of the associated AP by a specific threshold, the STA will request a handover. The associated AP then decides on the optimal AP and migrates the STA to it. The handover between APs is managed by the AC, and the STA is unaware of the transition.

Unique Association Between a STA and a Physical AP

All APs on the SFN network are virtualized as a single AP. For any STA, at any given moment, it is associated with only one physical AP, which provides wireless services for the STA.

STA Handover Between APs

No matter where the STA moves within the coverage area of the SFN network, it will not experience disconnection. However, as the STA's location changes, the physical AP providing wireless services for the STA may change. The condition for this change is that the SFN network system determines that another AP can provide better wireless service for the STA, in which case the physical AP serving the STA will be switched to this new AP.

1.4 Configuration

Configuration	Description and Command	
Creating an SFN Group and Associating the SFN Group with a Specified AP Group	(Mandatory) It is used to create an SFN group and apply it to the specified AP group, and to enable SFN for the specified radio.	
	sfn-group	Creates an SFN group.
	ap-group	Associates the SFN group with an AP group.
	enable-sfn radio	Enables SFN for the specified radio.
Configuring SFN Group Information	(Optional) It is used to enable the specified radio to support 802.11a/802.11g/802.11ac/802.11ax, configure the MCS index of 802.11n/802.11ac for the specified radio, configure the receiving/transmitting antenna type of the specified radio, configure the delivery traffic indication message (DTIM) period for the specified radio, configure a channel/channel width/working frequency band for the specified radio, configure the RSSI threshold for STA handover, configure the OUI field for the BSSID of a virtual port, and enable AP control mode intra-frequency handover.	
	11nasupport enable	Enables the specified radio to support 802.11a.
	11ngsupport enable	Enables the specified radio to support 802.11g.
	11acsupport enable	Enables the specified radio to support 802.11ac.
	11axsupport enable	Enables the specified radio to support 802.11ax.
	802.11n mcs support	Configures the MCS index of 802.11n for the specified radio.
	802.11ac mcs support	Configures the MCS index of 802.11ac for the specified radio.
	antenna	Configures the receiving/transmitting antenna type of the specified radio.
	beacon dtim-period	Configures the DTIM period for the specified radio.
	channel	Configures a channel for the specified radio.
	chan-width	Configures the channel width for the specified radio.
	handoff-rssi-thresh	Configures the RSSI threshold for STA handover.
	radio-type	Configures the working frequency band for the specified radio.
	sfn-vp-oui	Configures the OUI field for the BSSID of a virtual port.
	handoff-ap-mode enable	Enables AP control mode intra-frequency handover.

1.4.1 Creating an SFN Group and Associating the SFN Group with a Specified AP Group

Configuration Effect

- Create an SFN group.
- Apply the SFN group to the specified AP group.
- It takes effect after you enable the SFN function on the specified radio.

Notes

- Ensure that all APs in the same SFN group use the same configuration before joining the group. After APs are added to an SFN group, you are not advised to change configurations of some APs individually. Some common commands similar to those in AP configuration mode are available in SFN group configuration mode, allowing the configuration of radio attributes of the specified frequency band for all APs within the same group. If other AP configurations need to be changed, you are advised to remove APs from the SFN group first.
- Due to differences in wireless capabilities between different models of APs, you are not advised to add them to the same SFN group.
- By default, APs do not join any SFN group, so AP groups do not support the SFN configuration by default.
- When you delete the SFN group, its associated AP group is automatically disassociated, and all APs in the AP group automatically exit the SFN group.
- An AP group can be associated with only one SFN group, and an SFN group can be applied to only one AP group.
- After an SFN group is applied to an AP group, automatic channel and power adjustment of Radio Resource Management (RRM) is invalid for radios of APs in that group.
- Remote Intelligent Perception Technology (RIPT) and SFN cannot be enabled on an AP simultaneously.

Configuration Step

↘ Creating an SFN Group

- Mandatory.
- After an SFN group is successfully created, the system enters the SFN group configuration mode. Then you can continue to configure other information about the SFN group.

Command	**sfn-group** *group-id* **{ AP720-I | AP730-I | AP850-A | APD4930-AX }**
Parameter	*group-id*: Specifies the ID of an SFN group. The value range is from 1 to 64.
Description	**AP720-I** | **AP730-I** | **AP850-A** | **APD4930-AX**: Specifies the model of the AP associated with the SFN group.
Defaults	No SFN group is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

↘ Associating the SFN Group with an AP Group

- Mandatory.

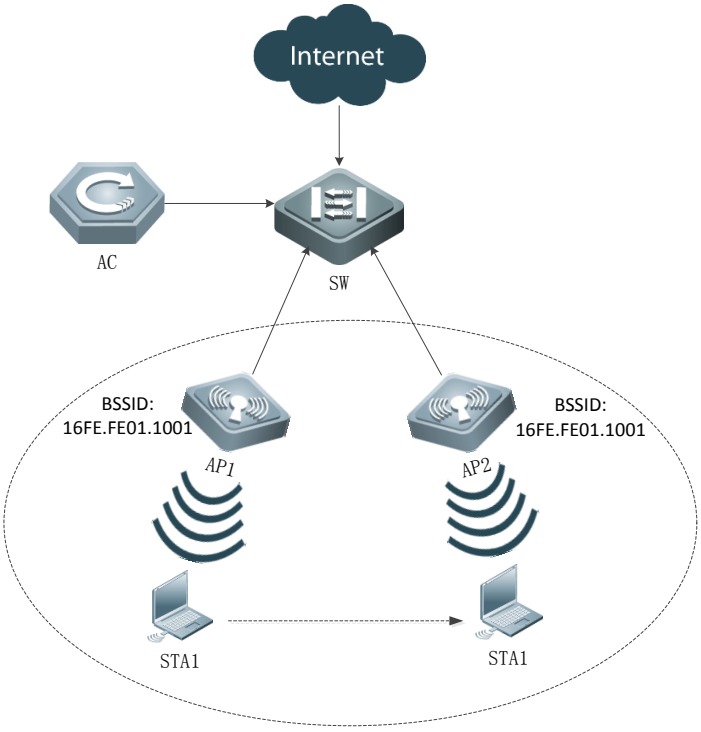
Command	**ap-group** *group-name*
Parameter Description	*group-name*: Specifies the name of an AP group to be associated with an SFN group.
Defaults	No AP group is associated with an SFN group by default.
Command Mode	SFN group configuration mode
Usage Guide	• An SFN group can be associated with only one AP group. • After an SFN group is associated with an AP group, all APs in the AP group join the SFN group.

Enabling SFN for the Specified Radio

- Mandatory.
- After creating an SFN group and applying it to the specified AP group, enable SFN for the specified radio and bind the SFN group to the specified WLAN. This SFN group will not take effect until you complete these configurations.

Command	**enable-sfn radio** *radio-id* **ap-wlan-id** *wlan-id*
Parameter Description	*radio-id*: Specifies the radio ID. The value is 1, 2, or 3. *wlan-id*: Specifies the ID of a WLAN. *ap-wlan-id* must be configured in the **interface-mapping** command in AP group configuration mode.
Defaults	SFN is not enabled for any radio by default.
Command Mode	SFN group configuration mode
Usage Guide	N/A

Verification



- Run the **show running-config** command to display the configuration.
- Run the **show sfn-group summary** command to display the SFN group list.
- Run the **show sfn-group summary** *group-id* command to display basic information about the SFN group and APs associated with the SFN group.
- Use wireless signal scanning software to scan two or more APs transmitting the same SSID, and check whether their corresponding BSSIDs are similar. For example, if two APs are associated with an SFN group, check whether they broadcast the same SSID with similar BSSIDs (for example, 16:fe:fe:02:10:02 and 16:fe:fe:01:10:01).

Configuration Example

Creating an SFN Group and Associating It with the Specified AP Group

Scenario	Normal fit AP environment

Figure 1-2

Assuming that AP1 and AP2 have joined the AP group **apg-1** in the fit AP environment, there are the following configuration requirements for SFN networking on the AC:

1. Create an SFN group.
2. Enable SFN for the AP group **apg-1**.
3. Enable SFN for radio 2 and bind it to WLAN 1.

-

Configuration Steps Create an SFN group and apply it to the specified AP group. Enable SFN for the specified radio.

AC

1. Create an SFN group.

```
Hostname# configure terminal
Hostname(config)# sfn-group 11 AP720-I
```

2. Apply the SFN group to the specified AP group.

```
Hostname(config)# sfn-group 11 AP720-I
Hostname(config-sfn-group)# ap-group apg-1
```

3. Enable SFN for radio 2.

```
Hostname(config)# sfn-group 11 AP720-I
Hostname(config-sfn-group)# enable-sfn radio 2
```

Verification After the SFN group is associated with the specified AP group, check whether the corresponding BSSIDs are similar when two or more than two APs send out the same SSID.

AC Run the **show sfn-group summary** command to display the SFN group list.

```
Hostname#show sfn-group summary

SFN Group  AP Model   AP Group Name                                    Radio  AP Wlan
Id

---------- ---------- ------------------------------------------------
------ ----------

11         AP720-I    apg-1                                            2      1

Total SFN Group Num: 1
```

1.4.2 Configuring SFN Group Information

Configuration Effect

- Support for multiple standards: Support 802.11a/g/ac/ax, enabling good network compatibility and scalability.
- Adjustable MCS range: Promote higher data transfer speed and lower bit error rate (BER), optimizing network efficiency.
- Receiving or transmitting antenna type optimization and DTIM period adjustment: Enhance signal coverage and device power-saving capabilities.
- Channel and channel width utilization: Optimize network throughput and reduce interference by properly configuring channels and channel width.
- RSSI threshold for STA handover: Adjust the RSSI threshold for STA handover, improving the handover experience when signal strength changes, reducing disconnection and latency.
- Operating frequency band selection: Flexibly select operating frequency bands to enhance network flexibility and adaptability, reducing congestion.
- Optimization of the OUI field for the BSSID of a virtual port: Configuring the OUI field improves virtual port identification and management, making network management more efficient.
- AP control mode intra-frequency handover: Implement AP control mode handover to optimize network resource utilization, reduce interference between APs, and improve overall performance and stability.

Notes

- The RF attribute configuration takes effect for the specified radios of all APs associated with the specified SFN group. You need to evaluate the impact before configuration.
- You do not need to perform optional configurations excluding the channel and channel width.

Configuration Step

Enabling the Specified Radio to Support 802.11a

- Optional.

Command	**11nasupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	802.11a is supported by default.
Command Mode	SFN group configuration mode
Usage Guide	The configuration is valid for the specified radio of an AP in the AP group on 5 GHz.

Enabling the Specified Radio to Support 802.11g

- Optional.

Command	**11ngsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	802.11g is supported by default.
Command Mode	SFN group configuration mode
Usage Guide	The configuration is valid for the specified radio of an AP in the AP group on 2.4 GHz.

Enabling the Specified Radio to Support 802.11ac

- Optional.

Command	**11acsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	802.11ac is supported by default.
Command Mode	SFN group configuration mode
Usage Guide	N/A

Enabling the Specified Radio to Support 802.11ax

- Optional.

Command	**11axsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	802.11ax is supported by devices of Wi-Fi 6 or higher capabilities by default.
Command Mode	SFN group configuration mode
Usage Guide	This command can be only configured on devices of Wi-Fi 6 or above.

Configuring the MCS Index of 802.11n

- Optional.

Command	**802.11n mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: Specifies the MCS index. The value range is from 0 to 15. *radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	The default MCS index of 802.11n is 15.
Command Mode	SFN group configuration mode
Usage Guide	The configuration is valid for the specified radio working in 802.11n mode of an AP in the AP group.

Configuring the MCS Index of 802.11ax

- Optional.

Command	**802.11ac mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: Specifies the MCS index. The value range is from 0 to 39. *radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	The default MCS index of 802.11ac is 19.
Command Mode	SFN group configuration mode
Usage Guide	The configuration is valid for the specified radio working in 802.11ac mode of an AP in the AP group.

Configuring the Receiving/Transmitting Antenna Type of the Specified Radio

- Optional.

Command	**antenna { transmit | receive }** *value* radio *radio-id*
Parameter Description	**transmit**: Configures the transmitting antenna type. **receive**: Configures the receiving antenna type. *value*: Specifies the antenna mask. The value range is from 1 to 7. *radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	The default antenna mask is 3.
Command Mode	SFN group configuration mode
Usage Guide	You must first check whether the APs joining the specified SFN group support the antenna direction to be configured. Otherwise, this command does not take effect.

Configuring the DTIM Period for the Specified Radio

- Optional.

Command	**beacon dtim-period** *period-num* **radio** *radio-id*
Parameter Description	*period-num*: Specifies the DTIM period, indicating the Beacon frame period. The value range is from 1 to 255. *radio-id*: Specifies the radio ID. The value is 1, 2, or 3.

Defaults	The default DTIM period is 1, that is, one Beacon frame period.
Command Mode	SFN group configuration mode
Usage Guide	N/A

Configuring a Channel for the Specified Radio

- Optional.

Command	**channel** *channel-id* **radio** *radio-id*
Parameter Description	*channel-id*: Specifies the ID of a channel. *radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	• RG-AP720-I: • The default channel ID for radio 1 is 1. • The default channel ID for radio 3 is 149. RG-AP730-I: • The default channel ID for radio 1 is 1. • The default channel ID for radio 2 is 36. • The default channel ID for radio 3 is 149. RG-AP850-A: • The default channel ID for radio 3 is 36. RG-APD4930-AX: • The default channel ID for radio 1 is 1. • The default channel ID for radio 2 is 149.
Command Mode	SFN group configuration mode
Usage Guide	• You must first confirm the frequency bands of the specified radios of all APs in the specified SFN group and the corresponding country codes before configuring the corresponding channels. Otherwise, this command does not take effect. • Channel switching will cause all STAs associated with the AP group to be disconnected. Exercise caution when you perform this operation.

Configuring the Channel Width for the Specified Radio

- Optional.

Command	**chan-width { 20 | 40 | 80 } radio** *radio-id*
Parameter Description	**20**: Configures the channel width as 20 MHz. **40**: Configures the channel width as 40 MHz. **80**: Configures the channel width as 80 MHz. *radio-id*: Specifies the radio ID. The value is 1, 2, or 3.
Defaults	The default channel width is 20 MHz on 2.4 GHz frequency band. The default channel width is 40 MHz on 5 GHz frequency band.
Command Mode	SFN group configuration mode

Usage Guide The channel width of 80 MHz is applicable to only radios on 5 GHz frequency band.

Configuring the RSSI Threshold for STA Handover

- Optional.
- The default threshold is 4 dB, meaning that the STA is only allowed to switch to another AP if the signal strength on the other AP is at least 4 dB stronger than the signal strength on the currently associated AP.

Command **handoff-rssi-thresh** *rssi*

Parameter Description *rssi*: Specifies the RSSI threshold for STA handover, in dB. The value range is from 1 to 100.

Defaults The default RSSI threshold is 4 dB.

Command Mode SFN group configuration mode

Usage Guide Configuring a low RSSI threshold for STA handover will cause the STA to switch between APs frequently, while configuring a high RSSI threshold may prevent the STA from switching to a better AP, leading to disconnection. You are advised to use the default value.

Configuring the Working Frequency Band for the Specified Radio

- Optional.

Command **radio-type { 802.11a | 802.11b } radio** *radio-id*

Parameter Description **802.11a**: Indicates the 5 GHz band.
802.11b: Indicates the 2.4 GHz band.
radio-id: Specifies the radio ID. The value is 1, 2, or 3.

Defaults The default value varies with modes of the AP.

Command Mode SFN group configuration mode

Usage Guide When an AP joins an SFN group, the radio type of the radio of the AP will switch to the radio type of the SFN group.
The configuration takes effect for the specified radios of all APs in the group.

Configuring the OUI Field for the BSSID of a Virtual Port

- Optional.

Command **sfn-vp-oui** *oui*

Parameter Description *oui*: Specifies the OUI field for the BSSID of a virtual port. The value is in the format of XX.XX.

Defaults By default, the 5th and 6th bytes of the AC's MAC address is used as the 2nd and 3rd bytes of the BSSID. Run the **show sysmac** command to display the MAC address of the AC.

Command Mode Global configuration mode

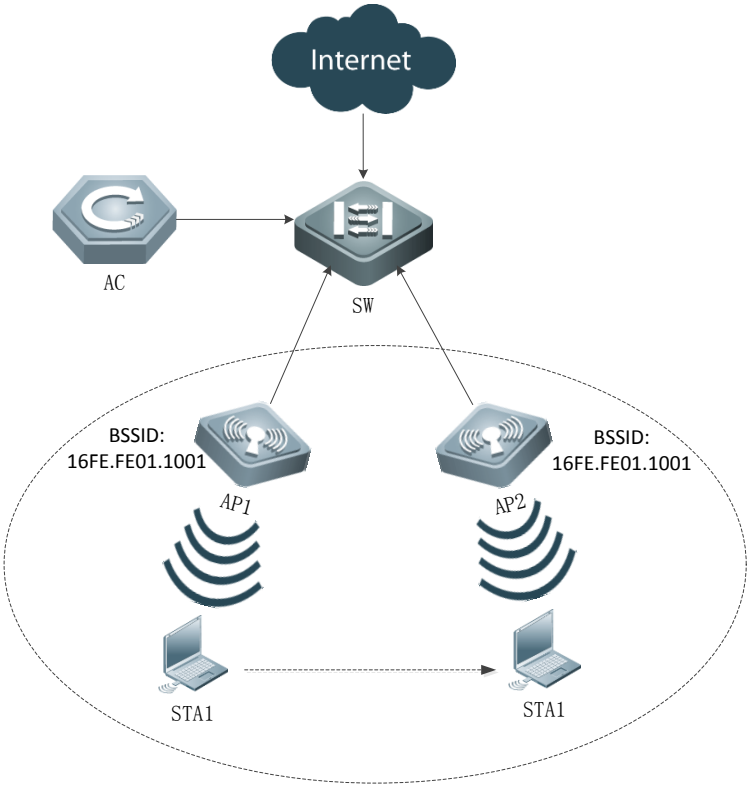
Usage Guide N/A

Enabling AP Control Mode Intra-frequency Handover

- Optional.

Command	**handoff-ap-mode enable**
Parameter Description	N/A
Defaults	AC control mode intra-frequency handover (except for the virtual AC) is enabled by default.
Command Mode	SFN group configuration mode
Usage Guide	Except for the virtual AC, the AC control mode is used by default. The virtual AC only supports the AP control mode. In a hierarchical AC environment, if the central AC is a virtual AC, the branch AC must be configured in AP control mode. Conversely, if the branch AC is a virtual AC, the central AC must also be configured in AP control mode.

Verification



- Run the **show running-config** command to display the configuration.
- Run the **show ap-config running** command to display the AP configuration.
- Run the **show sfn-group summary** *group-id* command to display basic information about the SFN group and APs associated with the SFN group.
- Use packet obtaining on the air interface to display Beacon frame information.

Configuration Example

Creating an SFN Group and Configuring Parameters

Scenario Normal fit AP environment

Figure 1-3

Assume that there are the following parameter configuration requirements for the SFN group on the AC in the fit AP environment:

1. Configure APs in the group to use radio 2 for SFN networking.
2. Configure the RSSI threshold for STA handover as 12 for APs in the group.
3. Configure radio 2 of APs in the group to support 802.11a.
4. Configure radio 2 of APs in the group to support 802.11ac.
5. Configure the MCS index of 802.11n as 13 for radio 2 of APs in the group.
6. Configure the MCS index of 802.11ac as 7 for radio 2 of APs in the group.
7. Configure the receiving/transmitting antenna mask as 1 for radio 2 of APs in the group.
8. Configure the channel ID as 40 for radio 2 of APs in the group.
9. Configure the channel width as 40 MHz for radio 2 of APs in the group.
10. Configure the DTIM period as 2 for radio 2 of APs in the group.
11. Enable AP control mode intra-frequency handover.

Note: For application scenarios where the operating frequency band of radios of APs in an AP group needs to be switched, you can run the **radio-type** command in SFN group configuration mode.

Configuration Steps

- Configure an SFN group.

AC

```
Hostname(config)#sfn-group 1 AP720-I
Hostname(config-sfn-group)#ap-group sfn-xxx
Hostname(config-sfn-group)#enable-sfn-radio 2
```

```
Hostname(config-sfn-group)#handoff-rssi-thresh 12
Hostname(config-sfn-group)#11nasupport enable radio 2
Hostname(config-sfn-group)#11acsupport enable radio 2
Hostname(config-sfn-group)#802.11n mcs support 13 radio 2
Hostname(config-sfn-group)#802.11ac mcs support 7 radio 2
Hostname(config-sfn-group)#antenna transmit 1 radio 2
Hostname(config-sfn-group)#antenna receive 1 radio 2
Hostname(config-sfn-group)#channel 40 radio 2
Hostname(config-sfn-group)#chan-width 40 radio 2
Hostname(config-sfn-group)#beacon dtim-period 2 radio 2
Hostname(config-sfn-group)#handoff-ap-mode enable
```

Verification

AC

- Run the **show running-config** command to display the SFN group configuration.

```
Hostname(config)#show running-config
!
sfn-group 1 AP720-I
 channel 40 radio 2
 802.11n mcs support 13 radio 2
 802.11ac mcs support 7 radio 2
 beacon dtim-period 2 radio 2
 chan-width 40 radio 2
 antenna transmit 1 radio 2
 antenna receive 1 radio 2
 handoff-rssi-thresh 12
 ap-group sfn-xxx
 enable-sfn-radio 2
 handoff-ap-mode enable
!
```

- Run the **show ap-config running** *ap-name* command to check whether the configuration is valid for specified APs in the SFN group.

AC

```
Hostname(config)#show ap-config running AP1
!
```

```
ap-config AP1
 ap-group sfn-xxx
 antenna receive 1 radio 2
 antenna transmit 1 radio 2
 802.11n mcs support 13 radio 2
 802.11ac mcs support 7 radio 2
 beacon dtim-period 2 radio 2
 channel 40 radio 2
 chan-width 40 radio 2
!
```

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show sfn-group summary	Displays the SFN group list.
show sfn-group summary *group-id*	Displays basic information about the SFN group and APs associated with the SFN group.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Configuring RF Management

1. Configuring WBS
2. Configuring Band Selection
3. Configuring HE Radio Selection
4. Configuring RF Resource Scheduling
5. Configuring RRM
6. Configuring 802.11kv
7. Configuring CorrectLink
8. Configuring Frequency Spectrum Scanning
9. Configuring Wireless Location
10. Configuring Smart Antenna

1 Configuring WBS

1.1 Overview

The Wireless Basic Service (WBS) is used to configure wireless-specific parameters on access controllers (ACs) when Fit access points (APs) are deployed.

Link integrity detection is a basic service of the WBS. It detects wired uplinks on APs. When a link of an AP is disconnected, access services of the AP are stopped to disconnect the connected stations (STAs). When the link is restored, the AP continues to provide wireless access services. Enabling link integrity detection in a Fit AP architecture with dense AP deployment helps reduce the network disconnection time and improve user experience.

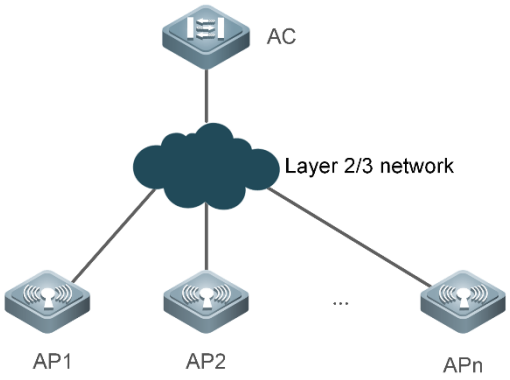
Protocols and Standards

- 802.11n: Enhancements for Higher Throughput
- 802.11ac: Enhancements for Very High Throughput for Operation in Bands below 6 GHz
- 802.11ax: Enhancements for High Efficiency WLAN

1.2 Applications

Application	Description
Configuring Fit APs	Run commands on an AC to configure parameters of Fit APs.
Enabling Link Integrity Detection	Enable link integrity detection in a Fit AP architecture to improve the quality of service (QoS) of wireless access.

1.2.1 Configuring Fit APs



Scenario

Configure Fit APs. A network administrator can manage the configuration of Fit APs on an AC in a centralized manner. Assume that a network has the following deployment requirements:

1. Allow the AC to monitor the status of feeder links on i-Share APs.
2. Prevent STAs with received signal strength indication (RSSI) smaller than 20 dB from accessing the network.
3. Enable short guard interval (GI) in 20 MHz.
4. Prevent the use of low data rates, such as 1 Mbps, 2 Mbps, and 5.5 Mbps.

Figure 1-1 shows the Fit AP networking topology.

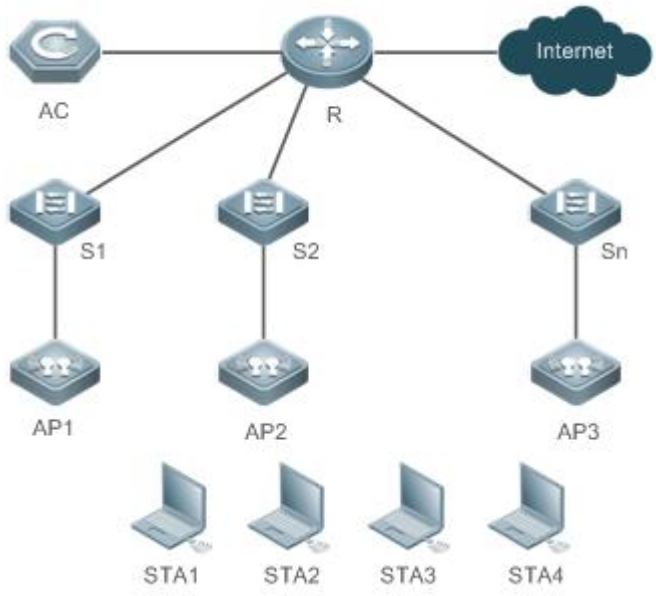
Figure 1-1 Fit AP Networking Topology

Deployment

Main configuration points on the AC:

1. Enable i-Share antenna feeder link detection for all the APs and set the detection interval.
2. Run **response-rssi** for radios of all the APs and set the threshold to 20 dB.
3. Run **short-gi enable** for radios of all the APs and set the bandwidth to 20 MHz.
4. Disable the use of 1 Mbps, 2 Mbps, and 5.5 Mbps data rates for 802.11b/g network users.

1.2.2 Enabling Link Integrity Detection



Scenario

Enable link integrity detection on wireless networks with the Fit AP architecture.

See Figure 1-2.

- An AC is connected to the Internet through a router. AP1, AP2, and AP3 are connected to the router through three switches and associated with the AC.
- STA1 is associated with AP1, STA2 and STA3 are associated with AP2, and STA4 is associated with AP3. The STAs access the Internet through the AC.

Figure 1-2

Remarks	The R is an egress router. S1, S2, and S3 are Layer 2 switches and function as access devices for APs. AP1, AP2, and AP3 are directly connected to S1, S2, and S3 respectively.

Deployment

- Layer 2 switches provide the access service for APs.
- The R sets up connections between ACs and APs and between STAs and the Internet.

1.3 Features

Basic Concepts

A-MPDU

The 802.11n standards utilize the aggregate MAC protocol data unit (A-MPDU). Multiple MPDUs are aggregated into an A-MPDU, retaining only one PHY header while removing those of other MPDUs. This approach reduces the additional information carried by the PHY header of each transmitted MPDU, resulting in a decrease in the number of ACK frames. As a result, it alleviates the burden and enhances network throughput.

A-MSDU

The 802.11n protocol introduces a new MAC feature known as the aggregate MAC service data unit (A-MSDU), which aggregates multiple MSDUs into one MSDU for transmission. Similar to A-MPDU, A-MSDU reduces additional information carried by the MAC header of each MSDU to be transmitted, thereby improving the transmission efficiency of the MAC layer.

MCS

The physical layer of 802.11n supports high data transmission rates and is compatible with 802.11a/b/g rates. The supported rates are called modulation and coding scheme (MCS) rates.

Beacon

APs on a wireless local area network (WLAN) periodically send beacon frames externally. The beacon frames contain AP information, and STAs receive beacon frames to discover WLANs.

RSSI

The RSSI indicates the quality of wireless connections.

Country or Region Code

A country or region code identifies a country or region with radio frequency (RF) usage. RFs, channels, and powers vary with country or region codes. Before you configure an AP, determine the country or region code supported by the AP. If the configured country or region code is changed, the RFs, channels, and powers mapped to the country or region code are also changed.

Frequency Band

The 2.4 GHz, 5 GHz, and 6 GHz frequency bands are supported.

Wireless Channel

Wireless channels transmit RF medium between APs and STAs. The use of channels varies with countries or regions and frequency bands.

The 2.4 GHz frequency band can be configured with 13 channels (channel 1 to channel 13). The overlapping channels in the 2.4 GHz frequency band cause interference. It is recommended that these channels be configured as non-overlapping channels (for example, channels 1, 6, and 11) to avoid radio signal collision.

The 5 GHz frequency band can be configured with 25 channels (channels 36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 120, 124, 128, 132, 136, 140, 144, 149, 153, 157, 161, and 165).

The 6 GHz frequency band can be configured with 15 channels (channels 5, 21, 25, 37, 53, 69, 85, 101, 117, 133, 149, 165, 181, 197, 213, and 229).

Transmit Power

The transmit power indicates the strength of RF signals transmitted by an AP. It is proportional to the radio signal coverage area of the AP.

Timeslot Type

Channel contention may occur when multiple STAs send data on the same WLAN. To mitigate this issue, STAs are required to first check the idle state of channels before sending data. If a STA detects that a channel is idle, the STA does not send data until the backoff time has elapsed. The backoff time is a random integer, measured in slot times, which serves as a timing mechanism specified in the MAC protocol. After each slot time interval, the value of the backoff time is automatically decremented by 1. Once the backoff time reaches 0, the STA can begin transmitting data. On WLANs, the slot time is categorized into two intervals: 20 μs and 9 μs, with the latter referred to as the "short slot time."

Antenna Transmit or Receive Types

You can configure some antennas on an RF card to transmit signals and the other antennas to receive signals.

Short GI

802.11n adds optional support for a 0.4 μs guard interval, compared to the standard 0.8 μs guard interval.

Fragmentation Threshold

To increase the transmission success rate, the IEEE 802.11 MAC protocol supports fragmentation of packets before transmission. This process entails packet fragmentation based on a threshold, thereby reducing the interference probability and saving bandwidth resources during retransmission.

RTS/CTS

To avoid channel conflicts and resulting data transmission failures, the IEEE 802.11 MAC protocol provides a handshake protocol called Request To Send (RTS) or Clear To Send (CTS). When STA A needs to send data to STA B, it first sends an RTS frame. STA B responds with a CTS frame if it permits STA A to send data. After receiving the CTS frame, STA A starts sending data. In cases where multiple STAs send RTS frames to the same STA, only those that receive CTS frames are permitted to send data. The STAs that do not receive CTS frames can attempt to resend RTS frames after a specific time because a channel conflict is considered to have occurred.

PHY Protection Modes

Frames can be transmitted in Greenfield mode or hybrid mode. The hybrid mode is intended to support compatibility with other physical layers, and the Greenfield mode is used to transmit physical layer headers at high speeds. A device which uses the high-throughput (HT) hybrid mode can transmit frames in 802.11a/b/g and 802.11n modes. Such a device first transmits a conventional format preamble, followed by an HT format preamble. The device must send a conventional CTS-to-Self or RTS/CTS frame before transmitting data. These protection mechanisms enable 802.11a/b/g devices, including those devices not connected to APs in HT hybrid mode to detect the busy state of channels.

Preamble Type

A preamble is a group of bits in a packet header and used to synchronize transmission signals between the transmit end and receive end. You can configure the preamble type (long or short) that an AP supports. The data frames with long preambles take a longer time to be transmitted than the data frames with a short preamble.

U-APSD

802.11e introduces Wi-Fi multimedia power save (WMM-PS) to reduce the delay of services with high real-time performance requirements during power management. WMM-PS adopts the Unscheduled Automatic Power Save Delivery (U-APSD) technology to disable transmission of radio signals during most of the time, which extends the battery life. U-APSD is an enhancement of the 802.11 power saving mechanism.

Transmit Beamforming

Transmit Beamforming (TxBF) can be optionally supported in the 802.11n protocol to improve reliability of packet transmission. The transmitter adjusts the transmission mode of WLAN signals based on the evaluated channel conditions at the receiving antenna, so that the signal is the strongest when it arrives at the receiver, thereby improving the success rate and throughput of the wireless link.

MU-MIMO

802.11ac uses downlink Multi-User Multiple-Input Multiple-Output (MU-MIMO) to enable an AP to send data to multiple STAs through TxBF. 802.11ax uses uplink MU-MIMO to enable multiple STAs to send data to an AP.

OFDMA

Orthogonal Frequency Division Multiple Access (OFDMA) is extended based on OFDM. Multiple access is achieved in OFDMA by assigning subsets of subcarriers to individual users.

DFS

Dynamic Frequency Selection (DFS) allows wireless devices to dynamically switch their channels to prevent interference with key services such as radar systems. When a wireless device detects radar signals on the current channel, DFS triggers an automatic switch to other available channels, reducing or eliminating potential interference and protecting key radar services.

Overview

Feature	Description
Detecting Feeder Link	Checks the status of feeder links on i-Share APs.
In i-Share antenna scenarios, when rooms are limited, some APs do not need to be configured with feeders directed to rooms. However, the system may mistakenly assume that the feeder is not in position and therefore report an exception in the feeder status. To facilitate management, administrators are allowed to configure the feeder status manually. Configuring STA Access Control	Controls access of specified STAs.
Configuring RF Parameters	Configures RF parameters for APs or radios.
Configuring RF Parameters	Configures RF parameters of data rate control.
Configuring Power Saving Parameters	Sets power saving parameters.
Enabling Link Integrity Detection	Detects integrity of links to improve the wireless service quality.
Configuring E-Bag Parameters	Provides a command to quickly configure E-bag network optimization in one-click mode, which improves user experience.
Configuring WLANs in One-Click Mode	Provides the one-click WLAN configuration to achieve fast configuration of unconfigured devices.
Canceling the Power Supply Limit	Cancels the power supply limit.
Managing RF with Insufficient Power Supply	Manages RF based on device capabilities when power supply is insufficient.

Feature	Description
Configuring Forced Power Supply for an AP	Forcibly configures the AP power supply mode as the specified mode.
Configuring the Frequency Band Mode	Configures the frequency band mode of a specified radio on AP.

1.3.1 Detecting Feeder Links of i-Share APs

Working Principle

There may be a large number of i-Share APs on a network, and each AP may have multiple feeders connected to it. To facilitate user management, the device provides feeder link detection, which can automatically detect whether each feeder on each i-Share AP is working properly. In this way, when any feeder on any i-Share AP is not working properly due to poor contact or human damage, the fault can be rapidly detected and eliminated.

In i-Share antenna scenarios, when rooms are limited, some APs do not need to be configured with feeders directed to rooms. However, the system may mistakenly assume that the feeder is not in position and therefore report an exception in the feeder status. To facilitate management, administrators are allowed to configure the feeder status manually.

1.3.2 Configuring STA Access Control

Working Principle

Ruijie Networks provides STA access control.

STAs search for APs through active and passive scan:

- Active scan: A STA sends a Probe Request frame to request access to an AP, which will respond with a Probe Response frame.
- Passive scan: APs broadcast beacon frames periodically. STAs listen to beacon frames and initiate connections to APs.

To control network coverage areas of APs and improve the transmission quality of radio signals, take the following measures to limit the access of STAs:

- Control the range for broadcasting beacon frames on APs to limit the access of long-distance STAs.
- Configure the minimum RSSI applied to STAs during the access process. The STAs which send request frames with RSSI smaller than the minimum value are denied access.
- Configure the minimum RSSI applied to STAs during data transmission. The STAs which send data frames with RSSI smaller than the minimum value are disconnected. Then the STAs can roam to other APs with better radio signals.

1.3.3 Configuring RF Parameters for APs

You can configure RF parameters for APs and radios.

Working Principle

A-MPDU

The 802.11n standards utilize A-MPDU. Multiple MPDUs are aggregated into an A-MPDU, retaining only one PHY header while removing those of other MPDUs. This approach reduces the additional information carried by the PHY header of

each transmitted MPDU, resulting in a decrease in the number of ACK frames. As a result, it alleviates the burden and enhances network throughput.

A-MPDU Aggregation Depth

It refers to the maximum number of MPDUs that can be aggregated in an A-MPDU.

AMSDU

The 802.11n protocol defines a new MAC feature called A-MSDU, which combines multiple MSDUs into one MSDU for transmission. Similar to A-MPDU, A-MSDU reduces the additional information on the MAC header of each MSDU to be transmitted, improving the transmission efficiency of the MAC layer.

A-MSDU Aggregation Depth

It refers to the maximum number of MSDUs that can be aggregated in an A-MSDU.

MCS

In 802.11n, RF rates are configured by using index values of the MCS, which is used to represent the communication rates on WLANs. The MCS is a rate table. The table columns list the factors that affect communication rates, and the table rows show the MCS indexes. Each MCS index maps a physical transmission rate which is determined by a group of parameters. For details of all the MCS rate tables, see the *IEEE P802.11n D2.00*.

Wireless Channel

Wireless channels transmit RF medium between APs and wireless STAs. The use of channels varies with different countries/regions and frequency bands.

The 2.4 GHz radio can be configured with 13 channels (channel 1 to channel 13). The overlapping channels in the 2.4 GHz radio cause interference. It is recommended that these channels be configured as non-overlapping channels (for example, channels 1, 6, and 11) to avoid radio signal collision.

The 5 GHz radio can be configured with 25 channels (channels 36, 40, 44, 48, 52, 56, 60, 64, 100, 104, 108, 112, 116, 120, 124, 128, 132, 136, 140, 144, 149, 153, 157, 161, and 165).

The 6 GHz radio can be configured with 15 channels (channels 5, 21, 25, 37, 53, 69, 85, 101, 117, 133, 149, 165, 181, 197, 213, and 229).

Packet Fragmentation

To increase the transmission success rate, the IEEE 802.11 MAC protocol supports fragmentation of packets before transmission. This process entails packet fragmentation based on a threshold, thereby reducing the interference probability and saves bandwidth resources during retransmission.

RTS/CTS

To avoid channel conflicts and resulting data transmission failures, the IEEE 802.11 MAC protocol provides a handshake protocol called RTS or CTS. When STA A needs to send data to STA B, it first sends an RTS frame. STA B responds with a CTS frame if it permits STA A to send data. After receiving the CTS frame, STA A starts sending data. In cases where STAs send RTS frames to the same STA, only those that receive CTS frames are permitted to send data. The STAs that do not receive CTS frames can attempt to resend RTS frames after a specific time because a channel conflict is considered to have occurred.

If each STA implements RTS/CTS handshake before sending data, many RTS frames will occupy channel bandwidth. To avoid this problem, you can configure an RTS threshold to specify the frame length of transmitted data. If a STA sends data with a frame length smaller than the RTS threshold, the STA will not implement RTS/CTS handshake.

Beacon

APs on a WLAN periodically send beacon frames externally. The beacon frames contain AP information, and STAs receive beacon frames to discover WLANs.

Preamble Type

A preamble is a group of bits in a packet header and used to synchronize transmission signals between the transmit end and receive end. You can configure the preamble type (long or short) that an AP supports. The data frames with long preambles take a longer time to be transmitted than the data frames with a short preamble.

Timeslot Type

Channel contention may occur when multiple STAs send data on the same WLAN. To mitigate this issue, STAs are required to check the idle state of channels before sending data. If a STA detects that a channel is idle, the STA does not send data until the backoff time has elapsed. The backoff time is a random integer, measured in slot times, which serves as a timing mechanism specified in the MAC protocol. Assume that the random integer is 3. After each slot time interval, the value of the backoff time is automatically decremented by 1. Once the backoff time reaches 0, the STA can begin transmitting data. Reducing the slot time can reduce the overall backoff time and increase network throughput.

Channel Bandwidth

In 802.11n and later protocols, channel bonding can be used to expand the communication bandwidth, increase the rate, and improve the throughput of wireless networks. 802.11n supports a maximum bandwidth of 40 MHz, while 802.11ac and 802.11ax support a maximum bandwidth of 160 MHz.

GI

802.11n adds optional support for a 0.4 μs guard interval, compared to the standard 0.8 μs guard interval.

802.11ax supports three types of guard interval: 0.8 μs, 1.6 μs, and 3.2 μs.

Country or Region Code

A country or region code identifies a country or /region with RF usage. RFs, channels, and powers vary with country or region codes. Before you configure an AP, determine the country or region code supported by the AP. If the configured country or region code is changed, the RFs, channels, and powers mapped to the country or region code are also changed.

Antenna Transmit/Receive Types

An AP can use different number of antennas when transmitting and receiving data. This enables the AP to adopt the multi-stream transmission mode to improve data transmission performance. 802.11n supports up to four spatial streams, while 802.11ac and 802.11ax support up to eight spatial streams.

Internal and External Antennas

Internal antennas are integrated inside the enclosures of APs, and external antennas are connected to reserved hardware interfaces of APs. External antennas achieve longer transmission distances than internal antennas with the same transmission power.

Omnidirectional and Directional Antennas

An omnidirectional antenna radiates signals equally in all directions, while a directional antenna radiates signals in a specific direction with a cone-shaped radiation range.

Maximum Distance of Radio Transmission Between AP Radios and the Peer End

Radio signals travel through space at the speed of light. As the distance of radio transmission between AP radios and the peer end increases, the duration for transmitting radio packets in space also increases, subsequently extending the timeout interval for APs to await ACK and CTS frames. It is crucial to adjust the timeout interval according to the distance of radio transmission between AP radios and the peer end; otherwise, radio data may fail to be transmitted. A long timeout interval leads to a wastage of resources on the air interface as APs continue to wait for ACK and CTS frames.

One-Click Configuration of AP's RF Parameters Including the Power, Channel, and Antenna Transmit/Receive Type

The power, channel, and antenna transmit/receive type vary with AP models. One-click configuration of AP's RF parameters can be used to automatically adjust the parameters based on radio types, achieving optimal network performance.

Exchanging Channels

In high-density scenarios, enabling the third radio is enabled for user access results in varying degrees of channel limitation across each RF interface. Directly changing the channel for an RF interface is not allowed, but it is possible to change working channels between two RF interfaces of the same type.

MCell

The MCell function effectively reduces receiving sensitivity and enhances air interface concurrency in high-density scenarios by disabling Low Noise Amplifier (LNA).

Transmit Beamforming

Transmit Beamforming (TxBF) is a technology supported as an option in the 802.11n protocol to improve the reliability of packet transmission. The transmitter adjusts the transmission mode of WLAN signals based on an assessment of the channel conditions between the transmitter and the receiver to target the receiving antenna. This ensures that the signals arrive at their strongest at the receiver, thereby increasing the success rate of wireless link transmissions and improving overall throughput.

Multi-BSSID

Mutli-BSSID (MBSSID) is an optional feature defined in the 802.11v protocol. It allows multiple virtual access points (VAPs) operating on the same radio to share one beacon, reducing the number of beacons and improving the data utilization of air interfaces, thereby improving the performance and throughput of wireless links.

RNR

Reduce Neighbor Report (RNR) enables STAs to learn about the available 6 GHz radio from the RNR information in beacon frames sent by the AP's 2.4 GHz and 5 GHz radios.

FILS

FILS Announcement is an improved passive scanning mechanism added to the 6 GHz radio. FILS Announcement packets are sent at an interval of 20 ms, reducing the waiting time of passive scanning.

UPRS

Unsolicited Probe Response (UPR) is a new passive scanning improvement mechanism in the 6 GHz radio. If UPR is implemented, the 6 GHz AP sends UPR frames at an interval of 20 ms to reduce the waiting time for passive scanning.

BSS Color

BSS Color is used to address the issue of Overlapping Basic Service Set (OBSS) in order to improve spatial reuse and reduce MAC layer competition caused by OBSS. 802.11ax-compliant devices distinguish BSSs by adding a BSS Color field to the physical header. If the BSS Color field in the physical header of different packets is the same, it indicates that the packets are within the same BSS (intra-BSS); otherwise, they are in different BSSs (inter-BSS). By increasing the signal detection threshold between BSSs (inter-BSS) while maintaining a low signal detection threshold within the same BSS (intra-BSS), and adjusting transmit power, the overall throughput and spatial reuse of the current channel can be improved.

TWT

Target Wakeup Time (TWT) is an 802.11ax scheduling algorithm. TWT requesters and TWT responders agree upon a time window called the Service Period (SP) through negotiation, during which the TWT requesters wake up for packet transmission while remaining in sleep mode outside the SP. This aims to achieve power savings for the STA and minimize the BSS activity management at the AP, reducing STA competition.

QBSS Load

The QoS Basic Set Service (QBSS) load enables an AP to inform STAs about the AP's load. When this function is enabled, beacon or probe response packets sent by the device contain the BSS load Information Element (IE) field. The BSS load IE contains information on the STA count, channel utilization, and other information in the BSS at a specific radio. STAs automatically select the optimal network for login according to the information.

BAR Retransmission Count

Block ACK Request (BAR) aggregates multiple acknowledgment frames into a single acknowledgment frame, thus improving channel transmission efficiency. Configuring the BAR retransmission count prevents BAR frame loss. A larger retransmission count indicates a lower probability of losing BAR frames. However, excessive retransmission may increase the load of an air interface.

1.3.4 Configuring RF Parameters for Rate Control

Set RF parameters for rate control.

Working Principle

802.11 is an industrial standard defined by IEEE for WLAN communication, and has been continuously supplemented and improved to form the 802.11x standard series. The main transmission standards are 802.11b/a/g/n/ac/ax/be, which are described as follows:

1. 802.11b

It operates in the 2.4 GHz frequency band, with a maximum data transmission rate of up to 11 Mbps, which can be lowered to 5.5 Mbps, 2 Mbps, or 1 Mbps as needed.

2. 802.11a

It operates in the 5 GHz frequency band, with a maximum data transmission rate of up to 54 Mbps, which can be lowered to 48 Mbps, 36 Mbps, 24 Mbps, 18 Mbps, 12 Mbps, 9 Mbps, or 6 Mbps according to actual needs.

3. 802.11g

It operates in the 2.4 GHz frequency band, with a maximum data transmission rate of up to 54 Mbps, which can be lowered to 48 Mbps, 36 Mbps, 24 Mbps, 18 Mbps, 12 Mbps, 9 Mbps, or 6 Mbps as needed. Devices that support 802.11g are backward compatible with 802.11b.

4. 802.11n

It operates in the 2.4 GHz and 5 GHz operating bands, with a maximum data transmission rate of 600 Mbps. 802.11n-compliant device are backward compatible with 802.11a/b/g.

5. 802.11ac

It operates in the 5 GHz frequency band, with a maximum data rate of 6.9 Gbps. 802.11ac-compliant devices are backward compatible with 802.11a/b/g/n.

6. 802.11ax

It operates in the 2.4 GHz, 5 GHz, and 6 GHz frequency bands, with a maximum data transmission rate of 9.6 Gbps. 802.11ax-compliant devices are backward compatible with 802.11a/b/g/n/ac in the 2.4 GHz and 5 GHz frequency bands, but not in the 6 GHz frequency band.

7. 802.11be

It operates in the 2.4 GHz, 5 GHz, and 6 GHz frequency bands, with a maximum data transmission rate of 46 Gbps. 802.11be-compliant devices are backward compatible with 802.11a/b/g/n/ac/ax in the 2.4 GHz and 5 GHz frequency bands, but not in the 6 GHz frequency band.

1.3.5 Configuring Power Saving Parameters

Working Principle

↘ DTIM Period

A delivery traffic indication map (DTIM) is a flag bit in a beacon frame, and is used to determine the interval at which an AP sends broadcast or multicast frames. APs buffer the data that STAs in sleeping state need to receive according to the DTIM period. After the DTIM period has elapsed, APs send the buffered data to STAs.

The DTIM period is expressed based on the number of sent beacon frames. Assume that the DTIM period is set to 3. APs send broadcast or multicast frames each time after three beacon frames are sent.

↘ U-APSD Power Saving

U-APSD is enhanced based on the power saving mode. When clients are associated with ACs, some ACs can be configured with the trigger attribute, some ACs can be configured with the delivery attribute, and the maximum number of packets to be sent after trigger can be set. The trigger and delivery attributes can be changed when flows are created through connection access control (CAC). When a client sleeps, data packets from the AC with the delivery attribute destined for the client are buffered. To retrieve the buffered packets, the client needs to send data packets from the AC

with the trigger attribute. After receiving such packets, the AP sends the buffered packets according to the number of packets to be sent during the access process. Other data packets from the AC without the delivery attribute are stored and transmitted in accordance with 802.11 standards.

1.3.6 Enabling Link Integrity Detection

APs implement functions of the physical layer and MAC layer, and typically do not provide switching functions. A Fat or Fit AP has only one wired uplink, which is the data channel allowing STAs to access the AP. When the wired uplink is disconnected because of a fault, all the STAs connected to the AP cannot access the Internet.

STAs cannot detect link disconnections immediately or take measures. As a result, the network connection cannot be restored for a long time.

Link integrity detection is introduced to solve this problem.

Working Principle

The link integrity detection function continuously detects the status of wired uplinks on APs. When a wired uplink is disconnected, the RF interface of the AP is disabled to stop the access service. STAs associated with the AP are disconnected and have to reconnect to other normal APs.

When the wired uplink is recovered, the link integrity detection function enables the RF interface of the AP to restore the wireless access service again.

When the wired uplink of an AP is disconnected, link integrity detection enables STAs that are associated with the AP to reconnect to other normal APs.

1.3.7 Configuring E-Bag Parameters

You can configure E-bag parameters for APs and radios.

Working Principle

You can run a command to quickly configure E-bag network optimization in one-click mode, which improves user experience.

↘ A-MPDU

A-MPDU is short for aggregate MAC protocol data unit.

↘ LDPC

A low-density parity-check (LDPC) code is a type of linear error correcting code. Known for its ease of use and low complexity, this coding method utilizes forward error correction (FEC) technology to enhance coding reliability and performance. LDPC was developed in the early 1960s and is designed to support information transmission in noisy frequency environments with significant background or content damage. Moreover, LDPC significantly reduces the probability of information loss during transmission in frequencies plagued by severe noise interference. However, note that a small number of STAs may be incompatible with LDPC, and enabling LDPC can lead to packet loss.

↘ STBC

Space time block coding (STBC) is a wireless communication technique that transmits multiple copies of a data stream over several antennas at different time points. This approach improves reliability of data transmission through a

combination of time and space diversity. The key benefit of STBC lies in its capability to leverage maximum likelihood decoding to achieve full antenna gains. Nonetheless, it is important to note that some STAs may be incompatible with STBC.

A-MPDU Software Retransmission Count

The A-MPDU software retransmission mechanism is specifically designed to prevent the loss of sub-frames in wireless communications. The probability of sub-frame loss decreases as the retransmission count increases. However, frequent packet retransmission can impose a higher burden on the air interface, thereby affecting real-time transmission of packets. If there is a high probability of sub-frame loss, increasing the retransmission count can be considered to mitigate packet loss.

A-MPDU-RTS

The RTS protection feature of A-MPDU is designed to prevent resource waste on the air interface caused by packet collision due to hidden nodes. Because RTS interaction consumes air interface resources and can have an adverse impact on several application scenarios, this feature is disabled by default. You are advised ot enable RTS protection only when the resource waste on the air interface caused by hidden nodes outweighs the resource consumption of RTS interaction on the air interface.

One-Time Received Ethernet Packet Quantity

A command is provided to adjust the number of Ethernet packets received at a time. Increasing the number of Ethernet packet received can improve network performance, but it may reduce APs' capability to handle key packets in real time. If high performance is not required but there is a need for real-time packet handling and user concurrency, it may be necessary to reduce the number of Ethernet packet received. In this case, it is recommended that the value be set to 25.

1.3.8 Configuring WLANs in One-Click Mode

The one-click WLAN configuration feature allows you to perform fast configuration on unconfigured devices.

Working Principle

One-Click Configuration

Perform the following configuration on an AC:

1. Assignment of virtual local area networks (VLANs): On the AC, configure VLAN 1 for APs and VLAN 2 for STAs.
2. Address pool: On the AC, configure the network segment 192.168.1.0 for APs and configure the network segment 192.168.2.0 for STAs. The default IP addresses of VLAN 1 and VLAN 2 are 192.168.1.1 and 192.168.2.1 respectively. The default management IP address is 88.88.88.88.
3. WLAN configuration: Name the WLAN **autowifi**_*XXXX*, where *XXXX* is the last four digits of the MAC address of the AC. You can use **wlan-id 1**.
4. Security: By default, WPA2 encryption is used. The password is **autowifi**.
5. WLAN-VLAN mapping: On the AC, configure the mapping between wlan-id 1 and VLAN 2 in the group named **ap-group default**.
6. Service: Enable the Dynamic Host Configuration Protocol (DHCP) service.

1.3.9 Canceling the Power Supply Limit

In situations where some APs with PoE+ power cannot negotiate PoE+ with certain special power supply devices, cancel the power supply limit to ensure that the APs can work at their full capacity.

Working Principle

When the negotiated power supply limit is 15.4 W, configure a command to cancel the power supply limit.

When using the command, ensure that the power supply device meets the maximum power consumption requirement of the corresponding AP. Otherwise, the AP may restart. Exercise caution when configuring this command.

1.3.10 Managing RF with Insufficient Power Supply

In situations where special power supply devices cannot negotiate PoE+ with some APs that have PoE+ power, the negotiated power supply limit may reduce to 15.4 W. This can result in insufficient power supply when all RFs are providing services. Therefore, depending on external power supply conditions, APs will disable certain types of RFs (2.4 GHz, 5 GHz, or 6 GHz) based on their device capability, to ensure sufficient power supply for the remaining RFs to function correctly. However, when the power supply is negotiated as PoE+, all RFs are enabled and can operate properly.

Working Principle

For some APs that are powered by PoE+ and have a negotiated power supply limit of 15.4 W during startup, the APs will disable specific RFs (2.4 GHz or 5 GHz) depending on their device capability. However, the AC can configure the AP to switch between RFs, namely, 2.4 GHz and 5 GHz.

1.3.11 Configuring Forced Power Supply for an AP

Forcibly configure the AP power supply mode as the specified mode.

Working Principle

Forcibly configure the power supply mode of an AP to af/at25w/36w/bt and save the configuration.

NOTE:

The **save** parameter can be specified in the command to indicate whether the forced power supply mode needs to be saved to the environment variables to avoid loss after restart.

1.3.12 Configuring the Frequency Band Mode

Some APs can switch the operating band of the radio by setting the frequency band mode.

Working Principle

Some APs allow the operating band of the radio (2.4 GHz, 5 GHz, or 6 GHz) to be set during startup, but not dynamically switched during operation.

↘ Freqnecy Band Mode

Configure the frequency band mode of a specified radio on an AP.

1.4 Configuration

Configuration	Description and Command	
Configuring Feeder Link Detection	(Optional) It is used to enable the feeder link status detection function on an AP.	
	antdetect enable	Enables the feeder link status detection function.
	antdetect interval	Configures the feeder status detection interval, in minutes.
	antdetect cfg *port_id state*	Configures of the feeder status.
Configuring STA Access Control	(Optional) It is used to configure STA access control.	
	{ **802.11a** | **802.11b** | **6GHz** } **network** { **enable** | **disable** }	Enables or disables the 2.4 GHz, 5 GHz, or 6 GHz network.
	11asupport enable	Enables 802.11a support for specified AP radios in 5 GHz.
	11bsupport enable	Enables 802.11b support for specified AP radios in 2.4 GHz.
	11gsupport enable	Enables 802.11g support for specified AP radios on the 2.4 GHz network.
	11nasupport enable	Enables 802.11n support for specified AP radios in 5 GHz.
	11ngsupport enable	Enables 802.11n support for specified AP radios in 2.4 GHz.
	11acsupport enable	Enables 802.11ac support for specified AP radios.
	11axsupport enable	Enables 802.11ax support for specified AP radios.
	11besupport enable	Enables 802.11be support for specified AP radios.
	802.11 mode max	Configures the highest access mode supported by a specified WLAN.
	coverage-area-control	Configures the management frame power for APs.
	extra-coverage	Configures the third radio for user access.
	response-rssi	Configures the minimum RSSI for wireless STAs to connect to specified AP radios.
	assoc-rssi	Configures the minimum RSSI for wireless STAs to maintain connections with specified AP radios.
Configuring AP's RF Parameters	(Optional) It is used to configure RF parameters for APs.	
	802.11n a-mpdu enable	Enables A-MPDU for specified AP radios.

Configuration	Description and Command	
	ampdu-depth	Configures the aggregation depth for specified AP radios.
	amsdu-depth	Configures the A-MSDU aggregation depth for specified AP radios.
	802.11n a-msdu enable	Configures A-MSDU support for specified AP radios.
	802.11n mcs support	Configures the maximum 802.11n MCS index value for specified AP radios.
	802.11ac mcs support	Configures the maximum 802.11ac MCS index value for specified AP radios.
	802.11ax mcs support	Configures the maximum 802.11ax MCS index value for specified AP radios.
	802.11be mcs support	Configures the maximum 802.11be MCS index value for specified AP radios.
	11ax-gi	Configures the guard interval for specified AP radios.
	antenna	Configures the antenna transmit/receive type for specified AP radios.
	antenna type	Configures an omnidirectional antenna or a directional antenna.
	antenna internal-direction enhance	Configures built-in directional antennas to work in enhanced mode.
	beacon period	Configures the interval for transmitting beacon frames for specified AP radios.
	chan-with	Configures bandwidth for specified AP radios.
	channel	Configures channels for specified AP radios.
	country	Configures the country or region code set supported by an AC or the country or region code used by AP radios.
	country-code	Configures the global country code supported by an AC.
	enable-radio	Enables specified or all AP radios.
	external-antenna enable	Enables usage of external antennas for specified AP radios, and disables usage of internal antennas.
	fragment-threshold	Configures the fragmentation threshold for specified AP radios.
	fragment-burst	Configures the fragment burst mechanism for specified AP radios.
	green-field enable	Enables the protection mode for specified AP radios.

Configuration	Description and Command	
	mcell	Configures the MCell function.
	cell-range-reduction	Reduces the receive sensitivity of a radio.
	anti-interference-level	Configures the anti-interference level of a radio.
	mu-mimo enablelong-gi	Configures MU-MIMO of a radio.
	ofdma	Enables OFDMA for the specified radio.
	peer-distance	Configures the maximum distance allowed between an AP and the peer end.
	power local	Configures the transmit power for specified AP radios (percentage).
	power local-dbm	Configures the transmit power for specified AP radios (dbm).
	preamble radio	Configures the operating preamble type for specified AP radios.
	radio-optimize	Configures radio parameters, including the power, channel, and antenna type.
	radio-type	Specifies the operating band for specified AP radios.
	rts-threshold	Configures the RTS threshold for specified AP radios.
	short-gi	Enables short GI for specified AP radios.
	short-slot-time	Configures the Short Slot Time (SST) function for specified AP radios.
	txbf enable	Configures the TxBF function of a radio.
	update-key-tsc enable	Enables TKIP Sequence Counter (TSC) update for APs during 802.11x re-authentication.
	multi-bssid enable	Sends the BSSID of the specified radio over one beacon.
	rnr enable	Configures the specified radio to probe 6 GHz radio signal through the 2.4 GHz or 5 GHz radio.
	ap-announcement-mode	Configures the announcement function for the specified AP radio to send Frequency Information Location Service (FILS) or Unsolicited Probe Response (UPRS) frames at an interval of 20 ms to reduce the waiting time of passive scanning.
	bss-color enable	Configures BSS color for the specified radio.
	twt enable	Configures TWT for the specified radio.
	qbss-load enable	Configures QBSS load for the specified AP radio.

Configuration	Description and Command	
	bar-retries	Configures the BAR retransmission count for the specified AP radio.
Configuring Data Rate Control Parameters	(Optional) It is used to configure parameters of data rate control.	
	{ **802.11a** | **6GHz** } **network rate**	Configures the data rate set supported by 802.11a (5 GHz) STAs or 6 GHz STAs.
	802.11b network rate	Configures the data rate set supported by 802.11b STAs.
	802.11g network rate	Configures the data rate set supported by 802.11g STAs.
	mcast-rate	Configures the WLAN multicast rate.
	beacon rate	Configures the beacon frame transmission rate.
Configuring Power Saving Parameters	(Optional) It is used to configure power saving parameters.	
	apsd	Enables or disables U-APSD power saving.
	beacon dtim-period	Configures the DTIM period.
Enabling Link Integrity Detection	(Mandatory) It is used to enable link integrity detection.	
	link-check enable	Enables link integrity detection.
Configuring E-Bag Parameters	(Optional) It is used to configure the parameters of E-bag.	
	ampdu-retries	Configures the A-MPDU retransmission count.
	ampdu-rts	Enables or disables RTS protection for A-MPDU packets.
	eth-schd	Configures the one-time received Ethernet packet quantity for APs.
	ldpc	Enables or disables LDPC.
	stbc	Enables or disables transmit or receive STBC.
	ebag	Configures E-bag network optimization in one-click mode.
Configuring WLANs in One-Click Mode	(Optional) It is used to configure WLANs in one-click mode.	
	autowifi	Configures WLANs in one-click mode.
Cancelling the Power Supply Limit	**poe-unlimit**	Cancels the power supply limit for specified AP radios.
Managing the Operating Frequency Band When Power Supply Is Insufficient	**hap-poe enable radio** { **802.11a** | **802.11b** }	Switches to 2.4 GHz or 5 GHz

Configuration	Description and Command	
Enabling or Disabling the PoE Power Supply by an AP to External Devices	**poeout**	Enables or disables the PoE function on an AP.
Configuring or Canceling Forced Power Supply Mode for an AP	**pdpoe-force** { **af** | **at25w** | **at36w** | **bt** } [**save**]	Forcibly configures the AP power supply mode.
Configuring a Frequency Band Mode	⚠ Optional.	
	ap-band-mode	Configures the frequency band mode.

1.4.1 Configuring Feeder Link Detection for i-Share APs

Configuration Effect

- Feeder link detection enables an i-Share AP to periodically detect the feeder link status. When the feeder link is abnormal, the i-Share AP can upload abnormal antenna information to the AC, so that network administrators can detect and troubleshoot the feeder link problem in a timely manner.

Notes

- This function is supported only on AP220-E(M) v3.0 and RG-APD4930.

Configuration Steps

↘ Enabling Feeder Link Detection

- Optional.
- On the AC, configure the AP that needs to be enabled with feeder link detection.
- After enabling this function, the AC will deliver this configuration to the corresponding AP, instructing the AP to enable the feeder link detection function. When the AP detects that the feeder link is abnormal, the AP uploads the link abnormal status to the AC, so that the network administrator can query the AP feeder link status.

Command	**antdetect enable**
Parameter Description	N/A
Defaults	The feeder link detection function is enabled by default.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The feeder link detection function is enabled by default.

↘ Configuring the Feeder Link Detection Interval

- Optional.
- On the AC, configure the AP that needs to be enabled with feeder link detection. The feeder link detection interval can be configured only when feeder link detection is enabled.

- The AC will deliver the parameter configuration to the corresponding AP, informing the AP of the feeder link detection interval, so that it can detect the feeder link status at the specified interval.

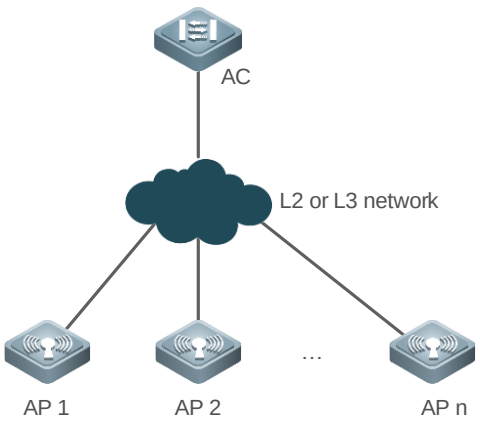
Command	**antdetect interval** *interval*
Parameter Description	*interval*: Indicates the detection interval, in minutes. The value range is from 1 to 10,000.
Defaults	The default value is 1 minute, indicating that the AP detects the link status every 1 minute.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The feeder link detection interval is set to 1 minute by default.

Configuring the Feeder Status

- Optional.
- On an AC, configure an AP enabled with the feeder link detection function. If the feeder link detection function is disabled, the configuration does not take effect.
- After configuration, the AC will record the status of the specified antenna of the AP as configured.

Command	**antdetect cfg** *port_id state*
Parameter Description	*port_id*: Indicates the AP port number, that is, antenna number. The value range is from 1 to 8. *state*: Indicates the antenna status. The value can be 1, 2, or 3. The value 1 indicates Y, that is, the feeder is in position. The value 2 indicates N, that is, the feeder is not in position. The value 3 indicates Idle, that is, the feeder is not connected. After configuration, you can view the antenna status on the web interface of the AC.
Defaults	If the feeder link detection function is enabled, the status of the feeder is automatically detected by default.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	1. The feeder link detection function must be enabled before you configure the feeder status. 2. This function is supported only on the RG-APD4930. Whether this command is supported varies depending on the product.

Verification



Run the **show antenna all** command to display the feeder link status of all APs.

Configuration Example

Configuring the Feeder Link Detection Function

Scenario

Figure 1-1

Assume that in a Fit AP environment. The following configurations are performed on the AC:

1. Enable feeder link detection of all APs.
2. Set the feeder link detection interval to 30 minutes.

Configuration Steps

Configure i-Share feeder link detection on the AC.

```
Hostname# configure terminal
Hostname(config)# ap-config all
Hostname(config-ap)# antdetect enable
Hostname(config-ap)# antdetect interval 30
```

Verification

Run the **show antenna all** command to display the feeder link status of all APs.

```
Hostname# show antenna all
ap's antenna state                                          R1       R2
R3       R4       R5       R6

                        ap                                0 1 2 3   0 1 2 3
0 1 2 3   0 1 2 3   0 1 2 3   0 1 2 3
-------------------------------------------------------------------   -------
-------   -------   -------   -------   -------

APD-M4                                                  - N N -   - N Y -
- N N -   - N N -   - - - -   - - - -
```

Common Errors

N/A

1.4.2 Configuring STA Access Control

Configuration Effect

- Control the access of a specified type of STAs so that a network administrator can easily manage the STAs.

Configuration Steps

Enabling or Disabling the 2.4 GHz, 5 GHz, or 6 GHz Network

- Optional.
- Enable or disable the 2.4 GHz, 5 GHz, or 6 GHz network on an AC.
- The AC delivers the configuration to all the APs to instruct the APs to enable or disable the 2.4 GHz, 5 GHz, or 6 GHz network.

Command	{ **802.11a** | **802.11b** | **6GHz** } **network** { **enable** | **disable** }
Parameter Description	N/A
Defaults	By default, the 2.4 GHz, 5 GHz, and 6 GHz networks are enabled.
Command Mode	AC configuration mode
Usage Guide	N/A

Enabling 802.11a Support

- Optional.
- The configuration takes effect only when the AP radios operate in 5 GHz.
- On the AC, enable 802.11a support for specified APs.
- The AC delivers the configuration to APs to instruct the APs to support the access of 802.11a STAs in 5 GHz.

Command	**11asupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11a support. The value range is from 1 to 96.
Defaults	By default, the access of 802.11a STAs is supported in 5 GHz.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 5 GHz. The configuration is supported only by specified APs.

Enabling 802.11b Support

- Optional.
- The configuration takes effect only when AP radios operate in 2.4 GHz.
- On the AC, enable 802.11b support for specified APs.
- The AC delivers the configuration to APs to instruct the APs to support the access of 802.11b STAs in 2.4 GHz.

Command	**11bsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11b support. The value range is from 1 to 96.
Defaults	By default, the access of 802.11b STAs is supported in 2.4 GHz.
Command Mode	AP configuration mode or all-AP configuration mode

Usage Guide	The configuration takes effect only when AP radios operate in 2.4 GHz. The configuration is supported only by specified APs.

Enabling 802.11g Support

- Optional.
- The configuration takes effect only when AP radios operate in 2.4 GHz.
- On the AC, enable 802.11g support for specified APs.
- The AC delivers the configuration to APs to instruct the APs to support the access of 802.11g STAs in 2.4 GHz.

Command	**11gsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11g support. The value range is from 1 to 96.
Defaults	By default, the access of 802.11g STAs is supported in 2.4 GHz.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 2.4 GHz. The configuration is supported only by specified APs.

Enabling 802.11na Support

- Optional.
- The configuration takes effect only when AP radios operate in 5 GHz.
- On the AC, enable 802.11na support for specified APs.
- The AC delivers the configuration to APs to instruct the APs to support the access of 802.11n STAs in 5 GHz.

Command	**11nasupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11na support. The value range is from 1 to 96.
Defaults	By default, the access of 802.11n STAs is supported in 5 GHz.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 5 GHz. The configuration is supported only by specified APs.

Enabling 802.11ng Support

- Optional.
- The configuration takes effect only when AP radios operate in 2.4 GHz.
- On the AC, enable 802.11ng support for specified APs.
- The AC delivers the configuration to APs to instruct the APs to support the access of 802.11n STAs in 2.4 GHz.

Command	**11ngsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11ng support. The value range is from 1 to 96.
Defaults	By default, the access of 802.11n STAs is supported in 2.4 GHz.

Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 2.4 GHz. The configuration is supported only by specified APs.

Enabling 802.11ac

- Optional.
- On the AC, enable 802.11ac support for specified APs.
- The AC delivers configuration to APs to instruct the APs to support the access of 802.11ac STAs.

Command	**11acsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11ac support. The value range is from 1 to 96.
Defaults	Only the radios with even IDs support the access of 802.11ac STAs.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Enabling 802.11ax

- Optional.
- On the AC, enable 802.11ax support for specified APs.
- The AC delivers configuration to APs to instruct the APs to support the access of 802.11ax STAs.

Command	**11axsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11ax support. The value range is from 1 to 96.
Defaults	802.11ax support l is disabled by default for radios that support 802.11ax.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Enabling 802.11be

- Optional.
- On the AC, enable 802.11be support for specified APs.
- The AC delivers configuration to APs to instruct the APs to support the access of 802.11be STAs.

Command	**11besupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with 802.11be support. The value range is from 1 to 96.
Defaults	802.11be is enabled for 802.11be-compliant radios.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring the Highest Access Mode for a WLAN

- Optional.
- Configure the highest access mode supported by a WLAN.
- After this function is configured, the AC delivers the configuration to APs on the WLAN.

Command	**802.11 mode max** { **11ac** | **11ax** | **11be** }
Parameter Description	**11ac**: Sets the highest access mode to 802.11ac. **11ax**: Sets the highest access mode to 802.11ax. **11be**: Sets the highest access mode to 802.11be.
Defaults	The access mode configured for a radio is used.
Command Mode	WLAN configuration mode
Usage Guide	Use this command to configure the highest access mode. When the highest access mode is configured for a WLAN and a radio simultaneously, the lower one takes effect.

Configuring the Management Frame Power for APs

- Optional.
- Perform the configuration only on the required device unless otherwise specified.
- On the AC, configure the management frame power for specified APs.
- The AC delivers the configuration to APs to instruct the APs to use the configured management frame transmit power. In this way, signal coverage areas of the APs are controlled to limit the access of STAs.

Command	**coverage-area-control** *power* **radio** *radio-id*
Parameter Description	*power*: Specifies the management frame power. The value range is from 0 to 32, in the unit of dBm. *radio-id*: Specifies the ID of a radio assigned with channels. The value range is from 1 to 96.
Defaults	By default, the management frame power for APs is 0 dBm.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	N/A

Configuring the Minimum RSSI for STAs to Access APs

- Optional.
- On the AC, configure the minimum RSSI for STAs to access specified AP.
- The AC delivers the configuration to the APs to instruct the APs to use the configured minimum RSSI for allowing the access of STAs.

Command	**response-rssi** *rssi* **radio** *radio-id*
Parameter Description	*rssi: Specifies* the minimum RSSI for STAs to access APs. The value range is from 0 to 100, in the unit of dB. *radio-id*: Specifies the ID of a radio assigned with the minimum RSSI. The value range is from 1 to 96.
Defaults	By default, the RSSI is set to 0, indicating that there is no RSSI limit on the access of STAs.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

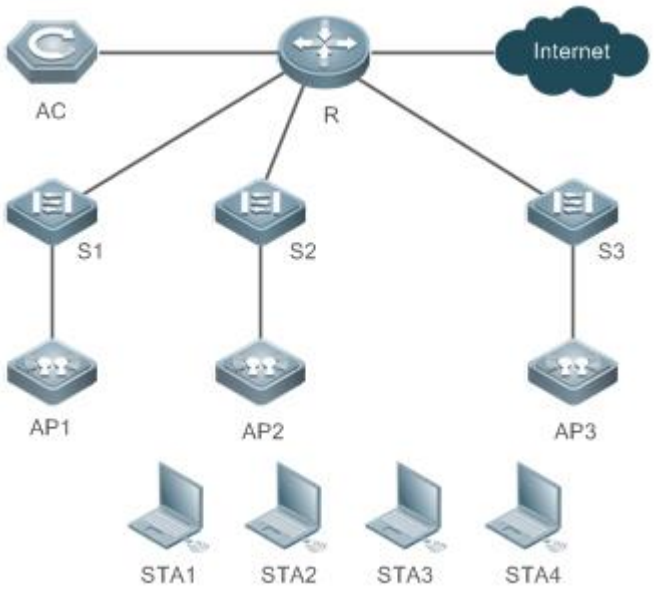
Configuring the Minimum RSSI for STAs to Maintain Connections with APs

- Optional.
- On the AC, configure the minimum RSSI for wireless STAs to maintain connections to specified AP.
- The AC delivers the configuration to the APs to instruct the APs to use the configured minimum RSSI as the threshold for maintaining the connections of wireless STAs.

Command	**assoc-rssi** *rssi* **radio** *radio-id*
Parameter Description	*rssi: Specifies* the minimum RSSI for wireless STAs to maintain connections. The value ranges from 0 to 100, in the unit of dB. *radio-id*: Specifies the ID of a radio assigned with the minimum RSSI. The value ranges from 1 to 96.
Defaults	By default, the RSSI is set to 0, indicating that there is no RSSI limit on the access of wireless STAs.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring the Third Radio for User Access

- Optional.
- On the AC, configure an AP in a high-density scenario.
- The channel, antenna, power, bandwidth will be adjusted for better access experience.



Command	**extra-coverage enable**
Parameter Description	N/A
Defaults	The third radio is disabled by default.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	Use the **no** form of this command to disable the function. Use the **default** form of this command to restore the default setting,

Verification

- Run **show ap-config running** *ap-name* to display parameter settings of STA access control.

Configuration Example

Configuring Parameters of STA Access Control

Scenario **Figure 1-4**	 In Figure 1-, an AC is connected to Fit APs. On the AC, configure STA access control for all the APs according to the following step: 1. Disable the 2.4 GHz network.
	On the AC, configure STA access control for AP1 according to the following steps: 1. Enable access of 802.11a and 802.11na STAs in 5 GHz 2. Enable access of 802.11g and 802.11ng STAs in 2.4 GHz. 3. Enable access of 802.11ac STAs. 4. Set the management frame power to 20 dBm. 5. Set the minimum RSSI for STAs to access APs to 20 dB. 6. Set the minimum RSSI for STAs to maintain connections to 15 dB. 7. Enable the third radio for user access.
Configuration Steps	● Disable the 2.4 GHz network on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ac-controller`
	`Hostname(config-ac)# 802.11b network disable`

	● Set STA access control parameters for AP1 on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# 11asupport enable radio 2`
	`Hostname(config-ap)# 11nasupport enable radio 2`
	`Hostname(config-ap)# 11gsupport enable radio 1`

	Hostname(config-ap)# 11ngsupport enable radio 1 Hostname(config-ap)# 11acsupport enable radio 1 Hostname(config-ap)# no 11bsupport enable radio 1 Hostname(config-ap)# coverage-area-control 20 Hostname(config-ap)# response-rssi 20 radio 1 Hostname(config-ap)# response-rssi 20 radio 2 Hostname(config-ap)# assoc-rssi 15 radio 1 Hostname(config-ap)# assoc-rssi 15 radio 2
Verification	● Run **show running-config** to check whether the 2.4 GHz or 5 GHz network is enabled or disabled.
AC	Hostname(config)# show running-config ! ac-controller sta-limit 1024 no capwap dtls enable 802.11b network disable country CN country US !
	● Run **show ap-config running** *ap-name* to display STA access control parameters for AP1.
AC	Hostname(config)# show ap-config running AP1 ! ap-config 220em no 11bsupport enable radio 1 coverage-area-control 20 response-rssi 20 radio 1 response-rssi 20 radio 2 assoc-rssi 15 radio 1 assoc-rssi 15 radio 2 radio-type 1 802.11b radio-type 2 802.11a !

1.4.3 Configuring AP's RF Parameters

Configuration Effect

- Configure RF parameters for APs and radios so that a network administrator can easily configure and manage APs.

Configuration Steps

Enabling A-MPDU

- Optional.
- On an AC, enable A-MPDU for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to enable A-MPDU.

Command	**802.11n a-mpdu enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the Is of a radio enabled with A-MPDU. The value range is from 1 to 96.
Defaults	By default, A-MPDU is enabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 802.11n, 802.11ac, or 802.11.ax mode. The configuration is supported only by specified APs.

Configuring the A-MPDU Aggregation Depth

- Optional.
- The AC will deliver the configuration to the corresponding AP, informing the AP of the supported aggregation depth.

Command	**ampdu-depth** *depth* **radio** *radio-id*
Parameter Description	*depth*: Indicates the aggregation depth to be configured. The value range is from 1 to 64. *radio-id*: Indicates the ID of a radio to be configured. The value range is from 1 to 96.
Defaults	By default, the A-MPDU aggregation depth is not configured, and the default aggregation depth of the device is used.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	The configuration only takes effect when the AP radio is operating in 802.11n, 802.11ac, or 802.11ax mode.

Enabling A-MSDU

- Optional.
- After enabling this function, the AC will deliver the configuration to the corresponding AP, instructing the AP to enable the A-MSDU function.

Command	**802.11n a-msdu enable** *radio radio-id*
Parameter Description	*radio-id:* Indicates the ID of a radio to be configured. The value range is from 1 to 96.
Defaults	The A-MSDU function is supported by default.

Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration only takes effect when the AP radio is operating in 802.11n, 802.11ac, or 802.11ax mode. This command cannot be configured for all APs simultaneously.

Configuring the A-MSDU Aggregation Depth

- Optional.
- The AC will deliver this configuration to the corresponding AP, informing the AP of the supported aggregation depth.

Command	**amsdu-depth** *depth* **radio** *radio-id*
Parameter Description	*Depth*: Indicates the aggregation depth. The value range is from 0 to 3. ● 0: Indicates that the maximum number of aggregated MSDU frames is not limited. ● 1: Indicates that the maximum number of aggregated MSDU frames is 32. ● 2: Indicates that the maximum number of aggregated MSDU frames is 16. ● 3: Indicates that the maximum number of aggregated MSDU frames is 8. *radio-id*: Indicates the ID of a radio. The value range is from 1 to 96.
Defaults	The A-MSDU aggregation depth is configured based on the AP capability by default.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	This configuration takes effect only when AP radios operate in 802.11n, 802.11ac, or 802.11ax mode.

Configuring the Maximum 802.11n MCS Index Value

- Optional.
- On an AC, configure the maximum 802.11n MCS index value for specified APs. Then the AC delivers the configuration to the APs to inform the APs of the maximum 802.11n MCS index value.

Command	**802.11n mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: Specifies the MCS index value, which ranges from 0 to 23. *radio-id*: Specifies the IDs of the radios assigned with the maximum 802.11n MCS index value. The value range is from 1 to 96.
Defaults	By default, the maximum 802.11n MCS index value is 23.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 802.11n or 802.11ac mode.

Configuring the Maximum 802.11ac MCS Index Value

- Optional.
- On an AC, configure the maximum 802.11ac MCS index value for specified AP. Then the AC delivers the configuration to the APs to inform the APs of the maximum 802.11ac MCS index value.

Command	**802.11ac mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: Specifies the MCS index value, which ranges from 0 to 79.

	radio-id: Specifies the IDs of the radios assigned with the maximum 802.11ac MCS index value. The value range is from 1 to 96.
Defaults	By default, the maximum 802.11n MCS index value is 79.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 802.11ac mode.

Configuring the Maximum 802.11ax MCS Index Value

- Optional.
- On an AC, configure the maximum 802.11ax MCS index value for specified APs. Then the AC delivers the configuration to the APs to inform the APs of the maximum 802.11ax MCS index value.

Command	**802.11ax mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: Specifies the MCS index value, which ranges from 0 to 95. *radio-id*: Specifies the IDs of the radios assigned with the maximum 802.11ac MCS index value. The value ranges from 1 to 96.
Defaults	By default, the maximum 802.11n MCS index value is 95.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	1. The configuration takes effect only when AP radios operate in 802.11ax mode. 2. Number of spatial streams = Maximum MCS index value/12 + 1 For example, if the maximum MCS index value is 31, the maximum number of spatial streams is 3.

Configuring the Maximum 802.11be MCS Index Value

- Optional.
- Configure the maximum 802.11be MCS index value for specified APs. After configuration, the MCS index value used by 802.11be does not exceed the configured value.

Command	**802.11be mcs support** *num* **radio** *radio-id*
Parameter Description	*num*: Specifies the MCS index value. The value range is from 0 to 223. *radio-id*: Indicates the ID of the radio to be configured. The value range is from 1 to 96.
Defaults	The maximum 802.11n MCS index value is 223.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	1. The configuration takes effect only when AP radios operate in 802.11be mode. 2. Number of spatial streams = Maximum MCS index value/14 + 1 For example, if the maximum MCS index value is 50, the maximum number of spatial streams is 4 and the maximum MCS index value of each spatial stream is 8 (that is, the remainder).

Configuring the Guard Interval

- Optional.

- The AC will deliver the configuration to the corresponding AP, instructing the AP radio to use the specified guard interval.

Command	**11ax-gi** { **0.8** | **1.6** | **3.2** | **auto** } **radio** *radio-id*
Parameter Description	*radio-id*: Indicates the ID of a radio to be configured. The value range is from 1 to 96. **0.8**: Configures it as 0.8 μs. **1.6**: Configures it as 1.6 μs. **3.2**: Configures it as 3.2 μs. **auto**: Configures the auto mode where parameters are adapted automatically.
Defaults	Auto mode
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring the Antenna Transmit/Receive Type

- Optional.
- On an AC, configure the antenna transmit/receive type for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to use the specified antenna selection masks to send and receive packets.

Command	**antenna** { **transmit** | **receive** } *value* **radio** *radio-id*
Parameter Description	**transmit**: Indicates the antenna transmit parameter. **receive**: Indicates the antenna receive parameter. *value*: Specifies the antenna selection mask. The value range is from 1 to 255. *radio-id*: Specifies the ID of a radio assigned with the antenna transmit/receive type. The value range is from 1 to 96.
Defaults	In AP configuration mode, the default antenna selection mask varies with different device models and antenna quantities, and is determined based on the device model. By default, no antenna transmit/receive type is configured in AP group configuration mode.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 802.11n or 802.11ac mode.

Enabling External Antennas for APs

- Optional.
- On an AC, enable external antennas for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to enable external antennas and disable internal antennas.

Command	**external-antenna enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with the external antenna. The value range is from 1 to 96.
Defaults	By default, internal antennas are enabled and external antennas are disabled.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring Omnidirectional or Directional Antennas

- Optional.
- The AC delivers the configuration to an AP to notify the AP of the antenna to be used.

Command	**antenna type** { **omnidirection** | **direction** } **radio** *radio-id*
Parameter Description	**omnidirection**: Specifies an omnidirectional antenna. **direction**: Specifies a directional antenna. *radio-id*: Specifies the ID of a radio. The value range is from 1 to 96.
Defaults	An omnidirectional antenna is used by default.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	1. This configuration is valid only for radios supporting both omnidirectional and directional antennas. 2. If internal and external antennas can be switched, the configuration of internal and external antennas takes precedence over that of omnidirectional and directional antennas. 3. When no radio is specified, the configuration takes effect for all radios of an AP. 4. The **antenna type omnidirection** and **antenna type direction radio** *radio-id* commands cannot be simultaneously configured for a specific AP, AP group, or all APs; otherwise, the latest configuration overrides the previous configuration.

Configuring Built-in Directional Antennas to Work in Enhanced Mode

- Optional.
- After this function is configured, the AC delivers this configuration to the corresponding AP, enabling the built-in directional antennas of the AP to work in enhanced mode, This will decrease the coverage angle of the built-in directional antenna and enhance the transmit power in a specific direction.

Command	**antenna internal-direction enhance radio** *radio-id*
Parameter Description	*radio-id*: Indicates the ID of the radio to be configured. The value range is from 1 to 96.
Defaults	The enhanced mode of directional antennas does not take effect.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	1. The configuration takes effect only on radios where directional antennas are used and external antennas are disabled. 2. The configuration takes effect only for radios supporting enhanced mode of built-in directional antennas. 3. If built-in antennas are switched to external antennas, the configuration becomes invalid. 4. If the built-in antenna mode is switched to omnidirectional antenna mode, the configuration becomes invalid. 5. If no radio is specified, the configuration takes effect on all radios of the AP.

Configuring the Interval for Transmitting Beacon Frames

- Optional.
- On an AC, configure the interval for transmitting beacon frames for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to transmit beacon frames at intervals.

Command	**beacon period** *milliseconds* **radio** *radio-id*
Parameter Description	*milliseconds*: Specifies the interval for transmitting beacon frames. The value range is from 20 to 1000, in milliseconds. *radio-id*: Specifies the IDs of the radios assigned with the beacon frame transmission period. The value range iss from 1 to 96.
Defaults	By default, the interval for transmitting beacon frames is 100 ms.
Command Mode	AP configuration mode
Usage Guide	The configuration is supported only by specified APs.

Configuring Bandwidth Assignments

- Optional.
- On an AC, configure bandwidth assignments for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to switch the channel bandwidth to the specified bandwidth.

Command	**chan-width** { **20** | **40 | 80** | **160** } **radio** *radio-id*
Parameter Description	**20**: Specifies the 20 MHz bandwidth. **40**: Specifies the 40 MHz bandwidth. **80**: Specifies the 80 MHz bandwidth. **160**: Specifies the **160** MHz bandwidth. *radio-id*: Specifies the IDs of the radios assigned with bandwidth. The value ranges from 1 to 96.
Defaults	The default channel bandwidth of 5G radio on new 802.11ax devices is 40 Mbps. The default channel bandwidth of the other radio is 20 Mbps.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The bandwidth configuration takes effect only when the AP operates in 802.11n or higher mode.

Configuring Channel Assignments

- Optional.
- On an AC, configure channel assignments for specified APs. Then the AC delivers the configuration to the APs to instruct the AP radios to operate in specified channels.

Command	**channel** { **global** | *channel-id* } **radio** *radio-id*
Parameter Description	*channel-id*: Specifies the operating channel for an AP radio. *radio-id*: Specifies the ID of a radio assigned with a channel. The value range is from 1 to 96.
Defaults	The radio resource management (RRM) system automatically adjusts channels. By default, no channel assignments are configured.
Command Mode	AP configuration mode
Usage Guide	The configuration is supported only by specified APs.

Configuring the Country or Region Code Set Supported by an AC

- Optional.

- Add a country or region code to the country or region code set supported by an AC before you configure AP radios to use the country or region code.

Command	**country** *country-code*
Parameter Description	*country-code*: Specifies the country/region code to be added.
Defaults	The country or region code set supported by the AC is {"CN"}.
Command Mode	AC configuration mode
Usage Guide	The country or region code "CN" supported by the AC cannot be deleted.

Configuring a Country Code

- Optional.
- Ensure that the configured country or region code is in the country or region code set supported by an AC. The AC will assign the settings to the APs to instruct the APs to use the configured country or region code.

Command	**country** *country-code* **radio** *radio-id*
Parameter Description	*country-code*: Specifies the country/region code to be added. *radio-id*: Specifies the IDs of the radios assigned with the country/region code. The value ranges from 1 to 48.
Defaults	The country or region code used by APs is "CN".
Command Mode	AP configuration mode
Usage Guide	1. The country or region code "CN" supported by the AC cannot be deleted. 2. The configuration is supported only by specified APs. 3. Before you configure APs, determine the country or region code set supported by the AC. If the country or region code used by an AP is changed, the RF band, channel, and power for the AP are also changed. 4. 2.4 GHz radios do not support channel 14.

Configuring the Country or Region Code Set Supported by an AC

- Optional.
- Add a country or region code to the country or region code set supported by an AC before you configure AP radios to use the country or region code.

Command	**country-code** *country-code*
Parameter Description	*country-code*: Specifies the country or region code to be added.
Defaults	The country or region code set supported by the AC is CN.
Command Mode	AP configuration mode
Usage Guide	The country or region code "CN" supported by the AC cannot be deleted. For details about country codes, see WLAN Country or Region Codes and Channel Compliance. The supported countries are subject to the country codes that can be configured in the version.

Enabling Radios

- Optional.
- Enable radios on an AC. Then the AC delivers the configuration to the APs to instruct the APs to enable the corresponding radios.

Command	**enable-radio** { *radio-id* | **all** }
Parameter Description	*radio-id*: Specifies the IDs of the radios to be enabled. The value range is from 1 to 96. **all**: Indicates that all radios are enabled.
Defaults	By default, radios are enabled.
Command Mode	AP configuration mode
Usage Guide	When radios are enabled or disabled, STAs connected to the radios will go offline. The configuration is supported only by specified APs.

Configuring the Fragmentation Threshold

- Optional.
- On an AC, configure the fragmentation threshold for specified APs. Then the AC delivers the configuration to the APs to instruct the AP radios to perform fragmentation according to the configured threshold.

Command	**fragment-threshold** *value* **radio** *radio-id*
Parameter Description	*value*: Specifies the fragmentation threshold, which must be an even number ranging from 256 to 2346. *radio-id*: Specifies the ID of a radio assigned with the fragmentation threshold. The value range is from 1 to 96.
Defaults	The default fragmentation threshold is 2346 bytes.
Command Mode	AP configuration mode
Usage Guide	The configuration is supported only by specified APs.

Configuring the Fragment Burst Mechanism

- Optional.
- The AC will deliver the configuration to the corresponding AP, instructing it to enable, disable, or dynamically adapt to the fragment burst mechanism of a radio.

Command	**fragment-burst** { **enable** | **disable** | **dynamic** } **radio** *radio-id*
Parameter Description	**enable**: Enables the fragment burst mechanism. **disable**: Disables the fragment burst mechanism. **dynamic**: Dynamically adapts to the fragment burst mechanism. *radio-id*: Indicates the ID of a radio to be configured. The value range is from 1 to 96.
Defaults	By default, the device dynamically adapts to the fragment burst mechanism.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Enabling the Protection Mode

- Optional.
- On an AC, enable the protection mode for specified APs. Then the AC delivers the configuration to the APs to instruct the AP radios to enable the protection mode.

Command	**green-field enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with the protection mode. The value range is from 1 to 96.
Defaults	By default, the protection mode is disabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 2.4 GHz.

Enabling the Mcell Function

- Optional.
- After this command is configured, the AP's receiving sensitivity will be reduced.

Command	**mcell enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio. The value range is from 1 to 96.
Defaults	By default, the Mcell function is disabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Reducing the Receive Sensitivity of a Radio

- Optional.
- After this command is configured, the receive sensitivity of a radio is reduced.

Command	**cell-range-reduction** *dbm* **radio** *radio-id*
Parameter Description	*dbm*: Specifies the receive sensitivity value to be decreased, in dBm. The value range is from 0 to 50. *radio-id*: Indicates the ID of the radio to be configured. The value range is from 1 to 96.
Defaults	The configuration is subject to the AP capability.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	N/A

Configuring the Anti-interference Level of a Radio

- Optional.
- After this command is configured, the anti-interference level of a radio can be adjusted.

Command	**anti-interference-level** *value* **radio** *radio-id*
Parameter Description	*value*: Configures the anti-interference level. The value range is from 0 to 15. *radio-id*: Indicates the ID of the radio to be configured. The value range is from 1 to 96.
Defaults	The anti-interference level of a radio is 0.

<table>
<tr><td>Command Mode</td><td>AP configuration mode, AP group configuration mode, or all-AP configuration mode</td></tr>
<tr><td>Usage Guide</td><td>When the co-channel interference in the environment is strong, a higher anti-interference level needs to be configured. The recommended configuration is as follows:
Distance between two APs: 8–15 m
<table>
<tr><th>Interference Strength</th><th>Anti-interference Level</th></tr>
<tr><td>Weak co-channel interference (< –95 dBm)</td><td>0</td></tr>
<tr><td>Weak co-channel interference (–95 dBm to –90 dBm)</td><td>2</td></tr>
<tr><td>Weak co-channel interference (–90 dBm)</td><td>3</td></tr>
<tr><td>Weak co-channel interference (–85 dBm)</td><td>4</td></tr>
<tr><td>Strong co-channel interference (–80 dBm)</td><td>5</td></tr>
</table>
Distance between two APs: 6–8 m
<table>
<tr><th>Interference Strength</th><th>Anti-interference Level</th></tr>
<tr><td>Weak co-channel interference (–90 dBm)</td><td>8</td></tr>
<tr><td>Weak co-channel interference (–85 dBm)</td><td>9</td></tr>
<tr><td>Strong co-channel interference (–80 dBm)</td><td>10</td></tr>
</table>
Distance between two APs:< 6 m
<table>
<tr><th>Interference Strength</th><th>Anti-interference Level</th></tr>
<tr><td>Weak co-channel interference (–85 dBm)</td><td>14</td></tr>
<tr><td>Strong co-channel interference (–80 dBm)</td><td>15</td></tr>
</table>
This command can be configured only on the RG-AP9751-R and RG-AP9520-RDX.</td></tr>
</table>

Configure MIMO

- Optional.
- After this command is configured, the AC will deliver the configuration to the AP to enable the MU-MIMO function on the AP.

Command	**mu-mimo enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio. The value range is from 1 to 96.
Defaults	If the radio does not support the MU-MIMO function, the AC does not support it by default. If the radio supports the MU-MIMO function and MU-MIMO is enabled on the AP by default, it is enabled on the AC by default. If the radio supports the MU-MIMO function and MU-MIMO is disabled on the AP by default, it is disabled on the AC by default.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	N/A

Enabling OFDMA for a Radio

- Optional.
- After this command is configured, 802.11ax STAs can transmit data by using OFDMA.

Command	**ofdma enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio. The value range is from 1 to 96.
Defaults	By default, OFDMA is enabled.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	N/A

Configuring the Maximum Distance of Wireless Transmission Between an AP and the Peer End

- Optional.
- On an AC, configure the maximum distance of wireless transmission between an AP and the peer end. Then the AC delivers the configuration to the AP to instruct the AP radios to send and receive packets based on the maximum distance.

Command	**peer-distance** *val* **radio** *radio-id*
Parameter Description	*val*: Specifies the maximum wireless transmission distance allowed by APs. The value ranges from 1000 to 25000, in the unit of m. *radio-id*: Specifies the ID of a radio assigned with the maximum wireless transmission distance. The value range is from 1 to 96.
Defaults	By default, the maximum wireless transmission distance is 1000 m.
Command Mode	AP configuration mode
Usage Guide	The configuration is supported only by specified APs. The configuration is mandatory only when the actual maximum distance of wireless transmission between an AP and the peer end is greater than 1000 m. You can set the distance to a large value but do not set it to a value smaller than the actual distance.

Configuring the Transmit Power

- Optional.
- On an AC, configure the transmit power for specified APs. Then the AC delivers the configuration to the APs to instruct the AP radios to use the transmit power.

Command	**power local** *power* **radio** *radio-id* **power local-dbm** *dbm-value* **radio** *radio-id*
Parameter Description	*power*: Specifies the percent of transmit power for APs. The value range is from 1 to 100. *radio-id*: Specifies the ID of a radio assigned with the transmit power. The value range is from 1 to 96. *dbm-value*: Specifies the transmit power of an AP in dBm. The value range is from 1 to 36.
Defaults	By default, the percentage of the transmit power is set to 100%.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	• The configuration is supported only by specified APs.

	● When both **local** and **local-dbm** are configured, the configuration of **local-dbm** takes effect.

Configuring the Preamble Type

- Optional.
- The AC will deliver the configuration to the corresponding AP to instruct it to work with the specified preamble code type.

Command	**preamable** { **long** | **short** } **radio** *radio-id*
Parameter Description	**long**: Specifies the AP to transmit frames with the long preamble code only. **short**: Specifies the AP to transmit frames with the short or long preamble code. *radio-id*: Indicates the ID of a radio to be configured. The value range is from 1 to 96.
Defaults	By default, the short preamble code is supported.
Command Mode	AP configuration mode
Usage Guide	The configuration is supported only by specified APs.

Configuring Radio Parameters (Power, Channel, and Antenna Receive/Transmit Type)

- Optional.
- After this command is configured, the AC will change the radio type or optimize the power, channel, antenna configuration and deliver the configuration to the AP.

Command	**radio-optimize**
Parameter Description	N/A
Defaults	By default, this function is disabled.
Command Mode	AP configuration mode
Usage Guide	This command cannot be configured in all-AP configuration mode. If the target AP is offline, you can optimize the radio configuration but cannot change the radio type. To change the radio type, run the radio-type command. The optimized configuration will be saved and take effect next time when the AP goes online. If the target AP is online, you can optimize the radio configuration and change the radio type. You can also optimize the current radio configuration without changing the radio type. If the AP does not support this function, the radio configuration will not be changed. If the AP supports this function, the radio configuration will be optimized immediately and this command will be saved.

Configuring a Frequency Band

- Optional.
- After a frequency band is assigned to AP radios, the RRM module analyzes the operating channel of the AP radios in global mode, adjusts the channel, and assigns the optimal channel to the AP. The AP radios are instructed to operate in the specified channel.

Command	**radio-type** *radio-id* { **802.11a** | **802.11b** | **6GHz** }
Parameter Description	*radio-id*: Specifies the IDs of the radios assigned with the frequency band. The value ranges from 1 to 96.

	802.11a: Specifies the 5 GHz operating band. **802.11b**: Specifies the 2.4 GHz operating band. **6GHz**: Specifies the 6 GHz operating band.
Defaults	A single-band AP (radio 1) supports the 2.4 GHz frequency band. For a dual-band AP, radio 1 supports the 2.4 GHz frequency band, and radio 2 supports the 5 GHz frequency band.
Command Mode	AP configuration mode
Usage Guide	The configuration is supported only by certain APs.

Configuring the RTS Threshold

- Optional.
- On an AC, configure the RTS threshold for specified APs. Then the AC delivers the configuration to the APs to instruct the AP radios to use the configured threshold.

Command	**rts-threshold** *value* **radio** *radio-id*
Parameter Description	*value*: Specifies the value of the RTS threshold. The value range is from 257 to 2347, in the unit of bytes. *radio-id*: Specifies the ID of a radio assigned with the RTS threshold. The value range is from 1 to 96.
Defaults	The default RTS threshold is 2347.
Command Mode	AP configuration mode
Usage Guide	N/A

Enabling Short GI

- Optional.
- On an AC, enable short GI for specified APs. Then the AC delivers the configuration to the APs to instruct the AP radios to use short GI.

Command	**short-gi enable radio** *radio-id* **chan-width** { **20** | **40** | **80** | **160** }
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with short GI. The value range is from 1 to 96. **20**: Specifies the 20 MHz bandwidth. **40**: Specifies the 40 MHz bandwidth. **80**: Specifies the 80 MHz bandwidth. **160**: Specifies the 160 MHz bandwidth.
Defaults	For 2.4G radio, enable 20 MHz and 40 MHz bandwidths and disable 80 MHz and 160 MHz bandwidths; for 5G radio, enable all bandwidths. The 6 GHz radio does not support this function.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring the Short Slot Time

- Optional.
- On an AC, configure the short slot time for specified APs. Then the AC delivers the configuration to the APs to instruct the AP radios to enable the short slot time feature.

Command	**short-slot-time radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio assigned with the short slot time. The value range is from 1 to 96.
Defaults	By default, the short slot time function is enabled
Command Mode	AP configuration mode
Usage Guide	N/A

Enabling Transmit Beamforming

- Optional.
- After this function is enabled, the AC will deliver the configuration to the corresponding AP, instructing it to enable or disable transmit beamforming.

Command	**txbf enable radio** *radio-id*
Parameter Description	*radio-id*: Indicates the ID of a radio to be configured. The value range is from 1 to 96.
Defaults	By default, the transmit beamforming function is supported.
Command Mode	AP configuration mode, all-AP configuration mode, or AP group configuration mode
Usage Guide	The configuration takes effect only when the AP radio operates in 802.11ac or 802.11ax mode.

Enabling TSC Update

- Optional.
- On an AC, enable TSC update for specified APs. Then the AC delivers the configuration to the APs to instruct the AP to enable TSC update.

Command	**update-key-tsc enable**
Parameter Description	N/A
Defaults	By default, TSC update is disabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring Multi-BSSID

- Optional.
- After this command is configured, the BSSID of the specified radio is sent over one beacon.

Command	**multi-bssid enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID, in the range from 1 to 96.
Defaults	This function is enabled on the 2.4 GHz and 5 GHz radios and disabled on the 6 GHz radio by default.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	The Multi-BSSID function cannot be disabled on the 6 GHz frequency band.

> ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Configuring RNR

- Optional.
- After this command is configured, the device advertises 6G radio information through beacon and probe response frames of 2.4 GHz and 5 GHz radios or advertises other channel information through Preferred Scanning Channel (PSC) of the 6 GHz radio.

Command	**rnr enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID, in the range from 1 to 96.
Defaults	This function is disabled on the 2.4 GHz, 5 GHz, and 6 GHz radios by default.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Configuring Announcement on a Radio

- Optional.
- When FILS announcement is configured, FILS frames are sent at an interval of 20 ms.
- When UPRS announcement is configured, UPRS packets are sent at an interval of 20 ms.

Command	**ap-announcement-mode** { **fils** | **uprs** } **radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID. The value range is from 1 to 96. **fils**: Enables FILS announcement and disables UPRS announcement. **uprs**: Enables UPRS announcement and disables FILS announcement.
Defaults	FILS and UPRS announcement are not applicable to 2.4 GHz and 5 GHz frequency bands, and they are disabled on the 6 GHz frequency band.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Configuring BSS Color

- Optional.
- After this command is configured, the BSS Color field is added to the packet header to distinguish BSS.

Command	**bss-color enable radio** *radio-id*

Parameter Description	*radio-id*: Specifies the radio ID, in the range from 1 to 96.
Defaults	BSS Color is disabled by default.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	N/A

Configuring TWT

- Optional.
- After this command is configured, the TWT field is added to the beacon packet.

Command	**twt enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the radio ID, in the range from 1 to 96.
Defaults	TWT is enabled by default.
Command Mode	AP configuration mode, AP group configuration mode, and all-AP configuration mode
Usage Guide	N/A

Configuring QBSS Load

- Optional.
- After this function is configured, the AC will deliver the configuration to the corresponding AP.

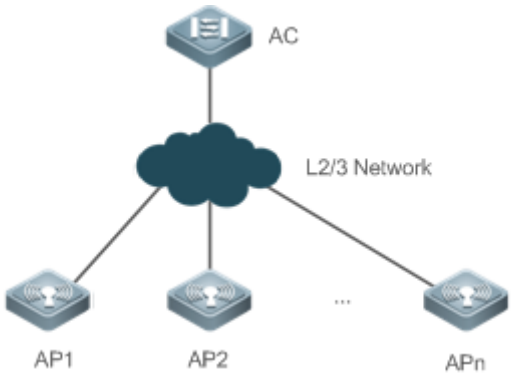
Command	**qbss-load enable radio** *radio-id*
Parameter Description	*radio-id*: Indicates the ID of a radio. The value range is from 1 to 96.
Defaults	By default, QBSS load is configured based on the AP capability value.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	N/A

Configuring the BAR Retransmission Count

- Optional.
- After the BAR retransmission count is configured, the AC will deliver the configuration to the corresponding AP.

Command	**bar-retries** *times* **radio** *radio-id*
Parameter Description	*times*: Indicates the BAR retransmission count. The value range is from 1 to 50. *radio-id*: Indicates the ID of a radio. The value range is from 1 to 96.
Defaults	By default, the BAR retransmission count is configured based on the AP capability value.
Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	N/A

Verification



- Run **show ap-config running** *ap-name* to display parameter settings of STA access control.

Configuration Example

Configuring AP RF Parameters

Scenario

Figure 1-5

In Figure 1-5, an AC is connected to Fit APs. On the AC, configure RF parameters for AP1 by performing the following steps:

1. Set the global country or region code to CN.
2. Configure CN support on the AC.
3. Enable A-MPDU for radio 1 of AP1.
4. Set the aggregation depth to 12 for radio 1 of AP 1.
5. Enable A-MSDU for radio 1 of AP 1.
6. Set the maximum 802.11n MCS index value to 15 for radio 1 of AP1.
7. Set the maximum 802.11ac MCS index value to 19 for radio 1 of AP1.
8. Set the maximum 802.11ax MCS index value to 21 for radio 2 of AP1.
9. Set the antenna selection masks of the transmit type and receive type to 7 and 5 respectively for radio 1 of AP1.
10. Enable external antennas and disable usage of internal antennas for radio 1 of AP1.
11. Enable the directional antenna on AP1.
12. Set the interval for transmitting beacon frames to 200 ms for radio 1 of AP1.
13. Configure the country code CN for radio 1 of AP1.
14. Assign channel 11 to radio 1 of AP1.
15. Assign 20 MHz bandwidth to radio 1 of AP1.
16. Enable short GI for radio 1 of AP1 in 20 MHz.
17. Enable the protection mode for radio 1 of AP1.
18. Configure 3.2 μs guard interval for 802.11ax packets on radio 2 of AP1.
19. Configure the short preamble type for radio 1 of AP1.
20. Configure the short slot time for radio 1 of AP1.
21. Assign channel 149 to radio 2 of AP1.
22. Assign 40 MHz bandwidth to radio 2 of AP1.
23. Enable radio 2 of AP1.
24. Set the fragmentation threshold to 2346 bytes for radio 2 of AP1.
25. Set the percent of the transmit power to 100% for radio 2 of AP1.
26. Set the RTS threshold to 2347 bytes for radio 2 of AP1.

	27. Enables TSC update for AP1. 28. Set the maximum distance of wireless transmission between an AP and the peer end to 3000 m for radio 1 of AP1. 29. Enable transmit beamforming for radio 2 of AP 1.
	30. Enable MU-MIMO for radio 2 of AP1. 31. Enable MCell for radio 1 of AP 1. 32. Enable OFDMA for radio 2 of AP1.
Configuration Steps	● On the AC, configure RF parameters for AP1.
	Hostname# configure terminal Hostname(config)# country-code CN Hostname(config)# ac-controller Hostname(config-ac)# country CN Hostname(config-ac)# exit Hostname(config)# ap-config AP1 Hostname(config-ap)# 802.11n a-mpdu enable radio 1 Hostname(config-ap)# ampdu-depth 12 radio 1 Hostname(config-ap)# 802.11n a-msdu enable radio 1 Hostname(config-ap)# 802.11n mcs support 15 radio 1 Hostname(config-ap)# 802.11ac mcs support 19 radio 1 Hostname(config-ap)# 802.11ac mcs support 21 radio 2 Hostname(config-ap)# antenna transmit 7 radio 1 Hostname(config-ap)# antenna receive 5 radio 1 Hostname(config-ap)# external-antenna enable radio 1 Hostname(config-ap)# country CN radio 1 Hostname(config-ap)# antenna type direction Hostname(config-ap)# beacon period 200 radio 1 Hostname(config-ap)# country CN radio 1 Hostname(config-ap)# channel 11 radio 1 Hostname(config-ap)# chan-width 20 radio 1 Hostname(config-ap)# short-gi enable radio 1 chan-width 20 Hostname(config-ap)# green-field enable radio 1 Hostname(config-ap)# preamble short radio 1 Hostname(config-ap)# short-slot-time radio 1 Hostname(config-ap)# channel 149 radio 2

 channel 149 radio 2
 beacon period 200 radio 1
 power local 100 radio 2
peer-distance 3000 radio 1
mu-mimo enable radio 2
mcell enable radio 1
!
```

1.4.4 Configuring Data Rate Control Parameters

Configuration Effect

- Configure data rate control parameters for Fit APs so that a network administrator can easily configure and manage them.

Configuration Steps

Configuring the Data Rate Set Supported by 802.11a (5 GHz) STAs or 6 GHz STAs

- Optional.
- On an AC, configure the data rate set supported by 802.11a STAs. Then the AC delivers the configuration to all the APs to instruct the APs to apply the configured data rate set to 802.11a (5 GHz) STAs or 6 GHz STAs.

Command	{ **802.11a** | **6GHz** } **network rate** { **6** | **9** | **12** | **18** | **24** | **36** | **48** | **54** } { **disabled** | **mandatory** | **supported** }
Parameter Description	**6**: Specifies the 6 Mbps data rate. **9**: Specifies the 9 Mbps data rate. **12**: Specifies the 12 Mbps data rate. **18**: Specifies the 18 Mbps data rate. **24**: Specifies the 24 Mbps data rate. **36**: Specifies the 36 Mbps data rate. **48**: Specifies the 48 Mbps data rate. **54**: Specifies the 54 Mbps data rate. **disabled**: Indicates that the data rate set is not supported. **mandatory**: Indicates that support for the data rate set is mandatory. **supported**: Indicates that support for the data rate set is optional.
Defaults	Support for the 6 Mbps, 12 Mbps, and 24 Mbps data rates is mandatory, whereas support for the 9 Mbps, 18 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps data rates is optional.
Command Mode	AC configuration mode, AP configuration mode, or AP group configuration mode
Usage Guide	N/A

Configuring the Data Rate Set Supported by 802.11b STAs

- Optional.
- On an AC, configure the data rate set supported by 802.11b STAs. Then the AC delivers the configuration to all the APs to instruct the APs to apply the configured data rate set to 802.11b STAs.

Command	**802.11b network rate** { **1** | **2** | **5** | **11** } { **disabled** | **mandatory** | **supported** }
Parameter Description	**1**: Specifies the 1 Mbps data rate. **2**: Specifies the 2 Mbps data rate. **5**: Specifies the 5.5 Mbps data rate. **11**: Specifies the 11 Mbps data rate. **disabled**: Indicates that the data rate set is not supported. **mandatory**: Indicates that support for the data rate set is mandatory. **supported**: Indicates that support for the data rate set is optional.

Defaults	Support for the 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps data rates is mandatory.
Command Mode	AC configuration mode, AP configuration mode, or AP group configuration mode
Usage Guide	The **disabled** configuration takes effect only when radio frequency is set to 802.11b mode. In addition, if low-speed rates that overlap with those of 802.11b are disabled in 802.11g mode, the corresponding rates in 802.11b will also be disabled.

Configuring the Data Rate Set Supported by 802.11g STAs

- Optional.
- On an AC, configure the data rate set supported by 802.11g STAs. Then the AC delivers the configuration to all the APs to instruct the APs to apply the configured data rate set to 802.11g STAs.

Command	**802.11g network rate** { **1** | **2** | **5** | **6** | **9** | **11** | **12** | **18** | **24** | **36** | **48** | **54** } { **disabled** | **mandatory** | **supported** }
Parameter Description	**1**: Specifies the 1 Mbps data rate. **2**: Specifies the 2 Mbps data rate. **5**: Specifies the 5.5 Mbps data rate. **6**: Specifies the 6 Mbps data rate. **9**: Specifies the 9 Mbps data rate. **11**: Specifies the 11 Mbps data rate. **12**: Specifies the 12 Mbps data rate. **18**: Specifies the 18 Mbps data rate. **24**: Specifies the 24 Mbps data rate. **36**: Specifies the 36 Mbps data rate. **48**: Specifies the 48 Mbps data rate. **54**: Specifies the 54 Mbps data rate. **disabled**: Indicates that the data rate set is not supported. **mandatory**: Indicates that support for the data rate set is mandatory. **supported**: Indicates that support for the data rate set is optional.
Defaults	Support for the 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps data rates is mandatory, whereas support for the 6 Mbps, 9 Mbps, 12 Mbps, 18 Mbps, 24 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps data rates is optional.
Command Mode	AC configuration mode, AP configuration mode, or AP group configuration mode
Usage Guide	When the low-speed rates of 1 Mbps, 2 Mbps, and 5.5 Mbps, which overlap with the 802.11b data rate set, are disabled in 802.11g mode, the corresponding rates in 802.11b will also be disabled.

Configuring the Rate at Which Beacon Frames Are Transmitted

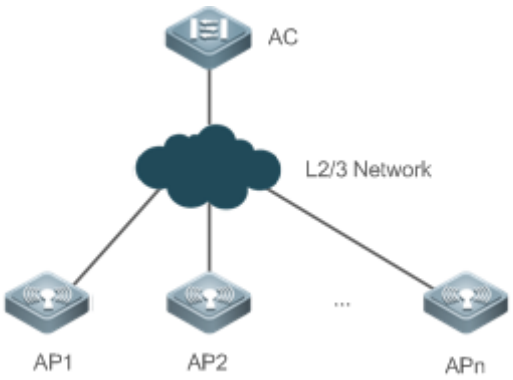
- Optional.
- On an AC, configure the rate at which beacon frames are transmitted for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to transmit beacon frames at the configured rate.

Command	**beacon rate** *rate-Mbps* **radio** *radio-id*
Parameter Description	*rate_Mbps*: Specifies the rate at which beacon frames are transmitted.

	radio-id: Specifies the ID of a radio assigned with the rate at which beacon frames are transmitted. The value range is from 1 to 96.
Defaults	By default, no rate at which beacon frames are transmitted is configured.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The rate that is disabled in the data rate set settings cannot be configured. Because the 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps rates are not supported in 5 GHz, do not set the rate to any of the preceding values for radios in 5 GHz.

Configuring the Multicast Rate

- Optional.
- On an AC, configure the multicast rate for a WLAN. Then the AC delivers the configuration to all the APs on the WLAN to instruct the APs to apply the configured multicast rate within the range of the WLAN.



Command	**mcast-rate** *mcas-num*
Parameter Description	*mcast-num*: Specifies the WLAN multicast rate. The 1 Mbps, 6 Mbps, 11 Mbps, 24 Mbps, and 54 Mbps options are available.
Defaults	The default multicast rate is 24 Mbps.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run **show running-config** to display parameter settings of data rate control.

Configuration Example

Configuring Data Rate Control Parameters

Scenario **Figure 1-6**	 In Figure 1-6, an AC is connected to Fit APs. On the AC, configure data rate control parameters by performing the following steps: 1. Disable the 6 Mbps rate for 802.11a STAs. 2. Disable the 1 Mbps, 2 Mbps, and 5.5 Mbps rates for 802.11b STAs. 3. Disable the 1 Mbps, 2 Mbps, and 5.5 Mbps rates for 802.11g STAs. 4. Set the multicast rate for WLAN1 to 54 Mbps.

	On the AC,configure the rate at which beacon frames are transmitted for radio 1 of AP1.
Configuration Steps	● On the AC, configure data rate control parameters.
	Hostname# configure terminal Hostname(config)# ac-controller Hostname(config-ac)# 802.11a network rate 6 disabled Hostname(config-ac)# 802.11b network rate 1 disabled Hostname(config-ac)# 802.11b network rate 2 disabled Hostname(config-ac)# 802.11b network rate 5 disabled Hostname(config-ac)# 802.11g network rate 1 disabled Hostname(config-ac)# 802.11g network rate 2 disabled Hostname(config-ac)# 802.11g network rate 5 disabled Hostname(config-ac)# exit Hostname(config)# wlan-config 1 Hostname(config-wlan)# mcast-rate 54
	● On the AC, configure the rate at which beacon frames are transmitted for AP1.
	Hostname# configure terminal Hostname(config)# ap-config AP1 Hostname(config-ap)# beacon rate 12.0 radio 1
Verification	● Run **show running-config** to display parameter settings of data rate control.
	Hostname# show running-config ... ! wlan-config 1 ss enable-broad-ssid mcast-rate 54 ! ... ! ac-controller

```

 channel 149 radio 2
```

	beacon period 200 radio 1 beacon rate 12.0 radio 1 power local 100 radio 2 !

1.4.5 Configuring Power Saving Parameters

Configuration Effect

- Configure power saving parameters for Fit APs so that a network administrator can easily configure and manage them.

Configuration Steps

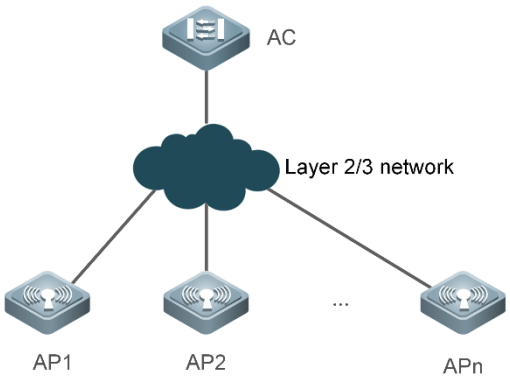
Enabling or Disabling U-APSD Power Saving

- Optional.
- Enable U-APSD power saving to reduce the delay of services with high real-time performance requirements during power management. The transmission of radio signals can be disabled during most of the time to extends the battery life.

Command	**apsd** { **enable** | **disable** } **radio** *radio-id*
Parameter Description	**enable**: Enables U-APSD power saving. **disable**: Disables U-APSD power saving. *radio-id*: Specifies the IDs of the radios enabled with U-APSD power saving. The value ranges from 1 to 96.
Defaults	By default, U-APSD power saving is enabled.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the DTIM Period

- Optional.
- The power saving effect is improved if the DTIM period is set to a large value, but the delay for downstream multicast packets is increased.



Command	**beacon dtim-period** *period-num* **radio** *radio-id*
Parameter Description	*period-num*: Specifies the DTIM period. The value range is from 1 to 255. The unit is expressed as the period of one beacon frame. *radio-id*: Specifies the ID of a radio assigned with the DTIM period. The value range is from 1 to 96.
Defaults	By default, the DTIM period is expressed as the period of one beacon frame.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run **show ap-config running** *ap-name* to display power saving parameter settings.

Configuration Example

Configuring Power Saving Parameters

Scenario **Figure 1-7**	
Configuration Steps	• On the AC, set the DTIM period to 3 for radio 1 of AP1. • On the AC, enable U-APSD power saving for radio 1 of AP1.

	`Hostname#configure terminal`
	`Hostname(config)#ap-config AP0001`
	`Hostname(config-ap)#beacon dtim-period 3 radio 1`
	`Hostname(config-ap)#apsd enable radio 1`

Verification	• Run **show ap-config running** *ap-name* to display power saving parameter settings of AP1.

	`Hostname(config)# show ap-config running AP1`
	`!`
	`ap-config AP1`
	`802.11n mcs support 15 radio 1`
	`802.11n mcs support 15 radio 2`
	`update-key-tsc enable`
	`short-gi enable radio 1 chan-width 20`
	`green-field enable radio 1`
	`station-role root-ap radio 1`
	`station-role root-ap radio 2`
	`chan-width 40 radio 2`
	`antenna receive 5 radio 1`
	`channel 11 radio 1`
	`channel 149 radio 2`

	beacon period 200 radio 1 beacon dtim-period 3 radio 1 power local 100 radio 2 !

1.4.6 Enabling Link Integrity Detection

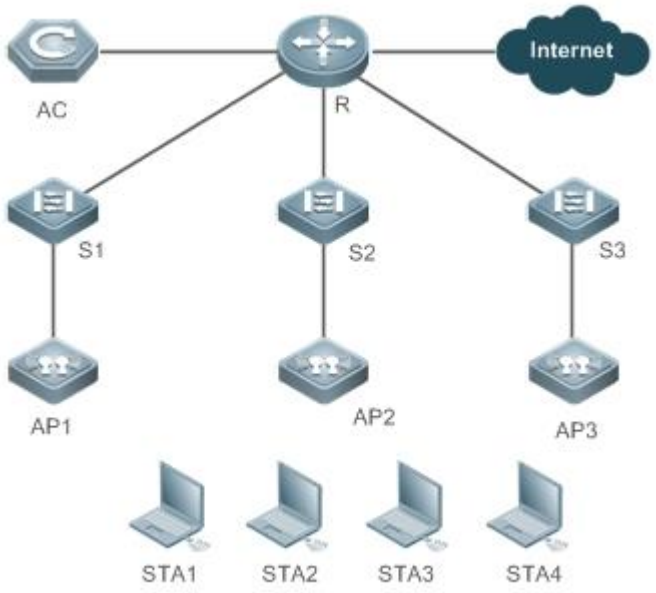
Configuration Effect

- Enable link integrity detection.

Configuration Steps

Enabling Link Integrity Detection

- Mandatory. Run **link-check enable** to enable link integrity detection.



Command	**link-check enable**
Parameter Description	N/A
Defaults	By default, link integrity detection is disabled.
Command Mode	Global configuration mode
Usage Guide	By default, link integrity detection is disabled.

Verification

Run **show running-config** to display the status of link integrity detection.

Configuration Example

Enabling Link Integrity Detection

Scenario **Figure 4-3**	 In Figure 4-3, an AC is connected to Fit APs. Enable link integrity detection.
Configuration Steps	Enable link integrity detection on the AC.
	`Hostname# configure terminal` `Hostname(config)# link-check enable`
Verification	Run **show running-config** to display the status of link integrity detection.

	`Hostname(config)# show running-config`
	`……`
	`link-check enable`
	`……`

1.4.7 Configuring E-Bag Parameters

Configuration Effect

Configure E-bag parameters for APs and radios so that a network administrator can easily configure and manage them.

Configuration Steps

Configuring the A-MPDU Software Retransmission Count

- Optional.
- On an AC, configure the A-MPDU software retransmission count for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to transmit A-MPDU packets based on the retransmission count.
- A larger retransmission count indicates a lower probability of sub-frame loss. If packets are retransmitted frequently, the burden on the air interface is increased, which affects the real-time transmission of packets on the air interface.

You can increase the retransmission times if you need to avoid packet loss when there is a high probability of sub-frame loss.

Command	**ampdu-retries** *times* **radio** *radio-id*
Parameter Description	*times*: Specifies the A-MPDU software retransmission count. The value range is from 1 to 10. *radio-id*: Specifies the ID of a radio assigned with the A-MPDU software retransmission count. The value range is from 1 to 96.
Defaults	By default, the A-MPDU software retransmission count is 10.
Command Mode	AP configuration mode
Usage Guide	The configuration takes effect only when AP radios operate in 802.11n or 802.11ac mode. The configuration is supported only by specified APs.

Enabling or Disabling RTS Protection for A-MPDU Packets

- Optional.
- On an AC, enable RTS protection for A-MPDU packets for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to transmit A-MPDU packets using RTS protection.
- Enable RTS protection only when the resource waste on the air interface caused by hidden nodes is greater than the resource consumption of RTS interaction on the air interface.

Command	**ampdu-rts radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with RTS protection. The value range is from 1 to 96.
Defaults	By default, RTS protection for A-PMDU packets is disabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring E-bag Network Optimization in One-Click Mode

- Optional.
- In AP configuration mode, run the **ebag** command to quickly configure e-bag network optimization.
- Optimization items for the AP530 are as follows:

  (1) Use default STA idle time of 1800 for radio 1 and 2

  (2) Optimization for radio 1: Disable the mandatory rate of 125 Mbps for 802.11b/802.11g STAs, disable the mandatory rate of 1124 Mbps for 802.11g STAs, and enable A-MPDU RTS.
- The AC will deliver the configuration to the corresponding AP, instructing it to use the specified parameters for packet transmission and receiving.

Command	**ebag**
Parameter Description	N/A
Defaults	By default configuration, e-bag network optimization is not configured.
Command Mode	AP configuration mode

Usage Guide It is typically used for e-bag scenarios. Use it with caution in other scenarios.

Configuring the Single-Time Received Ethernet Packet Quantity for APs

- Optional.
- By default, the single-time received Ethernet packet quantity varies with APs.
- On an AC, configure the single-time received Ethernet packet quantity for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to limit the number of Ethernet packets received at a single time according to the settings. Increasing Ethernet packet receiving can improve network performance but may reduce APs' capability to handle key packets in real time. You can reduce Ethernet packet receiving when the requirements for performance are not high but user concurrency and real-time packet handling are required. In this case, it is recommended that the single-time received Ethernet packet quantity be set to 25.

Command	**eth-schd** *limit*
Parameter Description	*limit*: Specifies the number of Ethernet packets received at a single time. The value rang is from 1 to 256.
Defaults	By default, the single-time received Ethernet packet quantity varies with APs.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Enabling or Disabling LDPC

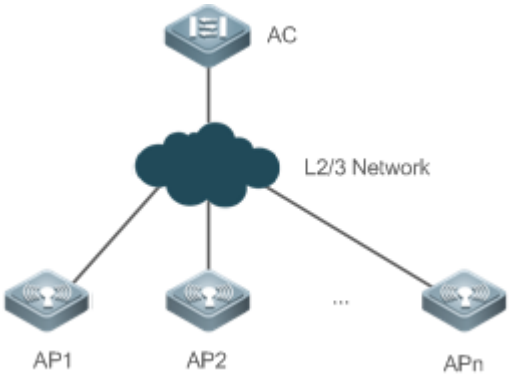
- Optional.
- On an AC, enable LDPC for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to send and receive packets using LDPC.
- LDPC improves the coding reliability and gains. It also greatly reduces the probability of information loss during transmission in frequencies with serious noise interference. However, a small number of STAs are incompatible with LDPC, and enabling LDPC will result in packet loss.

Command	**ldpc radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with LDPC. The value range is from 1 to 96.
Defaults	By default, LDPC is enabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Enabling or Disabling Transmit/Receive STBC

- Optional.
- On an AC, enable transmit/receive STBC for specified APs. Then the AC delivers the configuration to the APs to instruct the APs to send and receive packets using STBC.
- STBC improves the reliability of data transmission. Some STAs may be incompatible with STBC.

Command	**stbc radio** *radio-id*



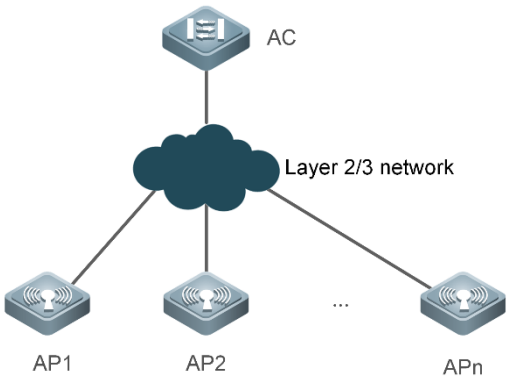
Parameter Description	*radio-id*: Specifies the ID of a radio enabled with STBC. The value range is from 1 to 96.
Defaults	By default, STBC is enabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Verification

- Run **show ap-config running** *ap-name* to display E-bag parameter settings.

Configuration Example

Configuring E-Bag Parameters



Scenario Figure 1-9	 In Figure 1-9, an AC is connected to APs. On the AC, configure the E-bag parameters for AP1 according to the following steps: 1. Set the A-MPDU software retransmission count to 3 for radio 1 of AP1. 2. Enable RTS protection for A-MPDU packets for radio 1 of AP1. 3. Set the single-time received Ethernet packet quantity to 100 for AP1. 4. Disable LDPC for radio 1 of AP1. 5. Disable transmit/receive STBC for radio 1 of AP1.
Configuration Steps	● On the AC, configure RF parameters for AP1.

	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# ampdu-retries 3 radio 1`
	`Hostname(config-ap)# ampdu-rts radio 1`
	`Hostname(config-ap)# eth-schd 100`
	`Hostname(config-ap)# no ldpc radio 1`
	`Hostname(config-ap)# no stbc radio 1`

Verification	● Run **show ap-config running** *ap-name* to display E-bag parameter settings of AP1.

	`Hostname(config)# show ap-config running AP1`
	`!`
	`ap-config AP1`
	` ap-mac 00d0.f801.0528`
	`channel 11 radio 1`
	` no 11acsupport enable radio 2`
	` ampdu-retries 3 radio 1`
	` ampdu-rts radio 1`
	` no stbc radio 1`
	` no ldpc radio 1`
	` eth-schd 100`
	` wmm edca-radio video aifsn 1 cwmin 3 cwmax 4 txop 90 radio 1`
	` wmm edca-radio back-ground aifsn 7 cwmin 4 cwmax 10 txop 5 radio 2`
	`!`

Configuring E-bag Network Optimization in One-Click Mode

Scenario **Figure 1-10**	 In Figure 1-10, an AC is connected to Fit APs. On the AC, configure E-bag network optimization for AP1 in one-click mode.
Configuration Steps	● On the AC, configure E-bag network optimization for AP1 in one-click mode.

	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# ebag`

Verification	● Run **show ap-config running** *ap-name* to display E-bag parameter settings of AP1.

```
Hostname(config)# show ap-config running AP1
!
ap-config AP1
 ap-mac 00d0.f801.0528

 channel 11 radio 1

```

1.4.8 Configuring WLANs in One-Click Mode

Configuration Effect

- Configure WLANs quickly on unconfigured devices in one-click mode. The one-click WLAN configuration feature helps the site survey personnel improve operation efficiency and the channel personnel execute performance tests conveniently.

Configuration Steps

↘ Configuring WLANs in One-Click Mode

- Optional.
- Run **autowifi** in configuration mode to configure WLANs in one-click mode, realizing fast configuration of wireless networks. The one-click WLAN configuration feature helps the site survey personnel improve operation efficiency and the channel personnel execute performance tests conveniently.

Command	**autowifi**
Parameter Description	N/A
Defaults	By default, the one-click WLAN configuration feature is not configured.
Command Mode	AC global configuration mode
Usage Guide	The one-click WLAN configuration feature allows you to perform fast configuration on unconfigured devices.

	The one-click WLAN configuration feature helps the site survey personnel improve the operation efficiency and the channel personnel execute performance tests conveniently.

Verification

- Run **show running-config** to display the one-click WLAN configuration.

Configuration Example

Configuring WLANs in One-Click Mode

Scenario **Figure 1-11**	 In Figure 1-11, an AC is connected to Fit APs. Configure WLANs in one-click mode on the AC.
Configuration Steps	● Configure WLANs in one-click mode on the AC.
	`Hostname# configure terminal` `Hostname(config)# autowifi`
Verification	● Run **show running-config** to display the one-click WLAN configuration.

	`Hostname(config)# show running-config`
	`!`
	`wlan-config 1 autowifi_1234`
	`!`
	`ap-group default`
	` interface-mapping 1 2 ap-wlan-id 1`
	`!`
	`ap-config all`
	` fair-schedule`
	`!`
	`ac-controller`

1.4.9 Cancelling the Power Supply Limit

Configuration Effect

When the negotiated power supply limit is 15.4 W, configure this command to cancel the power supply limit.

Notes

- N/A

Configuration Steps

↘ Configuring poe-unlimit

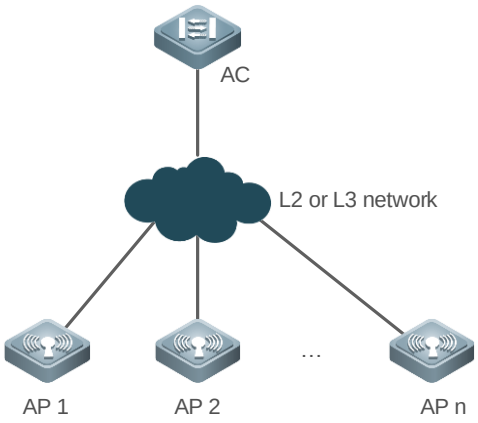
- Optional.
- The AC delivers the configuration to the corresponding AP, instructing it to cancel the power supply limit.
- For APs powered through PoE+, if the PoE+ mode cannot be negotiated because some special power supply devices fail to work properly, the power supply limit can be canceled to ensure that the APs can work at the maximum capacity.

Command	**poe-unlimit radio** { *radio-id* | **802.11a** | **802.11b** | **6GHz** } **poe-unlimit radio-type** { **802.11a** | **802.11b** | **6GHz** }
Parameter Description	*radio-id*: Indicates the ID of a radio to be configured. The value range is from 1 to 96. **802.11a**: Indicates the 5 GHz operating band. **802.11b**: Indicates the 2.4 GHz operating band. **6GHz**: Indicates the 6 GHz operating band.
Defaults	By default, PoE is disabled and limited based on the PoE negotiation result.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

Run the **show ap-config running** *ap-name* command to display the configuration.

NOTE:



Ensure that the power supply device meets the maximum power consumption requirement of a corresponding AP. Otherwise, the AP may restart. Exercise caution when configuring this command.

Configuration Example

Configuring Power Supply Limit Cancelation

Scenario

Figure 1-2

Assume that in a Fit AP high-density environment, radio 1 of AP 1 on the AC must cancel the power supply limit.

Configuration Steps

On the AC, cancel the power supply limit on AP 1.

```
Hostname# configure terminal
Hostname(config)# ap-config AP1
Hostname(config-ap)# poe-unlimit radio 1
```

Verification

Run the **show ap-config running** *ap-name* command to display the power supply limit of a specified AP.

```
Hostname(config)# show ap-config running AP1
!
ap-config AP1
 ap-mac 00d0.f801.0528
 poe-unlimit radio 1
!
```

1.4.10 Managing the Operating Frequency Band When Power Supply Is Insufficient

Configuration Effect

When the AP power supply mode is negotiated to 15.4 W, the AP can work only in 2.4 GHz or 5 GHz. This configuration enables the AP to switch the operating frequency band to 2.4 GHz or 5 GHz.

Notes

- None

Configuration Steps

- Optional
- After this command is configured, the AC delivers the configuration to an AP to notify the AP of the operating frequency band in the case of insufficient power supply.

Command	**hap-poe enable radio** { **802.11a** | **802.11b** }
Parameter Description	**802.11a**: Indicates the 5 GHz band. **802.11b**: Indicates the 2.4 GHz band.
Defaults	By default, the operating frequency band is selected based on the AP capability value.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	N/A

Verification

Run the **show ap-config running** *ap-name* command to display configurations in AP configuration mode and run the **show running-config** command to display configurations in AP group configuration mode and all-AP configuration mode.

Configuration Example

Switching to 5 GHz When AP Power Supply Is Insufficient

Configuration Steps The following example switches the operating frequency band to 5 GHz on the AC when power supply to AP1 is insufficient.

```
Hostname# configure terminal
Hostname(config)# ap-config AP1
Hostname(config-ap)# hap-poe enable radio 802.11a
```

Verification Run the **show ap-config running** *ap-name* command to display the configuration of a specific AP.

```
Hostname(config)# show ap-config running AP1
!
ap-config AP1
 ap-mac 00d0.f801.0528
 hap-poe enable radio 802.11a
!
```

1.4.11 Enabling or Disabling the PoE Power Supply by an AP to External Devices

Configuration Effect

- Enable or disable the PoE power supply by an AP to external devices.

Notes

- N/A

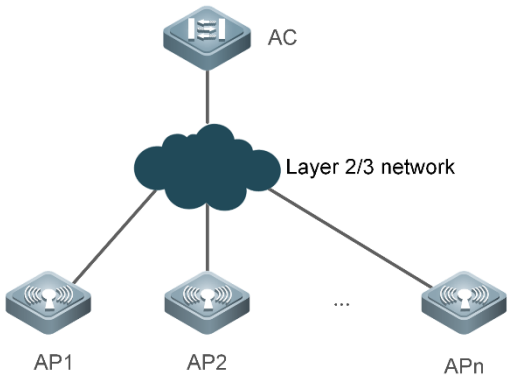
Configuration Steps

Configuring poeout

- Optional.
- The AC can enable or disable the PoE power supply by the Fit AP to external devices by running the **exec-cmd** command.

Command	**poeout** { **enable** | **disable** | **default** }
Parameter Description	**enable**: Enables PoE power supply by an AP to external devices. **disable**: Disables PoE power supply by an AP to external devices. **default**: Uses the default settings for PoE power supply by an AP to external devices.
Defaults	By default, the default PoE power supply settings of the device are used.
Command Mode	AP configuration mode
Usage Guide	After the command is configured, the configuration is saved automatically, without using the write command. This command does not support the no and default forms. After poeout default is configured, the default PoE power supply configuration of the device is adopted. In Fit AP mode, the AC can enable or disable PoE power supply by an AP to external devices by running the exec-cmd command. The default PoE power supply status may vary depending on the AP model. Run the poeout default command to make APs of different models in the same group stay in their respective default PoE power supply status.

Verification



Run the **show ap–config running** command to display the configuration. insufficient

Configuration Example

Configuring PoEoutpot.

Scenario

Figure 1-3

Configuration Steps

Enable PoE power supply by an AP to external devices.

```
Hostname#configure
Hostname(config)# ap-config ap1
Hostname(config-ap)# exec-cmd mode config cmd "poeout enable"
```

Verification

Run the **show ap–config running** command to display the configuration.

```
Hostname#show ap-config running
!
ap-config ap1
 exec-cmd mode config cmd " poeout enable"
!
```

1.4.12 Configuring or Canceling Forced Power Supply Mode for an AP

Configuration Effect

- This command is used to configure or cancel the forced power supply mode (including four power supply levels: AF, AT25W, AT36W, and BT) of an AP and confirm whether to save the configuration to the environment variables.

Notes

- N/A

Configuration Steps

Configuring the Forced Power Supply Mode

- Optional.
- The AC can configure the forced power supply mode or cancel the configuration for a Fit AP on the AC by running the **exec-cmd** command.

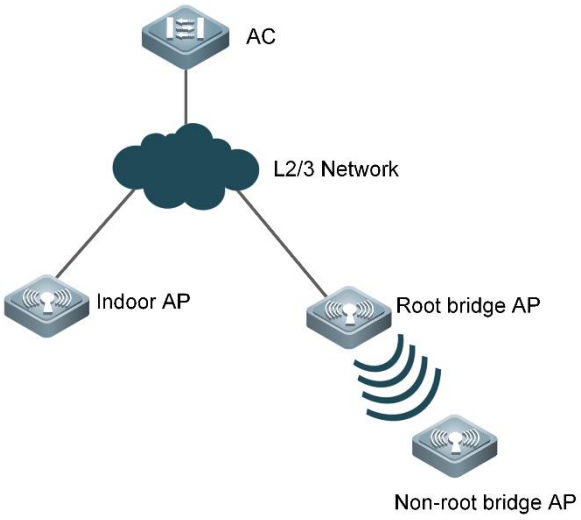
- For APs powered via PoE+, if the PoE+ mode cannot be negotiated because some special power supply devices fail to work properly, the power supply limit can be canceled to ensure that the APs can work at the maximum capacity.

Command	**pdpoe-force** { **af** | **at25w** | **at36w** | **bt** } [**save**]
Parameter Description	**af**: Indicates that the power supply mode is forcibly configured as AF, with the level-1 power consumption of 13.0 W. **at25w**: Indicates that the power supply mode is forcibly configured as AT, with the level-2 power consumption of 25.5 W. **at36w**: Indicates that the power supply mode is forcibly configured as AT36, with the level-3 power consumption of 36.0 W. **bt**: Indicates that the power supply mode is forcibly configured as BT, with the level-4 power consumption of 62.0 W. **save**: Indicates that the configured forced power supply mode will be saved to the environment variables and will not be lost after a restart.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	The configuration of the command is saved only when save is specified in the command. The no form of this command can be used to cancel the configuration. You can run the no pdpoe-force command to cancel the forced power supply mode. You can run the no pdpoe-force save command to cancel the forced power supply mode and remove the environment variables. In Fit AP mode, the AC can be configured to cancel the forced power supply mode or cancel the configuration for an AP on the AC by running the exec-cmd command. The default forced power supply mode is not supported.

Verification

Run the **show ap-config running** command to display the configuration.

NOTE:



Ensure that the power supply device meets the maximum power consumption requirement of a corresponding AP. Otherwise, the AP may restart. Exercise caution when configuring this command.

Configuration Example

Configuring the Forced Power Supply Mode

Scenario

Figure 1-4

Configuration Steps

Assume that the AP680 is configured as a non-root bridge and powered by a non-standard BT adapter. If the third frequency of BT cannot be identified, a bridge fails to be established. That is, the AP cannot be connected to the AC. In this case, the AP needs to be pre-configured.

On the AC, forcibly configure the AP to the BT power supply mode.

Run the **exec-cmd** command to configure the AP.

```
Hostname(config)# ap-config ap1
Hostname(config-ap)#exec-cmd mode config cmd "pdpoe-force bt save"
```

Verification

Run the **show ap-config running** command to display the configuration.

```
Hostname#show ap-config running
!
ap-config ap1
 exec-cmd mode config cmd "pdpoe-force bt save"
!
```

1.4.13 Configuring a Frequency Band Mode

Configuration Effect

- Configure a frequency band mode of an AP, and specify the operating frequency (802.11a or 802.11b) of the radio during startup.

Notes

- This configuration is supported only by some APs (including the AP680).

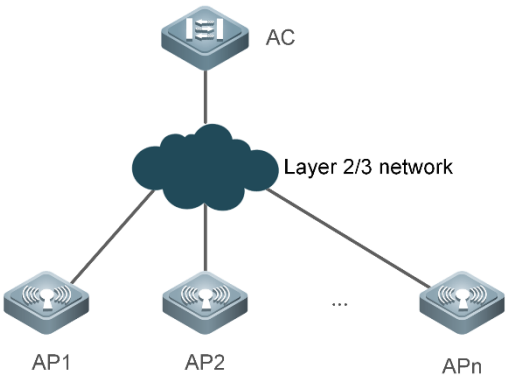
Configuration Steps

Configuring a Frequency Band Mode

- Optional.
- The AC will deliver the configuration to the corresponding AP, instructing it to switch to the specified operating band and restart.

Command	**ap-band-mode** { **802.11a** | **802.11b** | **6GHz** } **radio** [*radio-id*]
Parameter Description	**802.11a**: Indicates the 5 GHz operating band. **802.11b**: Indicates the 2 GHz operating band. **6GHz**: Indicates the 6 GHz operating band. *radio-id*: Indicates the ID of a radio to be configured. The value range is from 1 to 96.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	1. This configuration is used to set the initial mode and cannot be saved. 2. This configuration will automatically restart the AP.

Verification



- The AP will automatically restart after this command is configured. Then run the **show ap-config summary** command to confirm the operating band of the corresponding radio.

Configuration Example

Configuring the Operating Frequency Band

Scenario

Figure 1-10

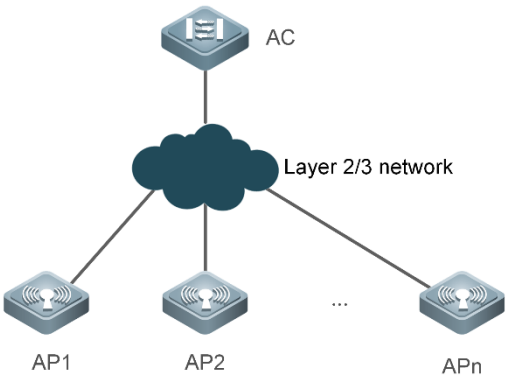
Configuration Steps

On the AC, configure the operating band for radio 3 of AP680 as 802.11a.

```
Hostname# configure terminal
Hostname(config)# ap-config ap680
Hostname(config-ap)# ap-band-mode 802.11a radio 3
Switch the band model will auto reload system, continue?(Y/N)  Y
```

Verification

After AP restart, run the **show ap-config summary** command to display the operating band of the corresponding radio.



```
Hostname#show ap-config summary
========= show ap status =========
Radio: Radio ID or Band: 2.4G = 1#, 5G = 2#
      E = enabled, D = disabled, N = Not exist, V = Virtual AP
      Current Sta number
      Channel: * = Global
      Power Level = Percent

Online AP number: 2
Offline AP number: 29

AP Name                              IP Address     Mac Address    Radio
Radio            Up/Off time   State
---------------------------------------- --------------- -------------- --
----------------- ------------------- ------------- -----
```

Scenario

Figure 1-10

Configuration Steps

On the AC, configure the operating band for radio 3 of AP680 as 802.11a.

```
Hostname# configure terminal
Hostname(config)# ap-config ap680
Hostname(config-ap)# ap-band-mode 802.11a radio 3
Switch the band model will auto reload system, continue?(Y/N)  Y
```

Verification

After AP restart, run the **show ap-config summary** command to display the operating band of the corresponding radio.

```
ap680                                172.30.103.216  f822.5896.5858 1  E   0
6   100 2  E   0  153   100    0:00:00:32 Run
                                                                    3  E   0   40
100 4  N   -    -     -
```

1.5 Monitoring

Displaying

Command	Description
linktest	Displays link information about STAs.
show ac-config { **802.11a** | **802.11b** | **6GHz** } **summary**	Displays the AP list that maps the 802.11a, 802.11b, or 6 GHz network on an AC.
show antenna all	Displays the antenna feeder status of all APs.
show antenna single *ap-name*	Displays the antenna feeder status of an AP.
show ap-config radio	Displays radio information about all APs.
show ap-config radio ap-name *ap-name*	Displays radio information about an AP.
show ap-config radio *radio-id* **config** *ap-name*	Displays the configuration of an AP radio.
show ap-config radio *radio-id* **status** *ap-name*	Displays status information about an AP radio.
show ap-config radio status *ap-name*	Displays the radio list of an AP.

Command	Description
show ap-config summary radio	Displays radio information about all APs.
show client details *sta-mac*	Displays STA information mapped to a MAC address.
show dfs adjustment-channels [**ap-name**]	Displays the frequency-hopping channel and bandwidth of the specified AP or all APs.
show dfs non-occupancy-channels [**ap-name**]	Displays the list of non-occupancy radar channels of the specified AP or all APs.
show dfs historical-radar-channels [**ap-name**]	Displays historical information about radar channels of the specified AP or all APs.
show wopt dcca	Displays the DCCA configuration.
show wopt dtpc	Displays the DTPC configuration.

1 Configuring Band Select

1.1 Overview

Band Select optimizes access band distribution for stations (STAs) on a WLAN.

Band steering technology steers STAs to connect to higher-capacity frequency bands, enhancing user experience.

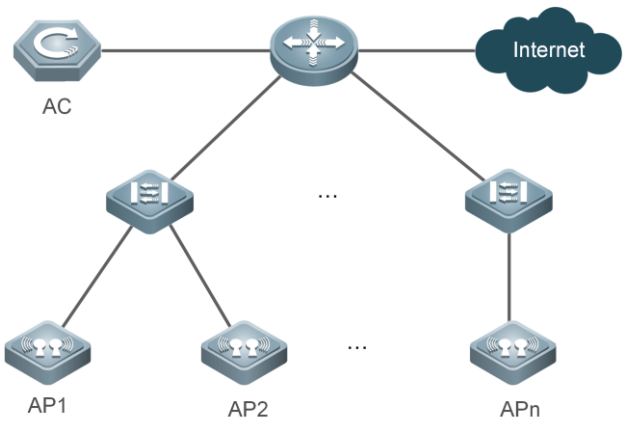
The Band Select function is suitable for the following scenario: multi-radio APs are used to provide coverage, and the multiple RF connectors of the APs operate at 2.4 GHz, 5 GHz, and 6 GHz respectively; meanwhile, a WLAN is mapped to multiple RF connectors of the APs and provides access service at the multiple radio simultaneously.

Protocols and Standards

IEEE 802.11

1.2 Applications

Application	Description
Band Select for a WLAN with a Fit AP Architecture	In a Fit AP architecture, a WLAN composed of multiple multi-band APs is enabled with the Band Select function.



1.2.1 Band Select for a WLAN with a Fit AP Architecture

Scenario

In a Fit AP architecture, a WLAN composed of multiple multi-band APs is enabled with the Band Select function, as shown in Figure 4-1:

- One AC is associated with multiple multi-band APs. The AC and APs are connected through Layer 2 switches and Layer 3 routers.
- The WLAN is mapped to the multiple RF interfaces of all APs.

Figure 1-1

Remarks	The AC is a wireless access controller. AP1, AP2 … AP*n* are multi-band APs.

Deployment

- Manage parameters of the Band Select function on the AC.
- Apply the Band Select function, identify STA types, and steer STA access on the AC.

1.3 Features

Basic Concepts

Frequency Bands Used by IEEE802.11 for Communication

IEEE802.11 uses three frequency bands:

- 2.4 GHz (2412 MHz to 2472 MHz) (IEEE 802.11b/g/n/ax operates in this frequency band)
- 5 GHz (5180 MHz to 5320 MHz, 5500MHz to 5700MH, and 5445MHz~5825MHz) (IEEE 802.11a/n/ac/ax operates in this frequency band)
- 6 GHz (5925 MHz to 7125 MHz) (IEEE 802.11ax operates in this frequency band)

With the popularization of WLAN, most clients are capable of both 2.4 GHz and 5 GHz radios. The publish of Wi-Fi 6E standard ushers in the brand new 6 GHz radio, which is supported by many countries worldwide. The 6 GHz radio provides 59 available channels, 5 GHz radio provides 25 available channels, and 2.4 GHz radio provides 3 non-overlapping channels. The wireless clients should be steered to the 6 GHz and 5 GHz radios preferentially which offer a greater access capacity.

STA Scanning

STAs discover a WLAN through passive or proactive scanning:

- Passive scanning: A STA monitors beacon frames sent by neighboring APs on all channels of all supported bands. The beacon frames contain WLAN and auxiliary information. The STA parses the information to learn about the WLANs that are available nearby.
- Proactive scanning: The STA broadcasts a Probe Request frame on all channels of all supported bands. After receiving the Probe Request frame, the APs providing WLAN access service send a Probe Response frame containing WLAN information to the STA.

Typically, a STA summarizes the SSIDs of all discovered WLANs and generates a list of accessible WLANs for users.

Multi-band STA

WLAN network interface cards (WNICs) used by STAs to connect to WLANs are classified into a, b, g, n, ac, and ax, which indicate the 802.11 protocol types supported by the WNICs. 802.11a operates at 5 GHz, 802.11b/g at 2.4 GHz, 802.11n at 5 GHz and 2.4 GHz, 802.11ac at 5 GHz, and 802.11ax at 2.4 GHz, 5 GHz, and 6 GHz.

Identify the frequency bands supported by the NIC according to the 802.11 specifications of the NIC..

Multi-band AP

A multi-band AP requires multiple RF connectors working at the 5 GHz, 2.4 GHz, and 6 GHz radios respectively.

To enable a WLAN for band steering, map the WLAN to multiple RF connectors on the multi-band AP and enable access service at each radio.

Overview

Feature	Description
Identifying STA Types	The Band Select function identifies whether a STA is a multi-band STA.
Controlling the Proactive Scanning Process	The Band Select function controls proactive scanning of a multi-band STA to prevent the STA from discovering WLANs of the 2.4 GHz band.
Preventing a Multi-band STA from Accessing the 2.4 GHz Band	The Band Select function rejects a multi-band STA from accessing the 2.4 GHz band and improves the chance of accessing the 5 GHz band.

1.3.1 Identifying STA Types

To steer a multi-band STA to access the 5 GHz or 6GHz band, it is necessary to first identify whether the STA is a multi-band STA; that is, identify the bands supported by the STA.

Working Principle

Proactive scanning is an approach for a STA to discover WLANs. A STA sends a Probe Request frame on each supported channel. If channel information in the Probe Request frame sent by the STA can be obtained, the bands supported by the STA can be identified.

For example, if an AP receives the Probe Request frame from the 2.4 GHz radio, the AP learns that the STA supports the 2.4 GHz radio. If the AP receives the Probe Request frame from the 5 GHz radio, the AP learns that the STA supports the 5 GHz radio. If the AP receives the Probe Request frame from the 6 GHz radio, the AP learns that the STA supports the 6 GHz radio.

Because a single-band AP can receive the Probe Request frame only on one band, only a multi-band AP can correctly identify the STA type. This is why the multi-band AP is required for the Band Select function.

STA Classification Criteria

A multi-band AP classifies STAs based on the following criteria:

- If the AP can receive the Probe Request frame from the 2.4 GHz, 5 GHz, and 6 GHz radios, this STA is a tri-radio STA.
- If the AP can receive the Probe Request frame from the 2.4 GHz and 5 GHz radio or from the 5 GHz and 6 GHz radio, the AP learns that this STA is a dual-radio STA.
- If the AP can receive the Probe Request frame from a STA only on the 6 GHz band, the AP learns that the STA is a 6 GHz STA.
- If the AP can receive the Probe Request frame from a STA only on the 5 GHz band, the AP learns that the STA is a 5 GHz STA.
- If the AP can receive the Probe Request frame from a STA only on the 2.4 GHz band, the AP learns that the AP is a 2.4 GHz STA.

Because an AP must wait for a period of time to verify that no Probe Request frame is received on a band, identifying a single-band STA is time-consuming. Among the five types of STAs, the first two types are called multi-band STAs in the Band Select function and the last three types are called the inhibition STAs.

It takes a period of waiting time (fixed to 2 seconds) to determine whether a Probe Request frame is sent from all radios. Due to different STA drivers, this time is not applicable to all multi-band STAs. Therefore, STA types may not be correctly identified in the beginning. As long as multi-band STAs can send Probe Request frames from all radios, the correct STA types can be identified.

STA Information Saving

STA information identified by a multi-band AP must be saved for enforcing subsequent responding policies.

Because Probe Request frames sent by STAs are broadcast, an AP may receive many Probe Request frames. It is unnecessary to save all the frames because some distant STAs may not access the AP. The Band Select function saves only the information of neighboring STAs based on the Received Signal Strength Indication (RSSI) of STAs. Only STAs with the RSSI exceeding a threshold can access the AP, and their information needs to be saved.

STA Information Aging

Frequency bands supported by some STAs are configurable. When a STA accesses the network, the frequency bands supported by the STA may change.

An 802.11a/g/n-compliant WNIC is used as an example. The WNIC works as a multi-band STA initially. However, the 802.11a mode or the support for the 5 GHz channels is disabled manually. In this case, the WNIC changes to a single-band 2.4 GHz STA.

An aging mechanism is introduced for the identified STA. After a period of time, the previously identified STA information is discarded.

1.3.2 Controlling the Proactive Scanning Process

After identifying the bands supported by a STA, a multi-band AP can control the proactive scanning process of the STA based on the STA information. The prevents a multi-band STA from discovering 2.4 GHz WLANs and steers the multi-band STA to access the optimal band.

Working Principle

During proactive scanning, the STA broadcasts a Probe Request frame. After receiving the Probe Request frame, an AP sends a Probe Response frame immediately to inform the STA of the accessible WLANs on this AP. During proactive scanning of a multi-band STA, the STA sends a Probe Request frame and waits for a Probe Response frame on the multiple bands. After the Band Select function is enabled, the AP controls proactive scanning and adopts different response approaches as needed.

Proactive Scanning Before the Band Select Function Identifies STA Types

If the Band Select function is enabled for a WLAN, the WLAN may have a change for the response to proactive scanning of a STA. Before STA types are identified, the following situations occur:

- The AP does not respond to Probe Request frames from the 2.4 GHz band.
- The AP responds to Probe Request frames from the 5 GHz and 6 GHz band.

After receiving a Probe Request frame from the 2.4 GHz band, the AP cannot determine whether the STA supports the 5 GHz and 6 GHz band. To prevent the STA from discovering that the WLAN provides access service on the 2.4 GHz band, the AP responds after the identification process ends.

If the AP receives a Probe Request frame from the 5 GHz and 6 GHz band, the STA supports the 5 GHz and 6 GHz band. In this case, the AP sends a Probe Response frame immediately to notify the STA that the WLAN provides access service on the 5 GHz and 6 GHz band.

Proactive Scanning After the Band Select Function Identifies STA Types

When the AP receives a Probe Request frame after identifying the STA type, the AP can find the source MAC address in the Probe Request frame stored on the AP.

- If the STA is a multi-band STA, the AP does not respond to a 2.4 GHz Probe Request. If the STA is an inhibition STA, the AP has a passive response.
- The AP responds to a 5 GHz and 6 GHz Probe Request.

Disabling the response to a 2.4 GHz Probe Request sent by a multi-band STA can prevent the multi-band STA from discovering that a WLAN provides access service on the 2.4 GHz band. In this way, the multi-band STA only discovers that the WLAN provides access service on the 5 GHz and 6 GHz band. The multi-band STA needs to connect to the 5 GHz and 6 GHz band for access.

The AP must respond to the 2.4 GHz Probe Request from an inhibition STA. Because an inhibition STA supports only the 2.4 GHz band, the inhibition STA cannot identify a WLAN if the AP does not respond to the 2.4 GHz Probe Request. However, the response to an inhibition STA is passive.

A 5 GHz and 6 GHz Probe Request is sent only by a multi-band STA. Therefore, the AP must send a Probe Response immediately to instruct the WLAN to provide access service on the 5 GHz and 6 GHz band.

Passive Response to an Inhibition STA

The Band Select function always proactively responds to 5 GHz and 6 GHz Probe Requests, does not respond to 2.4 GHz Probe Requests sent by multi-band STAs, and responds to Probe Requests from inhibition STAs passively. For example, when receiving multiple Probe Requests consecutively, the AP sends only one Probe Response.

The passive response depends on two parameters: STA scanning cycle threshold and probe count of the inhibition STA.

- STA scanning cycle threshold

The STA scanning cycle refers to the time for scanning all supported channels during proactive scanning of a STA. The time depends on characteristics of STAs. The STA scanning cycle can be configured and is the minimum value for limiting STA scanning. If the scanning cycle of a STA is smaller than this value, two consecutive scanning cycles may be considered to be one by an AP. This parameter is valid when some STAs send multiple Probe Requests within one scanning cycle.

Assume that a STA scans all channels every 150 milliseconds and sends two Probe Request frames consecutively on each channel. If an AP does not specify the minimum scanning cycle of the STA, the AP cannot identify whether the STA sends two frames within the same scanning cycle or sends the two frames in two consecutive scanning cycles. If the AP sets the minimum scanning cycle of the STA to 200 milliseconds, the two frames are considered to be sent within the same scanning cycle because their interval is shorter than 200 milliseconds. The probe count of the STA on the AP is 1. Because the specified minimum scanning cycle (200 milliseconds) and the actual scanning cycle (150 milliseconds) are different, the counts are also different. Assume that the STA performs scanning for three consecutive cycles, the count on the AP will be 2 because the first two cycles are considered to be one.

- Probe count of an inhibition STA

The probe count of an inhibition STA reflects the passive response degree of an RF interface to the STA. This parameter indicates the number of the cycles for which an inhibition STA performs proactive scanning before an AP sends one response. For example, if the default value is 2, the STA performs scanning for two consecutive cycles before the AP sends a Probe Response frame.

1.3.3 Preventing a Multi-band STA from Accessing the 2.4 GHz Band

The Band Select function controls only the proactive scanning process of a STA, but cannot prevent the STA from discovering a 2.4 GHz WLAN through passive scanning. Therefore, some multi-band STAs can still discover 2.4 GHz WLANs and attempt to access the WLANs. In this case, the Band Select function may take ineffective.

The Band Select function can reject 2.4 GHz access requests from multi-band STAs to improve the probability of multi-band STAs accessing the 5 GHz and 6 GHz band.

Rejecting a multi-band STA's 2.4 GHz access request helps improve the chance of successfully applying the Band Select function. However, the Band Select function may be unavailable.

Working Principle

After a STA discovers a WLAN, the STA sends an Authentication Request to the AP. Then the AP sends an Authentication Response to permit or reject the STA's authentication request.

The Band Select function processes the Authentication Request. If the Authentication Request is sent by a multi-band STA from the 2.4 GHz band, the Authentication Request will be rejected until the multi-band STA sends an Authentication Request from the 5 GHz or 6 GHz band. In this case, the STA is steered to access the 5 GHz or 6 GHz band.

When a multi-band STA searches for WLANs, the STA sends one or more Authentication Requests from one band and waits for responses. If the STA does not receive responses, the STA sends Authentication Requests from the other band and waits for responses. However, some multi-band STAs send Authentication Requests only from the 2.4 GHz. To achieve high availability, you can use the Band Select function to set the count for rejecting a multi-band STA.

Assuming that a multi-band STA sends Authentication Requests for *M* times before band change, and the count for rejecting a multi-band STA is set to *N*, if the multi-band STA attempts to access the 5 GHz band at first, the STA can access the 5 GHz or 6 GHz band immediately. If the multi-band STA attempts to access the 2.4 GHz band at first, the STA can access the 5 GHz or 6 GHz band only if *N* is equal to or greater than *M*; otherwise, the STA accesses the 2.4 GHz band. Regardless of the band a multi-band STA accesses, if the multi-band STA attempts to access the 2.4 GHz band at first, *M* or *N* (whichever is smaller) Authentication Requests are rejected or ignored. As a result, the STA's access is delayed. The delay depends on characteristics of the STA. For example, if the STA sends Authentication Requests at the interval of 100 milliseconds and four Authentication Requests are ignored, the access of the STA will be delayed for 400 milliseconds.

When the Band Select function rejects the access request of a multi-band STA while another access control function such as load balancing accepts the access request, the STA will still gain access. This is because the Band Select function is only used to steer STA access and has a lower priority. When the Band Select function conflicts with other functions, the other function takes effect.

1.4 Configuration

Configuration	Description and Command	
Configuring Band Select	(Mandatory) It is used to enable the Band Select function for a WLAN.	
	band-select enable	Enables the Band Select function.
	(Optional) It is used to set parameters of the Band Select function.	
	band-select acceptable-rssi	Configures the minimum RSSI for the Band Select function.
	band-select access-denial	Configures the count for rejecting a multi-band STA's 2.4 GHz access requests.
	band-select age-out	Configures the aging time of STA information.
	band-select probe-count	Configures the probe count of an inhibition STA.
	band-select scan-cycle	Configures the scanning cycle threshold of a STA.

1.4.1 Configuring Band Select

Configuration Effect

- Enable the Band Select function for a WLAN to steer multi-band STAs to access the 5 GHz or 6 GHz band.

Notes

- N/A

Configuration Steps

Enabling the Band Select Function for a WLAN

- Mandatory.
- Unless otherwise specified, enable this function on an AC.

Command	**band-select enable**
Parameter Description	N/A
Defaults	By default, the Band Select function is disabled.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Configuring the Minimum RSSI for the Band Select Function

- Optional.

- It is configured when you want to adjust the coverage of the Band Select function.
- Unless otherwise specified, enable this function on an AC.
- A higher value indicates a smaller coverage of the Band Select function. However, if the value exceeds a threshold, the STA that gains access may have weak signals, causing the entire network to slow down.

Command	**band-select acceptable-rssi** *value*
Parameter Description	*value*: Specifies the minimum SSID for the Band Select function. The value range is from -100 to -50 dBm.
Defaults	The default value is -80 dBm
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Count for Rejecting a Multi-band STA's 2.4 GHz Access Requests

- Optional.
- It is configured when it is necessary to reject the 2.4 GHz access request from multi-band STAs. If many STAs fail to access a band or it takes a long time to access the band, set a smaller value or use the value of 0.
- Unless otherwise specified, enable this function on an AC.
- A larger value indicates more difficult for the multi-band STA to access the 2.4 GHz band or longer time taken for the STA to access the 2.4 GHz band.

Command	**band-select access-denial** *value*
Parameter Description	*value*: Specifies the count for rejecting a multi-band STA's 2.4 GHz access requests. The value range is from 0 to 10.
Defaults	The default value is 2
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Aging Time of STA Information

- Optional.
- If no multi-band STAs change to single-band 2.4 GHz STAs, configure a longer aging time. Otherwise, configure a shorter aging time. If the situation is uncertain, use the default value.
- Unless otherwise specified, enable this function on an AC.
- A longer aging time indicates a longer lifecycle of STA information, and the less sensitivity of an AP to STA's band change.

Command	**band-select age-out** { **dual-band** *value* **| suppression** *value* }
Parameter Description	**dual-band** *value*: Specifies the aging time of multi-band STA information. The value range is from 20 to 120 seconds. **suppression** *value*: Specifies the aging time of inhibition STA information. The value range is from 10 to 60 seconds.
Defaults	By default, the aging time of multi-band STA information is 60 seconds and the aging time of inhibition STA information is 20 seconds.

Command Mode	Global configuration mode
Usage Guide	It is recommended that the aging time of multi-band STA information be set to twice or thrice that of inhibition STA information.

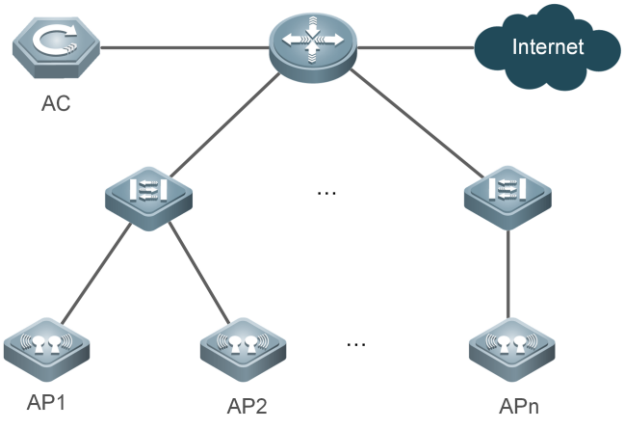
Configuring the Probe Count of an Inhibition STA

- Optional.
- If a single-band 2.4 GHz STA cannot discover a WLAN for a long time, use a smaller value.
- Unless otherwise specified, enable this function on an AC.
- The greater the probe count of a STA, the stronger inhibition the Band Select function performs on an inhibition STA, and the more difficult the inhibition STA discovers a WLAN.

Command	**band-select probe-count** *value*
Parameter Description	*value*: Specifies the probe count of an inhibition STA. The value range is from 1 to 10.
Defaults	The default value is 2.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Scanning Cycle Threshold of a STA

- Optional.
- If a single-band 2.4 GHz STA cannot discover a WLAN for a long time, use a smaller value. If the situation is uncertain, use the default value.
- Unless otherwise specified, enable this function on an AC or a fat AP.
- The greater the scanning cycle threshold of a STA, the more slowly the probe count of the STA increases, and the more difficult the STA discovers a WLAN



Command	**band-select scan-cycle** *value*
Parameter Description	*value*: Specifies the scanning cycle threshold of a STA. The value range is from 1 to 1000 milliseconds.
Defaults	The default value is 200 milliseconds.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show band-select configuration** command to display parameters of the Band Select function.
- Run the **show running-config** command to check whether the Band Select function is enabled.
- After a period of time, run the **show band-select statistics** command to check the statistics on the AC.
- Check whether the Band Select function controls the proactive scanning process by obtaining packets.

Configuration Example

Configuring Band Select for a WLAN with a Fit AP Architecture

Scenario **Figure 1-2**	 Figure 1-2 shows a typical WLAN with a Fit AP architecture. ● The AC is a wireless access controller. ● AP_1, AP_2 … AP_n are multi-band APs. ● The AC and APs are connected through Layer 2 switches and Layer 3 routers. ● The Band Select function is enabled on WLAN 99, whose SSID is **wlan-band select**. This WLAN is mapped to the two RF interfaces of all multi-band APs.
Configuration Steps	● (Optional) Configure parameters of the Band Select function on the AC. ● Enable the Band Select Function for WLAN 99 on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# wlan-config 99`
	`Hostname(config-wlan)# band-select enable`

Verification	Connect a multi-band STA to the WLAN with the SSID **wlan-band select**. ● The STA accesses the 5 GHz band. (The STA may also access the 2.4 GHz band upon band selection failure.) ● Check statistics of the Band Select function on the AC. The count should increase.

AC	`Hostname# show band-select statistics`
	`Band Select Statistics`
	`Number of dual band client..... 1`
	`Number of dual band client added..... 1`
	`Number of dual band client expired..... 0`
	`Number of suppressed client..... 0`
	`Number of suppressed client added..... 0`
	`Number of suppressed client expired..... 0`

Common Errors

- Parameters of the Band Select function are improper.
- The Band Select function is not enabled.

- One of the multiple RF interfaces of a multi-band AP is disabled.

1.5 Monitoring

Displaying

Command	Description
show band-select configuration	Displays the configuration of the Band Select function.
show band-select statistics	Displays statistics of the Band Select function.

1 Configuring HE Radio Selection

1.1 Overview

The high-efficiency (HE) radio selection technology selects an HE radio frequency (RF) interface on an access point (AP) based on the channel load and other conditions when multiple types of stations (STAs) coexist. This enables high-performance STAs (HIGH STAs) to preferentially access the HE RF interface to obtain a better user experience on a Wi-Fi 6 AP.

Protocols and Standards

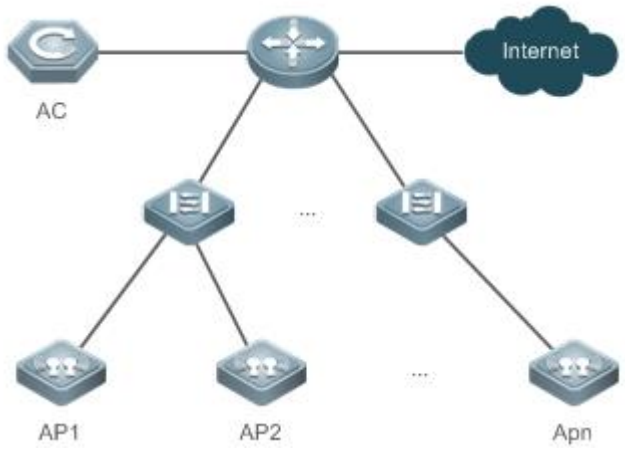
- IEEE 802.11

1.2 Applications

Application	Description
Configuring HE Radio Selection in the Fit AP Architecture	In the Fit AP architecture with densely deployed tri-radio APs, Wi-Fi 4, Wi-Fi 5, and Wi-Fi 6 STAs are randomly distributed across radios. Low-speed STAs affect the user experience of Wi-Fi 6. The HE radio selection function steers HIGH STAs to HE radios.

1.2.1 Configuring HE Radio Selection in the Fit AP Architecture

Scenario



On a wireless local area network (WLAN) formed by multiple tri-radio APs in the Fit AP architecture, a large number of Wi-Fi 4, Wi-Fi 5, and Wi-Fi 6 STAs exist and these STAs may connect to APs randomly. When low-speed STAs are used with Wi-Fi 6 STAs, Wi-Fi 6 STAs cannot unleash high throughput. With the HE radio selection function enabled, HE STAs can be steered to HE radios.

The HE radio selection technology dynamically assigns HIGH STAs to the most suitable RF when both high-speed and low-speed STAs exist. If there are only low-speed or high-speed STAs, you are not advised to enable this function.

In Figure 1-1:

- One access controller (AC) is associated with multiple tri-radio APs, and the AC connects to APs using Layer 2 switches and Layer 3 routers.
- WLAN signals are mapped to the three RF interfaces of all tri-radio APs.

Figure 1-1

Note	The AC is the wireless network controller. AP1, AP2, …AP*n* are tri-radio APs.

Deployment

- Manage and configure working parameters of the HE radio selection function on the AC.
- Run the HE radio selection function on APs. Based on the RF environment of an AP, the HE radio selection function automatically selects an HE radio, identifies HIGH STAs, and steers the HIGH STAs to the HE radio.

1.3 Features

Basic Concepts

Frequency Bands Used by IEEE802.11 for Communication

IEEE802.11 uses two frequency bands:

- 2.4 GHz (2.4 GHz to 2.4835 GHz), where 802.11b/g/n operates
- 5 GHz (5.15 GHz to 5.35 GHz and 5.725 GHz to 5.825 GHz), where 802.11a/n operates

As WLANs become popular, more and more wireless users increase on WLANs. Many users use dual-band wireless clients (STAs) supporting both 2.4 GHz and 5 GHz. However, 802.11b or 802.11g is more widely applied than 802.11a. Many dual-band STAs use 2.4 GHz, causing congestion on the 2.4 GHz band and underutilization of the 5 GHz band. However, the 5 GHz band has a higher access capacity. The 2.4 GHz band has up to three non-overlapping channels, whereas the 5 GHz band provides more non-overlapping channels.

STA Scanning

STAs discover a WLAN through passive or proactive scanning:

- Passive scanning: A STA monitors beacon frames sent by neighboring APs on all channels of all supported bands. The beacon frames contain WLAN and auxiliary information. The STA parses the information to learn about the WLANs that are available nearby.

- Proactive scanning: The STA broadcasts a Probe Request frame on all channels of all supported bands. After receiving the Probe Request frame, the APs providing WLAN access service send a Probe Response frame containing WLAN information to the STA.

Typically, a STA summarizes the SSIDs of all discovered WLANs and generates a list of accessible WLANs for users.

HIGH STA

As Wi-Fi 6 is introduced and tri-radio APs become popular, if wireless STAs are randomly associated with an AP's radio, the user experience of HIGH STAs that support 802.11ac/802.11ax is easily affected when they access 2.4 GHz radio, or when a large number of low-speed STAs occupy air interface resources of a radio. For STAs that support 802.11ac/802.11ax, the HE radio selection function can be used to steer these STAs to HE RF interfaces.

Dual-5G AP

Dual-5G APs can access two 5 GHz frequency bands simultaneously and tri-radio APs need to support dual-5G coverage. Signals of a WLAN enabled with HE radio selection must be mapped to the three RF interfaces of all tri-radio APs, and all the three RF interfaces provide access service to STAs.

Overview

Feature	Description
Identifying the STA Type	Identifies whether a STA is a HIGH STA. (STAs that support 802.11ax are identified as HIGH STAs by default, which is configurable.)
Automatically Selecting an HE Radio	Automatically selects an HE radio based on the RF load and interference of an AP.
Controlling the Proactive Scanning Process	Controls proactive scanning of different types of STAs to prevent non-HIGH-STAs from discovering WLAN signals of HE radios.
Rejecting STAs	Identifies the type of STAs and rejects HIGH STAs to access non-HE radios. Identifies the type of STAs and rejects non-HIGH STAs to access HE radios.
Automatically Adjusting the Selection Policy Based on the Radio Status	Automatically adjusts the selection policy based on the radio status.

1.3.1 Identifying the STA Type

Before the HE radio selection function takes effect, an AP needs to identify whether a STA is a HIGH STA, that is, check whether a STA supports HT_CAP.

Working Principle

Proactive scanning is a method for a STA to discover a WLAN. When a STA uses proactive scanning, it sends a probe request frame to each supported channel. If HT/VHT/HE information can be identified based on the 802.11 field carried in the probe request frame sent by the STA, protocols supported by the STA can be identified.

STA Classification Criteria

An AP classifies STAs based on the following criteria:

- HT-STAs: STAs that support 802.11a/b/g/n
- VHT-STAs: STAs that support 802.11ac
- HE-STAs: STAs that support 802.11ax

- Non-HIGH-STA: When a STA accesses an AP, the AP parses the Probe Request and Assoc Request packets to confirm capabilities supported by the STA. Based on the types of HIGH STAs specified by HE radios in the delivered configuration, the AP classifies STAs and defines non-identified HIGH STAs as non-HIGH-STAs.

⚠ STA identification depends on probe request and assoc request packets. However, in the authentication phase, the packets cannot be parsed.

STA Information Saving

STA information identified by a dual-band AP must be saved for enforcing subsequent responding policies.

Because Probe Request frames sent by STAs are broadcast, an AP may receive many Probe Request frames. It is unnecessary to save all the frames because some distant STAs may not access the AP. The Band Select function saves only the information of neighboring STAs based on the Received Signal Strength Indication (RSSI) of STAs. Only STAs with the RSSI exceeding a threshold can access the AP, and their information needs to be saved.

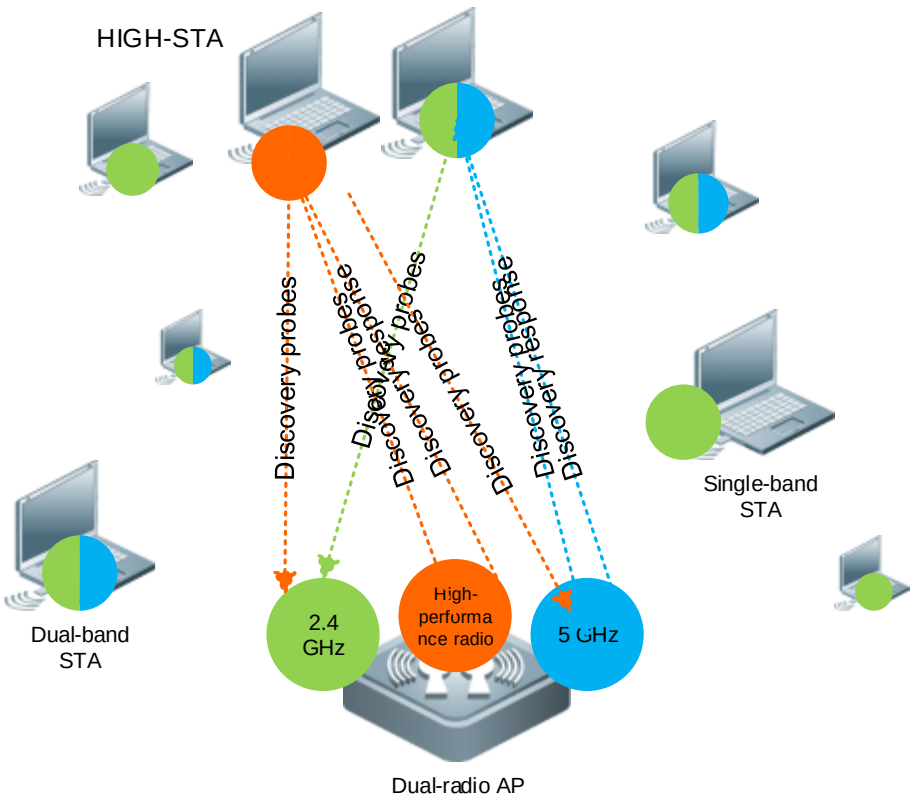
STA Information Aging

Frequency bands supported by some STAs are configurable. When a STA accesses the network, the frequency bands supported by the STA may change. In addition, more and more STAs support the random media access control (MAC) address function. Therefore, the STA information aging mechanism is introduced.

For example, a wireless network interface card (NIC) that supports 802.11ax is a HIGH STA that supports 802.11ac/ax when it is used. When the 802.11ac/ax mode is disabled manually, the NIC is changed to a non-HIGH-STA that supports 802.11n.

In this case, the aging mechanism is required for identified STA information. After a period of time, previously identified STA information needs to be discarded and STA information needs to be re-identified.

1.3.2 Automatically Selecting an HE Radio



The HE radio selection function requires an AP to support dual-band 5G and use an HE radio with small interference. After the HE radio selection function is enabled, the AP can automatically select a radio with a light load and low interference based on the channel environment to ensure user experience of HIGH STAs.

1.3.3 Controlling the Proactive Scanning Process

After identifying capabilities supported by a STA, a tri-radio AP can control proactive scanning of the STA. This prevents HIGH STAs from discovering signals of non-HE radios and steers HIGH STAs to access 5 GHz. In addition to preventing HIGH STAs from discovering signals of non-HE radios, the AP needs to prevent non-HIGH-STAs from accessing HE radios to ensure the air interface efficiency of HE radios.

Working Principle

During proactive scanning, a STA broadcasts a probe request frame. After an AP receives the frame, it responds with a probe response frame and notifies the STA of signals on the AP that can provide the access service. During proactive scanning, a STA sends a probe request to both frequency bands and waits for a probe response. After the HE radio selection function is enabled, the AP needs to control response to proactive scanning and adopts different response methods in different scenarios.

Response of HE Radio Selection to Proactive Scanning of STAs

If HE radio selection is enabled on an AP, response to proactive scanning of a STA will be changed. After identifying STA capability information:

✓ HE radios

- The AP does not respond to probe requests from non-HIGH-STAs but responds to probe requests from HIGH STAs.

✓ Non-HE radios

- The AP responds to probe requests from non-HIGH-STAs but does not respond to probe requests from HIGH STAs.

Passive Response of HE Radio Selection to Non-HIGH-STAs

HE RF interfaces proactively respond to probe requests from HIGH-STAs and do not respond to probe requests from non-HIGH-STAs. Non-HE RF interfaces passively respond to probe requests from HIGH STAs. That is, non-HE RF interfaces only respond with one probe response after receiving multiple consecutive probe requests.

The passive response degree of HE radio selection to probe requests from STAs depends on two parameters: STA scan cycle threshold and STA probe scan cycle count.

- STA scan cycle threshold
- The STA scan cycle indicates the time for scanning all supported channels during STA proactive scanning, and the time varies with the STA. The STA scan cycle threshold is a configurable value and indicates the minimum value for the STA scan cycle. If the STA scan cycle is less than the value, the AP regards two consecutive scan cycles as one . A STA may send multiple probe request frames in one scan cycle.

For example, a STA scans all channels every 150 ms and sends two consecutive probe request frames on each channel. If the minimum value of the STA scan cycle is not specified on the AP, the AP cannot determine whether a STA sends two probe request frames in one scan cycle or one probe request frame in two consecutive scan cycles. If the minimum value of the STA scan cycle configured on the AP is 200 ms and the interval between two packets is less than 200 ms, the AP regards that the packets are sent from the same scan cycle and the scan cycle count of the STA on the AP is 1. Because the minimum value of the STA scan cycle specified on the AP is 200 ms, which is different from the actual scan cycle of 150 ms, inconsistent counts may exist. When a STA has three scan cycles, only two cycles are counted on the AP because the AP regards the previous two cycles as one.

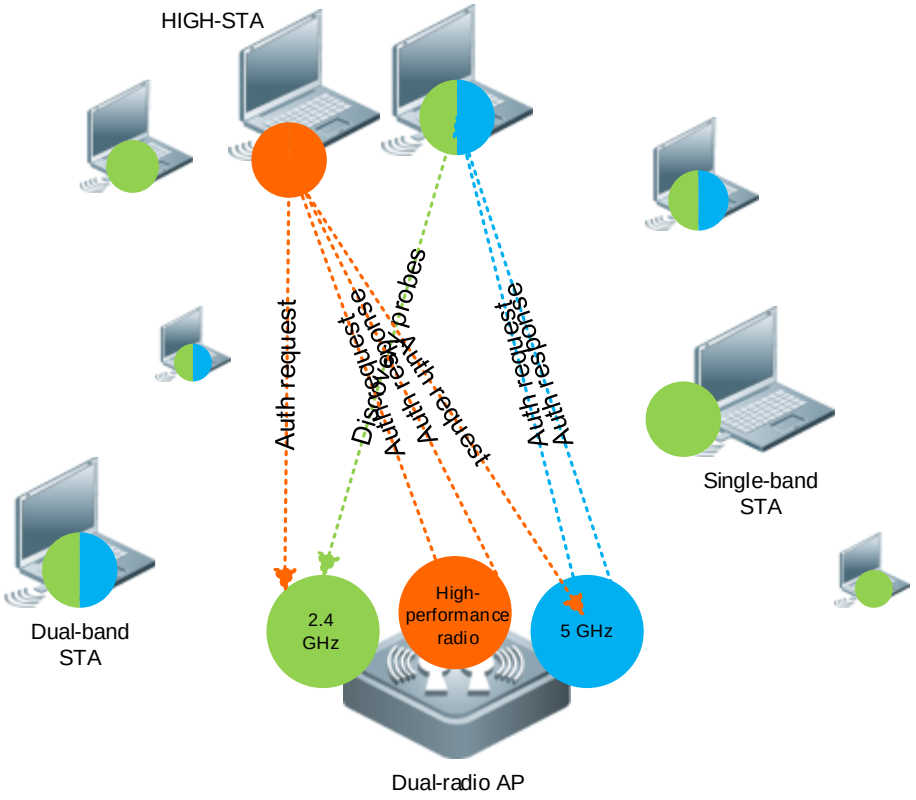
- STA scan cycle count

  The STA scan cycle count reflects the passive response degree of an HE RF interface to a STA. The count indicates the number of STA proactive scan cycles that an AP sends a response. For example, the default count is 2. That is, the AP sends a probe response frame after two consecutive scan cycles of a STA.

1.3.4 Rejecting STAs

⚠ The HE radio selection function only controls the proactive scanning process of a STA and cannot prevent the STA from discovering signals of non-HE radios through passive scanning. Therefore, some HIGH STAs can discover signals of non-HE radios and try to access. In this case, the HE radio selection function becomes invalid.

After the HE radio selection function is enabled, non-HE radios can reject access requests from HIGH STAs to improve the success rate for HIGH STAs to access HE radios. In addition, HE radios can reject access requests from non-HIGH-STAs to maintain high-speed throughput of air interfaces of HE radios.



⚠ Rejecting access requests from HIGH STAs in non-HE radios can improve the success rate of HE radio selection, but there is a possibility that HE radio selection becomes unavailable.

Working Principle

After a STA discovers and accesses a WLAN, the STA first sends an authentication request to an AP. The AP responds with an authentication response to allow or reject the authentication request of the STA.

The HE radio selection function can process authentication request frames. When a non-HIGH-STA sends an authentication request to an HE radio, the HE radio can reject its authentication request until it receives an authentication request from a HIGH STA. This steers tri-radio STAs to access HE radios.

When a HIGH STA accesses the network, it sends one or more authentication requests from one frequency band and waits for a response. If no response is received or the authentication request fails to be sent, the STA transfers to another frequency band to send an authentication request and waits for a response. However, a HIGH STA may send authentication requests only in non-HE radios. To ensure high availability, configure the number of times for rejecting access requests from non-HIGH-STAs.

For example, a HIGH STA accesses the WLAN and sends *M* authentication requests before switching to another frequency band, and the number of times that the HE radio selection function rejects access requests from a HIGH STA is configured as *N*, the following situations exist:

- If the HIGH STA first attempts to access an HE radio, the access is successful.
- If the HIGH STA first attempts to access a non-HE radio, the following situations exist:

  1) If *N* is greater than or equal to *M*, the STA can access the HE radio.

  2) If *N* is smaller than to *M*, the STA accesses a non-HE radio.

  In this scenario, M or N authentication requests (whichever is smaller) will be rejected or ignored. Therefore, it takes a long time for some STAs to access the WLAN. The delayed varies with the STA. For example, if a STA sends authentication requests every 100 ms and four authentication requests are ignored, the access of the STA will be delayed for 400 ms.

⚠ When the HE radio selection rejects the access request of a HIGH STA but another access control feature, such as load balancing accepts the access request of this STA, the STA is allowed to access. The HE radio selection function is only used to steer STAs during STA access and has a low priority. When this function conflicts with other functions, other functions are preferred.

1.3.5 Automatically Adjusting the Selection Policy Based on the Radio Status

When the HE radio selection function is enabled, an extreme situation may occur in some scenarios. For example, when there are a large number 802.11ax STAs or 802.11n low-speed STAs, some HE radios may not have STAs and a large number of 802.11ax STAs are congested in a radio. As a result, the user experience on the radio is poorer than that in random association.

Working Principle

The AP will analyze STA associations on HE radios and non-HE radios. Based on STA access and channel load of radios, the AP adjusts the selection policy to ensure effectiveness of this function.

1.4 Configuration

Configuration	Description and Command	
Configuring HE Radio Selection	(Mandatory) It is used to enable the HE radio selection function for an AC.	
	band-optimize he-radio enable [**auto | fixed**]	Configures the HE radio selection function.
	band-optimize he-radio mode [**11axonly | 11ac_11ax**]	Configures the type of STAs that access HE radios.
	(Optional) It is used to configure working parameters of the HE radio selection function.	
	band-select acceptable-rssi	Configures the lower limit of the STA RSSI that the HE radio selection function can accept, which also applies to band selection.
	band-select he-radio access-denial	Configures the number of times for rejecting STAs to a radio.
	band-select age-out	Configures the aging time of STA information, which also applies to band selection.
	band-select he-radio probe-count	Configures the STA scan cycle count.
	(Optional) It is used to configure working parameters of the HE radio selection function.	
	show ac-config client radio he-status	Displays STA access distribution of a radio.

1.4.1 Configuring HE Radio Selection

Configuration Effect

- Enable the HE radio selection function on an AP and steer HIGH STAs to HE radios.

Notes

N/A

Configuration Steps

Enabling HE Radio Selection for an AP

- Mandatory.
- Configure it on the AC unless otherwise specified.

Command	band-optimize he-radio enable
Parameter Description	N/A
Defaults	The HE radio selection function is disabled by default.
Command Mode	AC: AP configuration mode or AP group configuration mode (the AP configuration mode has a higher priority than AP group configuration mode)
Usage Guide	N/A

Configuring the Usage Mode of HE Radio Selection

- Optional. Configure it when HE radio selection needs to be adjusted.
- Configure it on the AC unless otherwise specified.
- Enable the HE radio selection function.

Command	band-optimize he-radio enable [auto | fixed]
Parameter Description	**auto**: Automatically adjusts the selection policy based on the STA load of a radio. **fixed**: Forcibly steer HIGH STAs to HE radios when the HE radio selection function is enabled, which is not changed due to RF environment differences.
Defaults	**auto**
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Type of STAs That Access HE Radios

- Optional. Based on the STA distribution in the environment, specify the type of STAs that access HE radios.
- Configure it on the AC unless otherwise specified.
-

Command	band-optimize he-radio mode { 11axonly | 11ac_11ax }
Parameter Description	**11axonly**: Steers only 802.11ax STAs to HE radios. **11ac_11ax**: Steers only 802.11ac and 802.11ax STAs to HE radios.
Defaults	The default mode is **11axonly**.
Command Mode	AC + Fit AP: AP configuration mode or AP group configuration mode (the AP configuration mode has a higher priority than the AP group configuration mode)
Usage Guide	N/A

Configuring the Number of Times That HE Radio Selection Rejects a STA

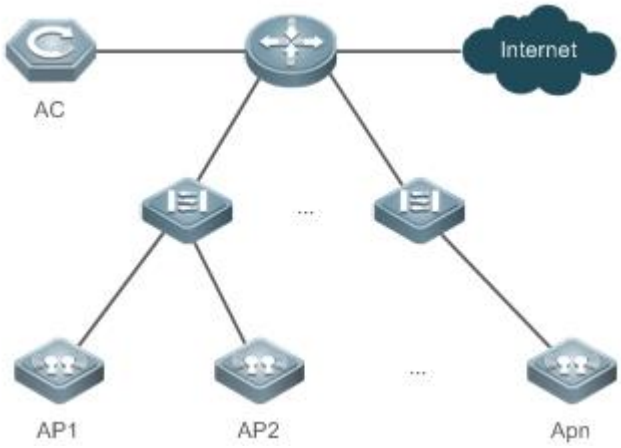
- Optional. Configure the number of times that an HE radio rejects authentication requests from a non-HIGH-STA or the number of times that a non-HE radio rejects authentication requests from a HIGH STA.
- To prevent STAs from accessing non-matching radios, the number of times that HE radio selection rejects a STA needs to be set to a smaller value or 0 if multiple STAs access the network after a long time or cannot access the network.
- Configure it on the AC unless otherwise specified.

- The larger the number of times that a radio rejects a STA, the more difficult and more time it takes for the STA to access the radio.

Command	**band-select he-radio access-denial** *access-denial-time*
Parameter Description	*access-denial-time*: Indicates the number of times for rejecting a STA. The value range is from 0 to 10.
Defaults	2
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Number of Times That the HE Radio Selection Function Suppresses a STA

- Optional. Configure the number of times that an HE radio rejects probe requests from a non-HIGH-STA or the number of times that a non-HE radio rejects probe requests from a HIGH STA.
- Configure it on the AC unless otherwise specified.
- A longer STA information aging time indicates a longer STA information lifecycle and less sensitive to radio switching of a STA. A shorter STA information aging time indicates a shorter STA information lifecycle and more sensitive to radio switching of a STA.



Command	**band-select he-radio probe-count** *probe-count*
Parameter Description	*probe-count*: Indicates the number of times that a non-HE radio rejects probe requests from a HIGH STA. The value range is from 0 to 10.
Defaults	2
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show band-select configuration** command to display HE radio selection parameter configuration on the AC.
- Run the **show running-config** command to check whether the HE radio selection function is enabled in WLAN configuration mode.
- After a period of time, run the **show band-select statistics** command to display running statistics on the AC.
- Obtain packets to confirm whether HE radio selection controls the proactive scanning process.
- After the STA accesses the network, run the **show ac-config client radio he-status** command to display STA access distribution on radios of the AC.

Configuration Example

Configuring HE Radio Selection in the Fit AP Architecture

Scenario **Figure 1-2**	 The preceding figure shows a typical wireless network with the fit AP architecture. ● AC is the wireless network controller. ● AP1, AP2. …AP*n* are tri-radio APs. ● The AC connects to the APs through a Layer 2 switch and Layer 3 router. ● The HE radio selection function is enabled, the WLAN is WLAN 99, the SSID is **wlan-bandoptimize**, and the WLAN maps to three RF interfaces of all tri-radio APs.
Configuration Steps	● Configure parameters for the HE radio selection function on the AC (optional). ● Enable HE radio selection for WLAN 99 on the AC.

AC	`AC# configure terminal`
	`AC(config)# ap-group 11axap_bandoptimize`
	`AC(config-group)# band-optimize he-radio enable`

Verification	Connect a HIGH STA to WLAN **wlan-bandselect**. ● The STA accesses an HE radio. (The HE radio selection may take ineffective, and the STA accesses a non-HE radio.) ● Check that the HE radio selection running statistics on the AC increase.

AC	`A# show band-select statistics`
	`Band Select Statistics`
	`  Number of dual band client.............................. 1`
	`  Number of dual band client added.......................... 1`
	`  Number of dual band client expired.......................... 0`
	`  Number of suppressed client.............................. 0`
	`  Number of suppressed client added.......................... 0`
	`  Number of suppressed client expired.......................... 0`
	
	`AP Name  IP Address  Radio  11n  11ac  11ax  Radio  11n  11ac  11ax`
	`-------------- ---------- ---- ------ ----- ----- ----- -------- ----- ------ ------`
	`AP-test  192.168.10.6  1#  3  4  0  2#  5  7  0`
	`3#P  0  0  8  NA`

Common Errors

- The HE radio selection parameters are not configured properly.
- The HE radio selection function is disabled.
- One of the two 5G RF interfaces of a tri-radio AP is disabled.

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show band-select statistics	Displays HE radio selection running statistics.
show ac-config client radio he-status	Displays STA distribution to radios of an AP connected to the AC to display STA distribution of HE radios.

Debugging

N/A

1 Configuring Radio Scheduling

1.1 Overview

Radio resources mentioned in this document include radios of an Access Point (AP) as well as the wireless local area network (WLAN) that provides access services.

Radio scheduling can perform automatic management of radio resources.

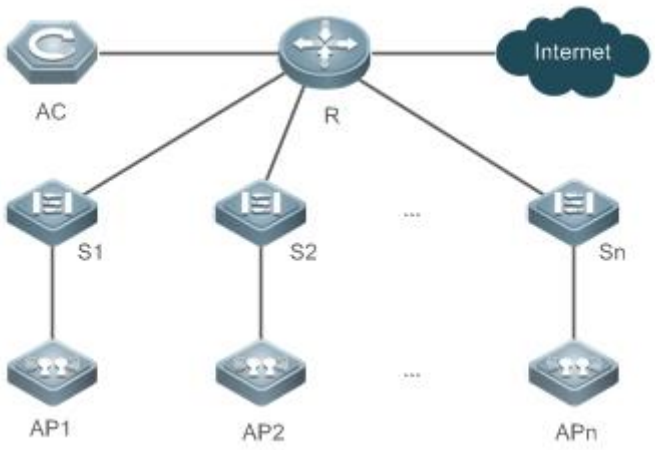
Radio scheduling can be used to disable the radio of an AP or a WLAN at the specified interval to realize the following functions:

- Reduce network traffic, saving network resources and preventing waste or abuse of network resources.
- Reduce radio interference and save energy.
- Disable access services in a certain period to reduce potential security risks.

Radio scheduling can be used in the scenarios where wireless access services are required in fixed time cycles.

1.2 Applications

Application	Description
AP RF Scheduling	In a Fit AP architecture, enables and disables AP RF as scheduled.
WLAN Scheduling	In a Fit AP architecture, enables and disables a WLAN as scheduled.



1.2.1 AP RF Scheduling

Scenario

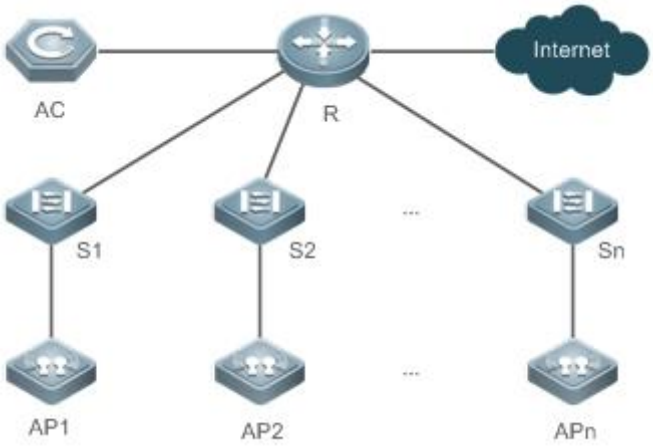
In the scenario where access services need to be provided to stations (STAs) in a specific period, AP radio scheduling can be used to disable radios in the period when no STAs access the WLAN, thereby preserving network resources and saving energy.

The following figure shows the deployment of a WLAN in a teaching building of a university, with the Fit AP architecture. AP1, AP2,…, and AP*n* are located in different places of the building. In the daytime, wireless services need to be provided to students and teachers, but such services are disabled in the nighttime. By using AP radio scheduling, radios of the entire building will be disabled automatically in the nighttime, and enabled again in the daytime. In this way, wireless services are available as scheduled, saving network resources and energy.

Figure 1-1

Deployment

In a Fit AP architecture, you can configure AP radio scheduling on an AC.



1.2.2 WLAN Scheduling

Scenario

Some specified WLANs should be enabled with radio scheduling as needed to reduce radio interference and ensure security.

The following figure shows the WLAN deployment of a bank business hall. The Fit AP architecture is used. AP1, AP2,…, and AP*n* are located in different places of the hall to provide free wireless access to customers. Typically, this WLAN does not require a password and is available only during business hours. When WLAN scheduling is applied, the WLAN is automatically enabled during business hours and disabled after work. In this way, the free customer-use WLAN is disabled, while other WLANs can continue to serve bank employees who are still working in the office.

Figure 1-2

Deployment

In a Fit AP architecture, configure WLAN scheduling on an AC.

1.3 Features

Basic Concepts

Scheduling Session

A scheduling session indicates a time interval for a radio resource. A simple scheduling session contains only one interval in a certain day, while a complex scheduling session contains many duplicate intervals in different days. One scheduling session supports eight identical or different intervals.

For example, you can specify scheduling sessions as follows: 12:00–14:00 and 18:00–8:00 from Monday to Friday; 8:00–12:00 and 17:00–8:00 from Saturday to Sunday.

Overview

Feature	Description
Configuring a Scheduling Session	Specifies a scheduling session.
Scheduling an AP	Applies a scheduling session to an AP radio to enable or disable the AP radio periodically.
Scheduling WLAN	Applies a scheduling session to a WLAN to enable or disable the WLAN periodically.

1.3.1 Configuring a Scheduling Session

Specify a scheduling session.

Working Principle

Before using the scheduling function, a scheduling session needs to be created first to specify the time for RF scheduling. Then the scheduling session can be applied to an AP RF interface or WLAN.

Configuring a Scheduling Session

First, you need to create a scheduling session and specify the time and cycle.

For example, in the preceding example, if you want to provide wireless access services only in the daytime to a teaching building, you can first create a scheduling session to specify the cycle as every day, and the scheduling interval as a period at night, for example, 21:00 to 6:00. If you want to provide WLAN services to customers of a bank only in the business hours of workdays, you can create a scheduling session to specify the cycle as workdays, and the scheduling time interval as off-work hours, for example, 18:00 to 9:00; and you can create the other cycle as weekends, and the scheduling interval as all day.

1.3.2 Scheduling an AP Radio

Enable or disable the AP radio periodically.

Working Principle

Before using the scheduling function, create a scheduling session and specify the time for radio scheduling. Then you can apply the scheduling session to an AP RF interface.

When the scheduling session starts or ends, the system sends a scheduling message. The RF interface of an AP or the RF interfaces of an AP group where this scheduling session is applied is enabled or disabled.

Applying a Scheduling Session to an RF Interface

After a scheduling session is created, it must be applied to the corresponding AP RF interface so that the scheduling can take effect.

You can specify an AP RF interface in the following several ways:

- Based on all APs
- Based on an AP group
- Based on a single AP

In the preceding several approaches, you can specify a radio ID for scheduling. If a radio ID is not specified, the scheduling will be applied to all radios of the AP.

In the example of the teaching building, the AP radio needs to be specified as needed.

If all APs in this scenario are in the same group or distributed in a few groups, the AP group-based configuration is recommended. If all the APs are located in the teaching building, the configuration based on all APs is also recommended. As the last choice, you can specify the AP RF interface based on a single AP.

Handling of a Scheduling Message

After a scheduling session is created and the cycle and interval are specified, the system will start the timer of the scheduling session, and send a message after entering or exiting from this scheduling session. A scheduling message includes the following information:

- Scheduling session ID
- Message type: scheduling state, including entering and exiting from the scheduling session

The handling of a scheduling message covers all APs. The system will determine whether to start scheduling based on the scheduling session ID configured for a single AP, AP group, and all APs in descending order of priority.

Scheduling priority: The priority of a session ID configured for a single AP, AP group, and all APs is in descending order. That is, when a session ID is configured for an AP, the AP group-based session ID and all APs-based session ID will not take effect on this AP. If no session ID is configured for an AP, the AP group-based session ID will take effect. If no AP group-based session ID is configured for an AP, the all APs-based session ID will take effect.

If the effective scheduling session ID of this AP radio is the same as that in the message, the message type will be checked. In scheduling state, the radio of this AP will be disabled. Otherwise, the radio will be enabled.

1.3.3 Scheduling WLAN

Enable or disable a WLAN periodically.

Working Principle

Before using the scheduling function, create a scheduling session and specify the time for WLAN scheduling. Then the scheduling session can be applied to a WLAN.

When the scheduling session starts or ends, the system sends a scheduling message. The WLAN where this scheduling session is applied to is enabled or disabled.

Applying a Scheduling Session on an RF Interface

After the scheduling session is created, it must be applied to the corresponding WLAN so that the scheduling can take effect.

You need to specify in WLAN configuration mode the scheduling session ID for the WLAN.

Handling of a Scheduling Message

After a scheduling session is created and the cycle and interval are specified, the system will start the timer of the scheduling session, and send a message after entering or exiting from this scheduling session. A scheduling message includes the following information:

- Scheduling session ID
- Message type: entering or exiting from the scheduling session

The handling of a scheduling message covers all WLANs. The system will first check the session to which the WLAN is applied. If the scheduling session ID to which the WLAN is applied is the same as that in the message, the message type will be checked. If the WLAN is in scheduling state, the WLAN will be disabled. Otherwise, the WLAN will be enabled.

1.4 Configuration

Configuration	Description and Command	
Configuring AP Radio Scheduling	(Mandatory) It is used to create a scheduling session, specify the interval, and apply the scheduling session to an AP or AP group.	
	schedule session	Creates a scheduling session.
	schedule session time-range	Specifies the interval of a scheduling session.
	schedule session	Applies the scheduling session to an AP or an AP group.
Configuring WLAN Scheduling	(Mandatory) It is used to create a scheduling session and apply it to a WLAN.	
	schedule session	Creates a scheduling session.
	schedule session time-range	Specifies the interval of a scheduling session.

	schedule session	Applies the scheduling session to a WLAN.

1.4.1 Configuring AP Radio Scheduling

Configuration Effect

- Create a scheduling session, specify a scheduling interval, and applies this scheduling session to an AP or an AP group to realize AP radio scheduling.

Configuration Steps

Creating a Scheduling Session

- Mandatory.
- A scheduling session must have been created.
- The command must be run on the AC where scheduling needs to be enabled.

Command	**schedule session** *session-id*
Parameter Description	*session-id*: Indicates the session ID. The value range is from 1 to 64 on an AC.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Specifying the Interval for a Scheduling Session

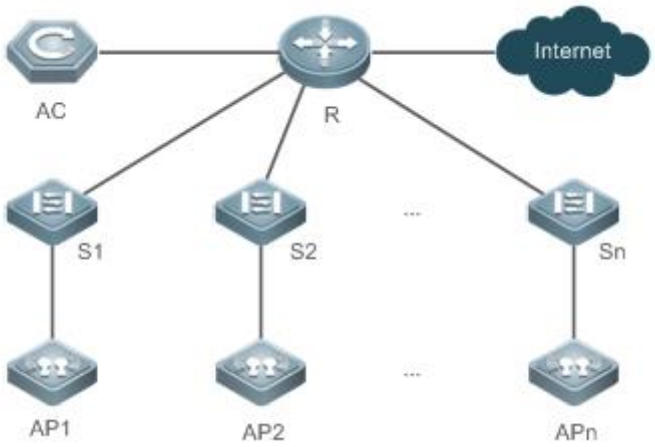
- Mandatory.
- The function must be applied on the AC to enable scheduling.

Command	**schedule session** *session-id* **time-range** *time-range-num* **period** { *day1* [**to** *day2*] | **everyday** } **time** { *hh1:mm1* **to** *hh2:mm2* | **all-day** }
Parameter Description	*session-id*: Indicates the session ID. The value range is from 1 to 64 on an AC. *time-range-num*: Indicates the number of an interval. The value range is from 1 to 8. *day1*: Indicates the start date of the scheduling session cycle, which can be set to { sun | mon | tue | wed | thu | fri | sat }. **to** *day2*: *day2* indicates the end date of the scheduling session cycle. By default, this parameter indicates that the scheduling cycle is one day. **everyday**: Indicates that the session occurs every day, which is the simplified form of **period** *sun* **to** *sat*. **time** *hh1:mm1* **to** *hh2:mm2*: Indicates the scheduling time period, and *hh1:mm1* and *hh2:mm2* indicate the start time and end time respectively in the unit of hours (ranging from 0 to 23) and minutes (ranging from 0 to 59). **time all-day**: Indicates that the session time range is a whole day, which is the simplified form of **time** *00:00* **to** *23:59*.
Defaults	By default, no scheduling interval or cycle is configured.

Command Mode	Global configuration mode
Usage Guide	N/A

Applying a Scheduling Session

- Mandatory.
- The function must be applied on the AC where scheduling needs to be enabled.
- In AP configuration mode, run the **schedule session** *session-id* command to specify the session ID for APs or a single AP.
- In AP group configuration mode, run the **schedule session** *session-id* command to specify the session ID for an AP group.
- After a scheduling session is applied, if the message for the scheduling session is displayed, the specified AP RF interface will automatically enter or exit from the scheduling state as specified by the massage type.



Command	**schedule session** *session-id* [**radio** *radio-id* | **slot** { *slot-id* | **all** }]
Parameter Description	*session-id*: Indicates the session ID. The value range is from 1 to 64 on an AC. *radio-id*: Indicates the ID of a radio on which the session is to be applied or deleted. The value range is from 1 to the number of radios on the AP. By default, the value is set to the number of radios on an AP. *slot-id*: Indicates ID of a slot on which the scheduling session is to be applied or deleted. The value range is from 1 to 24. **all**: Indicates all radios or all slots.
Defaults	By default, no scheduling session is applied to a single AP, an AP group, or all APs.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	N/A

Verification

- Run **show schedule session** to display the RF scheduling configuration.
- Check whether scheduling is still performed for an AP radio after a scheduling session expires.

Configuration Example

Providing WLAN Services to a Teaching Building of a University Only in the Daytime

Scenario **Figure 1-3**	 As shown in the figure, the Fit AP architecture is used in this scenario, and only one AC is applied. All the APs in the teaching buildings belong to the same AP group, whose group ID is **class-room**.
Configuration Steps	● Create a scheduling session on the AC. ● Specify the scheduling interval as the nighttime. ● On the AC, apply the scheduling session to AP group **class-room**.

AC	`Hostname# configure terminal`
	`Hostname(config)# schedule session 1`
	`Hostname(config)# schedule session 1 time-range 1 period sun to sat time 21:00 to 6:00`
	`Hostname(config)# ap-group class-room`
	`Hostname(config-ap-group)# schedule session 1`

Verification	● On the AC, run the **show running-config** command to display the configuration. ● Display the state of AP RF in the scheduling interval. ● Display the state of AP RF beyond the scheduling interval.

AC	`Hostname# show running-config`
	`.....`
	`schedule session 1`
	`schedule session 1 time-range 1 period Sun to Sat time 21:00 to 06:00`
	`.....`
	`ap-group class-room`
	`.....`
	`schedule session 1`
	`.....`

Common Errors

- No scheduling session is created.
- The interval of the scheduling session is incorrectly configured.
- The scheduling priorities on the AP are in conflict.
- Scheduling is not applied to the target radio.

1.4.2 Configuring WLAN Scheduling

Configuration Effect

- Create a scheduling session, specify a scheduling interval, and apply this scheduling session to a WLAN to realize WLAN scheduling.

Configuration Steps

Creating a Scheduling Session

- (Mandatory) In WLAN configuration mode, run the **schedule session** *sid* command to specify the scheduling session ID of a WLAN.
- The command must be run on the AC where scheduling needs to be enabled.
- After a scheduling session is applied, if the message for the scheduling session is displayed, the specified WLAN interface will automatically enter or exit from the scheduling state as specified by the massage type.

Command	**schedule session** *session-id*
Parameter Description	*session-id*: Indicates the session ID. The value range is from 1 to 64 on an AC.
Defaults	By default, no scheduling session is applied to a WLAN.
Command Mode	Global configuration mode
Usage Guide	N/A

Specifying the Time Interval for a Scheduling Session

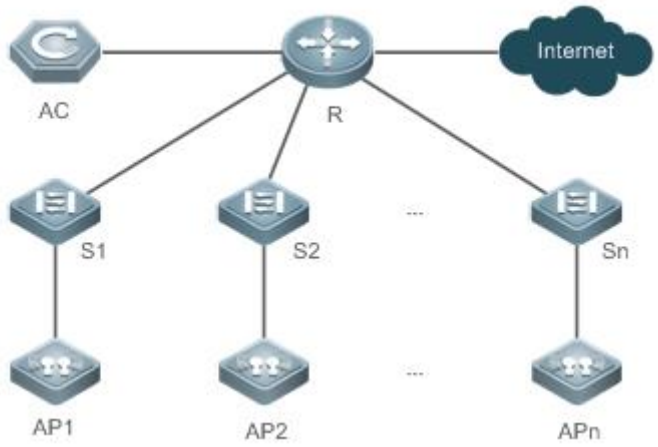
- Mandatory.
- The function must be applied on the AC to enable scheduling.

Command	**schedule session** *session-id* **time-range** *time-range-num* **period** { *day1* [**to** *day2*] **| everyday** } **time** { *hh1:mm1* **to** *hh2:mm2* **| all-day** }
Parameter Description	*session-id*: Indicates the session ID. The value range is from 1 to 64 on an AC. *time-range-num*: Indicates the number of an interval. The value range is from 1 to 8. **period** *day1*: Indicates the start date of the scheduling session cycle, which can be set to

	{ sun | mon | tue | wed | thu | fri | sat }. **to** *day2*: *day2* indicates the end date of the scheduling session cycle. By default, this parameter indicates that the scheduling cycle is one day. **everyday**: Indicates that the session occurs every day, which is the simplified form of **period** *sun* **to** *sat*. **time** *hh1:mm1* **to** *hh2:mm2*: Indicates the scheduling time period, and *hh1:mm1* and *hh2:mm2* indicate the start time and end time respectively in the unit of hours (ranging from 0 to 23) and minutes (ranging from 0 to 59). **time all-day**: Indicates that the session time range is a whole day, which is the simplified form of **time** *00:00* **to** *23:59*.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Applying a Scheduling Session

- Mandatory.
- The function must be applied to the AC where scheduling needs to be enabled.



Command	**schedule session** *session-id*
Parameter Description	*session-id*: Indicates the session ID. The value range is from 1 to 64 on an AC.
Defaults	By default, no scheduling session is configured. No scheduling session is applied to a WLAN or radio.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run **show running-config** to display the RF scheduling configuration.
- Check whether scheduling is still performed for a WLAN after a scheduling session expires.

Configuration Example

Providing WLAN Services to Customers in a Bank Only in the Daytime of Workdays

Scenario **Figure 1-4**	 As shown in the figure, the Fit AP architecture is used, and only one AC is applied. WLAN 99 is the customer-use WLAN, and the scheduling session ID is **wlan bank-free**. The APs include AP1, AP2, …, and AP*n*.
Configuration Steps	● Create a scheduling session on the AC. ● On the AC, specify the scheduling intervals as the nighttime of workdays and the whole weekends. ● On the AC, apply the scheduling session to WLAN 99.

AC	`Hostname# configure terminal`
	`Hostname(config)# schedule session 1`
	`Hostname(config)# schedule session 1 time-range 1 period mon to fri time 18:00 to 9:00`
	`Hostname(config)# schedule session 1 time-range 2 period sat to sun time 00:00 to 23:59`
	`Hostname(config)# wlan-config 99`
	`Hostname(config-wlan)# schedule session 1`

Verification	● On the AC, run the **show running-config** command to display the configuration. ● Display the state of the WLAN in the scheduling interval. ● Display the state of the WLAN beyond the scheduling interval.

AC	`Hostname# show running-config`
	`.....`
	`schedule session 1`
	`schedule session 1 time-range 1 period mon to fri time 18:00 to 9:00`
	`schedule session 1 time-range 2 period sat to sun time 00:00 to 23:59`
	`.....`
	`wlan-config 99 wlan-bank-free`

	…… schedule session 1 ……

Common Errors

- No scheduling session is created.
- The interval of the scheduling session is incorrectly configured.

1.5 Monitoring

Displaying

Command	Description
show schedule session [*session-id*]	Display the scheduling session configuration.

1 Configuring RRM

1.1 Overview

Radio resource management (RRM) is used on an access controller (AC) for managing radio resources of access points (APs).

RRM analyzes peripheral radio environments and adjusts the radio channel and power of APs based on specific algorithms to prevent signal interference between APs and ensure proper running of the wireless network.

When an AP has strong interference due to a complex radio environment, enabling RRM can improve user experience.

1.2 Features

Basic Concepts

STA, AP, and AC

- Station (STA): Is a device equipped with wireless network interface cards (NICs), for example, portable computer or mobile phone
- AP: Provides wireless signal access for STAs.
- AC: Manages APs and provides wireless network services.

RF Environment Information

- STA information: Includes the received signal strength indicator (RSSI) and signal-to-noise ratio (SNR) of STAs.
- Neighbor information: Includes the RSSI and working channels of neighboring APs.
- Noise: Indicates the noise value that affects 802.11 signal receiving, in dBm.
- Interference(%): Includes 802.11 signal interference and non-802.11 signal interference. The former indicates signal interference from other APs, and the latter indicates interference from other devices such as microwave ovens and Bluetooth devices.

Co-channel Interference

When two closely deployed APs work in the same channel, co-channel interference occurs, affecting 802.11 wireless packet receiving.

Overview

Feature	Description
Channel Adjustment	Based on the peripheral radio environment, the AC allocates a proper working channel to an AP to reduce co-channel interference and improve wireless access experience of users.
Power Control	When APs are closely deployed and the transmit power of an AP is high, the rest APs may be affected. Therefore, the transmit power of the AP needs to be lowered to reduce interference.
Automatic Coverage Hole Filling	When an AP is offline due to breakdown, the AC selects neighboring APs of the AP based on the neighbor relationship to increase the power and enlarge the coverage scope, so as to eliminate the signal coverage hole caused by the faulty AP.

To perform RRM 2.0 channel adjustment and power control, APs need to support RRM 1.0 or RRM 2.0. Channel adjustment and power control are supported for APs that support RRM 1.0 after they interwork with ACs that support RRM 2.0. However, scanning results reported by APs are limited. When multiple interference signals exist (for example, interference from private APs), the adjustment effect may be affected.

To display RRM versions supported by online APs, run the **show rrm support** command on the AC.

1.2.1 Channel Adjustment

From the perspective of an AP, channel adjustment prevents the AP from serious interference in a working channel.

From the perspective of the global radio environment, proper channel allocation to each AP reduces interference between APs and improves the spectrum resource utilization and user experience.

Working Principle

When two closely deployed APs work in the same channel, a wireless signal conflict or interference occurs, affecting wireless user experience.

The ADCA algorithm comprehensively analyzes various environment factors and allocates the optimized working channels to all APs, preventing channel conflicts.

For example, if two APs work in the same channel or two channels with overlapping spectrum resources, the ADCA algorithm will reallocate non-overlapping channels to optimize spectrum resources.

1.2.2 Power Control

Power control is used to lower the transmit power of an AP to reduce signal interference between APs.

Working Principle

When an AP is powered on for the first time, it uses the allowed maximum transmit power according to national or regional regulations. A higher transmit power indicates a larger signal coverage. If signal coverage of adjacent APs overlaps and the APs are in the same frequency band, strong co-channel interference exists. The Automatic Transfer Power Control (ATPC) algorithm determines whether to increase or reduce the transmit power of an AP based on neighbor information of the AP. When co-channel interference between APs is strong and overlapping channels cannot be avoided, the transmit power of APs needs to be lowered to reduce co-channel interference. If there is no co-channel interference between APs, increase the transmit power to expand the signal coverage area.

If both channel adjustment and power control are enabled, RRM 2.0 preferentially adjusts the channel and then the power. If overlapping channels can be avoided, the transmit power does not need to be lowered. Therefore, the ATPC algorithm is executed following the ADCA algorithm.

1.2.3 Automatic Coverage Hole Filling

After automatic coverage hole filling is enabled, if an AP is offline due to breakdown, the AC selects neighboring APs of the AP based on the neighbor relationship to increase the power and enlarge the coverage scope, so as to eliminate the signal coverage hole caused by the faulty AP.

Working Principle

When this function is enabled or network optimization is conducted on an AP through RRM, the neighbor relationship of the AP is recorded. When an AP goes offline abnormally, the AC selects neighboring APs of the AP to increase the power and enlarge the coverage scope, so as to eliminate the signal coverage hole caused by the offline AP. After the AP is restored and goes online, the AC reduces the increased power of the neighboring APs to their original power and reduce their coverage scope.

1.3 Configuration

Configuration	Description and Command	
Configuring Channel Adjustment	(Optional) It is used to configure channel adjustment parameters.	
	rrm [**2.4g** | **5g** | **6g**] **mode enable**	Enables automatic radio adjustment for newly deployed APs.
	rrm [**2.4g** | **5g** | **6g**] **channel dynamic enable**	Enables dynamic channel adjustment.
	rrm [**2.4g** | **5g** | **6g**] **channel bandwidth** { **current** | **optimal** | { **appoint 20** | **40** | **80** | **160** } }	Selects the channel bandwidth policy during channel adjustment.
	rrm [**2.4g** | **5g** | **6g**] **update** [**ap-group** *group-name*] **channel**	Manually enables channel planning.
	rrm [**2.4g** | **5g** | **6g**] **appoint** *date time* [**ap-group** *group-name*]	Reserves the time to adjust the channel and power for all online APs.
Configuring Power Control	(Optional) It is used to configure parameters related to power control.	
	rrm [**2.4g** | **5g** | **6g**] **mode enable**	Enables automatic RF adjustment for newly deployed APs.
	rrm [**2.4g** | **5g** | **6g**] **update** [**ap-group** *group-name*] **txpower**	Manually enables power planning.
	rrm [**2.4g** | **5g** | **6g**] **appoint** *date time* [**ap-group** *group-name*]	Reserves the time to adjust the channel and power for all online APs.
Enabling Automatic Coverage Hole Filling	**rrm** [**2.4g** | **5g** | **6g**] **blind enable**	Enables automatic coverage hole filling.
	rrm [**2.4g** | **5g** | **6g**] **scan** [**ap-group** *group-name*]	Configures scanning to obtain neighbor information.

1.3.1 Configuring Channel Adjustment

Configuration Effect

- After channel adjustment is enabled, the AC allocates proper working channels to APs based on their radio environments to improve the wireless network experience.

Configuration Steps

Configuring Channel Adjustment

- Optional. To enable the AC to allocate proper working channels to APs, configure the channel adjustment function.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **mode enable** command to enable automatic channel adjustment for newly deployed APs.
- Run the **rrm** [**2.4g | 5g** | **6g**] **channel bandwidth** { **current** | **optimal** | { **appoint 20** | **40** | **80** | **160** } } command to configure a channel bandwidth policy.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **channel dynamic enable** command to enable dynamic channel adjustment.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **update** [**ap-group** *group-name*] **channel** command to enable channel planning for online APs within the specified range.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **appoint** *date time* [**ap-group** *group-name*] command to reserve a time to adjust the channel and power for online APs within the specified range.

Command	**rrm** [**2.4g**	**5g**	**6g**] **mode enable**
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network.
Defaults	Automatic power adjustment is disabled for newly deployed APs on all frequency bands by default.
Command Mode	Global configuration mode or AP group configuration mode
Usage Guide	● When a newly deployed AP goes online, radio adjustment is performed for the AP. The original configuration is retained for existing APs when they go online. ● If no frequency band is specified, the configuration takes effect on all frequency bands. ● If the function is configured in global configuration mode, it will take effect globally. If the function is configured in AP group configuration mode, it will only take effect for the AP group. The configuration in AP group configuration mode takes precedence over that in global configuration mode. ● The channel and power of newly deployed APs in the same range and frequency band are adjusted simultaneously. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Command	**rrm** [**2.4g**	**5g**	**6g**] **channel bandwidth** { **current**	**optimal**	{ **appoint 20**	**40**	**80**	**160** } }
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network.

	current: Indicates that the current channel bandwidth configuration is selected during channel planning. **optimal**: Indicates that the channel bandwidth configuration is selected automatically during channel planning. **appoint:** Specifies the channel width configuration. Except the 2.4 GHz radio, the available channel width for other radios includes 20 MHz, 40 MHz, 80 MHz, and 160 MHz.
Defaults	The optimal channel bandwidth policy is configured for all frequency bands by default.
Command Mode	Global configuration mode
Usage Guide	1. The channel bandwidth configuration is selected automatically based on radio types of APs and effective channel ranges. The selection rules are as follows: (1) Use 20 MHz channel width for the 2.4 GHz frequency band. (2) Use 40 MHz channel width for the 5 GHz frequency band without channel limitations. (3) Use 40 MHz channel width for radios that are limited to channels 36 to 64. (4) Use 20 MHz channel width for radios that are limited to channels 149 to 165. (5) Use 20 MHz channel width for the 5G radio of the i-Share+ AP. (6) Use 80 MHz channel width for the 6G radio. 2. If no frequency band is specified, the configuration takes effect on all frequency bands. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Command	**rrm** [**2.4g** | **5g** | **6g**] **channel dynamic enable**
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network.
Defaults	Dynamic channel adjustment is disabled for all frequency bands by default.
Command Mode	Global configuration mode or AP group configuration mode
Usage Guide	1. When dynamic channel adjustment is enabled, RRM 2.0 checks channel interference of APs every 5 minutes. If the channel interference exceeds the threshold, RRM 2.0 triggers channel adjustment for the APs. 2. The adjusted channel configuration will overwrite original channel and channel bandwidth configuration (when the optimal policy is selected) of APs in AP configuration mode. In addition, STAs may be disconnected due to channel switching during adjustment. 3. If no frequency band is specified, the configuration takes effect on all frequency bands. 4. If the function is configured in global configuration mode, it will take effect globally. If the function is configured in AP group configuration mode, it will only take effect for the AP group. The configuration in AP group configuration mode takes precedence over that in global configuration mode. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Command	**rrm** [**2.4g** | **5g** | **6g**] **update** [**ap-group** *group-name*] **channel**
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network. *group-name*: Performs RF adjustment for the specified AP group. **channel**: Enables automatic channel adjustment for APs.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	1. If no frequency band is specified, the configuration takes effect on all frequency bands. 2. If **ap-group** is not configured, RF planning is performed for online APs on the entire network. Otherwise, it is performed only for online APs in the AP group. 3. If **channel** is configured, only the channel and bandwidth (when the optimal policy is selected) of APs are planned and the power configuration remains unchanged. 4. After adjustment is completed, automatic radio adjustment is enabled for newly deployed APs in the corresponding frequency band automatically. If **ap-group** is not configured, automatic radio adjustment is enabled on the entire network. Otherwise, it will only be enabled for online APs in the AP group. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Command	**rrm** [**2.4g** | **5g** | **6g**] **appoint** *date time* [**ap-group** *group-name*]
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network. *date*: Specifies the reservation date, in the format of yyyy-mm-dd. *time*: Specifies the reservation time, in the format of hh:mm:ss. *group-name*: Reserves radio adjustment for online APs in the specified AP group.
Defaults	By default, no reservation time is set.
Command Mode	Global configuration mode
Usage Guide	1. If the reservation time is configured, the AC will adjust the channel and power for online APs in a specific frequency band and range at the specified time. 2. If no frequency band is specified, the configuration takes effect on all frequency bands. 3. If **ap-group** is not configured, the AC will adjust the channel and power for online APs on the entire network. Otherwise, the AC will adjust the channel and power for online APs in the specified AP group. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Verification

- Run the **show rrm** [**2.4g** | **5g** | **6g**] **summary** command to display the channel adjustment status.
- Run the **show ap-config summary** command to display channel adjustment results of APs.

Configuration Example

Configuring Channel Adjustment Parameters

Configuration Steps	Enable automatic channel planning for newly deployed APs on the entire network.

AC	`Hostname# configure terminal`
	`Hostname(config)# rrm mode enable`
	`Hostname(config)# exit`

Verification	Display the channel adjustment status.

AC	`Hostname# show rrm 2.4g summary`
	`Radio Resource Management`
	`Radio Type..... 2.4G`
	`RRM Enable Mode..... Enable`
	`Channel Width Strategy..... Optimal`
	`Channel Dynamic Enable Mode..... Enable`
	`Run Status..... Finish`

1.3.2 Configuring Power Control

Configuration Effect

- After power control is enabled, the AC configures the transmit power for APs based on their radio environments to reduce co-channel interference between the APs.

Notes

- Power control is used to reduce co-channel interference of an AP to other APs. The ATPC algorithm needs to obtain the co-channel interference from other APs to determine whether to control the power.

Configuration Steps

Configuring Power Control

- Optional. To control APs' transmit power to prevent co-channel interference between APs, configure the power control function.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **mode enable** command to enable automatic power adjustment for newly deployed APs.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **update** [**ap-group** *group-name*] **txpower** command to manually enable power adjustment for online APs within the specified range.

- Run the **rrm** [**2.4g** | **5g** | **6g**] **appoint** *date time* [**ap-group** *group-name*] command to reserve a time to adjust the channel and power for online APs within the specified range.

Command	**rrm** [**2.4g** | **5g** | **6g**] **mode enable**
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network.
Defaults	By default, automatic power adjustment is disabled.
Command Mode	Global configuration mode or AP group configuration mode
Usage Guide	1. When a newly deployed AP goes online, RF adjustment is performed for the AP. The original configuration is retained for existing APs when they go online. 2. If no frequency band is specified, the configuration takes effect on all frequency bands. 3. If the function is configured in global configuration mode, it will take effect globally. If the function is configured in AP group configuration mode, it will only take effect for the AP group. The configuration in AP group configuration mode takes precedence over that in global configuration mode. 4. The channel and power of newly deployed APs in the same range and frequency band are adjusted simultaneously. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Command	**rrm** [**2.4g** | **5g** | **6g**] **update** [**ap-group** *group-name*] **txpower**
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network. *group-name*: Performs RF adjustment for online APs in the specified AP group.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	1. If no frequency band is specified, the configuration takes effect on all frequency bands. 2. If **ap-group** is not configured, radio adjustment is performed for online APs on the entire network. Otherwise, radio adjustment is performed for only online APs in the specified AP group. 3. If **channel** is configured, only the channel and bandwidth (when the optimal policy is selected) of APs are planned and the power configuration remains unchanged. If **txpower** is configured, only the power of the APs is planned and the channel and bandwidth configurations remain unchanged. If **channel** or **txpower** is not configured, the channel and bandwidth (when the optimal policy is selected) as well as the power of APs are planned. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Command	**rrm** [**2.4g** | **5g** | **6g**] **appoint** *date time* [**ap-group** *group-name*]
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. **6g**: Indicates the 6 GHz network. *date*: Specifies the reservation date, in the format of yyyy-mm-dd. *time*: Specifies the reservation time, in the format of hh:mm:ss. *group-name*: Reserves RF adjustment for a specified AP group.
Defaults	By default, no reservation time is set.
Command Mode	Global configuration mode
Usage Guide	1. If the reservation time is configured, RRM 2.0 will adjust the channel and power for online APs in a specific frequency band and range at the specified time. 2. If no frequency band is specified, the configuration takes effect on all frequency bands. 3. If **ap-group** is not configured, the AC will adjust the channel and power for online APs on the entire network. Otherwise, the AC will adjust the channel and power for online APs in the specified AP group. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Verification

- Run the **show rrm** [**2.4g** | **5g** | **6g**] **summary** command to display the power adjustment status.
- Run the **show ap-config summary** command to display channel adjustment results of APs.

Configuration Example

Configuring Power Control Parameters

Configuration Steps	Enable the power adjustment function on the entire network.

AC	`Hostname# configure terminal`
	`Hostname(config)# rrm mode enable`
	`Hostname(config)# exit`

Verification	Display the power control status.

AC	`Hostname# show rrm 2.4g summary`
	`Radio Resource Management`
	`Radio Type..... 2.4G`
	`RRM Enable Mode..... Enable`
	`Channel Width Strategy..... Optimal`
	`Channel Dynamic Enable Mode..... Enable`

	Run Status..... Finish

1.3.3 Enabling Automatic Coverage Hole Filling

Configuration Effect

After the coverage hole filling function is enabled, when an AP goes offline abnormally, the AC selects neighboring APs of the AP to increase the power and enlarge the coverage scope, so as to eliminate the signal coverage hole caused by the offline AP. After the AP is restored and goes online, the AC reduces the increased power of the neighboring APs to their original power and reduce their coverage scope.

Notes

Ensure that other APs are deployed around an abnormal AP, and they work in the same frequency band as the abnormal AP.

Configuration Steps

↘ Enabling Automatic Coverage Hole Filling

- Optional. To ensure high reliability of a wireless network, configure coverage hole filling.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **blind enable** command to enable coverage hole filling.
- Run the **rrm** [**2.4g** | **5g** | **6g**] **scan** [**ap-group group-name**] command to issue a scanning request to radios in a specified band or AP group.

Command	**rrm** [**2.4g** | **5g** | **6g**] **blind enable**
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network.
Defaults	By default, automatic coverage hole filling is disabled.
Command Mode	Global configuration mode or AP group configuration mode
Usage Guide	1. If no frequency band is specified, the configuration takes effect on all frequency bands. 2. If the function is configured in global configuration mode, it will take effect globally. If the function is configured in AP group configuration mode, it will only take effect for the AP group. The configuration in AP group configuration mode takes precedence over that in global configuration mode. After the APs are offline, there are two prerequisites for improving the effect of coverage hole filling of neighboring APs: (1) Other APs are deployed around the AP and they operate in the same frequency band. (2) The power configuration value of neighboring APs is less than 100%. 3. To maximize the networking experience, you are advised to enable automatic coverage hole filling in the following two scenarios: (1) When network-wide APs are online, you are advised to configure channel adjustment and power control to optimize the wireless network once, and then enable automatic coverage hole filling.

(2) You can also conduct network optimization manually or by using the WIS. Then, enable the automatic coverage hole filling and run the **rrm scan** command to scan the neighbor relationship of an AP.

4. Re-scanning is required when the AP goes online for the first time, the AP location is changed, or the AP RF band is changed.
5. Do not adjust the AP power randomly after automatic coverage hole filling takes effect. If the AP power must be adjusted, re-enable automatic coverage hole filling after adjustment.

⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Command	**rrm** [**2.4g** | **5g** | **6g**] **scan** [**ap-group** *group-name*]
Parameter Description	**2.4g**: Indicates the 2.4 GHz network. **5g**: Indicates the 5 GHz network. *group-name:* Conducts radio adjustment for a specified AP group.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	1. If no frequency band is specified, the configuration takes effect on all frequency bands. 2. If **ap-group** is not configured, scanning is performed on RF interfaces of online APs on the entire network. Otherwise, scanning is only conducted on online APs in that AP group. 3. After scanning is triggered, it takes some time for RF interfaces of APs to conduct scanning. You can run the **show rrm neighbor** command to display the acquired neighbor information about the AP. 4. Re-scanning is required when the AP goes online for the first time, the AP location is changed, or the AP RF band is changed. ⚠ Support for the 6 GHz frequency band depends on local rules and regulations in different countries and regions. In countries and regions where the 6 GHz frequency band is not supported, 6 GHz signals are unavailable even if related commands are executed.

Verification

- Run the **show rrm** [**2.4g** | **5g** | **6g**] **summary** command to display the status of the coverage hole filling function.
- Run the **show rrm** [**2.4g** | **5g** | **6g**] **neighbor** command to display information about neighbors of an online AP.

Configuration Example

↘ Enabling Coverage Hole Filling

Configuration	Enable automatic coverage hole filling on the entire network.

Steps

AC

```
Hostname# configure terminal
Hostname(config)# rrm blind enable
Hostname(config)# exit
```

Verification Display the channel adjustment status.

AC

```
Hostname# show rrm 2.4g summary
Radio Resource Management
  Radio Type.....  2.4G
  RRM Enable Mode.....  Enable
  Channel Width Strategy.....  Optimal
  Channel Dynamic Enable Mode.....  Enable
  Blind Mode.....  Enable
  Run Status.....  Finish
```

Triggering Scanning

Configuration Steps Enable automatic coverage hole filling on the entire network.

AC

```
Hostname# configure terminal
Hostname(config)# rrm scan
Hostname(config)# exit
```

Verification Display the channel adjustment status.

AC

```
Hostname# show rrm 2.4g neighbor
AP Neighbors ------------------------ 2.4G

1.4 Monitoring

Displaying

Command	Description
show rrm [**2.4g** | **5g** | **6g**] **summary**	Displays basic RRM configuration.
show rrm support	Displays RRM versions supported by online APs.
show rrm [**2.4g** | **5g** | **6g**] **neighbor**	Displays the information about neighbors of an AP.

1 Configuring 802.11kv

1.1 Overview

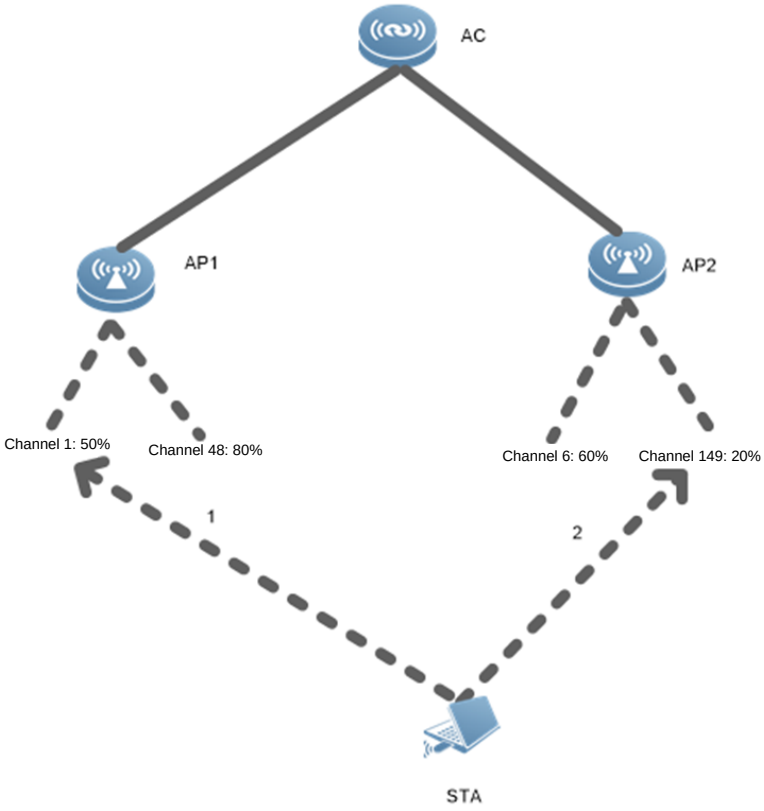
The 802.11k protocol revises radio resource measurement (RRM) of the 802.11 protocol, which enables access points (APs) and stations (STAs) to obtain RRM data of each other. The 802.11v protocol revised wireless network management (WNM) of the 802.11 protocol. The 802.11k or 802.11v protocol enables access controllers (ACs) to manage wireless network resources better and supports the load balancing function.

On wireless networks, STAs are often unable to proactively connect to low-utilization channels, centrally connect to an AP, or have poor STA signals because they are unable to detect the load of APs. 802.11kv can help realize load balancing, including channel load balancing and load balancing between radios. With the increasing mobile office scenarios, there are higher roaming requirements of STAs. To minimize the impact of 802.11k on STA services and enable immediate switching with 802.11v, the AI radio-based devices have added the roaming enhancement function. This guides STAs to switch to APs with better signals when the signal quality is poor, thereby improving STA service experience and wireless channel performance.

Protocols and Standards

- IEEE 802.11k-2008: Amendment 1: Radio Resource Measurement of Wireless LANs
- IEEE 802.11v-2011: Amendment 8: IEEE 802.11 Wireless Network Management

1.2 Applications



Application	Description
Channel Utilization Balancing	Uses Fit AP networking with at least one AC and two APs.
STA Balancing Between Radios	Uses Fit AP networking with at least one AC and two APs.
Guided Roaming for STAs with the Poor Signal Quality	Uses Fit AP networking with at least one AC and two APs. The 802.11v-based guided roaming is applied to STAs of associated APs that support 802.11v and enter areas with poor signal quality.

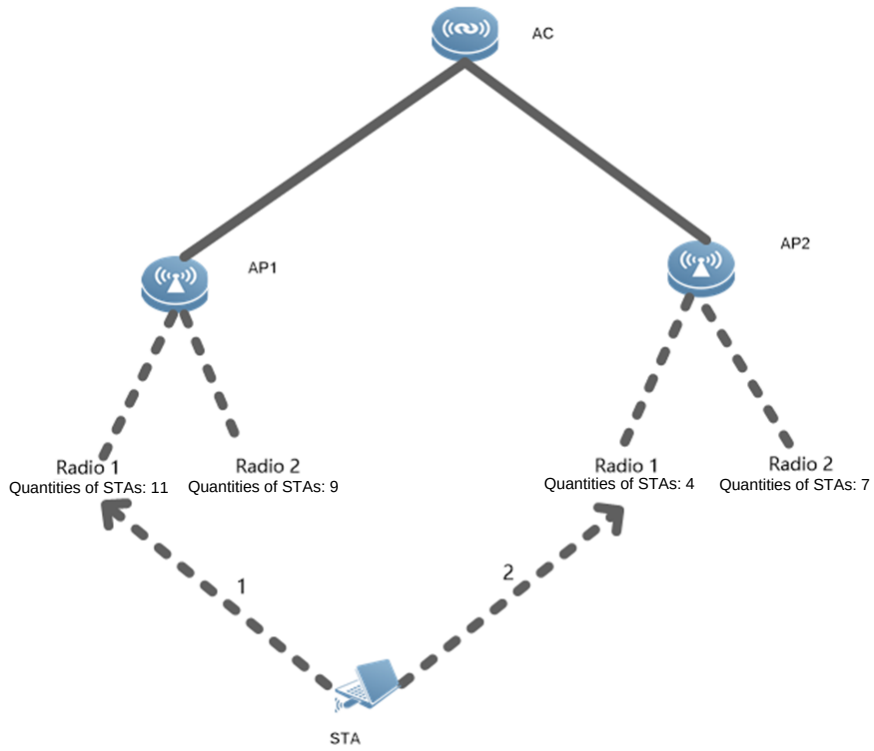
1.2.1 Channel Utilization Balancing

Scenarios

On a wireless network, especially in high-density STA deployment scenarios, channel utilization is unbalanced due to various reasons. Because STAs cannot detect channel utilization, they may select a channel with the higher utilization. Therefore, channel utilization balancing is required to migrate STAs to channels with low utilization within 2s to 10s after STAs go online, to improve user experience.

Figure 1-1

Deployment



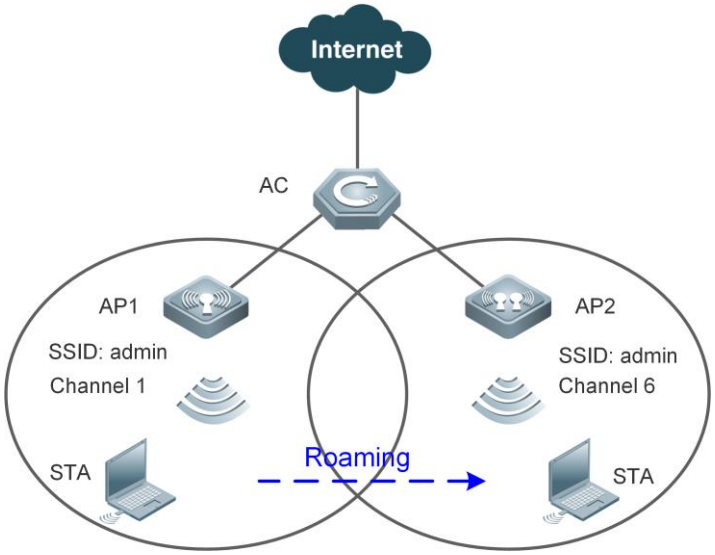
- Set the load balancing mode to channel utilization balancing on the AC.
- Set load balancing parameters on the AC.

1.2.2 STA Balancing Between Radios

Scenarios

When APs are deployed densely, multiple STAs may connect to the same AP. As a result, STA quantities on APs are unbalanced.

Figure 1-2



Deployment

- Set the load balancing mode to STA quantity balancing between radios on the AC.
- Set parameters of STA quantity balancing between radios on the AC.

1.2.3 Guided Roaming for STAs with the Poor Signal Quality

Scenario

On a wireless network, some STAs may have poor roaming aggressiveness, meaning they stay connected to their initially associated AP even when they are far away from the AP, experiencing weak signals, low communication rates, and high channel utilization of the AP. These STAs do not proactively roam to closer APs with stronger signals and lower channel utilization. To address this issue, introduce guided roaming for these STAs when 802.11v is supported, to improve the STAs' user experience and overall wireless channel performance.

Deployment

- Select the sensitivity of the roaming enhancement mode on the AC.
- Conduct 802.11v-based guided roaming for STAs with the poor signal quality on the AC based on the roaming sensitivity.

1.3 Features

Basic Concepts

Channel Utilization

Channel utilization is an important indicator that affects the STA connection quality. In scenarios where there are high levels of service traffic, a large number of connected STAs, or strong RF interference, the channel utilization of APs may be high. When a STA associates with a wireless network, it typically selects the strongest signal from multiple BSSIDs with the same Wi-Fi name. However, the strongest signal may come from an AP with high channel utilization.

Overview

Feature	Description
802.11kv-based Load Balancing	Improves the STA connection quality and balances the AP load.
802.11kv-based Guided Roaming	Steers STAs with the poor signal quality to connect to an AP with stronger signals.

1.3.1 802.11kv-based Load Balancing

Load balancing can steer STAs to evenly distribute themselves across different channels or RF interfaces when accessing Wi-Fi signals, in order to achieve better connectivity experience.

Working Principle

When a STA that supports the 802.11k protocol associates with an AC, the AC can obtain an available BSSID list from the STA in real time. Each BSSID is accompanied by a signal strength value. If the STA does not support the 802.11k protocol, the available BSSID list is obtained through probe frames from the STA.

When 802.11kv-based load balancing is enabled, the following two scenarios may occur:

1. Channel utilization balancing

If a STA is on a channel with 70% or higher utilization, the AC selects a BSSID from the available BSSID list that has 20% less channel utilization than the current channel and the highest signal strength of no less than –63 dBm. The AC then steers the STA to switch to this new BSSID, which balances channel utilization.

2. Load balancing between radios

If the number of STAs on the current radio is greater than 10, the AC selects a BSSID from the available BSSID list with five fewer STAs than the current channel and the highest signal strength of no less than –63 dBm. The AC then steers the STA to switch to this BSSID, achieving radio load balancing.

1.3.2 802.11kv-based Guided Roaming

Guided roaming can guide poorly performing STAs to switch to better APs through BSTM packets sent by APs through 802.11v. This is particularly helpful when STAs do not roam automatically or promptly, resulting in an enhanced STA service experience and improved wireless channel performance.

Working Principle

Based on BSSID information of neighboring APs reported by APs, the AC establishes a neighbor AP relationship table for each AP. When a STA moves away from the associated AP, the AP reports the STA's RSSI, association rate, channel utilization, and other information to the AC periodically. The AC processes the reported information and determines whether the STA is in an area with the poor signal quality.

When the STA is in an area with the poor signal quality, the AC distributes the STA information to neighboring APs of the associated AP. The neighboring APs start scanning the status of the STA through AI radio and report it to the AC. The AC selects multiple candidate APs suitable for the STA, generates an ordered list, and notifies the STA through BSTM packets. The STA detects the candidate APs based on its own strategy and switches to a suitable AP after finding one.

1.4 Configuration

Configuration	Description and Command	
Configuring Channel Utilization Balancing	(Optional) It is used to enable 802.11kv interaction.	
	802.11kv enable	Enables 802.11k/802.11v.
Configuring STA Balancing Between Radios	(Mandatory) It is used to set the load balancing mode.	
	802.11kv load-balance mode channel-utilization	Sets the load balancing mode to channel utilization balancing.
	802.11kv load-balance mode station-number	Sets the load balancing mode to STA balancing between radios.
	802.11kv load-balance mode none	Disables load balancing.

Configuring Guided Roaming for STAs with the Poor Signal Quality	(Mandatory) It is used to set the load balancing mode.	
	802.11kv roam-e mode disable	Disables the roaming enhancement mode.
	802.11kv roam-e mode sensitivity-high	Configures the high roaming sensitivity, indicating that it is easier to trigger the roaming function. This is suitable for scenarios with high requirements for roaming experience, such as situations where the STA has low receive and transmit sensitivity.
	802.11kv roam-e mode sensitivity-middle	Configures the medium roaming sensitivity, which is the default configuration mode (recommended).
	802.11kv roam-e mode sensitivity-low	Configures the low roaming sensitivity, meaning that it is less likely to trigger the roaming enhancement function. This is suitable for scenarios where roaming requirements are not high but STA's tendency to stick to a particular AP during association needs to be minimized.

1.4.1 Configuring Channel Utilization Balancing

Configuration Effect

When a STA that supports the 802.11v protocol connects to the wireless network, if the channel corresponding to the RF interface has a utilization higher than the preset value and another channel with lower utilization is available (the difference value is lower than the preset gain value), the STA will be migrated to the available channel.

Notes

- Load balancing takes effect only for the STAs that support 802.11k and 802.11v.
- If most STAs do not support 802.11k, roaming stickiness can be enabled for the corresponding AP group. This function is used to learn probe frames sent before a STA is associated, to determine the STA location.

Configuration Steps

Enabling 802.11kv

- Mandatory.
- Run the **802.11kv enable** command to enable 802.11k and 802.11v interaction in global configuration mode on the AC.

Command	**802.11kv enable**
Parameter Description	N/A
Defaults	By default, 802.11k and 802.11v interaction is disabled.
Command	Global configuration mode

Mode	
Usage Guide	N/A

Configuring the Load Balancing Mode Based on Channel Utilization

- Mandatory.
- Configure 802.11kv load balancing based on channel utilization in global configuration mode on the AC.

Command	**802.11kv load-balance mode channel-utilization**
Parameter Description	N/A
Defaults	By default, load balancing is not performed.
Command Mode	Global configuration mode
Usage Guide	Channel utilization balancing is triggered when a STA is associated with a channel with the utilization equal to or greater than 70% and there are neighboring channels with the utilization 20% less than the associated channel.

Verification

- Run the **show running-config** command to display the load balancing configuration.

1.4.2 Configuring STA Balancing Between Radios

Configuration Effect

When a STA is associated with a radio on which the number of connected STAs is greater than or equal to the preset limit value and there is a neighboring radio on which the number of connected STAs is less than the preset limit value, the STA will be steered to associate with the neighboring radio.

Notes

Load balancing takes effect only for the STAs that support 802.11k and 802.11v.

Configuration Steps

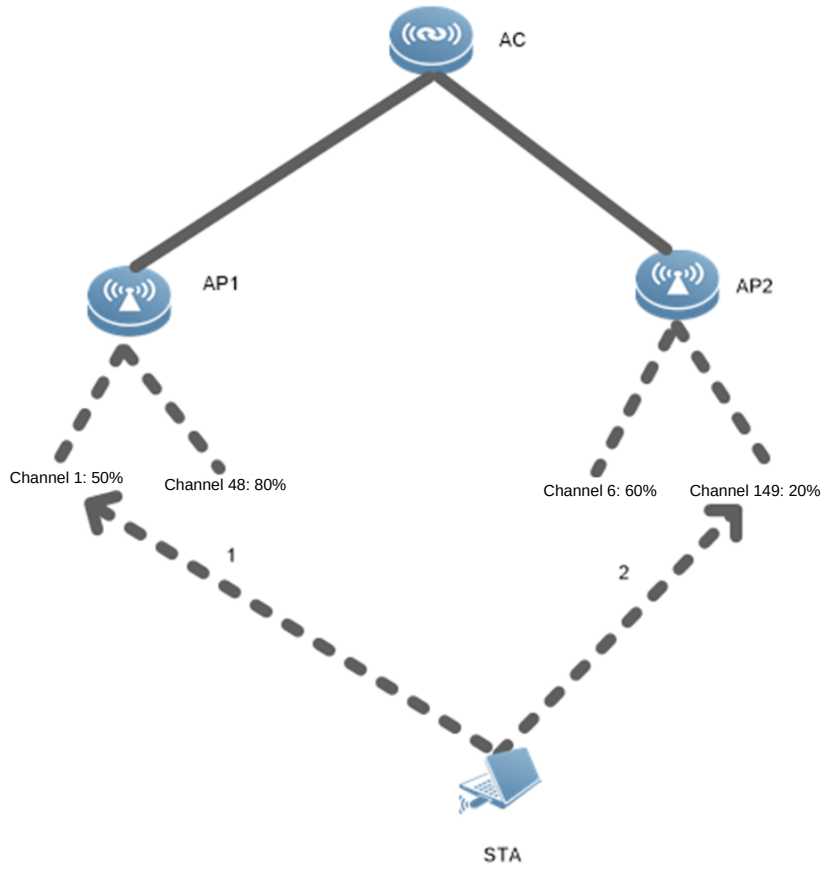
Configuring the Load Balancing Mode Based on the Number of STAs Between Radios

- Mandatory.
- Enable 802.11k and 802.11v interaction in global configuration mode on the AC.

Command	**802.11kv enable**
Parameter Description	N/A
Defaults	By default, 802.11k and 802.11v interaction is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Load Balancing Mode Based on the Number of STAs Between Radios

- Mandatory.
- Configure the 802.11kv load balancing mode based on the number of STAs between radios in global configuration mode on the AC.

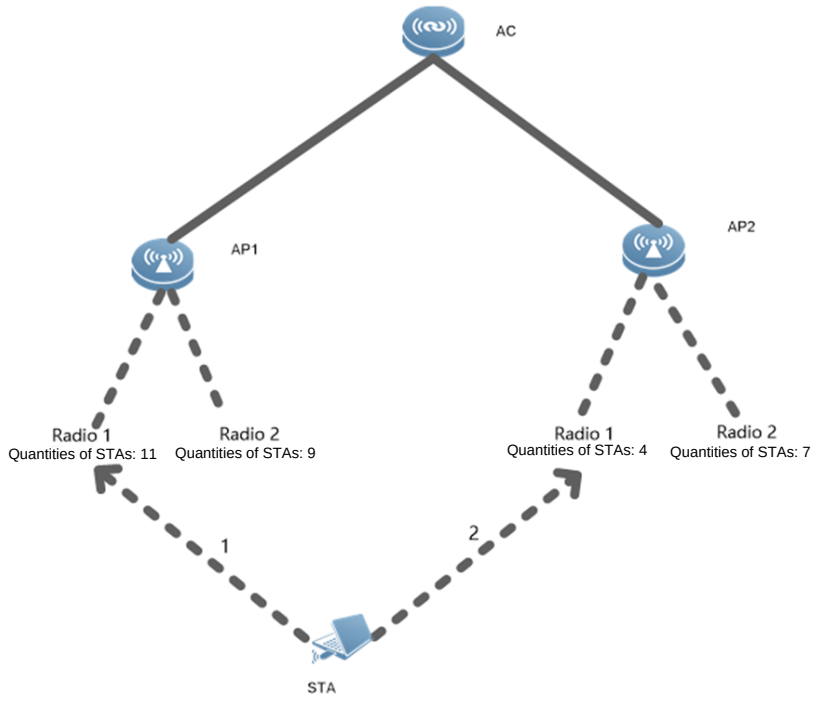


Command	**802.11kv load-balance mode station-number**
Parameter Description	N/A
Defaults	By default, load balancing is not performed.
Command Mode	Global configuration mode
Usage Guide	STA balancing between radios is triggered when a STA is associated with a radio on which the number of connected STAs is greater than 10 and there is a neighboring radio on which the number of connected STAs is less than 5.

Verification

Run the **show running-config** command to display the load balancing configuration.

Configuration Example



Configuring Channel Utilization Balancing

Scenario **Figure 1-3**	
Configuration Steps	Enable 802.11k and 802.11v interaction.

AC	`Hostname(config)# 802.11kv enable`
	Set the load balancing mode.
	`Hostname(config)# 802.11kv load-balance mode channel-utilization`
Verification	Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config | begin 802.11kv`
	`802.11kv enable`
	`802.11kv load-balance mode channel-utilization`

Configuring STA Balancing Between Radios

Scenario **Figure 1-4**	
Configuration Steps	Enable 802.11k and 802.11v interaction.
AC	`Hostname(config)# 802.11kv enable`
	Set the load balancing mode.
	`Hostname(config)# 802.11kv load-balance mode station-number`
Verification	Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config | begin 802.11kv`
	`802.11kv enable`
	`802.11kv load-balance mode station-number`

1.4.3 Configuring Guided Roaming for STAs with the Poor Signal Quality

Configuration Effect

For the STAs that support the 802.11v protocol, if they are associated with an AP and their signal quality falls into the poor signal quality interval, roaming enhancement can be introduced to steer the STAs to perform 802.11v-based roaming based on the configured roaming sensitivity. By doing so, the STAs can be associated with a better AP.

Notes

- Roaming enhancement only applies to the STAs that support 802.11v.
- Roaming enhancement is only supported on AR series APs.

Configuration Steps

Enabling 802.11kv

- Mandatory.
- Run the **802.11kv enable** command in global configuration mode on the AC.

Command	**802.11kv enable**
Parameter Description	N/A
Defaults	By default, 802.11k and 802.11v interaction is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Selecting the Sensitivity of the Roaming Enhancement Mode

- Mandatory.
- Run the **802.11kv roam-e mode** command in global configuration mode on the AC.

Command	**802.11kv roam-e mode** { **disable** | **sensitivity-high** | **sensitivity-low** | **sensitivity-middle** }
Parameter Description	**disable**: Disables the roaming enhancement mode. **sensitivity-high**: Sets the sensitivity of the roaming enhancement mode to high. **sensitivity-middle**: Sets the sensitivity of the roaming enhancement mode to medium. **sensitivity-low**: Sets the sensitivity of the roaming enhancement mode to low.
Defaults	The default mode is **sensitivity-middle**.
Command Mode	Global configuration mode
Usage Guide	1. When roaming enhancement is disabled, the AC will not execute roaming enhancement. Guided roaming will only be performed on STAs when roaming sensitivity is configured. 2. Layer 2 network connectivity between APs is required for using guided roaming.

Verification

Run the **show running-config** command to display 802.11kv-based association information.

1.5 Monitoring

Displaying

Command	Description
show 802.11kv all-bstms	Displays BSTM records sent by the AC to all STAs.
show 802.11kv bstms-per-station	Displays BSTM records sent by the AC to a specific STA.
show 802.11kv roam-e ap-info [*mac*]	Displays information about AR series APs under the AC.
show 802.11kv roam-e mode	Displays the roaming enhancement sensitivity configured on the AC.
show 802.11kv roam-e neighbor-ap [*mac*]	Displays information about neighboring APs of AR series APs on the AC.
show 802.11kv roam-e roam-station [*station-mac*]	Displays information about STAs that need to roam on the AC.
show 802.11kv roam-e roamed-station [*station-mac*]	Displays information about STAs that have already finished roaming on the AC.
show 802.11kv roam-e statistic	Displays statistics about roaming enhancement on the AC.

1 Configuring CorrectLink

1.1 Overview

CorrectLink provides an intelligent WLAN access solution to identify and guide access behaviors of stations (STAs), so that STAs can connect to access points (APs) with the optimal performance.

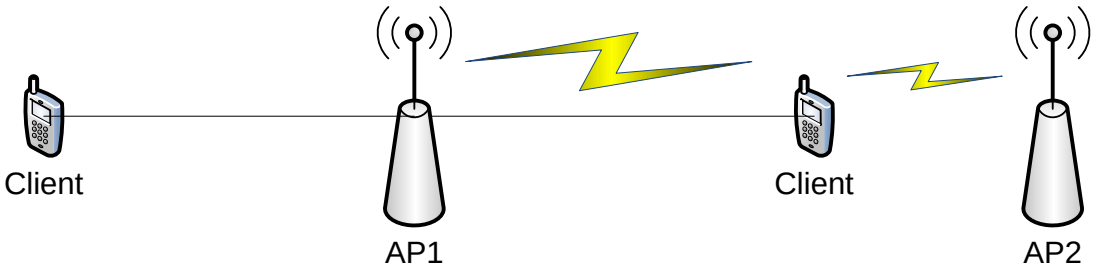
CorrectLink can perform guidance of 5 GHz preferred, remote association, and load balancing on STAs.

5 GHz preferred is to guide STAs with 5 GHz capabilities to associate with 5 GHz signals for better experience.

Remote association is to prevent STAs from associating with signals of low Received Signal Strength Indication (RSSI).

Load balancing is to make STAs connect to lower-load APs in the case of no remote association.

1.2 Applications



Application	Description
Remote Association	A STA is not connected to a near AP, but a far AP. In this case, the STA's uplink transmission rate is low with poor signals, resulting in poor wireless experience. Remote association can make the STA associate with a stronger-signal AP.
5 GHz Preferred	A dual-band STA does not select the 5 GHz frequency band, but the 2.4 GHz frequency band. The 2.4 GHz frequency band provides a small number of channels. It guarantees good user experience in idle time, but results in poor user experience in peak-load hours. 5 GHz preferred can guide STAs supporting 5 GHz to the 5 GHz frequency band.
Load Balancing	The excessive density of STAs is causing issues, restricting user experience due to access congestion. Even in an optimized network environment, where STAs are connected to the nearest APs and the 5 GHz frequency band is utilized, a high access density can compromise air interface service quality and ultimately impact the user experience.

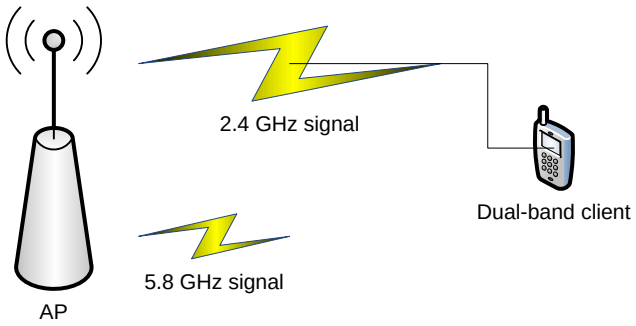
1.2.1 Remote Association

Scenario

As shown in the following figure, a STA is not connected to a near AP, but a far AP. In this case, the STA's uplink transmission rate is low with poor signals, resulting in poor wireless experience. Remote association can make the STA associate with a stronger-signal AP.

Figure 1-1

Deployment



- Enable CorrectLink to resolve remote association issues.

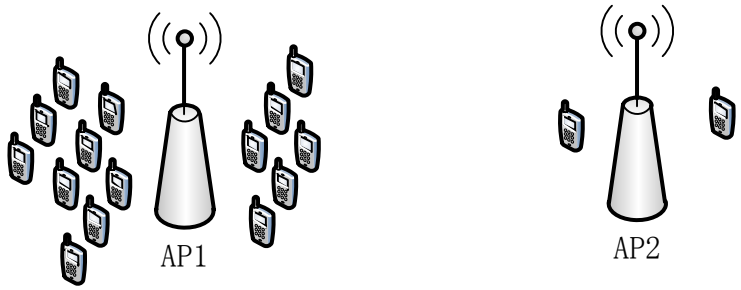
1.2.2 5 GHz Preferred

Scenario

As shown in the following figure, a dual-band STA does not select the 5 GHz frequency band, but the 2.4 GHz frequency band. The 2.4 GHz frequency band provides a small number of channels. It guarantees good user experience in idle time, but results in poor user experience in peak-load hours. 5 GHz preferred can steer STAs supporting 5 GHz to the 5 GHz frequency band.

Figure 1-2

Deployment



- Enable CorrectLink to resolve 5 GHz preferred issues.

1.2.3 Load Balancing

Scenario

As shown in the following figure, the distribution density of STAs is unmanageable, which is severely limiting their overall experience due to the high access density. Despite having optimal network optimization parameters and connecting to the nearest APs on the 5 GHz frequency band in a network environment, the air interface quality of service may suffer greatly from such high access density, causing a detrimental impact on the overall user experience.

Figure 1-3

Deployment

- Enable CorrectLink to resolve load balancing issues.

1.3 Features

Basic Concepts

CorrectLink

CorrectLink steers STAs to achieve optimal access, and provides functions of remote association, 5 GHz preferred, and load balancing.

Overview

Feature	Description
CorrectLink	Steers clients to achieve optimal access.

1.3.1 CorrectLink

During client access, perform guidance of remote association, 5 GHz preferred, and load balancing on clients, so that the clients achieve the optimal access state.

Working Principle

The AC determines whether a STA accesses the optimal AP based on the information detected during STA association and CorrectLink rules. If the STA fails to access the optimal AP, the AC steers the STA.

Access guidance rules:

If the difference between the detected RSSI of the AP and the highest RSSI is less than 10 dBm (default value), the set of APs is called an APset. If the load of an AP included in the APset is five (default value) fewer than that of the connected AP, a Cset exists.

If the connected AP does not belong to the APset, the STA cannot access the AP.

If the connected AP belongs to the APset but the Cset is not null, the STA cannot access the AP.

If the connected AP belongs to the APset and the Cset is null, the STA can access the AP.

1.4 Configuration

Configuration	Description and Command	
Configuring CorrectLink	(Optional) It is used to steer client access.	
	clink enable	Enables CorrectLink.
	clink rssi-delta-threshold	Configures the remote association RSSI difference threshold of CorrectLink.
	clink lb-client-threshold	Configures the load balancing determination threshold of CorrectLink.
	clink lb-client-delta-threshold	Configures the load balancing difference threshold of CorrectLink.
	clink bandsel-5g-rssi-threshold	Configures the 5G preferred RSSI threshold of CorrectLink.
	clink bandsel-5g-client-threshold	Configures the 5 GHz preferred load threshold of CorrectLink.
	clink max-fails	Configures the rate-limiting attempt threshold of CorrectLink.

1.4.1 Configuring CorrectLink

Configuration Effect

- Enable CorrectLink to identify and steer STAs based on CorrectLink rules.

Notes

- If APs in an area belong to different ACs and do not join the virtual AC group, CorrectLink takes effect only between APs connected to the same AC, but not across ACs. That is, CorrectLink ensures only STA steering between APs connected to the same AC.
- If CorrectLink is configured only on some AP groups, it takes effect only between APs in these AP groups. CorrectLink does not guarantee STA steering on the entire network.

Configuring CorrectLink

Enable CorrectLink in global configuration mode or AP group configuration mode.

Command	**clink enable**
Parameter Description	N/A
Defaults	Disabled
Command Mode	Global configuration mode or AP group configuration mode
Usage Guide	• When this function takes effect in global configuration mode, it is applied to all AP groups. • When configuring a single AP group, run the **show running** command to display the configuration of the AP group.

	When the function is configured in global configuration mode, it cannot be configured on a single AP group. If you need to configure the function on a single AP group, first disable the function globally.

Configuring the Remote Association RSSI Difference Threshold of CorrectLink

When the difference between the uplink associated RSSI of the client and the detected highest RSSI is greater than the configured remote association RSSI difference threshold, the STA is a remote one and cannot access the AP.

Command	**clink rssi-delta-threshold** *thrd*
Parameter Description	*thrd*: Indicates the remote association RSSI difference threshold. The value range is from 1 to 100.
Defaults	10
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Load Balancing Determination Threshold of CorrectLink

With load balancing enabled, when the load of STAs associated with the AP exceeds the load balancing determination threshold, the AC determines whether to perform load balancing.

Command	**clink lb-client-threshold** *thrd*
Parameter Description	*thrd*: Indicates the STA access threshold for dynamic load balancing. The value range is from 1 to 100.
Defaults	30
Command Mode	Global configuration mode
Usage Guide	The AC determines whether to perform load balancing when the number of STAs associated with an AP exceeds the configured load balancing threshold.

Configuring the Load Balancing Difference Threshold of CorrectLink

When a STA detects APs, if the difference between an AP's RSSI and the detected highest RSSI is less than the remote association RSSI threshold, the set of these APs is called an APset.

Command	**clink lb-client-delta-threshold** *thrd*
Parameter Description	*thrd*: Indicates the load balancing difference threshold. The value range is from 1 to 100.
Defaults	5
Command Mode	Global configuration mode
Usage Guide	Once the load balancing difference threshold is set, if the number of STAs associated with an AP surpasses the load balancing threshold and there is an APset containing an AP not currently linked to the STA, with fewer STAs connected to it compared to the current AP by at least the specified load balancing difference threshold, an imbalance is identified. This triggers the suppression of STA access to rectify the load imbalance issue.

Configuring the 5G Preferred RSSI Threshold of CorrectLink

- After the 5 GHz preferred RSSI threshold is configured, if a WLAN supports both the 2.4 GHz and 5 GHz frequency bands and the RSSI of 5 GHz signals is greater than the threshold on the WLAN, the STA cannot be associated with the WLAN in the 2.4 GHz frequency band.

Command	**clink bandsel-5g-rssi-threshold** *thrd*
Parameter Description	*thrd*: Indicates the 5 GHz preferred RSSI threshold. The value range is from 1 to 100.
Defaults	20
Command Mode	Global configuration mode
Usage Guide	N/A

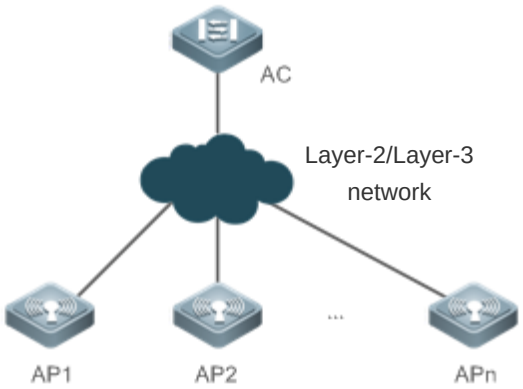
Configuring the 5 GHz Preferred Load Threshold of CorrectLink

- After the 5 GHz preferred load threshold is configured, if a WLAN supports both the 2.4 GHz and 5 GHz frequency bands and load of 5 GHz signals is less than the threshold on the WLAN, the STA cannot be associated with the WLAN in the 2.4 GHz frequency band.

Command	**clink bandsel-5g-client-threshold** *thrd*
Parameter Description	*thrd*: Indicates the 5 GHz preferred load threshold. The value range is from 1 to 100.
Defaults	100
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Rate-limiting Attempt Threshold of CorrectLink

- After a STA is rate-limited for a certain number of times equal to the rate-limiting attempt threshold, stop rate limiting to guarantee access experience of the STA.



Command	**clink max-fails** *thrd*
Parameter Description	*thrd*: Indicates the rate-limiting attempt threshold. The value range is from 1 to 100.
Defaults	2
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running** command to display the configuration.

Configuration Example

Enabling CorrectLink and Configuring the Remote Association RSSI Difference Threshold as 7

Scenario **Figure 1-4**	
Configuration Steps	● Enable the global CorrectLink function on the AC. ● Configure the remote association RSSI difference threshold as 7 on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# clink enable`
	`Hostname(config)# clink rssi-delta-threshold 7`

Verification	Display the configuration after CorrectLink is enabled. ● Run the **show running** command to display the configuration.

	`Hostname# show running-config`
	`!`
	`clink enable`
	`clink rssi-delta-threshold 7`
	`!`

1.5 Monitoring

Displaying

Command	Description
show clink result	Displays the CorrectLink result.
show clink statistic	Displays CorrectLink statistics.
show clink probe	Displays probe information.

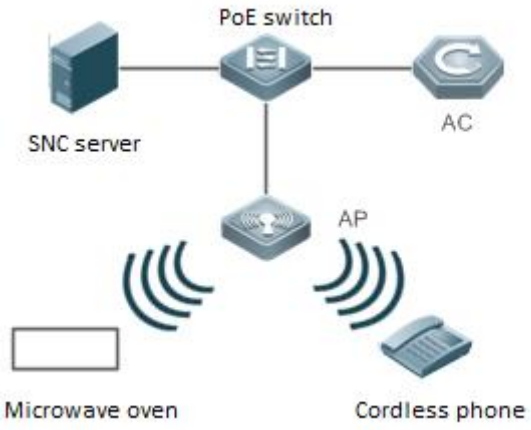
1 Configuring FSS

1.1 Overview

With Frequency Spectrum Scanning (FSS) enabled, an access point (AP) can operate in FSS mode and act as a wireless frequency spectrum sensor that is responsible for collecting and analyzing non-802.11 wireless signal frequency spectrum and sends results of frequency spectrum analysis to the frequency spectrum analysis server. Then the frequency spectrum analysis server shows frequency spectrum analysis results in intuitive forms such as graphic, list, and alarm.

FSS is used with RG-SNC to achieve frequency spectrum analysis.

1.2 Applications



Application	Description
Providing Frequency Spectrum Analysis	FSS is used with RG-SNC to achieve frequency spectrum analysis.

1.2.1 Providing Frequency Spectrum Analysis with RG-SNC

Scenario

Non-802.11 wireless interference devices such as microwave ovens and cordless phones are deployed in the RF environment.

Figure 1-1

Remarks	A. RG-SNC is installed on the SNC server. B. The AC and AP constitute the wireless Fit AP system. C. There are interferences from microwave ovens and cordless phones in the RF environment.

Deployment

- Enable the frequency spectrum analysis function on the AC.
- Establish a connection between RG-SNC and the AC.

1.3 Features

Basic Concepts

Video Bridge Interference

A working video bridge may generate wireless signals that interfere with WLAN transmission. FSS enables an AP to recognize and send the video bridge interferences to RG-SNC for analysis.

Microwave Oven Interference

A working microwave oven may generate microwave leakage that interferes with WLAN transmission. FSS enables an AP to recognize and send the microwave interferences to RG-SNC for analysis.

Cordless Phone Interference

A working cordless phone may generate wireless signals that interfere with WLAN transmission. FSS enables an AP to recognize and send the cordless phone interferences to RG-SNC for analysis.

Bluetooth Interference

A working Bluetooth device may generate wireless signals that interfere with WLAN transmission. FSS enables an AP to recognize and send the Bluetooth device interferences to RG-SNC for analysis.

Continuous Wave

A continuous wave may generate wireless signals that interfere with WLAN transmission. FSS enables an AP to recognize and send the continuous wave interferences to RG-SNC for analysis.

Scanning Precision

The scanning precision indicates the serial number of the scanned characteristic waveform which is then determined as a specific interference source. Typically, a higher scanning precision leads to a higher probability of correct determination.

Scanning Duration

When performing frequency spectrum scanning, an AP cannot provide wireless services. The system regularly switches between wireless services and frequency spectrum scanning to balance them. A longer scanning duration leads to a higher probability of locating interferences.

Overview

Feature	Description

SNC Connecting to the AC for Frequency Spectrum Analysis	Through interaction between the SNC server and AC, non-802.11 interference sources such as microwave ovens, cordless phones, and Bluetooth devices are recognized in a wireless environment.

1.3.1 SNC Connecting to the AC for Frequency Spectrum Analysis

An AP recognizes non-802.11 interference sources such as microwave ovens, cordless phones, and Bluetooth devices in a wireless environment and sends them to RG-SNC for sort-out and display through the connection channel established between the AC and RG-SNC.

Working Principle

Frequency spectrum analysis is achieved through the interaction and SOCKET connection between the SNC server and AC. After FSS is enabled, an AP regularly collects non-802.11 interference information in the RF environment and performs Fast Fourier Transform (FFT). Then the AP classifies the information for processing, recognizes and sends specific interference sources to RG-SNC through the agreed protocol. After receiving information, RG-SNC sorts out and displays the interference information in various ways. For details, refer to the user manual for RG-SNC.

1.4 Configuration

Configuration	Description and Command	
Enabling FSS	⚠ (Mandatory) It is used to enable FSS.	
	spectral enable	Enable FSS.
Configuring the FSS Interference Recognition Precision	⚠ Optional.	
	spectral stability	Configures the interference recognition precision for FSS.
Configuring the FSS Duration	⚠ Optional.	
	spectral period	Configures the FSS duration.

1.4.1 Enabling FSS

Configuration Effect

- Enable FSS.

Notes

- FSS is enabled in the AP configuration mode.

Configuration Steps

↘ **Enabling FSS**

- (Mandatory) Run the **spectral enable** command to enable or disable FSS in AP configuration mode.
- Enable FSS for the target AP that is FSS-capable in AP configuration mode.

Command	**spectral enable**
Parameter Description	N/A
Defaults	By default, FSS is disabled.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

Run the **show ap-config running** *ap-name* command to verify that the FSS precision is configured on the target AP.

Configuration Example

Enabling FSS

Configuration Steps	• Enable FSS for a specified AP.

	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP0001`
	`Hostname(config-ap)# spectral enable`
	`Hostname(config)# end`

Verification	Run the **show ap-config running** *ap-name* command to verify that FSS is enabled on the target AP.
	`Hostname# show ap-config running AP0001` `spectral enable`

Common Errors

This function is configured in all-AP configuration mode.

1.4.2 Configuring the FSS Interference Recognition Precision

Configuration Effect

- Configure the recognition precision of non-802.11 frequency spectrum signals where a larger value leads to a higher precision.

Notes

- FSS must be enabled.

Configuration Steps

Configuring the FSS Interference Recognition Precision

- Optional
- The scanning precision is configured in AP configuration mode, and the default value can be used.

Command	**spectral stability** { **bth** *bth-num* | **bts** *bts-num* | **cph** *cph-num* | **cwa** *cwa-num* | **mwo** *mwo-num* | **vbr** *vbr-num* }
Parameter Description	*bth-num*: Configures the precision of Bluetooth recognition. The value range is 1 to 4 and the default value is 1. *bts-num*: Configures the precision of Bluetooth earphone recognition. The value range is 1 to 2 and the default value is 1. *cph-num*: Configures the precision of cordless phone recognition. The value range is 3 to 5 and the default value is 5. *cwa-num*: Configures the precision of continuous wave recognition. The value range is 4 to 10 and the default value is 8. *mwo-num*: Configures the precision of microwave recognition. The value range is 1 to 5 and the default value is 1. *vbr-num:* Configures the precision of video bridge recognition. The value range is 1 to 5 and the default value is 5.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	If there are no special requirements, the default value can be used.

Verification

Run the **show ap-config running** *ap-name* command to verify that the FSS precision is configured on the target AP.

Configuration Example

Configuring the FSS Precision

Configuration Steps	● Configure the FSS precision for video bridges as 2.

	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP0001`
	`Hostname(config-ap)# spectral enable`
	`Hostname(config-ap)# spectral stability vbr 2`
	`Hostname(config)# end`

Verification	Run the **show ap-config running** *ap-name* command to verify the FSS precision on the target AP.

	`Hostname# show ap-config running AP0001`
	`spectral enable`
	`spectral stability vbr 2`

Common Errors

- FSS is not enabled.
- This function is configured in all-AP configuration mode.

1.4.3 Configuring the FSS Duration

Configuration Effect

A longer scanning duration leads to a higher probability of locating interferences but greater influence on normal communication of the AP.

Notes

FSS must be enabled.

Configuring the FSS Duration

- Optional
- The scanning duration is configured in AP configuration mode. If there are no special requirements, the default value can be used.

Command	**spectral period** *num*
Parameter Description	*num*: Indicates the FSS duration. The value range is from 1 ms to 100 ms and the default value is 5 ms.
Defaults	5
Command Mode	AP configuration mode
Usage Guide	If there are no special requirements, the default value can be used.

Verification

Run the **show ap-config running** *ap-name* command to verify that the FSS duration is configured on the target AP.

Configuration Example

Configuring the FSS Duration as 10 μs

Configuration Steps	- Configure the FSS duration as 10 μs.

	Hostname# configure terminal Hostname(config)# ap-config AP0001 Hostname(config-ap)# spectral enable Hostname(config-ap)# spectral period 10 Hostname(config)# end
Verification	Run the **show ap-config running** *ap-name* command to verify the FSS duration configured on the target AP.
	Hostname# show ap-config running AP0001 spectral enable spectral period 10

Common Errors

- FSS is not enabled.
- This command is configured in all-AP configuration mode.

1 Configuring Wireless Location

1.1 Overview

The wireless location function uses IEEE 802.11-compliant wireless signals to locate stations (STAs). It is supported on all 802.11 a/b/g/n-compliant STAs, such as portable computers, Mobile Units (MUs), and special Radio Frequency Identifications (RFIDs, referred to as TAGs). By analyzing and summarizing IEEE 802.11-compliant wireless signals sent from these STAs, this function can be used to locate STAs through software on the location server and to intuitively display STA locations in the form of maps, tables, or reports.

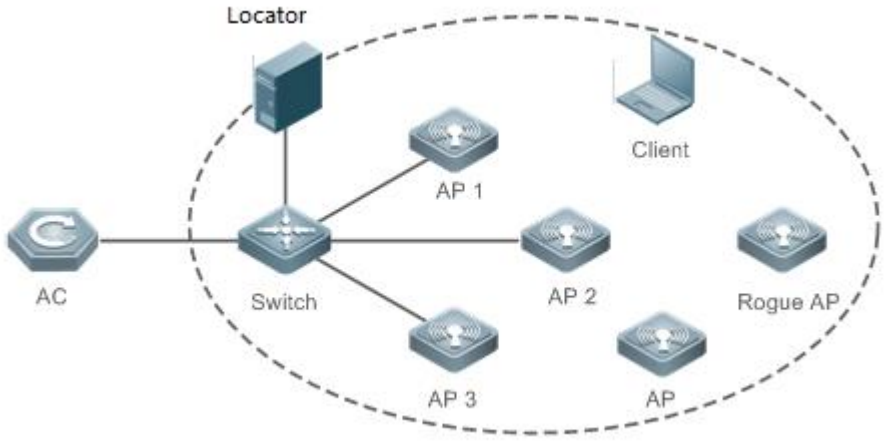
Wireless location has the following characteristics:

- Indoor and outdoor deployment
- Two algorithms supported: Received Signal Strength Indication (RSSI) and Time Difference of Arrival (TDOA) location
- Location of two types of devices: MUs and TAGs

1.2 Applications

Application	Description
Centralized Location Deployment	Deploys the location system in Fit AP mode.

1.2.1 Centralized Location Deployment



Scenario

On a WLAN in Fit AP mode where Access Points (APs) are managed uniformly by the Access Controller (AC), the IEEE 802.11-compliant STAs can be located by a location server or locator, under the condition that the following special requirements are met:

- Direct access is required between APs and the locator. Therefore, ensure that the ping operation between them is successful.
- The APs must support wireless location.
- It is necessary to deploy three APs for accurate location.

The following figure shows an example where AP 1, AP 2 and AP 3 can communicate with the locator. Each AP sends received STA information to the locator which then works out the STA locations.

Figure 1-1

Deployment

- The AC is responsible for wireless location configuration management and delivery.
- The APs are responsible for collecting STA information and sending the information to the locator.
- The locator summarizes all the information sent from all APs, works out the STA locations, and displays the locations in maps or tables based on configurations performed by the administrator.

1.3 Features

Basic Concepts

A location system contains three parts: target or source to be located, receiver, and backend location system.

Target or Source

WL supports two types of location targets:

- TAGs, produced by AeroScout, a type of light and portable RFIDs which are usually placed or stuck on the targets to be located
- MUs, IEEE 802.11-complicant wireless STAs which regularly transmit wireless signals.

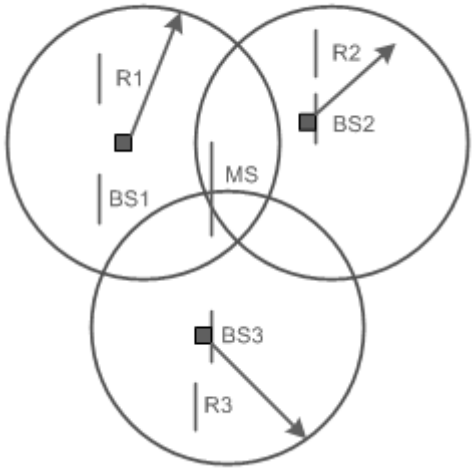
Receiver

The receiver can be a AP or an AeroScout tag exciter (used not to collect locations but to excite the TAGs to transmit specified wireless signals).

Backend Location System

The backend location system includes a locator, AeroScout Engine (AE) computing software, and all types of graphic programs.

Features



Feature	Description
Wireless Location	Enable wireless location for APs.

1.3.1 Wireless Location

Working Principle

Based on the RSSI from an MU received by a base station (BS) and the channel transmission model, the distance between the MU and BS can be estimated, indicated by the letter d. For a BS (i), the MU must be on the circle centered at BS (i) with a radius of d. When three or more BSs are used for distance measurement of the same MU, the location of this MU can be determined. In this method, the main causes for location errors are the multipath effect generated during signal transmission and the shadow effect generated during obstacle crossing. More accurate location can be achieved in an open space without obstacles. However, in many circumstances, the location accuracy is significantly affected because of uncertainties, such as the multipath effect, attenuation, and scattering, due to various obstacles.

Figure 1-2

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Functions of Wireless Location	(Mandatory) It is used to enable wireless location.	
	wlocation enable	Enables wireless location on a specified AP.
	wlocation ae-ip	Configures the IP address of the locator connected to a specified AP.
	wlocation ae-port	Configures the port ID (PID) of the locator connected to a specified AP.
	wlocation mu enable	Enables MU location on a specified AP.
	wlocation tag enable	Enables TAG location on a specified AP.
	(Optional) It is used to optimize wireless location transmission.	
	wlocation compound enable	Enables the WL aggregation.
	wlocation send-mu-time	Configures the interval for sending MU location information on a specified AP.

Configuration	Description and Command	
	wlocation send-tag-time	Configures the interval for sending TAG location information on a specified AP.
	wlocation mu report enable	Enables WL location report.
	wlocation tag report enable	Enables TAG location report.
	wlocation mu report reduce enable	Simplifies MU location information.
	wlocation ignore beacon enable	Filters Beacon packets sent by APs.

1.4.1 Configuring Basic Functions of Wireless Location

Configuration Effect

Enable wireless location to provide basic location services.

Notes

N/A

Configuration Steps

↘ Enabling Wireless Location on an AP

- Mandatory.
- Run the **wlocation enable** command to enable wireless location on an AP.
- On wireless networks where the location function is required, you are advised to enable the wireless location function on all APs that meet location conditions.

Command	**wlocation enable** [**radio** *radio-id*]
Parameter Description	*radio-id*: Indicates that the wireless location function is enabled on the designated RF interface.
Defaults	By default, wireless location is disabled.
Command Mode	AP configuration mode
Usage Guide	If **radio** is not configured, the wireless location function is enabled or disabled for the AP. If **radio** is configured, the wireless location function is enabled or disabled for a specified radio of the AP.

↘ Configuring the IP Address and Interface Number for the Locator

- Mandatory.
- The interface number has a default value depending on the configuration of a specific locator. You can modify the interface number of the locator on the device synchronously.
- The wireless location function of an AP is used only with the locator. Therefore, the IP address and interface number of the locator needs to be configured to guarantee communication with the AP.
- After the correct IP address and interface number are configured, the AP can normally enable the wireless location function.

Command	**wlocation ae-ip** *ip-address*
Parameter	*ip-address*: Indicates the IP address of the locator.

Description	
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	N/A

Command	**wlocation ae-port** *port*
Parameter Description	*port*: Indicates the interface number of the locator.
Defaults	The default interface number is 12092.
Command Mode	AP configuration mode
Usage Guide	N/A

Enabling MU or TAG Location

- Mandatory.
- To enable wireless location on an AP, you need to enable wireless location for MUs or TAGs. The configuration depends on the scenario and the STA to be located.

Command	**wlocation mu enable**
Parameter Description	N/A
Defaults	MU location is disabled.
Command Mode	AP configuration mode
Usage Guide	Both MU and TAG locations can be enabled simultaneously.

Command	**wlocation tag enable**
Parameter Description	N/A
Defaults	By default, TAG location is disabled.
Command Mode	AP configuration mode
Usage Guide	Both MU and TAG locations can be enabled simultaneously.

Configuring Aggregated Transmission of Wireless Location Information

- Optional.
- Enable aggregated transmission of wireless location information to reduce the network overhead for transmitting location information through information aggregation.

Command	**wlocation compound enable**
Parameter Description	N/A
Defaults	By default, this function is enabled.

Command Mode	AP configuration mode on the AC
Usage Guide	N/A

Configuring the Interval for Sending MU or TAG Location Information

- Optional.
- It is used to adjust the interval for sending location information. Unless otherwise specified, the default value is used.
- In the scenarios where a lot of STAs need to be located, reduce the interval to avoid information loss. (An AP can cache 500 to 700 pieces of location information.)

Command	**wlocation send-mu-time** *interval*
Parameter Description	*interval*: Indicates the interval for sending MU location information on a specified AP. The value range is from 100 to 5000, in milliseconds.
Defaults	The default interval is 300 ms.
Command Mode	AP configuration mode
Usage Guide	N/A

Command	**wlocation send-tag-time** *interval*
Parameter Description	*interval*: Indicates the interval for sending TAG location information on a specified AP. The value range is from 100 to 5000, in milliseconds.
Defaults	The default interval is 300 ms.
Command Mode	AP configuration mode
Usage Guide	N/A

Enabling MU Location Report

- Optional.
- The locator does not communicate with APs which directly send collected MU location information, for example, through the NAT network. Unless otherwise specified, the default value is used.

Command	**wlocation mu report enable**
Parameter Description	N/A
Defaults	By default, this function is disabled.
Command Mode	AP configuration mode
Usage Guide	After this function is enabled, the AP will skip the protocol handshake process with the locator, which is applicable to NAT scenarios.

Enabling TAG Location Report

- Optional.

- After this function is enabled, the AP only sends summarized location information to the locator, reducing the bandwidth and traffic consumed by large amounts of location information that may affect user experience.

Command	wlocation tag report enable
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	Enabling the function of summarizing MU location information will reduce the bandwidth occupied by location information. This function is only applicable to scenarios where a locator of a specified vendor (such as Ruijie) is deployed on a network.

Simplifying MU Location Information

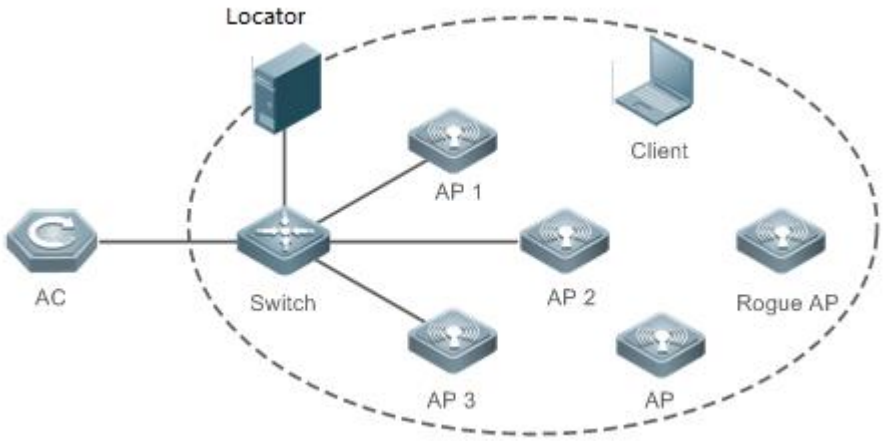
- Optional.
- Use this command where there is a requirement for lower traffic bandwidth, and the deployed location system interconnects with the location server developed by Ruijie Networks.

Command	wlocation mu report reduce enable
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	Enable the function of simplifying MU location information to reduce traffic. This function is used only when the deployed locator is developed by Ruijie Networks.

Filtering Beacon Packets Sent by APs

- Optional.
- Use this command when traffic bandwidth needs to be reduced.

Command	wlocation ignore beacon enable
Parameter Description	N/A
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	Enable the function of filtering Beacon packets sent by APs to reduce bandwidth.



Verification

On a network, enable STAs to send wireless packets.

- Verify that APs receive wireless location information.
- Verify that the locator receives location information.

Configuration Example

Enabling Wireless Location

Scenario **Figure 1-3**	
Configuration Steps	● Enable wireless location. ● Configure the IP address of the locator. ● Enable MU location as required. ● Enable TAG location as required. ● Assuming that AP1 is named **ap1-1**, run the following commands to enable wireless location for this AP.

AP1	`Hostname# configure terminal`
	`Enter configuration commands, one per line. End with CNTL/Z.`
	`Hostname(config)# ap-config ap1-1`
	`Hostname(ap-config)# wlocation enable`
	`Hostname(ap-config)# wlocation ae-ip 1.1.1.1`
	`Hostname(ap-config)# wlocation mu enable`
	`Hostname(ap-config)# wlocation tag enable`

Verification	● Run the **show ap-config** command to display the configuration of each AP and verify the wireless location configuration. ● Assuming that AP1 is named **ap1-1**, run the following commands to verify the wireless location configuration for this AP.

AP1	`Hostname# show ap-config running`
	`ap-config ap1-1`
	`wlocation enable`
	`wlocation ae-ip 1.1.1.1`
	`wlocation mu enable`

	wlocation tag enable

Common Errors

N/A

1 Configuring Smart Antennas

1.1 Overview

A smart antenna, also known as an adaptive antenna array, is composed of the antenna array, beam forming network, and beam forming algorithm. By adopting algorithms meeting certain criteria, the smart antenna adjusts the weighted amplitude and phase of each array signal and thereby adjusts the radiation pattern of the antenna array to enhance required signals and suppress interference signals.

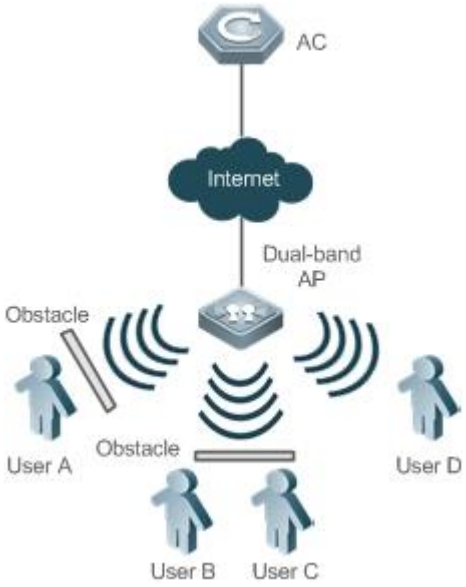
Smart antennas can solve network interference and signal fading, and increase system capacity.

Smart antennas are typically used in a complex environment where a lot of obstacles or certain interferences exist.

1.2 Applications

Application	Description
Obstacle Environment	Obstacles exist in a wireless network environment.

1.2.1 Obstacle Environment



Scenario

Obstacles, such as load bearing walls and glass windows, exist in a wireless network environment.

The networking topology is shown in the following figure, where:

- Stations (STAs) are evenly distributed around the access point (AP).
- The smart antenna function is enabled by default.
- Obstacles exist between STAs and the AP.

Figure 1-1 Networking Topology of Smart Antennas

Deployment

- The AP performs downlink wireless packet training and collects data required by smart antennas.
- Based on the collected data for smart antennas, the AP executes the beam forming algorithm to compute an antenna path for each STA.
- The AP sends data to each STA along the computed path.

1.3 Features

Basic Concepts

Smart Antenna

Based on beamwidth, antennas are classified into omni-directional and directional antennas. Omni-directional antennas usually provide a wide coverage but a narrow distance, which is contrary to directional antennas. Smart antennas combine advantages of both omni-directional and directional antennas. They can cover 360 degrees of horizontal radiation with a longer distance at each angle.

Wireless Packet Training

Smart antennas sample STA communication packets for training. When a STA transmits downlink traffic, the direction of packet transmission is changed by setting the transmitting antennas. The associated AP extracts the rates of packet loss in different antenna directions for evaluation, and finally computes a path for antenna transmission based on the beam forming algorithm.

Overview

Feature	Description
Smart Antenna Path Selection	Finds an optimal transmission path between the AP and STAs for better user experience.

1.3.1 Smart Antenna Path Selection

With the smart antenna is enabled, the AP can find an optimal transmission path for each STA.

Working Principle

Through downlink packet training and sampling by an AP, an optimal transmission path can be found to avoid interferences and obstacles

1.4 Configuration

Configuration	Description and Command	
Configuring Antennas	⚠ Optional.	
	smartant enable radio	Configures smart antennas.

1.4.1 Configuring Smart Antennas

Configuration Effect

- Configure the smart antenna status.

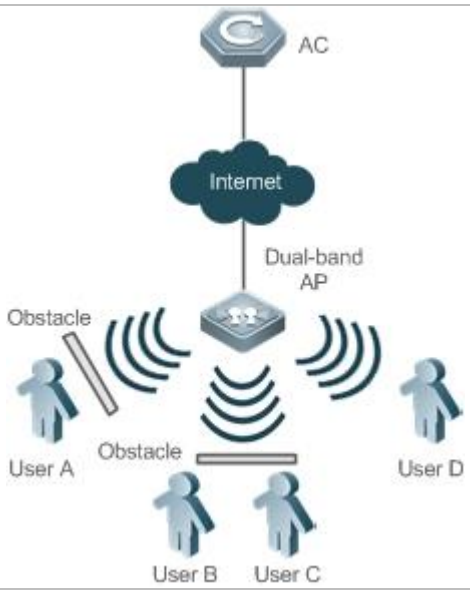
Notes

- If the AP does not support smart antennas, the configuration cannot take effect.

Configuration Steps

Configuring the Smart Antenna for a Specified Radio of a Specified AP

- Optional.
- The smart antenna is configured on per-radio and per-AP basis.



Command	**[no] smartant enable radio** *radio-id*
Parameter Description	*radio-id*: Indicates the ID of a radio to be configured with the smart antenna.
Defaults	By default, the smart antenna is enabled.
Command Mode	AP configuration mode
Usage Guide	This command is used to enable or disable the smart antenna function. For smart antenna-incapable devices, the configuration cannot take effect.

Verification

- Run the **show ap-config running** *ap-name* command to display the configuration.

Configuration Example

Configuring the Smart Antenna for a Specified Radio of a Specified AP

Scenario **Figure 1-2**	

Configuration Steps	● Configure the smart antenna for a specified radio of a specified AP.
	Hostname# configure terminal Hostname(config)# ap-config ap320 Hostname(config-ap)# smartant enable radio 1
Verification	After the smart antenna function is configured for the specified radio of the specified AP, check the configuration through the following ways. ● Run the **show running** *ap-name* command to display the configuration. Because the smart antenna is enabled by default, no configuration will not be displayed. When the smart antenna function is disabled, the disabled configuration can be displayed.
	Hostname# show ap-config running ap320 ! ap-config ap320 ... ... no smartant enable radio 2 ... ... !

1.5 Monitoring

N/A

Configuring WLAN Security

1. Configuring RSNA
2. Configuring STA Access Control Lists
3. Configuring WIDS

1 Configuring RSNA

1.1 Overview

The Robust Security Network Architecture (RSNA) function provides security mechanisms for WLANs.

A WLAN uses open media and public electromagnetic waves as a carrier to transmit data signals. Neither communication party is connected with a cable. If transmission links are not properly protected through encryption, data transmission will be at great risk. Therefore, security mechanisms are especially important on a WLAN.

To enhance the security, a WLAN should be provided with at least the authentication and encryption mechanisms:

- Authentication mechanism: The authentication mechanism is used to authenticate users and allow only specified users (authorized users) to use network resources.
- Encryption mechanism: The encryption mechanism is used to encrypt data on wireless links to ensure that WLAN data can be received and obtained only by intended users.

Protocols and Standards

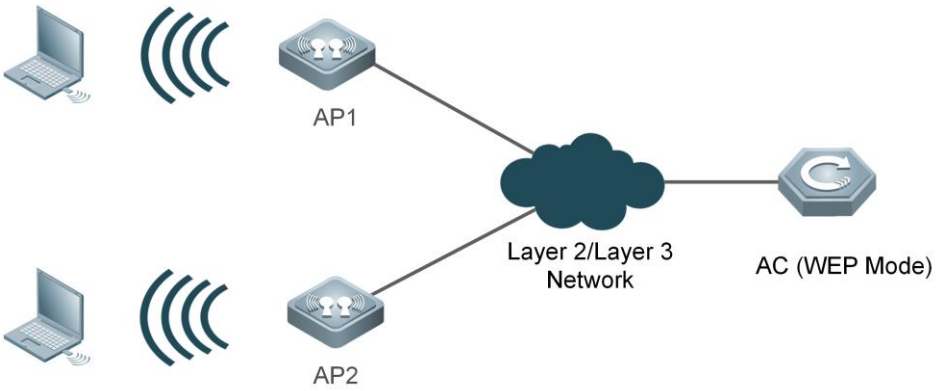
- IEEE Standard for Information technology – Telecommunications and information exchange between systems – Local and metropolitan area networks – Specific requirements -2007
- WI-FI Protected Access – Enhanced Security Implementation Based On IEEE P802.11i Standard -Aug 2004
- Information technology – Telecommunications and information exchange between systems—Local and metropolitan area networks—Specific requirements – 802.11, 1999 IEEE Standard for Local and metropolitan area networks "Port-Based Network Access Control" 802.1X™ -2004
- 802.11i IEEE Standard for Information technology—Telecommunications and information exchange between systems—Local and metropolitan area networks—Specific requirements
- 802.11r This amendment specifies the extensions to IEEE Std 802.11-2007 for wireless local area networks (WLANs) providing mechanisms for fast basic service set (BSS) transition

1.2 Applications

Application	Description
WEP Encryption	In a small WLAN that has a lower requirement for security, static WEP encryption can be used to protect wireless data communication.
PSK Access Authentication	For small and medium-sized enterprise networks or home users, access authentication based on pre-shared keys can be used to enhance the security of WLANs.
802.1X Access Authentication	For a scenario that has a higher requirement for security or unified management, port-based network access control can be used.
802.11r Fast Roaming	Fast BSS Transition (FT) is defined to reduce network delay caused by roaming.

1.2.1 WEP Encryption

Scenario



On a small WLAN that has a lower requirement for security, WEP encryption can be used.

WEP encryption can use the open-system or shared-key link authentication mode. Their differences are as follows:

- When open-system link authentication is used, WEP keys can be used only for data encryption. Even if inconsistent keys are configured, users can go online. However, data transmitted after the users go online is discarded by the receiver due to key inconsistency.
- When shared-key link authentication is used, WEP keys are used for link authentication and data encryption. If inconsistent keys are configured, link authentication fails and clients cannot go online.

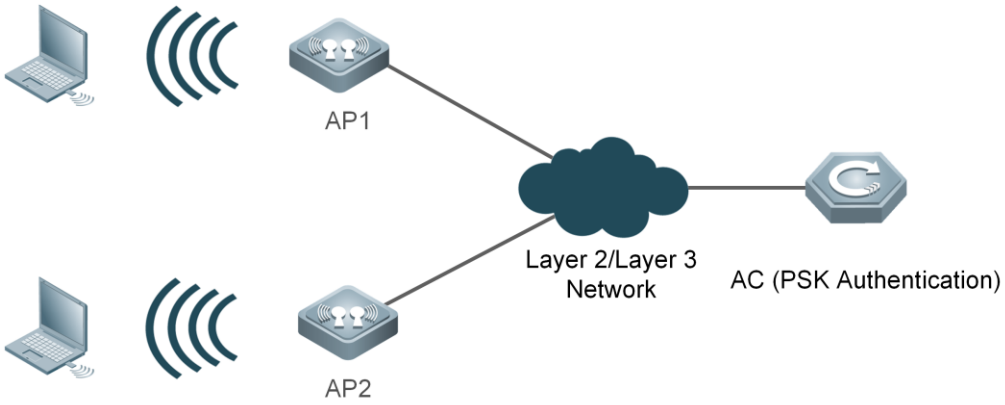
Figure 1-1 shows the scenario of static WEP encryption.

Figure 1-1

Deployment

- Configure a WLAN on the AC.
- Configure WEP encryption in WLAN security configuration mode.
- Deliver the WLAN configuration to APs.

1.2.2 PSK Access Authentication



Scenario

Small and medium-sized enterprise networks or home users can use the Wi-Fi Protected Access (WPA) or WPA2 standard to enhance WLAN security. The simplest method is using pre-shared key authentication (WPA-PSK and WPA2-PSK, respectively). In this case, WPA is similar to Wired Equivalent Privacy (WEP), and can achieve higher security based on IEEE 802.11i, including more robust authentication and better encryption algorithms.

In PSK authentication, the same pre-shared key should be configured for a STA and an access device to establish connection and communication. No additional authentication server is required.

Figure 1-2 shows the scenario of PSK authentication.

Figure 1-2

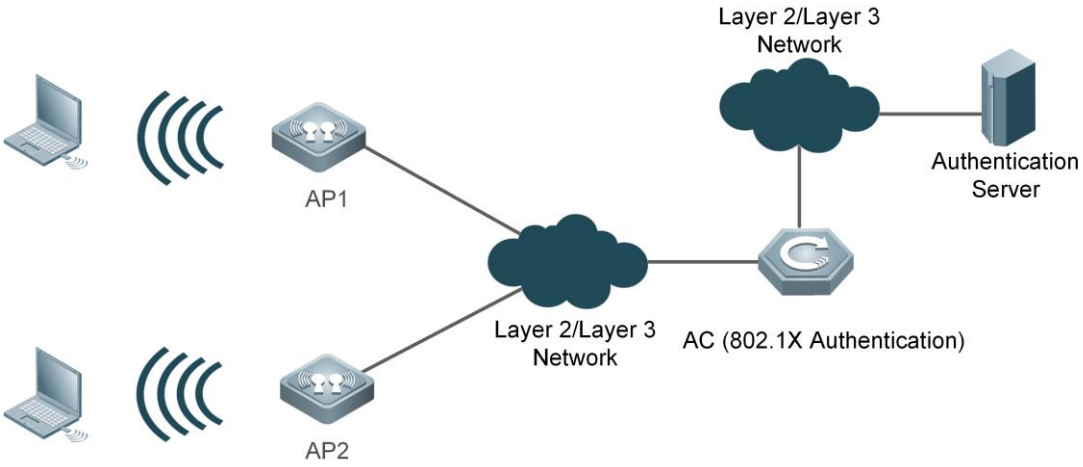
Deployment

- Configure a WLAN on the AC.
- Configure PSK authentication in WLAN security configuration mode.
- Deliver the WLAN configuration to APs.
- Use this authentication with web authentication to support web-based authentication and accounting.

1.2.3 802.1X Access Authentication

Scenario

In a scenario that has a higher requirement for security, 802.1X authentication can be used.



802.1X is a port-based network access control protocol. This authentication mode is used to authenticate and control STAs at the port level of WLAN access devices. STAs connected to the ports can access WLAN resources if they pass the authentication. Otherwise, the STAs cannot access WLAN resources.

Authentication client software needs to be installed on terminals to perform 802.1X authentication. However, in some cases, some client devices cannot be installed with the software, for example, wireless printers. For the sake of network management and security, although these client devices have no 802.1X authentication client software, administrators need to control the access of these client devices. MAC Authentication Bypass (MAB) provides a solution for this application.

After the MAB function is deployed for a WLAN, a wireless device can automatically detect the MAC address of a connected client device and use the MAC address to initiate a request to the authentication server.

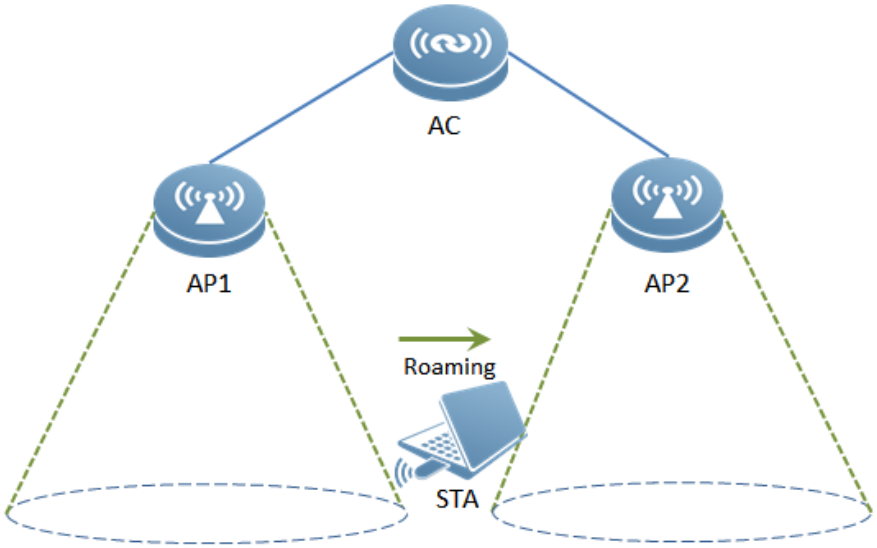
Figure 1-3 shows the scenario of 802.1X authentication.

Figure 1-3

Deployment

- Configure a WLAN on the AC.
- Configure an authentication server on the AC.
- Configure 802.1X authentication in WLAN security configuration mode.
- Deliver the WLAN configuration to APs.

1.2.4 802.11r Fast Roaming



Scenario

For applications that are sensitive to network delay, such as Voice over Wi-Fi and video, minimizing roaming authentication time is crucial. The 802.11r standard defines the FT roaming mode. In this mode, 802.1X authentication and the 4-way handshake are not required, thereby reducing the roaming handoff time.

FT provides the Over-the-Air and Over-the-DS methods. Currently, only Over-the-Air is supported. When Over-the-Air is used, STAs directly connect to a new AP for authentication in roaming scenarios.

Figure 1-4 shows the Over-the-Air scenario.

Figure 1-4

Deployment

- Configure a WLAN on the AC.
- In WLAN security configuration mode, set the authentication mode to RSN, Authentication and Key Management (AKM) to PSK or 802.1X, and encryption mode to AES.
- Deliver the WLAN configuration to APs.
- Simulate a scenario in which a STA roams from AP1 to AP2. If the 802.11r function is enabled, the STA directly connects to AP2 for FT authentication.

1.3 Features

Basic Concepts

WPA

Wi-Fi Protected Access (WPA) is a wireless security draft defined by the Wi-Fi Alliance. The IEEE 802.11i standard is compatible with this draft.

RSN

The IEEE 802.11i standard defines the concept of Robust Security Network (RSN): and makes many improvements against various defects of the WEP encryption mechanism. RSN is equivalent to WPA2 launched by the Wi-Fi Alliance in terms of functions.

TKIP

The Temporal Key Integrity Protocol (TKIP) enhances security compared with WEP. TKIP provides per-packet key mixing, message integrity check, and key re-generation mechanism, thereby eliminating risks of WEP.

AES

Advanced Encryption Standard (AES) is a new encryption standard published by the National Institute of Standards and Technology (NIST) of the United States. On October 2, 2000, the Rijndael algorithm designed by Joan Daemen and Vincent Rijmen from Belgium won with its excellent performance and anti-attack capabilities, and became the next-generation encryption standard AES.

CCMP

Counter Mode with CBC-MAC Protocol (CCMP) uses AES, which is more secure than TKIP.

AKM

Authentication and Key Management (AKM) is an access authentication mode for users to access a WLAN.

SAE

Simultaneous Authentication of Equals (SAE) is a peer authentication interaction. There are three encryption policies available:

- HnP: Hunting-and-Pecking loop.
- H2E: Hash to Element.
- Both: Both Hunting-and-Pecking loop and Hash-to-Element are enabled. The device determines the encryption mode according to the client capability. If both modes are supported, H2E encryption is used preferentially.

OWE

Opportunistic Wireless Encryption (OWE) does not require users to enter authentication information, and STAs and APs negotiate temporary PMKs.

Overview

Feature	Description
Link Authentication	Verify the security of a wireless link before a STA associates with a WLAN.
Access Authentication	Perform authentication for a STA that accesses a WLAN.
Wireless Data Encryption	Implement security protection for communication data of a STA that accesses a WLAN.
Management Frame Encryption	Implement encryption on management frames.
WPA3 Authentication	Perform authentication for a STA that accesses a WPA3 WLAN.

1.3.1 Link Authentication

Link authentication refers to 802.11 authentication, which is a low-level authentication mechanism. Link authentication is performed when a STA associates with an AP according to the 802.11 standard, which is earlier than access authentication. Before a STA accesses a WLAN, 802.11 authentication must be performed. 802.11 authentication marks the beginning of the handshake process when a STA accesses a WLAN and the first step for network connection.

The IEEE 802.11 standard defines two link-layer authentication modes:

- Open-system link authentication
- Shared-key link authentication

Working Principle

Open-System Link Authentication

Open-system link authentication allows all users to access a WLAN. In this sense, no data protection is provided, which means that no authentication is performed. That is, if the authentication mode is set to open-system authentication, all STAs that request authentication can pass the authentication.

The process of open-system link authentication is as follows:

Step 1: An STA requests authentication. The STA sends an authentication request that contains the ID (typically the MAC address) of the STA.

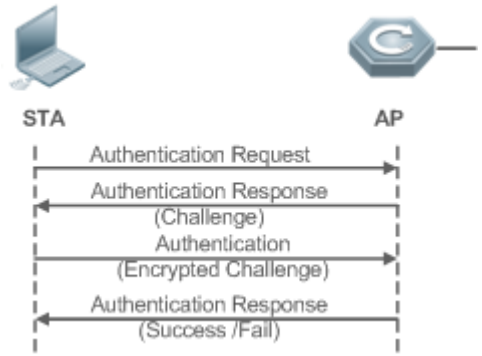
Step 2: An AP returns the authentication result. The AP sends an authentication response that contains information indicating whether the authentication succeeds or fails. If the authentication succeeds, the STA and AP pass the two-way authentication.

Figure 1-5

Shared-Key Link Authentication

Shared-key link authentication is another authentication mechanism in addition to open-system link authentication. Shared-key link authentication requires that the same shared key be configured for a STA and an AP. The shared-key link authentication can be configured only in static WEP encryption whereas open-system link authentication is available in all the other modes.

The process of shared-key link authentication is as follows:



Step 1: A STA sends an authentication request to an AP.

Step 2: The AP generates a Challenge packet (a random string) and sends the packet to the STA.

Step 3: The STA copies the received string to a new message, encrypts the message with a key and then sends the encrypted message to the AP.

Step 4: After receiving the message, the AP decrypts the message with the key, and then compares the decrypted string with the string sent to the STA. If the two strings are the same, it indicates that the STA has the same shared key as that on the AP and the shared-key authentication succeeds. Otherwise, the shared-key authentication fails.

Figure 1-6

1.3.2 Access Authentication

Access authentication is a solution that enhances WLAN security.

After a STA is associated with an AP, whether the STA can use the service provided by the AP depends on the result of access authentication. If the STA passes the authentication, the AP enables the logical port for the STA. Otherwise, the STA is not allowed to access the WLAN.

The IEEE 802.11 standard defines two access authentication modes:

- PSK access authentication
- 802.1X access authentication

Working Principle

PSK Access Authentication

Pre-shared Key (PSK) is an 802.11i authentication mode that performs authentication with pre-defined static keys. This authentication mode requires that a STA and an AP be configured with the same pre-shared key. If their keys are the same, the PSK access authentication succeeds. Otherwise, the PSK access authentication fails.

802.1X Access Authentication

802.1X is a port-based network access control protocol. This authentication mode is used to authenticate and control the STAs at the port level of WLAN access devices. STAs connected to the ports can access resources on a WLAN if they pass the authentication. Otherwise, the STAs cannot access resources on the WLAN.

A WLAN system with the 802.1X authentication function must provide the following elements to implement port-based authentication and authorization for network access control:

- Authentication client

Authentication client is typically installed on the STA. To access a WLAN, a user needs to activate the client program and enter the username and password. Then, the client program sends a connection request.

- Authenticator

An authenticator is an AP or a communication device functioning as an AP. It is responsible for uploading and delivering user authentication information and enables or disables a port based on the authentication result.

- Authentication server

The authentication server checks whether a user has the right to use the services provided by the network system based on identity information (username and password), and delivers the port enabling or disabling status to the authentication system based on the authentication result.

MAB authentication uses a MAC address as the username to initiate a request to the authentication server. In this case, client devices do not need to install the client software.

1.3.3 Wireless Data Encryption

Compared with a wired network, a wireless network is prone to higher security risks. Within an area, all WLAN devices share the same transmission medium and any device can receive data from all the other devices. This feature poses threats to WLAN access security.

The IEEE 802.11i protocol defines the following encryption algorithms:

- WEP encryption
- TKIP encryption
- AES encryption

Working Principle

WEP Encryption

Wired Equivalent Privacy (WEP) is a data encryption mode specified in the original IEEE 802.11 standard, and is the basis for WLAN security authentication and encryption. WEP is used to protect the privacy of data exchanged between authorized users on a WLAN and prevent the data from being stolen.

WEP uses the RC4 algorithm to protect data privacy and implements authentication by using a shared key. WEP does not specify a key management scheme. Typically, keys are configured and maintained manually. WEP that does not provide a key distribution mechanism is called manual WEP or static WEP.

A WEP key contains 64 bits or 128 bits. The 24-bit Initialization Vector (IV) is generated by the system. Therefore, a shared key to be configured on an AP and a STA consists of only 40 bits or 104 bits. In actual implementation, the 104-bit WEP keys are widely used to replace the 40-bit WEP keys. WEP using 104-bit keys is called WEP-104. Although WEP-104 increases the security of WEP encryption, WEP encryption is prone to security risks due to limitations of the RC4 encryption algorithm and manually configured keys. WEP encryption cannot guarantee the confidentiality and integrity of data or implement access authentication.

TKIP Encryption

Temporal Key Integrity Protocol (TKIP) is a temporary transitional solution created by the IEEE 802.11 organization for fixing the WEP encryption mechanism. Similar to WEP encryption, TKIP encryption also uses the RC4 algorithm. However, compared with WEP encryption, TKIP encryption can provide more secure protection for WLAN services in the following aspects:

- A static WEP key is manually configured and all users within the same service area share the same key. A TKIP key is generated through dynamic negotiation, and each packet has a unique key.
- TKIP increases the key length from 40 bits to 128 bits, and the IV length from 24 bits to 48 bits, thus improving the security of WEP encryption.
- TKIP supports Message Integrity Check (MIC) and the anti-replay function.

AES Encryption

The Counter Mode with CBC-MAC Protocol (AES-CCMP) is the most advanced wireless security protocol for the public.

The IEEE 802.11i standard requires that CCMP be used to provide four security services, namely, authentication, confidentiality, integrity, and anti-replay services. CCMP uses the 128-bit AES to guarantee confidentiality and uses CBC-MAC to ensure data integrity and perform authentication.

As a new advanced encryption standard, AES uses the symmetrical block encryption technology to provide better encryption performance than the RC4 algorithm in WEP/TKIP. It is the next-generation encryption technology that replaces WEP and provides more powerful security protection for WLANs.

The IEEE 802.11r standard requires that CCMP be used to encrypt EAPOL packets. Therefore, before enabling the 802.11r function, configure the AES-CCMP encryption mode.

1.3.4 Management Frame Encryption

Wireless management frames, such as authentication, de-authentication, association, disassociation, beacon, and probe frames, are transmitted using plaintext in the air. In this case, these frames may be used by unauthorized devices to attack wireless clients associated with APs. The Protected Management Frame (PMF) defined by the IEEE 802.11w standard is a management frame subset, which includes frames of De-authentication, Disassociation, Spectrum Management, QoS, DLS, Block Ack, Radio measurement, SA Query, Protected Dual of Public Action, Fast BSS Transition, and Vendor-specific Protected. Packets in this subset will be encrypted when being transmitted on air interfaces. The SA Query mechanism is used to prevent counterfeited association frames, de-authentication frames, and disassociation frames from disassociating STAs.

Working Principle

↘ SA Query

When a STA is online and applies the PMF and an AP receives an association request from a rogue STA, the AP rejects the association request first and returns an association response with the status code 30, indicating that the association request is rejected temporarily and retry is required later. Then the AP sends an SA Query request to the STA. If the STA is online, the STA sends an SA Query response. After the AP receives the SA Query response, it regards that the STA is online and does not process association requests within the association recovery time (10s). This prevents the real STA from being disassociated using counterfeited packets.

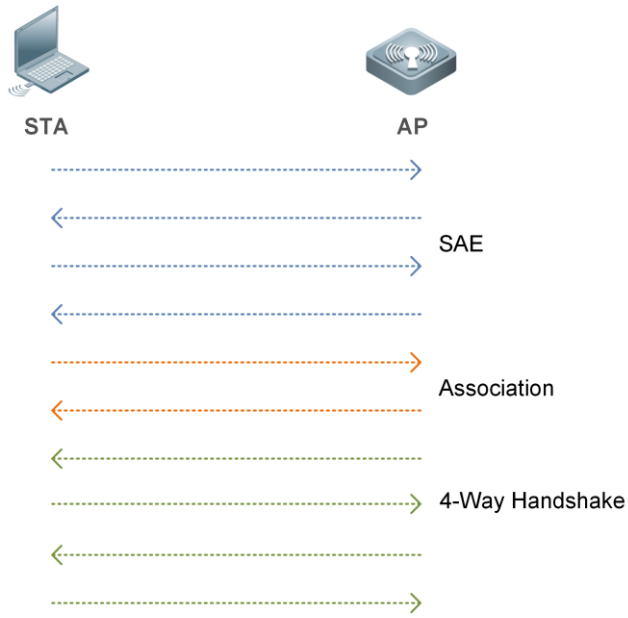
Similarly, when an online STA that applies the PMF receives an unencrypted disassociation or de-authentication frame, the STA sends an SA Query request to the AP. The AP returns an SA Query response. After the STA receives the SA Query response, it regards that the AP is still online and remains in the online state. This prevents the real STA from being disassociated using counterfeited packets.

1.3.5 WPA3 Authentication

Wi-Fi Protected Access 3 (WPA3) is a Wi-Fi encryption protocol released by the Wi-Fi Alliance. WPA3 is available in WPA3-Enterprise, WPA3-Personal, and OWE editions. WPA3-Enterprise provides WPA3-Enterprise only and WPA3-Enterprise 192-bit modes.

- WPA3-Personal Edition

Compared with WPA2-Personal, WPA3-Personal introduces Simultaneous Authentication of Equals (SAE) for management frame authentication. When a STA attempts to connect to the device enabled with WPA3-Personal, SAE adds an SAE handshake before the original WPA/WPA2-PSK 4-way handshake to dynamically negotiate a pairwise master key (PMK) using random variables and passwords through calculation. The PMK is used for the WPA/WPA2-PSK 4-way handshake, enhancing access security for WPA3.



There are three WPA3 SAE encryption options available:

HnP: The algorithm relates the password with calculation time. It is theoretically possible to crack the password using time difference.

H2E: To address the shortcomings of HnP, the Wi-Fi Alliance introduced the Hash to Element (H2E) encryption algorithm in the third version of WPA3. In this method, the secret PWE used in the SAE protocol is generated from a password. H2E-incapable clients cannot authenticate using this encryption method.

Both: Both HnP and H2E are supported. If the client supports both encryption modes, H2E encryption is used preferentially. If not, HnP is used preferentially.

Figure 1-7 Mutual Authentication of WPA3-Personal Edition

- WPA3-Enterprise Edition

Based on WPA2-Enterprise, the WPA3-Enterprise only mode introduces management frame protection. That is, Deauthentication, Disassociation, Spectrum Management, QoS, DLS, Block Ack, Radio measurement, SA Query, Protected Dual of Public Action, Fast BSS Transition, and Vendor-specific Protected packets are encrypted for transmission on air interfaces to enhance security.

An enhanced encryption suite is used for 4-way handshake in the WPA3-Enterprise 192-bit mode.

  - This suite increases the key length from 128 bits to 192 bits, enhancing data protection.
  - 256-bit Galois/Counter Mode Protocol (GCMP-256) and 256-bit Broadcast/Multicast Integrity Protocol Galois Message Authentication Code (BIP-GMAC-256) are used to replace CCMP, thereby protecting multicast management frames.

- OWE Authentication

OWE authentication, also known as Enhanced Open network authentication, does not require users to enter authentication information. The packets exchanged between STAs and APs are still encrypted, providing a certain level of privacy and defense against packet sniffing. In a scenario where OWE authentication is enabled, STAs that do not support OWE authentication are allowed to access in open authentication mode.

1.4 Configuration

Configuration	Description and Command	
Configuring Static WEP	(Mandatory) It is used to enable static WEP encryption.	
	wlansec	Enters the security configuration mode of the specified WLAN.
	security static-wep-key encryption	Enables static WEP for a WLAN and configures a static WEP key.

Configuration	Description and Command	
	(Optional) It is used to configure the link authentication mode.	
	security static-wep-key authentication	Configures the link authentication mode of static WEP.
Configuring WPA Authentication	(Mandatory) It is used to enable WPA authentication.	
	security wpa	Configures WPA authentication.
	security wpa ciphers	Configures the encryption mode for WPA authentication.
	security wpa akm	Configures the access authentication mode for WPA authentication.
	(Optional) It is used to configure a shared key for WPA PSK authentication.	
	security wpa akm psk set-key	Configures a shared key for WPA PSK authentication.
Configuring RSN Authentication	(Mandatory) It is used to enable RSN authentication.	
	security rsn	Configures RSN authentication.
	security rsn ciphers	Configures the encryption mode for RSN authentication.
	security rsn akm	Configures the access authentication mode for RSN authentication.
	(Optional) It is used to configure a shared key for RSN PSK authentication.	
	security rsn akm psk set-key	Configures a shared key for RSN PSK authentication.
Configuring MAB Authentication	(Optional) It is used to configure MAB authentication.	
	dot1x-mab	Enables MAB authentication.
Configuring Authentication Parameters	(Optional) It is used to configure key interaction parameters and the anti-jitter time in WEB authentication.	
	authtimeout forbidcount	Configures the association forbidding count after 4-way handshake key interaction fails.
	authtimeout forbidtime	Configures the association forbidding interval after 4-way handshake key interaction fails.
	authtimeout groupcount	Configures the multicast key negotiation packet re-transmission count.
	authtimeout grouptime	Configures the timeout duration of multicast key negotiation packets.
	authtimeout paircount	Configures the uncast key negotiation packet re-transmission count.
	authtimeout pairtime	Configures the timeout duration of unicast

Configuration	Description and Command	
		key negotiation packets.
	webauth prevent-jitter	Configures the anti-jitter time of web authentication.
Configuring 802.11r	**security rsn dot11r enable**	Enables the 802.11r fast roaming protocol.
	security rsn dot11r reassoc-timeout	Modifies the 802.11r re-association timeout duration.
Configuring Management Frame Encryption	**security pmf** { **disable | mandatory** | **optional** }	Configures management frame encryption.
Configuring WPA3 Authentication	**security wpa3 mode**	Sets the WPA3 authentication mode.
	security wpa3 personal passphrase	Sets a key for WPA3-Personal authentication.
	security wpa3 personal pwe	Sets a WPA SAE encryption mode.
	security wpa3 enhanced-open paired-wlan	Sets an equivalent WLAN for WPA3 authentication in enhanced-open mode.
Configuring the Response Delay Mode for Authentication Packets	**rsna lazy-response enable**	Enables or disables the response delay for authentication packets.
	rsna lazy-response time	Configures the response delay timeout for authentication packets.
Configuring PPSK	**security sta-psk enable**	Configures Private Pre-Shared Key (PPSK).
	security sta-psk external enable	Configures PPSK external authentication.

1.4.1 Configuring Static WEP

Configuration Effect

- Enable static WEP encryption and provide WEP encryption protection for WLAN data.
- Configure the link authentication mode.

Notes

- The link authentication mode can be configured only when static WEP encryption is enabled.
- In the security configuration mode of a WLAN, static WEP encryption cannot be configured together with other authentication and encryption modes.
- Only one WLAN can be configured with static WEP encryption

Configuration Steps

↘ Enabling Static WEP

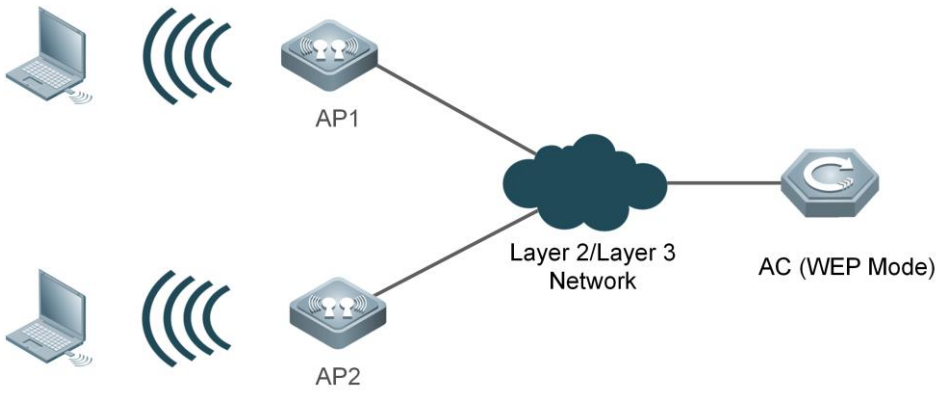
- Mandatory.
- Enable static WEP encryption in WLAN security configuration mode on the AC.

Command	**security static-wep-key encryption** *key-length* { **ascii** | **hex** } *key-index key*
Parameter Description	*key-length*: Indicates the key length, which can be 40 bits or 104 bits. **ascii**: Specifies that the WEP key is in ASCII format. **hex**: Specifies that the WEP key is in hexadecimal format.

	key-index: Indicates the key index. The range is from 1 to 4. *key*: Indicates key data.
Defaults	Static WEP is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to configure a static WEP key and enable static WEP encryption. This command can be configured repeatedly, but only the last configuration takes effect. The key length must be the same as the value of the *key-length* parameter in the command.

Configuring the Link Authentication Mode

- Optional. The default link authentication mode is open-system link authentication. This command can be used to configure shared-key link authentication.
- Enable static WEP encryption in security configuration mode on the AC first.
- The link authentication mode can be configured only after static WEP encryption is enabled. After configuring the shared-key link authentication mode, set the link authentication mode to shared-key link authentication on the STA. Otherwise, the STA cannot access the WLAN.



Command	**security static-wep-key authentication** { **open** | **share-key** }
Parameter Description	**open**: Configures open-system link authentication. **share-key**: Configures shared-key link authentication.
Defaults	A STA accesses a WLAN by using open-system link authentication.
Command Mode	WLAN security configuration mode
Usage Guide	Configure the link authentication mode after configuring a static WEP key. The link authentication mode can be configured only for static WEP encryption, but cannot configured for other security configuration modes.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring Static WEP Encryption and Shared-Key Link Authentication for WLAN 1

Scenario **Figure 1-8**	 In a fit AP environment, configure WLAN 1 on the AC and configure the security policies as follows:

	1. Enable static WEP encryption. 2. Configure shared-key link authentication.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable static WEP encryption and configure a WEP key. ● Set the link authentication mode to shared-key link authentication.

AC	`Hostname(config)#wlansec 1`
	`Hostname(config-wlansec)#security static-wep-key encryption 40 ascii 1 12345`
	`Hostname(config-wlansec)#security static-wep-key authentication share-key`

Verification	● Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

AC	`Hostname#show running-config | begin wlansec 1`
	`wlansec 1`
	` security static-wep-key encryption 40 ascii 1 12345`
	` security static-wep-key authentication share-key`
	`!`

Common Errors

- The configured key length is inconsistent with the key length specified in the command.
- Static WEP encryption is configured for multiple WLANs.
- The link authentication mode is configured before static WEP encryption is enabled.

1.4.2 Configuring WPA Authentication

Configuration Effect

- Enable WPA authentication for a WLAN.
- Specify the access authentication mode and encryption mode in WPA authentication.

Notes

- When WPA authentication is used, the encryption mode and access authentication mode must also be configured.
- If the access authentication mode is set to PSK, a PSK key must be configured.
- In the security configuration mode of a WLAN, WPA authentication and WEP authentication cannot be configured simultaneously.

Configuration Steps

↘ Configuring WPA Authentication

- Mandatory.
- Enable WPA authentication in WLAN security configuration mode on the AC.

Command	**security wpa** { **enable** | **disable** }

Parameter Description	**enable**: Enables WPA authentication. **disable**: Disables WPA authentication.
Defaults	WPA authentication is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode for WPA authentication can be configured only when WPA authentication is enabled. Otherwise, the configuration does not take effect. When WPA authentication is used, the encryption mode and access authentication mode must also be configured. If only the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

Configuring the Encryption Mode for WPA Authentication

- Mandatory.
- Enable WPA authentication in WLAN security configuration mode on the AC first.
- The encryption mode of WPA authentication can be configured only when WPA authentication is enabled. The AES and TKIP encryption modes can be enabled simultaneously in the security configuration mode of a WLAN. After an encryption mode is configured for a WLAN, communication data of a STA that accesses the WLAN is protected by the corresponding encryption mode.

Command	**security wpa ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode for WPA authentication. **disable**: Disables the encryption mode for WPA authentication.
Defaults	No encryption mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable an encryption mode for WPA authentication, which can be AES or TKIP. The AES and TKIP encryption modes can be enabled simultaneously in the security configuration mode of a WLAN.

Configuring the Access Authentication Mode for WPA authentication

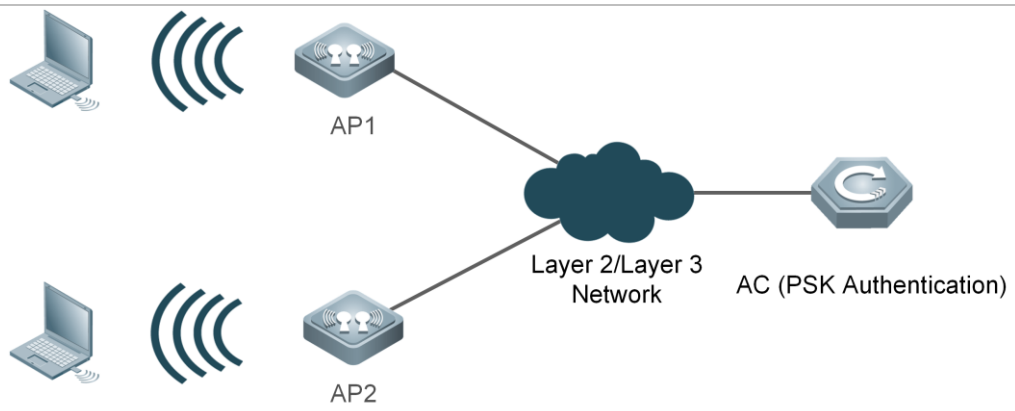
- Mandatory.
- Enable WPA authentication in WLAN security configuration mode on the AC first.
- The access authentication mode can be configured only when WPA authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN. A STA can access a WLAN that is enabled with access authentication only after passing the access authentication.

Command	**security wpa akm** { **psk** | **802.1x** } { **enable** | **disable** }
Parameter Description	**psk**: Sets the access authentication mode to pre-shared key authentication. **802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode for WPA authentication. **disable**: Disables the access authentication mode for WPA authentication.

Defaults	No access authentication mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only when WPA authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN.

Configuring a Shared Key for WPA Authentication

- Optional. It must be configured when WPA PSK authentication is enabled.
- Enable WPA PSK authentication in WLAN security configuration mode on the AC first.



Command	**security wpa akm psk set-key** { **ascii** [**0** | **7**] *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is in ASCII format. **0**: Optional. Configures a cleartext password. **7**: Optional. Configures a ciphertext password. The password must meet encryption specifications. *ascii-key*: Indicates a key in ASCII format, consisting of 8 to 63 ASCII characters. **hex**: Specifies that the PSK key is in hexadecimal format. *hex-key*: Indicates a key in hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	● This shared key takes effect only when PSK authentication is enabled. ● If you configure a cleartext password by using the **security wpa akm psk set-key ascii 0** *ascii-key* command, the configured password is converted into and saved as a ciphertext password, and command is displayed as **security wpa akm psk set-key ascii 7** *ascii-key*. ● If you configure a cleartext password by using the **security wpa akm psk set-key ascii** *ascii-key* command, the configured password is not converted into and saved as a ciphertext password.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring WPA PSK Authentication

Scenario **Figure 1-9**	

	In a fit AP environment, configure the security policies on the AC as follows: 1. Configure the WPA PSK authentication mode for WLANs 1, 2, and 3. 2. Configure the AES encryption mode for WLANs 1, 2, and 3. 3. Set the shared password to 12345678 for WLAN 1, the shared cleartext password to password@123 for WLAN 2, and the shared ciphertext password to $10$27c$8Wu2G++qd4mBlYzO$ for WLAN 3.
Configuration Steps	1. Enter the security configuration mode of WLANs 1, 2, and 3. 2. Enable the WPA authentication mode. 3. Set the data encryption mode of WPA authentication to AES. 4. Set the access authentication mode of WPA authentication to PSK. 5. Set the PSK password to 12345678 for WLAN 1, the PSK cleartext password to password@123 for WLAN 2, and the PSK ciphertext password to $10$27c$8Wu2G++qd4mBlYzO$ for WLAN 3.

AC	`Hostname(config)#wlansec 1`
	`Hostname(config-wlansec)#security wpa enable`
	`Hostname(config-wlansec)#security wpa ciphers aes enable`
	`Hostname(config-wlansec)#security wpa akm psk enable`
	`Hostname(config-wlansec)#security wpa akm psk set-key ascii 12345678`
	`Hostname(config-wlansec)#exit`
	`Hostname(config)#wlansec 2`
	`Hostname(config-wlansec)#security wpa enable`
	`Hostname(config-wlansec)#security wpa ciphers aes enable`
	`Hostname(config-wlansec)#security wpa akm psk enable`
	`Hostname(config-wlansec)#security wpa akm psk set-key ascii 0 password@123`
	`Hostname(config-wlansec)#exit`
	`Hostname(config)#wlansec 3`
	`Hostname(config-wlansec)#security wpa enable`
	`Hostname(config-wlansec)#security wpa ciphers aes enable`
	`Hostname(config-wlansec)#security wpa akm psk enable`
	`Hostname(config-wlansec)#security wpa akm psk set-key ascii 7`
	`$10$27c$8Wu2G++qd4mBlYzO$`
	`Hostname(config-wlansec)#exit`

Verification	● Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

AC	`Hostname#show running-config | begin wlansec 1`
	`wlansec 1`
	` security wpa enable`
	` security wpa ciphers aes enable`
	` security wpa akm psk enable`
	` security wpa akm psk set-key ascii 12345678`
	`!`
	`wlansec 2`

	security wpa enable security wpa ciphers aes enable security wpa akm psk enable security wpa akm psk set-key ascii 7 $10$27c$8Wu2G++qd4mBlYzO$! wlansec 3 security wpa enable security wpa ciphers aes enable security wpa akm psk enable security wpa akm psk set-key ascii 7 $10$27c$8Wu2G++qd4mBlYzO$!

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP).
- A WPA encryption mode is configured before WPA authentication is enabled in WLAN security configuration mode.
- An access authentication mode is configured before WPA authentication is enabled in WLAN security configuration mode.
- If an access authentication mode is enabled in WLAN security configuration mode, no other access authentication mode can be configured.
- A WPA PSK key is configured before WPA authentication is enabled.
- The ASCII key is shorter than 8 characters or longer than 63 characters.
- The hexadecimal key does not consist of 64 characters.

1.4.3 Configuring RSN Authentication

Configuration Effect

- Enable RSN authentication for a WLAN.
- Specify the access authentication mode and encryption mode in RSN authentication.

Notes

- When RSN authentication is used, the encryption mode and access authentication mode must also be configured.
- If the access authentication mode is set to PSK, a PSK key must be configured.
- In the security configuration mode of a WLAN, RSN authentication and WEP authentication cannot be configured simultaneously.

Configuration Steps

↘ Configuring RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC.

Command	**security rsn** { **enable** | **disable** }

Parameter Description	**enable**: Enables RSN authentication. **disable**: Disables RSN authentication.
Defaults	RSN authentication is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode for RSN authentication can be configured only when RSN authentication is enabled. Otherwise, the configuration does not take effect. When RSN authentication is used, the encryption mode and access authentication mode must also be configured. If only the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

Configuring the Encryption Mode for RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC first.
- The encryption mode for RSN authentication can be configured only when RSN authentication is enabled. The AES and TKIP encryption modes can be enabled simultaneously in the security configuration mode of a WLAN. After an encryption mode is configured for a WLAN, communication data between a STA that accesses the WLAN is protected by the corresponding encryption mode.

Command	**security rsn ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode for RSN authentication. **disable**: Disables the encryption mode for RSN authentication.
Defaults	No encryption mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable an encryption mode for RSN authentication, which can be AES or TKIP. The AES and TKIP encryption modes can be enabled simultaneously in the security configuration mode of a WLAN.

Configuring the Access Authentication Mode for RSN Authentication

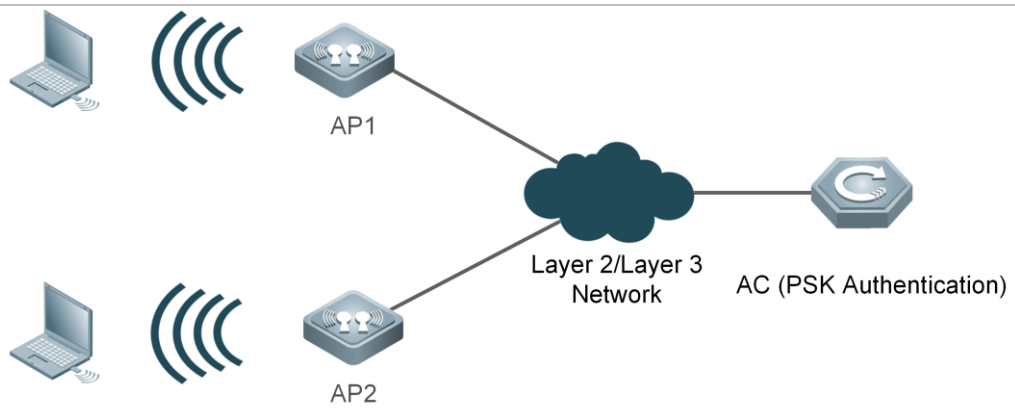
- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC first.
- The access authentication mode for RSN authentication can be configured only when RSN authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN. A STA can access a WLAN that is enabled with access authentication only after passing the access authentication.

Command	**security rsn akm** { **psk** | **802.1x** } { **enable** | **disable** }
Parameter Description	**psk**: Sets the access authentication mode to pre-shared key authentication. **802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode for RSN authentication. **disable**: Disables the access authentication mode for RSN authentication.

Defaults	No access authentication mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only when RSN authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN.

Configuring a Shared Key for RSN Authentication

- Optional. It must be configured when RSN PSK authentication is enabled.
- Enable RSN PSK authentication in WLAN security configuration mode on the AC first.



Command	**security rsn akm psk set-key** { **ascii** [**0** | **7**] *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is in ASCII format. **0**: Optional. Configures a cleartext password. **7**: Optional. Configures a ciphertext password. The password must meet encryption specifications. *ascii-key*: Indicates a key in ASCII format, consisting of 8 to 63 ASCII characters. **hex**: Specifies that the PSK key is in hexadecimal format. *hex-key*: Indicates a key in hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	● This shared key takes effect only when PSK authentication is enabled. ● If you configure a cleartext password by using the **security rsn akm psk set-key ascii 0** *ascii-key* command, the configured password is converted into and saved as a ciphertext password, and command is displayed as **security rsn akm psk set-key ascii 7** *ascii-key*. ● If you configure a cleartext password by using the **security rsn akm psk set-key ascii** *ascii-key* command, the configured password is not converted into and saved as a ciphertext password.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring RSN PSK Authentication

Scenario **Figure 1-10**	

	In a fit AP environment, configure the security policies on the AC as follows: 1. Configure the RSN PSK authentication mode for WLANs 1, 2, and 3. 2. Configure the AES encryption mode for WLANs 1, 2, and 3. 3. Set the shared password to 12345678 for WLAN 1, the shared cleartext password to password@123 for WLAN 2, and the shared ciphertext password to $10$27c$8Wu2G++qd4mBlYzO$ for WLAN 3.
Configuration Steps	1. Enter the security configuration mode of WLANs 1, 2, and 3. 2. Enable the RSN authentication mode. 3. Set the data encryption mode of RSN authentication to AES. 4. Set the access authentication mode of RSN authentication to PSK. 5. Set the PSK password to 12345678 for WLAN 1, the PSK cleartext password to password@123 for WLAN 2, and the PSK ciphertext password to $10$27c$8Wu2G++qd4mBlYzO$ for WLAN 3.

AC	`Hostname(config)#wlansec 1`
	`Hostname(config-wlansec)#security rsn enable`
	`Hostname(config-wlansec)#security rsn ciphers aes enable`
	`Hostname(config-wlansec)#security rsn akm psk enable`
	`Hostname(config-wlansec)#security rsn akm psk set-key ascii 12345678`
	`Hostname(config-wlansec)#exit`
	`Hostname(config)#wlansec 2`
	`Hostname(config-wlansec)#security rsn enable`
	`Hostname(config-wlansec)#security rsn ciphers aes enable`
	`Hostname(config-wlansec)#security rsn akm psk enable`
	`Hostname(config-wlansec)#security rsn akm psk set-key ascii 0 password@123`
	`Hostname(config-wlansec)#exit`
	`Hostname(config)#wlansec 3`
	`Hostname(config-wlansec)#security rsn enable`
	`Hostname(config-wlansec)#security rsn ciphers aes enable`
	`Hostname(config-wlansec)#security rsn akm psk enable`
	`Hostname(config-wlansec)#security rsn akm psk set-key ascii 7`
	`$10$27c$8Wu2G++qd4mBlYzO$`
	`Hostname(config-wlansec)#exit`

Verification	● Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

AC	`Hostname#show running-config | begin wlansec 1`
	`wlansec 1`
	` security rsn enable`
	` security rsn ciphers aes enable`
	` security rsn akm psk enable`
	` security rsn akm psk set-key ascii 12345678`
	`!`
	`wlansec 2`

```
 security rsn enable
 security rsn ciphers aes enable
 security rsn akm psk enable
 security rsn akm psk set-key ascii 7 $10$27c$8Wu2G++qd4mBlYzO$
!
wlansec 3
 security rsn enable
 security rsn ciphers aes enable
 security rsn akm psk enable
 security rsn akm psk set-key ascii 7 $10$27c$8Wu2G++qd4mBlYzO$
!
```

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP).
- An RSN encryption mode is configured before RSN authentication is enabled in WLAN security configuration mode.
- An access authentication mode is configured before RSN authentication is enabled in WLAN security configuration mode.
- If an access authentication mode is enabled in WLAN security configuration mode, no other access authentication mode can be configured.
- An RSN PSK key is configured before RSN authentication is enabled.
- The ASCII key is shorter than 8 characters or longer than 63 characters.
- The hexadecimal key does not consist of 64 characters.

1.4.4 Configuring MAB Authentication

Configuration Effect

- Enable MAB authentication for a WLAN.

Notes

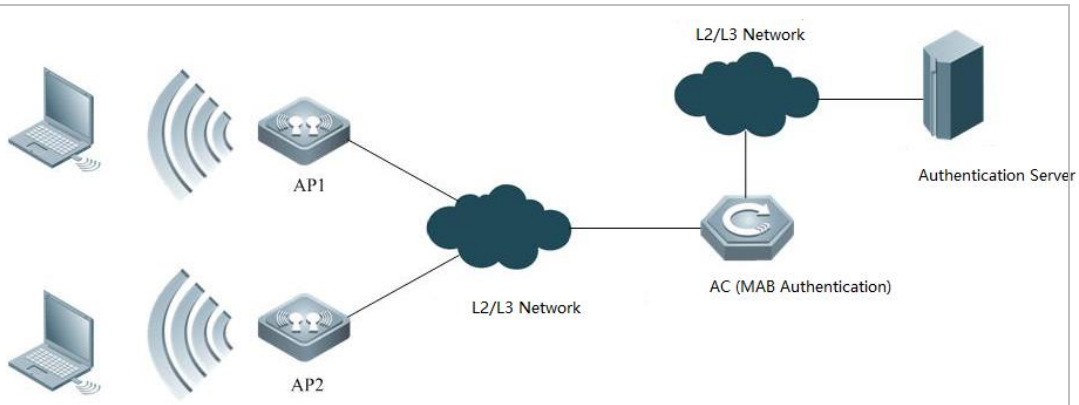
- In the security configuration mode of a WLAN, MAB authentication cannot be configured together with 802.1X access authentication or WEP authentication, but can be configured together with PSK authentication.

Configuration Steps

↘ Configuring MAB Authentication

- Mandatory.
- Enable MAB authentication in WLAN security configuration mode on the AC.
- Run the **dot1x-mab** command to enable MAB authentication or run the **no dot1x-mab** command to disable MAB authentication.

- MAB authentication can be configured independently, without RSN or WPA authentication enabled. MAB authentication can be used together with PSK access authentication, but cannot be used together with 802.1X access authentication.



Command	[**no**] **dot1x-mab**
Parameter Description	**no**: Disables MAB authentication.
Defaults	MAB authentication is not configured.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable MAB authentication. MAB authentication can be used together with PSK access authentication, but cannot be used together with 802.1X access authentication.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring MAB Authentication for WLAN 1

Scenario Figure 1-11	 In fit AP mode, configure the security policy of WLAN 1 on the AC as follows: 1. Configure MAB authentication.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable MAB authentication.
AC	`Hostname(config)#wlansec 1` `Hostname(config-wlansec)#dot1x-mab`
Verification	● Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

AC	`Hostname#show running-config | begin wlansec 1`
	`wlansec 1`
	` dot1x-mab`
	`!`

Common Errors

- The WLAN has been enabled with other encryption and authentication modes (such as WEP).
- If 802.1X access authentication is enabled in WLAN security configuration mode, MAB authentication cannot be configured.

1.4.5 Configuring Authentication Parameters

Configuration Effect

- Configure key interaction parameters.
- Configure the anti-jitter time in web authentication.

Notes

- Key interaction parameters take effect only in PSK or 802.1X authentication.
- The anti-jitter time in web authentication can be configured only when web authentication is enabled.

Configuration Steps

↘ Configuring Key Interaction Parameters

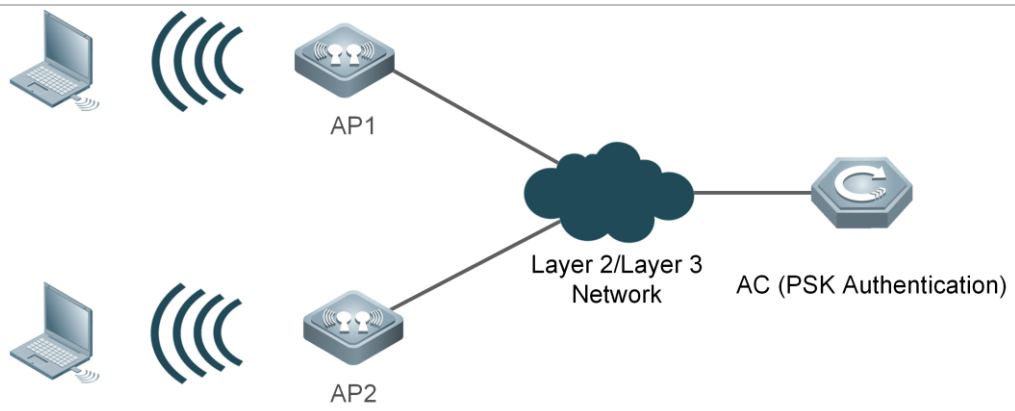
- Optional. Typically, you do not need to configure key interaction parameters. You are advised to set the packet re-transmission count and timeout duration to large values for a poor WLAN environment.
- Enable PSK or 802.1X authentication in WLAN security configuration mode on the AC first.

Command	**authtimeout** { **forbidcount** *count* | **forbidtime** *time* | **groupcount** *count* | **grouptime** *timeout* | **paircount** *count* | **pairtime** *timeout* }
Parameter Description	**forbidcount** *count*: Configures the association forbidding count after 4-way handshake key interaction fails. **forbidtime** *time*: Configures the association forbidding interval after 4-way handshake key interaction fails. **groupcount** *count*: Configures the multicast key negotiation packet re-transmission count. **grouptime** *timeout*: Configures the timeout duration of multicast key negotiation packets. **paircount** *count*: Configures the unicast key negotiation packet re-transmission count. **pairtime** *timeout*: Configures the timeout duration of unicast key negotiation packets.
Defaults	The association is not forbidden after 4-way handshake key interaction fails. The default multicast key negotiation packet re-transmission count is 4. The default timeout duration of multicast key negotiation packets is 1000 ms. The default unicast key negotiation packet re-transmission count is 4. The default timeout duration of unicast key negotiation packets is 1000 ms.
Command Mode	WLAN security configuration mode
Usage Guide	Key interaction parameters take effect only in PSK or 802.1X authentication.

↘ Configuring the Anti-jitter Time of Web Authentication

- Optional. The default anti-jitter time of web authentication is 300 seconds. You can configure the anti-jitter time based on actual requirements or disable the anti-jitter function of web authentication by setting the time to 0 seconds.

- Enable web authentication in WLAN security configuration mode on the AC first.



Command	**webauth prevent-jitter** *timeout*
Parameter Description	*timeout*: Configures the anti-jitter time of web authentication, in seconds. The range is from 0 to 86400. (The anti-jitter function of web authentication is disabled when this parameter is set to 0).
Defaults	The default anti-jitter time of web authentication is 300 seconds.
Command Mode	WLAN security configuration mode
Usage Guide	The anti-jitter time of web authentication can be configured only when web authentication is enabled.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Setting the RSN PSK+Web Authentication Mode, the Unicast Key Negotiation Packet Re-transmission Count to 5 and the Anti-jitter Time of Web Authentication to 900 Seconds for WLAN 1

Scenario **Figure 1-12**	 In fit AP mode, configure the security policies of WLAN 1 on the AC as follows: 1. Configure RSN PSK authentication. 2. Enable web authentication.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable RSN authentication. ● Configure the AES encryption mode for RSN authentication. ● Configure the PSK access authentication mode for RSN authentication. ● Configure the PSK key 12345678. ● Set the unicast key negotiation packet re-transmission count to 5. ● Configure web authentication. ● Set the anti-jitter time of web authentication to 900 seconds.

AC	`Hostname(config)#wlansec 1`
	`Hostname(config-wlansec)#security rsn enable`
	`Hostname(config-wlansec)#security rsn ciphers aes enable`
	`Hostname(config-wlansec)#security rsn akm psk enable`
	`Hostname(config-wlansec)#security rsn akm psk set-key ascii 12345678`
	`Hostname(config-wlansec)#authtimeout paircount 5`

	Hostname(config-wlansec)#webauth Hostname(config-wlansec)#webauth prevent-jitter 900
Verification	● Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	Hostname#show running-config | begin wlansec 1 wlansec 1 security rsn enable security rsn ciphers aes enable security rsn akm psk enable security rsn akm psk set-key ascii 12345678 webauth prevent-jitter 900 webauth authtimeout paircount 5

Common Errors

- The anti-jitter time of web authentication is configured before web authentication is enabled.

1.4.6 Configuring 802.11r

Whether this function is supported depends on the actual product version.

Configuration Effect

- If the 802.11r function is enabled for a WLAN, the 802.1X authentication and 4-way handshake are not required during fast roaming, thereby reducing network delay caused by roaming.

Notes

- 802.11r can be independently configured for RSN.
- The 802.11r function can be enabled for RSN only when the following conditions are met:
  - RSN authentication is enabled.
  - WPA authentication is disabled, that is, WPA and RSN cannot be enabled simultaneously.
  - The access authentication mode AKM is configured as PSK or 802.1X.
  - AES encryption is enabled.
  - TKIP encryption is disabled, that is, AES and TKIP cannot be enabled simultaneously.
- For roaming between an AC and a VAC and between ACs with the same SSID, the WLAN ID that corresponds to the SSID must be the same.
- The 802.1X LEAP authentication mode is not supported.
- 802.11r can be configured independently for RSN and WPA3.

Configuration Steps

Configuring RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC.

Command	**security rsn** { **enable** | **disable** }
Parameter Description	**enable**: Enables RSN authentication. **disable**: Disables RSN authentication.
Defaults	RSN authentication is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode can be configured for RSN authentication only when RSN authentication is enabled. Otherwise, the configuration does not take effect. When RSN authentication is used, the encryption mode and access authentication mode must also be configured. If only the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

Configuring the Encryption Mode for RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC first.
- The encryption mode for RSN authentication can be configured only when RSN authentication is enabled. The AES and TKIP encryption modes can be enabled simultaneously in the security configuration mode of a WLAN. After an encryption mode is configured for a WLAN and a STA accesses the WLAN, communication data of the STA is protected in the corresponding encryption mode.

Command	**security rsn ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode for RSN authentication. **disable**: Disables the encryption mode for RSN authentication.
Defaults	No encryption mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable the AES or TKIP encryption mode for RSN authentication. To use the 802.11r function, enable AES encryption first. In addition, TKIP encryption must be disabled. TKIP encryption is disabled by default.

Configuring the Access Authentication Mode for RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC first.
- The access authentication mode for RSN authentication can be configured only when RSN authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN. A STA can access a WLAN with access authentication enabled only after passing the access authentication.

Command	**security rsn akm** { **psk** | **802.1x** } { **enable | disable** }
Parameter	**psk**: Sets the access authentication mode to pre-shared key authentication.

Description	**802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode for RSN authentication. **disable**: Disables the access authentication mode for RSN authentication.
Defaults	No access authentication mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only when RSN authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN.

Configuring a Shared Key for RSN Authentication

- Optional. It must be configured when RSN PSK authentication is enabled.
- Enable RSN PSK authentication in WLAN security configuration mode on the AC first.

Command	**security rsn akm psk set-key** { **ascii** *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is in ASCII format. *ascii-key*: Indicates a key in ASCII format, consisting of 8 to 63 ASCII characters. **hex**: Specifies that the PSK key is in hexadecimal format. *hex-key*: Indicates a key in hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	The shared key takes effect only when PSK authentication is enabled. A key in ASCII format consists of 8 to 63 characters. A key in hexadecimal format consists of 64 characters.

Enabling 802.11r for RSN

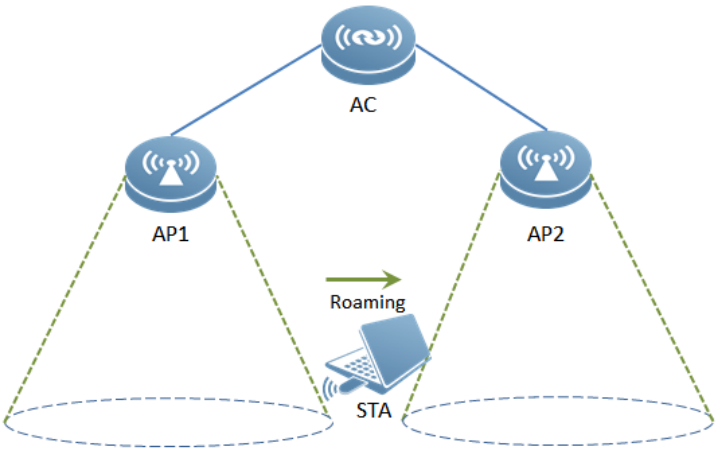
- Optional. This command is used to enable 802.11r fast roaming.

Command	**security rsn dot11r {disable | enable}**
Parameter Description	**disable**: Disables 802.11r fast roaming. **enable**: Enables 802.11r fast roaming.
Defaults	The 802.11r fast roaming function is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	When the 802.11r function is enabled, a judgment is made based on the conditions. For details about the conditions, see Notes. This command is valid only when AKM (802.1X or PSK) is enabled. This command is valid only when AES encryption is enabled.

Modifying 802.11r Re-association Timeout Duration

- Optional. This command is used to configure the re-association timeout duration (that is, the maximum interval for a client to send a re-association request after client authentication is completed).

Command	**security rsn dot11r reassoc-timeout** *timeout*
Parameter	*timeout:* Re-association timeout duration, in seconds. The range is from 1 to 120.



Description	
Defaults	The default re-association timeout duration is 20 seconds.
Command Mode	WLAN security configuration mode
Usage Guide	This command takes effect only when the 802.11r function is enabled. If the client does not initiate a re-association request within the re-association timeout duration, the roaming is stopped.

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring RSN PSK Authentication, AES Encryption, and Key 12345678 and Enabling 802.11r for WLAN 1

Scenario **Figure 1-13**	 In a fit AP environment, configure the following security policies for WLAN 1 on the AC: 1. Configure RSN PSK authentication. 2. Configure AES encryption. 3. Configure the shared key 12345678. 4. Enable 802.11r.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable RSN authentication. ● Configure the AES encryption mode for RSN authentication. ● Configure the PSK access authentication mode for RSN authentication. ● Set the PSK key to 12345678. ● Enable 802.11r.

AC	`Hostname(config)#wlansec 1`
	`Hostname(config-wlansec)#security rsn enable`
	`Hostname(config-wlansec)#security rsn ciphers aes enable`
	`Hostname(config-wlansec)#security rsn akm psk enable`
	`Hostname(config-wlansec)#security rsn akm psk set-key ascii 12345678`

	`Hostname(config-wlansec)#security rsn dot11r enable`
Verification	● Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

AC	`Hostname#show running-config | begin wlansec 1`
	`wlansec 1`
	` security rsn enable`
	` security rsn ciphers aes enable`
	` security rsn akm psk enable`
	` security rsn akm psk set-key ascii 12345678`
	` security rsn dot11r enable`
	`!`

Common Errors

- 802.11r is enabled when RSN authentication is disabled or both RSN and WPA are enabled.
- 802.11r is enabled when the access authentication mode (802.1X or PSK) is not configured.
- 802.11r is enabled when AES encryption is disabled or both AES encryption and TKIP encryption are enabled.
- The SSIDs of ACs are the same but the WLAN IDs are different, causing FT roaming failures.

1.4.7 Configuring Management Frame Encryption

Configuration Effect

- Transmit partial management frames through air interfaces in ciphertext.

Notes

- Only WPA2 supports management frame encryption. If the WLAN uses the open, WEP-40, WEP-104, or AES/TKIP (WPA authentication) mode for encryption, the management frame encryption function cannot be enabled.
- The operating systems of some STAs do not support management frame encryption.

Configuration Steps

↘ Configuring RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC.

Command	**security rsn** { **enable** | **disable** }
Parameter Description	**enable**: Enables RSN authentication. **disable**: Disables RSN authentication.
Defaults	RSN authentication is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	The encryption mode and access authentication mode for RSN authentication can be configured only

	when RSN authentication is enabled. Otherwise, the configuration does not take effect. When RSN authentication is used, the encryption mode and access authentication mode must also be configured. If only the encryption mode or the access authentication mode is configured or neither of them is configured, STAs cannot access a WLAN.

Configuring the Encryption Mode for RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC first.
- The encryption mode for RSN authentication can be configured only when RSN authentication is enabled. The AES and TKIP encryption modes can be enabled simultaneously in the security configuration mode of a WLAN. After a data encryption mode is configured for a WLAN and a STA accesses the WLAN, communication data of the STA is protected in the corresponding encryption mode.

Command	**security rsn ciphers** { **aes** | **tkip** } { **enable** | **disable** }
Parameter Description	**aes**: Configures the AES encryption mode. **tkip**: Configures the TKIP encryption mode. **enable**: Enables the encryption mode for RSN authentication. **disable**: Disables the encryption mode for RSN authentication.
Defaults	No encryption mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to enable the AES or TKIP encryption mode for RSN authentication. The AES and TKIP encryption modes can be enabled simultaneously in the security configuration mode of a WLAN.

Configuring the Access Authentication Mode for RSN Authentication

- Mandatory.
- Enable RSN authentication in WLAN security configuration mode on the AC first.
- The access authentication mode for RSN authentication can be configured only when RSN authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN. A STA can access a WLAN with access authentication enabled only after passing the access authentication.

Command	**security rsn akm** { **psk** | **802.1x** } { **enable | disable** }
Parameter Description	**psk**: Sets the access authentication mode to pre-shared key authentication. **802.1x**: Sets the access authentication mode to 802.1X authentication. **enable**: Enables the access authentication mode for RSN authentication. **disable**: Disables the access authentication mode for RSN authentication.
Defaults	No access authentication mode is configured.
Command Mode	WLAN security configuration mode
Usage Guide	The access authentication mode can be configured only when RSN authentication is enabled. Only one access authentication mode can be enabled in the security configuration mode of a WLAN.

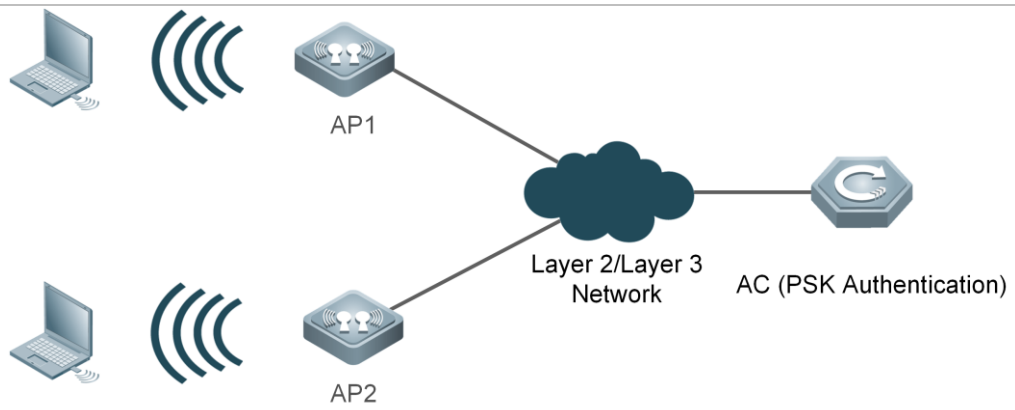
Configuring a Shared Key for RSN Authentication

- Optional. It must be configured when RSN PSK authentication is enabled.
- Enable RSN PSK authentication in WLAN security configuration mode on the AC first.

Command	**security rsn akm psk set-key** { **ascii** *ascii-key* | **hex** *hex-key* }
Parameter Description	**ascii**: Specifies that the PSK key is in ASCII format. *ascii-key*: Indicates a key in ASCII format, consisting of 8 to 63 ASCII characters. **hex**: Specifies that the PSK key is in hexadecimal format. *hex-key*: Indicates a key in hexadecimal format, consisting of 64 characters.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	The shared key takes effect only when PSK authentication is enabled. A key in ASCII format consists of 8 to 63 characters. A key in hexadecimal format consists of 64 characters.

Enabling Management Frame Encryption

- Mandatory.
- Enable management frame encryption on an AC.
- Management frame encryption can be configured only when RSN authentication is enabled.



Command	**security pmf** { **disable | mandatory** | **optional** }
Parameter Description	**disable**: Disables management frame encryption. **mandatory**: Sets management frame encryption to mandatory mode. In this mode, STAs must support management frame encryption. **optional**: Sets management frame encryption to optional mode. In this mode, STAs do not need to support management frame encryption.
Defaults	Management frame encryption is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Enabling RSN PSK Authentication and Management Frame Encryption for WLAN 1

Scenario **Figure 1-14**	 In a fit AP environment, configure the following security policies for WLAN 1 on the AC: 1. Configure RSN PSK authentication. 2. Enable management frame encryption.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable RSN authentication. ● Configure the AES encryption mode for RSN authentication. ● Configure the PSK access authentication mode for RSN authentication. ● Set the PSK key to 12345678. ● Enable management frame encryption.

AC	`Hostname(config)#wlansec 1`
	`Hostname(config-wlansec)#security rsn enable`
	`Hostname(config-wlansec)#security rsn ciphers aes enable`
	`Hostname(config-wlansec)#security rsn akm psk enable`
	`Hostname(config-wlansec)#security rsn akm psk set-key ascii 12345678`
	`Hostname(config-wlansec)#security pmf mandatory`

Verification	● Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.

AC	`Hostname#show running-config | begin wlansec 1`
	`wlansec 1`
	` security rsn enable`
	` security rsn ciphers aes enable`
	` security rsn akm psk enable`
	` security rsn akm psk set-key ascii 12345678`
	` security pmf mandatory`

Common Errors

- If an encryption mode is configured for WPA, management frame encryption cannot be enabled.
- If a STA cannot go online when **mandatory** is configured, the STA may not support management frame encryption.

1.4.8 Configuring WPA3 Authentication

Whether this function is supported depends on the actual product version.

Configuration Effect

- Enable the WPA3 authentication mode on a WLAN.

Notes

- WPA3-Personal can only be used with WPA2 for authentication. The encryption mode for WPA2 must be AES.
- WPA3-Enterprise cannot be used with WPA2 simultaneously.
- WPA3 relies on management frame encryption. Therefore, enable management frame encryption before configuring WPA3.
- WPA3 cannot be used with 802.11r.
- In scenarios where WPA3-Enterprise authentication is used, STAs that do not support WPA3 cannot access a WLAN.

Configuration Steps

Enabling Management Frame Encryption

- Mandatory.
- Configure it in WLAN security configuration mode on an AC.

Command	**security pmf** { **disable** | **optional** | **mandatory** }
Parameter Description	**disable**: Disables management frame encryption. **mandatory**: Sets management frame encryption to mandatory mode. In this mode, STAs must support management frame encryption. **optional**: Sets management frame encryption to optional mode. In this mode, STAs do not need to support management frame encryption.
Defaults	Management frame encryption is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	● When WPA3-Enterprise or OWE is used for authentication, management frame encryption must be set to mandatory mode. Otherwise, STAs may fail to access a WLAN. ● When WPA3 and WPA2 are used for authentication simultaneously, if management frame encryption is set to optional mode, STAs that support WPA2 or SAE are allowed to access a WLAN; if management frame encryption is set to mandatory mode, only WPA2 STAs that support PMF are allowed to access a WLAN.

Configuring the WPA3 Mode

- Mandatory.
- Configure the WPA3 mode in WLAN security configuration mode.

Command	**security wpa3 mode** { **enhanced-open** | **enterprise** [**ccmp-128** | **gcmp-256**] | **none** | **personal** }
Parameter	**enhanced-open**: Configures OWE authentication.

Description	**enterprise**: If the **ccmp-128** and **gcmp-256** parameters are not configured, GCMP-256 is used for encryption by default. **enterprise ccmp-128**: Configures CCMP-128 for WPA3-Enterprise authentication. **enterprise gcmp-256**: Configures GCMP-256 for WPA3-Enterprise authentication. **none**: Disables the WPA3 function. **personal**: Configures WPA3-Personal authentication**.**
Defaults	WPA3 is disabled.
Command Mode	WLAN security configuration mode
Usage Guide	● WPA3-Personal can only be used with WPA2 for authentication. The encryption mode for WPA2 must be AES. ● WPA3-Enterprise cannot be used with WPA2simultaneously. ● WPA3 cannot be used with WPA simultaneously.

Configuring an Equivalent WLAN for OWE Authentication

- Optional. It must be used together with OWE authentication. After configuration, if a STA supports OWE authentication, it accesses the WLAN using OWE authentication; if a STA does not support OWE authentication, it accesses the WLAN using open authentication.

Command	**security wpa3 enhanced-open paired-wlan** { **none** | *wlan-id* }
Parameter Description	**none**: Clears the configuration of equivalent WLANs for OWE authentication. *wlan-id*: Indicates the WLAN ID of the equivalent WLAN to be configured with OWE authentication.
Defaults	N/A
Command Mode	WLAN security configuration mode
Usage Guide	● To enable OWE authentication, an equivalent WLAN using the open authentication mode must be configured first. ● The QoS, schedule, and other configurations of the equivalent WLAN to be configured with OWE authentication must be consistent with those for OWE authentication. ● After configuring an equivalent WLAN, set the OWE authentication signal to the hidden mode. ● An equivalent WLAN can be associated with only one OWE authentication signal.

Configuring an Authentication Key for WPA3-Personal

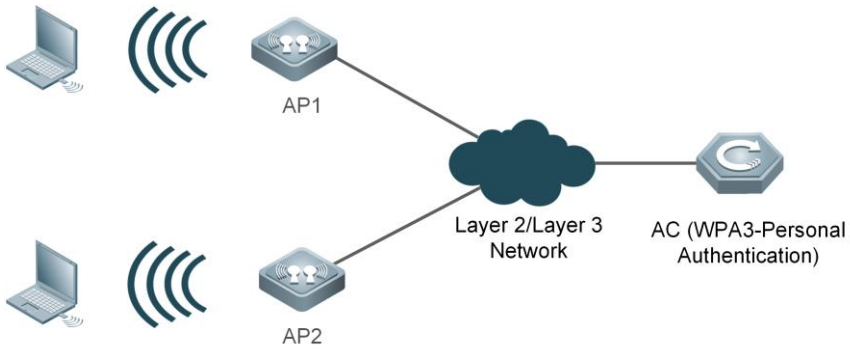
- The configuration is optional when WPA2 PSK authentication is enabled. It is mandatory only when WPA3-Personal authentication is enabled.
- If WPA3-Personal and WPA2 are used for authentication simultaneously, all STAs use the WPA2 PSK key to access a WLAN.

Command	**security wpa3 personal passphrase** { **none** | **ascii** [**0** | **7**] *password* }
Parameter Description	**none**: Clears the key. **ascii**: Configures an ASCII password. **0**: Optional. Configures a cleartext password. **7**: Optional. Configures a ciphertext password. The password must meet encryption specifications. *password*: Indicates a key in ASCII format, consisting of 8 to 63 ASCII characters.
Defaults	No key is configured for WPA3-Personal authentication.

Command Mode	WLAN security configuration mode
Usage Guide	● If you configure a cleartext password by using the **security wpa3 personal passphrase ascii 0** *password* command, the configured password is converted into and saved as a ciphertext password, and command is displayed as **security wpa3 personal passphrase ascii 7** *password*. ● If you configure a cleartext password by using the **security wpa3 personal passphrase ascii** ***password*** command, the configured password is not converted into and saved as a ciphertext password.

Configuring WPA3 SAE Encryption Mode

- Mandatory.
- In WLAN security configuration mode, set the WPA3 SAE encryption mode.



Command	**security wpa3 personal pwe** { **hnp** | **h2e** | **both** }
Parameter Description	**hnp**: Configures HnP for WPA3 SAE authentication. **h2e**: Configures H2E for WPA3 SAE authentication. **both**: Configures both HnP and H2E for WPA3 SAE authentication. The device determines the encryption mode according to the client capability. If both modes are supported, H2E encryption is used preferentially.
Defaults	The default encryption mode is HnP.
Command Mode	WLAN security configuration mode
Usage Guide	● H2E encryption is more secure than HnP encryption. When both encryption modes are supported, H2E encryption is used preferentially. ● If you configure H2E encryption, H2E-incapable clients will fail to access the network.

Verification

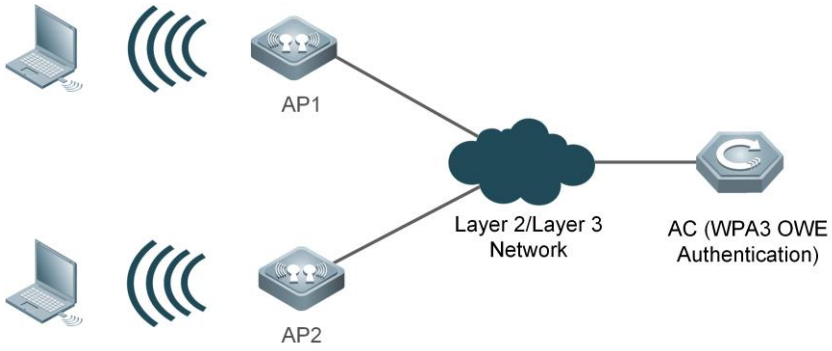
Run the **show running-config** | **begin wlansec** *wlan_id* command to check whether the configuration takes effect.

Configuration Example

Configuring the WPA3 Personal Authentication

Scenario **Figure 1-15**	 In a fit AP environment, configure the following security policies for WLAN 1 on the AC: 1. Configure the WPA3-Personal authentication mode (RSN disabled) for WLANs 1, 2, and 3.

	2. Set the shared password to 12345678 for WLAN 1, the shared cleartext password to password@123 for WLAN 2, and the shared ciphertext password to $10$27c$8Wu2G++qd4mBlYzO$ for WLAN 3. 3. Set the WPA3 SAE encryption mode to H2E for WLAN 1.
Configuration Steps	1. Enter the security configuration mode of WLANs 1, 2, and 3. 2. Enable management frame encryption. 3. Set the WPA3 password to 12345678 for WLAN 1, the cleartext password to password@123 for WLAN 2, and the ciphertext password to $10$27c$8Wu2G++qd4mBlYzO$ for WLAN 3. 4. Set the WPA3 mode to Personal. 5. Set the WPA3 SAE encryption mode to H2E.



AC	`Hostname(config)#wlansec 1`
	`Hostname(config-wlansec)#security pmf mandatory`
	`Hostname(config-wlansec)#security wpa3 personal passphrase ascii 12345678`
	`Hostname(config-wlansec)#security wpa3 mode personal`
	`Hostname(config-wlansec)#security wpa3 personal pwe h2e`

Configuring OWE Authentication for WLAN 1, Configuring WLAN 2 as an Equivalent WLAN for OWE Authentication and Setting WLAN ID to 2

Scenario **Figure 1-17**	 In a fit AP environment, configure the following security policies for WLANs on the AC: 6. Configure OWE authentication (enhanced-open mode) for WLAN 1. 7. Configure open authentication for WLAN 2. 8. Set the SSID of WLAN 1 to the hidden mode.
Configuration Steps	● Add WLAN 1. ● Add WLAN 2. ● Enter the security configuration mode of WLAN 1. ● Enable management frame encryption. ● Configure OWE authentication. Configure WLAN 2 as an equivalent WLAN for OWE authentication. ● Enter the configuration mode of WLAN 1. ● Set the SSID of WLAN 1 to the hidden mode.
AC	Hostname(config)#wlan-config 1 Open-SSID-OWE Hostname(config-wlan)#exit Hostname(config)#wlan-config 2 Open-SSID Hostname(config-wlan)#exit Hostname(config)#wlansec 1 Hostname(config-wlansec)#security pmf mandatory Hostname(config-wlansec)#security wpa3 mode enhanced-open Hostname(config-wlansec)#security wpa3 enhanced-open paired-wlan 2 Hostname(config)#exit Hostname(config-wlan)#wlan-config 1 Hostname(config-wlan)#no enable-broad-ssid Hostname(config)#exit
Verification	● Run the **show running-config | begin wlansec** *wlan_id* command to check whether the configuration takes effect.
AC	Hostname#show running-config | begin wlansec 1 wlansec 1

	security pmf mandatory security wpa3 enhanced-open paired-wlan 2 security wpa3 mode enhanced-open

Common Errors

- If WPA3-Personal or WPA3-Enterprise is configured, when WPA authentication is enabled for the WLAN, a configuration failure occurs.
- If WPA3-Personal is configured, when WPA2 (RSNA) authentication and TKIP encryption are enabled for the WLAN, a configuration failure occurs.
- If WPA3-Enterprise is configured, when WPA2 (RSNA) authentication is enabled for the WLAN, a configuration failure occurs.

1.4.9 Configuring the Response Delay Mode for Authentication Packets

Whether this function is supported depends on the actual product version.

Configuration Effect

To prevent STAs from being attacked by repeated authentication packets during the onboarding process, a response delay mode for authentication packets is introduced. After the response delay mode is enabled, if association request packets are being processed within 1,000 ms (by default), the device discards newly received authentication packets and continues to process the previous association request packets. If the processing of association request packets has timed out (for example, exceeding 1,000 ms), the device discards the previous association request packets and processes newly received authentication packets.

Notes

N/A

Configuration Steps

Configuring the Response Delay Mode for Authentication Packets

This function is enabled by default.

Command	**rsna lazy-response enable**
Parameter Description	N/A
Defaults	This function is enabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Response Delay Timeout Duration for Authentication Packets

Command	[**default**] **rsna lazy-response timer** *timer*
Parameter Description	*timer*: Indicates the delay for the device to respond to authentication packets, in milliseconds. The range is from 0 to 2000. **default**: Restores the default configuration.

Defaults	The default value is 1000.
Command Mode	Global configuration mode
Usage Guide	N/A

1.4.10 Configuring PPSK

Configuration Effect

- Enable PPSK on the WLAN.
- Clients adopt PPSK authentication upon access.

Notes

- PPSK is a PSK allocated for each client, with which you can choose not to configure the WPA-PSK or RSN-PSK.
- The WLAN should be enabled with WPA authentication mode, RSN authentication mode, or a combination of the two modes, and the PSK authentication.

Configuration Steps

Configuring PPSK

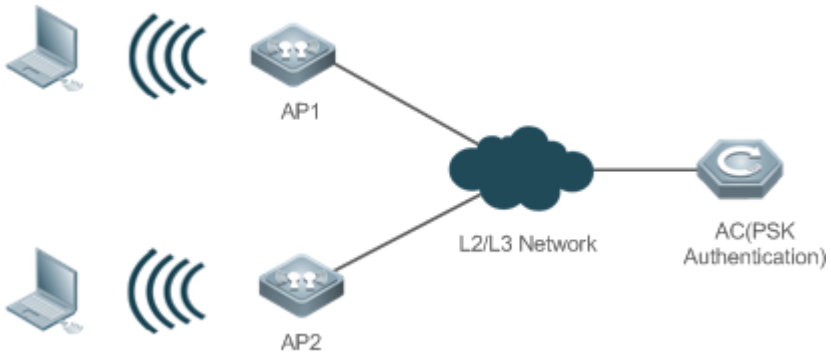
- Mandatory.
- Enter the WLAN security configuration mode to enable PPSK on the AC.

Command	**security sta-psk** { **enable** | **disable** }
Parameter Description	**enable**: Enables PPSK. **disable**: Disables PPSK.
Defaults	PPSK is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	PPSK is a PSK allocated for each client, with which you can choose not to configure the WPA-PSK or RSN PSK. If you have configured both WPA-PSK and RSN-PSK, the PPSK takes precedence over them during authentication.

Configuring PPSK External Authentication

- Optional.
- Enter the WLAN security configuration mode to enable PPSK external authentication on the AC.
- Enable PPSK before you configure this function.

Command	**security sta-psk external** { **enable** | **disable** }
Parameter Description	**enable**: Enables PPSK external authentication. **disable**: Disables PPSK external authentication.
Defaults	PPSK external authentication is disabled by default.
Command Mode	WLAN security configuration mode



Usage Guide	This command must be used with the external authentication server.

Verification

Run the **show running-config | begin wlansec** *wlan_id* command to verify the configuration result.

Configuration Example

Enabling RSN-PSK Authentication, configuring AES Encryption, and Enabling External PPSK Authentication on WLAN 1

Scenario **Figure 1-1**	 In a Fit AP environment, configure the following security policies for WLAN 1 on the AC: Configuring RSN-PSK authentication. Configuring AES encryption. Configuring external PPSK authentication.
Configuration Steps	● Enter the security configuration mode of WLAN 1. ● Enable the RSN authentication mode. ● Configure AES encryption. ● Enable RSN-PSK authentication. ● Enable PPSK. ● Enable external PPSK authentication mode.

AC	`Hostname(config)# wlansec 1`
	`Hostname(config-wlansec)# security rsn enable`
	`Hostname(config-wlansec)# security rsn ciphers aes enable`
	`Hostname(config-wlansec)# security rsn akm psk enable`
	`Hostname(config-wlansec)# security sta-psk enable`
	`Hostname(config-wlansec)# security sta-psk external enable`

Verification	Run the **show running-config	begin wlansec** *wlan_id* command to verify the configuration result.
AC	`Hostname# show running-config	begin wlansec 1` `wlansec 1` ` security rsn enable` ` security rsn ciphers aes enable` ` security rsn akm psk enable` ` security sta-psk enable` ` security sta-psk external enable` `!`

Common Errors

- The external authentication server is not configured before you enable external PPSK authentication.

1.5 Monitoring

Clearing

Running the **clear** commands may lose vital information and thus interrupt services.

Command	Purpose
N/A	N/A

Displaying

Command	Purpose
show wlan security *wlan-id*	Displays security configuration of a WLAN.
show wclient security *mac-address*	Displays security configuration of a STA.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Purpose
N/A	N/A

1 Configuring STA Access Control Lists

1.1 Overview

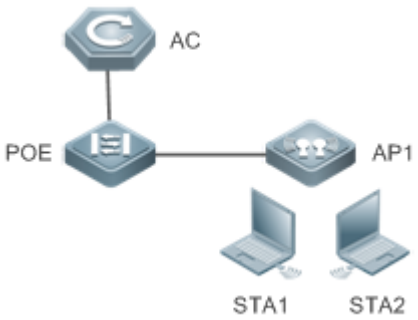
STA access control lists indicate large-capacity static blocklists and allowlists and provide the following functions:

- Blocklist and allowlist for an access controller (AC), access point (AP), AP group, or service set identifier (SSID). The maximum number of blocklists or allowlists on an AC is the maximum number of STAs supported by the AC divided by two, and the maximum number of blocklists or allowlists on an AP is 4096.
- Blocklist and allowlist based on the organizationally unique identifier (OUI), matched based on the first three bytes of the vendor identifier in the media access control (MAC) address.
- The STA access control list configuration can be exported to a file or imported from a file.

Protocols and Standards

N/A

1.2 Applications



Application	Description
Fit AP Networking	Fit AP networking is adopted, including at least one AC and one AP.

1.2.1 Fit AP Networking

Scenario

On a wireless network, deploy an AC and enable the AC-based, AP-based, AP group-based, or SSID-based blocklist or allowlist on the AC, as shown in the following figure.

Figure 1-1

Remarks	AC: wireless access controller PoE: switch, used as the gateway of the AP

	AP: wireless access point STA1 and STA2: wireless stations

Deployment

- Enable AC-based blocklist on the AC to add MAC addresses of illegal STAs to the blocklist.
- Enable AP-based allowlist on the AC to allow STAs with specified MAC addresses to access this AP only.
- Enable AP group-based allowlist on the AC to allow STAs with specified MAC addresses to access APs in this AP group only.
- Enable SSID-based allowlist on the AC to allow STAs with specified MAC addresses to access this SSID only.

1.3 Features

Basic Concepts

N/A

Overview

Feature	Description
Configuring an AC-based Blocklist and Allowlist	Disallows STAs in the blocklist to access the networks of the AC and allows STAs in the allowlist to access the networks of the AC.
Configuring an AP-based Blocklist and Allowlist	Disallows STAs in the blocklist to access the specific AP and allows STAs in the allowlist to access the AP.
Configuring an AP Group-based Blocklist and Allowlist	Disallows STAs in the blocklist to access APs in the specific AP group and allows STAs in the allowlist to access APs in the AP group.
Configuring an SSID-based Blocklist and Allowlist	Disallows STAs in the blocklist to access the specific SSID and allows STAs in the allowlist to access the SSID.
Importing and Exporting Configurations	Exports configurations to a file or imports configurations from a file.

1.3.1 Configuring an AC-based Blocklist and Allowlist

You can add the MAC addresses of illegal STAs to the MAC address blocklist of the AC to prevent these STAs from accessing all the networks of the AC.

If the network users are fixed, you can add the MAC addresses of legal STAs to the MAC address allowlist of the AC. In this case, only STAs with these MAC addresses can access the networks of the AC.

To disallow or allow STAs of specific vendors to access the AC, add the OUIs of these STAs to the OUI blocklist or allowlist of the AC. In this case, STAs of these vendors are disallowed or allowed to access the networks of the AC.

Working Principle

If the MAC address or OUI of a STA is in the blocklist or not in the allowlist when it goes online, the AC rejects the association request of the STA and sends an association failure response to it.

1.3.2 Configuring an AP-based Blocklist and Allowlist

The AP-based blocklist/allowlist function allows a network administrator to configure different blocklist and allowlist policies for different APs to control access of STAs to APs.

AP-based blocklist/allowlist includes the following two types:

- AP-based MAC address blocklist/allowlist

  To disallow or allow a STA with the specified MAC address to access the specified AP without affecting access of the STA to other APs, add the MAC address of the STA to the MAC address blocklist or allowlist of the AP. In this case, the STA is disallowed or allowed to access all the SSIDs released by the specified AP and access to other APs is not affected.

- AP-based OUI blocklist/allowlist

  To disallow or allow STAs of specific vendors to access an AP, add the OUIs of these STAs to the OUI blocklist or allowlist of the AP. In this case, STAs of these vendors are disallowed or allowed to access the SSIDs released by the AP.

Working Principle

When a STA goes online through an AP, the AC checks whether a blocklist or allowlist is configured for the AP. If the MAC address or OUI of the STA is in the blocklist or not in the allowlist, the AC disallows the STA to access the wireless network and sends an association failure response to it.

1.3.3 Configuring an AP Group-based Blocklist and Allowlist

The AP group-based blocklist/allowlist function allows a network administrator to configure different blocklist and allowlist policies for different AP groups to control access of STAs to APs in an AP group.

AP group-based blocklist/allowlist includes the following two types:

- AP group-based OUI blocklist/allowlist

  To disallow or allow STAs of specific vendors to access APs in an AP group, add the OUIs of these STAs to the OUI blocklist or allowlist of the AP group. In this case, STAs of these vendors are disallowed or allowed to access all the SSIDs released by the APs in this AP group.

- AP group-based OUI blocklist/allowlist with the specified WLAN ID

  After the AP group-based OUI blocklist/allowlist with the specified WLAN ID is enabled, when a STA attempts to access an AP through the SSID corresponding to the WLAN ID, the AC disallows or allows the STA to go online based on the blocklist or allowlist policy for the WLAN ID.

Working Principle

When a STA goes online through an AP, the AC checks whether a blocklist or allowlist is configured for the AP group to which the AP belongs. If the OUI of the STA is in the blocklist or not in the allowlist, the AC rejects the association request from the STA and sends an association failure response to it.

1.3.4 Configuring an SSID-based Blocklist and Allowlist

Some SSIDs may only allow specific STAs to access. In this case, you can configure an SSID-based blocklist or allowlist to prevent STAs out of the control scope from accessing an SSID.

To disallow or allow STAs of specific vendors to access an SSID, add the OUIs of these STAs to the OUI blocklist or allowlist of the SSID. In this case, STAs of these vendors are disallowed or allowed to access the SSID.

Working Principle

When a STA goes online through an SSID, the AC checks whether a blocklist or allowlist is configured for the SSID. If the MAC address or OUI of the STA is in the blocklist or not in the allowlist, the AC rejects the association request from the STA and sends an association failure response to it.

1.3.5 Importing and Exporting Configurations

The STA access control list configuration may be large in capacity and cannot be stored together with common configuration files. You can export it to a separate file for backup or transfer it to another AC.

You can run the **import** command to import the backup configuration file to the AC to append it to the current configuration or overwrite the current configuration. Identical configurations will be merged automatically.

Working Principle

Export: Write the current configuration to the specified file in command format. The file can be exported from the AC using the **copy** command for backup or transfer.

Import: Read the specified file and import the configuration commands to the AC. In overwriting mode, configurations on the AC will be cleared in advance. In merging mode, entries in the file will be appended to the current configuration.

1.4 Configuration

Configuration	Description and Command	
Configuring an AC-based Blocklist	⚠ (Mandatory) It is used to add STAs to the AC-based blocklist.	
	blacklist mac *sta-mac*	Adds MAC addresses of STAs to the MAC address blocklist of the AC.
	blacklist vendor mac *sta-oui*	Adds OUIs of STAs to the OUI blocklist of the AC.
Configuring an AC-based Allowlist	⚠ (Mandatory) It is used to add STAs to the AC-based allowlist.	
	whitelist mac *sta-mac*	Adds MAC addresses of STAs to the MAC address allowlist of the AC.
	whitelist vendor mac *sta-oui*	Adds OUIs of STAs to the OUI allowlist of the AC.
Configuring an AP-based Blocklist	⚠ (Mandatory) It is used to add STAs to the AP-based blocklist.	
	blacklist mac *sta-mac* **in-ap** *ap-mac*	Adds MAC addresses of STAs to the MAC address blocklist of an AP.
	blacklist vendor mac *sta-oui* **in-ap** *ap-mac*	Adds OUIs of STAs to the OUI blocklist of an AP.
Configuring an AP-based	⚠ (Mandatory) It is used to add STAs to the AP-based allowlist.	

Allowlist	**whitelist mac** *sta-mac* **in-ap** *ap-mac*	Adds MAC addresses of STAs to the MAC address allowlist of an AP.
	whitelist vendor mac *sta-oui* **in-ap** *ap-mac*	Adds OUIs of STAs to the OUI allowlist of an AP.
Configuring an AP Group-based Blocklist	(Mandatory) It is used to add STAs to the AP group-based blocklist.	
	blacklist mac *sta-mac* **in-apg** *apg-name* [**wlan** *wlan-id*]	Adds MAC addresses of STAs to the MAC address blocklist of an AP group.
	blacklist vendor mac *sta-oui* **in-apg** *apg-name* [**wlan** *wlan-id*]	Adds OUIs of STAs to the OUI blocklist of an AP group. (A WLAN ID can be specified.)
	blacklist vendor mac *sta-oui* [**wlan** *wlan-id*] (AP group configuration mode)	Adds OUIs of STAs to the OUI blocklist of the current AP group. (A WLAN ID can be specified.)
Configuring an AP Group-based Allowlist	(Mandatory) It is used to add STAs to the AP group-based allowlist.	
	whitelist mac *sta-mac* **in-apg** *apg-name* [**wlan** *wlan-id*]	Adds MAC addresses of STAs to the MAC address allowlist of an AP group.
	whitelist vendor mac *sta-oui* **in-apg** *apg-name* [**wlan** *wlan-id*]	Adds OUIs of STAs to the OUI allowlist of an AP group. (A WLAN ID can be specified.)
	whitelist vendor mac *sta-oui* [**wlan** *wlan-id*] (AP group configuration mode)	Adds OUIs of STAs to the OUI allowlist of the current AP group. (A WLAN ID can be specified.)
Configuring an SSID-based Blocklist	(Mandatory) It is used to add STAs to the SSID-based blocklist.	
	blacklist mac *sta-mac* **in-ssid** *ssid-string*	Adds MAC addresses of STAs to the MAC address blocklist of an SSID.
	blacklist vendor mac *sta-oui* **in-ssid** *ssid-string*	Adds OUIs of STAs to the OUI blocklist of an SSID.
Configuring an SSID-based Allowlist	(Mandatory) It is used to add STAs to the SSID-based allowlist.	
	whitelist mac *sta-mac* **in-ssid** *ssid-string*	Adds MAC addresses of STAs to the MAC address allowlist of an SSID.
	whitelist vendor mac *sta-oui* **in-ssid** *ssid-string*	Adds OUIs of STAs to the OUI allowlist of an SSID.
Importing and Exporting Configurations	(Optional) It is used to import and export configurations.	
	export	Exports the current STA access control list configuration to a file.
	import	Imports the STA access control list configuration from a file.

1.4.1 Configuring an AC-based Blocklist

Configuration Effect

- STAs added to the MAC address blocklist cannot access all the networks of the AC.
- STAs of vendors added to the OUI blocklist cannot access all the networks of the AC.

Notes

N/A

Configuration Steps

Adding MAC Addresses of STAs to the MAC Address Blocklist of the AC

- Mandatory. Configure it on the AC.

Command	**blacklist mac** *sta-mac* [**mnemonic** *string*]
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● After a blocklist is configured, STAs that meet the conditions are not allowed to access the network. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. ● When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations.

Adding OUIs of STAs to the OUI Blocklist of the AC

- Mandatory. Configure it on the AC.

Command	**blacklist vendor mac** *sta-oui* [**mnemonic** *string*]
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● The OUI blocklist is used to match OUIs of STAs. STAs of vendors in the OUI blocklist are not

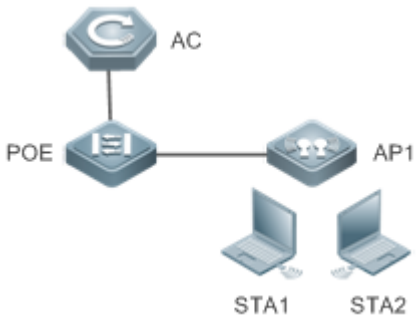
	allowed to access the network. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. ● When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list blacklist** command to display the information about STAs in the MAC address blocklist of the AC.
- Run the **show black-white-list blacklist vendor** command to display the vendor OUIs in the OUI blocklist of the AC.

Configuration Example

↘ Configuring a MAC Address Blocklist for the AC



Scenario **Figure 1-2**	
Configuration Steps	● Configure a MAC address blocklist for the AC.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# blacklist mac 0069.6c3f.2baa`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list blacklist** command. ● Check whether STAs added to the MAC address blocklist cannot associate with the AC.

AC	

Configuring an OUI Blocklist for the AC

Scenario Figure 1-3	
Configuration Steps	● Configure an OUI blocklist for the AC.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# blacklist vendor mac 0069.6c`
	`AC(black-white-list)# blacklist vendor mac 0c51.01`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list blacklist vendor** command. ● Check whether STAs of vendors added to the OUI blocklist cannot associate with the AC.
AC	

Common Errors

- N/A

1.4.2 Configuring an AC-based Allowlist

Configuration Effect

- When there are entries in the MAC address allowlist, STAs not added to the allowlist cannot access any network of the AC.
- When there are entries in the OUI allowlist, STAs of vendors not added to the OUI allowlist cannot access any network of the AC.

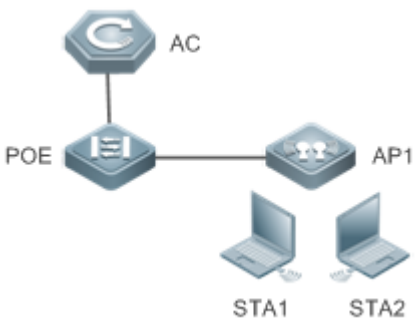
Notes

- N/A

Configuration Steps

Adding MAC Addresses of STAs to the MAC Address Allowlist of the AC

- Mandatory. Configure it on the AC.



Command	**whitelist mac** *sta-mac* **[mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	• After an allowlist is configured, only STAs that meet conditions are allowed to access the network. • If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the network. • Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. • The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. • Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. • When an entry is added to the allowlist, other STAs will not be kicked offline. • In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list whitelist** command to display information about the STAs in the MAC address allowlist of the AC.

Configuration Example

↘ Configuring a MAC Address Allowlist for the AC

Scenario **Figure 1-4**	

Configuration Steps	● Configure a MAC address allowlist for the AC.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# whitelist mac 0069.6c3f.2baa`
	`AC(black-white-list)# whitelist mac 0c51.016a.5d8e`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list whitelist** command. ● Check whether STAs not added to the allowlist cannot associate with the AC.
AC	

Adding OUIs of STAs to the OUI Allowlist of the AC

- Mandatory. Configure it on the AC.

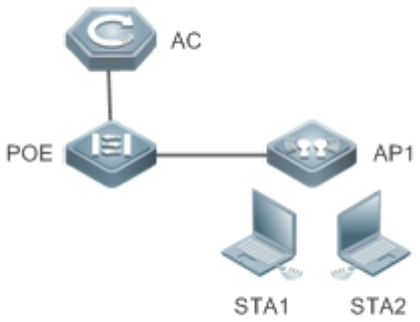
Command	**whitelist vendor mac** *sta-oui* **[mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● The OUI allowlist is used to match the OUIs of STAs. STAs of vendors in the OUI allowlist are allowed to access the network. ● If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the network. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. ● When an entry is added to the allowlist, other STAs will not be kicked offline. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Configuration Steps

Adding OUIs of STAs to the OUI Allowlist of the AC

- Mandatory. Configure it on the AC.

Command	**whitelist vendor mac** *sta-oui* **[mnemonic** *string***]**



Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● The OUI allowlist is used to match the OUIs of STAs. STAs of vendors in the OUI allowlist are allowed to access the network. ● If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the network. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list whitelist vendor** command to display the vendor OUIs in the OUI allowlist of the AC.

Configuration Example

↘ Configuring an OUI Allowlist for the AC

Scenario **Figure 1-5**	
Configuration	● Configure an OUI allowlist for the AC.

Steps	
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# black-white-list AC(black-white-list)# whitelist vendor mac 0069.6c AC(black-white-list)# whitelist vendor mac 0c51.01
Verification	● Run the **show black-white-list whitelist vendor** command to display the configuration entries. ● Check whether STAs of vendors not added to the OUI allowlist cannot associate with the AC.
AC	

Common Errors

- N/A

1.4.3 Configuring an AP-based Blocklist

Configuration Effect

- STAs added to the MAC address blocklist of an AP cannot access all the networks of the AP.
- STAs of vendors added to the OUI blocklist of an AP cannot access all the networks of the AP.

Notes

- N/A

Configuration Steps

↘ Adding MAC Addresses of STAs to the MAC Address Blocklist of the Specified AP

- Mandatory. Configure it on the AC.

Command	**blacklist mac** *sta-mac* **[in-ap** *ap-mac* **| mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● After a blocklist is configured, STAs that meet the conditions are not allowed to access the networks of the AP. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is

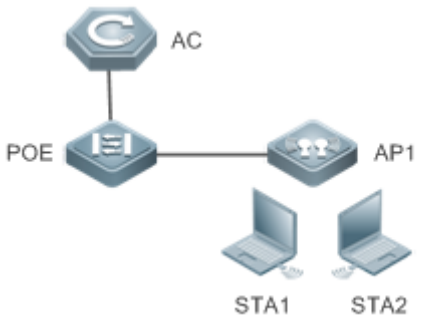
	added to allowlists of other types. ● When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list blacklist in-ap** *ap-mac* command to display information about the STAs in the MAC address blocklist of the AP.

Adding OUIs of STAs to the OUI Blocklist of the AP

- Mandatory. Configure it on the AC.

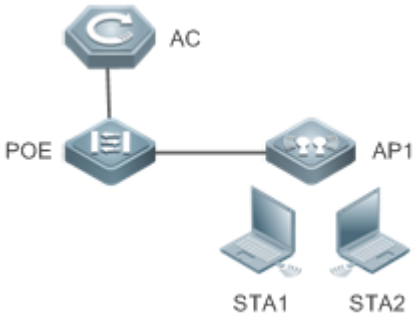


Command	**blacklist vendor mac** *sta-oui* **[in-ap** *ap-mac* **| mnemonic** *string* **]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● The OUI blocklist is used to match OUIs of STAs. STAs of vendors in the OUI blocklist are not allowed to access the network. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. ● When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list blacklist vendor** command to display the vendor OUIs in the OUI blocklist of the AP.

Configuration Example



Configuring a MAC Address Blocklist for an AP

Scenario **Figure 1-6**	
Configuration Steps	● Configure a MAC address blocklist for AP1 with the MAC address 0074.9c06.9afa.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# blacklist mac 0069.6c3f.2baa in-ap 0074.9c06.9afa`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list blacklist** command. ● Check whether STAs added to the MAC address blocklist cannot associate with the AP.
AC	

Configuring an OUI Blocklist for an AP

Scenario **Figure 1-7**	
Configuration Steps	● Configure an OUI blocklist for AP1 with the MAC address 0074.9c06.9afa.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# blacklist vendor mac 0069.6c in-ap 0074.9c06.9afa`
	`AC(black-white-list)# blacklist vendor mac 0c51.01 in-ap 0074.9c06.9afa`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list blacklist vendor in-ap** *ap-mac* command.

	● Check whether STAs of vendors added to the OUI blocklist cannot associate with the AP.
AC	

Common Errors

- N/A

1.4.4 Configuring an AP-based Allowlist

Configuration Effect

- When there are entries in the MAC address allowlist of an AP, STAs not added to the allowlist cannot access any network of the AP.
- When there are entries in the OUI allowlist of an AP, STAs of vendors not added to the OUI allowlist cannot access any network of the AP.

Notes

- N/A

Configuration Steps

↘ Adding MAC Addresses of STAs to the MAC Address Allowlist of the Specified AP

- Mandatory. Configure it on the AC.

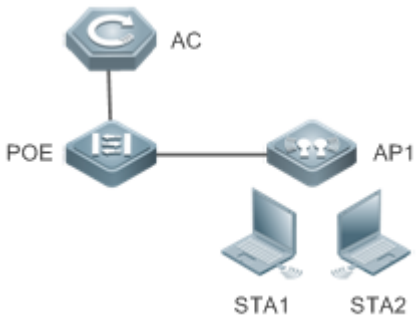
Command	**whitelist mac** *sta-mac* **in-ap** *ap-mac* [**mnemonic** *string*]
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● After an allowlist is configured, only STAs that meet conditions are allowed to access the networks of the AP. ● If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the networks of the AP. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. ● When an entry is added to the allowlist, other STAs will not be kicked offline. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list whitelist in-ap** *ap-mac* command to display information about the STAs in the allowlist of the AP.

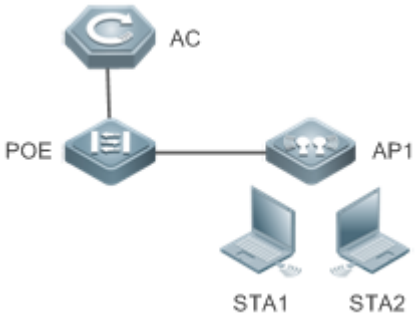
Adding OUIs of STAs to the OUI Allowlist of the Specified AP

- Mandatory. Configure it on the AC.



Command	**whitelist vendor mac** *sta-oui* **in-ap** *ap-mac* **[mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	• The OUI allowlist is used to match the OUIs of STAs. STAs of vendors in the OUI allowlist are allowed to access the networks of the AP. • If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the network. • Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. • The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. • Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. • When an entry is added to the allowlist, other STAs will not be kicked offline. • In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification



- Run the **show black-white-list whitelist vendor in-ap** *ap-mac* command to display the vendor OUIs in the OUI allowlist of the AP.

Configuration Example

Configuring a MAC Address Allowlist for an AP

Scenario **Figure 1-8**	
Configuration Steps	● Configure a MAC address allowlist for AP1 with the MAC address 0074.9c06.9afa.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# black-white-list AC(black-white-list)# whitelist mac 0069.6c3f.2baa in-ap 0074.9c06.9afa AC(black-white-list)# whitelist mac 0c51.016a.5d8e in-ap 0074.9c06.9afa
Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list whitelist in-ap** *ap-mac* command. ● Check whether STAs not added to the allowlist cannot associate with the AP.
AC	

Configuring an OUI Allowlist for an AP

Scenario **Figure 1-9**	
Configuration Steps	● Configure an OUI allowlist for AP1 with the MAC address 0074.9c06.9afa.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# black-white-list AC(black-white-list)# whitelist vendor mac 0069.6c in-ap 0074.9c06.9afa AC(black-white-list)# whitelist vendor mac 0c51.01 in-ap 0074.9c06.9afa

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list whitelist vendor in-ap** *ap-mac* command. ● Check whether STAs of vendors not added to the allowlist cannot associate with the AP.
AC	

Common Errors

N/A

1.4.5 Configuring an AP Group-based Blocklist

Configuration Effect

- STAs added to the MAC address blocklist of an AP cannot access all the networks of the AP group.
- STAs of vendors added to the OUI blocklist of an AP group cannot access all the networks of the AP group.

Notes

- AP groups support only the OUI blocklist and allowlist and do not support the MAC address blocklist and allowlist.
- Configurations in AP group configuration mode and STA access control list configuration mode with the **in-apg** parameter are the same. However, the **show running-config** command displays the configuration in AP group configuration mode. In a hierarchical AC scenario, the configuration can be synchronized from the central AC to a branch AC.
- A non-existent AP group name can be specified for the AP group-based OUI blocklist. The OUI of a STA is matched against the OUI blocklist only when the name of the AP group to which the AP that the STA accesses belongs is the same as the AP group name of the blocklist.
- When an AP group-based OUI blocklist with the specified WLAN ID is configured, a non-existent WLAN ID or a WLAN ID not added to the AP group can be specified. The WLAN ID range is from 1 to 4094.
- When the AP group-based OUI blocklist with the specified WLAN ID is configured, the OUI of the STA is matched against the OUI blocklist only when the STA accesses an AP in the AP group through the SSID corresponding to the WLAN ID. When no WLAN ID is specified, the OUI of the STA is matched against the OUI blocklist when the STA accesses an AP in the AP group through any SSID.
- The OUI blocklist is used to match OUIs of STAs. STAs of vendors in the OUI blocklist are not allowed to access the network.
- Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs.
- The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC.
- Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types.
- When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately.

Configuration Steps

Adding MAC Addresses of STAs to the MAC Address Blocklist of the Specified AP group

- Mandatory. Configure it on the AC.

Command	**blacklist mac** *sta-mac* **in-apg** *apg-name* [**wlan** *wlan-id*] [**mnemonic** *string*]
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	• After a blocklist is configured, STAs that meet the conditions are not allowed to access the networks of the AP. • Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. • The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. • Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. • When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately. • In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

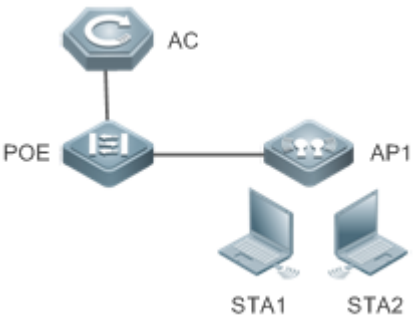
Verification

- Run the **show black-white-list blacklist in-ap** *ap-mac* command to display information about the STAs in the MAC address blocklist of the AP group.

Adding OUIs of STAs to the OUI Blocklist of an AP Group

- Mandatory. Configure it on the AC.

Command	**blacklist vendor mac** *sta-oui* **in-apg** *apg-name* [**wlan** *wlan-id*] [**mnemonic** *string*]
Parameter Description	*sta-oui*: OUI of a STA, in the format of hhhh.hh. If there are no parameters after *sta-oui*, the blocklist is configured for the AC. *apg-name*: Name of the AP group for which an OUI blocklist is configured. This parameter takes effect only on the AC. *wlan-id*: WLAN ID specified when an OUI blocklist is configured for an AP group. This parameter takes effect only on the AC. *string*: Mnemonic, which is displayed in the output of the **show** command to facilitate viewing.
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.



Command	**blacklist vendor mac** *sta-oui* [**wlan** *wlan-id*] [**mnemonic** *string*]
Parameter Description	*sta-oui*: OUI of a STA, in the format of hhhh.hh. If there are no parameters after *sta-oui*, the blocklist is configured for the AC. *apg-name*: Name of the AP group for which an OUI blocklist is configured. This parameter takes effect only on the AC. *wlan-id*: WLAN ID specified when an OUI blocklist is configured for an AP group. This parameter takes effect only on the AC. *string*: Mnemonic, which is displayed in the output of the **show** command to facilitate viewing.
Defaults	No entry is configured.
Command Mode	AP group configuration mode
Usage Guide	N/A

Verification

- Run the **show black-white-list blacklist vendor in-apg** *apg-name* [**wlan** *wlan-id*] command to display OUIs of vendors in the OUI blocklist of the AP group.

Configuration Example

Configuring an OUI Blocklist for an AP Group

Scenario Figure 1-10	
Configuration Steps	● Configure an OUI blocklist for AP group APG1.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# blacklist vendor mac 0069.6c in-apg APG1`
	`AC(black-white-list)# blacklist vendor mac 0069.6d in-apg APG1 wlan 1`
	`AC(black-white-list)# exit`
	`AC(config)# ap-group APG1`
	`AC(config-group)# blacklist vendor mac 0c51.01`
	`AC(config-group)# blacklist vendor mac 0c51.02 wlan 1`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list blacklist vendor in-apg** *apg-name* [**wlan** *wlan-id*] command. (Note: If no WLAN ID is specified, the OUI blocklist of the AP group without WLAN ID specified is displayed.) ● Check whether STAs of vendors added to the OUI blocklist cannot associate with APs in the AP group.

Common Errors

N/A

1.4.6 Configuring an AP Group-based Allowlist

Configuration Effect

- When there are entries in the MAC address allowlist of an AP, STAs not added to the allowlist cannot access any network of the AP group.
- When there are entries in the OUI allowlist of the specified AP group, STAs of vendors not added to the OUI allowlist cannot access APs in this AP group.

Notes

- A non-existent AP group name can be specified for the AP group-based OUI allowlist. The OUI of a STA is matched against the OUI allowlist only when the name of the AP group to which the AP that the STA accesses belongs is the same as the AP group name of the allowlist.
- A non-existent WLAN ID or a WLAN ID not added to an AP group can be specified for an AP group-based OUI allowlist. The WLAN ID range is from 1 to 4094. When a WLAN ID is specified, the OUI of a STA is matched against the OUI allowlist only when the STA accesses an AP in the AP group through the SSID corresponding to the WLAN ID. When no WLAN ID is specified, the OUI of a STA is matched against the OUI allowlist when the STA accesses an AP in the AP group through any SSID.
- The OUI allowlist is used to match the OUIs of STAs. STAs of vendors in the OUI allowlist are allowed to access the network.
- If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the network.
- Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs.
- The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC.
- Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types.
- When an entry is added to the allowlist, other STAs will not be kicked offline.
- Configurations in AP group configuration mode and STA access control list configuration mode with the **in-apg** parameter are the same. However, the **show running-config** command displays the configuration in AP group configuration mode. In a hierarchical AC scenario, the configuration can be synchronized from the center AC to a branch AC.

Configuration Steps

Adding MAC Addresses of STAs to the MAC Address Allowlist of the Specified AP group

- Mandatory. Configure it on the AC.

Command	**whitelist mac** *sta-mac* **in-apg** *apg-name* [**wlan** *wlan-id*] [**mnemonic** *string*]
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	• After an allowlist is configured, only STAs that meet conditions are allowed to access the networks of the AP. • If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the networks of the AP. • Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. • The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. • Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. • When an entry is added to the allowlist, other STAs will not be kicked offline. • In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

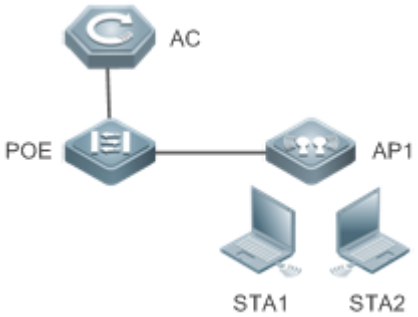
Run the **show black-white-list whitelist in-ap** *ap-mac* command to display information about the STAs in the allowlist of the AP group.

Adding OUIs of STAs to the OUI Allowlist of the Specified AP Group

- Mandatory. Configure it on the AC.

Command	**whitelist vendor mac** *sta-oui* **in-apg** *apg-name* [**wlan** *wlan-id*] [**mnemonic** *string*]
Parameter Description	*sta-oui*: OUI of a STA, in the format of hhhh.hh. If there are no parameters after *sta-oui*, the allowlist is configured for the AC. *apg-name*: Name of the AP group for which an OUI allowlist is configured. This parameter takes effect only on the AC. *wlan-id*: WLAN ID specified when an OUI allowlist is configured for an AP group. This parameter takes effect only on the AC. *string*: Mnemonic, which is displayed in the output of the **show** command to facilitate viewing.
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode

Usage Guide	● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.



Command	**whitelist vendor mac** *sta-oui* [**wlan** *wlan-id*] **[mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	AP group configuration mode
Usage Guide	N/A

Verification

- Run the **show black-white-list whitelist vendor in-apg** *apg-name* [**wlan** *wlan-id*] command to display the OUIs of vendors in the OUI allowlist of the AP group.

Configuration Example

Configuring an OUI Allowlist for an AP Group

Scenario Figure 1-11	
Configuration Steps	● Configure an OUI allowlist for AP group APG1.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# whitelist vendor mac 0069.6c in-apg APG1`
	`AC(black-white-list)# whitelist vendor mac 0069.6d in-apg APG1 wlan 1`
	`AC(black-white-list)# exit`
	`AC(config)# ap-group APG1`
	`AC(config-group)# whitelist vendor mac 0c51.01`
	`AC(config-group)# whitelist vendor mac 0c51.01 wlan 1`

Verification	● Configuration entries are displayed in the output of the **show black-white-list whitelist vendor in-apg** *apg-name* [**wlan** *wlan-id*] command. (Note: If no WLAN ID is specified, the OUI allowlist of the AP group without WLAN ID specified is displayed.) ● STAs of vendors not added to the allowlist cannot associate with APs in the AP group.

Common Errors

N/A

1.4.7 Configuring an SSID-based Blocklist

Configuration Effect

- STAs added to the MAC address blocklist of an SSID cannot access the SSID.
- When there are entries in the OUI blocklist of the specified SSID, STAs of vendors added to the OUI blocklist cannot access the SSID.

Notes

N/A

Configuration Steps

↘ Adding MAC Addresses of STAs to the MAC Address Blocklist of the Specified SSID

- Mandatory. Configure it on the AC.

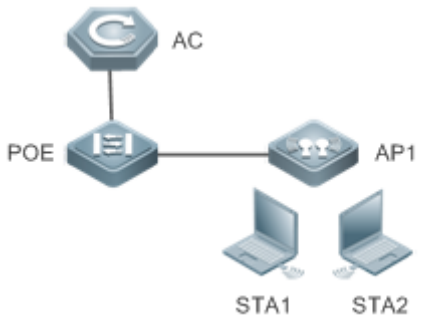
Command	**blacklist mac** *sta-mac* **in-ssid** *ssid* [**mnemonic** *string*]
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	● After a blocklist is configured, STAs that meet the conditions are not allowed to access the network. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. ● When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list blacklist in-ssid** *ssid* command to display information about the STAs in the MAC address blocklist of the SSID.

Adding OUIs of STAs to the OUI Blocklist of the Specified SSID

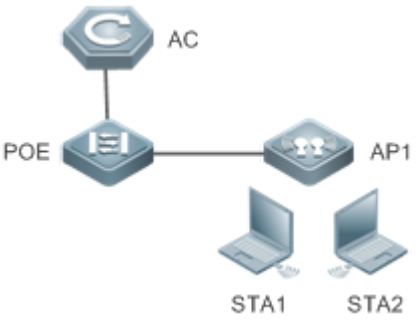
- Mandatory. Configure it on the AC.



Command	**blacklist vendor mac** *sta-oui* **in-ssid** *ssid* **[mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	• The OUI blocklist is used to match OUIs of STAs. STAs of vendors in the OUI blocklist are not allowed to access the network. • Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. • The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. • Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. • When the blocklist is enabled, an online STA that meets the conditions will be kicked offline immediately. • In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list blacklist vendor in-ssid** *ssid* command to display the OUIs of vendors in the OUI blocklist of the SSID.



Configuration Example

Configuring a MAC Address Blocklist for an SSID

Scenario **Figure 1-12**	

Configuration Steps	● Configure a MAC address blocklist for SSID Hostname-web.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# black-white-list AC(black-white-list)# blacklist mac 0069.6c3f.2baa in-ssid Hostname-web
Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list blacklist in-ssid** *ssid-string* command. ● Check whether STAs added to the blocklist cannot associate with the SSID.
AC	

Configuring an OUI Blocklist for an SSID

Scenario **Figure 1-13**	
Configuration Steps	● Configure an OUI blocklist for SSID Hostname-web.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# black-white-list AC(black-white-list)# blacklist vendor mac 0069.6c in-ssid Hostname-web AC(black-white-list)# blacklist vendor mac 0c51.01 in-ssid Hostname-web
Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list blacklist vendor in-ssid** *ssid-string* command. ● Check whether STAs of vendors added to the blocklist cannot associate with the SSID.
AC	

Common Errors

- N/A

1.4.8 Configuring an SSID-based Allowlist

Configuration Effect

- When there are entries in the MAC address allowlist of the specified SSID, STAs not added to the MAC address allowlist cannot access the SSID.
- When there are entries in the OUI allowlist of the specified SSID, STAs of vendors not added to the OUI allowlist cannot access the SSID.

Notes

- N/A

Configuration Steps

Adding MAC Addresses of STAs to the MAC Address Allowlist of the Specified SSID

- Mandatory. Configure it on the AC.

Command	**whitelist mac** *sta-mac* **in-ssid** *ssid* **[mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.
Command Mode	STA access control list configuration mode
Usage Guide	• After an allowlist is configured, only STAs that meet conditions are allowed to access the network. • If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the network. • Different types of blocklists and allowlists are complex in priority. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. • Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. • When an entry is added to the allowlist, other STAs will not be kicked offline. • In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

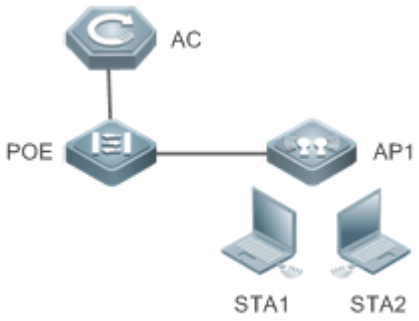
Verification

- Run the **show black-white-list whitelist in-ssid** *ssid* command to display information about the STAs in the MAC address allowlist of the SSID.

Adding OUIs of STAs to the OUI Allowlist of the Specified SSID

- Mandatory. Configure it on the AC.

Command	**whitelist vendor mac** *sta-oui* **in-ssid** *ssid* **[mnemonic** *string***]**
Parameter Description	N/A
Defaults	No entry is configured.

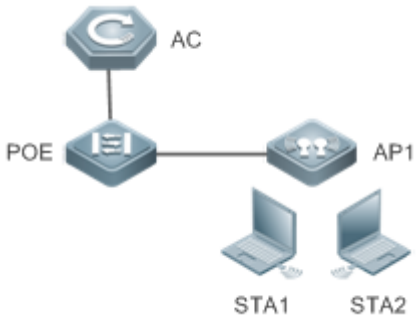


Command Mode	STA access control list configuration mode
Usage Guide	● The OUI allowlist is used to match the OUIs of STAs. STAs of vendors in the OUI allowlist are allowed to access the network. ● If the allowlist is empty, all STAs are allowed to access the network. If there is data in the allowlist, STAs not listed in the allowlist are immediately banned from accessing the network. ● Different types of blocklists and allowlists are complex in priority. You are advised to select a single type according to your needs. ● The MAC address allowlist and blocklist of the same type are mutually exclusive. For example, a MAC address added to the allowlist of an AC cannot be added to the blocklist of the AC. ● Blocklist has a higher priority than allowlist. For example, a STA added to any type of blocklist (MAC address or OUI blocklist of an AC, AP, AP group, or SSID) cannot go online even if it is added to allowlists of other types. ● When an entry is added to the allowlist, other STAs will not be kicked offline. ● In STA access control list configuration mode, run the **show black-white-list config** command to display the blocklist and allowlist configurations. The **show running-config** command is not supported in this configuration mode.

Verification

- Run the **show black-white-list whitelist vendor in-ssid** *ssid* command to display the OUIs of vendors in the OUI allowlist of the SSID.

Configuration Example



↘ Configuring a MAC Address Allowlist for an SSID

Scenario Figure 1-14	
Configuration Steps	● Configure a MAC address allowlist for SSID Hostname-web.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# whitelist mac 0069.6c3f.2baa in-ssid Hostname-web`
	`AC(black-white-list)# whitelist mac 0c51.016a.5d8e in-ssid Hostname-web`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list whitelist in-ssid** *ssid-string* command. ● Check whether STAs not added to the MAC address allowlist cannot associate with the SSID.
AC	

↘ Configuring an OUI Allowlist for an SSID

Scenario **Figure 1-15**	
Configuration Steps	● Configure an OUI allowlist for SSID Hostname-web.

AC	`AC# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`AC(config)# black-white-list`
	`AC(black-white-list)# whitelist vendor mac 0069.6c in-ssid Hostname-web`
	`AC(black-white-list)# whitelist vendor mac 0c51.01 in-ssid Hostname-web`

Verification	● Check whether configuration entries are displayed in the output of the **show black-white-list whitelist vendor in-ssid** *ssid-string* command. ● Check whether STAs of vendors not added to the OUI allowlist cannot associate with the SSID.
AC	

Common Errors

- N/A

1.4.9 Importing and Exporting Configurations

Configuration Effect

- Export the current STA access control list configuration to a file.
- Import the STA access control list configuration from a file. You can select whether the imported configuration is appended to or overwrites the current configuration. In overwriting mode, configurations on the AC will be cleared in advance. In merging mode, entries in the file will be appended to the current configuration.

Notes

- If the flash memory is insufficient during configuration export, a failure prompt is displayed.

Configuration Steps

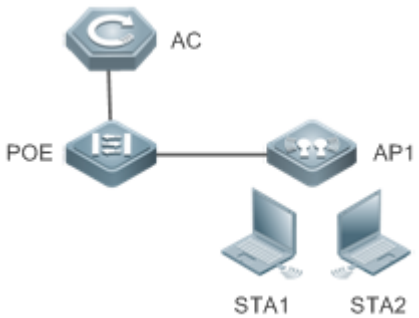
Exporting the Current Configuration to a File

- Optional. Configure it on the AC.
- This command takes effect only once and is not saved.

Command	**export**
Parameter Description	N/A
Defaults	N/A
Command Mode	STA access control list configuration mode
Usage Guide	The configuration will be exported to the **black-white-list.csv** file. You can run the **copy** command to upload the file to a PC and use Excel to edit it.

Importing the Configuration from a File

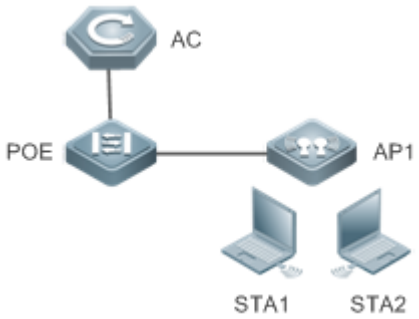
- Optional. Configure it on the AC.
- This command takes effect only once and is not saved.



Command	**import** *filename* **{replace | append}**
Parameter Description	N/A
Defaults	N/A
Command Mode	STA access control list configuration mode
Usage Guide	N/A

Verification

- Run the **show black-white-list config** command to display the configurations.
- Run the **dir** command to display files in the flash memory.



Configuration Example

Exporting the Current Configuration to a File

Scenario Figure 1-16	
Configuration	● Export the current configuration to the **black-white-list.csv** file.

Steps	
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# black-white-list Hostname(black-white-list)# export 10 entrys successfully exported.
Verification	● Run the **dir** command. Check whether the **black-white-list.csv** file is displayed in the command output. ● Run the **more black-white-list.csv** command. Check whether the file content is the STA access control list configuration.
AC	

↘ Importing the Configuration from a File

Scenario Figure 1-17	
Configuration Steps	● Import the configuration from the **black-white-list.csv** file and append it to the current configuration.
AC	AC# configure terminal Enter configuration commands, one per line. End with CNTL/Z. AC(config)# black-white-list AC(black-white-list)# import black-white-list.csv append
Verification	● Run the **show black-white-list config** command to display the configurations.
AC	

Common Errors

- N/A

1.5 Monitoring

Clearing

Command	Purpose

Command	Purpose
reset blacklist [**in-ap** *ap-mac* **| in-ssid** *ssid-string*]	Clears entries in the MAC address blocklist of an AC, AP, or SSID.
reset whitelist [**in-ap** *ap-mac* **| in-ssid** *ssid-string*]	Clears entries in the MAC address allowlist of an AC, AP, or SSID.
reset whitelist vendor [**in-ap** *ap-mac* **| in-apg** *apg-name* [**wlan** *wlan-id*] **| in-ssid** *ssid-string*]	Clears entries in the OUI allowlist of an AC, AP, AP group, or SSID.
reset blacklist vendor [**in-ap** *ap-mac* **| in-apg** *apg-name* [**wlan** *wlan-id*] | **in-ssid** *ssid-string*]	Clears entries in the OUI blocklist of an AC, AP, AP group, or SSID.

Displaying

Command	Purpose
show black-white-list summary	Displays basic information of a STA access control list.
show black-white-list config	Displays the STA access control list configuration.
show black-white-list conflict	Displays STAs in both the blocklist and allowlist.
show black-white-list sta-mac *sta-mac*	Displays the blocklist/allowlist configuration type of a specific STA.
show black-white-list blacklist [**in-ap** *ap-mac* **| in-ssid** *ssid-string*]	Displays entries in the MAC address blocklist of an AC, AP, or SSID.
show black-white-list blacklist vendor [**in-ap** *ap-mac* **| in-apg** *apg-name* [**wlan** *wlan-id*] **| in-ssid** *ssid-string*]	Displays entries in the OUI blocklist of an AC, AP, AP group, or SSID.
show black-white-list whitelist [**in-ap** *ap-mac* **| in-ssid** *ssid-string*]	Displays entries in the MAC address allowlist of an AC, AP, or SSID.
show black-white-list whitelist vendor [**in-ap** *ap-mac* | **in-apg** *apg-name* [**wlan** *wlan-id*] **| in-ssid** *ssid-string*]	Displays entries in the OUI allowlist of an AC, AP, AP group, or SSID.

1 Configuring WIDS

1.1 Overview

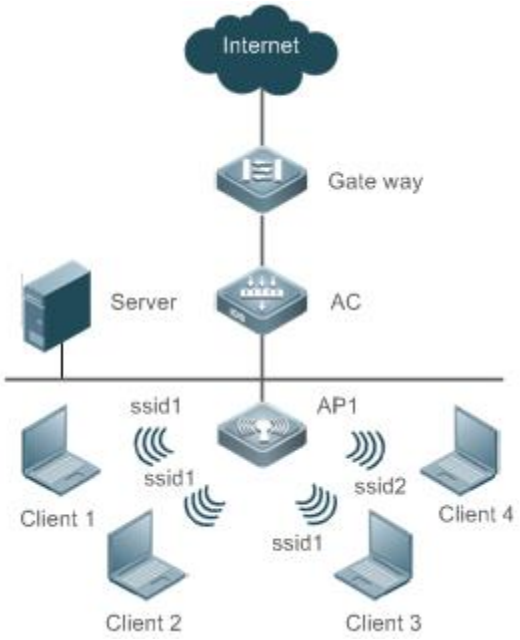
Compared with wired networks, the wireless LAN (WLAN) has unparalleled advantages, such as convenient deployment, flexible use, efficient cost, and easy extension. These benefits contribute to the increasing popularity of WLAN. However, due to channel openness, WLAN is vulnerable to various network threats, such as rogue access points (APs), ad hoc networks, and different types of protocol attacks. Therefore, security becomes a major factor that hinders WLAN development.

Wireless Intrusion Detection System (WIDS) can detect malicious station (STA) attacks and intrusions in an early stage, helping network administrators proactively discover and defend against potential risks on networks in a timely manner.

1.2 Applications

Application	Description
Frame Filtering	When unauthorized STAs attempt to access the WLAN, WIDS frame filtering can control STA access.
User Isolation	When a STA intends to access other STAs on the WLAN, WIDS user isolation can isolate their direct communication.
IDS	Intrusion Detection System (IDS) can detect different types of attacks and intrusions on the WLAN.
Rogue Detection and Containment	WIDS rogue device detection and containment can monitor and contain unauthorized devices that compromise normal STAs and services by providing counterfeit services on the WLAN.

1.2.1 Frame Filtering



Scenario

Frame filtering provides the STA access control service on the WLAN, including allowing specified STAs to access WLANs or specified WLANs, preventing STAs from accessing WLANs or specified WLANs, preventing low-rate STAs from accessing WLANs, as well as dynamically controlling STA access.

The following figure shows an example. Assume that the WLANs have the following deployment requirements:

- Allow Client 1 to access WLAN and Client 2 to access SSID 1.
- Prohibit Client 3 from accessing WLAN and Client 4 from accessing SSID 2.
- Filter out low-rate STAs and disconnect them.
- Dynamically control STA access.

Figure 2-1 Networking Topology of Wireless Access Control

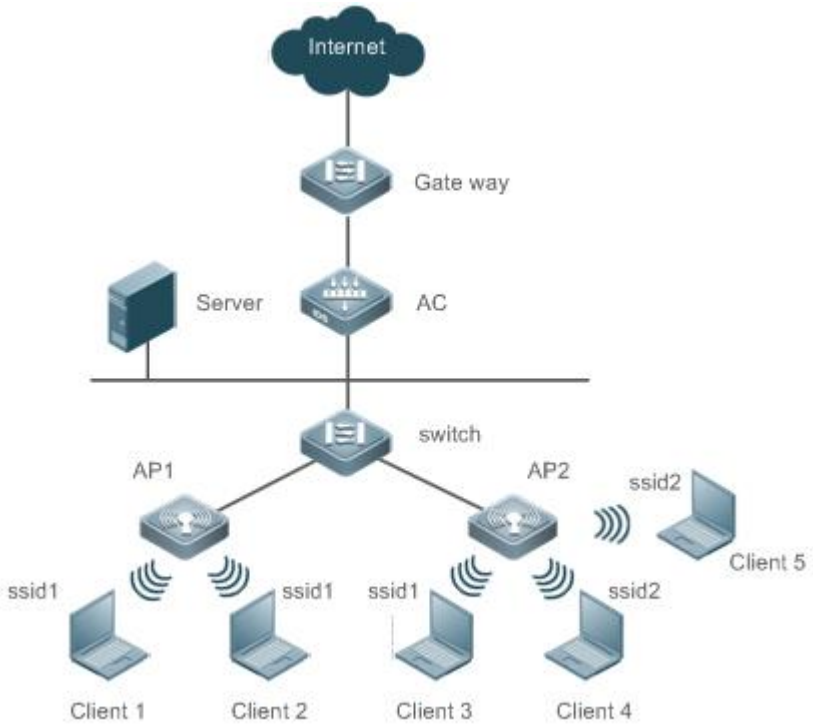
Deployment

The key configuration points for the devices are as follows:

- Add Client 1 to a WIDS allowlist. As a result, Client 1 can access the WLAN service provided by all APs connected to the AC. Other STAs not in the list cannot.
- Add Client 2 to the SSID 1-based allowlist. As a result, Client 2 can access SSID 1 provided by all APs connected to the AC. Other STAs not in the list cannot.
- Add Client 3 to a static blocklist. As a result, Client 3 cannot access the WLAN service provided by all APs connected to the AC.
- Add Client 4 to the SSID 1-based blocklist. As a result, Client 4 cannot access SSID 1 provided by all APs connected to the AC.
- Configure the threshold Rt for filtering out low-rate STAs. As a result, STAs with rates lower than the threshold will be disconnected.
- Enable the dynamic blocklist function, which can be used with the IDS function. After the dynamic blocklist and IDS functions are enabled, detected attacks are added to a dynamic blocklist. Before the blocklist ages out, the STAs that meet the conditions of the blocklist are prevented from communication and access through the AP.

1.2.2 User Isolation

Scenario



Layer 2 user isolation is provided on a WLAN, including AP-based, AP-SSID-based, and SSID-based user isolation. Assume that the WLANs have the following deployment requirements.

Client 1 to Client 3 are associated with SSID 1, and Client 4 and Client 5 are associated with SSID 2. SSID 1 and SSID 2 are mapped to the same VLAN. Client 1 to Client 5 are Layer 2 users.

- Direct communication cannot be conducted between Client 1 and Client 2, and between Client 3 to Client 5, but can be conducted among other users.

- Direct communication cannot be conducted between Client 1 and Client 2, and between Client 4 and Client 5, but can be conducted among other users.
- Direct communication cannot be conducted between Client 1 and Client 3, Client 4 or Client 5, and between Client 2 and Client 3, Client 4 or Client 5, but can be conducted among other users.
- Direct communication cannot be conducted between Client 3 and Client 1 or Client 2, but can be conducted among other users.
- Direct communication cannot be conducted between Client 3 and Client 4 or Client 5, but can be conducted between Client 4 and Client 5.
- Direct communication cannot be conducted between Client 1 to Client 3, but can be conducted among other users.

Figure 2-2 Networking Topology of Wireless User Isolation

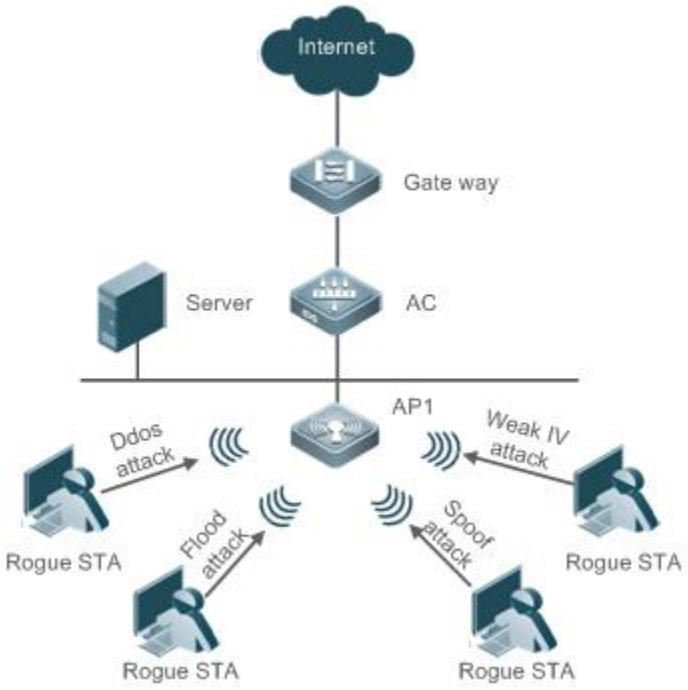
Deployment

The key configuration points for the devices are as follows:

- Configure AP-based user isolation. As a result, direct communication cannot be conducted between Client 1 and Client 2, and between Client 3 to Client 5.
- Configure AP-SSID based user isolation. As a result, direct communication cannot be conducted between Client 1 and Client 2, and between Client 4 and Client 5.
- Configure AC-based user isolation. As a result, direct communication cannot be conducted between Client 1 or Client 2 and Client 3 to Client 5.
- Configure AC-SSID-based user isolation. As a result, direct communication cannot be conducted between Client 3 and Client 1 or Client 2.

- Configuring AP-SSID based user isolation can isolate direct communication between Client 3 and Client 4, and between Client 3 and Client 5.
- Configure SSID 1-based user isolation. As a result, direct communication cannot be conducted between Client 1, Client 2, and Client 3.

1.2.3 IDS



Scenario

Wireless invasion attacks exist on networks, including Distributed Denial of Service (DDoS), spoofing, flooding, and Weak initialization vector (IV) attacks. APs need to detect these attacks and implement countermeasures.

Assume that an AP needs to detect and defend against the following attacks:

- DDoS attacks
- Spoofing attacks
- Flooding attacks
- Weak IV attacks

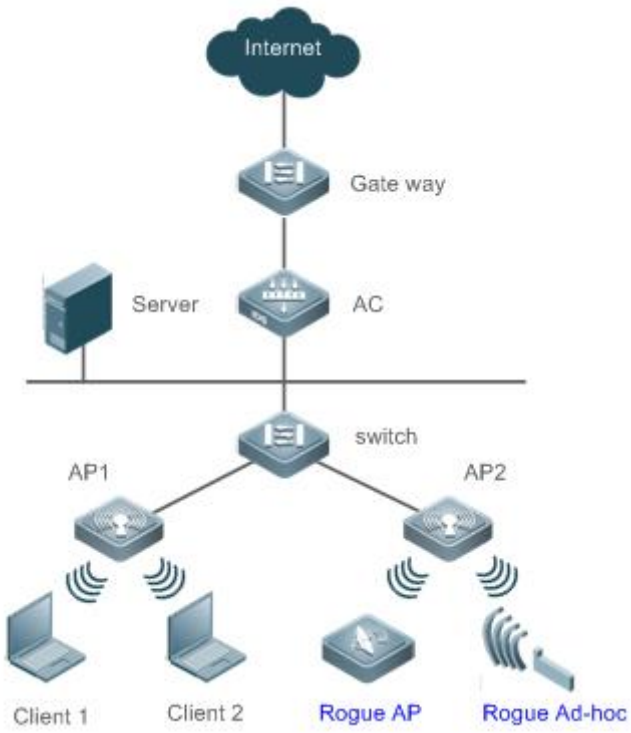
Figure 2-3 Networking Topology of IDS

Deployment

The key configuration points for the devices are as follows:

- Enable DDoS attack detection and configure thresholds for collecting statistics on ARP, SYN, and ICMP attack packets from STAs. If any threshold is exceeded and the dynamic blocklist is enabled, the detection result is logged, and the STAs are added to the dynamic blocklist.

- Enable spoofing attack detection and configure thresholds for detecting deauthentication and disassociation packets. If any threshold is exceeded and the dynamic blocklist is enabled, the detection result is logged, and the STAs are added to the dynamic blocklist.
- Enable flood attack detection and configure thresholds for detecting Authentication, Association, Reassociation, Deauthentication, Disassociation, Probe, Null, and Action packets. If any threshold is exceeded and the dynamic blocklist is enabled, the detection result is logged, and the STAs are added to the dynamic blocklist.
- Enable weak IV attack detection and configure thresholds for detecting the IV values of web packets. If the number of consecutive attacks exceeds the threshold and the dynamic blocklist is enabled, the detection result is logged, and the STAs are added to the dynamic blocklist.



1.2.4 Rogue Detection and Containment

Scenario

Assume that there is the following deployment requirement on the network:

- Rogue AP and Ad-hoc devices exist on a network, and detection and containment are required.

Figure 2-4 Networking Topology of Rogue Detection and Containment

Deployment

The key configuration points for devices are as follows:

- Enable the monitor or hybrid mode for a specified AP. Then the AP starts the scanning timer and obtains scanning data at the end of each scanning period.
- Enable device containment and configure a containment mode.

- Regularly contain rogue APs and ad hoc devices based on the device containment mode and scanning data to prevent STAs from associating with counterfeit services.
- Before enabling AP containment to take effect, verify that the WLAN service is available on the AP; otherwise, the containment function is unavailable.

1.3 Features

Basic Concepts

Working Modes

WIDS has the following working modes:

- Normal mode: Provides only the access service.
- Monitor mode: Provides only the monitoring service.
- Hybrid mode: Provides both monitoring and access services.

IDS Detection Types

IDS provides detection of the following attacks:

- DDoS attacks, including ARP, ICMP, and SYN packets
- Flood attacks, including single-user and multi-user management packets
- Spoofing attacks, including broadcast disassociation and deauthentication attacks
- Weak IV attacks
- Interworking DoS attacks

User Isolation Modes

User isolation has the following modes:

- AC-based mode for isolating Layer 2 STAs connected to different APs associated with an AC.
- AP-based mode for isolating Layer 2 STAs connected to the same AP
- AC-SSID mode for isolating Layer 2 STAs connected to different APs associated with an AC on the same WLAN.
- AP-SSID-based mode for isolating Layer 2 STAs connected to the same AP on the same WLAN
- SSID-based mode for isolating Layer 2 STAs on a specified WLAN

Rogue Device Containment Modes

Rogue device containment has the following modes:

- Ad-hoc mode for containing the rogue Ad-hoc devices
- Rogue mode for containing the rogue devices with RSSIs exceeding the threshold
- SSID mode for containing unauthorized devices connected to the same SSID
- Config mode for containing unauthorized devices in the static attack list or SSID-based blocklist

Fuzzy Containment on Rogue APs

- Fuzzy match is performed based on the SSID of rogue APs. For example, if the fuzzy containment function is enabled and the SSID of the local AP is RUIJIE-WEB, rogue APs with the SSID of RU1JIE-WEB are contained.
- Fuzzy containment can be performed by keyword. For example, if the fuzzy containment function is enabled and the fuzzy containment keyword **ruijie** is configured, rogue APs with SSIDs that include **ruijie** such as **ruijie-free** are contained. The keyword is case-insensitive. For example, the keyword **ruijie** has 2^6 uppercase and lowercase combinations, and any of the combinations (such as **RUIjie** and **RuiJie**) can be matched for fuzzy containment.

Detected Devices

Rogue devices that can be detected are as follows:

- APs
- Ad-hoc devices
- Unknown STAs

Overview

Feature	Description
Frame Filtering	Uses frame filtering rules to filter the packets from STAs for STA access control.
IDS	Discovers and defends against malicious or unintentional attacks on WLANs in a timely manner.
User Isolation	Prevents insecure access between STAs on WLANs to avoid private information interception.
Rogue Device Detection and Containment	Monitors abnormal devices on the entire WLAN, helping network administrators discover potential risks on a network. Rogue device containment refers to containing rogue devices by sending fake deauthentication frames to addresses of the rogue devices in an attack list.

1.3.1 Frame Filtering

STA access control includes filtering based on low-rate STAs, allowlists, static blocklists, dynamic blocklists, SSID-based allowlists, and SSID-based blocklists.

Working Principle

Filtering Based on Low-Rate STAs

Filtering based on low-rate STAs is performed based on a filtering threshold. When the threshold is larger than 0, this function is enabled. If the STA rate is lower than this threshold, the STA's packets are discarded and this STA is disconnected.

Allowlist

The allowlist includes MAC addresses of allowed STAs. If the allowlist function is enabled, only allowlisted STAs can access the WLAN. Other STAs are forced to go offline and cannot access the WLAN, thereby reducing the impact of invalid packets on the WLAN.

Static Blocklist

The static blocklist includes the MAC address of denied STAs. If the static blocklist function is enabled, STAs in the static blocklist are forced to go offline and cannot access the WLAN.

Dynamic Blocklist

The dynamic blocklist includes the MAC addresses of denied STAs, which can be dynamically added by WIDS if IDS attacks are detected or manually configured. For example, if IDS attacks from a STA are detected on the WLAN, the MAC address of the STA can be dynamically added to the blocklist to prevent packet receiving from the STA, thereby ensuring WLAN security.

SSID-based Allowlist

The SSID-based allowlist includes the MAC addresses of the STAs that are allowed to access a WLAN with a specified SSID. You can configure the SSID-based allowlist on the CLI. If the SSID-based allowlist function is enabled, only the STAs in the allowlist of the specified WLAN are allowed to access. Other STAs cannot access the specified WLAN and online STAs that are not in the allowlist are forced to go offline, thereby reducing the impact of invalid packets on the WLAN.

SSID-based Blocklist

The SSID-based blocklist includes the MAC addresses of the STAs that are prevented from accessing a WLAN with a specified SSID. You can configure the SSID-based blocklist on the CLI. If the SSID-based blocklist function is enabled, STAs in the blocklist are forced to go offline and cannot access this WLAN.

1.3.2 IDS Attack Detection

To discover and defend against malicious or unintentional attacks on WLANs in a timely manner, WIDS can detect various types of attacks. When an attack is detected, an alarm or a log is generated to remind the network administrator to handle it. According to detection results, the network administrator can promptly adjust network configurations to eliminate insecure factors on the WLANs.

The following IDS attack detection types are supported:

- DDoS attack detection
- Flood attack detection
- Spoofing attack detection
- Weak IV attack detection
- Interworking DoS attack detection

Working Principle

DDoS Attack Detection

In DDoS attacks, an attacker sends a large number of attack packets to target devices in a short period to prevent authorized STAs from associating with the attacked devices. ARP packets, ICMP packets, and SYN packets can be identified.

The DDoS attack detection function of WIDS collects statistics on attacker's packets, determines whether the number of packets per second exceeds the configured threshold, and records the detection result in a log if the threshold is exceeded. If the dynamic blocklist function is enabled, the attacker address is added to the dynamic blocklist.

Flood Attack Detection

In flood attacks, an attacker sends a large number of packets of the same type in a short period. As a result, WLAN devices fail to process authorized STA requests.

Flood attack detection prevents flood attacks by continuously monitoring the traffic of each device. If the traffic within the specified period exceeds the upper limit set by the network administrator, the device is deemed as a flood attacker and is therefore blocked. Flood attack detection can be used with the dynamic blocklist function. In this case, if WIDS detects flood attacks, the STA initiating the attacks is added to the dynamic blocklist to protect the WLAN system against intrusions of this STA and ensure network security.

Spoofing Attack Detection

In spoofing attacks, an attacker sends spoofed packets by disguising as another STA. For example, a spoofed deauthentication packet can cause legal STAs to go offline.

WIDS performs detection on broadcast deauthentication and broadcast disassociation packets. When such packets are received, they are immediately defined as a spoofing attack and logged.

Weak IV Attack Detection

In weak IV attacks, an attacker intercepts packets with weak IVs on WLANs that use WEP encryption, cracks the shared key, and finally obtains encrypted information.

If a WLAN uses WEP encryption, an IV is generated for each packet. The IV and shared key are used as input to generate a key string. The key string and plaintext are encrypted to generate a ciphertext. When a WEP packet is sent, the IV used for packet encryption is also sent as a part of the packet header. If the IV is generated using an insecure method (for example, the same IV is frequently or always used), the shared key will be exposed easily. If a potential attacker obtains the shared key, it can control network resources and pose a threat to network security.

WIDS prevents weak IV attacks by identifying the IV of each WEP packet. When a packet with a weak IV is detected, WIDS immediately determines that a vulnerability exists and logs the detection result.

Interworking DoS Attack Detection

In interworking DoS attacks, every STA which is connected or tries to access, if the number of Action, Association, Authentication, Deauthentication, Disassociation, Reassociation, Probe Request, or Null data packets of each STA that is connected or tries to access is larger than the configured threshold, an attack occurs.

1.3.3 User Isolation

Because of mobility of STAs, STA information privacy is important in some scenarios (especially in public areas). Therefore, direct STA communication should be restricted. The user isolation technology can avoid insecure access (for example, through My Network Places) between STAs in WLAN coverage areas to prevent private information interception.

User isolation isolates STAs and prevents them from accessing each other without affecting normal network access, guaranteeing service security. User isolation has the following types:

- AP-SSID-based Layer 2 user isolation
- Inter-AP-SSID based Layer 2 user isolation
- AC-based user isolation

- AC-SSID-based user isolation
- Interworking user isolation

Working Principle

AP-based User Isolation

Direct communication cannot be conducted between Layer 2 STAs associated with the same AP.

AP-SSID-based User Isolation

Direct communication cannot be conducted between STAs in the same WLAN who are associated with the same AP.

Inter-AP-SSID-based Layer 2 User Isolation

Direct communication cannot be conducted between STAs who are associated with the same AP but with different SSIDs.

AC-based User Isolation

Direct communication cannot be conducted between Layer 2 STAs who are associated with the same AC but with different APs. This is effective only in centralized forwarding mode.

AC-SSID-based User Isolation

Direct communication cannot be conducted between STAs in the same WLAN who are associated with the same AC but with different APs. This is effective only in centralized forwarding mode.

Interworking User Isolation

Interworking user isolation depends on SSID-based isolation functions. It takes effect on APs in local forwarding mode and on ACs in centralized forwarding mode.

1.3.4 Rogue Device Detection and Containment

Network devices are typically classified into two types: unauthorized (rogue) and authorized. Rogue devices may have security vulnerabilities or may be manipulated by attackers, which poses a major threat or hazard to network security. The rogue device detection function of WIDS can monitor abnormal devices on the entire WLAN, helping a network administrator discover potential risks on networks.

Rogue detection is applicable to different rogue devices on WLANs, including APs, clients, wireless bridges, and ad hoc devices. Only detection of rogue APs, ad hoc devices, and unknown STAs is supported.

Rogue device containment refers to containing rogue devices by sending fake deauthentication frames to addresses of the rogue devices, in order to prevent STAs from accessing unauthorized services or access devices.

Working Principle

Rogue Device Detection

Rogue device detection is conducted by an AP in monitor or hybrid mode. WIDS obtains wireless packets by deploying some APs on WLANs and configuring them to operate in monitor or hybrid mode. By conducting analysis and statistics of monitored wireless packets, the APs can obtain information on rogue devices. Additionally, a network administrator can also configure unauthorized device detection rules to monitor abnormal devices on the entire WLAN.

Unknown STA Detection

The unknown STA detection function monitors the probe request packets from non-connected STAs on a network. Additionally, a network administrator can specify information on unknown STAs.

Rogue Device Containment

The rogue device containment function contains rogue devices that meet containment rules by simulating fake broadcast deauthentication packets, thereby preventing normal STAs from accessing rogue devices.

Unknown STA Containment

The unknown STA containment function denies access of unknown STAs by directly constructing deauthentication packets.

Interworking Rogue AP Detection

The function of interworking rogue AP detection is aimed at preventing unauthorized APs from interfering with authorized APs in signal transmission, and even preventing authorized STAs from being intercepted out of registration information. Based on rogue device detection, interworking rogue AP detection is used to terminate the network connection of unauthorized APs in collaboration with the background system if permitted.

1.4 Configuration

Configuration	Description and Command	
Configuring Frame Filtering	(Optional) It is used to configure frame filtering.	
	kickout threshold	Configures the threshold for disconnecting low-rate STAs.
	whitelist mac-address [**name** *another-name*]	Adds an entry to the allowlist.
	whitelist max	Configures the length of the allowlist.
	static-blacklist mac-address [**name** *another-name*]	Adds an entry to the static blocklist.
	static-blacklist max	Configures the length of the static blocklist.
	dynamic-blacklist enable	Enables the dynamic blocklist function.
	dynamic-blacklist lifetime	Configures the lifetime of the dynamic blocklist.
	dynamic-blacklist ac-max	Configures the length of the dynamic blocklist on ACs.
	dynamic-blacklist ap-max	Configures the length of the dynamic blocklist on APs.
	dynamic-blacklist mac-address	Configures dynamic blocklist entries.
	dynamic-blacklist mac-address [**name** *another-name*]	Adds an entry to the dynamic blocklist.
	ssid-filter max	Configures the SSID-based blocklist and allowlist and their length.

Configuration	Description and Command	
	ssid-filter blacklist mac-address [**name** *another-name*]	Adds an entry to the SSID-based blocklist.
	ssid-filter blacklist max	Configures the length of the SSID-based blocklist. The default value is 256.
	ssid-filter whitelist mac-address	Adds an entry to the SSID-based allowlist.
	ssid-filter whitelist max	Configures the length of the SSID-based allowlist. The default value is 256.
Configuring IDS	(Mandatory) It is used to configure IDS.	
	attack-detection enable	Specifies the IDS type.
	attack-detection ddos	Configures the packet rate threshold and interval of DDoS attack detection.
	attack-detection flood multi-mac	Configures the packet rate threshold and interval of multi-STA flood attack detection.
	attack-detection flood single-mac	Configures the packet rate threshold and interval of single-user flood attack detection.
	attack-detection spoof	Configures the packet rate threshold and interval of the spoofing attack detection.
	attack-detection weak-iv	Configures the packet rate threshold and interval of the weak IV attack detection.
	attack-detection statistics ac-max	Configures the length of IDS statistics on ACs.
	attack-detection statistics ap-max	Configures the length of IDS statistics on APs.
	dos-detection	Configures interworking DoS attack detection.
Configuring User Isolation	(Optional) It is used to configure user isolation.	
	user-isolation enable	Enables AC-based, AP-based, AC-SSID-based, AP-SSID-based and interworking Layer 2 user isolation.
	user-isolation permit-mac	Adds an entry to the allowed MAC address list for user isolation.
	user-isolation permit-mac max	Configures the length of the allowed MAC address list for user isolation.
Configuring Rogue Detection and Containment	(Optional) It is used to set device detection and containment.	
	countermeasures enable	Enables rogue device containment.
	countermeasures ap-max	Configures the maximum number of contained devices once.
	countermeasures channel-match	Enables channel-based containment.
	countermeasures interval	Configures the containment interval.
	countermeasures mode	Configures the containment mode.
	countermeasures rssi-min	Configures the minimum containment RSSI.

Configuration	Description and Command	
	countermeasures fuzzy-enable	Enables fuzzy containment.
	countermeasures fuzzy-keyword	Configures a keyword for fuzzy containment.
	device aging duration	Configures the aging duration of detected devices.
	device attack mac-address	Adds an entry to the static attack list.
	device attack max	Configures the length of the static attack list.
	device black-ssid	Adds an entry to the SSID-based blocklist.
	device max-black-ssid	Configures the length of the SSID-based blocklist.
	device friendly-flags	Configures the device friendly flag.
	device permit mac-address	Adds an entry to the permissible MAC list.
	device permit mac-address max	Configures the length of the permissible MAC list.
	device permit ssid	Adds an entry to the permissible SSID list.
	device permit max-ssid	Configures the length of the permissible SSID list.
	device permit vendor bssid	Adds an entry to the permissible vendor list.
	device permit vendor bssid max	Configures the length of the permissible vendor list.
	device unknown-sta dynamic-enable	Enables unknown STA detection and containment.
	device unknown-sta mac-address	Adds an entry to the unknown STA list.
	device unknown-sta mac-address max	Configures the length of the unknown STA list.
	device unknown-sta report enable	Enables unknown STA detection information reporting.
	device channel-bind radio	Configures the scanning channel of a specified radio.
	device scan-para	Configures the interworking unauthorized AP detection.
	device detected-ap-max	Configures the maximum number of detected APs.
	hybrid-scan radio	Configures the scanning status of a specified radio.
	scan-channels { **802.11a** | **802.11b** | **6GHz** } **channels**	Configures the scanning channel of a specified AP.
	scan-channels { **dual-band** | **all-band** }	Configures automatic channel scanning between different frequency bands.
	rogue-ap countermeasures enable	Enables interworking rogue AP containment.
Configuring the AP Working Mode	⚠ (Optional) It is used to set the AP working mode.	
	device mode	Configures the AP working mode.

1.4.1 Configuring Frame Filtering

Configuration Effect

- Configure frame filtering rules to enable packet filtering.

Notes

- A STA cannot be configured in both the static blocklist and the allowlist.
- A STA cannot be configured in both the blocklist and allowlist of the same SSID.

Configuration Steps

Configuring Low-Rate STA Filtering

- Optional.
- The **kickout threshold** command is used in WIDS configuration mode to configure the low-rate STA filtering threshold. The threshold must be larger than 0 to make the filtering function take effect.

Command	**kickout threshold** *rate*
Parameter Description	*rate*: Indicates the low-rate STA filtering threshold. The value range is from 0 to 130, in Mbps.
Defaults	By default, low-rate STAs are not filtered out, and the low-rate STA filtering threshold is 0.
Command Mode	WIDS configuration mode
Usage Guide	Set a low-rate STA filtering threshold as required.

Configuring STA Disconnection

- (Optional) The **kickout client** command is used in WIDS configuration mode to disconnect online STAs.

Command	**kickout client** *H.H.H*
Parameter Description	*H.H.H*: Indicates the MAC address of a STA to be disconnected.
Defaults	N/A
Command Mode	WIDS configuration mode
Usage Guide	This command can be used to disconnect a specified online STA.

Configuring an Allowlist

- Optional.
- Configure an allowlist entry on the AC that needs to be enabled with the allowlist function.
- Configure an allowlist length on the AC that needs to be enabled with the allowlist function.
- Run the **whitelist mac-address** command to add an entry to the allowlist in WIDS configuration mode. The allowlist function takes effect only after an effective allowlist entry is configured.
- Run the **whitelist max** command to configure the maximum number of entries in the allowlist in WIDS configuration mode.
- If an allowlist is configured, all online STAs whose addresses are not in the allowlist will be forced to go offline 1 minute after the last configuration command is executed.
- One *another-name* may map to multiple MAC addresses, but one MAC address can map to only one *another-name*.
- *another-name* is empty if it is not configured.

Command	**whitelist** { **mac-address** *H.H.H* [**name**_*another-name*] |**max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the MAC address of an allowlist entry. **name** *another-name*: Indicates the alias of the MAC address in the allowlist. **max** *num*: Indicates the length of the allowlist. The value range is from 1 to 2048.
Defaults	By default, the allowlist is empty and the allowlist length is 1,024.
Command Mode	WIDS configuration mode
Usage Guide	The allowlist function takes effect only when the allowlist contains one or more entries.

Configuring a Static Blocklist

- Optional.
- Configure the static blocklist entry on the AC that needs to be enabled with the static blocklist function.
- Configure the static blocklist length on the AC that needs to be enabled with the static blocklist function.
- Run the **static-blacklist mac-address** command to add an entry to the static blocklist in WIDS configuration mode. The static blocklist-based filtering function takes effect only after an effective static blocklist entry is configured.
- Run the **static-blacklist max** command to configure the maximum number of entries in the static blocklist in WIDS configuration mode.
- After the MAC address of a STA is added to the static blocklist, the STA will be forced to go offline immediately if the STA is online.
- One *another-name* may map to multiple MAC addresses, while one MAC address can map to only one *another-name*.
- *another-name* is empty if it is not configured.

Command	**static-blacklist** { **mac-address** *H.H.H* [**name**_*another-name*] | **max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the MAC address of a static blocklist entry. **name** *another-name*: Indicates the alias of the MAC address in the static blocklist. **max** *num*: Indicates the length of the static blocklist. The value range is from 1 to 2048.
Defaults	By default, the static blocklist is empty and the static blocklist length is 1024.
Command Mode	WIDS configuration mode
Usage Guide	The static blocklist function takes effect only when the static blocklist contains one or more entries.

Configuring a Dynamic Blocklist

Whether this configuration is supported depends on the product version.

- Optional.
- Run the **dynamic-blacklist enable** command to enable the dynamic blocklist function in WIDS configuration mode. A dynamic blocklist entry is generated dynamically based on IDS attack detection and works only after the dynamic blocklist function is enabled.
- Run the **dynamic-blacklist lifetime** command to configure the lifetime of the dynamic blocklist in WIDS configuration mode, indicating how long the dynamic blocklist exists in the device.

- Run the **dynamic-blacklist** { **ac-max** | **ap-max** } command to configure the maximum number of dynamic blocklist entries on both ACs and APs in WIDS configuration mode.
- Run the **dynamic-blacklist mac-adress** command to configure the dynamic blocklist in WIDS configuration mode.

Command	**dynamic-blacklist** { **enable** | **lifetime** *time* |**ac-max** *num* |**ap-max** *num* | **mac-address** *H.H.H* }
Parameter Description	**enable**: Enables the dynamic blocklist function **lifetime** *time*: Indicates the lifetime of the dynamic blocklist. The value range is from 60 to 86400, in seconds. **ac-max** *num*: Indicates the length of the dynamic blocklist on ACs. **ap-max** *num*: Indicates the length of the dynamic blocklist on APs. **mac-address** *H.H.H*: Indicates the MAC address of a dynamic blocklist entry.
Defaults	By default, the dynamic blocklist function is disabled, the length of a dynamic blocklist on an AC or AP is 2048, and its lifetime is 300 seconds.
Command Mode	WIDS configuration mode
Usage Guide	A dynamic blocklist entry is generated based on IDS attack detection.

Configuring the SSID-Based Blocklist

- Optional.
-
- Configure the SSID-based blocklist entry on the AC that needs to be enabled with the SSID-based blocklist function.
- Configure the SSID-based blocklist length on the AC that needs to be enabled with the SSID-based blocklist function.
- Configure the SSID list length on the AC that needs to be enabled with the SSID-based blocklist function.
- Run the **ssid-blacklist mac-address** command to add an entry to the SSID-based static blocklist in WIDS configuration mode. The static blocklist function takes effect only after an effective static blocklist entry is configured.
- Run the **ssid-filter blacklist max** command to configure the maximum number of entries in the SSID-based static blocklist in WIDS configuration mode.
- After the MAC address of a STA is added to the blocklist, the STA will be forced to go offline immediately if the STA is online and associated with the SSID.
- One *another-name* may map to multiple MAC addresses, while one MAC address can map to only one *another-name*.
- *another-name* is empty if it is not configured.

Command	**ssid-filter** { **max** *num* | **blacklist mac-address** *H.H.H* [**name** *another-name*] **in-ssid** *string* | **blacklist max** *num* }
Parameter Description	**max** *num*: Indicates the maximum length of the SSID-based blocklist. The value range is from 1 to 128. The default value is 64. **blacklist mac-address** *H.H.H* **in-ssid** *string*: Adds an entry to the specified SSID-based blocklist. **name** *another-name*: Indicates the alias of the MAC address in the specified SSID-based blocklist.

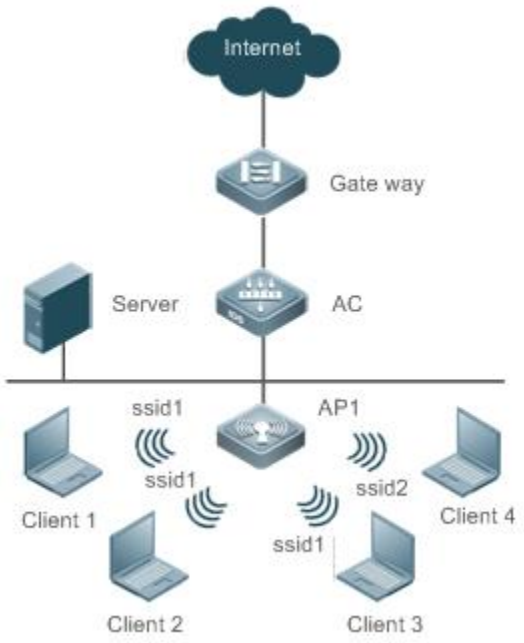
	blacklist max *num*: Configures the length of the SSID-based blocklist. The value range is from 1 to 2048.
Defaults	The SSID-based blocklist is empty.
Command Mode	WIDS configuration mode
Usage Guide	This function takes effect only when the SSID-based blocklist contains one or more entries.

Configuring the SSID-Based Allowlist

- Optional.
- Configure the SSID-based allowlist entry only on the AC that needs to be enabled with the SSID-based allowlist function.
- Configure the SSID-based allowlist length only on the AC that needs to be enabled with the SSID-based allowlist function.
- Run the **ssid-filter whitelist mac-address** command to add an entry to the SSID-based allowlist in WIDS configuration mode. The allowlist function takes effect only after an effective allowlist entry is configured.
- Run the **ssid-filter whitelist max** command to configure the maximum number of entries in the SSID-based allowlist in WIDS configuration mode.
- After the SSID-based allowlist is configured, STAs that are not in the allowlist of this SSID will be forced to go offline.
- One *another-name* may map to multiple MAC addresses, while one MAC address can map to only one *another-name*.
- *another-name* is empty if it is not configured.

Command	**ssid-filter** { **whitelist mac-address** *H.H.H* [**name** *another-name*] **in-ssid** *string* | **whitelist max** *num* }
Parameter Description	**whitelist mac-address** *H.H.H* **in-ssid** *string*: Configures the allowlist entry for a specified SSID. **name** *another-name*: Indicates the alias of the MAC address in the specified SSID allowlist. **whitelist max** *num*: Configures the length of the SSID-based allowlist. The value range is from 1 to 2048.
Defaults	The SSID-based allowlist is empty.
Command Mode	WIDS configuration mode
Usage Guide	This function takes effect only when the SSID-based allowlist contains one or more entries.

Verification



Verify functions based on corresponding frame filtering rules:

- Check the low-rate STA filtering function. The packets from the low-rate STAs are discarded and the low-rate STAs are successfully removed.
- Check the allowlist function. When the allowlist has an entry, the STAs not included in the allowlist cannot join the AP.
- Check the static blocklist function. When the static blocklist has an entry, the STAs in the static blocklist cannot join the AP.

- Check the dynamic blocklist function. When the dynamic blocklist function is enabled, entries are dynamically added to the dynamic blocklist based on IDS attack detection, and STAs in the dynamic blocklist cannot join the AP again.
- Check the SSID-based blocklist function. When the SSID-based blocklist has an entry, STAs in the SSID-based blocklist cannot access this SSID.
- Check the SSID-based allowlist function. When the SSID-based allowlist has an entry, STAs not included in the SSID-based allowlist cannot access this SSID.

Configuration Example

Configuring the Allowlist Entry

Scenario **Figure 2-5**	
Configuration Steps	● Add an entry to the allowlist on the AC.

	`Hostname# configure terminal`
	`Hostname(config)# wids`
	`Hostname(config-wids)# whitelist mac-address 0000.0000.0001`

Verification	After configuring the allowlist entry, you can use the following methods to check the configuration. ● Run the **show wids whitelist** command to display configured parameters. ● Associate the STA with this MAC address with the AC to verify whether the function has taken effect.

	`Hostname#show wids whitelist`
	`----------  Whitelist Information  ----------`
	`num  Mac-address`
	`1  0000.0000.0001`

Common Errors

N/A

1.4.2 Configuring IDS Attack Detection

Configuration Effect

- IDS attack detection can be used to discover and defend against malicious or unintentional attacks on WLANs in a timely manner.

Notes

- IDS attack detection needs to be used with the dynamic blocklist function to prevent attacks on WLANs more effectively.

Configuration Steps

Specifying the IDS Attack Detection Type

- Optional. IDS attack detection is disabled by default.
- Configure the IDS attack detection type.

Command	**attack-detection enable** { **all** | **ddos** | **flood** | **spoof** | **weak-iv** }
Parameter Description	**ddos**: Enables DDoS attack detection. **flood**: Enables flood attack detection. **spoof**: Enables spoofing attack detection. **weak-iv**: Enables weak IV attack detection. **all**: Enables all types of IDS attack detection.
Defaults	All types of IDS attack detection are disabled by default.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring DDoS Attack Detection

- Optional.
- Configure the packet rate thresholds and intervals for DDoS attack detection on different types of packets.

Command	**attack-detection ddos** { **arp-threshold** *num*| **icmp-threshold** *num*| **syn-threshold** *num* | **interval** *time* }
Parameter Description	**arp-threshold** *num*: Indicates the ARP packet rate threshold. The value range is from 1 to 10000, in pps. **icmp-threshold** *num*: Indicates the ICMP packet rate threshold. The value range is from 1 to 10000, in pps. **syn-threshold** *num*: Indicates the SYN packet rate threshold. The value range is from 1 to 10000, in pps. **interval** *time*: Indicates the interval of DDoS attack detection. The value range is from 10 to 60, in seconds.

Defaults	By default, the interval of DDoS attack detection is 30 seconds, and the DDoS attack detection thresholds for ARP packets, ICMP packets, and SYN packets are 50 pps, 100 pps, and 50 pps, respectively.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring Flood Attack Detection

Whether this configuration is supported depends on the product version.

- Optional. Flooding attack detection is disabled by default.
- Configure the packet rate thresholds and intervals for flood attack detection on different types of packets.
- Run the **attack-detection flood single-mac** { **total** | **assoc** | **reassoc** | **disassoc** | **probe** | **action** | **auth** | **deauth** | **null-data** } **threshold***num***interval***time* command to configure the packet rate threshold and interval of a specified type of packets for single-STA flood attack detection in WIDS configuration mode.
- Run the **attack-detection flood multi-mac** { **assoc** | **reassoc** | **disassoc** | **probe** | **action** | **auth** | **deauth** | **null-data** } **threshold** *num* **interval** *time* command to configure the packet rate threshold and interval of a specified type of packets for multi-STA flood attack detection in WIDS configuration mode.

Command	**attack-detection flood single-mac** { **total**	**assoc**	**reassoc**	**disassoc**	**probe**	**action**	**auth**	**deauth	null-data** } **threshold** *num* **interval** *time*
Parameter Description	**single-mac**: Configures single-STA attack detection. **total**: Configures all packets. **assoc**: Configures Association packets. **reassoc**: Configures Reassociation packets. **disassoc**: Configures Disassociation packets. **probe**: Configures Probe packets. **action**: Configures Action packets. **auth**: Configures Authentication packets. **deauth**: Configures Deauthentication packets. **null-data**: Configures Null packets. *num*: Indicates the packet rate threshold of flood attack detection. The value range is from 1 to 10000. *time*: Indicates the interval of flood attack detection. The value range is from 10 to 60, in seconds.
Defaults	By default, the packet rate thresholds for all types of single-STA and multi-STA flood attack detection are 300 and 4800, respectively, and the statistical interval is 10 seconds.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Command	**attack-detection flood multi-mac** { **assoc**	**reassoc**	**disassoc**	**probe**	**action**	**auth**	**deauth	null-data** } **threshold** *num* **interval** *time*
Parameter Description	**multi-mac**: Configures multi-STA detection. **assoc**: Configures Association packets. **reassoc**: Configures Reassociation packets.

	disassoc: Configures Disassociation packets. **probe**: Configures Probe packets. **action**: Configures Action packets. **auth**: Configures Authentication packets. **deauth**: Configures Deauthentication packets. **null-data**: Configures Null packets. *num*: Indicates the packet rate threshold of flood attack detection. The value range is from 1 to 10000. *time*: Indicates the interval of flood attack detection. The value range is from 10 to 60, in seconds.
Defaults	By default, the packet rate thresholds for all types of single-STA and multi-STA flood attack detection are 300 and 4800, respectively, and the statistical interval is 10 seconds.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring Spoofing Attack Detection

- Optional. Spoofing attack detection is disabled by default.
- Configure the packet rate thresholds and intervals for spoofing attack detection on different types of packets.

Command	**attack-detection spoof** { **threshold** *num* |**interval** *time* }
Parameter Description	**threshold** *num*: Indicates the packet rate threshold of spoofing attack detection. The value range is from 1 to 1000. **interval** *time*: Indicates the interval of spoofing attack detection. The value range is from 10 to 60, in seconds.
Defaults	By default, the packet threshold is 1 and the detection interval is 50 seconds.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring Weak IV Attack Detection

- Optional. The Weak IV attack detection function is disabled by default.
- Configure the packet rate thresholds and intervals for weak IV attack detection on different types of packets.

Command	**attack-detection weak-iv** { **threshold** *num*| **interval** *time* }
Parameter Description	**threshold** *num*: Indicates the packet rate threshold of weak IV attack detection. The value range is from 1 to 10000. **interval** *time*: Indicates the interval of weak IV attack detection. The value range is from 1 to 60, in seconds.
Defaults	By default, the interval of weak IV detection is 15 seconds and the detection threshold is 10.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring the Length of the IDS Attack Detection List on the AC

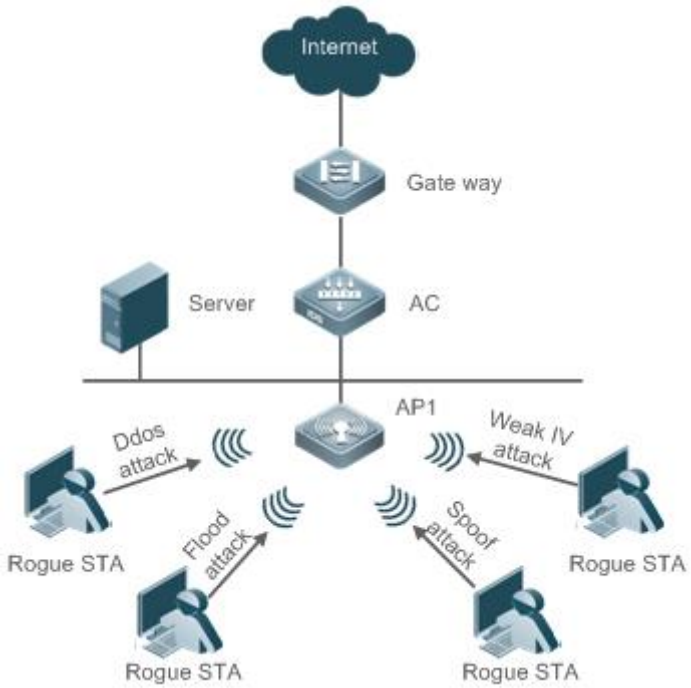
- Optional.

Command	**attack-detection statistics ac-max** *num*
Parameter Description	*num*: Indicates the maximum number of IDS attack detection entries on the AC. The value range is from 1 to 4096.
Defaults	It is 2048 by default.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring the Length of IDS Attack Detection Statistics on APs

- Optional.

Command	**attack-detection statistics ap-max** *num*
Parameter Description	*num*: Indicates the length of IDS attack detection statistics on APs. The value range is from 1 to 1024.
Defaults	The default value is 512.
Command Mode	WIDS configuration mode
Usage Guide	N/A



Verification

Verify detection functions based on the IDS attack detection type:

- DDoS attack detection: Check whether ARP packet attacks, ICMP packet attacks, and SYN packet attacks are detected.
- Flood attack detection: Check whether multi-STA flood attacks and single-STA flood attacks are detected.
- Spoofing attack detection: Check whether broadcast disassociation and deauthentication packet attacks are detected.
- Weak IV attack detection: Check whether weak IV packet attacks are detected.
- Interworking DoS attack detection: Check whether DoS attacks are detected.

Configuration Example

Configuring DDoS Attack Detection

Scenario **Figure 2-6**	
Configuration Steps	● Specify DDoS attack detection and configure the threshold and interval on the AC.

	`Hostname# configure terminal`
	`Hostname(config)# wids`
	`Hostname(config-wids)# attack-detection enable flood`
	`Hostname(config-wids)# attack-detection ddos interval 10`

Verification	● If a DDoS attack exists, related syslog information will be displayed on the AC.

	`*Feb 7 13:37:03: %WIDS-6-ATTACK: Client(0025.64b8.2ffa): ARP DDOS attack to Ap (1414.0902.0016).`
	`Feb 7 13:37:03: %WIDS-6-ATTACK: Client(0025.64b8.2ffa): ICMP DDOS attack to Ap (1414.0902.0016).`
	`Feb 7 13:37:03: %WIDS-6-ATTACK: Client(0025.64b8.2ffa): SYN DDOS attack to Ap (1414.0902.0016).`

Common Errors

N/A

1.4.3 Configuring User Isolation

Configuration Effect

- After user isolation is configured, direct communication cannot be conducted between STAs meeting user isolation rules.

Notes

- User isolation is only valid for Layer 2 STAs.

Configuration Steps

Configuring a User Isolation Mode

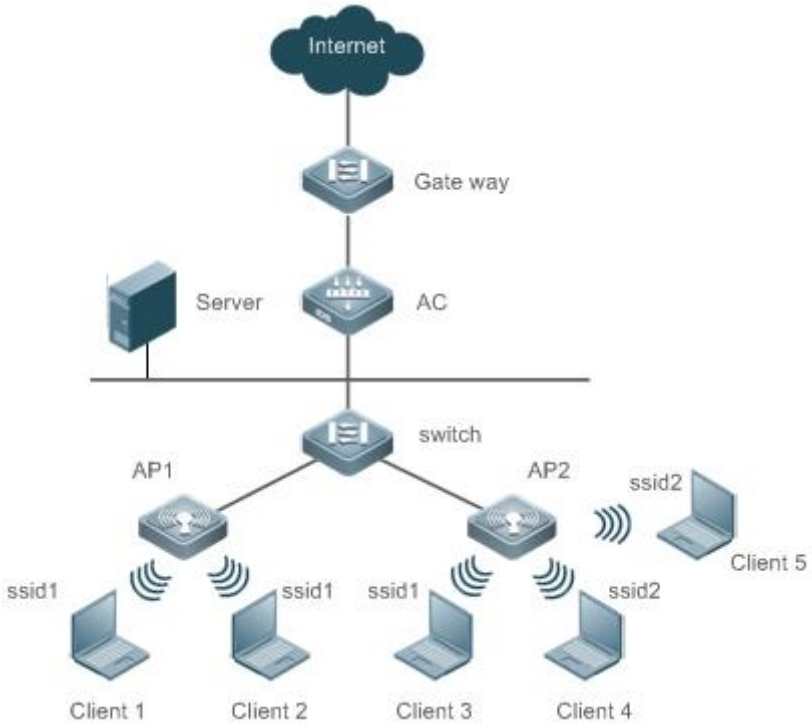
- Optional.
- Unless otherwise noted, configure this function on ACs.

Command	**user-isolation** { **ac** | **ap** | **ssid-ac** | **ssid-ap** | **wlan-id** *num* } **enable**
Parameter Description	**ac**: Configures AC-based Layer 2 user isolation. **ap**: Configures AP-based Layer 2 user isolation. **ssid-ac**: Configures AC-SSID-based Layer 2 user isolation. **ssid-ap**: Configures AP-SSID-based Layer 2 user isolation **wlan-id** *num*: Configures SSID-based Layer 2 user isolation.
Defaults	User isolation is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The AC-based and AC-SSID-based Layer 2 user isolation modes take effect only in centralized forwarding mode.
	Whether this configuration is supported depends on the product version.

Configuring the Allowed MAC Address List for User Isolation

- Optional.
- Unless otherwise specified, configure this function on the AC.
- To cConfigure the length of the allowed MAC address list for user isolation.

Command	**user-isolation permit-mac** { *H.H.H* | **max** *num* }
Parameter Description	*H.H.H*: Indicates the allowed MAC address list entry for user isolation. **max** *num*: Indicates the length of the allowed MAC address list for user isolation. The value range is from 1 to 1024.
Defaults	By default, the allowed MAC address list for user isolation is empty, and the list length is 1024.
Command Mode	WIDS configuration mode
Usage Guide	N/A



Verification

- Verify functions based on the isolation mode.

Configuration Example

Configuring User Isolation

Scenario	

Figure 2-7	
Configuration Steps	● Configure AP-based Layer 2 user isolation on the AC.

	`Hostname# configure terminal`
	`Hostname(config)# wids`
	`Hostname(config-wids)# user-isolation ap enable`

Verification	● Run the **show running-config** command to display configured parameters.

	`Hostname#show running-config`
	`…`
	`!`
	`wids`
	` user-isolation ap enable`
	`!`

Common Errors

N/A

1.4.4 Configuring Rogue Detection and Containment

Configuration Effect

Rogue device detection and containment can contain unauthorized devices and maintain WLAN security.

Notes

The rogue device detection and containment function takes effect only when the AP works in hybrid or monitor mode.

Configuration Steps

Enabling Rogue Device Containment

- Optional.
- Run the **countermeasures enable** command to enable rogue device containment in WIDS configuration mode.

Command	**countermeasures enable**
Parameter Description	N/A
Defaults	By default, rogue device containment is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Rogue Device Containment Interval

- Optional. Run the **countermeasures interval** *time* command to configure the interval of rogue device containment in WIDS configuration mode.

Command	**countermeasures interval** *time*
Parameter Description	time: Indicates the rogue device containment interval. The value range is from 100 to 10000, in milliseconds.
Defaults	The default containment interval is 1000 ms.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Rogue Device Detection and Containment Mode

- Optional.
- Run the **countermeasures mode** { **all** | **adhoc** | **config** | **rogue** | **ssid** } command to configure the rogue device detection and containment mode in WIDS configuration mode.

Command	**countermeasures mode** { **all** | **adhoc** | **config** | **rogue** | **ssid** }
Parameter Description	**adhoc**: Configures ad hoc containment mode to contain ad hoc devices. **config**: Configures config containment mode to contain devices that meet entries in the SSID-based blocklist and static attack list. **rogue**: Configures rogue containment mode to contain devices with RSSIs exceeding the threshold. **ssid**: Configures SSID containment mode to contain devices connected to the same SSID but different ACs. **all**: Configures all the preceding containment modes.
Defaults	By default, no rogue device containment mode is specified.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Static Attack List

- Optional.
- Run the **device attack mac-address** *H.H.H* command to configure the static attack statistic list information in WIDS configuration mode.

Command	**device attack** { **mac-address** *H.H.H* |**max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the MAC address entry of a static attack list. **max** *num*: Indicates the length of the static attack list. The value range is from 1 to 1024.
Defaults	By default, the static attack list is empty, and the length of the static attack list is 512.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the SSID-based Blocklist

- Optional.
- Run the **device black-ssid** *ssid* command to configure the SSID-based blocklist information in WIDS configuration mode.

Command	**device { black-ssid** *ssid* |**max-black-ssid** *num* }
Parameter Description	**black-ssid** ssid: Indicates the SSID-based blocklist entry. **max-black-ssid** *num*: Indicates the length of the SSID-based blocklist. The value range is from 1 to 1024.
Defaults	By default, the SSID-based blocklist is empty and the length of the SSID-based blocklist is 512.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Lists of Allowed MAC Addresses, SSIDs, and Vendors

- Optional.
- Run the **device permit mac-address** *H.H.H* command to configure the allowed MAC address list entry in WIDS configuration mode.
- Run the **device permit ssid** *ssid* command to configure the allowed SSID list entry in WIDS configuration mode.
- Run the **device permit vendor bssid** *H.H.H* command to configure the allowed vendor list entry in WIDS configuration mode.

Command	**device permit** { **mac-address** *H.H.H*	**mac-address max** *num*	**ssid** *ssid*	**max-ssid** *num*	**vendor bssid** *H.H.H*	**vendor bssid max** *num* }
Parameter Description	**mac-address** *H.H.H*: Indicates the allowed MAC address list entry. It is empty by default. **mac-address max** *num*: Indicates the length of the allowed MAC address list. The value range is from 1 to 2048. The default value is 1024. **ssid** *ssid*: Indicates the allowed SSID list entry. It is empty by default. **max-ssid** *num*: Indicates the length of the allowed SSID list. The value range is from 1 to 1024. The default value is 512. **vendor bssid** *H.H.H*: Indicates the allowed vendor list entry. It is empty by default. **vendor bssid max** *num*: Indicates the length of the allowed vendor list. The value range is from 1 to 1024. The default value is 512.

Defaults	See **Parameter Description**.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Maximum Number of Contained Devices in One Containment

- Optional.
- Run the **countermeasures ap-max** *ap-num* command to configure the maximum number of contained devices in one rogue device containment in WIDS configuration mode.

Command	**countermeasures ap-max** *ap-num*
Parameter Description	*ap-num*: Indicates the maximum number of devices contained in each containment interval. The value range is from 1 to 256.
Defaults	By default, the maximum number of contained devices in one containment is 30.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Aging Duration of Detected Devices

- Optional.
- Run the **device aging duration** *time* command to configure the aging duration of detected devices in WIDS configuration mode.

Command	**device aging duration** *time*
Parameter Description	*time*: Indicates the aging duration of detected devices. The value range is from 500 to 5000, in seconds.
Defaults	The default aging duration is 1200 seconds.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Device Friendly Flag

- Optional.
- Run the **device friendly-flags** *value* command to configure the device friendly flag in WIDS configuration mode. With the device friendly flag, the AP can identify devices on the same AC.

Command	**device friendly-flags***value*
Parameter Description	*value*: Indicates the device friendly flag. The value range is from 1 to 4294967295.
Defaults	The default value is 0.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring the Minimum RSSI for Containment

- Optional.
- Run the **countermeasures rssi-min** *num* command to configure the minimum RSSI for rogue device containment in WIDS configuration mode. A rogue device with an RSSI exceeding this threshold will be contained.
- Unless otherwise specified, configure this function on the AC where logs need to be written into the memory buffer.

Command	**countermeasures rssi-min** *num*
Parameter Description	*num*: Indicates the minimum RSSI for rogue device containment. The value range is from 0 to 75 (–95 to –20 dBm).
Defaults	The default minimum RSSI for containment is 25 (–70 dBm).
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Enabling Channel-Based Containment

- Optional. Run the **countermeasures channel-match** command to enable the channel-based containment function in WIDS configuration mode. This function enables containment based on the channel on which a detected rogue device operates.
-

Command	**countermeasures channel-match**
Parameter Description	**channel-match**: Enables channel-based containment.
Defaults	By default, channel-based containment is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Configuring Fuzzy Containment

- Optional.
- Run the **countermeasures fuzzy-enable** command to configure the fuzzy containment function in WIDS configuration mode. This function enables fuzzy match for the SSIDs of rogue APs. For example, if the SSID of the local AP is TEST-WEB, the rogue AP whose SSID is TE1ST-WEB can be contained after the fuzzy containment function is enabled.

Command	**countermeasures fuzzy-enable**
Parameter Description	N/A
Defaults	By default, the fuzzy containment function is disabled.
Command Mode	WIDS configuration mode
Usage Guide	If containment modes include the config containment mode, rogue APs whose SSIDs are similar to those in the SSID-based blocklist are contained. If containment modes include the SSID containment mode, rogue APs whose SSIDs are similar to the SSID of the local AP are contained. Fuzzy containment takes effect only in config containment mode and SSID containment mode.

Configuring a Fuzzy Containment Keyword

- Optional.
- Run the **countermeasures fuzzy-keyword** *string* command to configure a fuzzy containment keyword in WIDS configuration mode. Fuzzy containment can be performed by keyword. For example, if the configured fuzzy containment keyword is **ruijie**, rogue APs whose SSIDs contain **ruijie** such as **ruijie-free** can be contained after the fuzzy containment function is enabled. The keyword is case-insensitive. For example, assume that the configured fuzzy containment keyword is **ruijie**. There are 2^6 uppercase and lowercase combinations of **ruijie**. Once the fuzzy containment keyword is set to any of the combinations, APs whose SSIDs contain any combination of ruijie can be identified, such as **RUIjie** and **RuiJie**.

Command	**countermeasures fuzzy-keyword** *string*
Parameter Description	*strin*g: Indicates the fuzzy containment keyword, which is case-insensitive and saved in lowercase.
Defaults	By default, no fuzzy containment keyword is configured.
Command Mode	WIDS configuration mode
Usage Guide	The configuration takes effect only after the **countermeasures fuzzy-enable** command is executed. When the containment modes include the SSID containment mode, rogue APs whose SSIDs contain the configured keyword will be contained. The fuzzy containment keyword takes effect only in SSID containment mode.

Enabling Unknown STA Detection and Containment

- Optional.
- Run the **device unknown-sta dynamic-enable** command to enable the unknown STA detection and containment function in WIDS configuration mode.
- Run the **device unknown-sta mac-address** *H.H.H* command to configure the unknown STA list entry in WIDS configuration mode.

Command	**device unknown-sta** { **dynamic-enable** | **mac-address** *H.H.H* | **mac-address max** *num* }
Parameter Description	**dynamic-enable**: Enables unknown STA detection and containment. **mac-address** *H.H.H*: Configures the unknown STA list entry. The list is empty by default. **mac-address max** *num*: Configures the length of the unknown STA list. The value range is from 1 to 256.
Defaults	By default, unknown STA detection and containment is disabled.
Command Mode	WIDS configuration mode
Usage Guide	The containment function does not take effect when the AP works in normal mode.

Enabling Unknown STA Detection Information Reporting

- Optional.
- This command is used to report detected unknown STAs to the AC.
- Run the **device unknown-sta report enable** command to enable unknown STA detection information reporting in WIDS configuration mode.

Command	**device unknown-sta report enable**
Parameter Description	N/A
Defaults	By default, the unknown STA detection information reporting function is disabled.
Command Mode	WIDS configuration mode
Usage Guide	This function takes effect only when the AP does not operate in normal mode. The scanning result can be reported to the AC.
	Whether this configuration is supported depends on the product version.

Configuring Interworking Rogue Device Detection

- Optional.
- Run the **device channel-bind radio** *radio-id* { **channel** *num*| **max-cycles** *value* } command to configure the scanning channel of a specified radio for interworking rogue device detection in AP configuration mode.
- Run the **device scan-para** { **radio** *radio-id* **scan-type** { **active** | **passive** } **device-detect** { **enable** | **disable** } | **ap-mode** { **normal** | **monitor** } } command to configure scanning parameters for detection of interoperability with rogue APs in AP configuration mode.
- Run the **rogue-ap countermeasures enable** command to configure the function of containing interoperability with rogue APs in WIDS configuration mode.
- Configure scanning channel information on interoperability with rogue APs.

Command	**device channel-bind radio** *radio-id*{ **channel** *num* | **max-cycles** *value* }
Parameter Description	*radio-id*: Indicates the radio ID of a specified AP. **channel** *num*: Indicates the channel number. The Chinese channel is used by default. **max-cycles** *value*: Indicates the scanning count. The value is 10 by default and the value range is from 0 to 255.
Defaults	For details, see **Parameter Description**.
Command Mode	AP configuration mode
Usage Guide	N/A
	Whether this configuration is supported depends on the product version.

Command	**device scan-para** { **radio** *radio-id* **scan-type** { **active** | **passive** } **device-detect** { **enable** | **disable** } **|** **ap-mode** { **normal** | **monitor** } }
Parameter Description	**radio** *radio-id*: Indicates the radio ID. **scan-type active**: Indicates active scanning. Passive scanning is used by default. **scan-type passive**: Indicates passive scanning. **device-detect enable**: Enables detection. Detection is disabled by default. **device-detect disable**: Disables detection. **ap-mode normal**: Indicates that the AP works in normal mode. **ap-mode monitor**: Indicates that the AP works in monitor mode.
Defaults	For defaults, see **Parameter Description**.
Command	AP configuration mode

Mode	
Usage Guide	N/A

Command	**rogue-ap countermeasures enable**
Parameter Description	N/A
Defaults	By default, this function is disabled.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring the Maximum Number of Detected APs in the List

- Optional.
- Run the **device detected-ap-max** *num* command to configure the maximum number of detected APs in WIDS configuration mode. A smaller value indicates that a smaller amount of data will be detected on the AP, which affects the device containment function. A larger value requires a larger memory space.

Command	**device detected-ap-max** *num*
Parameter Description	*num*: Indicates the maximum number of detected APs in the list. The value range is from 1 to 4096.
Defaults	The default maximum number of detected APs in the list is 2048.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring the Scanning Status of a Specified Radio

- Optional.
- Run the **hybrid-scan radio** *num* **{ disable | enable }** command to configure the scanning status of a specified radio in AP configuration mode. If the scanning status of a radio is disabled, the AP works in non-normal mode, and no device detection data can be obtained.

Command	**hybrid-scan radio** *num* **{ enable	disable }**
Parameter Description	*num*: Indicates a radio ID.
Defaults	By default, scanning on all radios is enabled.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the Scanning Channel of a Specified AP

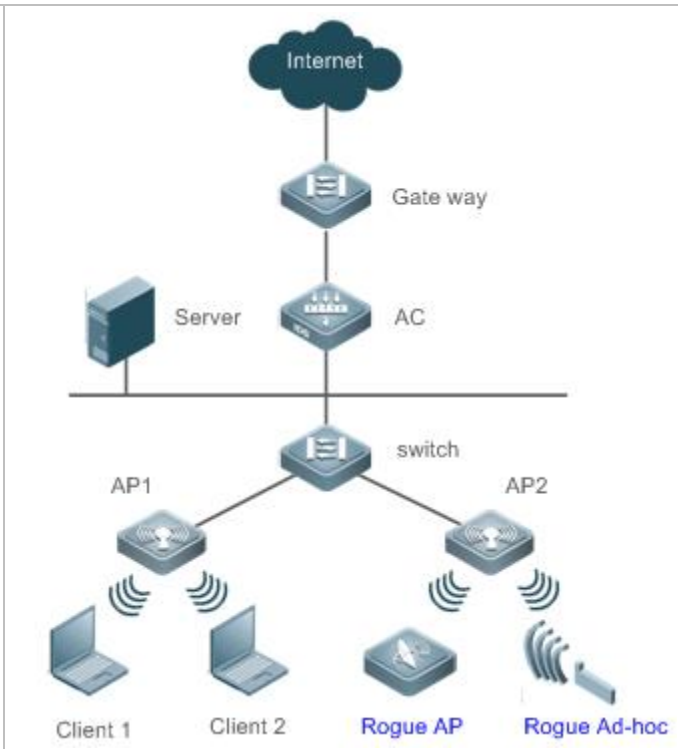
- Optional.
- Run the **scan-channels** { **802.11a** | **802.11b** | **6GHz** } **channels** *channels* command to configure the scanning channel in AP configuration mode. If no scanning channel is configured, the AP works in non-normal mode, and no device detection data can be obtained.

Command	**scan-channels { 802.11a | 802.11b** | **6GHz } channels** *channels*
Parameter Description	*num*: Indicates the number of the scanning channel. Multiple parameters can be input, separated by spaces.
Defaults	By default, the scanning channel is empty.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring Automatic Radio Switchover and Scanning

- Optional.
- Run the **scan-channels** { **dual-band** | **all-band** } **radio** *radio-id* command to configure automatic dual-radio switchover and scanning. The scanning results of two radios can be obtained for containment.

Command	**scan-channels** { **dual-band** | **all-band** } **radio** *radio-id*
Parameter Description	*radio-id*: Indicates the radio ID for multi-radio switchover.
Defaults	By default, automatic multi-radio switchover and scanning is disabled.
Command Mode	AP configuration mode
Usage Guide	The RF modules of partial APs support multiple frequency bands. When the RF modules are used for channel scanning, this command can be used for automatic channel scanning among multiple frequency bands, to obtain the scanning results of these frequency bands and perform containment. After the frequency bands are switched, channels configured by running the **scan-channels** { **802.11a** | **802.11b** | **6GHz** } **channels** command are scanned. Dual-band scans only 2.4 GHz and 5 GHz radios while all-band scans all radios supported by the AP. In addition, for some APs that have channel restrictions, the restricted channels will be automatically skipped during channel scanning.



Verification

- Run the **show wids detected** command to display detected results.

Configuration Example

Configuring Rogue Device Containment

Scenario	

Figure 2-8	
Configuration Steps	● Configure rogue device containment information on the AC. Before configuring containment, confirm that the WLAN service has been deployed on the contained AP; otherwise, containment will not take effect.

	`Hostname# configure terminal`
	`Hostname(config)# wids`
	`Hostname(config-wids)# countermeasures enable`
	`Hostname(config-wids)# countermeasures mode ssid`

Verification	● Run the **show running-config** command to display configured parameters and the log information generated by the system.

	`Hostname#show running-config`
	`Hostname#show running-config`
	`...`
	`!`
	`wids`
	` countermeasures enable`
	` countermeasures mode SSID`
	`!`
	`...`

Common Errors

N/A

1.4.5 Configuring the AP Working Mode

Whether this function is supported depends on the product version.

Configuration Effect

- APs in different working modes can provide different services.

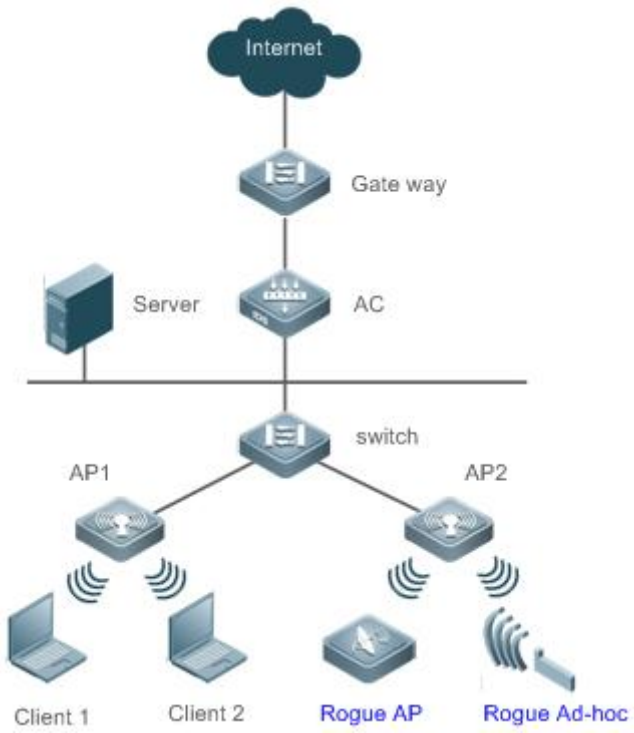
Notes

N/A

Configuration Steps

Configuring an AP Working Mode

- Optional.
- Unless otherwise specified, configure this function on each AP.



Command	**device mode** { **hybrid** | **monitor** [**radio** *radio-id*] | **normal** }
Parameter Description	**hybrid**: Configures the hybrid mode, in which the device provides both monitoring and access services. **monitor:** Configures the monitor mode, in which the device provides only the monitoring service. *radio-id*: Specifies a radio ID. The value range is from 1 to 96. **normal**: Configures the normal mode, in which the device provides only the access service.
Defaults	By default, an AP works in normal mode.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

- Run the **show ap-config running** *ap-name* command to display the working mode of the AP.

Configuration Example

Configuring the AP Working Mode

Scenario **Figure 2-9**	
Configuration Steps	● Configure the working mode of a specified AP on the AC.

	`Hostname# configure terminal`
	`Hostname(config)# ap-config ap220`
	`Ruijie (config-ap)#device mode hybrid`

Verification	● Run the **show ap-config running** *ap-name* command to display configured parameters.

	`Hostname#show ap-config running ap220`
	`!`
	`ap-config ap220`
	` device mode hybrid`
	` 11acsupport enable radio 1`
	` 11acsupport enable radio 2`
	` 802.11n mcs support 23 radio 1`
	` 802.11n mcs support 23 radio 2`
	` 802.11ac mcs support 29 radio 1`
	` 802.11ac mcs support 29 radio 2`
	` antenna receive 7 radio 1`
	` antenna receive 7 radio 2`
	` antenna transmit 7 radio 1`
	` antenna transmit 7 radio 2`
	`!`

Common Errors

N/A

1.5 Monitoring

Clearing

Command	Description
reset attack-list all	Clears entries in the static attack list.
reset black-ssid all	Clears entries in the SSID-based blocklist.
reset detected { all | adhoc | rogue { ap | client } | mac-address *H.H.H* **}**	Clears information about a specified device that is detected.
reset dos-detected	Clears interworking DoS attack detection information.
reset dynamic-blacklist { all | mac-address *H.H.H* **}**	Clears entries in the dynamic blocklist.
reset fuzzy-keyword all	Clears the configuration of fuzzy containment keywords.
reset permit-mac all	Clears entries in the allowed MAC address list.
reset permit-ssid all	Clears entries in the allowed SSID list.
reset permit-vendor all	Clears entries in the allowed vendor list.
reset rogue-ap detected	Clears information about interworking rogue AP device detection.
reset ssid-filter { ssid all | in-ssid *ssid* **}**	Clears all or specified entries in the SSID-based blocklist and allowlist.
reset ssid-filter { blacklist all | in-ssid *ssid* **}**	Clears all or specified entries in the SSID-based blocklist.
reset ssid-filter { whitelist all | in-ssid *ssid* **}**	Clears all or specified entries in the SSID-based allowlist.
reset static-blacklist all	Clears entries in the static blocklist.
reset statistic all	Clears information about the static attack statistic list.
reset unknown-sta all	Clears entries in the unknown STA list.
reset user-isolation-permit-list all	Clears allowed entries for user isolation.
reset whitelist all	Clears allowlist entries.

Displaying

Command	Description
show wids attack-list	Displays the attack list configuration.
show wids blacklist { **dynamic** | **static** }	Displays the dynamic or static blocklist configuration.
show wids black-ssid	Displays the SSID-based blocklist configuration.
show wids detected { **adhoc** | **all** | **friendly ap** |**interfering ap** | **rogue** { **adhoc-ap** | **ap** | **client** | **config-ap** | **ssid-ap** } | **mac-address** *H.H.H* }	Displays information about detected devices of a specified type.
show wids ssid-filter { **blacklist all** [**in-ssid** *string*] | **ssid all** | **whitelist all** [**in-ssid string**] }	Displays the SSID-based blocklist and allowlist configuration.
show wids permitted { **mac-address** | **ssid** | **vendor** }	Displays the configuration of allowed MAC, SSID, and vendor lists.
show wids statistics	Displays IDS attack detection information.

show wids unknown-sta	Displays the unknown STA list configuration.
show wids user-isolation permit-mac	Displays allowed MAC entries for user isolation.
show wids whitelist	Displays allowlist entries.
show running-config	Displays other WIDS configuration.
show wids dos-detected	Displays interworking DoS detection information.
show wids rogue-ap detected	Displays interworking rogue device detection information.
show wids fuzzy-keyword	Displays the configuration of fuzzy containment keywords.

Configuring WLAN Authentication

1. Configuring AAA
2. Configuring RADIUS
3. Configuring TACACS
4. Configuring IEEE 802.1X
5. Configuring Local EAP
6. Configuring Web-based Authentication
7. Configuring ROLE-MGMT
8. Configuring SCC
9. Configuring GSN

1 Configuring AAA

1.1 Overview

Authentication, authorization, and accounting (AAA) provides a unified framework for configuring authentication, authorization, and accounting services.

AAA provides the following services in a modular way:

- Authentication: Authenticates user identities for network access and network services. Authentication is classified into local authentication and authentication through Remote Authentication Dial In User Service (RADIUS) and Terminal Access Controller Access Control System+ (TACACS+).
- Authorization: Grants specific network services to users according to a series of defined attribute-value (AV) pairs. The pairs describe the operations which users are authorized to perform. AV pairs are stored on network access servers (NASs) or remote authentication servers.
- Accounting: Tracks resource usage of users. When accounting is enabled, NASs collect statistics on the network resource usage of users and send them in AV pairs to authentication servers. The records will be stored on authentication servers, and can be read and analyzed by dedicated software to realize accounting, statistics, and tracking of network resource usage.

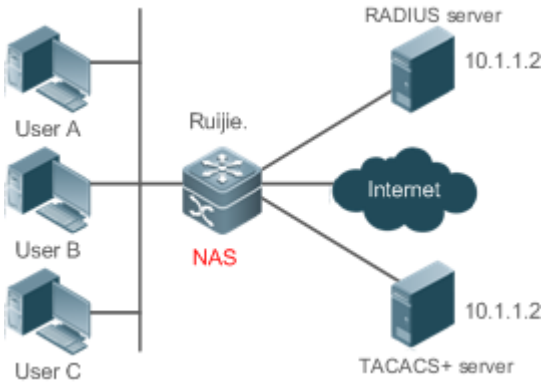
AAA is the main access control method. The device also provides other simple access control functions, such as local username authentication and online password authentication. Compared to them, AAA offers higher network security.

AAA has the following advantages:

- Robust flexibility and controllability
- Scalability
- Standards-compliant authentication
- Multiple standby systems

1.2 Applications

Application	Description
Configuring AAA in a Single-Domain Environment	AAA is performed for all the users in one domain.
Configuring AAA in a Multi-Domain Environment	AAA is performed for the users in different domains by using different methods.



1.2.1 Configuring AAA in a Single-Domain Environment

Scenario

In the network scenario shown in Figure 2-1, the following application requirements must be satisfied to improve security management on the NAS:

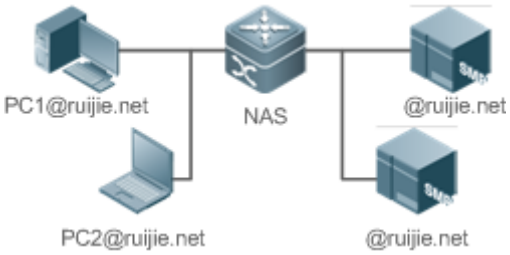
1. To facilitate account management and avoid information disclosure, each administrator has an individual account the unique username and password.
2. To access the NAS, users are required to pass identity authentication. This authentication process can be in local or centralized mode. You are advised to combine the two modes, with centralized mode as the primary option and local mode as the backup. In centralized authentication mode, users must undergo authentication by the RADIUS server first. If the RADIUS server does not respond, local authentication is used.
3. During authentication, users can be restricted from accessing specific network devices.
4. Rights-based management: Network management users are classified into the super user and common user. Super users have the rights to view and configure the NAS, and common users are only allowed to view the NAS configuration.
5. AAA records of users are stored on servers and can be viewed and referenced for auditing (TACACS+ is used for accounting in this example).

Figure 2-1

Remarks	User A, User B, and User C are connected to the NAS in wired or wireless mode. The RADIUS server can be the Windows 2000/2003 Server (IAS), UNIX system component, and dedicated server software provided by a vendor. The TACACS+ server can be the dedicated server software provided by a vendor.

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Configure authentication on the NAS.
- Configure authorization on the NAS.
- Configure accounting on the NAS.



1.2.2 Configuring AAA in a Multi-Domain Environment

Scenario

Configure the domain-based AAA service on the NAS.

- A user can log in by entering the username **PC1@ruijie.net** or **PC2@ruijie.com.cn** and correct password on an 802.1X client.
- Rights-based management: Network management users are classified into the super user and common user. Super users have the rights to view and configure the NAS, and common users are only allowed to view the NAS configuration.
- AAA records of users are stored on servers and can be viewed and referenced for auditing.

Figure 2-2

Remarks	The clients with the usernames **PC1@ruijie.net** and **PC2@ruijie.com.cn** are connected to the NAS in wired or wireless mode. The NAS is an access device. The Security Accounts Manager (SAM) server is a universal RADIUS server provided by Ruijie Networks.

Deployment

- Enable AAA on the NAS.
- Configure an authentication server on the NAS.
- Configure local users on the NAS.
- Define an AAA method list on the NAS.
- Enable domain-based AAA on the NAS.
- Create domains and AV sets on the NAS.

1.3 Features

Basic Concepts

↘ Local Authentication and Remote Server Authentication

Local authentication is the process where input passwords are verified by the user database on the NAS.

Remote server authentication is the process where input passwords are verified by the database on a remote server. It is mainly implemented by the RADIUS server and TACACA+ server.

↘ Method List

AAA is implemented using different security methods. A method list defines a method implementation sequence, and can contain one or more security protocols so that a standby method can be available when the first method becomes unavailable. The device uses the first method in the list in the beginning and then the next if there is no response for the first method. This method selection process continues until a security method responds or all the security methods in the list are tried out. Authentication fails if no method in the list responds.

A method list contains a series of security methods that will be queried in sequence to verify user identities. It defines one or more security protocols used for authentication, so that the standby authentication method is used when the active security method becomes unavailable. The device uses the first method in the list in the beginning and then the next if there is no response for the first method. This method selection process continues until a security method responds or all the security methods in the list are tried out. Authentication fails if no method in the list responds.

The next authentication method proceeds on devices only when the current method does not respond. When a method denies user access, the authentication process ends without trying other methods.

Figure 2-3

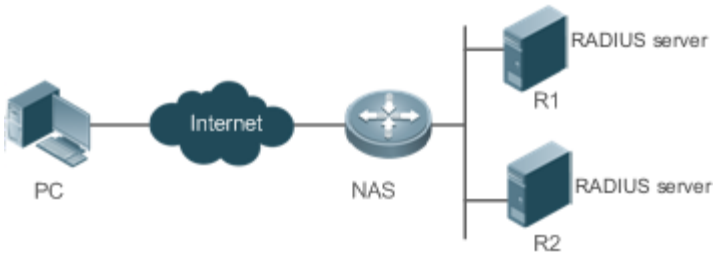


Figure 2-3 shows a typical AAA network topology, where two RADIUS servers (R1 and R2) and one NAS are deployed. The NAS can be the client for the RADIUS servers.

Assume that the system administrator defines a method list, where the NAS selects R1 and R2 in sequence to obtain user identity information and then accesses the local username database on the server. For example, when a remote PC user initiates dial-up access, the NAS first queries the user's identity on R1. When the user passes authentication on R1, R1 returns an Accept response to the NAS. Then the user is permitted to access the Internet. If R1 returns a Reject response, the user is denied and the connection is terminated. If R1 does not respond, the NAS considers that the R1 method times out and continues to query the user's identity on R2. This process continues as the NAS keeps trying the remaining authentication methods, until the user request is authenticated, rejected, or terminated. If all the authentication methods are responded with Timeout, authentication fails and the connection will be terminated.

The Reject response is different from the Timeout response. The Reject response indicates that the user does not meet the criteria of the available authentication database and therefore fails in authentication, and the Internet access request is denied. The Timeout response indicates that the authentication server fails to respond to the identity query. When detecting a timeout event, AAA proceeds to the next method in the list to continue the authentication process.

This document describes how to configure AAA on the RADIUS server. For details about TACACS+, see *Configuring TACACS+*.

AAA Server Group

You can define an AAA server group to include one or more servers of the same type. If the server group is referenced by a method list, the NAS preferentially sends requests to the servers in the referenced server group when the method list is used to implement AAA.

Overview

Feature	Description
AAA Authentication	Authenticates user identities for accessing the Internet.
AAA Authorization	Determines services or permissions users can enjoy.
AAA Accounting	Records the network resource usage of users.

Multi-Domain AAA	Creates domain-specific AAA schemes for users in different domains.

1.3.1 AAA Authentication

Authentication, authorization, and accounting are three independent services. Authentication user identities for accessing the Internet. During authentication, the username, password, and other user information are exchanged between devices to complete users' access or service requests. You can choose to use only the authentication service of AAA.

To configure AAA authentication, you need to first configure an authentication method list. Applications perform authentication according to the method list. The method list defines the types of authentication and the sequence in which they are performed. The defined authentication methods must be implemented by specified applications except the default method list. All applications use the default method list if no method list is configured.

AAA Authentication Scheme

- No authentication (**none**)

The identity of trusted users is not checked. This method is not used in most situations.

- Local authentication (**local**)

Authentication is performed on the NAS, which is configured with user information (including usernames, passwords, and AV pairs). Before local authentication is enabled, run the **username password/secret** command to create a local user database.

- Remote server-group authentication (**group**)

Authentication is performed by the NAS and a remote server-group through RADIUS. A server group consists of one or more servers of the same type. User information is managed centrally on a remote server, thus realizing centralized and unified authentication of multiple devices with high reliability. You can configure local authentication as the backup to avoid authentication failures when all the servers in the server group fail.

AAA Authentication Types

The device supports the following authentication types:

- Login authentication

Users log in to the command line interface (CLI) of the NAS for authentication through Secure Shell (SSH), Telnet, or File Transfer Protocol (FTP).

- Enable authentication

After users log in to the CLI of the NAS, they must be authenticated before CLI permission update. This process is called Enable authentication in privileged EXEC mode.

- PPP authentication

PPP authentication is performed for the users that initiate dial-up access through Point-to-Point Protocol (PPP).

- 802.1X authentication

802.1X authentication is performed for users that initiate dial-up access through 802.1X.

- iPortal (built-in portal) authentication

iPortal authentication is performed by the first-generation portal server.

- Web-based (second-generation portal) authentication

Web-based authentication is performed by the second-generation portal server.

- General authentication

Specify a general authentication method for 802.1X authentication, built-in portal authentication, and the second-generation portal authentication.

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Authentication Scheme

By default, no AAA authentication scheme is configured.

Before you configure an AAA authentication scheme, determine whether to use local authentication or remote server authentication. If remote server authentication is used, first configure a RADIUS or TACACS+ server. If local authentication is selected, configure local user database information on the NAS.

Configuring an AAA Authentication Method List

By default, no AAA authentication method list is configured.

Determine the access mode to be configured, and then configure authentication methods according to the access mode.

1.3.2 AAA Authorization

AAA authorization allows administrators to control services or permissions of users. After AAA authorization is enabled, the NAS configures user sessions according to the user configuration files stored on the NAS or servers. After authorization, users can use only the services or have only the permissions permitted by the configuration files.

AAA Authorization Scheme

- Direct authorization (**none**)

Direct authorization is intended for highly trusted users, who are assigned the default permissions specified by the NAS.

- Local authorization (**local**)

Local authorization is performed on the NAS, which authorizes users according to the AV pairs configured for local users.

- Remote server-group authorization (**group**)

Authorization is performed by the NAS and a remote server group. You can configure local or direct authorization as the backup to avoid authorization failures when all the servers in the server group fail.

AAA Authorization Types

- EXEC authorization

After users log in to the CLI of the NAS, they are assigned permission levels (0 to 15).

- Config-commands authorization

Users are assigned permissions to run specific commands in configuration modes (including the global configuration mode and sub-modes).

- Console authorization

After users log in through consoles, they are authorized to run commands.

- Command authorization

After users log in to the CLI of the NAS, they are authorized to run specific commands.

- Network authorization

After users access the Internet, they are authorized to use specific session services. For example, after users access the Internet through PPP and Serial Line Internet Protocol (SLIP), they are authorized to use the data service, bandwidth, and timeout service.

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Authorization Scheme

By default, no AAA authorization scheme is configured.

Before you configure an AAA authorization scheme, determine whether to use local authorization or remote server--group authorization. If remote server-group authorization needs to be implemented, first configure a RADIUS server. If local authorization needs to be implemented, configure local user database information on the NAS.

Configuring an AAA Authorization Method List

By default, no AAA authorization method list is configured.

Determine the access mode to be configured, and then configure authorization methods according to the access mode.

1.3.3 AAA Accounting

In AAA, accounting is an independent process similar to authentication and authorization. During accounting, start-accounting, update-accounting, and end-accounting requests are sent to the configured accounting server. The accounting server records the network resource usage of users and performs accounting, audit, and tracking of users' activities.

The accounting scheme is optional.

AAA Accounting Schemes

- No accounting (**none**)

Accounting is not performed on users.

- Local accounting (**local**)

Accounting is completed on the NAS, and the NAS collects statistics on and limits the number of local user connections. Billing is not performed.

- Remote server-group accounting (**group**)

Accounting is performed by the NAS and a remote server group. You can configure local accounting as the backup to avoid accounting failures when all the servers in the server group fail.

AAA Accounting Types

- EXEC accounting

Accounting is performed when users log in to and out of the CLI of the NAS.

- Command accounting

The device records commands that users run on the CLI of the NAS.

- Network accounting

The device records sessions that users set up after users pass 802.1X or web-based authentication to access the Internet.

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Accounting Scheme

By default, no AAA accounting method is configured.

Before you configure an AAA accounting scheme, determine whether to use local accounting or remote server-group accounting. If remote server-group accounting needs to be implemented, first configure a RADIUS server. If local accounting needs to be implemented, configure local user database information on the NAS.

Configuring an AAA Accounting Method List

By default, no AAA accounting method list is configured.

Determine the access mode to be configured, and then configure accounting methods according to the access mode.

1.3.4 Multi-Domain AAA

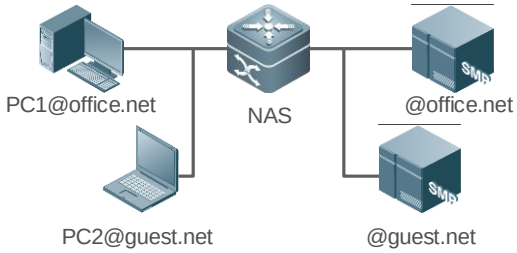
In a multi-domain environment, the NAS can provide AAA services for users in different domains. The user AVs (such as usernames and passwords, service types, and permissions) may vary with different domains. It is necessary to configure domains to differentiate user AVs in different domains and configure an AV set (including an AAA service method list, for example, RADIUS) for each domain.

The device supports the following username formats:

1. userid@domain-name
2. domain-name\userid
3. userid.domain-name
4. userid

The userid format does not contain a domain name, and the **default** domain name is used.

The NAS provides the domain-based AAA service based on the following principles:



- Resolves the domain name carried by a user.
- Searches for the user domain according to the domain name.

- Searches for the corresponding AAA method list name according to the domain configuration on the NAS.
- Searches for the corresponding method list according to the method list name.
- Provides AAA services based on the method list.

If any of the preceding procedures fails, AAA services cannot be provided.

Figure 2-4 shows the typical multi-domain topology.

Figure 2-4

Related Configuration

Enabling AAA

By default, AAA is disabled.

To enable AAA, run the **aaa new-model** command.

Configuring an AAA Method List

By default, no AAA method list is configured.

Enabling the Domain-Based AAA Service

By default, the domain-based AAA service is disabled.

To enable the domain-based AAA service, run the **aaa domain enable** command.

Creating a Domain

By default, no domain is configured.

To configure a domain, run the **aaa domain** *domain-name* command.

Configuring an AV Set for a Domain

By default, no AV set is configured for a domain.

An AV set for a domain contains the AAA method list, the maximum number of online users, whether to remove the domain name from the username, and whether the domain name takes effect.

Displaying Domain Configuration

To display the domain configuration, run the **show aaa domain** command.

The system supports a maximum of 32 domains.

1.4 Configuration

Configuration	Description and Command	
Configuring AAA Authentication	⚠ Mandatory if user identities need to be verified.	
	aaa new-model	Enables AAA.
	aaa authentication login	Defines a method list of login authentication.
	aaa authentication enable	Defines a method list of Enable authentication.
	aaa authentication dot1x	Defines a method list of 802.1X authentication.
	aaa authentication ppp	Defines a method list of PPP authentication.
	aaa authentication sslvpn	Defines a method list of SSL VPN authentication.
	aaa authentication web-auth	Defines a method list of web-based authentication.
	aaa authentication iportal	Defines a method list of built-in portal authentication.
	aaa authentication general	Defines a method list of general authentication.
	aaa local authentication attempts	Sets the maximum number of login attempts.
	aaa local authentication lockout-time	Sets the maximum lockout time upon a login failure.
Configuring AAA Authorization	⚠ Mandatory if different permissions and services need to be assigned to users.	
	aaa new-model	Enables AAA.
	aaa authorization exec	Defines a method list of EXEC authorization.
	aaa authorization commands	Defines a method list of command authorization.
	aaa authorization network	Configures a method list of network authorization.
	authorization exec	Applies EXEC authorization methods to a specified VTY line.
	authorization commands	Applies command authorization methods to a specified VTY line.
Configuring AAA Accounting	⚠ Mandatory if accounting, statistics, and tracking need to be performed on the network resource usage of users.	
	aaa new-model	Enables AAA.

Configuration	Description and Command	
	aaa accounting exec	Defines a method list of EXEC accounting.
	aaa accounting commands	Defines a method list of command accounting.
	aaa accounting network	Defines a method list of network accounting.
	accounting exec	Applies EXEC accounting methods to a specified VTY line.
	accounting commands	Applies command accounting methods to a specified VTY line.
	aaa accounting update	Enables accounting update.
	aaa accounting update periodic	Configures the accounting update interval.
Configuring an AAA Server Group	⚠ Recommended if a server group needs to be configured to handle AAA through different servers in the group.	
	aaa group server	Creates a user-defined AAA server group.
	server	Adds an AAA server group member.
Configuring the Domain-Based AAA Service	⚠ Mandatory if AAA management of 802.1X access STAs needs to be performed according to domains.	
	aaa new-model	Enables AAA.
	aaa domain enable	Enables the domain-based AAA service.
	aaa domain	Creates a domain and enters domain configuration mode.
	authentication dot1x	Associates the domain with an 802.1X authentication method list.
	authentication ppp	Associates the domain with a PPP authentication method list.
	authentication web-auth	Associates the domain with a web-based authentication method list.
	accounting network	Associates the domain with a network accounting method list.
	authorization network	Associates the domain with a network authorization method list.
	state	Configures the domain status.
	username-format	Configures whether to contain the domain name in usernames.
	access-limit	Configures the maximum number of domain users.

Configuration	Description and Command	
Configuring a Policy for Accounting-Start Failures	**aaa accounting start-fail**	Configures a policy for accounting-start failures.
Configuring Heartbeat Packet Detection	[**no**] **aaa heartbeat enable**	Configures heartbeat detection.
Configuring AAA Logging	[**no**] **aaa log enable**	Configures AAA logging.
	aaa log rate-limit *num*	Configures an AAA logging rate limit.
	aaa user-diag log-num	Adjusts the number of tracks that can be recorded for each AAA user.
	aaa user-diag user-num	Adjusts the total number of all AAA user tracks.

1.4.1 Configuring AAA Authentication

Configuration Effect

Authenticate user identities for accessing the Internet.

Notes

- If an authentication scheme contains multiple authentication methods, these methods are executed according to the sequence in which they were configured.
- The next authentication method is executed only when the current method does not respond. If the current method fails, the next method will be not tried.
- When the **none** method is used, users can obtain access even when no authentication method receives the response. Therefore, the **none** method is used only as the backup.

The **none** method is typically not used. You can use the **none** method as the last optional authentication method in special cases. For example, all the users who may request access are trusted users and the users' work must not be delayed by system faults. Then you can use the **none** method to assign access permissions to these users when the authentication server does not respond. It is recommended that the local authentication method be added for the **none** method.

- If AAA authentication is enabled but no authentication method is configured and the default authentication method does not exist, users can directly log in to the console without being authenticated. If users log in by other means, the users must pass local authentication.
- When a user enters the CLI after passing login authentication (the **none** method is not used), the username is recorded. When the user performs Enable authentication, the user is not asked to enter the username again. This is because the input username during login authentication is automatically filled in. However, the user must enter the password previously used for login authentication.
- The username is not recorded if the user does not perform login authentication when entering the CLI or the **none** method is used during login authentication. Then a user is required to enter the username each time when performing Enable authentication.

Configuration Steps

↘ **Enabling AAA**

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

Defining a Method List of Login Authentication

- Run the **aaa authentication login** command to configure a method list of login authentication.
- This configuration is mandatory if you need to configure a login authentication method list including the configuration of the default method list.
- By default, no method list of login authentication is configured.

Defining a Method List of Enable Authentication

- Run the **aaa authentication enable** command to configure a method list of Enable authentication.
- This configuration is mandatory if you need to configure an Enable authentication method list. You can configure only the default method list.
- By default, no method list of Enable authentication is configured.

Defining a Method List of 802.1X Authentication

- Run the **aaa authentication dot1x** command to configure a method list of 802.1X authentication.
- This configuration is mandatory if you need to configure an 802.1X authentication method list including the configuration of the default method list.
- By default, no method list of 802.1X authentication is configured.

Defining a Method List of PPP Authentication

- Run the **aaa authentication ppp** command to configure a method list of PPP authentication.
- This configuration is mandatory if you need to configure an authentication method list for PPP dial-up access.
- By default, no method list of PPP authentication is configured.

Defining a Method List of Web-based Authentication

- Run the **aaa authentication web-auth** command to configure a method list of web-based authentication.
- This configuration is mandatory if you need to configure a web-based authentication method list including the configuration of the default method list.
- By default, no method list of web-based authentication is configured.

Defining a Method List of iPortal Web-based Authentication

- Run the **aaa authentication iportal** command to configure a method list of iPortal web-based authentication.
- This configuration is mandatory if you need to configure an iPortal web-based authentication method list including the configuration of the default method list.
- By default, no method list of iPortal web-based authentication is configured.

Defining a General Method List of 802.1X Authentication, Web-based Authentication, and iPortal Authentication

- Run the **aaa authentication general** command to configure a method list for 802.1X authentication, web-based authentication, and iPortal authentication.
- If the **aaa authentication dot1x**, **aaa authentication web-auth**, or **aaa authentication iportal** command is configured, it takes precedence over the **aaa authentication general** command.
- By default, no general authentication method list is configured.

Defining a Method List of SSL VPN Authentication

- Run the **aaa authentication sslvpn** command to configure a method list of SSL VPN authentication.
- This configuration is mandatory if you need to configure an SSL VPN authentication method list including the configuration of the default method list.
- By default, no method list of SSL VPN authentication is configured.

Setting the Maximum Number of Login Attempts

- Optional.
- By default, a user is allowed to enter passwords up to three times during login.

Setting the Maximum Lockout Time After a Login Failure

- Optional.
- By default, a user is locked for 15 minutes after entering incorrect passwords three times.

Verification

- Run the **show aaa method-list** command to display the configured method lists.
- Run the **show aaa lockout** command to display the maximum number of login attempts and the maximum lockout time after a login failure.
- Run the **show running-config** command to display the authentication method lists associated with login authentication and 802.1X authentication.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA security service, run this command. If AAA is not enabled, AAA commands cannot be configured.

Defining a Method List of Login Authentication

Command	**aaa authentication login** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	**default:** Indicates that the configured method list is the default one for login authentication. *list-name*: Indicates the name of a login authentication method list. It can be any character string.

	method: Indicates keyword **local**, **none**, **group**, or **subs**. A method list contains up to four methods. **local**: Indicates that the local user database is used for authentication. **none**: Indicates that authentication is not performed. **group**: Indicates that a server group is used for authentication. The RADIUS and TACACS+ server groups are supported. **subs**: Indicates that the subs database is used for authentication.
Command Mode	Global configuration mode
Usage Guide	If the AAA login authentication service is enabled on the NAS, users must perform login authentication negotiation through AAA. Run the **aaa authentication login** command to configure the default or optional method list for login authentication. In a method list, the next method is executed only when the current method does not receive the response. After you configure login authentication methods, apply the methods to the VTY lines that require login authentication; otherwise, the methods will not take effect.

Defining a Method List of Enable Authentication

Command	**aaa authentication enable default** *method1* [*method2*...]
Parameter Description	**default**: Indicates that the configured method list is the default one for Enable authentication. *list-name*: Indicates the name of an Enable authentication method list. It can be any character string. *method*: Indicates keyword **enable**, **local**, **none**, or **group**. A method list contains up to four methods. **enable**: Indicates that the password that is configured using the **enable** command is used for authentication. **local**: Indicates that the local user database is used for authentication. **none**: Indicates that authentication is not performed. **group**: Indicates that a server group is used for authentication. The RADIUS and TACACS+ server groups are supported.
Command Mode	Global configuration mode
Usage Guide	● If the AAA login authentication service is enabled on the NAS, users must perform Enable authentication negotiation through AAA. Run the **aaa authentication enable** command to configure the default or optional method lists for Enable authentication. ● In a method list, the next method is executed only when the current method does not receive the response. ● The Enable authentication function automatically takes effect after configuring the Enable authentication method list. ● When the **local** method of Enable authentication is enabled for AAA authentication, the authentication permission level cannot exceed the permission level of the account.

Defining a Method List of 802.1X Authentication

Command	**aaa authentication dot1x** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	**default**: Indicates that the configured method list is the default one for 802.1X authentication. *list-name*: Indicates the name of an 802.1X authentication method list. It can be any character string. *method*: Indicates keyword **local**, **none**, or **group**. A method list contains up to four methods.

	local: Indicates that the local user database is used for authentication. **none**: Indicates that authentication is not performed. **group**: Indicates that a server group is used for authentication. The RADIUS server group is supported.
Command Mode	Global configuration mode
Usage Guide	If 802.1X authentication is enabled on the NAS, users must perform 802.1X authentication negotiation through AAA. Run the **aaa authentication dot1x** command to configure the default or optional method lists for 802.1X authentication. In a method list, the next method is executed only when the current method does not receive the response.

Defining a Method List of PPP, Web-based, iPortal, or SSL VPN Authentication

Command	**aaa authentication** { **ppp | web-auth** | **iportal** | **sslvpn** } { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	**ppp:** Configures a method list of PPP authentication. **web-auth**: Configures a method list of web-based authentication. **iportal**: Configures a method list of iPortal authentication. **sslvpn**: Configures a method list of SSL VPN authentication. **default**: Indicates that the configured method list is the default one for PPP authentication. *list-name*: Indicates the name of a PPP authentication method list. It can be any character string. *method*: Indicates authentication methods from **local**, **none**, **group**, and **subs**. A method list contains up to four methods. **local**: Indicates that the local user database is used for authentication. **none**: Indicates that authentication is not performed. **group**: Indicates that a server group is used for authentication. The RADIUS server group is supported. **subs**: Specifies the SUBS authentication method using the SUBS database.
Command Mode	Global configuration mode
Usage Guide	If PPP authentication is enabled on the NAS, users must perform PPP authentication negotiation through AAA. Run the **aaa authentication ppp** command to configure the default or optional method lists for PPP authentication. In a method list, the next method is executed only when the current method does not receive the response.

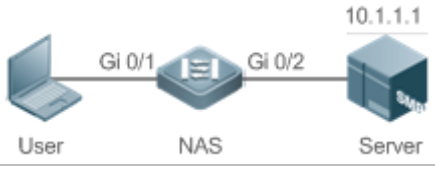
Defining a General Method List of 802.1X, Web-based, and iPortal Authentication

Command	**aaa authentication general** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	**default**: Indicates that the defined method list applies to all front-end authentication. *list-name*: Indicates the name of a general authentication list. It can be any character string. *method*: Indicates keyword **local**, **none**, or **group**. A method list contains up to four methods. **local**: Indicates that the local user database is used for authentication. **none**: Indicates that authentication is not performed.

	group: Indicates that a server group is used for authentication. The RADIUS server group is supported.
Command Mode	Global configuration mode
Usage Guide	The general method list applies to only front-end services of 802.1X authentication, web-based authentication, and iPortal authentication. If there is no response to method 1, method 2 will take effect.

Setting the Maximum Number of Login Attempts

Command	**aaa local authentication attempts** *max-attempts*
Parameter Description	*max-attempts*: Indicates the maximum number of login attempts. The value ranges from 1 to 2,147,483,647.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum number of login attempts.



Setting the Maximum Lockout Time After a Login Failure

Command	**aaa local authentication lockout-time** *lockout-time*
Parameter Description	*lockout-time*: Indicates the time during which a user is locked after entering incorrect passwords up to the specified number of times. The value ranges from 1 to 43,200, in minutes.
Command Mode	Global configuration mode
Usage Guide	Use this command to set the maximum time during which a user is locked after entering incorrect passwords up to the specified number of times.

Configuration Example

Configuring AAA Login Authentication

On the NAS, configure a login authentication method list containing **group** *radius* and **local** methods in order.

Scenario Figure 2-5	
Configuration Steps	Step 1: Enable AAA. Step 2: First configure a RADIUS or TACACS+ server if remote group server authentication needs to be implemented. Configure local user database information on the NAS if local authentication needs to be implemented. (This example requires the configuration of a RADIUS server and local database information.) Step 3: Configure an AAA authentication method list for login authentication users. (This example uses **group** *radius* and **local** in order.) Step 4: Apply the configured method list to an interface or line. Skip this step if the default authentication method is used.
NAS	`Hostname#configure terminal`

	Hostname(config)#username user password pass Hostname(config)#aaa new-model Hostname(config)#radius-server host 10.1.1.1 Hostname(config)#radius-server key ruijie Hostname(config)#aaa authentication login list1 group radius local Hostname(config)#line vty 0 20 Hostname(config-line)#login authentication list1 Hostname(config-line)#exit
Verification	Run the **show aaa method-list** command on the NAS to display the configuration.
NAS	Hostname#show aaa method-list Authentication method-list: aaa authentication login list1 group radius local Accounting method-list: Authorization method-list:
	Assume that a user remotely logs in to the NAS through Telnet. The user is asked to enter the username and password on the CLI. The user must enter the correct username and password to access the NAS.
User	User Access Verification Username:user Password:pass

Configuring AAA Enable Authentication

On the NAS, configure an Enable authentication method list containing **group** *radius*, **local**, and then **enable** methods in order.

Scenario **Figure 2-6**	
Configuration Steps	Step 1: Enable AAA. Step 2: First configure a RADIUS server if remote server-group authentication needs to be implemented. Configure local user database information on the NAS if local authentication needs to be implemented. Configure Enable authentication passwords on the NAS if you use Enable password authentication. Step 3: Configure an AAA authentication method list for Enable authentication users. You can define only one Enable authentication method list globally. You do not need to define the list name. You can configure only the default method list that will be applied automatically.
NAS	Hostname#configure terminal

	Hostname(config)#username user privilege 15 password pass Hostname(config)#enable secret w Hostname(config)#aaa new-model Hostname(config)#radius-server host 10.1.1.1 Hostname(config)#radius-server key radius-key Hostname(config)#aaa authentication enable default group radius local enable
Verification	Run the **show aaa method-list** command on the NAS to display the configuration.
NAS	Hostname#show aaa method-list Authentication method-list: aaa authentication enable default group radius local enable Accounting method-list: Authorization method-list:
	The CLI displays an authentication prompt when the user level is updated to level 15. The user must enter the correct username and password to access the NAS.
NAS	Hostname>enable Username:user Password:pass Hostname#

Configuring AAA 802.1X Authentication

On the NAS, configure an 802.1X authentication method list containing **group** *radius*, and then **local** methods in order.

Scenario **Figure 2-7**	
Configuration Steps	Step 1: Enable AAA. Step 2: First configure a RADIUS server if remote server-group authentication needs to be implemented. Configure local user database information on the NAS if local authentication needs to be implemented. (This example requires the configuration of a RADIUS server and local database information.) Step 3: Configure an AAA authentication method list for 802.1X authentication users. (This example uses **group** *radius* and **local** in order.) Step 4: Apply the AAA authentication method list. Skip this step if the default authentication method is used. Step 5: Enable 802.1X authentication on an interface.
NAS	Hostname#configure terminal Hostname(config)#username user1 password pass1 Hostname(config)#username user2 password pass2

	Hostname(config)#aaa new-model Hostname(config)#radius-server host 10.1.1.1 Hostname(config)#radius-server key radius-key Hostname(config)#aaa authentication dot1x default group radius local Hostname(config)#interface gigabitEthernet 0/1 Hostname(config-if-gigabitEthernet 0/1)#dot1 port-control auto Hostname(config-if-gigabitEthernet 0/1)#exit
Verification	Run the **show aaa method-list** command on the NAS to display the configuration.
NAS	Hostname#show aaa method-list Authentication method-list: aaa authentication dot1x default group radius local Accounting method-list: Authorization method-list:

Common Errors

- The RADIUS or TACACS+ server is not configured.
- Usernames and passwords are not configured in the local database.

1.4.2 Configuring AAA Authorization

Configuration Effect

- Determine services or permissions that authenticated users can enjoy.

Notes

- EXEC authorization is often used with login authentication, which can be implemented on the same line. Authorization and authentication can be performed using different methods and servers. Therefore, authorization and authentication results of the same user may be different. If a user passes login authentication but fails in EXEC authorization, the user cannot enter the CLI.
- Authorization methods in an authorization scheme are executed according to the sequence in which they were configured. The next authorization method is executed only when the current method does not receive the response. If authorization fails using a method, the next method will be not tried.
- Command authorization is supported only by TACACS+.
- Console authorization: The device can differentiate the users who log in through the console and other types of clients. You can enable or disable command authorization for the users who log in through the console. If command authorization is disabled for these users, the command authorization method list applied to the console line no longer takes effect.

Configuration Steps

↘ **Enabling AAA**

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

Defining a Method List of EXEC Authorization

- Run the **aaa authorization exec** command to configure a method list of EXEC authorization.
- This configuration is mandatory if you need to configure an EXEC authorization method list including the configuration of the default method list.
- By default, no EXEC authorization method list is configured.

The default access permission level of EXEC users is the lowest. Console users can connect to the NAS through the console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user and SSH user.

Defining a Method List of Command Authorization

- Run the **aaa authorization commands** command to configure a method list of command authorization.
- This configuration is mandatory if you need to configure a command authorization method list including the configuration of the default method list.
- By default, no command authorization method list is configured.

Configuring a Method List of Network Authorization

- Run the **aaa authorization network** command to configure a method list of network authorization.
- This configuration is mandatory if you need to configure a network authorization method list including the configuration of the default method list.
- By default, no authorization method is configured.

Applying EXEC Authorization Methods to a Specified VTY Line

- Run the **authorization exec** command in line configuration mode to apply EXEC authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list

Applying Command Authorization Methods to a Specified VTY Line

- Run the **authorization commands** command in line configuration mode to apply command authorization methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command authorization method list to a specified VTY line.
- By default, all VTY lines are associated with the default authorization method list.

Enabling Authorization for Commands in Configuration Modes

- Run the **aaa authorization config-commands** command to enable authorization for commands in configuration modes.
- By default, authorization is disabled for commands in configuration modes.

Enabling Authorization for Console Users to Run Commands

- Run the **aaa authorization console** command to enable authorization for console users to run commands.
- By default, authorization is disabled for console users to run commands.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA security service, run this command. If AAA is not enabled, AAA commands cannot be configured.

Defining a Method List of EXEC Authorization

Command	**aaa authorization exec** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	**default**: Indicates that the configured method list is the default one for EXEC authorization. *list-name*: Indicates the name of an EXEC authorization method list. It can be any character string. *method*: Indicates keyword **local**, **none**, or **group**. A method list contains up to four methods. **local**: Indicates that the local user database is used for EXEC authorization. **none**: Indicates that EXEC authorization is not performed. **group**: Indicates that a server group is used for EXEC authorization. The RADIUS and TACACS+ server groups are supported.
Command Mode	Global configuration mode
Usage Guide	The device supports authorization of the users who log in to the CLI of the NAS. The NAS assigns the users CLI operation permissions (0 to 15). EXEC authorization is performed only on the users who have passed login authentication. If a user fails in EXEC authorization, the user cannot enter the CLI. After you configure EXEC authorization methods, apply the methods to the VTY lines that require EXEC authorization; otherwise, the methods will not take effect.

Defining a Method List of Command Authorization

Command	**aaa authorization commands** *level* { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	**default**: Indicates that the configured method list is the default one for command authorization. *list-name*: Indicates the name of a command authorization method list. It can be any character string. *method*: Indicates keyword **none** or **group**. A method list contains up to four methods. **none**: Indicates that command authorization is not performed. **group**: Indicates that a server group is used for command authorization.

Command Mode	Global configuration mode
Usage Guide	The device supports authorization of the commands that can be executed by users. When a user enters a command, the AAA module sends the command to the authentication server. If the authentication server permits command execution, the command is executed. If the authentication server rejects command execution, the command is not executed and a message is displayed indicating that command execution is rejected. When you configure command authorization, specify the command level, which is used as the default level. For example, if a command above level 14 is visible to users, the default level of the command is 14. After you configure command authorization methods, apply the methods to the VTY lines that require command authorization; otherwise, the methods will not take effect.

Configuring a Method List of Network Authorization

Command	**aaa authorization network** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	**default**: Indicates that the configured method list is the default one for network authorization. *list-name*: Indicates the name of a network authorization method list. It can be any character string. *method*: Indicates keyword **none** or **group**. A method list contains up to four methods. **none**: Indicates that authentication is not performed. **group**: Indicates that a server group is used for network authorization.
Command Mode	Global configuration mode
Usage Guide	The device supports authorization of network service requests such as PPP and SLIP requests. After authorization is configured, all authenticated users or interfaces are authorized automatically. You can configure three different authorization methods. The next authorization method is executed only when the current method does not receive the response. If authorization fails using a method, the next method will be not tried. RADIUS servers return a series of AV pairs to authorize authenticated users. Network authorization is based on authentication. That is, only authenticated users can perform network authorization.

Enabling Authorization for Commands in Configuration Modes (Including the Global Configuration Mode and Sub-Modes)

Command	**aaa authorization config-commands**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable authorization for commands only in non-configuration modes (for example, privileged EXEC mode), disable authorization in configuration modes by using the **no** form of this command. Then you can run commands in configuration mode and sub-modes without authorization.

Enabling Authorization for Console Users to Run Commands

Command	**aaa authorization console**

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The device can differentiate the users who log in through the console and other types of clients. You can enable or disable command authorization for the users who log in through the console. If command authorization is disabled for these users, the command authorization method list applied to the console line no longer takes effect.

Configuration Example

Configuring AAA EXEC Authorization

Configure login authentication and EXEC authorization for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC authorization is performed on a RADIUS server. If the RADIUS server does not respond, local authorization is used.

Scenario Figure 2-8	
Configuration Steps	Step 1: Enable AAA. Step 2: First configure a RADIUS server if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure local user database information on the NAS. Step 3: Configure an AAA authorization method list according to different access modes and service types. Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used. EXEC authorization is often used with login authentication, which can be implemented on the same line.

NAS	`Hostname#configure terminal`
	`Hostname(config)#username user password pass`
	`Hostname(config)#username user privilege 6`
	`Hostname(config)#aaa new-model`
	`Hostname(config)#radius-server host 10.1.1.1`
	`Hostname(config)#radius-server key test`
	`Hostname(config)#aaa authentication login list1 group local`
	`Hostname(config)#aaa authorization exec list2 group radius local`
	`Hostname(config)#line vty 0 4`
	`Hostname(config-line)#login authentication list1`
	`Hostname(config-line)# authorization exec list2`
	`Hostname(config-line)#exit`

Verification	Run the **show run** and **show aaa method-list** commands on the NAS to display the configuration.
NAS	`Hostname#show aaa method-list`

	Authentication method-list: aaa authentication login list1 group local Accounting method-list: Authorization method-list: aaa authorization exec list2 group radius local
	Hostname# show running-config aaa new-model ! aaa authorization exec list2 group local aaa authentication login list1 group radius local ! username user password pass username user privilege 6 ! radius-server host 10.1.1.1 radius-server key 7 093b100133 ! line con 0 line vty 0 4 authorization exec list2 login authentication list1 ! End

Configuring AAA Command Authorization

Provide command authorization for login users according to the following default authorization method: Authorize level-15 commands first by using a TACACS+ server. If the TACACS+ server does not respond, local authorization is performed. Authorization is applied to the users who log in through the Console and the users who log in through other types of clients.

Scenario **Figure 2-9**	
Configuration Steps	Step 1: Enable AAA. Step 2: First configure a RADIUS or TACACS+ server if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure local user database information on the NAS. Step 3: Configure an AAA authorization method list according to different access modes and service types.

	Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.
NAS	Hostname#configure terminal Hostname(config)#username user1 password pass1 Hostname(config)#username user1 privilege 15 Hostname(config)#aaa new-model Hostname(config)#tacacs-server host 192.168.217.10 Hostname(config)#tacacs-server key aaa Hostname(config)#aaa authentication login default local Hostname(config)#aaa authorization commands 15 default group tacacs+ local Hostname(config)#aaa authorization console
Verification	Run the **show run** and **show aaa method-list** commands on the NAS to display the configuration.
NAS	Hostname#show aaa method-list Authentication method-list: aaa authentication login default local Accounting method-list: Authorization method-list: aaa authorization commands 15 default group tacacs+ local
	Hostname#show run ! aaa new-model ! aaa authorization console aaa authorization commands 15 default group tacacs+ local aaa authentication login default local ! ! nfpp ! vlan 1 ! username user1 password 0 pass1 username user1 privilege 15 no service password-encryption ! tacacs-server host 192.168.217.10 tacacs-server key aaa ! line con 0 line vty 0 4 !

	! end

Configuring AAA Network Authorization

Scenario **Figure 2-10**	
Configuration Steps	Step 1: Enable AAA. Step 2: First configure a RADIUS or TACACS+ server if remote server-group authorization needs to be implemented. If local authorization needs to be implemented, configure local user database information on the NAS. Step 3: Configure an AAA authorization method list according to different access modes and service types. Step 4: Apply the configured method list to an interface or line. Skip this step if the default authorization method is used.
NAS	Hostname#configure terminal Hostname(config)#aaa new-model Hostname(config)#radius-server host 10.1.1.1 Hostname(config)#radius-server key test Hostname(config)#aaa authorization network default group radius none Hostname(config)# end
Verification	Run the **show aaa method-list** command on the NAS to display the configuration.
NAS	Hostname#show aaa method-list Authentication method-list: Accounting method-list: Authorization method-list: aaa authorization network default group radius none

Common Errors

N/A

1.4.3 Configuring AAA Accounting

Configuration Effect

- Record the network resource usage of users.
- Record the user login and logout processes and the commands executed by users during device management.

Notes

Accounting methods:

- If an accounting scheme contains multiple accounting methods, these methods are executed according to the sequence in which they were configured. The next accounting method is executed only when the current method does not receive the response. If accounting fails using a method, the next method will be not tried.
- After the default accounting method list is configured, it is applied to all VTY lines automatically. If a non-default accounting method list is applied to a line, it will replace the default one. If you apply a non-defined method list to a line, the system will display a message indicating that accounting on this line is ineffective. Accounting will take effect only when a defined method list is applied.

EXEC accounting:

- EXEC accounting is performed only when login authentication on the NAS is completed. EXEC accounting is not performed if login authentication is not configured or the **none** method is used for authentication. If Start-accounting is not performed for a user upon login, Stop-accounting will not be performed when the user logs out.

Command accounting:

- Only the TACACS+ protocol supports command accounting.

Configuration Steps

Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

Defining a Method List of EXEC Accounting

- Run the **aaa accounting exec** command to configure a method list of EXEC accounting.
- This configuration is mandatory if you need to configure an EXEC accounting method list including the configuration of the default method list.
- The default access permission level of EXEC users is the lowest. Console users can connect to the NAS through the console port or Telnet. Each connection is counted as an EXEC user, for example, a Telnet user or an SSH user.
- By default, no EXEC accounting method list is configured.

Defining a Method List of Command Accounting

- Run the **aaa accounting commands** command to configure a method list of command accounting.
- This configuration is mandatory if you need to configure a command accounting method list including the configuration of the default method list.
- By default, no command accounting method list is configured.

Defining a Method List of Network Accounting

- Run the **aaa accounting network** command to configure a method list of network accounting.
- This configuration is mandatory if you need to configure a network accounting method list including the configuration of the default method list.

- By default, no network accounting method list is configured.

Applying EXEC Accounting Methods to a Specified VTY Line

- Run the **accounting exec** command in line configuration mode to apply EXEC accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply an EXEC accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

Applying Command Accounting Methods to a Specified VTY Line

- Run the **accounting commands** command in line configuration mode to apply command accounting methods to a specified VTY line.
- This configuration is mandatory if you need to apply a command accounting method list to a specified VTY line.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

Applying 802.1X Network Accounting Methods

- Run the **dot1x accounting network** command to configure 802.1X network accounting methods.
- This configuration is mandatory if you need to specify 802.1X network accounting methods.
- You do not need to run this command if you apply the default method list.
- By default, all VTY lines are associated with the default accounting method list.

Enabling Accounting Update

- Optional.
- It is recommended that accounting update be configured for improved accounting accuracy.
- By default, accounting update is disabled.

Configuring the Accounting Update Interval

- Optional.
- It is recommended that the accounting update interval be not configured unless otherwise specified.

Verification

Run the **show running-config** command to verify the configuration.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A

Command Mode	Global configuration mode
Usage Guide	To enable the AAA security service, run this command. If AAA is not enabled, AAA commands cannot be configured.

Defining a Method List of EXEC Accounting

Command	**aaa accounting exec** { **default** | *list-name* } **start-stop** *method1* [*method2*...]
Parameter Description	**default**: Indicates that the configured method list is the default one for EXEC accounting. *list-name*: Indicates the name of an EXEC accounting method list. It can be any character string. *method*: Indicates keyword **none** or **group**. A method list contains up to four methods. **none**: Indicates that EXEC accounting is not performed. **group**: Indicates that a server group is used for EXEC accounting. The RADIUS and TACACS+ server groups are supported.
Command Mode	Global configuration mode
Usage Guide	The device enables EXEC accounting only when login authentication is completed. EXEC accounting is not performed if login authentication is not performed or the **none** authentication method is used. When a user logs in to the CLI of the NAS enabled with accounting, the NAS sends a start-accounting message to the authentication server. When the user logs out, the NAS sends a stop-accounting message to the authentication server. If the NAS does not send a start-accounting message upon user login, the NAS will not send a stop-accounting message when the user logs out. After you configure EXEC accounting methods, apply the methods to the VTY lines that require EXEC accounting; otherwise, the methods will not take effect.

Defining a Method List of Command Accounting

Command	**aaa accounting commands** *level* { **default** | *list-name* } **start-stop** *method1* [*method2*...]
Parameter Description	*level*: Indicates the command level for which accounting will be performed. The value ranges from 0 to 15. After a command of the configured level is executed, the accounting server records related information based on the received accounting packet. **default**: Indicates that the configured method list is the default one for command accounting. *list-name*: Indicates the name of a command accounting method list. It can be any character string. *method*: Indicates keyword **none** or **group**. A method list contains up to four methods. **none**: Indicates that command accounting is not performed. **group**: Indicates that a server group is used for command accounting. The TACACS+ server group is supported.
Command Mode	Global configuration mode
Usage Guide	The device enables command accounting only when login authentication is completed. Command accounting is not performed if login authentication is not performed or the **none** authentication method is used. The NAS enabled with accounting records information about the commands of the configured level that users run and sends the information to the authentication server. After you configure command accounting methods, apply the methods to the VTY lines that require command accounting; otherwise, the methods will not take effect.

Defining a Method List of Network Accounting

Command	**aaa accounting network** { **default** | *list-name* } **start-stop** *method1* [*method2*...]
Parameter Description	**default**: Indicates that the configured method list is the default one for network accounting. *list-name*: Indicates the name of a network accounting method list. It can be any character string. **start-stop**: Indicates that a start-accounting message and a stop-accounting message are sent when a user accesses a network and when the user disconnects from the network respectively. The start-accounting message indicates that the user is allowed to access the network, regardless of whether accounting is enabled. *method*: Indicates keyword **none** or **group**. A method list contains up to four methods. **none**: Indicates that network accounting is not performed. **group**: Indicates that a server group is used for network accounting. The RADIUS and TACACS+ server groups is supported.
Command Mode	Global configuration mode
Usage Guide	The device sends recorded attributes to the authentication server to perform accounting of user activities. The **start-stop** keyword is used to configure user accounting options.

Enabling Accounting Update

Command	**aaa accounting update**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Accounting update are unavailable if AAA is not enabled. After AAA is enabled, run this command to enable accounting update.

Configuring the Accounting Update Interval

Command	**aaa accounting update periodic** *interval*
Parameter Description	*interval*: Indicates the accounting update interval, in minutes. The value ranges from 1 to 525,600.
Command Mode	Global configuration mode
Usage Guide	Accounting update are unavailable if AAA is not enabled. After AAA is enabled, run this command to configure the accounting update interval.

Configuration Example

Configuring AAA EXEC Accounting

Configure login authentication and EXEC accounting for users on VTY lines 0 to 4. Login authentication is performed in local mode, and EXEC accounting is performed on a RADIUS server.

Scenario **Figure 2-11**	

Configuration Steps	Step 1: Enable AAA. Step 2: If remote server-group accounting needs to be implemented, first configure the RADIUS or TACACS+ server. Step 3: Configure an AAA accounting method list according to different access modes and service types. Step 4: Apply the configured method list to an interface or line. Skip this step if the default accounting method is used.

NAS	`Hostname#configure terminal`
	`Hostname(config)#username user password  pass`
	`Hostname(config)#aaa new-model`
	`Hostname(config)#radius-server host 10.1.1.1`
	`Hostname(config)#radius-server key  test`
	`Hostname(config)#aaa authentication login list1 group local`
	`Hostname(config)#aaa accounting exec list3 start-stop group radius`
	`Hostname(config)#line vty 0 4`
	`Hostname(config-line)#login authentication list1`
	`Hostname(config-line)# accounting  exec list3`
	`Hostname(config-line)#exit`

Verification	Run the **show run** and **show aaa method-list** commands on the NAS to display the configuration.

NAS	`Hostname#show aaa method-list`
	
	`Authentication method-list:`
	`aaa authentication login list1 group local`
	
	`Accounting method-list:`
	`aaa accounting exec list3 start-stop group radius`
	`Authorization method-list:`

	`Hostname# show running-config`
	`aaa new-model`
	`!`
	`aaa accounting exec list3 start-stop group radius`
	`aaa authentication login list1 group local`
	`!`
	`username user password  pass`
	`!`
	`radius-server host 10.1.1.1`
	`radius-server key 7 093b100133`
	`!`
	`line con 0`
	`line vty 0 4`
	` accounting  exec list3`
	` login authentication list1`

	! End

Configuring AAA Command Accounting

Configure command authentication for login users and apply the default accounting method. Login authentication is performed in local mode, and the TACACS+ server is used for accounting.

Scenario **Figure 2-12**	
Configuration Steps	Step 1: Enable AAA. If remote server-group accounting needs to be implemented, configure a RADIUS or TACACS+ server in advance. Step 2: Configure an AAA accounting method list according to different access modes and service types. Step 3: Apply the configured method list to an interface or line. Skip this step if the default accounting method is used.
NAS	Hostname#configure terminal Hostname(config)#username user1 password pass1 Hostname(config)#username user1 privilege 15 Hostname(config)#aaa new-model Hostname(config)#tacacs-server host 192.168.217.10 Hostname(config)#tacacs-server key aaa Hostname(config)#aaa authentication login default local Hostname(config)#aaa accounting commands 15 default start-stop group tacacs+
Verification	Run the **show aaa method-list** command on the NAS to display the configuration.
NAS	Hostname#show aaa method-list Authentication method-list: aaa authentication login default local Accounting method-list: aaa accounting commands 15 default start-stop group tacacs+ Authorization method-list:
	Hostname#show run ! aaa new-model !

	aaa authorization config-commands aaa accounting commands 15 default start-stop group tacacs+ aaa authentication login default local ! ! nfpp ! vlan 1 ! username user1 password 0 pass1 username user1 privilege 15 no service password-encryption ! tacacs-server host 192.168.217.10 tacacs-server key aaa ! line con 0 line vty 0 4 ! ! end

Configuring AAA Network Accounting

Configure a network accounting method list for 802.1X users, and configure a remote RADIUS server for authentication and accounting.

Scenario **Figure 2-13**	
Configuration Steps	Step 1: Enable AAA. Step 2: If remote server-group accounting needs to be implemented, first configure a RADIUS server. Step 3: Configure an AAA accounting method list according to different access modes and service types. Step 4: Apply the configured AAA accounting method list. Skip this step if the default accounting method is used. Accounting is performed only when 802.1X authentication is completed.
NAS	Hostname#configure terminal Hostname(config)#username user password pass Hostname(config)#aaa new-model Hostname(config)#radius-server host 10.1.1.1 Hostname(config)#radius-server key test Hostname(config)#aaa authentication dot1x aut1x group radius local

	Hostname(config)#aaa accounting network acc1x start-stop group radius Hostname(config)#dot1x authentication aut1x Hostname(config)#dot1x accounting acc1x Hostname(config)#interface gigabitEthernet 0/1 Hostname(config-if-GigabitEthernet 0/1)#dot1 port-control auto Hostname(config-if-GigabitEthernet 0/1)#exit
Verification	Run the **show aaa method-list** command on the NAS to display the configuration.
NAS	Hostname#show aaa method-list Authentication method-list: aaa authentication dot1x aut1x group radius local Accounting method-list: aaa accounting network acc1x start-stop group radius Authorization method-list:

Common Errors

N/A

1.4.4 Configuring an AAA Server Group

Configuration Effect

- Create a user-defined server group and add one or more servers to the group.
- When you configure authentication, authorization, and accounting method lists, name the methods after the server group name so that the servers in the group are used to handle authentication, authorization, and accounting requests.
- Use self-defined server groups to separate authentication, authorization, and accounting.

Notes

In a user-defined server group, you can specify and apply only the servers in the default server group.

Configuration Steps

↘ Creating a User-Defined AAA Server Group

- Mandatory.
- Assign a proper name to the user-defined server group. Do not use the pre-defined **radius** and **tacacs+** keywords in naming.

↘ Adding an AAA Server Group Member

- Mandatory.
- Run the **server** command to add AAA server group members.
- By default, a user-defined server group does not have servers.

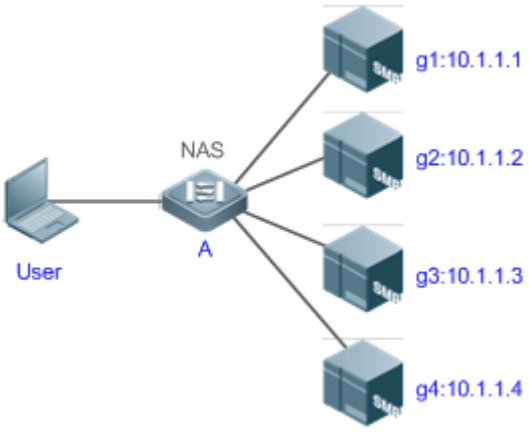
Verification

Run the **show aaa group** command to verify the configuration.

Related Commands

Creating a User-Defined AAA Server Group

Command	**aaa group server** { **radius** | **tacacs+** } *name*
Parameter Description	*name*: Indicates the name of the server group to be created. The name cannot contain the **radius** or **tacacs+** keyword because they are the names of the default RADIUS and TACACS+ server groups.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure an AAA server group. The RADIUS and TACACS+ server groups are supported.



Adding an AAA Server Group Member

Command	**server** *ip-addr* [**auth-port** *port1*] [**acct-port** *port2*]
Parameter Description	*ip-addr*: Indicates the IP address of a server. *port1*: Indicates the authentication port of a server, which is supported only by the RADIUS server group. *port2*: Indicates the accounting port of a server, which is supported only by the RADIUS server group.
Command Mode	Server group configuration mode
Usage Guide	When you add servers to a server group, the default ports are used if you do not specify ports.

Configuration Example

Creating an AAA Server Group

Create RADIUS server groups named **g1** and **g2**. The IP addresses of the servers in **g1** are 10.1.1.1 and 10.1.1.2, and the IP addresses of the servers in **g2** are 10.1.1.3 and 10.1.1.4.

Scenario **Figure 2-14**	
Prerequisites	1. The required interfaces, IP addresses, and VLANs have been configured on the network, network connections have been set up, and the routes from the NAS to servers are reachable.

	2. AAA has been enabled.
Configuration Steps	Step 1: Configure a server that belongs to the default server group. Step 2: Create user-defined AAA server groups. Step 3: Add servers to the AAA server groups.

NAS	`Hostname#configure terminal`
	`Hostname(config)#radius-server host 10.1.1.1`
	`Hostname(config)#radius-server host 10.1.1.2`
	`Hostname(config)#radius-server host 10.1.1.3`
	`Hostname(config)#radius-server host 10.1.1.4`
	`Hostname(config)#radius-server key secret`
	`Hostname(config)#aaa group server radius g1`
	`Hostname(config-gs-radius)#server 10.1.1.1`
	`Hostname(config-gs-radius)#server 10.1.1.2`
	`Hostname(config-gs-radius)#exit`
	`Hostname(config)#aaa group server radius g2`
	`Hostname(config-gs-radius)#server 10.1.1.3`
	`Hostname(config-gs-radius)#server 10.1.1.4`
	`Hostname(config-gs-radius)#exit`

Verification	Run the **show aaa group** and **show run** commands on the NAS to display the configuration.

NAS	`Hostname#show aaa group`
	`Type Reference Name`
	`---------- ---------- ----------`
	`radius 1 radius`
	`tacacs+ 1 tacacs+`
	`radius 1 g1`
	`radius 1 g2`

	`Hostname#show run`
	`!`
	`radius-server host 10.1.1.1`
	`radius-server host 10.1.1.2`
	`radius-server host 10.1.1.3`
	`radius-server host 10.1.1.4`
	`radius-server key secret`
	`!`
	`aaa group server radius g1`
	` server 10.1.1.1`
	` server 10.1.1.2`
	`!`
	`aaa group server radius g2`
	` server 10.1.1.3`
	` server 10.1.1.4`
	`!`

	!

Common Errors

- For RADIUS servers that use non-default authentication and accounting ports, when you run the **server** command to add servers, specify the authentication or accounting port.

1.4.5 Configuring the Domain-Based AAA Service

Configuration Effect

Create AAA schemes for 802.1X users in different domains.

Notes

Referencing method lists in domains:

- The AAA method lists that you select in domain configuration mode should be pre-defined. When you select the method lists are not pre-defined in domain configuration mode, the system prompts that the configuration does not exist.
- The names of the AAA method lists selected in domain configuration mode must be consistent with those of the method lists defined for the AAA service. If they are inconsistent, the AAA service cannot be properly provided for users in the domain.

Default domain:

- Default domain: After the domain-based AAA service is enabled, if a username does not carry domain information, the AAA service is provided for the user based on the default domain. If the domain information carried by the username is not configured in the system, the system determines that the user is unauthorized and will not provide the AAA service for the user. If the default domain is not configured initially, it must be created manually.
- When the domain-based AAA service is enabled, the default domain is not configured by default and needs to be created manually. The default domain name is **default**. It is used to provide the AAA service for the users whose usernames do not carry domain information. If the default domain is not configured, the AAA service is not available for the users whose usernames do not carry domain information.

Domain names:

- The domain names carried by usernames and those configured on the NAS are matched based on the longest matching principle. For example, if two domains of **domain.com** and **domain.com.cn** are configured on a NAS and a user sends a request carrying **aaa@domain.com**, the NAS determines that the user belongs to **domain.com** but not **domain.com.cn**.
- If the username of an authenticated user carries domain information but the domain is not configured on the NAS, the AAA service is not provided for the user.

Configuration Steps

↘ Enabling AAA

- Mandatory.
- Run the **aaa new-model** command to enable AAA.
- By default, AAA is disabled.

Enabling the Domain-Based AAA Service

- Mandatory.
- Run the **aaa domain enable** command to enable the domain-based AAA service.
- By default, the domain-based AAA service is disabled.

Creating a Domain and Entering Domain Configuration Mode

- Mandatory.
- Run the **aaa domain** command to create a domain or enter the configured domain.
- By default, no domain is configured.

Associating the Domain with an 802.1X Authentication Method List

- Run the **authentication dot1x** command to associate the domain with an 802.1X authentication method list.
- This configuration is mandatory if you need to apply a specified 802.1X authentication method list to the domain.
- The domain-based AAA service is applicable only to 802.1X access.

Associating the Domain with PPP and Web-based Authentication Method Lists

- Run the **authentication ppp** command to associate the domain with a PPP authentication method list.
- Run the **authentication Web** command to associate the domain with a web-based authentication method list.
- This configuration is mandatory if you need to apply a specified PPP or web-based authentication method list to the domain.
- If no method list is associated to the domain, the default global method list is applied.

Associating the Domain with a Network Accounting Method List

- Run the **accounting network** command to associate the domain with a network accounting method.
- This configuration is mandatory if you need to apply a specified network accounting method list to the domain.
- If a domain is not associated with a network accounting method list, the global default method list is used for accounting by default.

Associating the Domain with a Network Authorization Method List

- Run the **authorization network** command to associate the domain with a network authorization method list.
- This configuration is mandatory if you need to apply a specified network authorization method list to the domain.
- If a domain is not associated with a network authorization method list, the global default method list is used for authorization by default.

Configuring the Domain Status

- Optional.
- When a domain is in **block** state, users in the domain cannot log in.
- By default, after a domain is created, its state is **active**, indicating that all the users in the domain are allowed to request network services.

Configuring Whether to Contain the Domain Name in Usernames

- Optional.
- By default, the usernames exchanged between the NAS and an authentication server carry domain information.

Configuring the Maximum Number of Domain Users

- Optional.
- By default, the maximum number of access users allowed in a domain is not limited.

Verification

Run the **show aaa domain** command to verify the configuration.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	To enable the AAA security service, run this command. If AAA is not enabled, AAA commands cannot be configured.

Enabling the Domain-Based AAA Service

Command	**aaa domain enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to enable the domain-based AAA service. If there are authenticated users, enabling or disabling this function may cause accounting failures. In this case, you can use either of the following methods to restore accounting: ● Run the **clear dot1x user all** command to trigger authentication for 802.1X authentication users automatically. ● Run the **clear web-auth user all** command to disconnect web-based authentication users. The users need to initiate authentication requests manually.

Creating a Domain and Entering the Domain Configuration Mode

Command	**aaa domain** { **default** | *domain-name* }
Parameter Description	**default**: Uses this parameter to configure the default domain. *domain-name*: Indicates the name of the domain to be created.
Command Mode	Global configuration mode

Usage Guide	Use this command to configure a domain to provide the domain-based AAA service. The **default** parameter specifies the default domain. If a username does not carry domain information, the NAS uses the method list associated with the default domain to provide the AAA service for the user. The *domain-name* parameter specifies the name of the domain to be created. If the domain name carried by a username matches the configured domain name, the NAS uses the method list associated with this domain to provide the AAA service for the user. The system supports a maximum of 32 domains.

Associating the Domain with an 802.1X Authentication Method List

Command	**authentication dot1x** { **default** | *list-name* }
Parameter Description	**default**: Indicates that the default method list is used. *list-name*: Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a 802.1X authentication method list.

Associating the Domain with a PPP Authentication Method List

Command	**authentication ppp** { **default** | *list-name* }
Parameter Description	**default**: Indicates that the default method list is used. *list-name*: Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a PPP authentication method list.

Associating the Domain with a Web-based Authentication Method List

Command	**authentication web-auth** { **default** | *list-name* }
Parameter Description	**default**: Indicates that the default method list is used. *list-name*: Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a Web authentication method list.

Associating the Domain with a Network Accounting Method List

Command	**accounting network** { **default |** *list-name* }
Parameter Description	**default**: Indicates that the default method list is used. *list-name*: Indicates the name of the method list to be associated.
Command Mode	Domain configuration mode
Usage Guide	Use this command to associate the domain with a network accounting method list.

Associating the Domain with a Network Authorization Method List

Command	**authorization network** { **default** | *list-name* }
Parameter Description	**default**: Indicates that the default method list is used. *list-name*: Indicates the name of the method list to be associated.

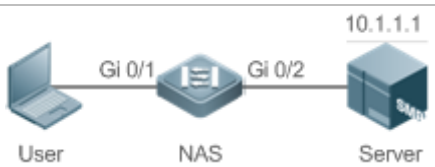
Command Mode	Domain configuration mode
Usage Guide	

Configuring the Domain Status

Command	**state** { **block** | **active** }
Parameter Description	**block**: Indicates that the configured domain is unavailable. **active**: Indicates that the configured domain is available.
Command Mode	Domain configuration mode
Usage Guide	Use this command to make the configured domain valid or invalid.

Configuring Whether to Contain the Domain Name in Usernames

Command	**username-format** { **without-domain** | **with-domain** }
Parameter Description	**without-domain**: Indicates that domain information is removed from usernames. **with-domain**: Indicates that domain information is retained in usernames.
Command Mode	Domain configuration mode
Usage Guide	Use this command in domain configuration mode to determine whether to include domain information in usernames when the NAS interacts with an authentication server in a specified domain.



Configuring the Maximum Number of Domain Users

Command	**access-limit** *num*
Parameter Description	*num*: Indicates the maximum number of access users allowed in a domain, which applies only to 802.1X users.
Command Mode	Domain configuration mode
Usage Guide	Use this command to limit the number of access users in a domain.

Configuration Example

Configuring the Domain-Based AAA Services

Configure authentication and accounting through a RADIUS server for 802.1X users (username: ***user*@domain.com**) that access the NAS. The usernames that the NAS sends to the RADIUS server do not carry domain information, and the number of access users is not limited.

Scenario Figure 2-15	

Configuration Steps	The following example shows how to configure RADIUS authentication and accounting. The RADIUS server must have been configured. Step 1: Enable AAA. Step 2: Define an AAA method list. Step 3: Enable the domain-based AAA service. Step 4: Create a domain. Step 5: Associate the domain with the AAA method list. Step 6: Configure the domain attribute.

NAS	`Hostname# configure terminal`
	`Hostname(config)# aaa new-model`
	`Hostname(config)# radius-server host 10.1.1.1`
	`Hostname(config)# radius-server key  test`
	`Hostname(config)# aaa authentication dot1x default group radius`
	`Hostname(config)# aaa accounting network list3 start-stop group radius`

1.4.6 Configuring a Policy for Accounting-Start Failures

Configuration Effect

- Configure a policy for accounting-start failures.

Notes

Configure a policy for accounting-start failures as required.

Configuration Steps

↘ Configuring a Policy for Accounting-Start Failures

- Optional
- By default, no policy is configured for accounting-start failures.

Verification

Run the **show run** to verify the configuration.

Related Commands

↘ Configuring a Policy for Accounting-Start Failures

Command	**aaa accounting start-fail** { **online** | **offline** }
Parameter Description	**online**: Allows the users that encounter accounting-start failures to be online. **offline**: Disconnects the users that encounter accounting-start failures.

Command Mode	Global configuration mode
Usage Guide	Use this command to configure a policy for accounting-start failures.

Configuration Example

The following example involves the configuration about only the policy for accounting-start failures.

Configure a policy for accounting-start failures.

Scenario Figure 1-16	
Configuration Steps	Configure a policy for accounting-start failures.
NAS	`Hostname#configure terminal` `Hostname(config)#aaa accounting start-fail offline`
Verification	Run the **show run** command on the NAS to display the configuration.
NAS	`Hostname#sh run | inc aaa` `aaa accounting start-fail offline`

Common Errors

N/A

1.4.7 Configuring Heartbeat Packet Detection

Configuration Effect

Enable heartbeat packet detection. After this function is enabled, AAA processes and AAA databases can detect whether the peer end is available through heartbeat packets.

Notes

Heartbeat packet detection is supported only by some front-end AAA modules, including RADIUS and 802.1X modules.

Configuration Steps

Detecting AAA Heartbeats

- Optional.
- By default, heartbeat packet detection is enabled.

Verification

Run the **show run** command to verify the configuration.

Related Commands

Allowing Users to Get Online After Accounting Fails to Start

Command	[**no**] **aaa heartbeat enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Detecting AAA Heartbeats

Scenario Figure 1-17	
Configuration Steps	Disable heartbeat packet detection.
NAS	`Hostname#configure terminal` `Hostname(config)#no aaa heartbeat enable`
Verification	Run the **show run** command on the NAS to display the configuration.
NAS	`Hostname#sh run | inc heart`
	`no aaa heartbeat enable`

Common Errors

N/A

1.4.8 Configuring AAA Logging

Configuration Effect

- Disable AAA logging or configure an AAA logging rate limit.

Notes

N/A

Configuration Steps

Configuring AAA Logging

- Optional
- By default, AAA logging is enabled.

Configure an AAA Logging Rate Limit

- Optional
- By default, five logs are generated per second.

Verification

Run the **show run** command to verify the configuration.

Related Commands

Configuring AAA Logging

Command	[**no**] **aaa log enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	If many users go online, AAA logging may cause screen information to be refreshed or device performance to deteriorate. You can configure this command to disable AAA logging.

Configuring an AAA Logging Rate Limit

Command	**aaa log rate-limit** *num*
Parameter Description	*num*: Configures a logging rate limit. By default, the device generates five logs per second. The value ranges from 0 to 65535. The value 0 indicates that the log generation rate is not limited.
Command Mode	Global configuration mode
Usage Guide	If many users go online, AAA logging may cause screen information to be refreshed or device performance to deteriorate. You can configure this command to configure a logging rate limit.

Adjusting the Number of Tracks That Can Be Recorded for Each AAA User

Command	**aaa user-diag log-num** *num*
Parameter Description	*num*: Indicates the number of tracks that can be recorded for each AAA user. The value range is from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	When a large number of users go online or offline, the memory usage of the process for recording user tracks may increase quickly. This command is used to adjust the number of track records for each AAA user to reduce the memory usage of the process.

Adjusting the Total Number of AAA User Track Records

Command	**aaa user-diag user-num** *num*
Parameter Description	*num*: Indicates the total number of AAA user track records. The value range is from 1 to 10000.
Command Mode	Global configuration mode

Usage Guide	When a large number of users go online, the memory usage of the process for recording user tracks may increase quickly. This command is used to adjust the total number of AAA user track records to reduce the memory usage of the process.

Configuration Example

The following example involves only configuration about AAA logging.

Configure AAA logging.

Scenario **Figure 1-18**	
Configuration Steps	Configure the device to generate 10 logs per second.

NAS	`Hostname# configure terminal`
	`Hostname(config)# aaa log enable`
	`Hostname(config)# aaa log rate-limit 10`

Verification	Run the **show run** command on the NAS device to display the configuration

NAS	`Hostname# show run | inc aaa log`
	`aaa log enable`
	`aaa log rate-limit 10`

Common Errors

N/A

1.5 Monitoring

Clearing

Command	Description
clear aaa local user lockout { **all** | **user-name** *username* }	Clears locked users.
clear aaa user diag	Clears all AAA user tracks.

Displaying

Command	Description
show aaa accounting update	Displays accounting update information.
show aaa domain	Displays the current domain configuration.
show aaa lockout	Displays the current lockout configuration.
show aaa group	Displays AAA server groups.
show aaa method-list	Displays AAA method lists.

show aaa user	Displays AAA users.
show aaa user diag { **all** | **by-id** *session-id* | **by-mac** *mac-address* | **by-ip** *ip-address* }	Displays information about AAA user tracks.

1 Configuring RADIUS

1.1 Overview

The Remote Authentication Dial-In User Service (RADIUS) is a distributed client/server system.

RADIUS is used with Authentication, Authorization, and Accounting (AAA) to conduct identity authentication on users who attempt to access a network and prevent unauthorized access. A RADIUS client runs on a device or Network Access Server (NAS) and transmits identity authentication requests to the RADIUS server, where all user identity authentication information and network service information are stored. In addition to the authentication service, the RADIUS server provides authorization and accounting services for access users.

RADIUS is typically applied to network environments that demand high security and allow access of remote users. RADIUS is an open protocol, and the RADIUS server is installed on many operating systems as a component, for example, UNIX, Windows 2000, and Windows 2008. Therefore, RADIUS is the most widely applied security server.

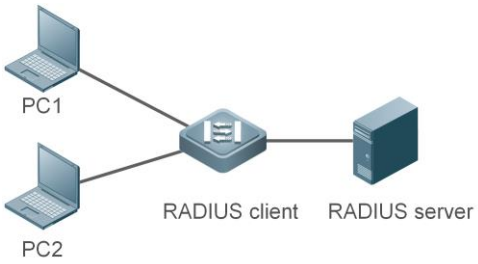
The Dynamic Authorization Extensions to Remote Authentication Dial In User Service is defined in RFC 3576, which defines a user offline management method. Devices communicate with the RADIUS server through the Disconnect-Messages (DMs) to bring authenticated users offline. This protocol implements compatibility between devices of different vendors and the RADIUS server in terms of user offline processing.

In the DM mechanism, the RADIUS server proactively initiates a user offline request to a device. The device locates a user according to the user session, user name, and other information carried in the request and brings the user offline. Then the device returns a response packet that carries the processing result to the RADIUS server, thereby implementing user offline management of the RADIUS server.

Protocols and Standards

- RFC 2865: Remote Authentication Dial In User Service (RADIUS)
- RFC 2866: RADIUS Accounting
- RFC 2867: RADIUS Accounting Modifications for Tunnel Protocol Support
- RFC 2868: RADIUS Attributes for Tunnel Protocol Support
- RFC 2869: RADIUS Extensions
- RFC 3576: Dynamic Authorization Extensions to Remote Authentication Dial In User Service (RADIUS)

1.2 Applications



Application	Description
Providing Authentication, Authorization, and Accounting Services for Access Users	Authentication, authorization, and accounting are conducted on access users on a network, to prevent unauthorized access or operations.
Forcing Users to Go Offline	The server forces an authenticated user to go offline.

1.2.1 Providing Authentication, Authorization, and Accounting Services for Access Users

Scenario

RADIUS is typically applied for authentication, authorization, and accounting of access users. A network device serves as a RADIUS client and transmits user information to a RADIUS server. After completing processing, the RADIUS server returns the authentication acceptance/authentication rejection/accounting response information to the RADIUS client. The RADIUS client performs processing on the access user according to the response from the RADIUS server.

Figure 1-1 Typical RADIUS Networking

Remarks	PC 1 and PC 2 are connected to the RADIUS client as access users in wired or wireless mode, and initiate authentication and accounting requests. The RADIUS client is usually an access device. The RADIUS server can be a component built in the Windows 2000/2003, Server (IAS), or UNIX operating system or dedicated server software provided by a vendor.

Deployment

- Configure access device information on the RADIUS server, including the IP address and shared key of the access devices.
- Configure the AAA method list on the RADIUS client.
- Configure RADIUS server information on the RADIUS client, including the IP address and shared key.
- Enable access control on the access port of the RADIUS client.
- Configure the network so that the RADIUS client communicates with the RADIUS server successfully.

1.2.2 Forcing Users to Go Offline

Scenario

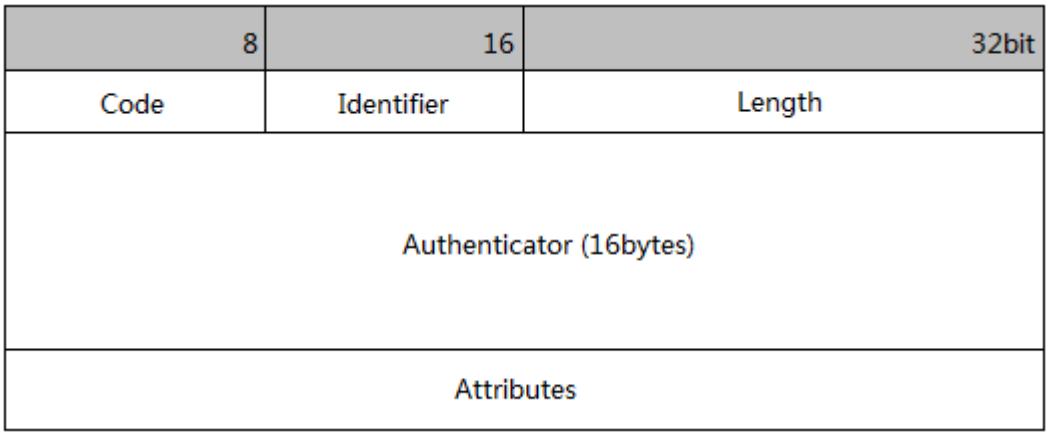
The RADIUS server forces authenticated online users to go offline for management.

0 shows the networking topology.

Deployment

- Perform the following operation according to 3.2.1 "Deployment".
- Enable the RADIUS dynamic authorization extension function on the RADIUS client.

1.3 Features



Basic Concepts

Client/Server Mode

- Client: A RADIUS client initiates RADIUS requests and usually runs on a device or NAS. It transmits user information to the RADIUS server, receives responses from the RADIUS server, and accepting or rejecting user access, or collecting more user information for the RADIUS server.
- Server: Multiple RADIUS clients map to one RADIUS server. The RADIUS server maintains the IP addresses and shared keys of all RADIUS clients as well as information on all authenticated users. It receives requests from a RADIUS client, conducts authentication, authorization, and accounting, and returns processing information to the RADIUS client.

Format of RADIUS Packets

- The following figure shows the format of RADIUS packets.

- Code: Identifies the type of RADIUS packets, which occupies 1 byte. The following table lists the values and meanings.

Code	Packet Type	Code	Packet Type
1	Access-Request	4	Accounting-Request
2	Access-Accept	5	Accounting-Response
3	Access-Reject	11	Access-Challenge

- Identifier: Indicates the identifier for matching request packets and response packets, which occupies 1 byte. The identifier values of request packets and response packets of the same type are the same.
- Length: Identifies the length of a RADIUS packet, which includes **Code**, **Identifier**, **Length**, **Authenticator**, and **Attributes**. It occupies 2 bytes. Bytes that are beyond the **Length** field will be truncated. If the length of a received packet is smaller than the value of **Length**, the packet is discarded.
- Authenticator: Verifies response packets of the RADIUS server by a RADIUS client, which occupies 16 bytes. This field is also used for encrypting or decrypting user passwords.
- Attributes: Carries authentication, authorization, and accounting information, with the variable length. The **Attributes** field usually contains multiple attributes. Each attribute is represented in the Type, Length, Value (TLV) format. **Type**

occupies 1 byte and indicates the attribute type. The following table lists common attributes of RADIUS authentication, authorization, and accounting. **Length** occupies 1 byte and indicates the attribute length, which is expressed in bytes. **Value** indicates the attribute information.

Attribute No.	Attribute Name	Attribute No.	Attribute Name
1	User-Name	43	Acct-Output-Octets
2	User-Password	44	Acct-Session-Id
3	CHAP-Password	45	Acct-Authentic
4	NAS-IP-Address	46	Acct-Session-Time
5	NAS-Port	47	Acct-Input-Packets
6	Service-Type	48	Acct-Output-Packets
7	Framed-Protocol	49	Acct-Terminate-Cause
8	Framed-IP-Address	50	Acct-Multi-Session-Id

40	Acct-Status-Type	85	Acct-Interim-Interval
41	Acct-Delay-Time	86	Acct-Tunnel-Packets-Lost
42	Acct-Input-Octets	87	NAS-Port-Id

Shared Key

A RADIUS client and a RADIUS server confirm their identities by using a shared key during communication. The shared key cannot be transmitted over a network. In addition, user passwords are encrypted for transmission to ensure security.

RADIUS Server Group

The RADIUS security protocol, also called RADIUS method, is configured in the form of a RADIUS server group. Each RADIUS method corresponds to one RADIUS server group, and one or more RADIUS severs can be added to one RADIUS server group. For details about the RADIUS method, see Configuring AAA. In a RADIUS server group to which multiple RADIUS servers are added, when the communication between a device and the first RADIUS server in this group fails or the first RADIUS server becomes unreachable, the device automatically attempts to communicate with the next RADIUS server till the communication is successful or the communication with all the RADIUS servers fails.

RADIUS Attribute Type

- Standard attributes

The RFC standards specify the RADIUS attribute numbers and attribute content but do not specify the format of some attribute types. Therefore, the format of attribute contents needs to be configured to adapt to different RADIUS server requirements. The format of the RADIUS Calling-Station-ID attribute (attribute No.: 31) can be configured.

The RADIUS Calling-Station-ID attribute is used to identify user identities when a network device transmits request packets to the RADIUS server. The RADIUS Calling-Station-ID attribute is a string, which can adopt multiple formats. It needs to uniquely identify a user. Therefore, it is often set to the MAC address of a user. For example, when 802.1X authentication is used, the Calling-Station-ID attribute is set to the MAC address of the device where the 802.1X client is installed. The following table describes the format of MAC addresses.

Format	Description
ietf	Indicates the standard format specified in RFC 3580, which is separated by the separator (-). Example: 00-D0-F8-33-22-AC
normal	Indicates the common format that represents a MAC address in dotted hexadecimal notation, which is separated by the separator (.). Example: 00d0.f833.22ac
unformatted	Indicates the format without separators. This format is used by default. Example: 00d0f83322ac

- Private attributes

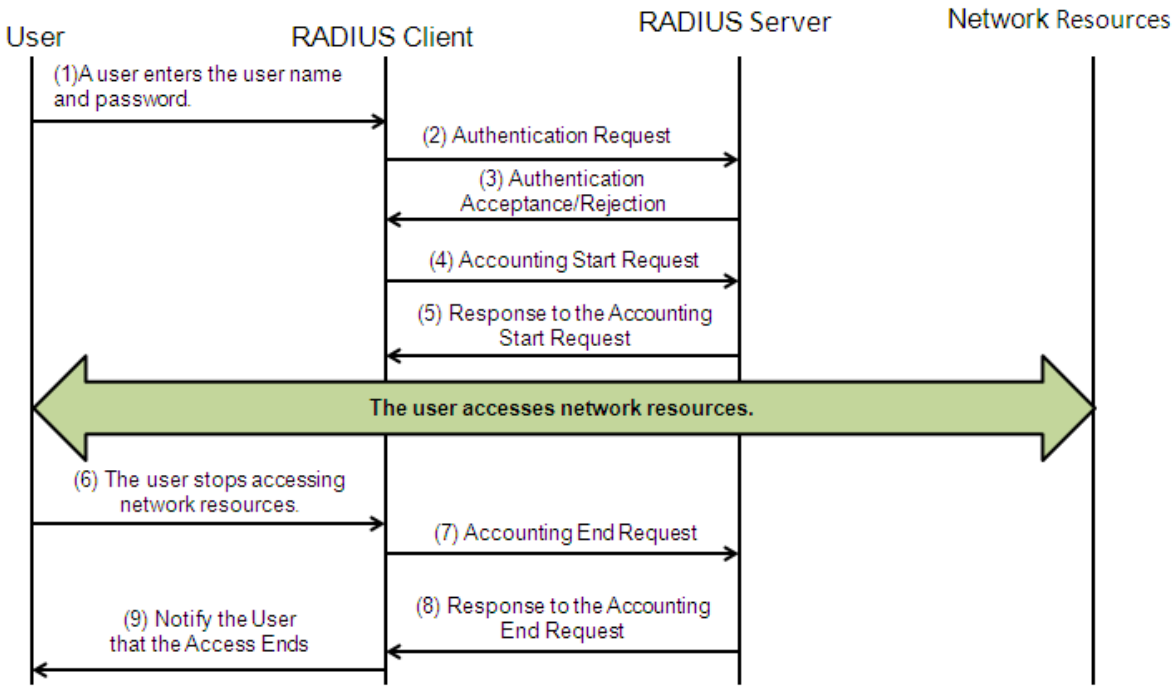
RADIUS is an extensible protocol. As defined by RFC 2865, the Vendor-Specific attribute (attribute No.: 26) is used by device vendors to extend the RADIUS protocol to implement private functions or functions that are not defined in the standard RADIUS protocol. Table 1-3 lists private attributes supported by Ruijie products. The **TYPE** column indicates the default configuration of private attributes of Ruijie products and the **Extended TYPE** column indicates the default configuration of private attributes of other non-Ruijie products.

ID	Function	TYPE	Extended TYPE
1	max-down-rate	1	76
2	port-priority	2	77
3	user-ip	3	3
4	vlan-id	4	4
5	last-supplicant-version	5	5
6	net-ip	6	6
7	user-name	7	7
8	password	8	8
9	file-directory	9	9
10	file-count	10	10
11	file-name-0	11	11
12	file-name-1	12	12
13	file-name-2	13	13

ID	Function	TYPE	Extended TYPE
14	file-name-3	14	14
15	file-name-4	15	15
16	max-up-rate	16	16
17	current-supplicant-version	17	17
18	flux-max-high32	18	18
19	flux-max-low32	19	19
20	proxy-avoid	20	20
21	dailup-avoid	21	21
22	ip-privilege	22	22
23	login-privilege	42	42
26	ipv6-multicast-address	79	79
27	ipv4-multicast-address	87	87
62	sdg-type	62	62
85	sdg-zone-name	85	85
103	sdg-group-name	103	103

Overview

Feature	Description
RADIUS Authentication, Authorization, and Accounting	Conducts identity authentication and accounting on access users, safeguards network security, and facilitates management for network administrators.
Source IP Address of RADIUS Packets	Specifies the source IP address used by a RADIUS client to transmit packets to a RADIUS server.
RADIUS Retransmission Upon Timeout	Specifies packet retransmission parameters for a RADIUS client when a RADIUS server does not respond to packets transmitted from the RADIUS client within a period of time.
RADIUS Server Accessibility Detection	Enables a RADIUS client to proactively detect whether a RADIUS server is reachable and maintain accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve handling performance of RADIUS services.
Forcible Disconnection	Enables a RADIUS server to proactively force authenticated users to go offline.



Configuring the DSCP Value of RADIUS Packets	The DSCP field is contained in the Type of Service (ToS) field of IP packets. The DSCP value marks the packet priority for transmission. The default DSCP value of RADIUS packets is 0. You can specify the DSCP value for RADIUS packets using commands. A larger DSCP value represents a higher priority of RADIUS packets.
Configuring the Units of Data Flows and Data Packets Sent to the RADIUS Server	By default, the unit of data flows sent to the RADIUS server is bytes, and the unit of data packets sent to the RADIUS server is packets. You can specify the unit of data flows and data packets sent to the RADIUS server using commands.
Configuring Load Balancing for the RADIUS Server Group	Enables load balancing of the RADIUS server group to reduce the resource consumption of a single server.
Configuring Hot Standby for the RADIUS Server	Enables the hot standby function to back up the server status and ensures that the active and standby servers in the same context maintain the same server status.
Configuring the Function of Copying Accounting Packets	Enables the RADIUS server to copy accounting packets and send them to servers (only the first three servers configured in a server group) in a specified server group.
RadSec Server	RadSec combines Transport Layer Security (TLS) and Transmission Control Protocol (TCP), which is securer than User Datagram Protocol (UDP) used for RADIUS transmission.

1.3.1 RADIUS Authentication, Authorization, and Accounting

Conduct identity authentication and accounting on access users, safeguard network security, and facilitate management for network administrators.

Working Principle

Figure 1-2 RADIUS Authentication and Authorization Process

The RADIUS authentication and authorization process is described as follows:

- A user enters the user name and password and transmits them to the RADIUS client.
- After receiving the user name and password, the RADIUS client transmits an authentication request packet to the RADIUS server. The password is encrypted for transmission. For the encryption method, see RFC2865.
- The RADIUS server accepts or rejects the authentication request according to the user name and password. When accepting the authentication request, the RADIUS server also delivers authorization information apart from the authentication acceptance information. The authorization information varies with the type of access users.

The RADIUS accounting process is described as follows:

1. If the RADIUS server returns authentication acceptance information in Step (3), the RADIUS client sends an accounting start request packet to the RADIUS server immediately.
2. The RADIUS server returns the accounting start response packet, indicating accounting start.
3. The user stops accessing network resources and requests the RADIUS client to terminate the network connection.
4. The RADIUS client transmits the accounting end request packet to the RADIUS server.
5. The RADIUS server returns the accounting end response packet, indicating accounting end.
6. The user is disconnected and cannot access network resources.

Related Configuration

↘ Configuring RADIUS Server Parameters

No RADIUS server is configured by default.

You can run the **radius-server host** command to configure a RADIUS server.

At least one RADIUS server must be configured so that RADIUS services run normally.

Configuring the AAA Authentication Method List

No AAA authentication method list is configured by default.

You can run the **aaa authentication** command to configure a method list for different user types and select **group radius** when setting the authentication method.

RADIUS authentication can be conducted only after the AAA authentication method list of relevant user types is configured.

Configuring the AAA Authorization Method List

No AAA authorization method list is configured by default.

You can run the **aaa authorization** command to configure an authorization method list for different user types and select **group radius** when setting the authorization method.

RADIUS authorization can be conducted only after the AAA authorization method list of relevant user types is configured.

Configuring the AAA Accounting Method List

No AAA accounting method list is configured by default.

You can run the **aaa accounting** command to configure an accounting method list for different user types and select **group radius** when setting the accounting method.

RADIUS accounting can be conducted only after the AAA accounting method list of relevant user types is configured.

1.3.2 Source IP Address of RADIUS Packets

Specify the source IP address used by a RADIUS client to transmit packets to a RADIUS server.

Working Principle

When configuring RADIUS, specify the source IP address to be used by a RADIUS client to transmit RADIUS packets to a RADIUS server, reducing the workload of maintaining a large amount of NAS information on the RADIUS server.

Related Configuration

Global routing is used to determine the source address for transmitting RADIUS packets by default.

Run the **ip radius source-interface** command to specify the source interface for transmitting RADIUS packets. The device uses the first IP address of the specified interface as the source address of RADIUS packets.

1.3.3 RADIUS Retransmission Upon Timeout

Working Principle

After a RADIUS client transmits a packet to a RADIUS server, a timer is started to detect the response of the RADIUS server. If the RADIUS server does not respond within a given period of time, the RADIUS client retransmits the packet.

Related Configuration

Configuring the Timeout Interval of the RADIUS Server

The default timeout interval is 5s.

You can run the radius-server timeout command to configure the timeout interval. The value ranges from 1 to 1,000, in seconds.

The response time of a RADIUS server is relevant to its performance and the network environment. Set an appropriate timeout interval as required.

Configuring the Retransmission Count

The default retransmission count is 3.

You can run the **radius-server retransmit** command to configure the retransmission count. The value ranges from 0 to 100.

Configuring the Device Whether to Retransmit Accounting Update Packets

Accounting update packets are not retransmitted by default.

You can run the **radius-server account update retransmit** command to configure the device to retransmit accounting update packets for authenticated users.

1.3.4 RADIUS Server Accessibility Detection

Working Principle

A RADIUS client proactively detects whether a RADIUS server is reachable and maintains accessibility of each RADIUS server. A reachable RADIUS server is selected preferentially to improve handling performance of RADIUS services.

Related Configuration

Configuring the Criteria for the Device to Determine That a RADIUS Server Is Unreachable

A RADIUS server is unreachable when the two conditions are met:

1. The device does not receive a correct response packet from the RADIUS security server within 60 seconds.
2. The device transmits the request packet to the same RADIUS security server for 10 consecutive times.

You can run the **radius-server dead-criteria** command to configure the criteria for the device to determine that the RADIUS security server is unreachable.

Configuring the Test User Name for Proactively Detecting the RADIUS Security Server

No test user name is specified for proactively detecting the RADIUS security server by default.

You can run the **radius-server host** *x.x.x.x* **testusername** *xxx* command to configure the test user name.

1.3.5 Forcible Disconnection

Working Principle

Figure 1-1 DM Message Exchange of the RADIUS Dynamic Authorization Extension Protocol

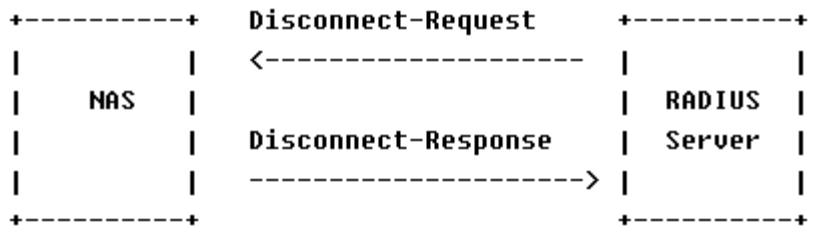


Figure 1-3 shows the exchange of DM messages between the RADIUS server and the device. The RADIUS server transmits the Disconnect-Request message to UDP port 3799 of the device. Then the device returns the Disconnect-Response message that carries the processing result to the RADIUS server.

Related Configuration

N/A

1.3.6 Configuring the DSCP Value of RADIUS Packets

Working Principle

The DSCP field is contained in the Type of Service (ToS) field of IP packets. The DSCP value determines the packet priority for transmission. The default DSCP value of RADIUS packets is 0. You can specify the DSCP value for RADIUS packets using commands. A larger DSCP value represents a higher priority of RADIUS packets.

Related Configuration

↘ Configuring the DSCP Value of RADIUS Packets

Run the **radius dscp** command to specify the DSCP value of RADIUS packets. The value ranges from 0 to 63.

1.3.7 Configuring the Units of Data Flows and Data Packets Sent to the RADIUS Server

Working Principle

By default, the units of data flows and data packets sent to the RADIUS server are bytes and packets, respectively. You can specify the units of data flows and data packets sent to the RADIUS server using commands.

Related Configuration

↘ Configuring the Units of Data Flows and Data Packets Sent to the RADIUS Server

Run the **radius data-flow-format data** { **byte** | **kilo-byte** | **mega-byte** | **giga-byte** } **packet** { **one-packet** | **kilo-packet** | **mega-packe**t | **giga-packet** } command to configure the unit of data flows and data packets sent to the RADIUS server.

1.3.8 Configuring Load Balancing for the RADIUS Server Group

Working Principle

The client is authenticated through the first server in the server group. The next server will be selected only when the first server is unreachable. After load balancing is enabled, polling is adopted. In this case, the authentication packet from the first client is sent to the first server, that from the second to the second server, and so on. After the last server receives the authentication packet from the client, the cycle restarts from the first server.

Related Configuration

Configuring Load Balancing for the RADIUS Server Group

Run the load-balance command to enable load balancing for the RADIUS server group.

1.3.9 Configuring Hot Standby for the RADIUS Server

Working Principle

When configuring the RADIUS server, you can enable the hot standby function to back up the server status and ensure that the active and standby servers in the same context maintain the same status.

Related Configuration

Configuring Hot Standby for the RADIUS Server

Run the **radius-server host** *ipv4-address* **context** *id hb_ipv4* **key** *text-string* command to enable hot standby for the RADIUS server.

1.3.10 Configuring the Function of Copying Accounting Packets

Working Principles

RADIUS accounting packets are sent to one server specified in the accounting method list by default. After this function is enabled, the server copies accounting packets and sends the packets to servers (only the first three servers configured in a server group) in a specified server group.

Related Configuration

Configuring the Function of Copying Accounting Packets

Run the **accounting-copy** *group_name* command in the accounting server group to copy accounting packets to servers in a specified server group.

1.3.11 RadSec Server

Working Principle

TLS RADIUS, also called RadSec, leverages the TLS protocol to ensure secure communication of RADIUS requests. RadSec redirects the normal RADIUS traffic to the remote server over TLS to ensure transmission security of RADIUS identity verification, authorization, and accounting data over insecure networks.

Combining TLS and TCP, RadSec provides higher security than the earlier RADIUS that uses UDP. UDP-based RADIUS uses the MD5 algorithm to encrypt the shared key, which is prone to attacks. RadSec exchanges valid loads in RADIUS data packets over TLS-encrypted tunnels to effectively reduce the risks of being attacked.

Related Configuration

Configuring the RadSec Service

The RadSec server is implemented by the RadSec target. To enable the RadSec service, you need to configure a RadSec server as a specific target and divert the RADIUS traffic to the target. Each RadSec target has a unique ID for easy

identification. In addition, the system supports multiple RadSec targets, which can be distinguished by different parameters, even if they point to the same RadSec server.

If you want to divert traffic from the traditional RADIUS server to the RadSec server, you only need to associate the RADIUS server with the specified RadSec target. For example, the IP address of the RADIUS server is 10.1.1.1. If you want to associate this server with RadSec target 10, run the following command: radius-server host 10.1.1.1 radsec-destination 10.

1.4 Configuration

Configuration	Description and Command	
Performing RADIUS Basic Configuration	(Mandatory) It is used to configure RADIUS authentication, authorization, and accounting.	
	radius-serverhost	Configures the IP address of the remote RADIUS security server.
	radius-serverkey	Configures the shared key for communication between the device and the RADIUS server.
	radius-serverretransmit	Configures the request transmission count, after which the device confirms that a RADIUS server is unreachable.
	radius-servertimeout	Configures the waiting time, after which the device retransmits a request.
	radius-server account update retransmit	Configures the device to retransmit accounting update packets for authenticated users.
	ip radius source-interface	Configures the source address of RADIUS packets.
Configuring the RADIUS Attribute Type	(Optional) It is used to define attribute processing adopted when the device encapsulates and parses RADIUS packets.	
	radius-server attribute31	Configures the MAC address format of RADIUS attribute No. 31 (Calling-Station-ID).
	radius-server attribute class	Configures the parsing mode of the RADIUS Class attribute.
	radius-server attribute 30	Configures the format of RADIUS attribute No. 30 (Called-Station-ID).

Configuration	Description and Command	
	radius set qoscos	Sets the private attribute port-priority issued by the server to the CoS value of an interface. For CoS-relevant concepts, see *Configuring QoS*.
	radius support cui	Configures the device to support the CUI attribute.
	radius vendor-specific	Configures the mode of parsing private attributes by the device.
	radius vendor-specific attribute support	Configures whether the RADIUS server parses vendors' private attributes contained in packets.
	radius-server account attribute	Configures RADIUS accounting request packets to contain a specified attribute.
	radius-server authentication vendor	Configures RADIUS authentication request packets to contain a vendor-specific attribute (VSA).
	radius-server account vendor	Configures RADIUS accounting request packets to contain a VSA.
Configuring RADIUS Accessibility Detection	⚠ (Optional) It is used to detect whether a RADIUS server is reachable and maintain accessibility of the RADIUS server.	
	radius-server dead-criteria	Configures the global criteria for determining that a RADIUS security server is unreachable.
	radius-server deadtime	Configures the duration for the device to stop transmitting request packets to an unreachable RADIUS server.
	radius-server host	Configures the IP address of the remote RADIUS security server, authentication port, accounting port, and proactive detection parameters.
Configuring the DSCP Value of RADIUS Packets	**radius dscp**	Configures the DSCP value of RADIUS packets.

Configuration	Description and Command	
Configuring the Units of Data Flows and Data Packets Sent to the RADIUS Server	**radius data-flow-format data** { **byte** | **kilo-byte** | **mega-byte** | **giga-byte** } **packet** { **one-packet** | **kilo-packet** | **mega-packet** | **giga-packet** }	Configures the unit of data flows and data packets sent to the RADIUS server.
Configuring Load Balancing for the RADIUS Server Group	**load-balance**	Enables load balancing for the RADIUS server group.
Configuring the Function of Copying Accounting Packets	⚠ (Optional) It is used to configure the function of copying accounting packets.	
	accounting-copy	Configures the function of copying accounting packets.
Configuring RadSec Target Attributes	⚠ (Optional) It is used to configure the port number, IP address, and keepalive parameters for the RadSec target server. This command is required after you configure RadSec traffic redirection.	
	radsec destination	Configures the port number, IP address, timeout period, and keepalive interval for the RadSec target server.

1.4.1 Performing RADIUS Basic Configuration

Configuration Effect

RADIUS authentication, authorization, and accounting can be conducted after RADIUS basic configuration is complete.

Notes

- Before configuring RADIUS on the device, ensure that the network communication of the RADIUS server is in good condition.
- When running the **ip radius source-interface** command to configure the source address of RADIUS packets, ensure that the device can use the source IP address to communicate with the RADIUS server successfully.
- When conducting RADIUS IPv6 authentication, ensure that the RADIUS server supports RADIUS IPv6 authentication.

Configuration Steps

↘ Configuring the Remote RADIUS Security Server

- Mandatory.
- Configure the IP address, authentication port, accounting port, and shard key of the RADIUS security server.

↘ Configuring the Shared Key for Communication Between the Device and the RADIUS Server

- Optional.

- Configure a shared key in global configuration mode for servers without a shared key.

The shared key on the device must be consistent with that on the RADIUS server.

Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable

- Optional.
- Configure the request transmission count, after which the device confirms that a RADIUS server is unreachable, according to the actual network environment.

Configuring the Waiting Time, After Which the Device Retransmits a Request

- Optional.
- Configure the waiting time, after which the device retransmits a request, according to the network environment.

In an 802.1X authentication environment where the RADIUS security protocol is used, if a network device serves as the 802.1X authenticator and Ruijie SU is used as the 802.1X client software, it is recommended that **radius-server timeout** be set to 3s (the default value is 5s) and **radius-server retransmit** be set to 2 (the default value is 3) on the network device.

Configuring the Device to Retransmit Accounting Update Packets for Authenticated Users

- Optional.
- Determine whether to enable the device to retransmit accounting update packets of authenticated users as needed.

Configuring the Source Address of RADIUS Packets

- Optional.
- Configure the source address of RADIUS packets according to the network environment.

Verification

- Configure the AAA method list that specifies RADIUS for authentication, authorization, and accounting on users.
- Enable the device to interact with the RADIUS server. Obtain packets to confirm that the device communicates with the RADIUS server through RADIUS.

Related Commands

Configuring the Remote RADIUS Security Server

Command	**radius-server host** { *ipv4-address* | *ipv6-address* } [[**acct-port** *port-number* | **auth-port** *port-number*] * [**test username** *name* [**ignore-auth-port**] [**ignore-acct-port**] [**idle-time** *time*]] | **context** *id hb-ipv4* | **radsec-destination** *id-number*] * [**key** [**0** | **7**] *text-string*]
Parameter Description	*ipv4-address*: Indicates the IPv4 address of the RADIUS security server. *Ipv6-address*: Indicates the IPv6 address of the RADIUS security server. **auth-port** *port-number*: Indicates the UDP port for RADIUS identity authentication. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct identity authentication. **acct-port** *port-number*: Indicates the UDP port for RADIUS accounting. The value ranges from 0 to 65,535. If it is set to 0, the host does not conduct accounting.

	context *id hb_ipv4*: Enables the hot standby function for the RADIUS server and specifies the hot standby context ID and peer IP address. The server status can be backed up so that the active and standby servers in the same context maintain the same status. **test username** *name*: Enables the device to proactively detect the RADIUS security server and specifies the user name used for active detection. **idle-time** *time*: Indicates the interval for the device to transmit test packets to a reachable RADIUS security server. The default value is 60 minutes. The value ranges from 1 minute to 1,440 minutes (24 hours). **ignore-auth-port**: Disables the device from detecting the authentication port of the RADIUS security server. It is enabled by default. **ignore-acct-port**: Disables the device from detecting the accounting port of the RADIUS security server. It is enabled by default. **Key** [**0** | **7**] *text-string* : Configures the shared key of the server. The global shared key is used if it is not configured. The configured key is displayed as "*" and you are required to enter the same key twice. If the entered keys are inconsistent, you need to re-enter the key. If inconsistency occurs for five consecutive times, the configuration will fail. **radsec-destination** *id-number*: Indicates the ID of the RadSec target to which traffic from the RADIUS server is redirected.
Command Mode	Global configuration mode
Usage Guide	A RADIUS security server must be defined to implement the AAA security service by using RADIUS. You can run the **radius-server host** command to define one or more RADIUS security servers.

Configuring the Shared Key for Communication Between the Device and the RADIUS Server

Command	**radius-server key** [**0** | **7**] *text-string*
Parameter Description	**0** | **7**: Indicates the encryption type of the key. The value 0 indicates no encryption and 7indicates simple encryption. The default value is 0. *text-string*: Indicates the text of the shared key.
Command Mode	Global configuration mode
Usage Guide	A shared key is the basis for correct communication between the device and the RADIUS security server. The same shared key must be configured on the device and RADIUS security server so that they can communicate with each other successfully.

Configuring the Request Transmission Count, After Which the Device Confirms That a RADIUS Server Is Unreachable

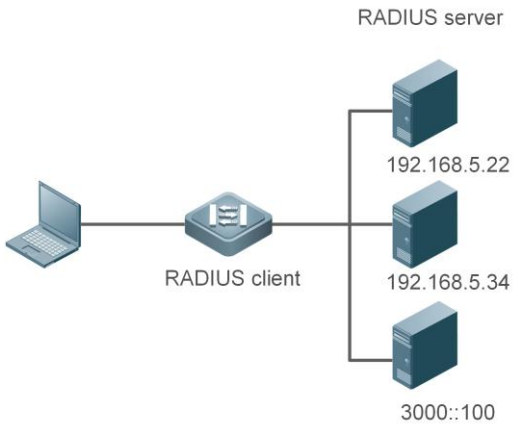
Command	**radius-server retransmit** *retries*
Parameter Description	*retries*: Indicates the RADIUS retransmission count. The value ranges from 0 to 100.
Command Mode	Global configuration mode
Usage Guide	The prerequisite for AAA to use the next user authentication method is that the current security server used for authentication does not respond. The criteria for the device to determine that a security

	server does not respond as follows: The security server does not respond within the RADIUS packet retransmission duration of the specified retransmission count, and there is the timeout interval between two consecutive retransmissions.

Configuring the Waiting Time, After which the Device Retransmits a Request

Command	**radius-server timeout** *seconds*
Parameter Description	*seconds*: Indicates the timeout interval, in seconds. The value ranges from 1 to 1,000.
Command Mode	Global configuration mode
Usage Guide	Use this command to adjust the timeout interval for packet retransmission.

Configuring Retransmission of Accounting Update Packets for Authenticated Users



Command	**radius-server account update retransmit**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure the device to retransmit accounting update packets for authenticated users. Accounting update packets are retransmitted by default. The configuration does not affect users of other types.

Configuring the Device to Send Accounting-On Packets After the NAS Device Restarts

Command	**radius-server accounting-on enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure the device to send accounting-on packets upon NAS restart. This function is enabled by default. Run the **no** form of this command to disable this function.

Configuration Example

Using RADIUS Authentication, Authorization, and Accounting for Login Users

Scenario **Figure 3-2**	
Configuration Steps	1. Enable AAA. 2. Configure RADIUS server information. 3. Configure RADIUS authentication, authorization, and accounting methods. 4. Apply the configured authentication method on the interface.

RADIUS Client	`Hostname#configure terminal`
	`Hostname(config)#aaa new-model`
	`Hostname(config)# radius-server host 192.168.5.22`
	`Hostname(config)#radius-server host 3000::100`
	`Hostname(config)# radius-server key aaa`
	`Hostname(config)#aaa authentication login test group radius`
	`Hostname(config)#aaa authorizationexectest group radius`
	`Hostname(config)#aaa accountingexectest start-stop group radius`
	`Hostname(config)# line vty 0 4`
	`Hostname(config-line)#login authentication test`
	`Hostname(config-line)# authorization exec test`
	`Hostname(config-line)# accounting exec test`

Verification	Log in to a device from a PC in Telnet mode. The user is asked to enter the user name and password. Enter the correct user name and password to log in to the device. After obtaining an access level granted by the server, only commands under this access level can be executed. Check the authentication log of the user on the RADIUS server; perform management operations on the device and then log out; check accounting information on the user on the RADIUS server.

	`Hostname#show running-config`
	`!`
	`radius-server host 192.168.5.22`
	`radius-server host 3000::100`
	`radius-server key aaa`
	`aaa new-model`
	`aaa accounting exec test start-stop group radius`
	`aaa authorization exec test group radius`
	`aaa authentication login test group radius`
	`no service password-encryption`

```
iptcp not-send-rst
!
vlan 1
!
line con 0
line vty 0 4
accounting exec test
authorization exec test
login authentication test
!
```

Common Errors

- The key configured on the device is inconsistent with that configured on the server.
- No method list is configured.

1.4.2 Configuring the RADIUS Attribute Type

Configuration Effect

Define the attribute processing adopted when the device encapsulates and parses RADIUS packets.

Notes

Private attributes involved here refer to Ruijie private attributes.

Configuration Steps

Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)

- Optional.
- Set the MAC address format of **Calling-Station-Id** to a type supported by the server.

Configuring the Parsing Mode of the RADIUS Class Attribute

- Optional.
- Configure the parsing mode of the Class attribute according to the server type.

Configuring the Format of RADIUS Attribute No. 30 (Called-Station-ID)

- Optional.
- Configure the address format of Called-Station-ID to a type supported by the server.

Configuring the RADIUS Private Attribute Type

- Optional.
- If the server is a Ruijie application server, the RADIUS private attribute type needs to be configured.

Setting the Private Attribute port-priority Issued by the Server to the CoS Value of an Interface

- Optional.
- Set the private attribute port-priority issued by the server to the CoS value of an interface as required.

Configuring the Device to Support the CUI Attribute

- Optional.
- Configure whether the device supports the RADIUS CUI attribute as required.

Configuring a Mode for the Device to Parse Private Attributes

- Optional.
- Configure the index of a Ruijie private attribute parsed by the device as required.

Configuring the Device to Encapsulate a Specified Attribute in RADIUS Authentication Request Packets

- Optional.
- Configure RADIUS authentication request packets to contain a specified attribute.

Configuring the Device to Encapsulate a Specified Attribute in RADIUS Accounting Request Packets

- Optional.
- Configure RADIUS accounting request packets to contain a specified attribute.

Configuring the Device to Encapsulate a VSA in RADIUS Authentication Request Packets

- Optional.
- Configure RADIUS authentication request packets to contain a VSA.

Configuring the Device to Encapsulate a VSA in RADIUS Accounting Request Packets

- Optional.
- Configure RADIUS accounting request packets to contain a VSA.

Configuring Whether the RADIUS Server Parses the Private Attribute of Cisco, Huawei, or Microsoft

- Optional.
- Configure whether RADIUS server parses the private attribute of Cisco, Huawei, or Microsoft.

Configuring the NAS-Port-ID Encapsulation Format of RADIUS Packets

- Optional.
- Configure the NAS-Port-ID encapsulation format of RADIUS packets for QinQ and non-QinQ scenarios. The default is the common encapsulation format.

Verification

- Configure the AAA method list that specifies RADIUS for authentication, authorization, and accounting on users.
- Enable the device to interact with the RADIUS server. Obtain packets to check the MAC address format of Calling-Station-Id.

- Enable the device to interact with the RADIUS server. Check debugging information of the device to determine that Ruijie private attributes are correctly parsed by the device.
- Enable the device to interact with the RADIUS server. Check debugging information of the device to determine that the CUI attribute is correctly parsed by the device.

Related Commands

Configuring the MAC Address Format of RADIUS Attribute No. 31 (Calling-Station-ID)

Command	**radius-server attribute 31 mac format** { **ietf** | **normal** | **unformatted** | **dot-split** | **colon-split** | **hyphen-split** } [**mode1** | **mode2**] [**lowercase** | **uppercase**]
Parameter Description	**ietf**: Indicates the standard format specified in RFC 3580, which is separated by the separator (-), for example, 00-D0-F8-33-22-AC. **normal**: Indicates the common format that represents a MAC address (dotted hexadecimal notation), which is separated by the separator (.), for example, 00d0.f833.22ac. **unformatted**: Indicates the format without separators, for example, 00d0f83322ac. This format is used by default. **dot-split**: Indicates the format of MAC address, which is separated by the period (.).This parameter should be used with **mode1** or **mode2**. **colon-split**: Indicates the format of MAC address, which is separated by the semicolon (:). This parameter should be used with **mode1** or **mode2**. **hyphen-split**: Indicates the format of MAC address, which is separated by the hyphen (-). This parameter should be used with **mode1** or **mode2**. **mode1**: Indicates the format of MAC address. Four characters make up one group. This parameter should be configured with **dot-split**, **colon-split**, or **hyphen-split**. For example: 00D0.F833.22AC, 00D0:F833:22AC, and 00D0-F833-22AC. **mode2**: Indicates the format of MAC address. Two characters make up one group. This parameter should be used with **dot-split**, **colon-split**, or **hyphen-split**. For example: 00.D0.F8.33.22.AC, 00:D0:F8:33:22:AC, and 00-D0-F8-33-22-AC. **lowercase**: Indicates lowercase letters to be used in the MAC address. **uppercase**: Indicates uppercase letters to be used in the MAC address.
Command Mode	Global configuration mode
Usage Guide	Some RADIUS security servers (mainly used for 802.1X authentication) can identify only MAC addresses in the IETF format. In this case, set the MAC address format of Calling-Station-ID to IETF.

Configuring a Mode for the Device to Parse the RADIUS Class Attribute

Command	**radius-server attribute class user-flow-control** { **format-16bytes** | **format-32bytes** }
Parameter Description	**user-flow-control**: Parses the rate limit from the class attribute. **format-16bytes**: Sets the format of the rate limit to 16 bytes in the **class** attribute. **format-32bytes**: Sets the format of the rate limit to 32 bytes in the **class** attribute.
Command Mode	Global configuration mode
Usage Guide	Configure this command if the server needs to issue the rate limit value by using the Class

	attribute.

Configuring the Format of RADIUS Attribute No. 30 (Called-Station-ID)

Command	**radius-server attribute 30** { **ap-mac** | **ap-name** }
Parameter Description	**ap-mac**: Specifies the attribute format of Called-Station-ID as ap-mac:SSID, which is the default format. **ap-mac**: Specifies the attribute format of Called-Station-ID as ap-name:SSID.
Command Mode	Global configuration mode
Usage Guide	Configure the desired format based on the server. The default format is ap-mac:SSID.

Setting the Private Attribute port-priority Issued by the Server to the CoS Value of an Interface

Command	**radius set qos cos**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to use the issued QoS value as the CoS value. The QoS value is used as the DSCP value by default.

Configures the Device to Support the CUI Attribute

Command	**radius support cui**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure this command to enable the RADIUS-compliant device to support the CUI attribute.

Configuring a Mode for the Device to Parse Private Attributes by the Device

Command	**Radius vendor-specific extend**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Use this command to identify attributes of all vendor IDs by type.

Configuring the Device to Encapsulate a Specified Attribute in RADIUS Authentication Request Packets

Command	**radius-server account attribute** *type* **package** **radius-server account attribute** *type* **unpackage**
Parameter Description	*type*: Indicates the type of a RADIUS attribute. The value ranges from 1 to 255.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure the device to encapsulate a specified attribute in RADIUS

	authentication request packets.

Configuring the Device to Encapsulate a Specified Attribute in RADIUS Accounting Request Packets

Command	**radius-server account attribute** *type* **package** **radius-server account attribute** *type* **unpackage**
Parameter Description	*type*: Indicates the type of a RADIUS attribute. The value ranges from 1 to 255.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure the device to encapsulate a specified attribute in RADIUS accounting request packets.

Configuring the Device to Encapsulate a VSA in RADIUS Authentication Request Packets

Command	**radius-server authentication vendor** *vendor_name* **package**
Parameter Description	*vendor_name*: Indicates a vendor name, which can be **cmcc**, **microsoft**, **cisco**, or **hw**.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure the device to encapsulate a VSA in RADIUS authentication request packets.

Configuring the Device to Encapsulate a VSA in RADIUS Accounting Request Packets

Command	**radius-server account vendor** ***vendor***_*name* **package**
Parameter Description	*vendor_name*: Indicates a vendor name, which can be **cmcc**, **microsoft**, **cisco**, or **hw**.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure the device to encapsulate a VSA in RADIUS accounting request packets.

Configuring Whether the Server Parses the Private Attribute of Cisco, Huawei or Microsoft

Command	**radius vendor-specific attribute support** ***vendor***_*name*
Parameter Description	*vendor_name*: Indicates the vendor name, which can be **cisco**, **huawei**, or **ms**.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure whether the RADIUS server parses the private attribute of Cisco, Huawei or Microsoft.

Configuring the NAS-Port-ID Encapsulation Format of RADIUS Packets

Command	**radius-server attribute nas-port-id format** { **qinq** | **normal** | **port-vid** | **mode1** }
Parameter Description	**qinq**: Indicates that the device encapsulates the NAS-Port-ID attribute based on a predefined combination of the interface name, inner VLAN ID (VID) and outer VID. **port-vid**: Indicates that the device encapsulates the NAS-Port-ID attribute based on a predefined

	combination of the interface name and VID. **normal**: Indicates that the device encapsulates the NAS-Port-ID attribute based on the interface name. **mode1**: Indicates that the device encapsulates the NAS-Port-ID attribute in the following format: slot=XX; subslot=XX; port=XXX; VLAN ID=XXXX. The slot value ranges from 0 to 15; the subslot value ranges from 0 to 15; the port value ranges from 0 to 255; the VLAN ID ranges from 1 to 4094. If the port value exceeds 255, this format is unavailable.
Command Mode	Global configuration mode
Usage Guide	Configure the NAS-Port-ID encapsulation format of RADIUS packets for QinQ and non-QinQ scenarios.

Configuration Example

↘ Configuring the RADIUS Attribute Type

Scenario	One authentication device
Configuration Steps	1. Configure the MAC address format of RADIUS Calling-Station-Id. 2. Set the QoS value issued by the RADIUS server to the CoS value of the interface. 3. Configure the RADIUS function to support the CUI attribute. 4. Configure the device to support private attributes of other vendors. 5. Configure the device not to encapsulate the NAS-Port-ID attribute in RADIUS authentication request packets. 6. Configure the device to encapsulate CMCC VSA in RADIUS accounting request packets. 7. Configure the RADISU server not to parse Cisco VSA. 8. Configure the NAS-Port-ID encapsulation format of RADIUS packets in the QinQ scenario.

	`Hostname(config)#radius-server attribute 31 mac format ietf`
	`Hostname(config)#radius set qos cos`
	`Hostname(config)#radiussupport cui`
	`Hostname(config)#radiusvendor-specific extend`
	`Hostname(config)#radius-server authentication attribute 87 unpackage`
	`Hostname(config)#radius-server account vendor cmcc package`
	`Hostname(config)#no radius vendor-specific attribute support cisco`
	`Hostname(config)#radius-server attribute nas-port-id format qinq`

Verification	Obtain packets to check debugging information of the device. Check whether the RADIUS standard attributes and private attributes are encapsulated or parsed correctly.

1.4.3 Configuring RADIUS Accessibility Detection

Configuration Effect

The device maintains the accessibility status of each configured RADIUS server: reachable or unreachable. The device will not transmit authentication, authorization, or accounting requests of access users to an unreachable RADIUS server unless all the other servers in the same RADIUS server group are all unreachable.

The device proactively detects a specified RADIUS server. The proactive detection function is disabled by default. If the proactive detection function is enabled for a specified RADIUS server, the device will periodically transmits detection authentication or accounting requests to the RADIUS server. The transmission interval is as follows:

- For a reachable RADIUS server, the interval is the proactive detection interval of the reachable RADIUS server (the default value is 60 minutes).
- For an unreachable RADIUS server, the interval has a fixed value of 1 minute.

Notes

- All the following conditions need to be met before the proactive detection function is enabled for a specified RADIUS server:
- The test user name of the RADIUS server is configured on the device.
- At least one tested port (authentication or accounting port) of the RADIUS server is configured on the device.
- If the following two conditions are met, the device considers that a reachable RADIUS server becomes unreachable:
- After the previous correct response is received from the RADIUS server, the time set in **radius-server dead-criteria time** *seconds* has elapsed.
- After the previous correct response is received from the RADIUS server, the count that the device transmits requests to the RADIUS server but fails to receive correct responses (including retransmission) reaches the value set in **radius-server dead-criteria tries** *number*.
- If any of the following conditions is met, the device considers that an unreachable RADIUS server becomes reachable:
- The device receives correct responses from the RADIUS server.
- The duration that the RADIUS server is in unreachable state exceeds the time set in **radius-server deadtime** and the proactive detection function is disabled for the RADIUS server.
- The authentication or accounting port of the RADIUS server is updated on the device.

Configuration Steps

Configuring the Global Criteria for Determining That a RADIUS Security Server Is Unreachable

- Mandatory.
- Before enabling the proactive detection function, you must configure the global criteria for determining that a RADIUS security server is unreachable.

Configuring the IP Address of the Remote RADIUS Security Server, Authentication Port, Accounting Port, and Proactive Detection Parameters

- Mandatory.
- Configuring proactive detection parameters of the RADIUS server is the prerequisite for enabling the proactive detection function.

Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server

- Optional.

- The configured duration for the device to stop transmitting request packets to an unreachable RADIUS server takes effect only when the proactive detection function is disabled for the RADIUS server.

Verification

Run the **show radius server** command to check accessibility information of each RADIUS server.

Related Commands

Configuring the Global Criteria for Determining That a RADIUS Security Server Is Unreachable

Command	**radius-server dead-criteria** { **time** *seconds* [**tries** *number*] | **tries** *number* }
Parameter Description	**time** *seconds*: Indicates the time condition parameter. If the device fails to receive a correct response packet from a RADIUS security server within the specified time, the device considers that the RADIUS security server meets the inaccessibility duration condition. The value ranges from 1 to 120, in seconds. **tries** *number*: Indicates the consecutive request timeout count. If the timeout count of request packets transmitted by the device to the same RADIUS security server reaches the preset count, the device considers that the RADIUS security server meets the consecutive timeout count condition of inaccessibility. The value ranges from 1 to 100.
Command Mode	Global configuration mode
Usage Guide	If a RADIUS security server meets the condition of the duration condition and consecutive request timeout count, the device considers that the RADIUS security server is unreachable. You can use this command to adjust the duration condition and consecutive request timeout count.

Configuring the Duration for the Device to Stop Transmitting Request Packets to an Unreachable RADIUS Server

Command	**radius-server deadtime** *minutes*
Parameter Description	*minutes*: Indicates the duration for the device to stop transmitting requests to an unreachable RADIUS security server, in minutes. The value ranges from 1 to 1,440 (24 hours).
Command Mode	Global configuration mode
Usage Guide	If the proactive detection function is enabled for a RADIUS security server on the device, the time parameter in **radius-server deadtime** does not take effect on the RADIUS server. If the proactive detection function is disabled for a RADIUS security server, the device automatically restores the RADIUS security server to the reachable state when the duration that the RADIUS security server is in unreachable state exceeds the time specified in **radius-server deadtime**.

Configuration Example

Configuring Accessibility Detection on the RADIUS Server

Scenario **Figure 3-3**	

Configuration Steps	1. Configure the global criteria for determining that a RADIUS security server is unreachable. 2. Configure the IP address of the remote RADIUS security server, authentication port, accounting port, and active detection parameters.
RADIUS Client	`Hostname(config)#radius-server dead-criteria time120 tries 5` `Hostname(config)# radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90`
Verification	Disconnect the device from the server at 192.168.5.22. Perform RADIUS authentication on the device. After 120 seconds, run the **show radius server** command to check that the server state is dead.

	`Hostname#show running-config`
	`...`
	`radius-server host 192.168.5.22 test username test ignore-acct-port idle-time 90`
	`radius-server dead-criteria time 120 tries 5`
	`...`

1.4.4 Configuring the DSCP Value of RADIUS Packets

Configuration Effect

Configure the DSCP value of RADIUS packets.

Notes

A larger DSCP value represents a higher priority of RADIUS packets.

Configuration Steps

↘ Configuring the DSCP Value of RADIUS Packets

Optional.

Verification

Run the **show running-config** command to check the configuration.

Related Command

↘ Configuring the DSCP Value of RADIUS Packets

Command	**radius dscp** *dscp-value*
Parameter Description	*dscp-value*: Indicates the DSCP value.
Command Mode	Global configuration mode
Usage Guide	The value ranges from 0 to 63.

1.4.5 Configuring the Units of Data Flows and Data Packets Sent to the RADIUS Server

Configuration Effect

Configure the units of data flows and data packets sent to the RADIUS server.

Notes

Specify the units of data flows and data packets as required.

Configuration Steps

↘ **Configuring the Units of Data Flows and Data Packets Sent to the RADIUS Server**

Optional.

Verification

Run the **show running-config** command to check the configuration.

Related Commands

↘ **Configuring the Units of Data Flows and Data Packets Sent to the RADIUS Server**

Command	**radius data-flow-format data** { **byte** | **kilo-byte** | **mega-byte** | **giga-byte** } **packet** { **one-packet** | **kilo-packet** | **mega-packet** | **giga-packet** }
Parameter Description	**byte**: Sets the unit of data flows to bytes. **kilo-byte**: Sets the unit of data flows to kilobytes. **mega-byt**: Sets the unit of data flows to megabytes. **giga-byte**: Sets the unit of data flows to gigabytes. **one-packet**: Sets the unit of data packets to packets. **kilo-packet**: Sets the unit of data packets to kilo-packets. **mega-packet**: Sets the unit of data packets to mega-packets. **giga-packet**: Sets the unit of data packets to giga-packets.
Command Mode	Global configuration mode
Usage Guide	Specify the unit of data flows and data packets as required.

1.4.6 Configuring Load Balancing for the RADIUS Server Group

Configuration Effect

Client authentication packets are sent to different servers in the server group through polling. The authentication packets from one client are sent to the same server, while the authentication packets from the next client are sent to the next server.

Notes

- The servers in the same server group must have the same configurations, including the username, password, and authorization policy.

- Ensure that the accounts registered on one server are automatically synchronized to the other servers in the server group, or the authentication will be affected.

Configuration Steps Configuring Load Balancing for the RADIUS Server Group

Optional.

Command	**load-balance**
Parameter Description	N/A
Command Mode	Server group configuration mode
Usage Guide	When multiple servers form a server group and they share the same configurations, enable load balancing to reduce the resource consumption of a single server.

Verification

Run the **show running-config** command to verify the configuration result.

1.4.7 Configuring the Function of Copying Accounting Packets

Configuration Effect

- Accounting packets are copied and sent to servers in a specified server group based on the configuration. Currently, accounting packets are sent to only the first three servers configured in the specified server group.

Notes

- When you configure the target server group to which accounting packets are copied and sent, ensure that the servers in the target server group are different from the servers in the current server group. Otherwise, accounting may be inaccurate.

Configuration Steps

Configuring the Function of Copying Accounting Packets

- Optional.

Command	**accounting-copy** *group_name*
Parameter Description	*group_name*: Indicates the name of the target server group that receives accounting packets to be synchronized. The value is a string of 1 to 64 characters.
Command Mode	Server group configuration mode
Usage Guide	1. When you configure the target server group to which accounting packets are copied and sent, ensure that the servers in the target server group are different from the servers in the current server group. Otherwise, accounting may be inaccurate. 2. By default, accounting packets are copied and sent to only the first three servers configured in the target server group. If the first three servers contain a server that sends and receives accounting packets, this server is automatically ignored, and accounting packets are sent to the first three servers configured in the server group in sequence.

Verification

- Run the **show running-config** command to display the configured target server group for accounting packet synchronization.

- Run the **show radius group** command to display detailed information about the target server group for accounting packet synchronization.

1.4.8 Configuring RadSec Target Attributes

Configuration Effect

The TLS protocol guarantees secure communication of RADIUS requests.

Notes

To use the RadSec service, you must define a RadSec server as the target and divert the RADIUS traffic to the target.

Configuration Steps

Associating a RADIUS Server with a RadSec Target

- Mandatory.
- Configure a RadSec server as the target to receive traffic redirected from the standard RADIUS server.

Configuring RadSec Attributes

- Mandatory.
- Specify related parameters for the RadSec server. This step is required if you want to enable the RadSec function.

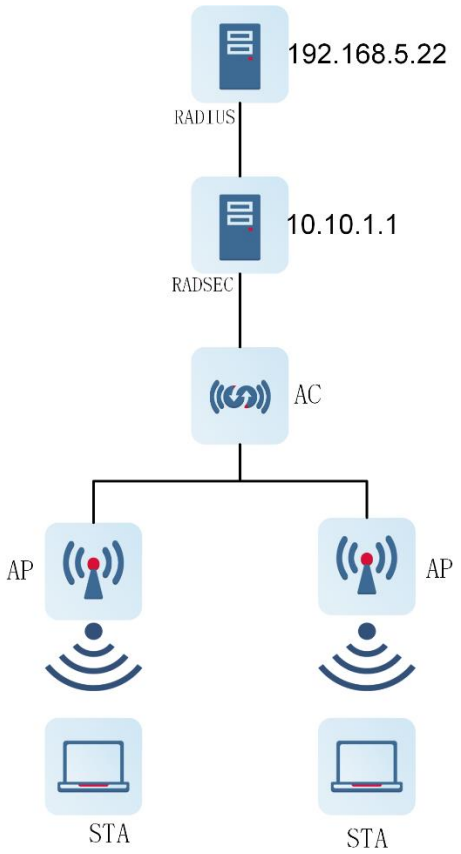
Verification

- Configure RADIUS traffic redirection and perform user authentication, authorization, and accounting.
- When the device exchanges data with a RadSec server, obtain TLS packets.
- When the device exchanges data with a RADIUS server, check whether exchange between the device and the RadSec server is normal based on the debugging information.

Related Commands

Configuring Attributes of the RadSec Server

Command	**radsec destination** *id-number* **host** *ipv4-address* [**port** *port-number*] [**tls-timeout** *seconds*] [**keep-alive** *times*]
Parameter Description	*id-number*: Indicates the unique ID of the RadSec server. *ipv4-address*: Indicates the IP address of the RadSec target server. *port-number*: Indicates the port number of the RadSec server. *seconds*: Indicates the TLS connection timeout period, in seconds. *times*: Indicates the keepalive packet sending interval, in seconds.
Command Mode	Global configuration mode
Usage Guide	This command can be used to configure the required information of the RadSec target server. The RadSec server and the RADIUS server can be the same server or different servers. Null RADIUS requests are used as keepalive packets. The minimum keepalive packet sending interval is 20s, and the maximum interval is 86400s. The keepalive packet sending interval must be smaller than the server keepalive interval.



Configuration Example

The following configuration example describes RadSec-related configuration only.

Configuring RadSec Target Attributes

Scenario

Figure 1-1

Prerequisites

1. Interfaces, IP addresses, and VLANs are configured on the network, the network is connected, and the route from the NAS device to the server is reachable.
2. 802.1X authentication is enabled.

Configuration Steps

- Associate the RADIUS server with the RadSec target.
- Set the unique ID of the RadSec target server to 10, the IP address to 10.10.1.1, the port number to 2022, and the TLS keepalive interval to 300s.

```
Hostname(config)# radius-server host 192.168.5.22 radsec-destination 10

Hostname(config)# radsec destination 10 host 10.10.1.1 port 2022 keep-alive 300
```

Verification

- Obtain packets or view debugging information to check whether TLS packets are correctly encapsulated or parsed.
- Run the **show radsec state** command to display the configuration.

```
Hostname# show radsec state

Radsec server ip    : 10.10.1.1
```

```
Radsec id number   : 10

Radsec server State: Active

Radsec server port : 2022

tls-timeout        : 5 Seconds

Keep alive time    : 300 Seconds
```

1.5 Monitoring

Clearing

Running the clear commands may lose vital information and thus interrupt services.

Command	Description
clear radius user diag	Clears RADIUS user tracks.
clear radius event diag	Clears RADIUS message tracks.

Displaying

Command	Description
show radius parameter	Displays global parameters of the RADIUS server.
show radius server	Displays the configuration of the RADIUS server.
show radius vendor-specific	Displays the configuration of the RADIUS private attribute type.
show radius dynamic-authorization-extension statistics	Displays statistics on the RADIUS dynamic authorization extension function.
show radius auth statistics	Displays statistics on RADIUS authentication.
show radius acct statistics	Displays statistics on RADIUS accounting.
show radius group	Displays configuration of RADIUS server groups.
show radius attribute	Displays RADIUS standard attributes.
show radius user diag { **all** | **by-id** *session-id* | **by-mac** *mac-address* | **by-ip** *ip-address* }	Displays information about RADIUS user tracks.
show radius event diag coa { **all** | **by-id** *msg-id* }	Displays information about RADIUS Change of Authorization (CoA) message tracks.
show radius event diag dm { **all** | **by-id** *msg-id* }	Displays information about RADIUS DM message tracks.
show radsec statistics	Displays statistics on a RadSec target.
show radsec state	Displays the RadSec connection status.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debugradiusevent	Debugs the RADIUS event.

debugradiusdetail	Debugs RADIUS packet printing.
debug radiusextension event	Debugs the RADIUS dynamic authorization extension function.
debug radius extension detail	Debugs the RADIUS dynamic authorization extension packet printing.

Adjusting

Description	Command
radius event-diag msg-num *num*	Adjusts the total number of RADIUS message track records.
radius event-diag log-num *num*	Adjusts the number of tracks that can be recorded for each RADIUS message.
radius user-diag user-num *num*	Adjusts the total number of RADIUS user track records.

1 Configuring TACACS+

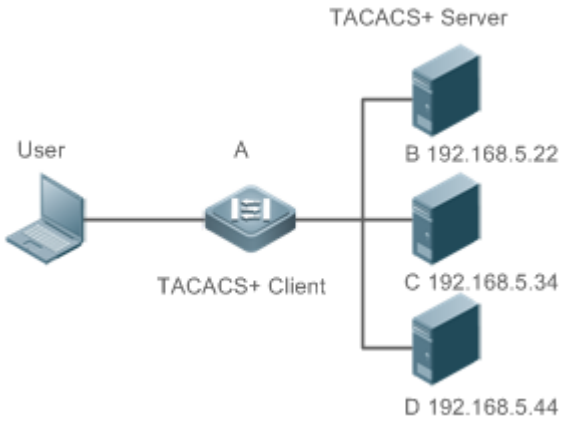
1.1 Overview

TACACS+ is an enhanced security protocol based on the Terminal Access Controller Access Control System (TACACS) protocol. It provides advanced functionality for implementing authentication, authorization, and accounting (AAA) for multiple users.

Protocols and Standards

- RFC 1492: Terminal Access Controller Access Control System

1.2 Applications



Application	Description
Managing and Controlling Login of End Users	Password authentication and authorization need to be performed on end users.

1.2.1 Managing and Controlling Login of End Users

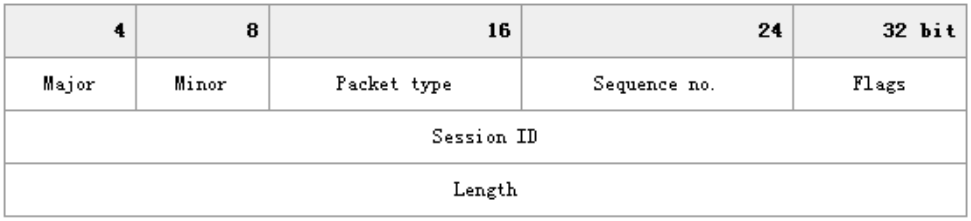
Scenario

TACACS+ is typically applied for login management and control of end users. A network device serves as the TACACS+ client and sends the user name and password to the TACACS+ server for authentication. The user is allowed to log in to the network device and perform operations after passing authentication and obtaining authorization.

Figure 1-1

Remarks	
	● Device A is a client that initiates TACACS+ requests. ● Server B, Server C, and Server D process TACACS+ requests.

Deployment



- Start the TACACS+ server on Server B, Server C, and Server D, and configure information on the access device (Device A) so that the servers provide AAA functions based on TACACS+ for the access device. Enable the AAA function on Device A to start authentication for user login.
- Enable the TACACS+ client function on Device A, configure IP addresses of TACACS+ servers (Server B, Server C, and Server D) and the shared key so that Device A communicates with the TACACS+ servers to implement AAA functions.

1.3 Features

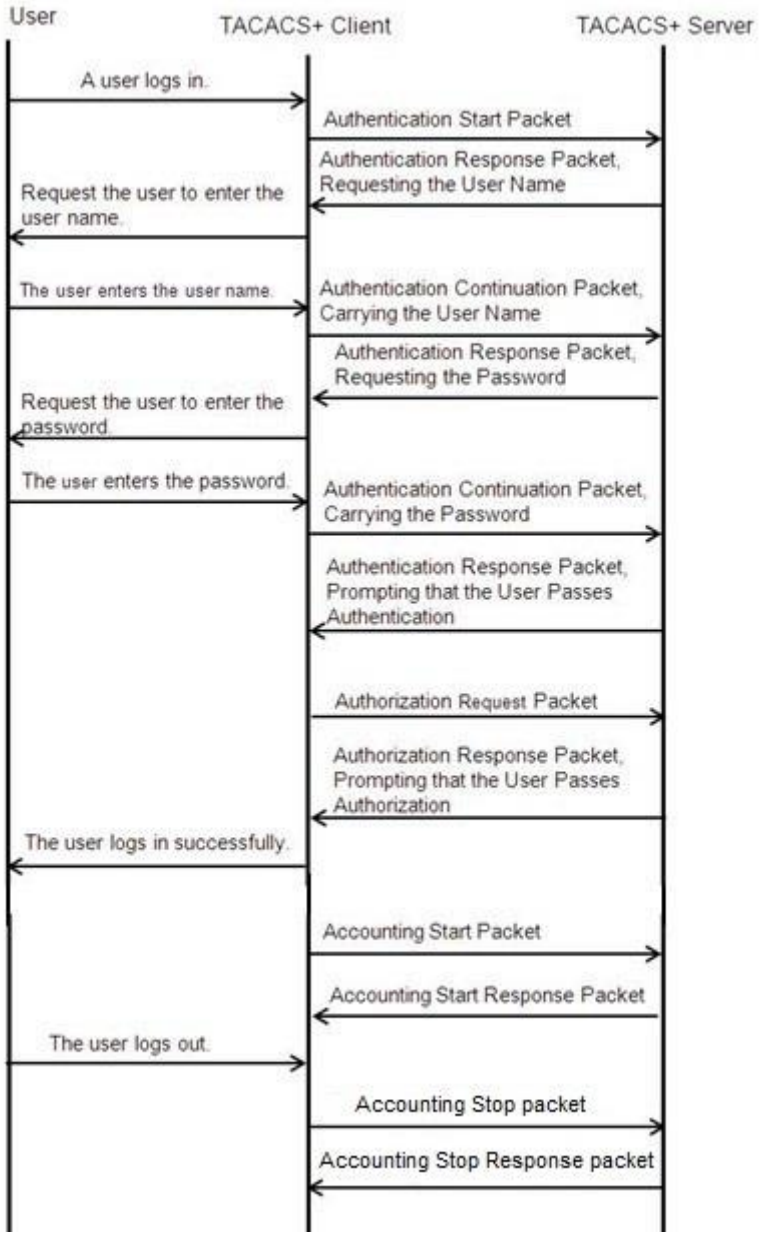
Basic Concepts

↘ Format of TACACS+ Packets

Figure 1-2

- Major: Indicates the major TACACS+ version number.
- Minor: Indicates the minor TACACS+ version number.
- Packet Type: Indicates the type of packets:
  - TAC_PLUS_AUTHEN: = 0x01 (authentication)
  - TAC_PLUS_AUTHOR: = 0x02 (authorization)
  - TAC_PLUS_ACCT: = 0x03 (accounting)
- Sequence no.: Indicates the sequence number of a data packet in a session. The sequence number of the first TACACS+ data packet in a session must be 1 and that of each subsequent data packet increases by one. Therefore, the client sends data packets only with an odd sequence number and TACACS+ Daemon sends packets only with an even sequence number.
- Flags: Contains various bitmap format flags. The value specifies whether data packets need to be encrypted.
- Session ID: Indicates the ID of a TACACS+ session.
- Length: Indicates the body length of a TACACS+ data packet (excluding the header). Packets are encrypted for transmission on a network.

Overview



Feature	Description
TACACS+ Authentication, Authorization, and Accounting	Performs authentication, authorization, and accounting on end users.

1.3.1 TACACS+ Authentication, Authorization, and Accounting

Working Principle

Figure 1-3 uses basic authentication, authorization, and accounting of user login to describe exchange of TACACS+ data packets.

Figure 1-3

Packet exchange involves authentication, authorization, and accounting processes:

1. Authentication process:

   (1) A user requests to log in to a network device.

   (2) After receiving the request, the TACACS+ client sends an Authentication Start packet to the TACACS+ server.

   (3) The TACACS+ server returns an authentication response packet, requesting the user name.

(4) The TACACS+ client requests the user to enter the user name.

(5) The user enters the login user name.

(6) After receiving the user name, the TACACS+ client sends an Authentication Continue packet that carries the user name to the TACACS+ server.

(7) The TACACS+ server returns an authentication response packet, requesting the login password.

(8) The TACACS+ client requests the user to enter the login password.

(9) The user enters the login password.

(10) After receiving the login password, the TACACS+ client sends an Authentication Continue packet that carries the login password to the TACACS+ server.

(11) The TACACS+ server returns an authentication response packet, indicating that the user passes authentication.

2. User authorization starts after successful authentication:

(1) The TACACS+ client sends an authorization request packet to the TACACS+ server.

(2) The TACACS+ server returns an authorization response packet, indicating that the user passes authorization.

(3) After receiving the authorization success packet, the TACACS+ client displays the network device configuration interface for the user.

3. Accounting and audit need to be conducted on the login user after successful authorization:

(1) The TACACS+ client sends an Accounting Start packet to the TACACS+ server.

(2) The TACACS+ server returns an accounting response packet, indicating that the Accounting Start packet has been received.

(3) The user logs out.

(4) The TACACS+ client sends an Accounting Stop packet to the TACACS+ server.

(5) The TACACS+ server returns an accounting response packet, indicating that the Accounting Stop packet has been received.

1.4 Configuration

Configuration	Description and Command	
Configuring TACACS+ Basic Functions	(Mandatory) It is used to enable the TACACS+ security service.	
	tacacs-server host	Configures the TACACS+ server.
	tacacs-server key	Specifies the key shared by the server and network device.
	tacacs-server timeout	Configures the global waiting timeout time of the TACACS+ server for communication between a network device and the TACACS+ server.

	ip tacacs source-interface *interface-name*	Specifies the source address for TACACS+ packets.
Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+	⚠ (Optional) It is used to separately process authentication, authorization, and accounting requests.	
	aaa group server tacacs+	Configures TACACS+ server groups and assigns TACACS+ servers to different groups.
	server	Adds servers to TACACS+ server groups.

1.4.1 Configuring TACACS+ Basic Functions

Configuration Effect

- TACACS+ basic functions are available after the configuration is complete. When configuring the AAA method list, specify the TACACS+ method to implement TACACS+ authentication, authorization, and accounting.
- When authentication, authorization, and accounting operations are performed, TACACS+ initiates authentication, authorization, and accounting requests to configured TACACS+ servers according to the sequence in which they were configured. If response timeout occurs on a TACACS+ server, TACACS+ traverses the TACACS+ server list in sequence.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

↘ Enabling AAA

- Mandatory. The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

Command	**aaa new-model**
Parameter Description	N/A
Defaults	The AAA function is disabled.
Command Mode	Global configuration mode
Usage Guide	The AAA method list can be configured only after AAA is enabled. TACACS+ provides services according to the AAA method list.

↘ Configuring the IP Address of the TACACS+ Server

- Mandatory. Otherwise, a device cannot communicate with the TACACS+ server to implement the AAA function.

Command	**tacacs-server host** { *ipv4-address* | *ipv6-address* } [**port** *integer* | **timeout** *integer*] * [**key** [**0** | **7**] *text-string*]
Parameter Description	*ipv4-address*: Indicates the IPv4 address of the TACACS+ server. *ipv6-address*: Indicates the IPv6 address of the TACACS+ server. **port** *integer*: Indicates the TCP port used for TACACS+ communication. The default TCP port is 49. **timeout** *integer*: Indicates the timeout interval for communication with the TACACS+ server. The global timeout interval is used by default. **key** [**0** | **7**] *text-string*: Indicates the shared key of the server. The global key is used if it is not configured. An encryption type can be specified for the configured key. The value **0** indicates no encryption and **7** indicates simple encryption. The default value is **0**.
Defaults	No TACACS+ server is configured.
Command Mode	Global configuration mode
Usage Guide	1. You can specify the shared key of the server when configuring the IP address of the server. If no shared key is specified, the global key configured using the **tacacs-server key** command is used as the shared key of the server. The shared key must be the same as that configured on the server. 2. You can specify the communication port of the server when configuring the IP address. 3. You can specify the communication timeout interval of the server when configuring the IP address. 4. You can specify the mode of a TCP connection with the server.

Configuring the Shared Key of the TACACS+ Server

- Optional.
- If no global communication protocol is configured using this command, set **key** to specify the shared key of the server when running the **tacacs-server host** command to add server information. Otherwise, a device cannot communicate with the TACACS+ server.
- If no shared key is specified by specifying **key** when you run the **tacacs-server host** command to add server information, the global key is used.

Command	**tacacs-server** [**key** [**0** | **7**] *text-string*]
Parameter Description	*text-string*: Indicates the text of the shared key. **0 | 7**: Indicates the encryption type of the key. The value **0** indicates no encryption and **7** indicates simple encryption.
Defaults	No shared key is configured for any TACACS+ server.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the global shared key for servers. To specify a different key for each server, set **key** when running the **tacacs-server host** command.

Configuring the Timeout Time of the TACACS+ Server

- Optional.
- You can set the timeout interval to a large value when the link between the device and the server is unstable.

Command	**tacacs-server timeout***seconds*

Parameter Description	*seconds*: Indicates the timeout interval, in seconds. The value range is from 1 to 1,000.
Defaults	The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	This command is used to configure the global server response timeout interval. To set the different timeout interval for each server, set **timeout** when running the **tacacs-server host** command.

Configuring the Source Address for TACACS+ Packets

- Optional.
- To reduce the workload of maintaining a large number of NAS information on the TACACS+ server, you can use this command to set the source address for TACACS+ packets.

Command	**ip tacacs source-interface** *interface-name*
Parameter Description	*interface-name*: Indicates the name of the interface with the source address for TACACS+ packets.
Defaults	The source address for TACACS+ packets is specified by the network layer by default.
Command Mode	Global configuration mode
Usage Guide	To reduce the workload of maintaining a large number of NAS information on the TACACS+ server, you can use this command to set the source address for TACACS+ packets. Then the source address for TACACS+ packets will be set to the first IP address of the specified interface.

Verification

Configure the AAA method list that specifies TACACS+ for authentication, authorization, and accounting on users.

- Enable the device to interact with the TACACS+ server and obtain packets to check the TACACS+ exchange process between the device and the TACACS+ server.
- View server logs to check whether authentication, authorization, and accounting are normal.

Configuration Example

Using TACACS+ for Login Authentication

Scenario **Figure 1-4**	
Remarks	• Device A is a client that initiates TACACS+ requests. • Server B processes TACACS+ requests.
Configuration	• Enable AAA.

Steps	● Configure TACACS+ server information. ● Configure the TACACS+ method for authentication. ● Apply the configured authentication method to an interface.

Device A	`Hostname# configure terminal`
	`Hostname(config)# aaa new-model`
	`Hostname(config)# tacacs-server host 192.168.5.22`
	`Hostname(config)# tacacs-server key aaa`
	`Hostname(config)# aaa authentication login test group tacacs+`
	`Hostname(config)# line vty 0 4`
	`Hostname(config-line)# login authentication test`

Verification	Log in to a device from a PC through Telnet. The user is asked to enter the user name and password. Enter the correct user name and password to log in to the device. View the authentication log of the user on the TACACS+ server.

Common Errors

- The AAA security service is disabled.
- The key configured on the device is inconsistent with the key configured on the server.
- No method list is configured.

1.4.2 Configuring Separate Processing of Authentication, Authorization, and Accounting of TACACS+

Configuration Effect

- Authentication, authorization, and accounting in the security service are processed by different TACACS+ servers, which improves security and achieves load balancing.

Notes

- The TACACS+ security service is a type of AAA service. You need to run the **aaa new-model** command to enable the security service.
- Only one security service is provided after TACACS+ basic functions are configured. To make the TACACS+ functions take effect, specify the TACACS+ service when configuring the AAA method list.

Configuration Steps

↘ Configuring TACACS+ Server Groups

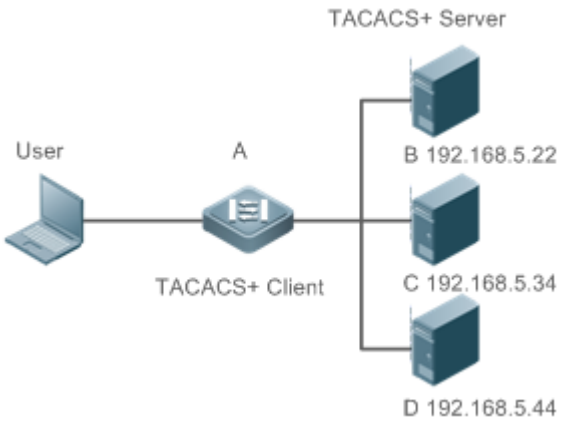
- Mandatory. There is only one TACACS+ server group by default, which cannot implement separate processing of authentication, authorization, and accounting.
- Three TACACS+ server groups need to be configured for separately processing authentication, authorization, and accounting.

Command	**aaa group server tacacs+***group-name*
Parameter Description	*group-name*: Indicates the name of a group. A group name cannot be **radius** or **tacacs+**, which are the names of embedded groups.
Defaults	No TACACS+ server group is configured.
Command Mode	Global configuration mode
Usage Guide	Group TACACS+ servers so that authentication, authorization, and accounting are completed by different server groups.

Adding Servers to TACACS+ Server Groups

- Mandatory. If no server is added to a server group, a device cannot communicate with TACACS+ servers.
- In server group configuration mode, add the servers that are configured using the **tacacs-server host** command.

Command	**server {***ipv4-address* | *ipv6-address*}
Parameter Description	*ipv4-address*: Indicates the IPv4 address of the TACACS+ server. *ipv6-address*: Indicates the IPv6 address of the TACACS+ server.
Defaults	No server is configured.
Command Mode	TACACS+ server group configuration mode
Usage Guide	Before configuring this command, you must run the **aaa group server tacacs+** command to enter the TACACS+ server group configuration mode. For the address of a server configured in a TACACS+ server group, the server must be configured using the **tacacs-server host** command in global configuration mode. If multiple servers are added to one server group, when one server does not respond, the device continues to send a TACACS+ request to another server in the server group.



Verification

Configure the AAA method list that specifies TACACS+ for authentication, authorization, and accounting on users.

- Enable a device to interact with TACACS+ servers. Obtain packets to check that authentication, authorization, and accounting packets are exchanged with different servers, and check the source addresses in packets.

Configuration Example

Configuring Different TACACS+ Server Groups for Separately Processing Authentication, Authorization, and Accounting

Scenario **Figure 1-5**	
Remarks	● Device A is a client that initiates TACACS+ requests. ● Server B processes TACACS+ authentication requests. ● Server C processes TACACS+ authorization requests. ● Server D processes TACACS+ accounting requests.
Configuration Steps	● Enable AAA. ● Configure TACACS+ server information. ● Configure TACACS+ server groups. ● Add servers to TACACS+ server groups. ● Configure the method of using TACACS+ for authentication. ● Configure the method of using TACACS+ for authorization. ● Configure the method of using TACACS+ for accounting. ● Apply the configured authentication method to an interface. ● Apply the configured authorization method to an interface. ● Apply the configured accounting method to an interface.
	Hostname# configure terminal Hostname(Hostname(config)# aaa new-model Hostname(config)# tacacs-server host 192.168.5.22 Hostname(config)# tacacs-server host 192.168.5.34 Hostname(config)# tacacs-server host 192.168.5.44 Hostname(config)# tacacs-server key aaa Hostname(config)# aaa group server tacacs+ tacgrp1 Hostname(config-gs-tacacs)# server 192.168.5.22 Hostname(config-gs-tacacs)# exit Hostname(config)# aaa group server tacacs+ tacgrp2 Hostname(config-gs-tacacs)# server 192.168.5.34 Hostname(config-gs-tacacs)# exit Hostname(config)# aaa group server tacacs+ tacgrp3

	Hostname(config-gs-tacacs)# server 192.168.5.44 Hostname(config-gs-tacacs)# tacacs-server single-connect-timeout 5 Hostname(config-gs-tacacs)# exit Hostname(config)# aaa authentication login test1 group tacacs+ Hostname(config)# aaa authentication enable default group tacgrp1 Hostname(config)# aaa authorization exec test2 group tacgrp2 Hostname(config)# aaa accounting commands 15 test3 start-stop group tacgrp3 Hostname(config)# line vty 0 4 Hostname(config-line)# login authentication test1 Hostname(config-line)#authorization exec test2 Hostname(config-line)# accounting commands 15 test3
Verification	Log in to a device from a PC through Telnet. The user is asked to enter the user name and password. Enter the correct user name and password to log in to the device. Enter the **enable** command and enter the correct **enable** password to initiate Enable authentication. Enter the privilege EXEC mode after passing authentication. Perform operations on the device and then exit the device. View the authentication log of the user on the server at 192.168.5.22. View the **enable** authentication log of the user on the server at 192.168.5.22. View the **exec** authorization log of the user on the server at 192.168.5.34. View the command accounting log of the user on the server at 192.168.5.44.

Common Errors

- The AAA security service is disabled.
- The key configured on the device is inconsistent with the key configured on the server.
- Undefined servers are added to a server group.
- No method list is configured.

1.5 Monitoring

Displaying

Command	Description
show tacacs	Displays interaction with each TACACS+ server.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug tacacs+ detail	Debugs TACACS+.

1 Configuring 802.1X

1.1 Overview

IEEE 802.1X is a port-based network access control that provides secure access service for local area networks (LANs).

On an IEEE 802-compliant LAN, users connecting to the network access devices (NASs) can access network resources without authentication and authorization, bringing security risks to the LAN. The IEEE 802.1X standard is proposed to resolve security problems of such a LAN.

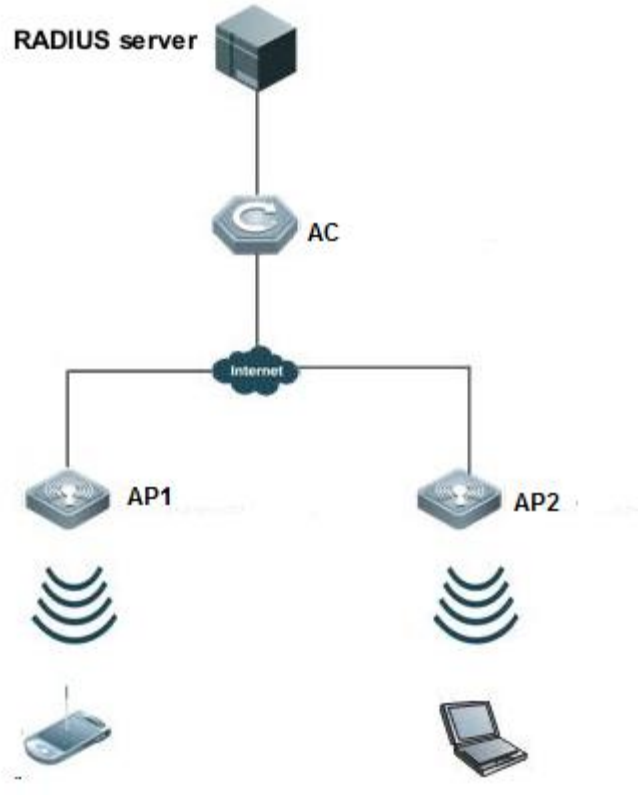
802.1X provides authentication, authorization, and accounting (AAA):

- Authentication: Controls network access and restricts unauthorized users.
- Authorization: Grants services to users and controls permissions of authorized users.
- Accounting: Records network resources consumed by users for subsequent billing.
- 802.1X can be deployed on a network to realize user authentication, authorization, and other functions.

Protocols and Standards

- IEEE 802.1X: Port-Based Network Access Control

1.2 Applications



Application	Description
Wireless 802.1X Authentication	When an enterprise deploys a wireless LAN (WLAN), 802.1X authentication is enabled on the access controller (AC).
EAP Termination	When an enterprise deploys a WLAN, the Extensible Authentication Protocol (EAP) termination function of 802.1X authentication is enabled on the AC.

1.2.1 Wireless 802.1X Authentication

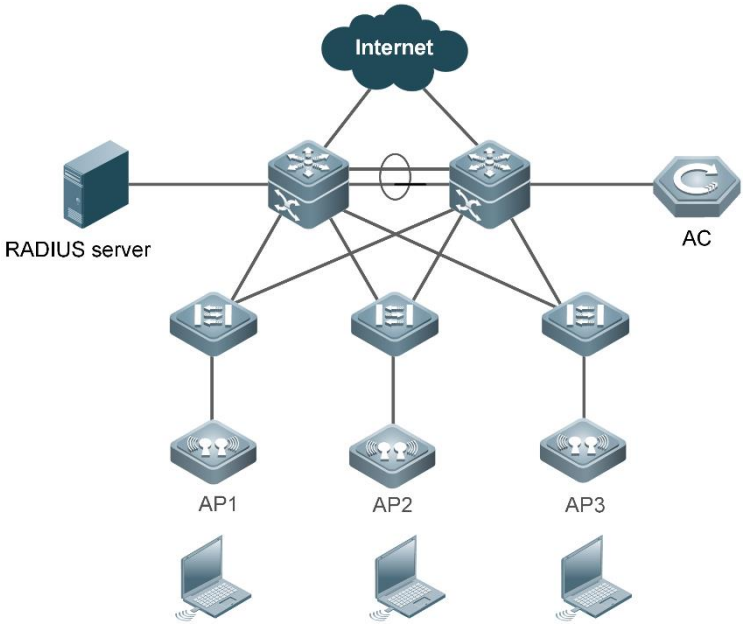
Scenario

- On the wireless authentication network where Fat APs and the authentication server are deployed, 802.1X is enabled on fat APs for secure access control. Wireless stations (STAs) must pass 802.1X authentication to access the enterprise network, as shown in Figure 1-1: STAs have the IEEE 802.1X-compliant software installed, which may come with the operating system or others such as Ruijie Supplicant.
- The AC supports 802.1X.
- One or more Remote Authentication Dial in User Service (RADIUS) servers are used for authentication.

Figure 1-1

Remarks	STAs support 802.1X authentication. After connecting to APs, they will be authenticated through 802.1X. 802.1X authentication is enabled on the AC. The RADIUS server runs the RADIUS server software to perform identity verification.

Deployment



- Enable 802.1X authentication on the AC based on the WLANs broadcast by APs to control access of associated STAs. Only authenticated STAs can access the network.
- Configure an AAA authentication method list so that an appropriate method and the authentication server are adopted in 802.1X authentication.
- Configure RADIUS parameters to ensure communication between the AC and the RADIUS server. For details, see Configuring RDS.
- If a Ruijie RADIUS server is used, configure Simple Network Management Protocol (SNMP) parameters so that the RADIUS server can search and configure connected devices.
- Create accounts, register IP addresses of connected devices, and configure RADIUS parameters so that the RADIUS server can respond to requests of the AP or AC.

1.2.2 EAP Termination

Scenario

As shown in Figure1-2, an AC, APs, and a RADIUS authentication server are deployed on a wireless network. 802.1X authentication is configured on the AC for network access. The RADIUS authentication server does not support the EAP protocol. Therefore, EAP termination of 802.1X authentication needs to be enabled on the AC.

Figure 1-11

Deployment

- Configure a WLAN.
- Configure 802.1X authentication mode to ensure wireless network security.
- Configure the 802.1X authentication method list of AAA.
- Configure a RADIUS server.
- Enable EAP termination of 802.1X authentication.

1.3 Features

Basic Concepts

User

IEEE 802.1X, a LAN-based protocol, identifies users based on physical information but not accounts. Except for them, all other information such as the account ID and IP address may vary. On WLANs, one MAC address represents an STA.

RADIUS

RADIUS is a widely used remote authentication protocol defined in RFC 2865. With this protocol deployed, the authentication server can be remotely deployed to perform authentication. Authentication information between the NAS and the authentication server is transmitted through RADIUS packets.

Timeout

During authentication, an NAS needs to communicate with the authentication client and server. If the client or server does not respond and authentication times out, authentication fails. Ensure that the 802.1X authentication timer is longer than the RADIUS timer.

MAB

MAC address bypass (MAB) authentication uses the MAC address as the username and password for authentication. Because some dumb terminals such as printers cannot have Ruijie Supplicant installed, MAB authentication is adopted to perform security control.

EAP

802.1X uses the Extensible Authentication Protocol (EAP) to carry authentication information. Defined in RFC 3748, EAP provides a universal authentication framework with multiple authentication modes embedded, including Message Digest Algorithm 5 (MD5), Challenge Handshake Authentication Protocol (CHAP), Password Authentication Protocol (PAP), and Transport Layer Security (TLS). The NAS supports various authentication modes including MD5, CHAP, PAP, PEAP-MSCHAP, and TLS.

Authorization

Authorization provides the following binding options for authentication users: IP address binding, VLAN binding, Access Control List (ACL) binding, and QoS binding.

Accounting

Accounting performs network audit on online duration and traffic usage, which facilitates network O&M and management.

Some RADIUS servers such as RG-SAM+ and RG-SMP servers need to check the online and offline status based on accounting packets. Therefore, accounting must be enabled on these RADIUS servers.

RIPT

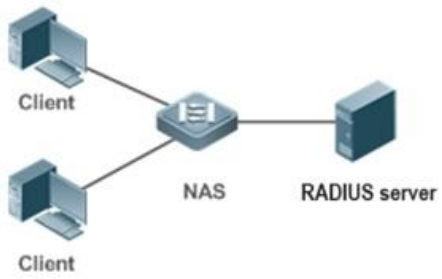
The Remote Intelligent Perceptive Technology (RIPT) ensures availability of Wireless Local Area Networks (WLANs) when the AC fails or the CAPWAP tunnel between an AP and an AC is terminated, allowing the AP to continue providing wireless services. 802.1X can be used with RIPT.

Overview

Feature	Description
Authentication	Provides secure access for users. Only authenticated users can access the network.
Authorization	Grants permissions to authenticated users, such as IP address binding and ACL binding.
Accounting	Audits online records, such as the online duration and traffic.
EAP Termination	Terminates EAP packets and forwards simple authentication information carried in the EAP protocol to the external server.

1.3.1 Authentication

Authentication aims to check clients' identities and prevent unauthorized access to a network. Clients must pass authentication to obtain the network access permission, and can access the network only after the authentication server verifies the account. Before authentication succeeds, only Extensible Authentication Protocol over LAN (EAPOL) packets) can be transmitted over the network for authentication.



Working Principle

802.1X authentication is simple. After a client submits its account information, the NAS sends the account information to the remote RADIUS server for identity authentication. If the authentication succeeds, the client can access the network.

Roles in Authentication

802.1X authentication involves three roles: supplicant, authenticator, and server, which correspond to the client, NAS, and authentication server (RADIUS server typically) respectively.

Figure 4-3

- Supplicant

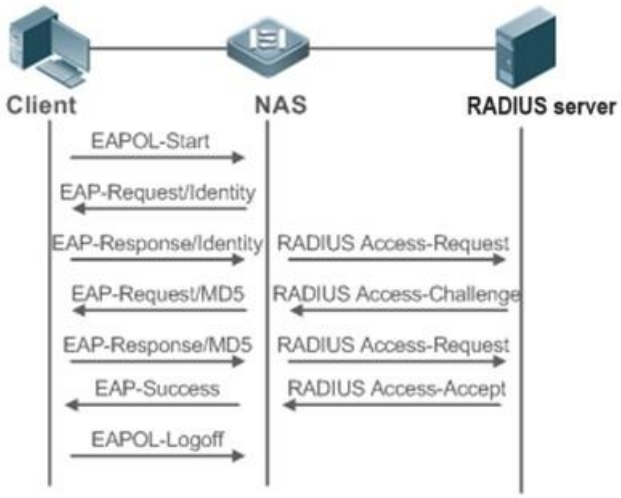
The supplicant is the role of clients, which is usually a PC. It requests to access network services and replies to the request packets of the authenticator. The supplicant must run software in compliance with the IEEE 802.1X standard. Except for the typical 802.1X-compliant software that comes with the operating system, Ruijie Supplicant also meets the requirement.

- Authenticator

The authenticator is typically an NAS such as a wireless access hotspot. It controls the network connection of a client based on the client's authentication status. As a proxy between the client and the authentication server, the authenticator requests the user name from the client, verifies authentication information from the server, and forwards it to the client. In addition to the 802.1X authenticator, the NAS also acts as a RADIUS client. It encapsulates the response packet of the client into the RADIUS packets and forwards the packets to the RADIUS server. After receiving information from the RADIUS server, it interprets the information and forwards it to the client.

The authenticator has two types of ports: controlled port and uncontrolled port. Clients connected to the controlled ports can access network resources only when being authenticated. Clients connected to the uncontrolled ports can directly access network resources without authentication. Clients can be connected to the controlled ports for security control. The uncontrolled ports are mainly used to connect the authentication server to ensure communication between the authentication server and the NAS.

- Authentication server



The authenticator server is usually an RADIUS server. It is used with the authenticator to provide the authentication service for clients. The authentication server saves usernames, passwords, and related authorization information. One server can provide the authentication service for multiple authenticators to achieve centralized client management. The authentication server also manages accounting data received from authenticators. The NAS enabled with IEEE 802.1Xis compatible with the standard RADIUS server, including Microsoft IAS/NPS, FreeRADIUS, and Cisco Access Control Server (ACS).

↘ Authentication Process and Packet Exchange

The supplicant exchanges information with the authenticator through EAPOL and exchanges information with the authentication server through RADIUS. The EAPOL packet is encapsulated over the MAC layer, with the Ethernet type of 0x888E. The multicast MAC address 01-80-C2-00-00-03 is assigned to EAPOL for packet transmission during initial authentication. Ruijie Supplicant may also use 01-D0-F8-00-00-03 for initial authentication packets.

Figure 4-4 shows the typical authentication process of a wired client.

Figure 4-4

This is a typical authentication process initiated by a user. In special cases, the NAS may take the place of the user to initiate an authentication request.

Authenticating the User Status

802.1X determines whether a user on a port can access the network based on the authentication status of the port. Based on 802.1X, the NAS realizes access control based on users (identify a wired user by the MAC address and VLAN ID and identify a STA by the MAC address) by default. 802.1X can also be enabled in interface configuration mode on the NAS.

All users on an uncontrolled port can access network resources, while users on a controlled port can access network resources only after being authorized. When a user initiates authentication, its status remains unauthorized and cannot access the network. After it passes authentication, its status changes to authorized and can access network resources.

If the user connected to a controlled port does not support 802.1X, it will not respond to the packet requesting the user name of the user by the NAS. In this case, the user remains unauthorized and cannot access network resources.

In the scenario where the user supports 802.1X but the NAS does not support 802.1X, if the user does not receive any response after sending a specified number of EAPOL-Start packets, the user considers that the connected port is the uncontrolled port and directly accesses network resources.

On the 802.1X-enabled device, all ports are uncontrolled by default. A port can be configured as controlled so that all users connected to this port need to be authorized.

If a user passes authentication (that is, the NAS receives a success packet from the RADIUS server), the user becomes authorized and can freely access network resources. If the user fails in authentication, it remains unauthorized and re-initiates authentication. If the communication between the NAS and the RADIUS server fails, the user remains unauthorized and cannot access network resources.

When a user sends an EAPOL-LOGOFF packet, the user's status changes from authorized to unauthorized.

When a port becomes LINK-DOWN, all users connected to the port are unauthorized.

When the NAS restarts, all users on it become unauthorized.

To enforce an STA to be free from authentication, you are advised to add a static MAC address or configure IP-MAC binding.

Deploying the Authentication Server

802.1X uses the RADIUS server as the authentication server. That is, when 802.1X is deployed, the RADIUS server also needs to be deployed. Common RADIUS servers include Microsoft IAS/NPS, Cisco ACS, and RG-SAM/SMP.

Configuring Authentication Parameters

To use 802.1X authentication, enable 802.1X authentication on the access port and configure an AAA authentication method list and RADIUS server parameters. To ensure accessibility between the NAS and RADIUS server, configure the 802.1X server timer to be longer than the RADIUS server timer.

Supplicant

A user should start Ruijie Supplicant to enter the user name and initiate authentication. If the authentication client of the operating system is used, a dialog box will be displayed, asking the user to enter the user name. Different clients may have different implementation processes and Graphical User Interfaces (GUIs). It is recommended that Ruijie Supplicant be used as the authentication client. If other software is used, see related software description.

Logout

If a user does not want to access the network, it can choose to go offline by multiple approaches, such as powering off the device, shutting down the connected port, and using the offline function provided by some supplicants.

1.3.2 Authorization

After a user passes authentication, the NAS restricts accessible network resources of the user in multiple approaches, such as accessible VLANs.

Working Principle

Authorization indicates binding permissions to users. A user is identified based on the MAC address and VLAN ID, as mentioned before. Besides MAC-VID binding, some other information such as the IP address and VLAN ID are bound to a user to implement authorization.

ACL Authorization

After user authentication is complete, the authentication server delivers an ACL or ACE to users. The ACL must have been configured on the authentication server, while no extra configuration is required for the ACE. In this mode, an ACL is delivered based on RADIUS attributes such as standard attributes, Ruijie-proprietary attributes, and Cisco-proprietary attributes.

Logout

The 802.1X authentication server can be used with RG-SAM+ or RG-SMP to disconnect online users. The disconnected users are not allowed to access the network. This function can be used to control the online duration and monitor accounting in real time.

1.3.3 Accounting

Accounting allows a network operator to audit network access or fees of accessed users, including the online time and traffic.

Working Principle

Accounting is enabled on the NAS. The RADIUS server supports accounting defined in RFC 2869. When a user goes online, the NAS sends an Accounting Start packet to the RADIUS server which then starts accounting. When the user goes offline, the NAS sends an Accounting End packet to the RADIUS server which then completes accounting and generates a network fee accounting list. Different servers may perform accounting in different ways. Moreover, not all servers support accounting. Therefore, refer to the usage guide of the authentication server during actual deployment and accounting.

Accounting Start

After a user passes authentication, the accounting-enabled NAS sends the RADIUS server an Accounting Start packet carrying user accounting attributes such as the user name and accounting ID. After receiving the packet, the RADIUS server starts accounting.

Accounting Update

The NAS periodically sends Accounting Update packets to the RADIUS server, improving the real-time performance of accounting. The accounting update interval can be provided by the RADIUS server or configured on the NAS.

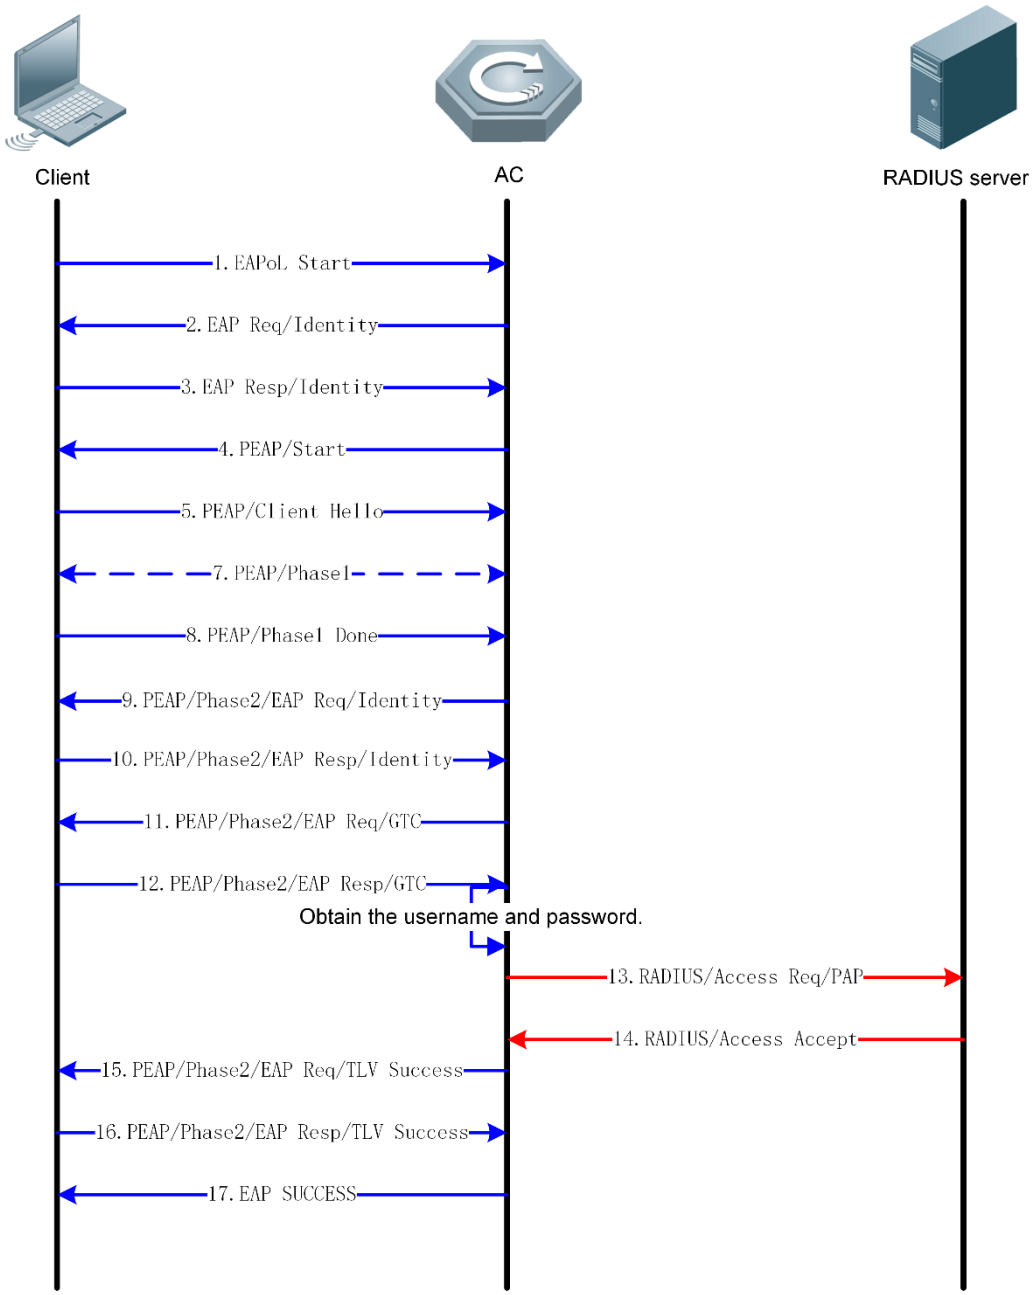
Accounting End

After a user goes offline, the NAS sends the RADIUS server an Accounting End packet carrying the online period and traffic of the user. The RADIUS server generates online records based on the information carried in this packet.

1.3.4 EAP Termination

The device can terminate EAP packets and forward simple authentication information carried in the EAP protocol to the external server. In this case, the device can adapt to external authentication servers that cannot provide the required EAP method. For example, Protected Extensible Authentication Protocol version 1/Generic Token Card (PEAPv1/GTC) is required for client authentication, and the external authentication server can only provide the Password Authentication Protocol (PAP) for authentication.

Working Principle



EAP-GTC termination is used as an example to describe the working principle of EAP termination. Figure 1-3 shows the flowchart of EAP-GTC termination. The RADIUS server supports the PAP authentication method only. However, the PEAPv1/GTC authentication method is used between the AC and a client.

- Steps 1 to 12: The AC exchanges packets with a client required by the PEAPv1/GTC authentication method. After step 12 is performed, the AC obtains the client's authentication credential (including the username and cleartext password).
- Steps 13 to 14: The 802.1X module uses the obtained authentication credential to initiate a PAP authentication to the RADIUS server and obtains the authentication success result.

- Steps 15 to 17: Based on the result returned by the RADIUS server, the 802.1X module continues to perform the PEAPv1/GTC authentication process.

In the following flowchart, when the AC performs EAP-GTC termination, the client does not perceive it and regards that a PEAPv1/GTC authentication is performed. However, the RADIUS server regards that the client is performing a PAP authentication. The flowcharts of PEAP termination and EAP-MSCHAPv2 termination are similar.

Figure 1-12

Related Configuration

Configuring EAP Termination

EAP termination is not configured by default.

Run the **dot1x eap-terminate peap inner-methods gtc** command to enable EAP-GTC termination. Run the **dot1x eap-terminate peap inner-methods mschapv2** command to enable EAP-MSCHAPV2 termination.

1.4 Configuration

Configuration	Description and Command	
Configuring 802.1X Basic Functions	(Mandatory) It is used to configure basic authentication and accounting.	
	aaa new-model	Enables AAA.
	aaa authentication dot1x	Configures an AAA authentication method list.
	aaa accounting networks	Configures an AAA accounting method list.
	radius-server host	Configures RADIUS server parameters.
	radius-server key	Configures the pre-shared key for communication between the NAS and the RADIUS server.
	dot1x port-control auto	Configures 802.1X authentication on a port.
Configuring 802.1X Parameters	(Optional) It is used to configure 802.1X parameters. Ensure that the 802.1X server timeout is longer than the RADIUS server timeout. Online Ruijie client detection applies only to Ruijie Supplicant.	
	dot1x re-authentication	Enables re-authentication.
	dot1x timeout re-authperiod	Configures the re-authentication interval.
	dot1x timeout tx-period	Configures the interval for retransmitting EAP-Request/Identity packets.
	dot1x reauth-max	Configures the maximum count of EAP-Request/Identity packet retransmission.
	dot1x timeout supp-timeout	Configures the interval for retransmitting EAP-Request/Challenge packets.
	dot1x max-req	Configures the maximum count of EAP-Request/Challenge packet retransmission.
	dot1x timeout server-timeout	Configures the authentication server timeout.
	dot1x timeout quiet-period	Configures the quiet period after authentication fails.
	dot1x auth-mode	Specifies the authentication mode (EAP/CHAP/PAP).
	dot1x client-probe enable	Configures the connection status detection for Ruijie Supplicant.
	dot1x probe-timer interval	Configures a detection interval for Ruijie Supplicant.

Configuration	Description and Command	
	dot1x probe-timer alive	Configures a detection timer for Ruijie Supplicant.
Configuring Authorization	(Optional). It is used to configure 802.1X parameters. Supplicant authorization is based on Ruijie Supplicant.	
	dot1x private-supplicant-only	Configures the device to filter non-Ruijie supplicants.
	dot1x redirect	Configures the second-generation supplicant update for users to download the supplicant through redirection to the specified website.
	snmp	Configures SNMP parameters. RG-SAM+ or RG-SMP can log off 802.1X authentication users through the SNMP protocol. This function requires SNMP parameter configuration.
Configuring MAB	(Optional) It is used to configure MAC Authentication Bypass (MAB) authentication. 802.1X authentication takes precedence over MAB authentication. Single-MAB authentication and multi-MAB authentication cannot be configured simultaneously. MAB authentication uses PAP. Ensure that the server configuration is correct.	
	dot1x mac-auth-bypass	Configures single-MAB authentication.
	dot1x mac-auth-bypass multi-user	Configures multi-MAB authentication.
	dot1x multi-mab quiet-period	Configures the quiet period after a multi-MAB authentication failure.
	dot1x mac-auth-bypass timeout-activity	Configures the timeout interval of MAB authentication.
	dot1x mac-auth-bypass violation	Configures MAB violation.
	dot1x mac-auth-bypass vlan	Configures a VLAN for MAB authentication.
Configuring EAP Termination	(Optional) It is used to enable EAP termination.	
	dot1x eap-terminate peap inner-methods	Enables EAP termination.
Configuring PKI Information	(Optional) It is used to regenerate or import Public Key Infrastructure (PKI) information.	
	dot1x pki-manage generate self-signed	Regenerates the self-signed PKI information.

Configuration	Description and Command	
	dot1xpki-manage import pfx	Imports PKI information in PKCS#12 format.
Configuring Extended Functions	(Optional) It is used to configure active authentication requests on a port. (Optional) It is used to configure the authenticated client list. (Optional) It is used to configure the device to send 802.1X packets that carries the bogus source MAC address. (Optional) It is used to configure multiple accounts for the same MAC address.	
	dot1x auto-req	Configures the device to initiate 802.1X authentication.
	dot1x auto-req packet-num	Configures the number of automatic authentication request packets.
	dot1x auto-req user-detect	Configures automatic authentication user detection.
	dot1x auto-req req-interval	Configures the interval for the device to initiate authentication requests.
	dot1x auth-address-table address	Configures the trusted host list.
	dot1x pseudo source-mac	Configures the device to use the virtual MAC address as the source MAC address in outgoing 802.1X packets.
	dot1x multi-account enable	Enables multi-account authentication with one MAC address.
	dot1x valid-ip-acct enable	Enables IP address-triggered accounting.
	dot1x valid-ip-acct timeout	Configures the timeout interval for obtaining IP addresses after users are authenticated. If the timeout interval is reached, they will be disconnected.
	dot1x event server-invalid action bypass-wlan	Configures the bypass WLAN for the RADIUS server.
	dot1x encryption only	Configures 802.1X authentication for encryption only when 802.1X and web-based authentication are both enabled.
	dot1x logging rate-limit	Limits the rate of generating online and offline logs.
	dot1x offline-detect	Enables traffic detection on users on a WLAN.
	dot1x user-trap enable	Enables SNMP trap during user login and logout.
	dot1x mab-default-role	Configures the default role of clients after they pass the MAB authentication.

Configuration	Description and Command	
	dot1x dot1x-default-role	Configures the default role of clients after they pass the 802.1X authentication.
	dot1x domain-name	Configures a domain name for 802.1X authentication.
	dot1x dbg-filter	Enables the print information filter.
	dot1x no-ip-before-mab	Disables the clients to obtain the IP address before they pass the MAB authentication.
	dot1x mab-pass-to-web	Configures the web authentication after clients pass the MAB authentication.

1.4.1 Configuring 802.1X Basic Functions

Configuration Effect

- Enable basic authentication and accounting services.
- On a wired network, run the **dot1x port-control auto** command in interface configuration mode to enable or disable 802.1X authentication on a port.
- On a wireless network, set the WLAN security mode to WPA or WPA2 and enabled 802.1X authentication for the WLAN. The STAs connected to the WLAN can communicate only when they pass 802.1X authentication.
- Run the **radius-server host** *ip-address* command to configure the IP address and port information of the RADIUS server and the **radius-server key** command to configure the RADIUS communication key between the NAS and the RADIUS server to ensure secure communication.
- Run the **aaa accounting update** command in global configuration mode to enable accounting update and the **aaa accounting update interval** command on the NAS to configure the accounting update interval. If the RADIUS server supports accounting update, you can also configure it on the RADIUS server. The parameters assigned by the authentication server takes precedence over the parameters configured on the NAS.

Notes

- Configure accurate RADIUS parameters to ensure correct RADIUS communication.
- The 802.1X authentication method list and accounting method list must be configured in AAA. Otherwise, errors may occur during authentication and accounting.
- If port-based 802.1X authentication is enabled and the number of users to be authenticated exceeds the maximum allowed by port security, port security cannot be enabled.
- If both port security and 802.1X authentication are enabled, and the secure address ages out, the users who are authenticated through 802.1X must be re-authenticated for communication.
- Users with static addresses or users who comply with IP+MAC binding can access the network without authentication.
- 802.1X uses the default method list by default. If the default method list is not configured for AAA, run the **dot1x authentication** and **dot1x accounting** commands to reconfigure it.

- When RG-SAM+ or RG-SMP is used, accounting must be enabled. Otherwise, the RADIUS server will fail to detect users going offline, causing offline users to remain in the online user table.

Configuration Steps

Enabling AAA

- (Mandatory) 802.1X authentication and accounting take effect only after AAA is enabled.
- Enable AAA on the NAS that needs to control client access through 802.1X authentication.

Command	**aaa new-model**
Parameter Description	N/A
Defaults	AAA is disabled by default.
Command Mode	Global configuration mode
Usage Guide	AAA is disabled by default. This command is mandatory for deploying of 802.1X authentication.

Enabling an AAA Authentication Method List

- Mandatory.
- The AAA authentication method list must be consistent with the 802.1X authentication method list.
- Enable an AAA authentication method list after 802.1X authentication is enabled on the NAS.

Command	**aaa authentication dot1x** *list-name* **group radius**
Parameter Description	*list-name*: Indicates the 802.1X authentication method list of AAA.
Defaults	No AAA authentication method list is configured by default.
Command Mode	Global configuration mode
Usage Guide	• AAA authentication modes are disabled by default. • The AAA authentication mode must be consistent with the 802.1X authentication mode.

Configuring RADIUS Server Parameters

- (Mandatory) RADIUS server parameters must be configured to ensure communication between the NAS and the RADIUS server.
- Configure RADIUS server parameters after 802.1X authentication is enabled on the NAS.

Command	**radius-server host** *ip-address* [**auth-port** *port1*] [**acct-port** *port2*]
Parameter Description	*ip-address*: Indicates the IP address of the RADIUS server. *port1*: Indicates the authentication port. *port2*: Indicates the accounting port.
Defaults	No RADIUS server parameters are configured by default.
Command Mode	Global configuration mode

Usage Guide	N/A

Configuring the Pre-shared Key for Communication between the NAS and RADIUS Server

- (Mandatory) The pre-shared key for communication between the NAS and RADIUS server must be configured to ensure communication between the NAS and the RADIUS server.
- Configure the pre-shared key of the RADIUS server after 802.1X authentication is enabled on the NAS.

Command	**radius-server key** *string*
Parameter Description	*string*: Indicates the pre-shared key.
Defaults	No pre-shared key is configured for communication between the NAS and RADIUS server by default.
Command Mode	Global configuration mode
Usage Guide	• The IP address of the NAS must be the same as that registered on the RADIUS server. • The pre-shared key on the NAS must be the same as that on the RADIUS server. • If the default RADIUS communication ports are changed on the RADIUS server, you need to change the communication ports on the NAS correspondingly.

Enabling 802.1X on a Wired Port

- This command is mandatory for a wired port.

Command	**dot1x port-control auto**
Parameter Description	N/A
Defaults	802.1X is disabled on a port by default.
Command Mode	Interface configuration mode and VXLAN mode
Usage Guide	• 802.1X is disabled on a port by default. This command is mandatory for deploying 802.1X authentication. • The default method list is used by default. If the 802.1X authentication method list in AAA is not the default one, the 802.1X authentication method list configured by **dot1x authentication list-name** is used.

Enabling 802.1X

- This function is mandatory on a wireless network.
- Enable 802.1X on an AC.
- If 802.1X is enabled on a WLAN, only 802.11 management frames and EAP packets are allowed to pass.
- For related commands, see *Configuring RSNA*.

Verification

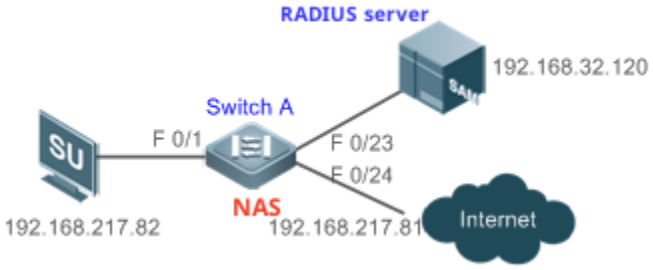
Start Ruijie Supplicant, enter the correct account information, and initiate authentication. Then check whether the 802.1X and RADIUS configurations are correct.

Checking 802.1X Authentication Entries

Command	**show dot1x summary**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	Display entries of authenticated users to check the authentication status of users, for example, authenticating, authenticated, or quiet.

Command Display	`Hostname#show dot1x summary`
	`ID Username MAC Interface VLAN Auth-State`
	`Backend-state Port-Status User-Type Time`
	`--------- ---------- -------------- --------- ---- --------------- -----`
	`-------- ----------- --------- -----------------`
	`16777302 ts-user b048.7a7f.f9f3 wlan 1 1 Authenticated Idle`
	`Authed static 0days 0h 0m12s`

Checking AAA User Entries

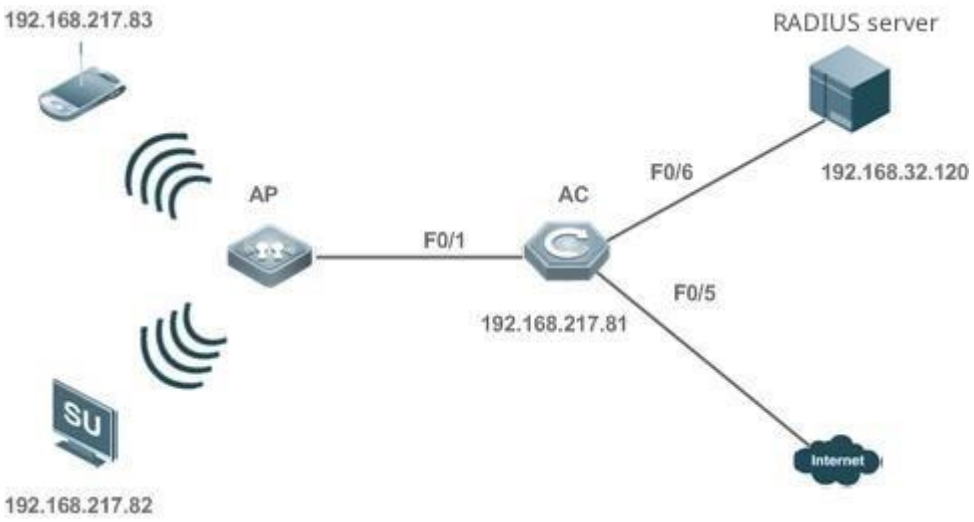


Command	**show aaa user all**
Parameter Description	N/A
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	Display information of AAA users.

Command Display	`Hostname#show aaa user all`
	`----------------------------`
	`Id ----- Name`
	`2345687901 wwxy`
	`----------------------------`

- Check whether the RADIUS server responds to authentication based on the RADIUS packets between the NAS and the RADIUS server. If not, the network is disconnected or parameter configurations are incorrect. If the RADIUS server directly returns a rejection response, check the log file on the RADIUS server to identify the cause. For example, check whether the authentication mode of the authentication server is correctly configured.

Configuration Example



Configuring Wired 802.1X Authentication

Scenario **Figure 1-3**	
Configuration Steps	● Register the IP address of the device on the RADIUS server and configure the key for the device to communicate with the server. ● Create an account on the RADIUS server. ● Enable AAA on the device. ● Configure RADIUS parameters on the device. ● Enable 802.1X authentication on interfaces of the device. ● The following displays the device configuration. For details about the server configuration, see the server configuration guide.

	`Hostname# configure terminal`
	`Hostname(config)# aaa new-model`
	`Hostname(config)# radius-server host 192.168.32.120`
	`Hostname(config)# radius-server key Hostname`
	`Hostname(config)# interface FastEthernet 0/1`
	`Hostname(config-if)# dot1x port-control auto`

Verification	Check whether authentication can be performed normally and whether network access behavior changes after authentication.
	● Create an account on the server, for example, **username:tests-user** or **password:test**.
	● The user fails to ping 192.168.32.120 before authentication.
	● After the user enters account information and click **Authenticate** on Ruijie Supplicant, the authentication succeeds and the user can successfully ping 192.168.32.120.
	● Information about the authenticated user is displayed.
	`Hostname# show dot1x summary`
	`ID Username MAC Interface VLAN Auth-State`
	`Backend-State Port-Status User-Type Time`
	`--------- ---------- -------------- --------- ---- --------------- -`
	`------------ ----------- --------- -------------------`
	`16778217 ts-user 0023.aeaa.4286 Fa0/1 2 Authenticated`
	`Idle Authed static 0days 0h 0m 7s`

Configuring 802.1X Authentication on a WLAN

Scenario **Figure 4-5**	
Configuration Steps	● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the NAS. ● Configure RADIUS parameters on the NAS. ● Enable 802.1X authentication on ports of the NAS. ● The NAS configuration is as follows. For details about the configuration of the RADIUS server, see *Configuring RADIUS*.

	`Hostname# configure terminal`
	`Hostname(config)# aaa new-model`
	`Hostname(config)# radius-server host 192.168.32.120`
	`Hostname(config)# radius-server key radius-key`
	`Hostname(config)# wlansec 1`
	
	`Hostname(config-wlansec)# security rsn enable`
	`Hostname(config-wlansec)# security rsn ciphers aes enable`
	`Hostname(config-wlansec)# security rsn akm 802.1x enable`

Verification	Check whether authentication is normal and whether network access behaviors change after authentication.
	● The account is successfully created, such as **username: tests-user, password: test**.
	● The user fails to ping 192.168.32.120 before authentication.
	● After the user enters account information and click **Authenticate** on Ruijie Supplicant, the authentication succeeds and the user can successfully ping 192.168.32.120.
	● Information of the authenticated user is displayed.
	`Hostname# show dot1x summary`
	`ID Username MAC Interface VLAN Auth-State`
	`Backend-State Port-Status User-Type Time`
	`--------- ---------- -------------- --------- ---- --------------- -`
	`------------ ----------- --------- ------------------`

	16778217 ts-user 0023.aeaa.4286 wlan 1 2 Authenticated Idle Authed static 0days 0h 0m 7s

Common Errors

- RADIUS parameters are incorrectly configured.
- The RADIUS server has a special access policy, for example, the RADIUS packets must carry certain attributes.
- The AAA authentication mode list is different from the 802.1X authentication mode list, causing authentication failures.

1.4.2 Configuring 802.1X Parameters

Configuration Effect

- Adjust 802.1X parameter configurations based on the network situation. For example, if the authentication server has poor performance, you can increase the timeout interval of the authentication server.

Notes

- 802.1X and RADIUS have separate server timeout intervals. By default, the authentication server timeout interval of 802.1X is 5 seconds while that of RADIUS is 15 seconds. In practice, ensure that the former is greater than the latter. You can run the **dot1x timeout server-timeout** command to adjust the authentication server timeout interval of 802.1X. For details, see *Configuring RADIUS*
- Connection status detection for Ruijie supplicants is only supported in Ruijie supplicants.

Configuration Steps

↘ Enabling Re-authentication

- (Optional) After re-authentication is enabled, the NAS can periodically re-authenticate online users.
- Enable re-authentication after 802.1X authentication is enabled on the NAS.

Command	**dot1x re-authentication**
Parameter Description	N/A
Defaults	Re-authentication is disabled by default.
Command Mode	Global configuration mode
Usage Guide	You can run this command to periodically re-authenticate users.

↘ Configuring the Re-authentication Interval

- (Optional) You can configure the re-authentication interval for users.
- Configure the re-authentication interval after 802.1X authentication is enabled on the NAS. The re-authentication interval takes effect only after re-authentication is enabled.

Command	**dot1x timeout re-auth period** *period*
Parameter Description	*period*: Indicates the re-authentication interval, in seconds.

Defaults	The default value is 3,600 seconds.
Command Mode	Global configuration mode
Usage Guide	Adjust the re-authentication interval as required.

Configuring the Interval for Retransmitting EAP-Request/Identity Packets

- (Optional) A larger value indicates a longer interval of packet retransmission.
- Configure the interval for retransmitting EAP-Request/Identity packets after 802.1X authentication is enabled on the NAS.

Command	**dot1x timeout tx-period** *period*
Parameter Description	*period*: Indicates the interval for retransmitting EAP-Request/Identity packets, in seconds.
Defaults	The default value is 4 seconds.
Command Mode	Global configuration mode
Usage Guide	The default value is recommended. Adjust the value based on the duration during which the authentication client responds to the NAS's requests.

Configuring the Maximum Count of EAP-Request/Identity Packet Retransmission

- (Optional) A larger value indicates more frequent retransmission.
- Configure the maximum count of EAP-Request/Identity packet retransmission after 802.1X authentication is enabled on the NAS.

Command	**dot1x reauth-max** *num*
Parameter Description	*num*: Indicates the maximum count of EAP-Request/Identity packet retransmission.
Defaults	The default value is 6.
Command Mode	Global configuration mode
Usage Guide	The default value is recommended. In the case of high packet loss rate, increase this value so that the clients can easily receive packets from the NAS.

Configuring the Interval for Retransmitting EAP-Request/Challenge Packets

- (Optional) A larger value indicates a longer retransmission interval.
- Configure the interval for retransmitting EAP-Request/Challenge packets after 802.1X authentication is enabled on the NAS.

Command	**dot1x timeout supp-timeout** *time*
Parameter Description	*time*: Indicates the interval for retransmitting EAP-Request/Challenge packets, in seconds.
Defaults	The default value is 3 seconds.
Command Mode	Global configuration mode

Usage Guide	The default value is recommended. Increase this value in the case of high packet loss rate.

Configuring the Maximum Count of EAP-Request/Challenge Packet Retransmission

- (Optional) A larger value indicates more frequent retransmission.
- Configure the maximum count of EAP-Request/Challenge packet retransmission after 802.1X authentication is enabled on the NAS.

Command	**dot1x max-req** *num*
Parameter Description	*num*: Indicates the maximum count of EAP-Request/Challenge packet retransmission, in seconds.
Defaults	The default value is 3.
Command Mode	Global configuration mode
Usage Guide	• Optional. • The default value is recommended. Increase this value in the case of high packet loss rate.

Configuring the Timeout Interval of the Authentication Server

- (Optional) A larger value indicates a longer timeout interval of the authentication server.
- Configure the timeout interval of the authentication server after 802.1X authentication is enabled on the NAS.
- The timeout interval of RADIUS authentication must be greater than that of 802.1X authentication.

Command	**dot1x timeout server-timeout** *time*
Parameter Description	*time*: Indicates the timeout interval of the authentication server, in seconds.
Defaults	The default value is 5 seconds.
Command Mode	Global configuration mode
Usage Guide	The default value is recommended. Increase this value if the communication between the NAS and RADIUS server is unstable.

Configuring the Quiet Period after Authentication Fails

- (Optional) A larger value indicates a longer quiet period.
- Configure the quiet period after 802.1X authentication is enabled on the NAS.

Command	**dot1x timeout quiet-period** *time*
Parameter Description	*time*: Indicates the quiet period after authentication fails, in seconds.
Defaults	The default value is 10 seconds.
Command Mode	Global configuration mode
Usage Guide	The default value is recommended. Increase this value to prevent users from frequently initiating authentication to the RADIUS server, thereby reducing the load of the authentication server.

Specifying the Authentication Mode

- (Optional) Configure the mode for 802.1X authentication.
- Configure the authentication mode after 802.1X authentication is enabled on the NAS.

Command	**dot1x auth-mode** { **eap** | **chap** | **pap** }
Parameter Description	**eap**: Indicates EAP authentication. **chap**: Indicates CHAP authentication. **pap**: Indicates PAP authentication.
Defaults	The default value is **eap**.
Command Mode	Global configuration mode
Usage Guide	Select the authentication mode supported by the supplicant and the authentication server.

Configuring Connection Status Detection for Ruijie Supplicant

- (Optional) After this function is enabled, Ruijie Supplicant disconnection will be detected in a timely manner, avoiding inaccurate accounting.
- The supplicant must be a Ruijie Supplicant.
- Configure this function after 802.1X authentication is enabled.

Command	**dot1x client-probe enable**
Parameter Description	N/A
Defaults	This function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	You are advised to enable this function when using Ruijie Supplicant.

Configuring a Detection Interval for Ruijie Supplicant

- (Optional) A greater value indicates a longer interval at which the supplicant sends heartbeat packets.
- Configure this function after 802.1X authentication is enabled.

Command	**dot1x probe-timer interval** *time*
Parameter Description	*time:* Indicates the interval at which Ruijie Supplicant sends heartbeat packets to the device. The value is expressed in seconds and the default value is 20.
Defaults	The default value is 20.
Command Mode	Global configuration mode
Usage Guide	The default value is recommended.

Configuring a Detection Timer for Ruijie Supplicant

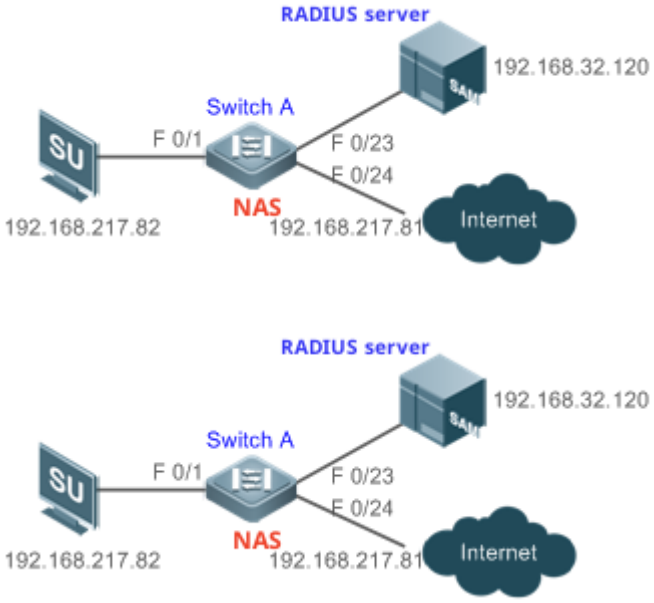
- (Optional) A greater value indicates a longer interval at which the device identifies disconnection of Ruijie Supplicant.
- Configure this function after 802.1X authentication is enabled.

Command	**dot1x probe-timer alive** *time*

Parameter Description	*time:* Indicates the interval at which the device identifies disconnection of Ruijie Supplicant, in seconds. The default value is 250.
Defaults	The default value is 250.
Command Mode	Global configuration mode
Usage Guide	● Optional. ● If the device does not receive any response packets from Ruijie Supplicant within the period defined by the detection timer, the device identifies disconnection of Ruijie Supplicant. The default value is recommended.

Verification

Run the **show dot1x** command to check whether parameter configurations take effect.



Configuration Example

Specifying the Authentication Mode

Scenario	The NAS is deployed in standalone mode.
Configuration Steps	● Set the authentication mode to **chap**.
	`Hostname(config)#dot1x auth-mode chap`

Verification	● Display the configurations.
	`Hostname(config)#show dot1x`
	
	`802.1X basic information:`
	`  802.1X Status ..... enable`
	`  Authentication Mode ..... chap`
	`  Authorization mode ..... disable`
	`  Total User Number ..... 0 (exclude dynamic user)`
	`  Authenticated User Number ..... 0 (exclude dynamic user)`
	`  Dynamic User Number ..... 0`
	`  Re-authentication ..... disable`
	`  Re-authentication Period ..... 3600 seconds`
	`  Re-authentication max ..... 3 times`
	`  Quiet Period ..... 10 seconds`
	`  Tx Period ..... 30 seconds`
	`  Supplicant Timeout ..... 3 seconds`
	`  Server Timeout ..... 5 seconds`
	`  Maximum Request ..... 3 times`
	`  Client Online Probe ..... disable`
	`  Eapol Tag ..... disable`
	`  802.1x redirect ..... disable`
	`  Private supplicant only ..... disable`

Configuring Connection Status Detection for Ruijie Supplicant

Scenario **Figure 1-4**	
Configuration Steps	Enable connection status detection for Ruijie Supplicant.
	`Hostname(config)#dot1x client-probe enable`
Verification	● Ruijie Supplicant keeps online by sending heartbeat packets periodically. ● Display the configuration.

	`Hostname(config)#show dot1x`
	
	`802.1X basic information:`
	`  802.1X Status ..... enable`
	`  Authentication Mode ..... chap`
	`  Authorization mode ..... disable`
	`  Total User Number ..... 0 (exclude dynamic user)`
	`  Authenticated User Number ..... 0 (exclude dynamic user)`
	`  Dynamic User Number ..... 0`
	`  Re-authentication ..... disable`
	`  Re-authentication Period ..... 3600 seconds`
	`  Re-authentication max ..... 3 times`
	`  Quiet Period ..... 10 seconds`
	`  Tx Period ..... 30 seconds`
	`  Supplicant Timeout ..... 3 seconds`
	`  Server Timeout ..... 5 seconds`
	`  Maximum Request ..... 3 times`
	`  Client Online Probe ..... enable`
	`  Eapol Tag ..... disable`
	`  802.1x redirect ..... disable`

Common Errors

- The timeout interval of the authentication server is shorter than the timeout interval for RADIUS authentication.
- Connection status detection is configured for non-Ruijie supplicants.

1.4.3 Configuring Authorization

Configuration Effect

- Filtering non-Ruijie supplicants can require STAs to authenticate using Ruijie Supplicant, so the STAs can enjoy services provided by Ruijie Supplicant, such as anti-proxy or short message functions.
- The redirection function supports second-generation supplicant deployment. The second-generation supplicant deployment indicates that STAs download Ruijie Supplicant through a web page and are authenticated through Ruijie Supplicant. This facilitates rapid deployment of Ruijie Supplicant in environments with a large number of users.

Notes

- When using RG-SAM+ or RG-SMP for real-time user logout, correct SNMP parameters need to be configured. You can refer to the SNMP configuration guide for detailed instructions.
- If there are multiple types of authentication client software in the environment, do not enable the device to filter non-Ruijie supplicants.
- Second-generation supplicant deployment and web-based authentication cannot be used simultaneously.
- Configuring redirection parameters is required for second-generation supplicant deployment. For details, see *Configuring Web-based Authentication*.
- SNMP is used for user disconnection of RG-SAM+ or RG-SMP, so SNMP parameters need to be configured. For details, see *Configuring SNMP*.

Configuration Steps

↘ Configuring Second-Generation Supplicant Deployment

- (Optional) After second-generation supplicant deployment is configured, users without the 802.1X authentication client on controlled ports can download and install 802.1X authentication clients through a web page.
- It is configured after 802.1X authentication is enabled on the device.
- You must configure redirection parameters. For details, see *Configuring Web-based Authentication*.

Command	**dot1x redirect**
Parameter Description	N/A
Defaults	Disabled
Command Mode	Global configuration mode
Usage Guide	You need to configure redirection parameters properly. For details, see *Configuring Web-based Authentication*.

↘ Filtering Non-Ruijie Clients

- (Optional) When enabled, non-Ruijie clients will not be able to authenticate.

- It is configured after enabling 802.1X authentication on the device.

Command	dot1x private-supplicant-only
Parameter Description	N/A
Defaults	Disabled
Command Mode	Global configuration mode
Usage Guide	To configure this feature, the STA must use Ruijie Supplicant software for authentication.

Verification

- Enable second-generation su deployment and open a Web browser to access a specific URL. The client will be automatically redirected to the download page to download the authentication client. The client must pass authentication through the client before being able to access the network.
- If a user goes online after authentication, you can perform the kickoff function on the Ruijie SAM/SMP. The device will then disconnect the user, and the user will not be able to access the network.

Common Errors

- There are multiple authentication clients on the network, but the device is enabled to filter non-Ruijie supplicants, causing authentication failures of some STAs.
- RG-SAM+ or RG-SMP is used, but the device is not configured with SNMP parameters, resulting in disconnection failures.
- The second-generation supplicant upgrade function cannot be used due to incorrect configuration of redirection parameters.

1.4.4 Configuring MAB Authentication

Configuration Effect

- MAB authentication uses the MAC address of a STA as the authentication account, eliminating the need to install a supplicant on the STA. MAB authentication is applicable to dumb terminals, such as network printers.
- Single-MAB authentication is applicable when there is only one dumb STA connected to a port or when only one STA needs to be authenticated. Other STAs can also access the network after this STA is authenticated. For example, if a wireless router is connected to a port, real-time MAB authentication can be configured for the wireless router, and users connected to the wireless router can access the network after authentication.
- Multi-MAB authentication is applicable when there are multiple types of dumb STAs connected to a port. For example, multiple VoIP access devices are deployed in a network call center.
- Multi-MAB authentication can be used with 802.1X authentication, and is applicable to mixed access environments. For example, voice and data flows are transmitted in the voice VLAN and data VLAN respectively, and office personnel need to use PC for data communication and IP phones for voice communication.
- On a WLAN, WLAN-based MAB authentication is supported. If MAB authentication is enabled, the NAS automatically uses the MAC address of a STA on the WLAN as the user name and password to initiate authentication to the authentication server.

Notes

- A port configured with MAB authentication sends an authentication request packet an intervals specified by *tx-period*at intervals. If there is no response after the maximum re-authentication count, the port enters the MAB authentication mode. Ports in MAB authentication mode can learn MAC addresses and use these MAC addresses as accounts for authentication.
- When configuring the username and password of the MAC account on the server, ensure that the format cannot contain separators. For example, if the MAC address of a STA is 00-d0-f8-00-01-02, the account needs to be configured as 00d0f8000102 on the server.
- 802.1X authentication takes precedence over MAB authentication. Therefore, if a STA passes MAB authentication and then uses the client software to perform 802.1X authentication, the MAB authentication entry will be deleted.
- MAB authentication only supports PAP, so the server needs to be correctly configured.
- MAB authentication mainly proactively discovers whether a STA can perform 802.1X authentication, , so proactive authentication must be enabled during MAB authentication deployment.
- If MAB authentication is enabled on a WLAN, set the WLAN security mode to OPEN.

Configuration Steps

Configuring Single-MAB Authentication

- Optional.
- It applies to scenarios where only one STA needs to be authenticated on a port.
- It is configured on the 802.1X controlled port of the device.

Command	**dot1x mac-auth-bypass**
Parameter Description	N/A
Defaults	Disabled
Command Mode	Interface configuration mode
Usage Guide	To limit the number of STAs, configure MAB violation.

Configuring the Timeout Interval for MAB Authentication

- Optional.
- For the STA whose MAC address is authenticated goes online in MAB authentication mode, the device considers that the STA remains online unless there is a re-authentication failure, port Down event, or logout due to a management policy (for example, forcible disconnection by an administrator). You can configure the online time allowed for these authenticated addresses, with a default value of 0, which means no time limit.
- It is configured on the 802.1X controlled port of the device.

Command	**dot1x mac-auth-bypass timeout-activity** *value*
Parameter Description	*value*: Indicates the MAB authentication online time, in seconds. It is 0 by default, indicating that the online time is not limited.

Defaults	The value is 0 by default, indicating that the online time is not limited.
Command Mode	Interface configuration mode
Usage Guide	It is applicable to both single-MAB and multi-MAB authentication scenarios.

Configuring MAB Violation

- Optional.
- It is configured on the 802.1X controlled port of the device.
- By default, after one MAC address passes MAB authentication, data from all devices on the port is allowed to be forwarded. However, in some security applications, an administrator may require only one MAC address on a port enabled with MAB authentication. In this case, MAB violation can be configured on the port. When the port enters the MAB authentication mode, a violation will be triggered if more than one MAC address is detected on the port.

Command	**dot1x mac-auth-bypass violation**
Parameter Description	N/A
Defaults	Disabled
Command Mode	Interface configuration mode
Usage Guide	• This command can only be configured when it is required to limit the number of dumb STAs under a port to only one. • It applies to the single-MAB authentication scenario only.

Configuring Multi-MAB Authentication

- Optional.
- It is configured on the 802.1X controlled port of the device.

Command	**dot1x mac-auth-bypass multi-user**
Parameter Description	N/A
Defaults	Disabled
Command Mode	Interface configuration mode
Usage Guide	Use this command when multiple dumb STAs on a port need to be authenticated.

Configuring the Quiet Period After a Multi-MAB Authentication Failure

- Optional.
- It is configured after multi-MAB authentication is enabled on the device.
- When multi-MAB authentication is enabled, to prevent unauthorized users connected to the port from attacking the device, disable frequent authentication attempts by unauthorized users to reduce the load on the server. The quiet period for multi-MAB authentication users is configured globally, with the default value of 30s. That is, if a STA's MAC address fails to be authenticated, the STA needs to wait for 30s before initiating authentication again. The quiet period

can be configured according to the environment. If the value is configured as 0, the STA can immediately attempt authentication again after an authentication failure.

Command	**dot1x multi-mab quiet-period** *value*
Parameter Description	*value*: Indicates the quiet period after an authentication failure.
Defaults	It is 30s by default.
Command Mode	Global configuration mode
Usage Guide	You can configure this command to limit the authentication frequency when many dumb STAs connected to a port need to be authenticated.

Configuring a VLAN for MAB Authentication.

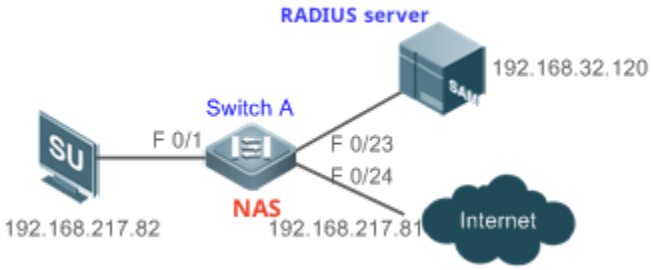
- Optional.
- It is configured after enabling multi-MAB authentication is enabled on the device.
- To allow only users within certain VLANs on the interface to perform MAB authentication, configure the VLANs as VLANs for MAB authentication. Then STAs not in the VLANs cannot perform MAB authentication.

Command	**dot1x mac-auth-bypass vlan** *vlan-list*
Parameter Description	*vlan-list*: Indicates the VLANs allowed for MAB authentication.
Defaults	Disabled
Command Mode	Interface configuration mode
Usage Guide	Use this command when only users within specific VLANs on the port are allowed to perform MAB authentication.

Enabling WLAN-based MAB Authentication

- Optional.
- Enable MAB authentication on the WLAN connected to STAs.

Command	**dot1x-mab**
Parameter Description	N/A
Defaults	WLAN-based MAB authentication is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	• Run this command when STAs on a WLAN need to perform authentication using MAC addresses. • This command applies only to wireless devices.



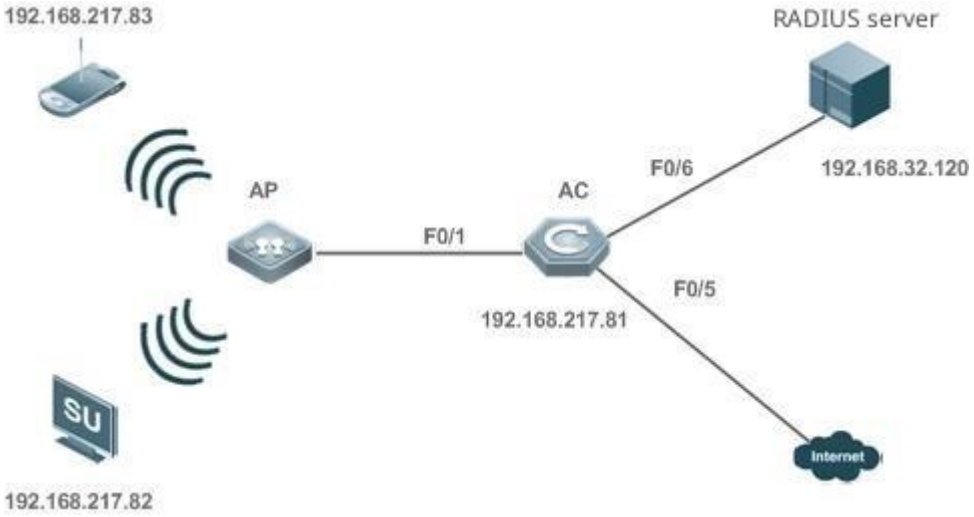
Verification

- Check whether a dumb STA can access the network. If so, MAB authentication takes effect. If not, MAB authentication does not take effect.
- Check whether MAB authentication is configured on the authentication server and NAS.

- Check whether dumb STAs with invalid MAC addresses cannot access the network.
- Check whether dumb STAs with invalid MAC addresses can access the network.

Configuration Example

Configuring Wired Multi-MAB Authentication



Scenario **Figure 1-5**	
Configuration Steps	● Register the IP address of the device on the RADIUS server and configure the key for the device to communicate with the server. ● Create an account on the RADIUS server. ● Enable AAA on the device. ● Configure RADIUS parameters on the device. ● Enable 802.1X authentication and multi-MAB authentication on device ports. ● The following shows the device configuration. For details about the server configuration, see the server configuration guide.

	`Hostname# configure terminal`
	`Hostname(config)# aaa new-model`
	`Hostname(config)# radius-server host 192.168.32.120`
	`Hostname(config)# radius-server key Hostname`
	`Hostname(config)# interface FastEthernet 0/1`
	`Hostname(config-if)# dot1x port-control auto`
	`Hostname(config-if)# dot1x mac-auth-bypass multi-user`

Verification	Check whether authentication can be performed normally and whether network access behavior changes after authentication.
	● Create an account on the server. For example, the value of username is 0023aeaa4286 and the value of password is **0023aeaa4286**.
	● A non-authenticated STA fails to ping 192.168.32.120.
	● The STA connects to the device, a page indicating the authentication succeeds is displayed, and the STA can successfully ping 192.168.32.120.
	● Check the information about authenticated users.
	`Hostname# show dot1x summary`
	`ID Username MAC Interface VLAN Auth-State`
	`Backend-State Port-Status User-Type Time`
	`--- --- --- --- --- --- -`
	`--- --- --- ---`

	16778217 0023aea... 0023.aeaa.4286 Fa0/1 2 Authenticated Idle Authed static 0days 0h 5m 8s

Enabling WLAN-based MAB Authentication

Scenario **Figure 4-6**	
Configuration Steps	● Register the IP address of the NAS on the RADIUS server and configure the communication key between the NAS and the RADIUS server. ● Create an account on the RADIUS server. ● Enable AAA on the NAS. ● Configure RADIUS parameters on the NAS. ● Enable WLAN-based MAB on the NAS. ● NAS configurations are as follows. For detailed configuration on the RADIUS server, see *Configuring RADIUS*.
	Hostname# configure terminal Hostname(config)# aaa new-model Hostname(config)# radius-server host 192.168.32.120 Hostname(config)# radius-server key radius-key Hostname(config)#wlansec 1 Hostname(config-wlansec)#dot1x-mab
Verification	Check whether authentication is normal and whether network access behaviors change after authentication. ● The account is successfully created. For example, the value of username is 0023aeaa4286 and the value of password is **0023aeaa4286**. ● The user fails to ping 192.168.32.120 before authentication. ● The user connects to the NAS, the authentication succeeds, and the user can successfully ping 192.168.32.120. ● Information about the authenticated user is displayed. Hostname# show dot1x summary ID Username MAC Interface VLAN Auth-State Backend-State Port-Status User-Type Time

```
--------- ---------- --------------  --------- ---- --------------- -
------------ ----------- --------- ------------------
16778217  0023aea...  0023.aeaa.4286  Fa0/1    2    Authenticated
Idle          Authed      static    0days 0h 5m 8s
```

Common Errors

The MAC account format is incorrect on the authentication server.

1.4.5 Configuring EAP Termination

Configuration Effect

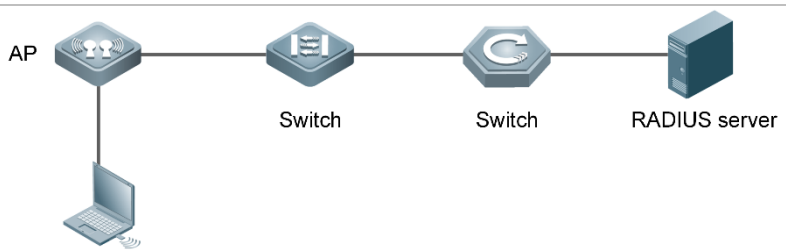
Configure the device to terminate EAP packets and act a proxy to forward simple authentication information carried in the EAP protocol to the external server. In this case, the device can adapt to external authentication servers that cannot provide the required EAP method.

Configuration Steps

Enabling EAP Termination

- Mandatory.
- Only two types of termination are supported. You can configure either one or both of them.

Related Commands



Enabling EAP Termination

Command	**dot1x eap-terminate peap inner-methods** { **gtc** | **mschapv2** }
Parameter Description	**gtc**: Sets the termination type to EAP-GTC termination. **mschapv2**: Sets the termination type to EAP-MSCHAPv2 termination.
Command Mode	WLAN security configuration mode
Usage Guide	• When GTC termination is enabled, the authentication mode of the device is changed from EAP-GTC to PAP authentication, and the device sends a PAP authentication request to the external authentication server. • When MSCHAPv2 termination is enabled, the device encapsulates the challenge and peer response obtained from the PEAP-MSCHAPv2 protocol into one MSCHAPv2 authentication packet and sends the packet to the external authentication server. • EAP termination of 802.1X authentication supports VAC scenarios. • When EAP termination of 802.1X authentication and local EAP termination are enabled simultaneously, traffic continues to be processed by local EAP termination after being terminated by EAP termination of 802.1X authentication, though it is determined that termination is not required. • You are advised to use EAP termination of 802.1X authentication when EAP termination needs to be configured.

Configuration Examples

The following configuration example only describes configuration related to EAP termination.

Enabling EAP-GTC Termination

Scenario **Figure 1-116**	
Configuration Steps	• Configure a WLAN. • Configure 802.1X authentication mode to ensure wireless network security. • Configure the 802.1X authentication method list. • Configure a RADIUS server. • Enable EAP termination of 802.1X authentication.

Switch	# Assign the downlink ports of the switch to VLAN 100 to which the AP belongs.
	`Hostname# configure terminal`
	`Hostname(config)# interface GigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# poe enable`
	`Hostname(config-if-GigabitEthernet 0/1)# switchport access vlan 100`
	# Configure the uplink ports of the switch as trunk ports.
	`Hostname(config)# exit`
	`Hostname(config)# interface GigabitEthernet 0/2`
	`Hostname(config-if-GigabitEthernet 0/2)# switchport mode trunk`

AC	# Configure GigabitEthernet 0/1 connected to the switch as a trunk port.
	`Hostname# configure terminal`
	`Hostname(config)# interface GigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# switchport mode trunk`
	# Configure the IP address of Loopback 0 for the AC to establish a CAPWAP tunnel with the AP.
	`Hostname(config-if-GigabitEthernet 0/1)# exit`
	`Hostname(config)# interface Loopback 0`
	`Hostname(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255`
	# Configure AP VLAN 100 and STA VLAN 10, and configure the AC as the DHCP server for VLAN 100 and VLAN 10.
	`Hostname(config)#vlan 100`
	`Hostname(config-vlan)#exit`
	`Hostname(config)#interface vlan 100`
	`Hostname(config-if-VLAN 100)# ip address 192.168.100.1 255.255.255.0`
	`Hostname(config)#vlan 10`
	`Hostname(config-vlan)#exit`
	`Hostname(config)#interface vlan 10`
	`Hostname(config-if-VLAN 100)# ip address 192.168.10.1 255.255.255.0`
	`Hostname(config-if-VLAN 100)# exit`

	Hostname(config)# service dhcp Hostname(config)# ip dhcp pool ap_vlan100 Hostname(dhcp-config)# option 138 ip 10.1.1.1 # here must be the IP address of loopback 0. Hostname(config)#wlansec 1 Hostname(config-wlansec)# dot1x authentication default Hostname(config-wlansec)# dot1x eap-terminate peap inner-methods gtc Hostname(config-wlansec)#dot1x eap-terminate peap inner-methods mschapv2 Hostname(config)# aaa new-model Hostname(config)# aaa authentication login default none Hostname(config)# aaa authentication dot1x default group radius # Configure the RADIUS server. Hostname(config)# radius-server host 192.168.197.79 Hostname(config)# radius-server key ruijie
Verification	If both username and password configured on the RADIUS server are **admin**, enter the username and password on the STA (such as a mobile phone). The STA can access WLAN **miaosf_eap**.

Common Errors

The 802.1X authentication method list is incorrectly configured.

1.4.6 Configuring PKI Information

Configuration Effect

The device can generate self-signed PKI information, or users can import PKI information in PKCS#12 format through the CLI.

Configuration Steps

Regenerating the Self-signed PKI Information

- Optional.
- When no PKI information exists on the device, the device automatically generates the self-signed PKI information. Typically, users do not need to generate PKI information through the CLI. For security reasons, users can regenerate the self-signed PKI information by using this function.

Importing PKI Information in PKCS#12 Format

- Optional.
- When the self-signed PKI information generated by the device does not meet user requirements, users can import the required PKI information to the device using a file in PKCS#12 format (file name extension is pfx or p12).
- Note that importing a certificate will cause the client that is being authenticated to fail the authentication.

Verification

- Run the **show dot1x pki** [**self-signed | pfx** command to display PKI information.

Related Commands

Regenerating the Self-signed PKI Information

Command	**dot1x pki-manage generate self-signed**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	● When no PKI information exists on the device, the device automatically generates the self-signed PKI information. Typically, users do not need to generate PKI information through the CLI. For security reasons, users can regenerate the self-signed PKI information by using this function. ● The generated PKI information is stored in the flash memory and loaded from the flash memory during system startup. This command is not saved in the configuration file.

Importing PKI Information in PKCS#12 Format

Command	**dot1x pki-manage import pfx** *filepath* [**password** *password*]
Parameter Description	*filepath:* Indicates the path of the PKCS#12 file in the flash memory. *password:* Indicates the password for decrypting the imported file (optional). If the file is not encrypted, no password needs to be input.
Command Mode	Global configuration mode

Usage Guide	● When the self-signed PKI information generated by the device does not meet user requirements, users can import the required PKI information to the device using a file in PKCS#12 format (file name extension is pfx or p12). The imported information is stored in the flash memory, and loaded from the flash memory during system startup. This command is not saved in the configuration file. ● The PKI information imported by users takes precedence over the PKI information generated by the device. When both the self-signed PKI information generated by the device and the PKI information imported by a user exist, the device will use the PKI information imported by the user. When the device finds that the preceding two types of PKI information do not exist upon startup, the device will automatically generate and use the self-signed PKI information.

Configuration Examples

↘ Uploading the PKCS#12 File to the Device and Importing PKI Information in PKCS#12 Format

Configuration Steps	● Upload the PKCS#12 file to the device. ● Import PKI information in PKCS#12 format.

	# Upload the PKCS#12 file to the device.
	`Hostname# copy tftp://192.168.1.1/pki.pfx flash:pki.pfx`
	Import PKI information in PKCS#12 format.
	`Hostname# config terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#dot1x pki-manage import pfx pki.pfx password filepassword`
	`Import PKI from file [pki.pfx] successfully`

Verification	● Run the **show dot1x pki** [**self-signed | pfx** command to display PKI information.

1.4.7 Configuring Extended Functions

Configuration Effect

- Some STAs use built-in authentication clients in their operating systems, which may not initiate authentication immediately upon network access. Proactive authentication allows STAs to initiate authentication immediately after network access.
- Proactive authentication indicates that STAs proactively sends request/id packets, which can trigger Ruijie Supplicant to perform 802.1X authentication. This function can be used to detect whether STAs are using Ruijie Supplicant. For example, Ruijie Supplicant is required if MAB authentication is deployed.
- The authenticated host list can restrict authentication of STAs connected to an access port, thereby improving network security by controlling physical locations of STAs.
- The multi-account function allows a user to switch its account upon re-authentication. In special scenarios such as Windows domain authentication, authentication needs to be performed for multiple times to access the domain and the user account changes during authentication.
- By default, the device uses its own MAC address as the source MAC address for EAP packets during 802.1X authentication. In some versions of Ruijie Supplicant, the source MAC address of EAP packets is used to determine whether the access device is a Ruijie device and to implement proprietary features. If you need to use these

proprietary features during 802.1X authentication with Ruijie Supplicant of such verisons, you can enable the virtual source MAC address function.

- 802.1X allows users to obtain IP addresses before accounting, meeting the requirement that an IP address is carried during user accounting. After a user is authenticated and goes online, the NAS can obtain the IP address of the user from the supplicant or through DHCP snooping, and then the 802.1X server initiates an accounting request. The NAS does not initiate accounting if it does not obtain the IP address of the authentication client. To avoid this situation, configure the IP detection timeout interval. If the NAS does not obtain the IP address of the user within the configured timeout interval (5 minutes by default), it disconnects the user.
- 802.1X allows users to switch to the preset bypass WLAN when the RADIUS server is inaccessible. The bypass WLAN typically uses the OPEN mode and services of the bypass WLAN are unavailable by default. If 802.1X-based WLAN services are unavailable, enable the bypass WLAN and disable WLAN-based 802.1X authentication so that users can switch to the bypass WLAN to properly access the network.
- 802.1X can be used with web-based authentication. If web-based authentication is enabled on an 802.1X-enabled WLAN, performing 802.1X authentication can achieve only encryption. To access the network, users need to pass web-based authentication. In this case, user data on the air interface is encrypted, enhancing security.
- 802.1X provides notifications about user login and logout logs. You can adjust the rate for generating user login and logout logs based on the user authentication rate. This prevents high CPU utilization due to frequent log generation for a large number of users that go online or offline.
- In the WLAN-based 802.1X authentication scenario, the NAS sends the authentication server SNMP traps to notify the online/offline status of users.
- In the WLAN-based 802.1X authentication scenario, traffic monitoring can be enabled on a WLAN. That is, if traffic of an authenticated user is lower than the configured threshold within the specified period, the user will be disconnected so that the authentication server can perform accounting in a timely manner.
- The device enabled with 802.1X authentication can initiate an accounting request to the authentication server after receiving information about the STA that has a supplicant installed. By doing this, the device can send information about the STA to the authentication server. To prevent a wired device's failure to obtain information of the STA for a long period of time, you can configure a timer. If the wired device does not obtain the STA information when the timer expires, the STA is disconnected.
- For wireless 802.1X authentication, WLAN-based domain authentication can be configured. That is, a domain name is configured on the WLAN. Then an authentication user without a domain name can be authenticated through the authentication server with the domain name.

Notes

- The multi-account function must be disabled if accounting is enabled. Otherwise, accounting may be inaccurate.
- Proactive authentication is required during MAB authentication, so proactive authentication must be enabled in the environment where MAB is deployed.
- IP-based accounting is not required in two situations:

  IPv4 addresses and Ruijie Supplicant are deployed. This function is not required because Ruijie Supplicant can upload the IPv4 addresses of users.

  Static IP addresses are deployed.

- It is recommended that the SSID of the bypass WLAN be different from that of the 802.1X-based WLAN so that the bypass WLAN services can be queried easily. Moreover, when the WLAN needs to be switched due to server inaccessibility, users can manually switch the SSID once. Because the supplicant can retain the SSID record, the SSID can be switched automatically.
- Encryption is used for 802.1X users only, authorization such as ACL assignment and rate limit assignment, is ineffective for 802.1X users. However, users need to pass web-based authentication and be authorized to access the network.

Configuration Steps

Configuring Proactive Authentication

- (Optional) The controlled port sends a proactive authentication request packet. The authentication client initiates 802.1X authentication after receiving the authentication request packet.
- Configure this function after enabling 802.1X authentication.

Command	**dot1x auto-req**
Parameter Description	N/A
Defaults	This function is enabled by default.
Command Mode	Global configuration mode
Usage Guide	The destination IP address of proactive authentication packets is a multicast address. The downlink client may not initiate an authentication proactively. In this case, you can use this command to configure the device to initiate authentication. If the controlled port is a trunk port, the device configured with this command will send an authentication request based on each VLAN on the trunk port.

Configuring the Maximum Number of Proactive Authentication Request Packets

- (Optional) Configure the maximum number of proactive authentication request packets.
- Configure this function after enabling 802.1X authentication.

Command	**dot1x auto-req packet-num** *num*
Parameter Description	*num*: Configures the maximum number of proactive authentication request packets.
Defaults	The value is not configured by default.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure the maximum number of proactive authentication request packets.

Configuring User Detection for Proactive Authentication

- (Optional) Configure the controlled port not to send a proactive authentication request packet if there are authentication users on the port.
- Configure this function after enabling 802.1X authentication.

Command	**dot1x auto-req user-detect**

Parameter Description	N/A
Defaults	User detection for proactive authentication is enabled by default.
Command Mode	Global configuration mode
Usage Guide	If the controlled port is an access port, it will not send proactive authentication request packets if there are authentication users on the port. If the controlled port is a trunk port, it will not send proactive authentication request packets from the VLAN to which authentication users belong.

Configuring the Interval for the Device to Send Proactive Authentication Request Packets

- (Optional) Configure the interval for the device to send proactive authentication request packets.
- Configure this function after enabling 802.1X authentication.

Command	**dot1x auto-req req-interval** *time*
Parameter Description	*time*: Configures the interval for the device to send proactive authentication request packets.
Defaults	The value is 30 seconds by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Allowed Host List

- (Optional) Configure the allowed host list on the controlled port. Only hosts in the list are allowed for 802.1X authentication.
- Configure this function after enabling 802.1X authentication.

Command	**dot1x auth-address-table address** *mac-addr* **interface** *interface*
Parameter Description	*mac-addr*: Configures the MAC address of the host. *interface*: Configures the interface of the host.
Defaults	All hosts are allowed for authentication by default.
Command Mode	Global configuration mode
Usage Guide	Use this command to configure the allowed host list on the controlled port.

Configuring the Virtual MAC Address as the Source MAC Address of 802.1X Authentication Packets

- (Optional) Configure this command if the Ruijie supplicant fails to identify the MAC address of the Ruijie device.
- Configure this function after enabling 802.1X authentication.

Command	**dot1x pseudo source-mac**
Parameter Description	N/A
Defaults	This function is disabled by default.
Command Mode	Global configuration mode

Usage Guide	Some Ruijie supplicants may fail to identify the Ruijie device based on the MAC address of the EAPOL packet. Use this command to configure 00-1A-A9-17-FF-FF as the source MAC address of the EAPOL packet, thereby ensuring that the supplicant can identify the Ruijie device.

Enabling Multi-account Authentication with One MAC Address

- (Optional) Run the **dot1x multi-account enable** command to allow the same MAC address to be used by multiple accounts.
- Enable multi-account authentication with one MAC address after 802.1X authentication is enabled on the NAS.

Command	**dot1x multi-account enable**
Parameter Description	N/A
Defaults	Multi-account authentication is disabled by default.
Command Mode	Global configuration mode
Usage Guide	Configure this command when multi-account authentication is required in 802.1X authentication, for example, in the case of Windows domain authentication. In this case, the authentication client can directly use a new account to initiate authentication while the previous account is still online. Multi-account authentication is disabled by default.

Configuring the Maximum Number of Authenticated Users on a Port

- (Optional) You can restrict the number of online users on a controlled port, including static and dynamic users.
- Configure the maximum number of authenticated users on a port after 802.1X authentication is enabled on the NAS.

Command	**dot1x default-user-limit** *num*
Parameter Description	*num*: Indicates the maximum number of online users.
Defaults	The number of online users is not limited on a port by default.
Command Mode	Interface configuration mode and VXLAN mode
Usage Guide	Configure this command when the number of authenticated users needs to be limited on a port.

Enabling IP Address-triggered Accounting

- (Optional) If IP address-triggered accounting is enabled, the NAS sends an accounting request to the authentication server after obtaining the IP address of the user.
- Enable IP address -triggered accounting after 802.1X authentication is enabled on the NAS.

Command	**dot1x valid-ip-acct enable**
Parameter Description	N/A
Defaults	IP address-triggered accounting is disabled by default.
Command Mode	Global configuration mode

Usage Guide	If both accounting and IP address-triggered accounting are enabled, the NAS initiates accounting only after obtaining the IP address of the authentication client, and disconnects the user if it fails to obtain the IP address. If accounting is disabled but IP address-triggered accounting is enabled, the NAS does not initiate accounting after obtaining the IP address of the authentication client, and disconnects the user if it fails to obtain the IP address within the timeout interval.

Configuring the Timeout Interval for Obtaining IP Addresses After Authentication

- (Optional) Configure the timeout interval for obtaining IP addresses if IP address-triggered accounting is enabled.
- Configure the timeout interval for obtaining IP addresses after 802.1X authentication is enabled on the NAS.

Command	**dot1x valid-ip-acct timeout** *time*
Parameter Description	*time:* Indicates the timeout interval for obtaining IP addresses, in minutes.
Defaults	The default value is 5 minutes.
Command Mode	Global configuration mode
Usage Guide	The default value is recommended. Configure this command when there is a need to change the timeout interval for obtaining IP addresses after users pass authentication.

Configuring the Bypass WLAN for the RADIUS Server

- Optional.
- Enable bypass WLAN for the RADIUS server after 802.1X authentication is enabled on the NAS.

Command	**dot1x event server-invalid action bypass-wlan** *wlan_id*
Parameter Description	*wlan_id:* Indicates the bypass WLAN.
Defaults	Bypass WLAN is disabled by default.
Command Mode	Global configuration mode/WLAN security configuration mode
Usage Guide	• This command applies only to wireless devices. • The default setting is recommended. Run this command to configure the bypass WLAN when the server is unreachable.

Hiding the WLAN Signals During RADIUS Authentication Escape

- Optional.
- Hide the WLAN signals during RADIUS authentication escape after the 802.1X authentication is enabled on the device.

Command	**dot1x event server-invalid original-wlan action hide**
Parameter Description	N/A
Defaults	By default, the WLAN signals are disabled during RADIUS authentication escape.
Command Mode	Global configuration mode
Usage Guide	When the RADIUS server is unreachable, this command can be used to hide the WLAN signals.

	This command takes effect only when the WLAN is enabled with client escape upon RADIUS server failures.

Configuring 802.1X Authentication for Encryption Only When 802.1X and Web-based Authentication Are Enabled

- (Optional) If both 802.1X and web-based authentication is enabled, 802.1X is used only for encryption.
- Enable this function after 802.1X authentication is enabled on the NAS.

Command	**dot1x encryption only**
Parameter Description	N/A
Defaults	This function is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	● The default setting is recommended. ● This command applies only to wireless devices.

Limiting the Rate of Generating Login and Logout Logs

- (Optional)
- You can limit the log generation rate for 802.1X users going online or offline.
- Enable the log generation rate limit after 802.1X authentication is enabled on the NAS.

Command	**dot1x logging rate-limit** *value*
Parameter Description	*value:* Indicates the log generation rate per second for 802.1X users going online or offline. Five logs are generated per second by default. The value 0 indicates that the rate is not limited.
Defaults	Five logs are generated per second by default.
Command Mode	Global configuration mode
Usage Guide	● The default value is recommended. If a large number of users frequently go online or offline, reduce the rate. ● This command applies only to wireless devices.

Enabling SNMP Trap During Login and Logout

- (Optional) The **dot1x user-trap enable** command is used to configure the NAS whether to send traps to the SNMP server when 802.1X users go online or offline.
- Enable SNMP trap after 802.1X authentication is enabled on the NAS.

Command	**dot1x user-trap enable**
Parameter Description	N/A
Defaults	SNMP trap is disabled by default.
Command Mode	Global configuration mode
Usage Guide	● This command applies only to wireless 802.1X authentication devices. ● Configure this command when the NAS needs to send login or logout traps to the SNMP server. You also need to enable trap on the SNMP server. For details, see *Configuring SNMP*.

Enabling Traffic Detection

- (Optional) If traffic detection is enabled, 802.1X authentication users with traffic lower than the threshold in the detection period will be disconnected to avoid incorrect accounting.
- Enable traffic detection after 802.1X authentication is enabled on the NAS.

Command	**dot1x offline-detect** [**interval** *val* | **flow** *num*] *
Parameter Description	*val*: Indicates the detection period. The default value is 8 hours. *num*: Indicates the traffic threshold. The default value is 0 KB.
Defaults	By default, traffic detection is enabled.
Command Mode	WLAN security configuration mode
Usage Guide	• This command applies only to wireless 802.1X authentication devices. • Configure this command when the NAS needs to detect STA logout in a timely manner to prevent incorrect accounting.

Configuring the Default Role of Clients After They Pass the MAB Authentication

- (Optional) Configure the default role of clients after they pass the MAB authentication.

Command	**dot1x mab-default-role** *role-name*
Parameter Description	role-name: Indicates the default role name assigned to the clients after they pass the authentication.
Defaults	No default role is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	This configuration takes effect only in the standalone MAB authentication scenario.

Configuring the Default Role of Clients After They Pass the 802.1X Authentication

- (Optional) Configure the default role of clients after they pass the 802.1X authentication.

Command	**dot1x dot1x-default-role** *role-name*
Parameter Description	*role-name*: Indicates the default role name assigned to the clients after they pass the authentication.
Defaults	No default role is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	After the clients pass the combination of MAB authentication and 802.1X authentication, they are assigned with the same default role as 802.1X authentication.

Configuring the 802.1X Authentication Domain Attribute

- (Optional) It is used to specify an authentication domain for a WLAN.
- It is configured after 802.1X authentication is enabled on the device.

Command	**dot1x domain-name** *domain-name*
Parameter Description	*domain-name*: Specifies the domain name.

Defaults	No domain is configured by default.
Command Mode	WLAN security mode
Usage Guide	During domain name configuration in WLAN security mode, if the username does not include a domain name for authentication, the username will be appended with @ and the configured domain name for authentication. If the username already includes a domain name for authentication, the username will not be appended with @ and the configured domain name for authentication.

Configuring the Device to Filter Logs

- Optional.
- Configure this function after 802.1X authentication is enabled.

Command	**dot1x dbg-filter** *H.H.H*
Parameter Description	*H.H.H*: Indicates the MAC address of a user whose debugging information needs to be output.
Defaults	Debugging information of all authentication users is generated by default.
Command Mode	Global configuration mode
Usage Guide	To identify a fault on a network involving numerous users, you can run this command to filter debugging information of specified users. Avoid too much debugging information, which may affect device performance.

Disabling the Clients to Obtain the IP Address Before They Pass the MAB Authentication

- Optional. This configuration determines whether the clients can obtain the IP address before they pass the MAB authentication.
- Configure this function after enabling the device with the MAB authentication.

Command	**dot1x no-ip-before-mab**
Parameter Description	N/A
Defaults	This function is disabled by default.
Command Mode	WLAN security configuration mode
Usage Guide	This command is used to disable the clients to obtain the IP address before they pass the MAB authentication.

Configuring the Web Authentication After the Clients Pass the MAB Authentication

- Optional. This configuration determines whether the clients need to pass the web authentication after the MAB authentication.
- The device needs to be enabled with both MAB authentication mode and web authentication mode. If the pop-up window for authentication is not automatically displayed on some clients, visit the authentication page manually.

Command	**dot1x mab-pass-to-web**
Parameter Description	N/A
Defaults	This configuration is disabled by default.

Command Mode	WLAN security configuration mode
Usage Guide	This configuration is executed if the web authentication is required after the clients pass the MAB authentication.

1.5 Monitoring

Clearing

⚠ Authentication user information can be cleared after 802.1X is disabled.

Command	Description
no do1x port-control auto	Clears 802.1X user information.
clear dot1x user	Clears 802.1X user information.
dot1x default	Restores the default 802.1X configuration.

Displaying

Command	Description
show radius server	Displays the parameters and status of the RADIUS server.
show dot1x	Displays 802.1X status and parameters.
show dot1x auto-req	Displays the proactive authentication status.
show dot1x port-control	Displays information about controlled ports.
show dot1x probe-timer	Displays the status and parameters of host probe.
show dot1x summary	Displays information about authenticated users.
show dot1x max-req	Displays the maximum count of EAP-Request/Challenge packet retransmission.
show dot1x private-supplicant-only	Displays filtering of non-Ruijie supplicants.
show dot1x re-authentication	Displays the -eauthentication status.
show dot1x reauth-max	Displays the maximum count of EAP-Request/Identity packet retransmission.
show dot1x timeout quiet-period	Displays the quiet period after authentication fails.
show dot1x timeout re-authperiod	Displays the re-authentication interval.
show dot1x timeout server-timeout	Displays the timeout interval of the authentication server.
show dot1x timeout supp-timeout	Displays the timeout interval of the supplicant.
show dot1x timeout tx-period	Displays the interval for retransmitting EAP-Request/Identity packets.
show dot1x user mac	Displays user information based on the MAC address.
show dot1x user name	Displays user information based on the user name.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug aaa	Debugs AAA. (For details, see *Configuring AAA*.)
debug radius	Debugs RADIUS. (For details, see *Configuring RADIUS*.)
debug dot1x event	Debugs 802.1X events.
debug dot1x packet	Debugs 802.1X packets.
debug dot1x stm	Debugs 802.1X state machine (STM).
debug dot1x com	Debugs 802.1X internal communication.
debug dot1x error	Debugs 802.1X errors.

1 Configuring Local EAP

1.1 Overview

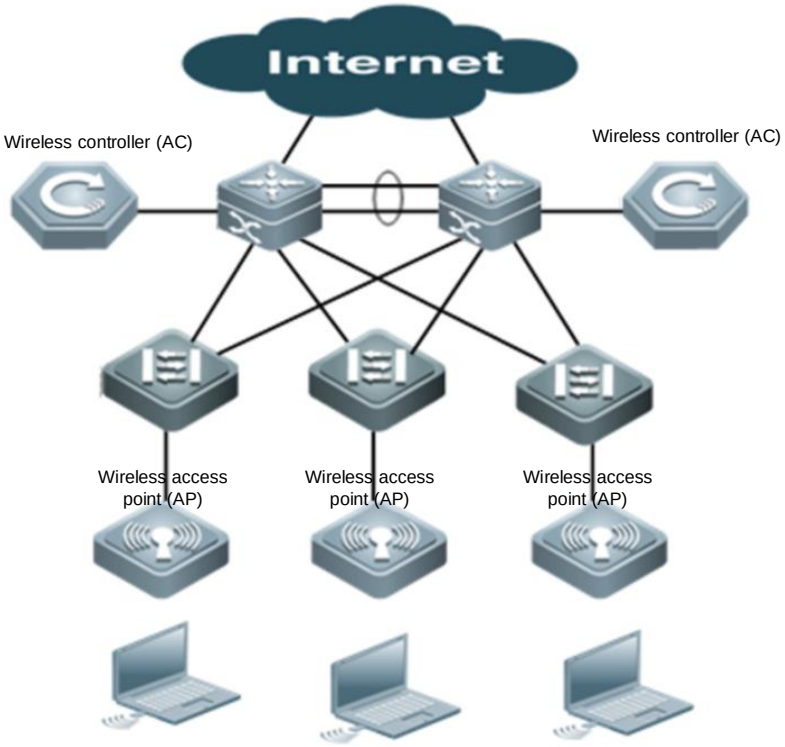
The Local Extensible Authentication Protocol (EAP) functions as a local authentication service, allowing the device to authenticate clients locally using an EAP authentication protocol, eliminating the need for an external authentication server deployment. For example, the device can authenticate STAs that use 802.1X authentication. The device that provides the local EAP function serves as an EAP server. It can function as the preferred authentication server to provide the authentication service or be used as the backup of the external authentication server to provide the authentication service when the external authentication server is unavailable. Local EAP supports Protected Extensible Authentication Protocol v0 (PEAPv0)/Microsoft Challenge Handshake Authentication Protocol version 2 (MS-CHAPv2) and PEAPv1/Generic Token Card (GTC).

Local EAP also provides the EAP termination function. EAP termination enables the device to terminate EAP packets on itself and to forward EAP packets with simple authentication information to the external server. In this case, the device can be used with an external authentication server that cannot provide the required EAP mode. For example, PEAPv1/GTC is required for client authentication, and the external authentication server can only provide the PAP authentication mode.

Protocols and Standards

- RFC 3748: Extensible Authentication Protocol (EAP)
- RFC 4137: State Machines for Extensible Authentication Protocol (EAP)
- RFC 5216: The EAP-TLS Authentication Protocol
- RFC 5246: The Transport Layer Security (TLS) Protocol Version 1.2
- RFC 5280: Internet X.509 Public Key Infrastructure Certificate and Certificate Revocation List (CRL) Profile

1.2 Applications



Application	Description
Local Authentication	EAP functions as a local authentication service, allowing the device to authenticate clients locally using an EAP authentication protocol, eliminating the need for an external authentication server deployment.
EAP Termination	EAP termination enables the device to terminate EAP packets on itself and to forward EAP packets with simple authentication information to the external server.

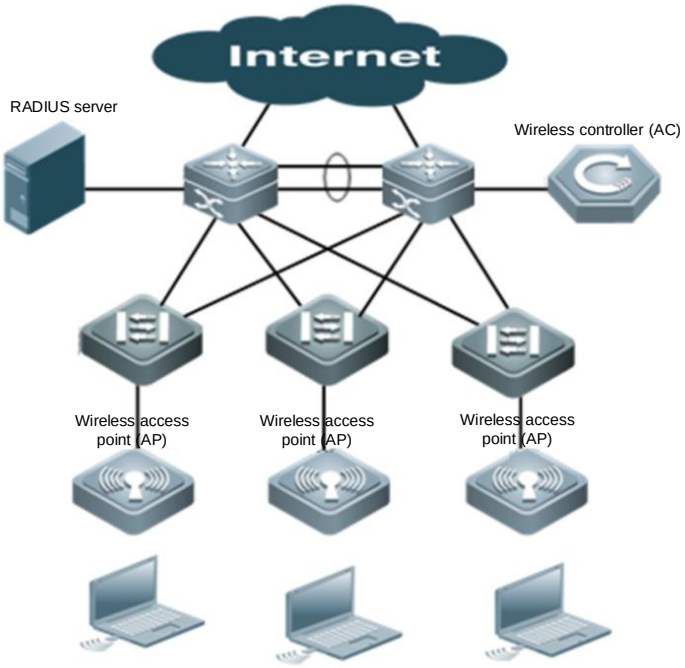
1.2.1 Local Authentication

Scenario

As shown in Figure 1-1, wireless access controllers (ACs) and wireless access points (APs) form a wireless network. The ACs are configured to adopt 802.1X authentication and local authentication of the local EAP service. The AC functions as the authentication server, without deploying an external authentication server.

Figure 1-1

Deployment



- Configure a wireless local area network (WLAN).
- Configure 802.1X authentication to ensure security of the WLAN.
- Configure the 802.1X authentication method list.
- Configure local EAP and use the account of the local authentication server as the authentication username and password.

1.2.2 EAP Termination

Scenario

As shown in Figure 1-2, ACs and APs form a wireless network, and a RADIUS authentication server is deployed on the network. 802.1X access authentication is configured on ACs. Because the RADIUS authentication server does not support EAP, the EAP termination function of the local EAP service needs to be enabled on the ACs.

Figure 1-2

Deployment

- Configure a WLAN.
- Configure the 802.1X authentication mode to ensure security of the WLAN.
- Configure the 802.1X authentication method list.
- Configure the RADIUS server.
- Enable the EAP termination function of the local EAP service.

1.3 Features

Basic Concepts

EAP

EAP is an authentication framework that defines the basic authentication process and message format, but does not define the specific authentication method. The data exchange process and encapsulation format need to be defined for each authentication protocol based on the EAP framework. Common EAP authentication protocols include EAP-MD5, EAP-GTC, EAP-TLS, EAP-MS-CHAPv2, PEAPv0/MS-CHAPv2, and PEAPv1/GTC. EAP-TLS, EAP-MS-CHAPv2, PEAPv0/MS-CHAPv2, and PEAPv1/GTC are commonly used on wireless networks.

- PEAPv0/MS-CHAPv2

  PEAPv0/MS-CHAPv2 is the most commonly used authentication protocol on wireless networks and supported most systems. It uses outer-layer PEAP to establish a Transport Layer Security (TLS) tunnel to protect authentication information; it uses inner-layer EAP-MS-CHAPv2 to verify users' identities.

- PEAPv1/GTC

PEAPv1/GTC is similar to PEAPv0/MS-CHAPv2 and is supported by most mobile devices. However, Windows OSs do not support the protocol by default. It uses outer-layer PEAP and inner-layer EAP-GTC that is used to verify users' identities.

EAP Termination

An EAP authentication protocol is run between the device enabled with the local EAP service and an authentication client, while another authentication protocol (may be not an EAP protocol) is run between the device enabled with the local EAP service and the external authentication server. The device enabled with the local EAP service functions as the agent to forward authentication packets or results between the client and external authentication server, the EAP termination function enables the device enabled with the local EAP service local EAP service to terminate EAP packets on the device, to extract necessary authentication information, and to forward it to the external authentication server. The device enabled with the local EAP service encapsulates authentication results returned by the external authentication server or authentication information that needs to be transferred to the client into the specified EAP packet, and then forwards it to the authentication client. This function is used when the device interworks with an authentication server that does not support the specified EAP authentication mode. ACs support two types of EAP termination: EAP-GTC termination and EAP-MS-CHAPv2 termination.

- EAP-GTC termination

  When EAP-GTC is run between the device enabled with the local EAP service and a client, the device obtains the username and password submitted by the client through EAP-GTC and uses the username and password to send a PAP authentication request to the external authentication server. The external authentication server determines the authentication result.

- EAP-MS-CHAPv2 termination

  When EAP-MS-CHAPv2 is run between the device enabled with the local EAP service and a client, the device obtains the challenge and peer response through EAP-MSCHAPv2, encapsulates them into an MS-CHAPv2 authentication request, and sends it to the external authentication server. The external authentication server determines the authentication result.

PKI

Some EAP modes supported by the local EAP service require the support of Public Key Infrastructure (PKI). For example, PEAP needs to adopt an asymmetric encryption algorithm to establish a trusted encrypted tunnel, such as a TLS tunnel with the client.

PKI is an identity identification and communication encryption system based on the asymmetric password system, and uses certificates. In PKI, the communication parties use a trusted third party to determine whether the identity of the peer is consistent as stated. The trusted third party is a certificate authority (CA). The identity information in PKI is identified using the X509 certificate. The certificate includes the identity information of the owner, public key of the owner, and signature of the trusted third-party to the information. In addition, certificates are classified into self-signed and CA-issued certificates.

- Self-signed certificates are signed by CAs. A CA uses a private key to sign the identity information and public key to obtain a CA certificate, and the certificate is the ID of the CA. Because the certificate of a CA contains the public key of the CA, the public key can be used to verify certificates issued by the CA. These certificates are signed using the private key of the CA and can be verified using the public key of the CA. When a CA is trusted, a

communication party can use the certificate of the CA to verify the certificate of the peer to ensure that it communicates with the correct entity.

- CA-issued certificates are obtained by using the private key of a CA to sign certificate requests. An entity can send a certificate issuing request to a CA. The request contains the identity and public key of the entity. After the CA uses its private key to sign the request, the certificate required by the entity is obtained. Then the entity can use the certificate to identify its own identity. If the peer trusts the same CA, the peer can verify the identity of the entity.

In addition to identity verification, the public and private key pairs have the asymmetric encryption and decryption function. Communication parties can use their private keys and public keys of the peer to establish an encrypted communication channel. This tunnel cannot be decrypted by others, so data transmitted in this tunnel is secure and trusted.

EAP-TLS and PEAP depend on PKI. The two protocols will establish a TLS tunnel between the authentication client and authentication server for subsequent identity authentication. To establish the tunnel, use the certificate and public and private keys of the server as well as the CA certificate (optical) for PEAP. If the client chooses not to verify the server certificate, the CA certificate is not required. To establish the tunnel, EAP-TLS needs the certificates and public and private keys of the server and client as well as the CA certificate.

Overview

Feature	Description
Local Authentication	The device locally authenticates clients that use an EAP authentication protocol, eliminating the need for an external authentication server deployment. The device can function as the preferred authentication server to provide the authentication service or be used as the backup of the external authentication server to provide the authentication service when the external authentication server is unavailable.
EAP Termination	EAP termination enables the device to terminate EAP packets on itself and to forward EAP packets with simple authentication information to the external server. In this case, the device can be used with an external authentication server that cannot provide the required EAP mode. For example, PEAPv1/GTC is required for client authentication, and the external authentication server can only provide the PAP authentication mode.

1.3.1 Local Authentication

The device locally authenticates clients that use an EAP authentication protocol, eliminating the need for an external authentication server deployment. The device can function as the preferred authentication server to provide the authentication service or be used as the backup of the external authentication server to provide the authentication service when the external authentication server is unavailable.

Working Principle

During local authentication, the working principle of the device enabled with the local EAP service is similar to that of the RADIUS server and can be regarded as an authentication server. When an external RADIUS authentication server is used, EAP authentication requests of authentication clients need to be encapsulated into RADIUS packets before being sent to the RADIUS server. When the device enabled with the local EAP service is used as the authentication server, EAP authentication requests of authentication clients are directly processed by the device.

The device enabled with the local EAP service supports various EAP modes and different internal modes of PEAP. The device will select the mode for authenticating the client based on the sequence in which the modes were configured. During EAP authentication, the EAP mode is determined by the server.

Related Configuration

Configuring the 802.1X Authentication Method List

If the device enabled with the local EAP service is used as the authentication server, the local method needs to be specified in the 802.1X authentication method list.

Run the **aaa authentication dot1x** {**default** | *list-name*} *method1* [*method2*...] command to specify the 802.1X authentication method list, for example, **aaa authentication dot1x default local**.

Authentication request packets of clients are sent to the device enabled with the local EAP service for local authentication only when the local method is specified in the 802.1X authentication method list.

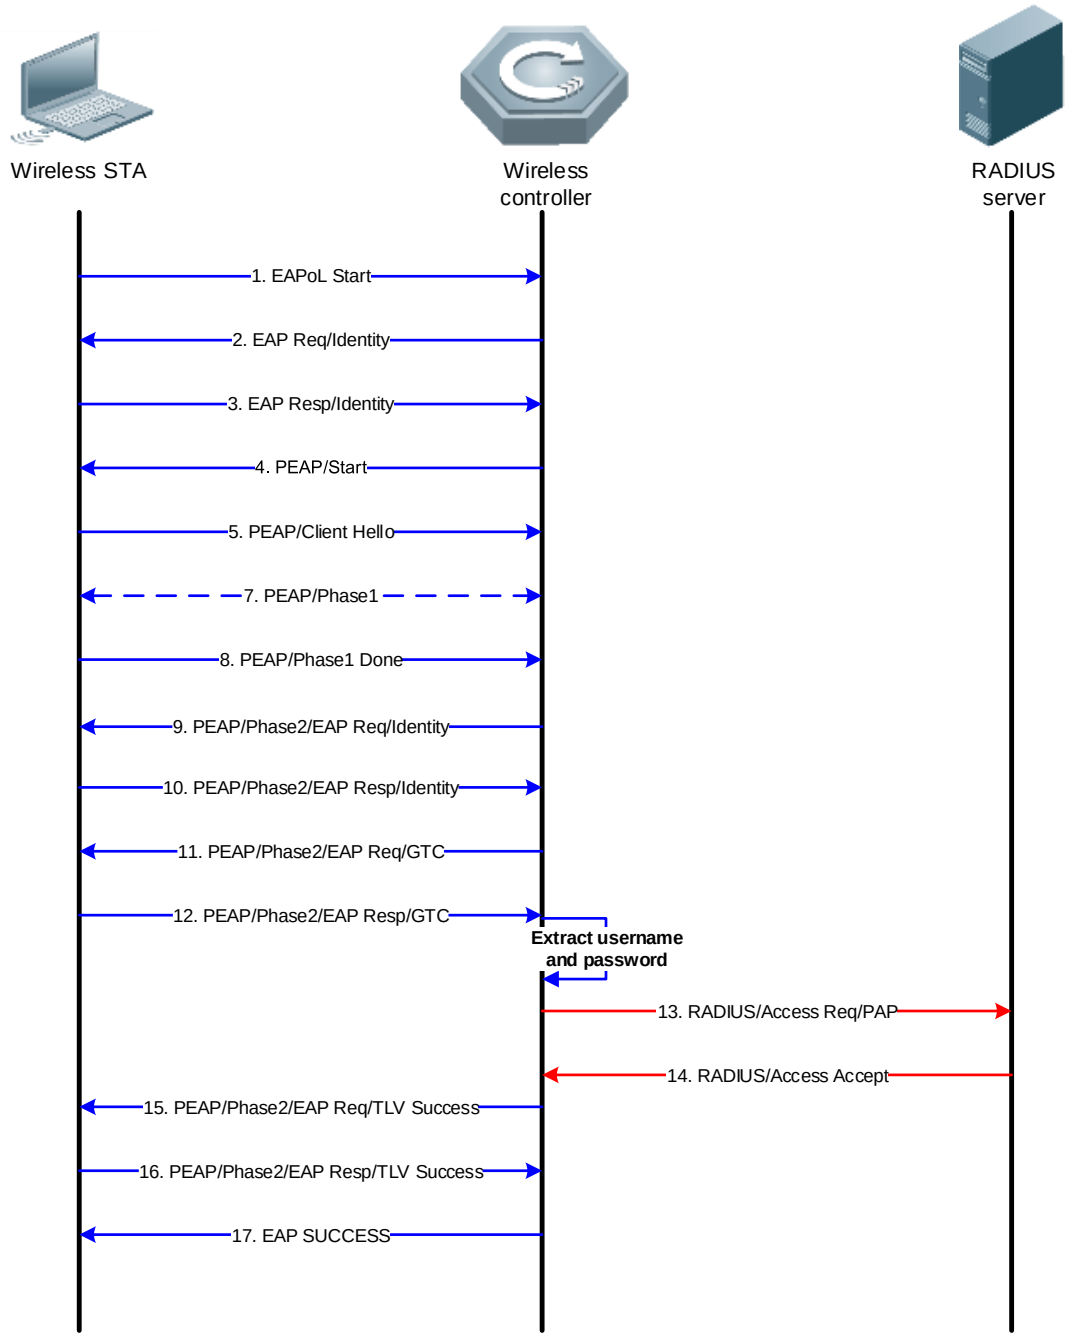
Configuring the Modes Used for Identity Authentication with a Client

Configure the EAP modes of the local EAP service to authenticate identities of clients. By default, only PEAP is supported, and PEAP internal modes of EAP-MS-CHAPv2 and EAP-GTC are supported and in descending order of priroity.

Only PEAP is supported, and cannot be changed. The supported PEAP internal modes and sequence can be changed by running the **peap inner-methods** { **eap-mschapv2** [**eap-gtc**] | **eap-gtc** [**eap-mschapv2**] } command. The mode that was configured first is preferred.

1.3.2 EAP Termination

EAP termination enables the device to terminate EAP packets on itself and to forward EAP packets with simple authentication information to the external server. In this case, the device can be used with an external authentication server that cannot provide the required EAP mode. For example, PEAPv1/GTC is required for client authentication, and the external authentication server can only provide the PAP authentication mode.



Working Principle

EAP-GTC termination is used as an example to describe the working principle of EAP termination. Figure 1-3 shows the flowchart of EAP-GTC termination. The RADIUS server supports PAP authentication only. However, PEAPv1/GTC is used between the AC and STA.

- Steps 1 to 12: The AC exchanges packets with the STA, which is required by PEAPv1/GTC. After step 12 is performed, the AC obtains the STA's authentication credential, including the username and cleartext password.
- Steps 13 to 14: The local EAP module uses the obtained authentication credential to initiate PAP authentication to the RADIUS server and obtains the result that authentication succeeds.
- Steps 15 to 17: Based on the result returned by the RADIUS server, the local EAP module continues to perform PEAPv1/GTC authentication.

In Figure 1-3, when the AC performs EAP-GTC termination, the STA does not detect the operation and regards that PEAPv1/GTC authentication is performed. However, the RADIUS server regards that the STA is experiencing PAP authentication. The flowcharts of PEAP termination and EAP-MSCHAPv2 are similar.

Figure 1-3

Related Configuration

↘ Configuring the AAA Authentication Method List and the RADIUS Authentication Server

When the EAP termination function is used, the device enabled with the local EAP service serves as the agent and forwards some information to the external server. Therefore, the external authentication server needs to be configured.

Run the **radius-server host** { *ipv4-address* | *ipv6-address*} [**auth-port** *port-number*] [**acct-port** *port-number*] command to specify the external authentication server. Run the **aaa authentication localeap default group** { **radius |**

group-name } command to specify the external authentication server to which the authentication request packets are sent for authentication after termination.

Configuring EAP Termination

EAP termination is not configured by default.

Run the **eap-gtc terminate** command to enable EAP-GTC termination; run the **eap-mschapv2 terminate** command to enable EAP-MS-CHAPV2 termination.

1.4 Configuration

Configuration	Description and Command	
Configuring Local Authentication	(Optional) It is used to configure the device as the authentication server, without deploying an external authentication server or using the device as the backup of the external authentication server.	
	eap-methods { **peap** }	Configures the EAP mode used by the device enabled with the local EAP service to authenticate identities of clients. Only PEAP is supported.
	peap inner-methods { **eap-mschapv2** [**eap-gtc**] | **eap-gtc** [**eap-mschapv2**] }	Configures the PEAP internal mode used by the device enabled with the local EAP service to authenticate the identities of clients. The mode configured first is preferred. At least one mode needs to be selected.
Configuring EAP Termination	(Optional) It is used to configure the device to terminate EAP packets on itself and to forward EAP packets with simple authentication information to the external server. In this case, the device can be used with an external authentication server that cannot provide the required EAP mode.	
	eap-gtc terminate	Configures EAP-GTC termination.
	eap-mschapv2 terminate	Configures EAP-MS-CHAPv2 termination.
Configuring PKI	(Optional) It is used to configure whether the device enabled with the local EAP service uses the self-signed PKI information generated by the device or the PKI information in PKCS#12 format imported by using a command. The self-signed PKI information generated by the device is used by default.	
	pki-manage generate self-signed default	Enables the device to generate the self-signed PKI information when no PKI information exists on the device. In most situations, PKI information does not need to be generated using a command. In special cases (for example, security is required), this command can be used to re-generate the self-signed PKI information.

	pki-manage import pfx *filepath* [**password**]	Imports required PKI information to the device using a file in PKCS#12 format (file name extension is pfx or p12) when the self-signed PKI information generated by the device does not meet user requirements.
	server restart	Restarts the device enabled with the local EAP service for the new PKI information to take effect after the PKI information used by the device is updated.

1.4.1 Configuring Local Authentication

Configuration Effect

- Optional.
- Local authentication is performed for clients that use an EAP authentication protocol, without the need to deploy an external authentication server. The device can serve as the preferred authentication server to provide the authentication service directly or be used as the backup of the external authentication server to provide the authentication service when the external authentication server is unavailable.

Configuration Steps

↘ Configuring the EAP Mode Sequence

- Optional.
- Only PEAP is supported and the default EAP mode is PEAP., so there is no need to configure the EAP mode sequence.

↘ Configuring the PEAP Internal Mode Sequence

- Optional.
- By default, the supported PEAP internal modes are EAP-MSCHAPv2 and EAP-GTC, and EAP-MSCHAPv2 and EAP-GTC are in descending order of priority. Unless otherwise specified, the PEAP internal mode sequence does not need to be configured.

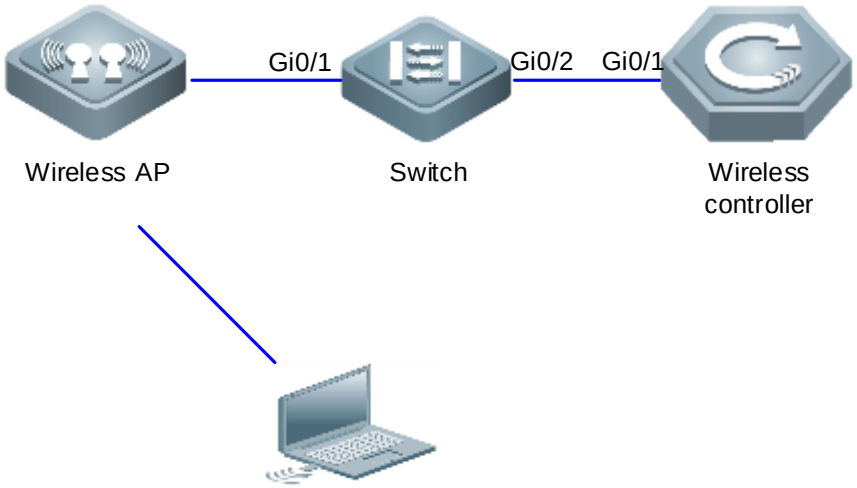
Verification

- Run the **show localeap methods** command to display the authentication mode configuration.

Related Commands

↘ Configuring the EAP Mode Sequence

Command	**eap-methods** { **peap** }
Parameter Description	N/A
Command Mode	Local EAP mode
Usage Guide	This command is used to configure the EAP modes used by the device enabled with the local EAP service for authenticating identities of clients. Only PEAP is supported.



↘ Configuring the PEAP Internal Mode Sequence

Command	**peap inner-methods** { **eap-mschapv2** [**eap-gtc**] | **eap-gtc** [**eap-mschapv2**] }
Parameter Description	N/A
Command Mode	Local EAP mode
Usage Guide	This command is used to configure the PEAP internal modes used by the device enabled with the local EAP service to authenticate identities of clients. The mode configured first is preferred. At least one mode needs to be selected.

Configuration Example

Configuring Local Authentication

As shown in Figure 1-4, the AC and AP form a wireless network. The AC is configured to adopt 802.1X authentication and local authentication of the local EAP service. The AC functions as the authentication server, and no external authentication server needs to be deployed.

Scenario **Figure 1-4**	
Configuration Steps	● Configure a WLAN. ● Configure 802.1X authentication to ensure security of the WLAN. ● Configure the 802.1X authentication method list. ● Configure local EAP function and use the account of the local authentication server as the authentication username and password.

Switch	`# Assign the downlink ports of the switch to VLAN 100 to which the AP belongs.`
	`Hostname# configure terminal`
	`Hostname(config)# interface GigabitEthernet 0/1`
	`Hostname(config-if-GigabitEthernet 0/1)# poe enable`
	`Hostname(config-if-GigabitEthernet 0/1)# switchport access vlan 100`
	`# Configure the uplink ports of the switch as Trunk ports.`
	`Hostname(config)# exit`
	`Hostname(config)# interface GigabitEthernet 0/2`
	`Hostname(config-if-GigabitEthernet 0/2)# switchport mode trunk`

AC	`# Configure GigabitEthernet 0/1 connected with the switch as a Trunk port.` `Hostname# configure terminal`

```
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport mode trunk
# Configure the IP address of Loopback 0 for the AC to establish a CAPWAP tunnel with the AP.
Hostname(config-if-GigabitEthernet 0/1)# exit
Hostname(config)# interface Loopback 0
Hostname(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255
# Configure AP VLAN 100 and STA VLAN 10, and configure the AC as the DHCP server for VLAN 100 and VLAN 10.
Hostname(config)#vlan 100
Hostname(config-vlan)#exit
Hostname(config)#interface vlan 100
Hostname(config-if-VLAN 100)# ip address 192.168.100.1 255.255.255.0
Hostname(config)#vlan 10
Hostname(config-vlan)#exit
Hostname(config)#interface vlan 10
Hostname(config-if-VLAN 100)# ip address 192.168.10.1 255.255.255.0
Hostname(config-if-VLAN 100)# exit
Hostname(config)# service dhcp
Hostname(config)# ip dhcp pool ap_vlan100
Hostname(dhcp-config)# option 138 ip 10.1.1.1   # Here must be the IP address of Loopback 0.
Hostname(dhcp-config)#  network  192.168.100.0  255.255.255.0  192.168.100.10 192.168.100.100
Hostname(dhcp-config)# default-router 192.168.100.1
Hostname(dhcp-config)# exit
Hostname(config)# ip dhcp pool sta_vlan10
Hostname(dhcp-config)#  network  192.168.100.0  255.255.255.0  192.168.10.10 192.168.10.100

Hostname(dhcp-config)# exit
# Configure a WLAN.
Hostname(config)#wlan-config 1 miaosf_eap
Hostname(config-wlan)#exit
Hostname(config)#ap-group default
Hostname(config-ap-group)#interface-mapping 1 10
Hostname(config-ap-group)# exit
# Configure the 802.1X access authentication mode to ensure wireless network security.
Hostname(config)#wlansec 1
Hostname(config-wlansec)# security rsn enable
Hostname(config-wlansec)# security rsn ciphers aes enable
Hostname(config-wlansec)# security rsn akm 802.1x enable
Hostname(config-wlansec)# exit
```

	# Configure the 802.1X authentication method list. Hostname(config)# dot1x authentication default Hostname(config)# aaa new-model Hostname(config)# aaa authentication login default none Hostname(config)# aaa authentication dot1x default local Hostname(config)# aaa authentication enable default none # Configure local EAP function and use the account of the local authentication server as the authentication username and password. Hostname(config)# username admin password admin
Verification	Enter the username and password (**admin**) on the STA (such as a mobile phone). The STA can connect to WLAN **miaosf_eap**.

Common Errors

- The 802.1X authentication method list is incorrectly configured.

1.4.2 Configuring EAP Termination

Configuration Effect

- Optional.
- Configure the device to terminate EAP packets on itself and to forward EAP packets with simple authentication information to the external server. In this case, the device can be used with an external authentication server that cannot provide the required EAP mode.

Configuration Steps

↘ Configuring the AAA Authentication Method List and the RADIUS Authentication Server

- Mandatory.
- When EAP termination is used, the device enabled with the local EAP service serves as the agent to forward authentication information to the external authentication server. Therefore, the external authentication server needs to be configured.

↘ Configuring EAP-GTC Termination and EAP-MS-CHAPv2 Termination

- Mandatory.
- Only two types of termination are supported. You can select either one or configure both of them.

Verification

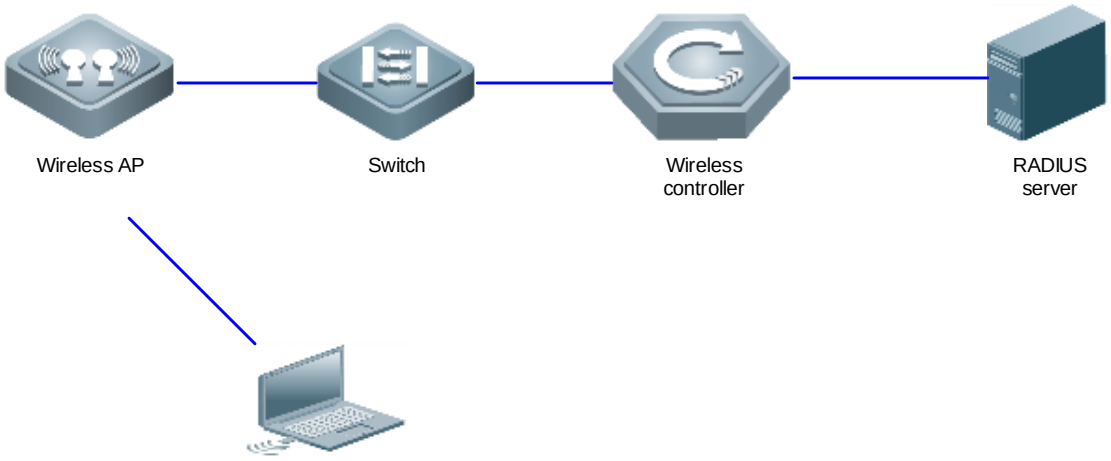
- Run the **show localeap methods** command to display the EAP termination configuration.

Related Commands

↘ Configuring the AAA Authentication Method List and the RADIUS Authentication Server

Command	**radius-server host** { *ipv4-address* | *ipv6-address*} [**auth-port** *port-number*] [**acct-port** *port-number*] **aaa authentication localeap default group** { **radius |** *group-name* }
Parameter	*group-name*: Indicates the name of the server group from which the server is used by the device enabled

Description	with the local EAP service as the external authentication server.
Command Mode	Global configuration mode
Usage Guide	The first command is provided by the RADIUS module, and the second command is provided by the AAA module.



Configuring EAP-GTC Termination and EAP-MS-CHAPv2 Termination

Command	**eap-gtc terminate** **eap-mschapv2 terminate**
Parameter Description	**N/A**
Command Mode	Local EAP mode
Usage Guide	The commands are used to enable EAP-GTC termination and EAP-MSCHAPv2 termination.

Configuration Example

Configuring EAP Termination

As shown in Figure 1-5, the AC and AP form a wireless network, and the AC connects to the RADIUS authentication server. 802.1X authentication is configured on the AC. The STA adopts PEAPv1/GTC. Because the RADIUS authentication server does not support PEAPv1/GTC termination, EAP-GTC termination needs to be configured on the AC.

Scenario **Figure 1-5**	
Configuration Steps	● Configure a WLAN. ● Configure 802.1X authentication to ensure security of the WLAN. ● Configure the 802.1X authentication method list. ● Configure the RADIUS authentication server. ● Enable the EAP termination function on the device enabled with the local EAP service.
Switch	`# Assign the downlink ports of the switch to VLAN 100 to which the AP belongs.`

	Hostname# configure terminal Hostname(config)# interface GigabitEthernet 0/1 Hostname(config-if-GigabitEthernet 0/1)# poe enable Hostname(config-if-GigabitEthernet 0/1)# switchport access vlan 100 # Configure the uplink ports of the switch as Trunk ports. Hostname(config)# exit Hostname(config)# interface GigabitEthernet 0/2 Hostname(config-if-GigabitEthernet 0/2)# switchport mode trunk
AC	# Configure GigabitEthernet 0/1 connected with the switch as a Trunk port. Hostname# configure terminal Hostname(config)# interface GigabitEthernet 0/1 Hostname(config-if-GigabitEthernet 0/1)# switchport mode trunk # Configure the IP address of Loopback 0 for the AC to establish a CAPWAP tunnel with the AP. Hostname(config-if-GigabitEthernet 0/1)# exit Hostname(config)# interface Loopback 0 Hostname(config-if-Loopback 0)# ip address 10.1.1.1 255.255.255.255 # Configure AP VLAN 100 and STA VLAN 10, and configure the AC as the DHCP server for VLAN 100 and VLAN 10. Hostname(config)#vlan 100 Hostname(config-vlan)#exit Hostname(config)#interface vlan 100 Hostname(config-if-VLAN 100)# ip address 192.168.100.1 255.255.255.0 Hostname(config)#vlan 10 Hostname(config-vlan)#exit Hostname(config)#interface vlan 10 Hostname(config-if-VLAN 100)# ip address 192.168.10.1 255.255.255.0 Hostname(config-if-VLAN 100)# exit Hostname(config)# service dhcp Hostname(config)# ip dhcp pool ap_vlan100 Hostname(dhcp-config)# option 138 ip 10.1.1.1 # Here must be the IP address of Loopback 0. Hostname(config)#wlan-config 1 miaosf_eap Hostname(config-wlan)#exit

	Hostname(config)#ap-group default Hostname(config-ap-group)#interface-mapping 1 10 Hostname(config-ap-group)# exit # Configure the 802.1X access authentication mode to ensure wireless network security. Hostname(config)#wlansec 1 Hostname(config-wlansec)# security rsn enable Hostname(config-wlansec)# security rsn ciphers aes enable Hostname(config-wlansec)# security rsn akm 802.1x enable Hostname(config-wlansec)# exit # Configure the 802.1X authentication method list. Hostname(config)# dot1x authentication default Hostname(config)# aaa new-model Hostname(config)# aaa authentication login default none Hostname(config)# aaa authentication dot1x default local Hostname(config)# aaa authentication enable default none Hostname(config)# aaa authentication localeap default group radius # Configure the RADIUS server. Hostname(config)# radius-server host 192.168.197.79 Hostname(config)# radius-server key Hostname
Verification	If the username and password configured on the RADIUS server are **admin**, enter the username and password on the STA (such as a mobile phone). The STA can connect to WLAN **miaosf_eap**.

Common Errors

- The 802.1X authentication method list is incorrectly configured.

1.4.3 Configuring PKI

Configuration Effect

- Optional.
- The device enabled with the local EAP service can use the self-signed PKI information generated by the device or the PKI information in PKCS#12 format imported by using a command. The self-signed PKI information generated by the device is used by default.
- The PKI information imported by using a command is prior to the PKI information generated by the device. When both the self-signed PKI information generated by the device and the imported PKI information exist, the device will use the imported PKI information. When the device finds that the preceding two types of PKI information do not exist upon startup, the device will automatically generate self-signed PKI information and use it.

Configuration Steps

↘ Configuring the Device to Re-generate the Self-signed PKI Information

- Optional.

- When no PKI information existson the device, the device automatically generates the self-signed PKI information. Typically, PKI information does not need to be generated using a command. In specified scenarios (for example, security is required), the device can be configured to re-generate the self-signed PKI information.

Importing PKI Information in PKCS#12 Format

- Optional.
- When the self-signed PKI information generated by the device does not meet user requirements, you can import the required PKI information to the device using a file in PKCS#12 format (file name extension is pfx or p12).

Restarting the Device Enabled with the Local EAP Service for New PKI Information to Take Effect

- Optional.
- After the PKI information used by the device enabled with the local EAP service is updated, the device needs to be restarted for the new PKI information to take effect in the following scenarios:
  - The self-signed PKI information is being used. However, the self-signed PKI information is re-generated, or PKI information is imported externally.
  - The PKI information imported externally is being used. However, the externally imported PKI information is deleted, or new PKI information is re-imported.
- Note: After the device enabled with the local EAP service is restarted, all STAs that go online after being authenticated by the local EAP service will go offline.

Verification

- Run the **show localeap pki** [**self-signed | pfx** command to display PKI information on the device enabled with the local EAP service.

Related Commands

Re-generating the Self-signed PKI Information

Command	**pki-manage generate self-signed default**
Parameter Description	**N/A**
Command Mode	Local EAP configuration mode
Usage Guide	When no PKI information exists on the device, the device automatically generates the self-signed PKI information. Typically, PKI information does not need to be generated using a command. In specified scenarios (for example, security is required), the device can be configured to re-generate the self-signed PKI information. After the self-signed PKI information is re-generated, the device enabled with the local EAP service needs to be restarted for the PKI information to take effect.

Importing PKI Information in PKCS#12 Format

Command	**pki-manage import pfx** *filepath* [**password** *password*]
Parameter Description	*filepath*: Indicates the path for restoring the file in PKCS#12 format in the flash memory. *password*: Indicates the password for decrypting the imported file. If the file is not encrypted, no

	password needs to be entered.
Command Mode	Local EAP mode
Usage Guide	When the self-signed PKI information generated by the device does not meet user requirements, you can import the required PKI information to the device using a file in PKCS#12 format (file name extension is pfx or p12). After the PKI information is imported or the imported PKI information is deleted, the device enabled with the local EAP service needs to be restarted for the PKI information to take effect.

Restarting the Device Enabled with the Local EAP Service for New PKI Information to Take Effect

Command	**service restart**
Parameter Description	**N/A**
Command Mode	Local EAP mode
Usage Guide	After the PKI information used by the local EAP service is updated, the device enabled with the local EAP service needs to be restarted for the new PKI information to take effect in the following scenarios: ■ The self-signed PKI information is being used. However, the self-signed PKI information is re-generated, or PKI information is imported externally. ■ The PKI information imported externally is being used. However, the externally imported PKI information is deleted, or new PKI information is re-imported. After the device enabled with the local EAP service is restarted, all STAs that go online after being authenticated by the local EAP service will go offline.

Configuration Example

Uploading the PKCS#12 File to the Device and Configuring the Device Enabled with the Local EAP Service to Import PKI Information in PKCS#12 Format

Configuration Steps	● Upload the PKCS#12 file to the device. ● Configure the device enabled with the local EAP service to import PKI information in PKCS#12 format.

	`# Upload the PKCS#12 file to the device.`
	`Hostname# copy tftp://192.168.1.1/pki.pfx flash:pki.pfx`
	`# Configure the local EAP service to import PKI information in PKCS#12 format.`
	`Hostname# config`
	`Enter configuration commands, one per line. End with CNTL/Z.`
	`Hostname(config)#localeap`
	`Hostname(config-localeap)#pki-manage import pfx pki.pfx password filepassword`
	`Apr 29 23:03:27: %LOCALEAP-6-PKIMANAGE: Import PKI from file [pki.pfx] successfully`

Verification	● Run the **show localeap pki** [**self-signed | pfx** command to display PKI information on the device enabled with the local EAP service.

Configuration Steps	● Upload the PKCS#12 file to the device. ● Configure the device enabled with the local EAP service to import PKI information in PKCS#12 format.

	`# Upload the PKCS#12 file to the device.`
	`Hostname# copy tftp://192.168.1.1/pki.pfx flash:pki.pfx`
	`# Configure the local EAP service to import PKI information in PKCS#12 format.`
	`Hostname# config`
	`Enter configuration commands, one per line. End with CNTL/Z.`
	`Hostname(config)#localeap`
	`Hostname(config-localeap)#pki-manage import pfx pki.pfx password filepassword`
	`Apr 29 23:03:27: %LOCALEAP-6-PKIMANAGE: Import PKI from file [pki.pfx] successfully`

Verification	● Run the **show localeap pki** [**self-signed | pfx** command to display PKI information on the device enabled with the local EAP service.

	`Hostname#show localeap pki`
	`TYPE ACTIVATED`
	`----------`
	`Self-Signed Yes`
	`* PFX-Imported Yes`

1.5 Monitoring

Displaying

Command	Description
show localeap methods	Displays information related to EAP methods.
show localeap pki [**self-signed | pfx**]	Displays PKI summary information.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug localeap pki	Debugs the device enabled with the local EAP service.
debug localeap user {verbose | error | add mac *mac-address* **| delete mac** *mac-address***}**	Debugs user authentication on the device enabled with the local EAP service.

1 Configuring Web-based Authentication

1.1 Overview

1.1.1 Web-based Authentication

Web-based authentication is a method of identity authentication that regulates user permissions for network access. It effectively manages user network access by employing the use of common web browsers, eliminating the need for dedicated authentication software on clients.

When non-authenticated users attempt to access the Internet using a browser, the network access server (NAS) forcibly redirects them to a specified site, which is a web-based authentication server, also known as a portal server. Users can access services on the portal server without authentication, such as downloading security patches and reading notices. However, if a user wants to access network resources beyond the portal server, the user must be authenticated by the portal server through a browser.

Besides providing convenient authentication, the portal server interacts with browsers by providing personalized services, such as advertisements, notices, and business links on the authentication page.

Web-based Authentication Versions

Ruijie offers three web-based authentication modes: first-generation, second-generation, and built-in portal authentication. The authentication process varies depending on the version being used. For details, see 1.3 Features.

The three web-based authentication modes differ significantly in features and configurations. You are advised to read through relevant chapters carefully before proceeding with the configuration.

Both second-generation web-based authentication and built-in portal web-based authentication support local account authentication on the NAS. Because Remote Authentication Dial In User Service (RADIUS) authentication is used in most situations, it is used as an example in 1.2 "Applications".

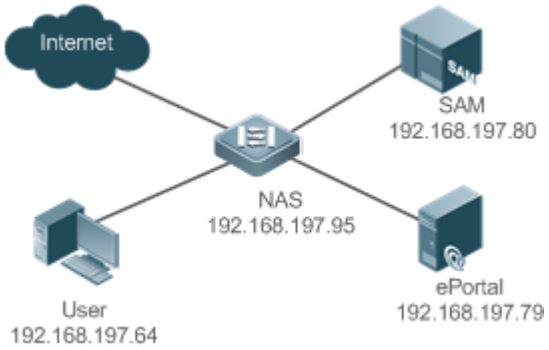
Web-based authentication supports user online traffic detection. For details, see *Configuring SCC*.

Web-based authentication allows for authentication of domain names, meaning that accounts can be authenticated in the format of user name@domain name. To enable this function, you must enable domain-name-based authentication, authorization, and accounting (AAA). For details, see *Configuring AAA*.

Protocols and Standards

- HTTP: RFC 1945 and RFC 2068
- HTTPS: RFC 2818
- SNMP: RFC 1157 and RFC 2578
- RADIUS: RFC 2865, RFC 2866, and RFC 3576
- For the standards related to MAC address-based SMS authentication, see the *CMCC WLAN Device Interface Standards V3.1.0_20130901 (MAC Address-Based Authentication Extension), Zhejiang CMCC WLAN Fast Authentication Scheme – Interface Standards V1.1-2011.3.22*, and *WLAN Fast MAC Address-Based SMS Authentication Scheme V1.1-2011.3.21*.

1.2 Applications



Application	Description
Basic Scenario of Web-based Authentication	In the typical Layer 2 authentication scenario, the NAS, portal server, and RADIUS server constitute an authentication system that connects clients to the NAS through the Layer 2 network.

1.2.1 Basic Scenario of Web-based Authentication

Scenario

- A web-based authentication scheme is deployed on the NAS.
- A downstream user connected to the NAS needs to pass web-based authentication before accessing the Internet.

Figure 1-1 Networking Topology of Web-based Authentication

Remarks	Web-based authentication is applicable to both Layer 2 and Layer 3 networks. On a Layer 3 network, the source MAC address and VLAN ID (VID) of a packet are changed after the packet is routed, but the source IP address remains the same and is used as the only identifier of a client. Therefore, a policy associated with web-based authentication on a Layer 3 device must adopt the IP-only binding mode. Here, the Layer 2 NAS is used as an example. RG-SAM+ is installed on the RADIUS server and RG-ePortal is installed on the portal server.

Deployment

- Enable web-based authentication on the interface to which a client is connected or globally on the NAS.
- Configure the ePortal server and the communication key on the NAS (for only Ruijie first-generation and second-generation web-based authentication).
- Configure Simple Network Management Protocol (SNMP) communication parameters of the ePortal server on the NAS (for only Ruijie first-generation and second-generation web-based authentication).
- Configure communication parameters on the ePortal server and SAM server (for only Ruijie first-generation web-based authentication).
- Create user accounts on the SAM server.
- Configure AAA and method lists on the NAS (for only Ruijie second-generation and iPortal web-based authentication).

- Configure the IP address of the SAM server on the NAS (for only Ruijie second-generation and iPortal web-based authentication).
- Configure names of the web-based authentication method lists on the NAS (for only Ruijie second-generation and iPortal web-based authentication).

1.3 Features

Basic Concepts

First-Generation Web-based Authentication

Ruijie first-generation web-based authentication requires the support of RG-ePortal. The server that has RG-ePortal installed (ePortal server) provides a login page to submit user authentication information, and initiates an authentication request directly to the RADIUS server. Once authentication succeeds, the NAS obtains user information delivered through SNMP, enabling control over user access permissions. This authentication mode depends on private SNMP nodes. Moreover, the ePortal server assumes the role of authentication and accounting, which relieves the NAS from service burden.

Second-Generation Web-based Authentication

Ruijie second-generation web-based authentication complies with *CMCC WLAN Service Portal Specification*. The portal server is responsible for interacting with users through web pages. The NAS interacts with the RADIUS server to implement authentication. The interaction between the portal server and NAS complies with *CMCC WLAN Service Portal Specification*. The portal server provides a login page where users can submit their information, and then informs the NAS of user information through the portal protocol. The NAS completes authentication by interacting with the RADIUS server based on the user information, assigns access permissions to authenticated clients, and returns authentication results to the portal server.

The implementation process of Ruijie second-generation web-based authentication is mainly completed on the NAS. This places a higher demand on the NAS's capability to handle heavy tasks. In this case, the configuration of the portal server is simplified. The widely supported *CMCC WLAN Service Portal Specification* allows various vendors to develop compatible products.

iPortal Web-based Authentication

In iPortal web-based authentication, the NAS integrates web page interaction of the portal server with partial authentication interaction of the RADIUS server. The NAS comes with a default authentication page suite, which can be customized based on instructions provided in this manual. Once configured, the page suite can be downloaded and stored on the storage medium of the NAS.

Comparison Between Different Authentication Modes

Authentication roles:

- Client:
- The functions remain the same for the three web-based authentication modes.
- NAS: In first-generation web-based authentication, the NAS implements only URL redirection and exchanges user login/logout notifications with the portal server. In second-generation web-based authentication, the NAS is

responsible for redirecting and authenticating users as well as notifying the portal server of authentication results. In iPortal web-based authentication, the NAS integrates multiple functions including URL redirection, web page interaction, and authentication.

- Portal server: In first-generation web-based authentication, the portal server is responsible for interacting with clients through web pages, authenticating users, and notifying the NAS of authentication results. In second-generation web-based authentication, the portal server is responsible for interacting with clients through web pages, notifying the NAS of users' authentication information, and receiving authentication results from the NAS. In iPortal web-based authentication, the portal server is built into the NAS and provides simplified functions, and is mainly responsible for interaction with clients through web pages.
- RADIUS server: The functions remain the same for the three web-based authentication modes.

Authentication process:

- In second-generation web-based authentication, authentication and accounting functions are transferred from the portal server to the NAS.
- In second-generation web-based authentication, because authentication is performed on the NAS, the NAS does not need to wait for the authentication results notified by the portal server.
- iPortal web-based authentication simplifies and integrates features of the portal servers into the NAS compared with first- and second-generation web-based authentication.

Logout process:

- In first-generation web-based authentication, a logout action may be triggered by a notification from the portal server, or traffic or port status detection performed by the NAS. In second-generation web-based authentication, a logout action may be triggered by a notification from the portal server, a disconnection notification from the RADIUS server, or traffic or port status detection performed by the NAS. In iPortal web-based authentication, a logout action may be triggered by logout of a user that clicks the logout button on the online page, a disconnection notification from the RADIUS server, or traffic or port status detection performed by the NAS.
- In first-generation web-based authentication, Accounting Stop packets are sent by the portal server. In second-generation and iPortal web-based authentication, Accounting Stop packets are sent by the NAS.

The web-based authentication mode selected depends on the type of the portal server in use.

Command parameters in this document may be shared by the three web-based authentication modes or not. Read through this document carefully to avoid parameter misconfiguration that will affect web-based authentication.

Overview

Feature	Description
First-Generation Web-based Authentication	The portal server is deployed and supports only first-generation web-based authentication.
Second-Generation Web-based Authentication	The portal server is deployed and complies with *CMCC WLAN Service Portal Specification*.
iPortal Web-based Authentication	The portal server is not deployed, and the NAS supports web page interaction.

Feature	Description
MAC Address-Based SMS Authentication	A non-authenticated user is allowed to access the Internet after accessing the WLAN. After the traffic used over the specified interval reaches the specified threshold, the authentication device sends a request to query the bound MAC address.
RIPT Web-based Authentication	When the AC fails or the connection between the AC and AP is terminated, the web-based authentication module of the AP can still provide authentication services.
WiFiDog Web-based Authentication	A non-authenticated user will be redirected to the authentication page for authentication.
WeChat Web-based Authentication	After assessing the WLAN, a mobile phone user will be redirected to the **Connect to Wi-Fi via WeChat** page through the browser. The user can enable the WeChat client for authentication with a tap on the link.
ClearPass Authentication	Non-authenticated users can be redirected to the authentication page for authentication.

1.3.1 First-Generation Web-based Authentication

- **HTTP Interception**

HTTP interception means that the NAS intercepts to-be-forwarded HTTP packets. These HTTP packets are initiated by browsers of clients connected to the NAS, but they are not destined for the NAS. For example, when a client attempts to visit www.google.com using Internet Explorer, the NAS is expected to forward the HTTP request packets to a gateway. However, if HTTP interception is enabled, these packets will not be forwarded.

Once HTTP interception is successful, the NAS redirects the client's HTTP requests to itself, establishing a session between them. Then the NAS pushes a redirection page to the client through HTTP redirection. A web page pops up on the client's browser, on which authentication, software download, or other operations can be performed.

You can specify the clients and destination interfaces to enable or disable HTTP interception for web-based authentication. In most cases, HTTP requests from non-authenticated clients will be intercepted, and those from authenticated clients will not. HTTP interception is the basis for web-based authentication, that is, web-based authentication is automatically triggered after successful HTTP interception.

- **HTTP Redirection**

As defined by HTTP, when the NAS receives an HTTP GET or HEAD request packet from a client, it replies with a packet with 200 (Ok) status code if it can provide required resources. Alternatively, a packet with 302 (Moved Temporarily) status code is returned if it cannot. The 302 packet includes another URL for redirection. After receiving the packet, the client may resend an HTTP GET or HEAD request packet to the new URL for requesting resources. This process is called redirection.

HTTP redirection is crucial in web-based authentication after HTTP interception. It utilizes the 302 status code defined in HTTP. HTTP interception creates a session between the NAS and a client. The client sends HTTP GET or HEAD request packets (originally intended for another site) to the NAS. The NAS responds with a 302 packet with a specific redirection page. As a result, the client resends the requests to the redirection page.

Because more and more applications run HTTP, the use of the 302 redirection packet may redirect a large amount of non-browser HTTP traffic to the portal server, which will affect network authentication. To address this problem, the NAS adopts noise reduction in its HTTP redirection technology, replacing the 302 packets with JavaScript scripts.

Working Principle

Figure 1-1 shows the networking topology of web-based authentication.

First-generation web-based authentication roles:

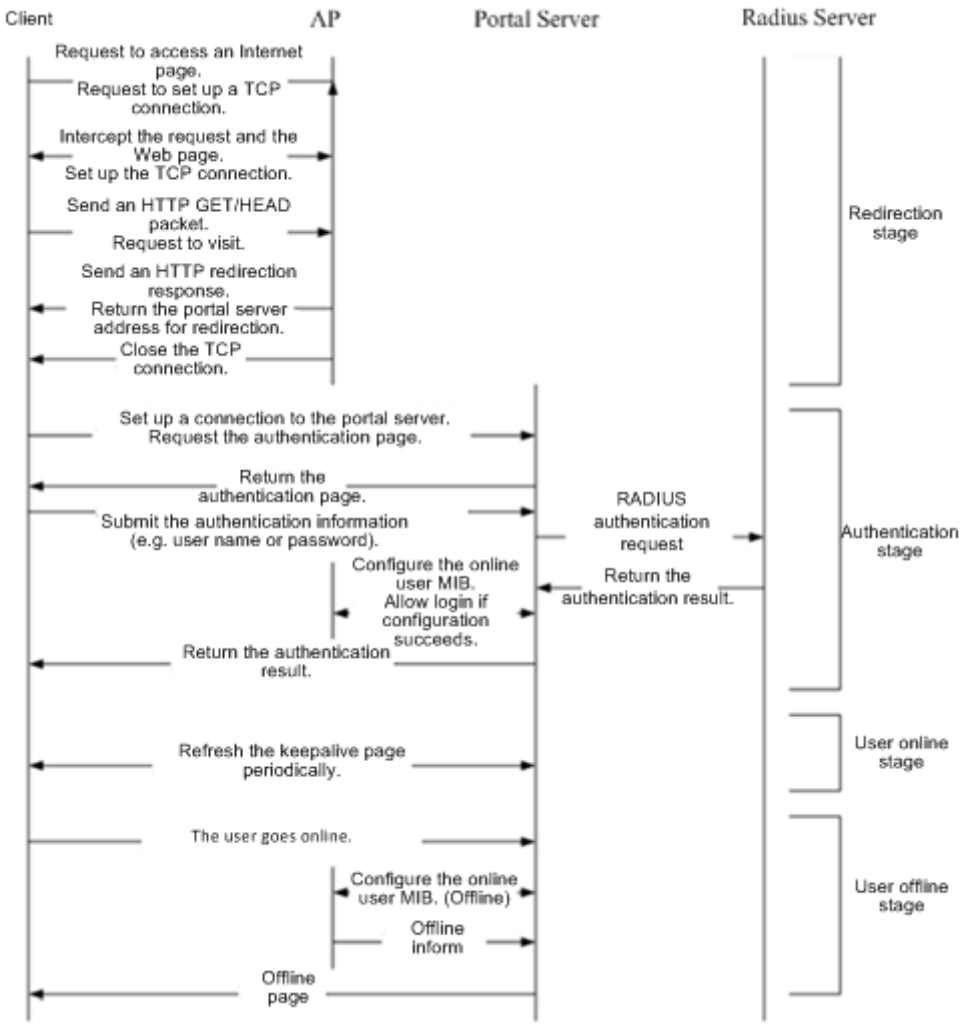
1 Authentication client: Is usually a browser running HTTP. It sends HTTP requests for accessing the Internet.

2 NAS: Is an access-layer device on a network, for example, a wireless access point (AP) on a wireless network. The NAS is directly connected to clients and must be enabled with web-based authentication.

3 Portal server: Provides a web page for web-based authentication and related operations. After receiving an HTTP authentication request from a client, the portal server extracts account information from the request, sends the information to the RADIUS server for authentication, and notifies the client and NAS of the authentication result. Figure 1-1 shows Ruijie ePortal server.

4 RADIUS server: Provides the RADIUS-based authentication service for remote clients. The portal server extracts users' authentication account information from HTTP packets and initiates authentication requests to the RADIUS server through the RADIUS protocol. The RADIUS server returns the authentication result to the portal server through the RADIUS protocol. Figure 1-1 shows the RADIUS server that has RG-SAM+ installed.

First-generation web-based authentication process:



1 Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the portal server. Then an authentication page is displayed on the browser.

2 During authentication, the client enters information, for example, username, password, and verification code, on the authentication page to interact with the portal server and complete authentication.

3 After the user is authenticated, the portal server notifies the NAS that the client has passed authentication, and the NAS allows the client to access resources on the Internet.

Figure 1-2 shows the flowchart of Ruijie first-generation web-based authentication by using an AP as the NAS.

Figure 1-2 Flowchart of Ruijie First-Generation Web-based Authentication

Client logout process:

There are two scenarios of client logout. In the first scenario, the NAS detects that a client has gone offline due to reasons such as reaching the maximum online time, exceeding the traffic limit, or experiencing a disconnection in the link. The second scenario occurs when the portal server detects that a client has initiated logout by clicking the logout button on the logout page or when the keepalive page becomes unavailable.

1 Scenario 1: When the NAS detects a client logging out, it informs the portal server. Subsequently, the portal server uses SNMP to delete user information from the NAS and pushes a logout page to the client.

2 Scenario 2: When the portal server detects a client logging out, it informs the NAS through SNMP and pushes a logout page to the client.

3 In the two scenarios, the portal server sends an Accounting Stop packet to the RADIUS server, notifying it that the client has logged out.

Related Configuration

↘ Configuring the First-Generation Web-based Authentication Template

By default, the first-generation web-based authentication template is not configured.

Run the **web-auth template eportalv1** command in global configuration mode to create the first-generation web-based authentication template.

The template is used to implement web-based authentication.

Configuring the IP Address of the Portal Server

By default, the IP address of the portal server is not configured.

Run the **ip** *ip-address* command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

Configuring the Web-based Authentication URL of the Portal Server

By default, the web-based authentication URL of the portal server is not configured.

Run the **url** *url-string* command in template configuration mode to configure the web-based authentication URL of the portal server.

The URL to which clients are redirected is the address of the web-based authentication URL provided by the portal server.

Specifying the Web-based Authentication Binding Mode

The default web-based authentication binding mode is IP-only.

Run the **bindmode** command in template configuration mode to specify the web-based authentication binding mode.

In web-based authentication across the Layer 3 network, the source MAC address in a packet is changed after the packet is routed. In such case, configure the IP-only binding mode.

Configuring the Web-based Authentication Communication Key

By default, the web-based authentication communication key is not configured.

Run the **web-auth portal key** [**0** | **1** | **7**] *key-string* command in global configuration mode to configure the web-based authentication communication key.

The communication key is used to encrypt URL parameters to avoid information disclosure.

Enabling First-Generation Web-based Authentication

By default, first-generation web-based authentication is disabled.

Run the **webauth** command in WLAN security configuration mode to enable first-generation web-based authentication.

Configuring the SNMP Server

By default, the SNMP server and community string are not configured.

Run the **snmp-server host** *ip-address* **version 2c** *community-string* **web-auth** command in global configuration mode to configure the SNMP server and community string for web-based authentication.

The SNMP server is configured to receive Inform or Trap packets of user logout.

Configuring the SNMP Server Community String

By default, the SNMP server community string is not configured.

Run the **snmp-server community** *community-string* **rw** command in global configuration mode to configure the SNMP server community string.

The SNMP server community string is configured to read/write user information from/to the NAS.

↘ Enabling the SNMP Trap or Inform Function

By default, the SNMP Trap or Inform function is disabled.

Run the **snmp-server enable traps web-auth** command in global configuration mode to enable the SNMP Trap or Inform function.

The SNMP Trap or Inform function is configured to enable the NAS to inform the portal server of user logout.

1.3.2 Second-Generation Web-based Authentication

- **HTTP Interception**

It is the same as the HTTP interception technology of first-generation web-based authentication.

- **HTTP Redirection**

It is the same as the HTTP redirection technology of first-generation web-based authentication.

Working Principle

Figure 1-1 shows the networking topology of web-based authentication.

Second-generation web-based authentication roles:

1 Authentication client: Is usually a browser running HTTP. It sends HTTP requests for accessing the Internet.

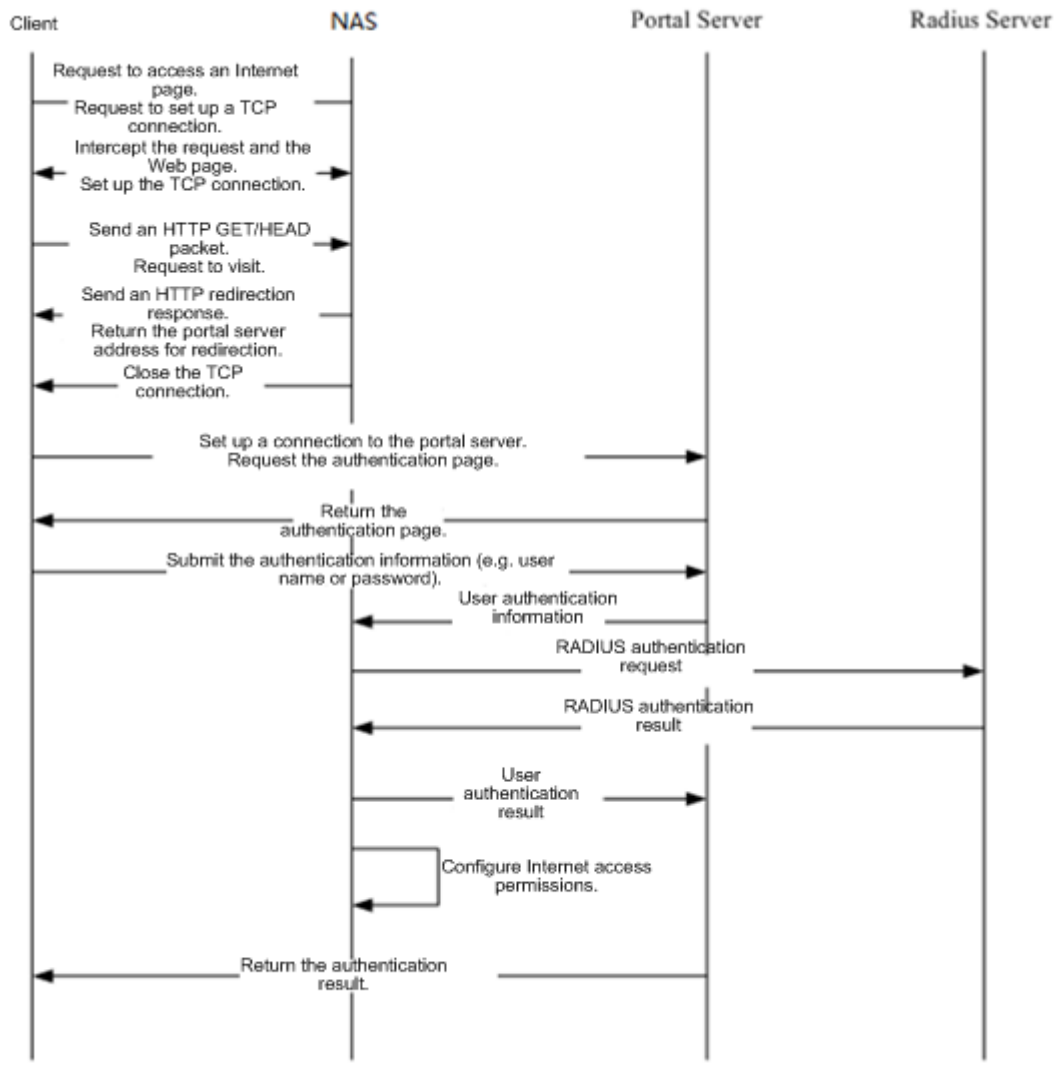
2 NAS: Is an access-layer device on a network (for example, an AP on a wireless network). The NAS is directly connected to clients and must be enabled with web-based authentication. The NAS receives user authentication information from the portal server, sends authentication requests to the RADIUS server, determines whether users can access the Internet according to authentication results, and returns the authentication results to the portal server.

3 Portal server: Provides a web page for web-based authentication and related operations. After receiving an HTTP authentication request from a client, the portal server extracts account information from the request, transfers the information to the NAS, and displays the authentication result returned by the NAS to the user on a page. Figure 1-1 shows Ruijie ePortal server.

4 RADIUS server: Provides the RADIUS-based authentication service for remote clients. When a device initiates authentication to the RADIUS server, authentication packets include the following parameters: wlanuserip (user IP address), wlanacname (AC name), ssid (SSID), nasip (NAS device's IP address), mac (user MAC address), and url (URL accessed by the user before redirection). Figure 1-1 shows the RADIUS server that has RG-SAM+ installed.

Second-generation web-based authentication process:

1 Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the portal server. Then an authentication page is displayed on the browser.



2 During authentication, the client enters information, for example, username, password, and verification code, on the web-based authentication URL to interact with the portal server.

3 The portal server sends the user authentication information to the NAS.

4 The NAS initiates authentication to the RADIUS server and returns the authentication result to the portal server.

5 The portal server displays the authentication result (success or failure) to the user on a page.

Figure 1-3 Flowchart of Ruijie Second-Generation Web-based Authentication

Client logout process:

There are two scenarios of client logout. In the first scenario, the NAS detects that a client has gone offline due to reasons such as reaching the maximum online time, exceeding the traffic limit, or experiencing a disconnection in the link. The second scenario occurs when the portal server detects that a client has initiated logout by clicking the logout button on the logout page or when the keepalive page becomes unavailable.

1 When a user clicks the logout button on the online page, the portal server instructs the NAS to disconnect the user.

2 The NAS disconnects a client with traffic lower than the threshold based on parameters of user online traffic detection.

3 When the RADIUS server intends to forcibly disconnect a client based on a specific policy, the NAS instructs the portal server to push a logout page to the client.

Related Configuration

↘ Configuring the Second-Generation Web-based Authentication Template

By default, the second-generation web-based authentication template is not configured.

Run the **web-auth template** { **eportalv2** | *template-name* **v2** } command in global configuration mode to create a second-generation web-based authentication template.

The template is used to implement web-based authentication.

Configuring the IP Address of the Portal Server

By default, the IP address of the portal server is not configured.

Run the **ip** *ip-address* command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

Configuring the Web-based Authentication URL of the Portal Server

By default, the web-based authentication URL of the portal server is not configured.

Run the **url** *url-string* command in template configuration mode to configure the web-based authentication URL of the portal server.

The URL to which clients are redirected is the address of the web-based authentication URL provided by the portal server.

Specifying the Web-based Authentication Binding Mode

The default web-based authentication binding mode is IP-only.

Run the **bindmode** command in template configuration mode to specify the web-based authentication binding mode.

In web-based authentication across the Layer 3 network, the source MAC address in a packet is changed after the packet is routed. In such case, configure the IP-only binding mode.

Configuring the Web-based Authentication Communication Key

By default, the web-based authentication communication key is not configured.

Run the **web-auth portal key** [**0** | **1** | **7**] key-*string* command in global configuration mode to configure the web-based authentication communication key.

The communication key is used to encrypt URL parameters to avoid information disclosure.

Enabling Second-Generation Web-based Authentication

By default, second-generation web-based authentication is disabled.

Run the **webauth** command in WLAN security configuration mode to enable second-generation web-based authentication.

Enabling AAA

By default, AAA is disabled.

Run the **aaa new-model** command in global configuration mode to enable AAA.

Ruijie second-generation web-based authentication relies on AAA. Therefore, enable AAA before you use second-generation web-based authentication.

Configuring the RADIUS Server and Communication Key

By default, the RADIUS server and communication key are not configured.

Run the **radius-server host** command in global configuration mode to configure the RADIUS server and communication key.

The RADIUS server is responsible for authenticating users.

Configuring an AAA Method List for Ruijie Second-Generation Web-based Authentication

By default, no AAA method list is configured for Ruijie second-generation web-based authentication.

Run the **aaa authentication web-auth** command in global configuration mode to configure an AAA method list for Ruijie second-generation web-based authentication.

The AAA authentication method list is used for interaction during web-based authentication.

Configuring an AAA Method List for Ruijie Second-Generation Web-based Accounting

By default, no AAA method list is configured for Ruijie second-generation web-based accounting.

Run the **aaa accounting network** command in global configuration mode to configure an AAA method list for Ruijie second-generation web-based accounting.

The AAA method list for web-based accounting is used for accounting interaction during web-based authentication.

Specifying an AAA Method List

The default AAA method list is used if no list is specified.

Run the **authentication** command in template configuration mode to specify an AAA method list.

The AAA method list is specified to send authentication requests to the AAA module.

Specifying an AAA Accounting Method List

The default AAA accounting method list is used if no list is specified.

Run the **accounting** command in template configuration mode to specify an AAA accounting method list.

The AAA accounting method list is specified to send accounting requests to the AAA module.

Specifying the UDP Port of the Portal Server

By default, UDP port 50100 is used.

Run the **port** command in template configuration mode to specify the UDP port of the portal server.

The UDP port is specified for the portal server to communicate with the NAS.

1.3.3 iPortal Web-based Authentication

- **HTTP Interception**

It is the same as the HTTP interception technology of Ruijie first-generation web-based authentication.

- **HTTP Redirection**

It is the same as the HTTP redirection technology of Ruijie first-generation web-based authentication.

Working Principle

Compared with Ruijie first-generation web-based authentication shown in Figure 1-1, Ruijie iPortal web-based authentication does not require the portal server.

iPortal web-based authentication roles:

1 Authentication client: Is typically a browser running HTTP. It sends HTTP requests for accessing the Internet.

2 NAS: Is an access-layer device on a network. It is directly connected to clients on a wired or wireless network and must be enabled with Ruijie iPortal web-based authentication. The NAS resolves the account information that clients enter on a web page and sends authentication requests to the RADIUS server. It determines whether clients can access the Internet according to authentication results and pushes the authentication results to the browser.

3 RADIUS server: Provides the RADIUS-based authentication service for remote clients. Figure 1-1 shows the RADIUS server that has RG-SAM+ installed.

iPortal web-based authentication process:

1 Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the iPortal server. Thereafter, an authentication page is displayed on the browser.

2 During authentication, the client enters information, for example, username, password, and verification code, on the web-based authentication URL to interact with the iPortal server (NAS).

3 The NAS initiates authentication to the RADIUS server and pushes the authentication result (success or failure) to the client on a page.

Client logout process:

1 The NAS disconnects a client when the user clicks the logout button on the web page.

2 The NAS disconnects a client with traffic lower than the threshold based on parameters of user online traffic detection.

3 When the RADIUS server disconnects a client offline based on a certain policy, the NAS pushes a logout page to the client.

Related Configuration

Configuring the iPortal Web-based Authentication Template

By default, the iPortal web-based authentication template is not configured.

Run the **web-auth template iportal** command in global configuration mode to create an iPortal web-based authentication template.

The template is used to configure authentication parameters on the iPortal server.

Customizing a Page Suite

By default, the factory file package is used.

Run the **page-suite** command in template configuration mode to specify the use of a page suite.

Before you specify the use of a page suite, download it to the flash memory.

Configuring an Advertisement Push Method and URL

The advertisement is pushed after authentication by default.

Run the **login-popup** *url* command to configure the advertisement URL pushed before authentication in template configuration mode. Run the **online-popup** *url* command to configure the advertisement URL pushed after authentication in template configuration mode.

Specifying the Web-based Authentication Binding Mode

The default web-based authentication binding mode is IP-only.

Run the **bindmode** command in template configuration mode to specify the web-based authentication binding mode.

In web-based authentication across the Layer 3 network, the source MAC address in a packet is changed after the packet is routed. In such case, configure the IP-only binding mode.

Enabling Ruijie iPortal Web-based Authentication

By default, Ruijie iPortal web-based authentication is disabled.

Run the **webauth** command in WLAN security configuration mode to enable iPortal web-based authentication.

Enabling AAA

By default, AAA is disabled.

Run the **aaa new-model** command in global configuration mode to enable AAA.

Ruijie iPortal web-based authentication relies on AAA. Enable AAA before you implement web-based authentication.

Configuring the RADIUS Server and Communication Key

By default, the RADIUS server and communication key are not configured.

Run the **radius-server host** command in global configuration mode to configure the RADIUS server and communication key.

The RADIUS server in web-based authentication is responsible for authenticating users.

Configuring an AAA Method List for Ruijie iPortal Web-based Authentication

By default, no AAA method list is configured for Ruijie iPortal web-based authentication.

Run the **aaa authentication iportal** command in global configuration mode to configure an AAA method list for Ruijie iPortal web-based authentication.

The AAA authentication method list is used for interaction during web-based authentication.

Configuring an AAA Method List for Ruijie iPortal Web-based Accounting

By default, no AAA method list is configured for Ruijie iPortal web-based accounting.

Run the **aaa accounting network** command in global configuration mode to configure an AAA method list for Ruijie iPortal web-based accounting.

The AAA accounting method list is used for accounting interaction during web-based authentication.

Specifying an AAA Method List

The default AAA method list is used if no list is specified.

Run the **authentication** command in template configuration mode to specify an AAA method list.

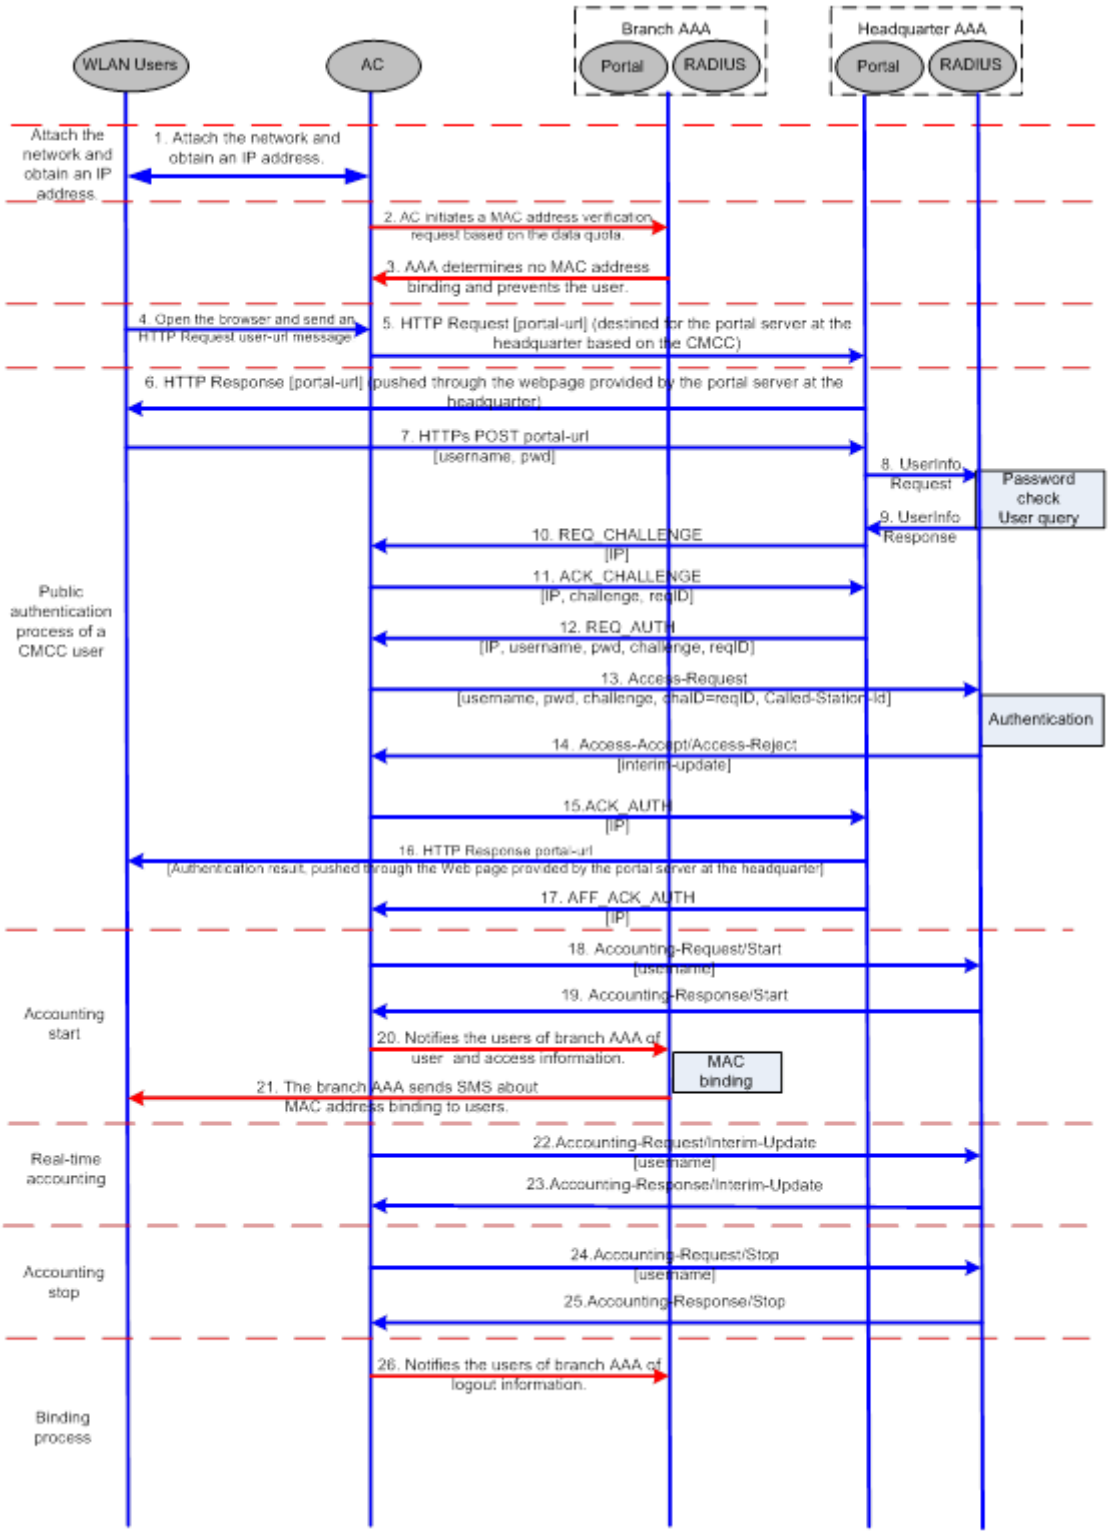
The AAA method list is specified to send authentication requests to the AAA module.

Specifying an AAA Accounting Method List

The default AAA accounting method list is used if no list is specified.

Run the **accounting** command in template configuration mode to specify an AAA accounting method list.

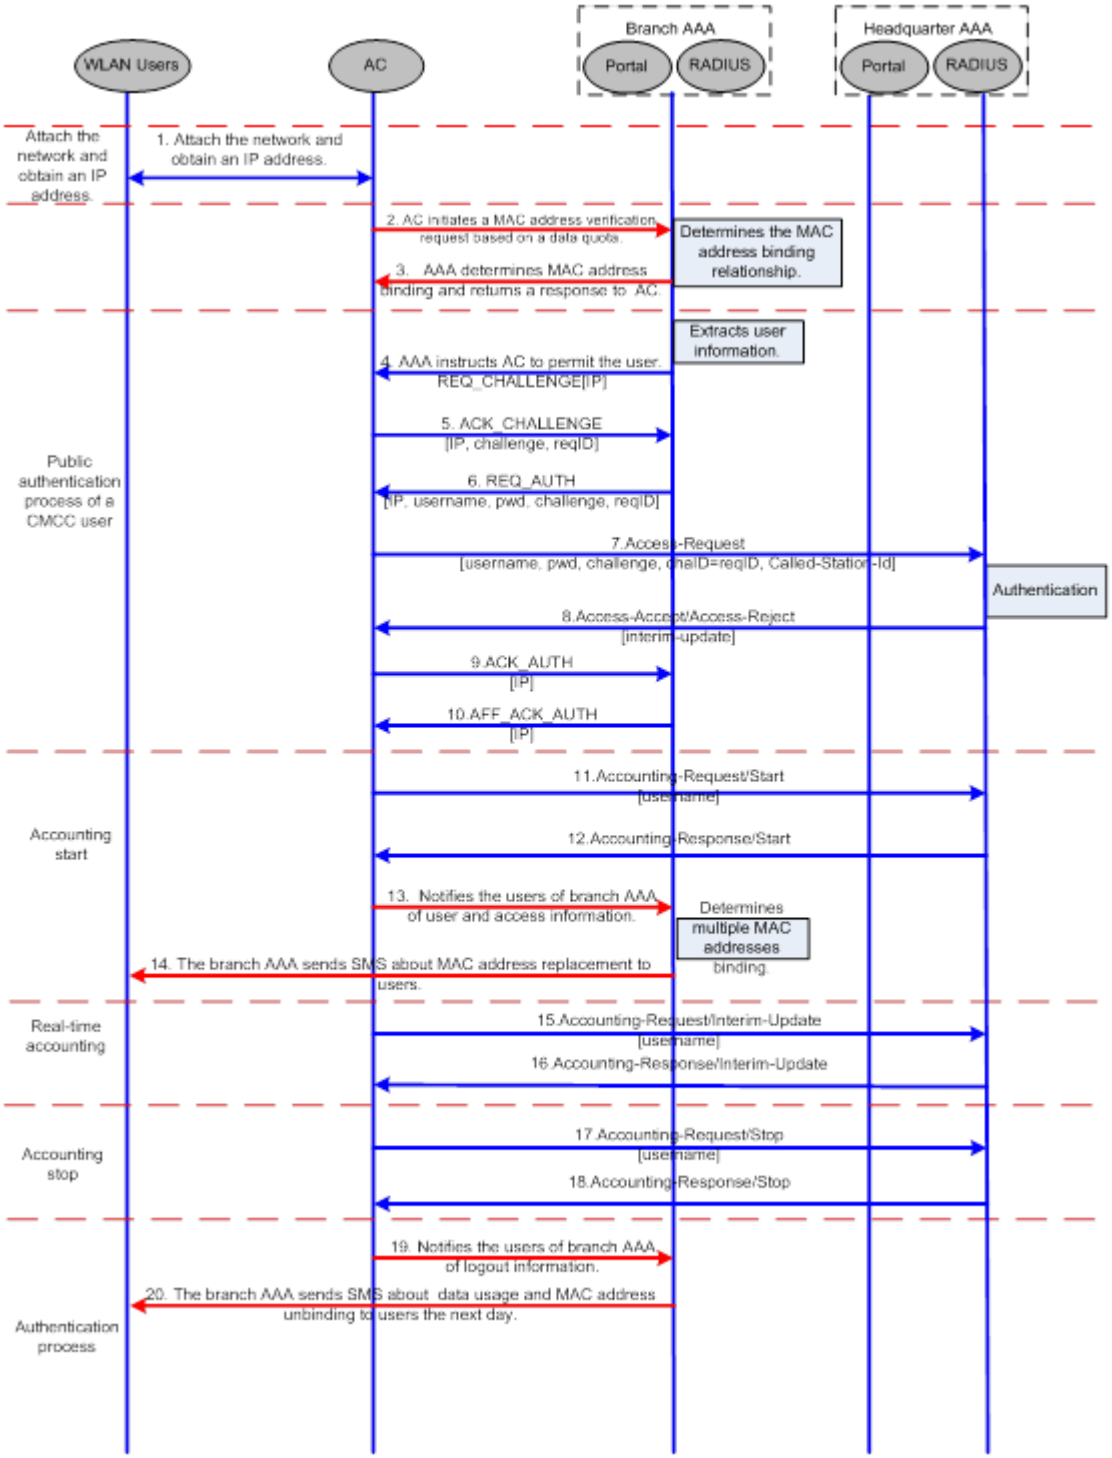
The AAA accounting method list is specified to send accounting requests to the AAA module.



1.3.4 MAC Address-Based SMS Authentication

Working Principle

After a STA is associated with an SSID enabled with MAC address-based SMS authentication, the STA obtains an IP address through the Dynamic Host Configuration Protocol (DHCP). Then the STA is allowed to access the Internet. When the STA uses up the traffic allowed during a time period, the access controller (AC) initiates a MAC address binding query to the bound portal server. If the STA is bound to a MAC address, the portal server sends an authentication request. If the STA is not bound to a MAC address, the STA needs to re-perform authentication on the portal server before accessing the Internet.



SMS Authentication Process for Unbound STAs

In the following figure, the SSID is enabled with MAC address-based SMS authentication, and a STA that is not bound to a MAC address is associated with the SSID to access the Internet. Compared with Ruijie second-generation web-based authentication, MAC address-based SMS authentication involves querying MAC address binding and notifying the bound portal server of user login or /logout. If the STA selects the binding check box when performing authentication on the portal server, the portal server will bind the STA to a MAC address. The STA can directly access the Internet during subsequent connections.

↘ SMS Authentication Process for Bound STAs

After a STA is bound to a MAC address, the user does not need to open the browser to perform authentication for Internet access. Network access is automatically completed after the STA is associated with a network, which greatly facilitates wireless network access.

1.3.5 RIPT Web-based Authentication

Web-based authentication supports the Remote Intelligent Perception Technology (RIPT) function. When an AC is faulty or the connection between an AC and an AP is terminated, RIPT allows the AP to provide web-based authentication services.

Working Principle

To enable RIPT, configure an RIPT AP group on an AC. For details, see *Configuring RIPT*. In RIPT AP authentication mode, the configurations related to web-based authentication on the AC are delivered to the AP. The AP can function as access devices to provide the web-based authentication service externally. STAs do not need to perform web-based authentication on the AC. The information of STAs who pass authentication on the APs is synchronized to the AC and can be queried on the AC.

↘ Delivering Configurations

In RIPT AP authentication mode, the configurations of AAA and RADIUS on the AC and port-based web-based authentication control in RSNA will be issued to the APs. Then the APs can provide WLAN services externally, including the web-based authentication service.

↘ Synchronizing STA Information from the AP to the AC

If STAs pass authentication by an RIPT AP which provides the web-based authentication service externally, information about the STAs will be synchronized to the AC and can be queried on the AC.

1.3.6 WiFiDog Web-based Authentication

- **HTTP Interception**

It is the same as the HTTP interception technology of Ruijie first-generation web-based authentication.

- **HTTP Redirection**

It is the same as the HTTP redirection technology of Ruijie first-generation web-based authentication.

Working Principle

The networking topology of WiFiDog web-based authentication is the same as that shown in Figure 1-1.

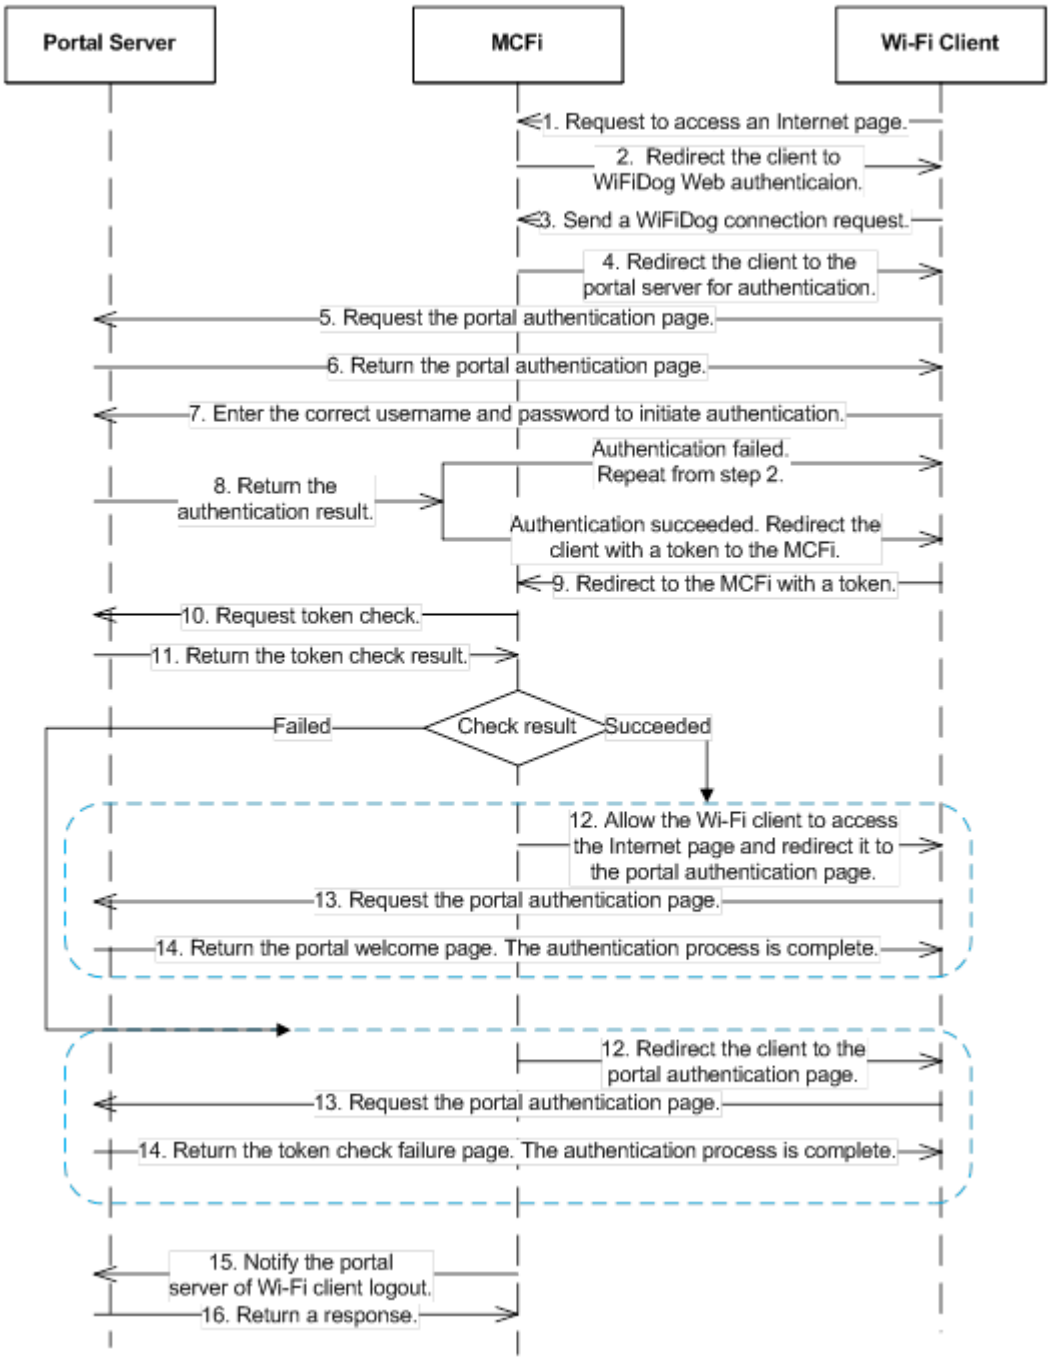
Roles involved in WiFiDog web-based authentication:

1 Authentication client: Is typically a browser running HTTP. It sends HTTP requests for accessing the Internet.

2 NAS: Is an access-layer device on a network, for example, an AP on a wireless network. The NAS is directly connected to clients and must be enabled with web-based authentication. The NAS controls users' Internet access permissions, receives token check requests or Internet access requests from authentication clients, and initiates identity check to the portal server.

3 Portal server: Provides a web page for web-based authentication and related operations. The portal server receives HTTP-based authentication requests from authentication clients and extracts account information from the requests. When authentication is complete in the background, the authentication clients forward the authentication results to the NAS. The NAS redirects the authentication clients to a web page provided by the portal server.

4 Authentication server: Provides the authentication service. The authentication server negotiates with the portal server to determine the authentication protocol (for example, RADIUS) used.



5 WiFiDog web-based authentication process: Before authentication, the NAS intercepts all HTTP requests from a client and redirects these requests to the iPortal server. Then an authentication page is displayed on the browser.

6 During authentication, the client enters information, for example, username, password, and verification code, on the web-based authentication URL to interact with the portal server.

7 The portal server checks the validity of the client information in the background. If authentication fails, the portal server displays the failed authentication result to the client on a web page. If authentication is successful, the portal server redirects the client to the NAS.

8 After receiving a request from the client, the NAS initiates check to the portal server. The NAS redirects the client to a web page provided by the portal server based on the check result.

Figure 1-4 Flowchart of WiFiDog Web-based Authentication

Client logout process:

There are two scenarios of client logout. In the first scenario, the NAS detects that a client has gone offline due to reasons such as reaching the maximum online time, exceeding the traffic limit, or experiencing a disconnection in the

link. The second scenario occurs when the portal server detects that a client has initiated logout by clicking the logout button on the logout page.

1 When a client clicks the logout button, a logout request is sent to the portal server and NAS. (The logout request may be sent to the portal server and NAS at different time points, depending on the capability of the portal server.)

2 The NAS disconnects a client with traffic lower than the threshold based on parameters of user online traffic detection.

Related Configuration

Configuring a WiFiDog Web-based Authentication Template

By default, the WiFiDog web-based authentication template is not configured.

Run the **web-auth template** { **wifidog** | *template-name* **wifidog** } command in global configuration mode to create a WiFiDog web-based authentication template.

The template is used to implement web-based authentication.

Configuring the IP Address of the Portal Server

By default, the IP address of the portal server is not configured.

Run the **ip** *ip-address* command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

Configuring the Web-based Authentication URL of the Portal Server

By default, the Webauth URL of the portal server is not configured.

Run the **url** *url-string* command in template configuration mode to configure the web-based authentication URL of the portal server.

The URL to which clients are redirected is the address of the web-based authentication URL provided by the portal server.

Configuring the IP Address of the NAS

By default, the IP address of the NAS is not configured.

Run the **nas-ip** *ip-address* command in template configuration mode to configure the IP address of the NAS.

Ensure that the configured IP address is accessible by clients.

Configuring the Gateway ID

By default, the gateway ID is set to the serial number of the device. It is mandatory in hot standby and VAC scenarios. It can be set to the MAC address of a device.

Run the **gateway-id** *string* command in template configuration mode to configure the gateway ID.

This parameter is carried in the WiFiDog packets and provided for the interconnected third-party portal.

Enabling WiFiDog Web-based Authentication

By default, WiFiDog web-based authentication is disabled.

Run the **webauth** command in WLAN security configuration mode to enable the WiFiDog web-based authentication.

1.3.7 WeChat Web-based Authentication

- **HTTP Interception**

It is the same as the HTTP interception technology of Ruijie first-generation web-based authentication.

- **HTTP Redirection**

It is the same as the HTTP redirection technology of Ruijie first-generation web-based authentication.

Working Principle

The networking topology of WeChat web-based authentication is the same as that shown in Figure 1-1.

Roles involved in WeChat web-based authentication:

1 User: Sets up a Wi-Fi connection through WeChat to access the Internet.

2 In-shop AP: Is a Fat or Fit AP.

3 Authentication server: Is a portal server or other authentication server such as Marketing Cloud Platform (MCP), Wireless Marketing Cloud (WMC), or a third-party server.

4 WeChat server: Is a WeChat background server.

Process of scanning quick response (QR) codes by WeChat for authentication:

1 A user initiates a Wi-Fi connection request by scanning the QR code through WeChat.

2 The WeChat App identifies the QR code and calls the WeChat server (through the GSM by a mobile phone.)

3 The WeChat server checks the connection request based on the QR code policy.

4 The WeChat server returns an SSID to the WeChat user for its connection.

5 The WeChat user sends a connection request to the AP.

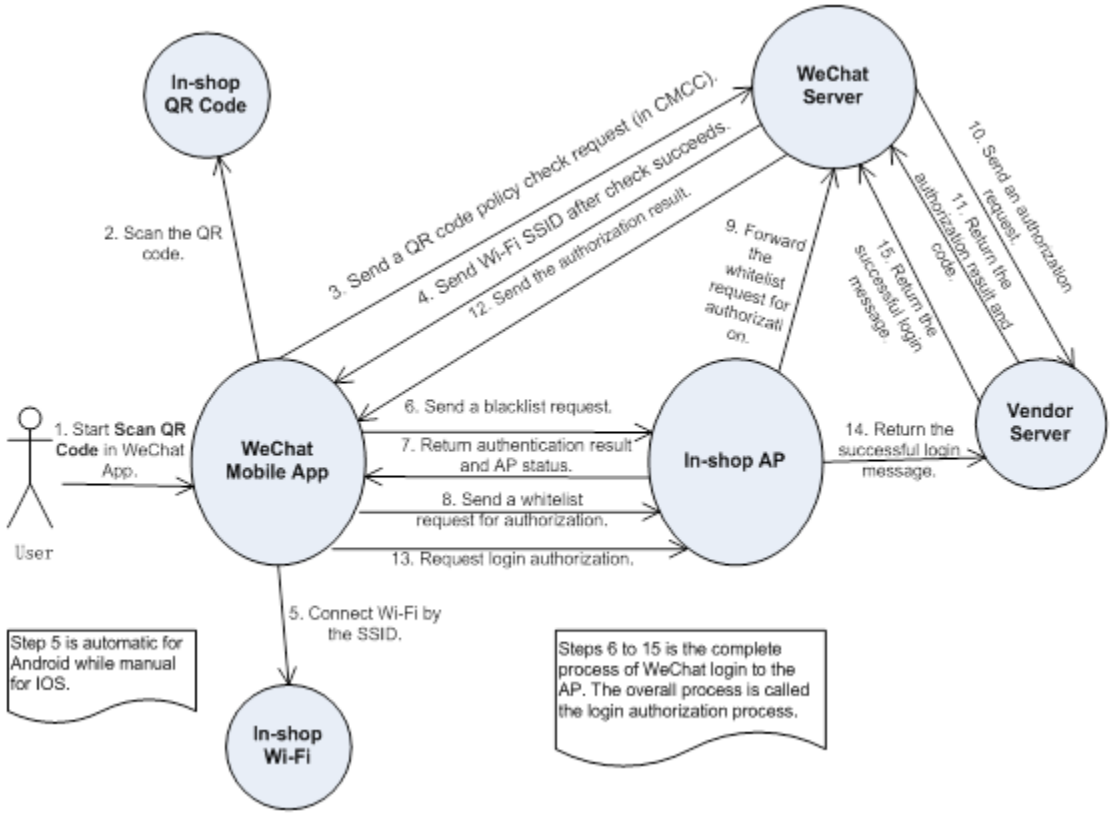
6 After connecting to the AP, the WeChat user sends a blocklist request, with the requested address being http://10.1.0.6/redirect. The request aims to inform the AP that the request is sent by a WeChat client.

7 After receiving the blocklist request, the AP sends a 302 redirection request, in which the auth parameter carries the MAC addresses of the mobile phone and AP in encryption mode.

8 After receiving the auth parameters, the WeChat client sends the WeChat server an allowlist request carrying the auth parameters for Wi-Fi connection authorization. The IP address of the WeChat server must be added to the allowlist of the AP to enable the AP to permit the authentication request to pass before authentication on the AP is complete.

9 The AP determines that the requested IP address is in the allowlist and permits the allowlisted request to pass to the WeChat server.

10 The WeChat server sends an HTTP-based authorization request to the device vendor server. The request maps interface 8. Ensure that interface 13 has been called to set the device vendor server URL and token parameter.



11 The device vendor server implements authorization according to the authorization request and returns an authentication address and the login parameter on interface 8.

12 The WeChat server returns the authentication address and parameter to the WeChat client.

13 The WeChat client requests the authentication address by sending a login request.

14 The AP or device vendor's server implements Internet access authentication. The AP permits the MAC address of the mobile phone to pass, and the device vendor's server calls interface 7 to notify the WeChat server of successful Internet access (see step 15 in Figure 1-5). The AP returns a 302 redirection packet carrying the res=success parameter to the WeChat client. The WeChat client determines that Internet access authorization is successful based on this parameter. A page indicating that a Wi-Fi connection is set up successfully is displayed on the WeChat client.

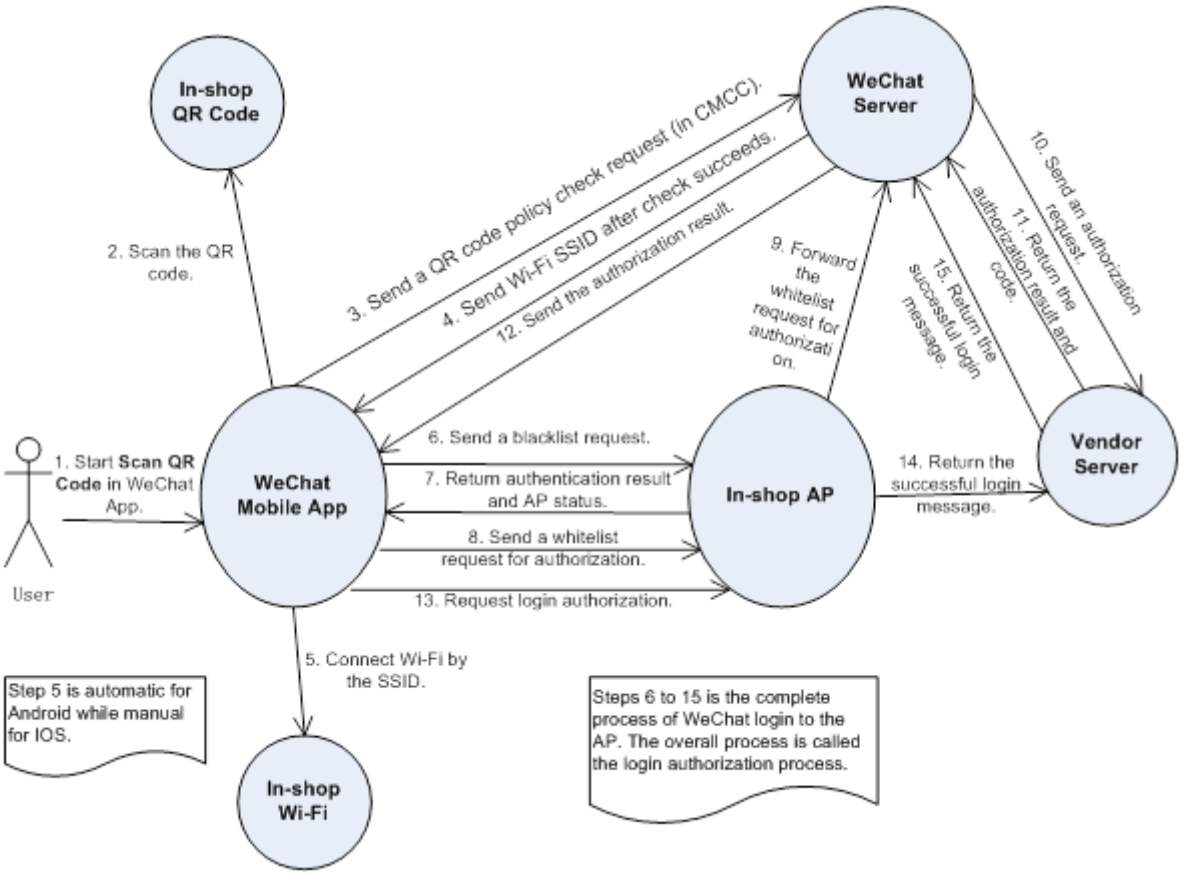
Figure 1-5 QR Code Scan Process in WeChat-Based Wi-Fi Connection Authentication

Process of the Internet access of multiple mobile devices by scanning dynamic QR codes on a PC:

1 Steps 1 and 2: A user starts a PC to set up a Wi-Fi connection and chooses to connect to an SSID.

2 Step 3: When the user opens the browser and accesses a website, the browser sends a network request.

3 Step 4: The AP returns a 302 packet to display a portal authentication page on the browser. To enable a mobile phone to connect to the Internet by scanning a QR code displayed on the PC, the AP sends a request to the device vendor's server.



4 Step 5: The device vendor's server calls interface 2 of the WeChat server to obtain the URL of the QR code photo.

5 Step 6: The WeChat server returns the URL of the QR code photo to the device vendor's server.

6 Step 7: The device vendor's server sends the URL to the AP.

7 Steps 8 to 10: The AP sends the browser a 302 packet carrying the URL, which will be embedded into the portal authentication page. The mobile phone can scan the QR code and connect to the Internet based on the normal access process.

Figure 1-6 **Process Where Multiple Mobile Devices Access the Internet by Scanning Dynamic QR Codes on a PC**

The NAS detects logout when a user's time is reached, the data quota is reached, or the link is disconnected.

1 The NAS disconnects a client with traffic lower than the threshold based on parameters of user online traffic detection.

2 The link disconnection duration depends on anti-jitter parameters.

Related Configuration

↘ Configuring a WeChat Web-based Authentication Template

By default, the WeChat web-based authentication template is not configured.

Run the **web-auth template** { **wechat** | *template-name* **wechat** } command in global configuration mode to create a WeChat web-based authentication template.

The template is used to implement web-based authentication.

↘ Configuring the IP Address of the Portal Server

By default, the IP address of the portal server is not configured.

Run the **ip** *ip-address* command in template configuration mode to configure the IP address of the portal server.

Any request packets to access the portal server will be filtered and rate-limited by the NAS.

↘ Configuring the WeChat Web-based Authentication URL

By default, no WeChat web-based authentication URL is configured.

Run the **service-url** *url-string* command in template configuration mode to configure the WeChat web-based authentication URL.

The URL address is used for the communication between the NAS and portal server.

The URL can contain a domain name for interconnection with a MACC server. Ensure that only one IP address corresponding to the domain name is resolved. The protocol name will be removed automatically from the domain name. The device supports only HTTP URL resolution.

Run the **service_url** command to configure a domain name. The server IP address in the template will be overwritten by the IP address resolved from the domain name.

Configuring the URL of the Portal Server

By default, the URL of the portal server is the SMS authentication redirection URL when both WeChat and SMS authentication are enabled.

Run the **url** *url-string* command to configure the URL of the portal server in template configuration mode.

The URL is the SMS authentication redirection URL when both WeChat and SMS authentication are enabled.

Configuring the IP Address of the NAS

By default, the IP address of the NAS is not configured.

Run the **nas-ip** *ip-address* command in template configuration mode to configure the IP address of the NAS.

The access service IP address for WeChat web-based authentication is used for communicating with the portal server.

The access service IP address of the NAS cannot be configured as the passthrough address.

When the access service IP address is configured as the IP address of the NAS and a STA in the authentication template accesses this IP address, the NAS intercepts the request of the STA and forwards it to the server. As a result, the STA fails to access the web management page of the NAS.

If a STA in the authentication template accesses this IP address for device management, configure the access service IP address as the unused virtual service IP address, for example, 1.1.1.1 and 2.2.2.2.

If the actual IP address of a device is used to log in to the device, there are security issues. In this case, the IP address for device management is mapped to the extranet IP address. Security devices such as firewalls are deployed between the extranet and servers to ensure security, whereas no security measures are taken for access through the intranet. If the actual IP address of the device is visible, the device can be easily attacked. The virtual IP address is recommended.

Configuring the Encryption Key

By default, no encryption key is configured.

Run the **key** *key-string* command in template configuration mode to configure an encryption key used for communicating with the portal server.

The encryption key is used to encrypt user authentication information and must be consistent with the key configured on the portal server.

Configuring NAS ID

By default, the NAS ID is the MAC address of the NAS.

The NAS ID is mandatory in hot standby or VAC scenarios.

In AC configuration mode, run the **nas-id** *nas-id-string* command to configure the NAS ID.

Enabling Web-based Authentication

By default, web-based authentication is disabled.

Run the **web-auth portal** { **wechat** | *template-name* **wechat** } command in WLAN security configuration mode and **webauth** command to enable web-based authentication on the port connected to STAs.

After web-based authentication is enabled, the non-authenticated STAs connecting to the port will be redirected to a one-click Internet access page provided by the portal server, and the non-authenticated PCs connecting to the port will be redirected to a QR code page.

Enabling the Escape Function

By default, the escape function is disabled.

Run the **web-auth wechat-escape interval** *minutes* command to configure this function in global configuration mode or WLAN security configuration mode.

The escape function in the WLAN security configuration mode is preferred. If the espace function is not configured in WLAN security configuration mode, the configuration in global configuration mode takes effect.

When the server fails or the escape function is required, subsequent users connected to the device enabled with the escape function can be free of authentication. The online duration of escape users is specified by **interval** *minutes*.

To disable the escape function, run the **web-auth wechat-escape recover** command in global configuration mode.

Configuring Server Detection

By default, server detection is disabled.

Run the **web-auth wechat-check interval** *minutes* command in global configuration mode to enable server detection.

After the function is configured, the device detects the server. If it does not receive a response from the server or receives a response indicating that the server is unavailable within the value specified by **interval** *minutes*, subsequent users gain access without authentication.

To cancel server detection, run the **no web-auth wechat-check** command in global configuration mode.

1.3.8 ClearPass Authentication

- **HTTP Interception**

It is the same as the HTTP interception technology of Ruijie first-generation web-based authentication.

- **HTTP Redirection**

It is the same as the HTTP redirection technology of Ruijie first-generation web-based authentication.

Working Principle

The networking topology is the same as that in Figure 1-7.

Roles in web-based authentication:

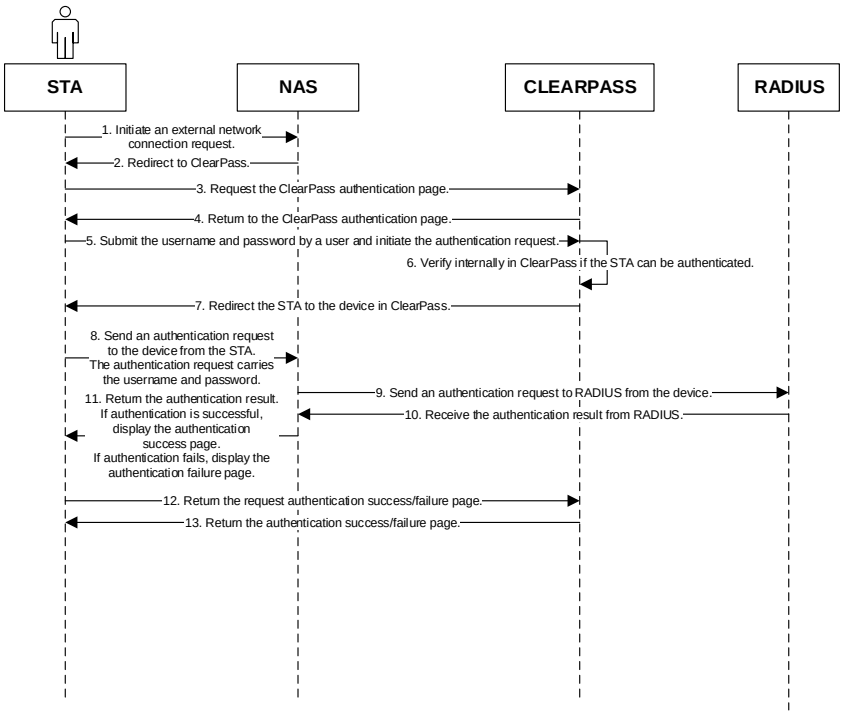
1 Authentication client: Is usually a browser running HTTP. It sends HTTP requests for accessing the Internet.

2 Network device: Typically refers to an access-layer device, for example, an AP on a WLAN. Generally, a network device is directly connected to STAs and needs to be enabled with web-based authentication. The device controls user's Internet access permissions, receives token verification requests or network release requests from the authentication client, and is responsible for verifying token information for the portal server.

3 Portal server: Provides a web page for web-based authentication and allows related operations. The portal server receives HTTP-based authentication requests from an authentication client, extracts account information from the requests, performs background authentication, and transfers the authentication result to the network device through the authentication client, and requests the authentication client to redirect to the relevant page of the portal server after network device verification.

4 Authentication server: Provides user authentication services. The specific authentication protocol such as RADIU is determined through negotiation between the portal server and the authentication server.

Process of ClearPass authentication:



1 Before authentication, the device intercepts all HTTP requests sent by a non-authenticated user and redirects them to the portal server. Then an authentication page pops up on the browser of the user.

2 The user enters authentication information including the username, password, and verification code on the authentication page for the browser to interact with the portal server.

3 The portal server validates user information in the background. If authentication fails, the server returns a failure page to the client. Otherwise, the client is redirected to the network device.

4 Upon receiving the request from the authentication client, the network device verifies information with the portal server, and redirects the client to a page of the portal server based on the verification result.

Figure 1-7 ClearPass Authentication Process

User logout process:

There are two scenarios of client logout. In the first scenario, the NAS detects that a client has gone offline due to reasons such as reaching the maximum online time, exceeding the traffic limit, or experiencing a disconnection in the link. The second scenario occurs when a client has initiated logout by clicking the logout button on the logout page.

1 The client clicks the logout button on the web page, selects logout, and initiates logout requests to the portal server and network device simultaneously or at different time points, depending on the implementation of the portal server.

2 The NAS disconnects a client with traffic lower than the threshold based on parameters of user online traffic detection.

Related Configuration

Creating a ClearPass Template

By default, a ClearPass template is not configured.

Run the **web-auth template** { **cpweb** | *template-name* **cpweb** } command in global configuration mode to create a ClearPass template.

You can use the ClearPass template for web-based authentication.

Configuring Server IP Address

By default, the server IP address is not configured.

Run the **ip** *ip-address* command in template configuration mode to configure the server IP address.

Server access requests are allowed by the device and rate limiting can be performed on requests transmitted to the server.

Configuring Server Authentication URL

By default, the server authentication URL is not configured.

Run the **url** *url-string* command in template configuration mode to configure the URL that users will be redirected to. Typically, the portal authentication page is used.

Configuring a Response Mode After Successful Authentication

By default, the response mode is to return a page with a success message (msg mode).

Run the **login-success response** { **redirect-init-url** [**default-url** *url-string*] **| msg** *msg-string* | **redirect-url** *url-string* } command in template configuration mode to configure one of the following three response modes:

- redirect-init-url: Redirects users back to the initially accessed page, depending on the URL provided by the server. You can specify the default URL when the server does not provide a URL.
- msg: Returns a page with a specified message after successful authentication.
- redirect-url: Redirects users to a specified page after successful authentication.

Configuring a Response Mode Upon an Authentication Failure

By default, the response mode is to redirect users to the login page upon an authentication failure.

Run the **login-fail response** { **redirect-login-url** | **redirect-url** *url-string* [**errmsg-key** *key-string*] **| msg** *msg-string* } command in template configuration mode to configure one of the following three response modes:

- redirect-login-url: Redirects users back to the login page upon an authentication failure.
- redirect-url: Redirects users to a specified URL upon an authentication failure. The parameter name for error messages can be configured.

- msg: Returns a page with a specified message upon an authentication failure.

Configuring a Mode for the Device to Resolve Authentication Requests

By default, authentication paramters include username, password, and URL.

By default, passwords are not in cleartext mode and not encrypted.

Run the **http-method post** [**username-key** *key-string*] [**password-key** *key-string*] [**init-url-key** *key-string*] [**password-encrypt** { **none** | **uam** }] command in template configuration mode to configure a mode for the device to resolve authentication requests on a device.

uam: Uses ASCII to encrypt passwords.

Configuring Whether to Display a Window for Proactive Logout After Successful Authentication

NBy default, no window for proactive logout is displayed.

Run the **logout-popup-window** command in template configuration mode to configure the window for proactive logout to be displayed.

Configuring the IP Address of the NAS

By default, the device's IP address is not configured.

Run the **web-auth auth-server ip** *ip-address* command in global configuration mode to configure the IP address of the NAS.

Set the access service IP address of the device for ClearPass, which is used for communication from the server to the IP address.

The access service IP address of the NAS cannot be set to a passthrough address.

When the access service IP address is configured as the IP address of the NAS and a STA in the authentication template accesses this IP address, the NAS intercepts the request of the STA and forwards it to the server. As a result, the STA fails to access the web management page of the NAS.

If a STA in the authentication template accesses this IP address for device management, configure the access service IP address as the unused virtual service IP address, for example, 1.1.1.1 and 2.2.2.2.

If the actual IP address of a device is used to log in to the device, there are security issues. In this case, the IP address for device management is mapped to the extranet IP address. Security devices such as firewalls are deployed between the extranet and servers to ensure security, whereas no security measures are taken for access through the intranet. If the actual IP address of the device is visible, the device can be easily attacked. The virtual IP address is recommended.

Configuring the Port of the NAS

By default, the port of the NAS is not configured.

Run the **web-auth auth-server http** [***port***] command in global configuration mode to configure the port of the NAS. Then the device will start listening on this port.

The port is used by ClearPass for listening, and a STA will initiate HTTP requests to this port during authentication.

Configuring the URL for Initiating Authentication from a STA

By default, the URL is http://ip:port/login.

Run the **web-auth auth-server submit-url** command in global configuration mode to configure the URL.

The URL is used by ClearPass for STAs to initiate authentication, and must start with **http://** and cannot contain question marks (?). It must be consistent in ClearPass.

Submitting authentication information to this URL will trigger an authentication request.

Enabling AAA Authentication

By default, AAA authentication is disabled.

Run the **aaa new-model** command in global configuration mode to enable AAA authentication.

ClearPass authentication relies on AAA authentication, so AAA authentication must be enabled when ClearPass is used.

Configuring the RADIUS Server and Communication Key

By default, the RADIUS server and communication key are not configured.

Run the **radius-server host** command in global configuration mode to configure the RADIUS server and communication key.

The RADIUS server is used for web-based authentication.

Configuring the Method List for Web-based Authentication of the AAA Module

By default, the method list for web-based authentication of the AAA module is not configured.

Run the **aaa authentication cpweb** command in global configuration mode to configure the authentication method for second-generation web-based authentication.

Web-based authentication can be configured to use this method list for authentication interaction.

Configuring the Method List for Network Accounting of the AAA Module

By default, the method list for network accounting of the AAA module is not configured.

Run the **aaa accounting network** command in global configuration mode to configure the network accounting method.

Web-based authentication can be configured to use this method list for accounting interaction.

Configuring the AAA Authentication Method List Name for Web-based Authentication

By default, the default method is used.

Run the **web-auth authentication cpweb** command in global or WLAN security configuration mode to configure the method list name.

Web-based authentication initiates authentication requests to AAA authentication using this method list name.

Configuring the AAA Accounting Method List Name for Web-based Authentication

By default, the default method is used.

Run the **web-auth accounting cpweb** command in global or WLAN security configuration mode to configure the method list name.

Web-based authentication sends accounting requests to AAA authentication using this method list name.

Enabling Web-based Authentication

By default, web-based authentication is disabled.

Run the **webaut** command in interface configuration mode to enable web-based authentication on the port connected to STAs.

After authentication is enabled, non-authenticated users on the port will be redirected to the authentication page.

1.4 Configuration

Configuration	Description and Command	
Configuring First-Generation Web-based Authentication	⚠ (Mandatory) It is used to set basic parameters of Ruijie first-generation web-based authentication.	
	web-auth template eportalv1	Configures the web-based authentication template.
	ip *ip-address*	Configures the IP address of the portal server.
	context	Configures the context ID and IP address of the hot standby server.
	url *url-string*	Configures the web-based authentication URL of the portal server.
	fmt { **ace** | **default** }	Configures the URL format of the portal server.
	bindmode { **ip-mac-mode** | **ip-only-mode** }	Configures a binding mode.
	redirect { **http** | **js** }	Configures a redirection mode.
	web-auth portal key [**0** | **1** | **7**] *key-string*	Configures the web-based authentication communication key.
	snmp-server community *community-string* **rw**	Configures the SNMP server community string.
	snmp-server host *ip-address* **inform version 2c** *community-string* **web-auth**	Configures the SNMP server.
	snmp-server enable traps web-auth	Enables the SNMP server Trap/Inform function.
	webauth	Enables web-based authentication on an interface.
Configuring Second-Generation Web-based Authentication	⚠ (Mandatory) It is used to set basic parameters of Ruijie second-generation web-based authentication.	
	aaa new-model	Enables AAA.
	radius-server host *ip-address* [**auth-port** *port-number*] [**acct-port** *port-number*] **key** *string*	Configures the RADIUS server and communication key.

	aaa authentication web-auth { **default** | *list-name* } *method1* [*method2*...]	Configures an AAA method list for web-based authentication. (RADIUS authentication is implemented.)
	aaa accounting network { **default** | *list-name* } **start-stop** *method1* [*method2*...]	Configures an AAA method list for web-based accounting. (RADIUS accounting is implemented.)
	web-auth template { **eportalv2** | *portal-name***v2** }	Configures a web-based authentication template.
	ip *ip-address*	Configures the IP address of the portal server.
	context	Configures the context ID and IP address of the hot standby server.
	url *url-string*	Configures the web-based authentication URL of the portal server.
	fmt { **cmcc-ext1** | **cmcc-ext2** | **cmcc-mtx** | **cmcc-normal** | **cmcc-ext3** | **ct-jc** | **cucc** | **default** | **custom** }	Configures the URL format of the portal server.
	bindmode { **ip-mac-mode** | **ip-only-mode** }	Configures a binding mode.
	redirect { **http** | **js** }	Configures a redirection mode.
	pack-attr { **session-id** | **bas-ip** | **nas-id** } **position first**	Configures a specific attribute at the beginning of a Portal packet.
	web-auth portal key [**0** | **1** | **7**] *key-string*	Configures the web-based authentication communication key.
	webauth	Enables second-generation web-based authentication on an interface.
Configuring iPortal Web-based Authentication	⚠ (Mandatory) It is used to set basic parameters of Ruijie iPortal web-based authentication.	
	aaa new-model	Enables AAA.
	radius-server host *ip-address* [**auth-port** *port-number*] [**acct-port** *port-number*] **key** *string*	Configures the RADIUS server and communication key.
	aaa authentication iportal { **default** | *list-name* } *method1* [*method2*...]	Configures an AAA method list for Ruijie iPortal web-based authentication. (RADIUS authentication is implemented.)

	aaa accounting network { **default** | *list-name* } **start-stop** *method1* [*method2*...]	Configures an AAA method list for Ruijie iPortal web-based accounting. (RADIUS accounting is implemented.)
	web-auth template iportal	Configures the iPortal web-based authentication template.
	login-popup *url-string*	Configures the advertisement pushing URL before authentication.
	online-popup url-string	Configures the advertisement pushing URL after successful authentication.
	page-suit *filename*	Configures the custom page suite.
	time-interval *hour*	Configures the built-in advertisement pop-up interval.
	webauth	Enables Ruijie iPortal web-based authentication on an interface.
Configuring MAC Address-Based SMS Authentication	(Mandatory) It is used to set basic parameters of MAC address-based SMS authentication.	
	aaa new-model	Enables AAA.
	radius-server host *ip-address* [**auth-port** *port-number*] [**acct-port** *port-number*] **key** *string*	Configures the RADIUS server and communication key.
	aaa accounting network { **default** | *list-name* } **start-stop** *method1* [*method2*...]	Configures the accounting method list.
	aaa authentication web-auth { **default** | *list-name* } *method1* [*method2*...]	Configures the web-based authentication method list.
	web-auth template { **eportalv2** | *portal-name* **v2** }	Configures a web-based authentication template.
	ip { *ip-address* | *ipv6-address* }	Configures the server IP address.
	url *url-string*	Configures the server URL.
	fmt { **cmcc-ext1** | **cmcc-normal** | **default** }	Configures the URL format of the portal server.
	web-auth portal key *key-string*	Configures the encryption key of the server.
	web-auth sms-flow interval *interval* **threshold** *flows*	Configures the detection interval and traffic threshold for MAC address-based SMS authentication.
	web-auth bind-portal *string* [**type** { **group-spec** | **local-spec** }]	Configures the portal server bound for MAC address-based SMS authentication.

	web-auth winterface *string*	Sets the **winterface** field in the redirected URL.
	web-auth wlan-ac-ip *ipv4*	Sets the **ACIP** field in the redirection URL.
Configuring WiFiDog Authentication	(Mandatory) It is used to set basic parameters of WiFiDog authentication.	
	web-auth template wifidog	Configures a WiFiDog authentication template.
	ip *ip-address*	Configures the IP address of the portal server.
	url *url-string*	Configures the web-based authentication URL of the portal server.
	nas-ip *ip-address*	Configures the IP address of the NAS.
	web-auth sta-perception enable	Configures WiFiDog MAB authentication.
	gateway-id *string*	Configures the gateway ID.
	web-auth portal wifidog	Specifies a WiFiDog authentication template.
	webauth	Enables web-based authentication.
Configuring WeChat Web-based Authentication	(Mandatory) It is used to set basic parameters of WeChat authentication.	
	web-auth template { **wechat** | *portal-name* **wechat** }	Configures a WeChat web-based authentication template.
	ip *ip-address*	Configures the IP address of the portal server.
	service-url *url-string*	Configures the WeChat web-based authentication URL.
	url *url-string*	Configures the authentication page URL of the portal server.
	key *key-string*	Configures the encryption key of the portal server.
	nas-ip *ip-address*	Configures the access service IP address of the NAS.
	web-auth sta-perception enable	Configures WeChat web-based authentication.
	web-auth wechat-escape interval *minutes*	Configures the escape function.
	web-auth wechat-check interval *minutest*	Configures server detection.
	web-auth valid-ip-acct [**timeout** *seconds*]	Configures IP check.

	web-auth portal wechat	Specifies a WeChat web-based authentication template.
	webauth	Enables web-based authentication.
Configuring ClearPass Authentication	(Mandatory) It is used to configure basic parameters of WeChat Wi-Fi authentication.	
	aaa new-model	Enables AAA.
	radius-server host *ip-address* [**auth-port** *port-number*] [**acct-port** *port-number*] **key** *string*	Configures the RADIUS server and key.
	aaa authentication cpweb { **default** | *list-name* } *method1* [*method2*...]	Configures the method list for web-based authentication (using RADIUS authentication).
	aaa accounting network { **default** | *list-name* } **start-stop** *method1* [*method2*...]	Configures the method list for network accounting (using RADIUS accounting).
	web-auth template cpweb	Creates a ClearPass authentication template.
	ip *ip-address*	Configures the IP address of the server.
	context	Configures the context ID and IP address of the hot standby server.
	url *url-string*	Configures the URL of the server.
	login-success response { **redirect-init-url** [**default-url** *def-string*] | **msg** *msg-string* | **redirect-url** *url-string* }	Configures a response mode after successful authentication.
	login-fail response { **redirect-login-url** | **redirect-url** *url-string* [**errmsg-key** *key-string*] | **msg** *msg-string* }	Configures a response mode upon an authentication failure.
	http-method post [**username-key** *key-string*] [**password-key** *key-string*] [**init-url-key** *key-string*] [**password-encrypt** { **none**|**uam** }]	Configures a mode for the device to resolve authentication requests.
	logout-popup-window	Configures whether to pop up a window to actively go offline after successful authentication.
	web-auth auth-server ip *ip-address*	Configures the IP address of the device.
	web-auth auth-server http [*port*]	Configures the port of the device.
	web-auth auth-server submit-url *url-string*	Configures the URL for STAs to initiate authentication.

	webauth	Enables web-based authentication.
Specifying an Authentication Method List	(Optional) It is used to specify an AAA authentication method list in template configuration mode. The name of the method list must be correctly specified.	
	authentication *mlist-name*	Specifies an AAA authentication method list (only for Ruijie second-generation web-based authentication and Ruijie iPortal web-based authentication).
Specifying an Accounting Method List	(Optional) It is used to specify an AAA accounting method in template configuration mode. The name of the method list must be correctly specified.	
	accounting *mlist-name*	Specifies an AAA accounting method list (only for Ruijie second-generation web-based authentication and Ruijie iPortal web-based authentication).
Configuring the Communication Port of the Portal Server	(Optional) It is used to specify the UDP port of the portal server in template configuration mode. The configured port number must be consistent with that on the RADIUS server.	
	port *port-num*	Configures the communication port of the portal server.
Specifying the Web-based Authentication Binding Mode	(Optional) It is used to specify the entry binding mode in template configuration mode.	
	bindmode { **ip-mac-mode** | **ip-only-mode** }	Specifies the template binding mode.
Customizing a Page Suite	(Optional) It is used to configure the page suite used by Ruijie iPortal web-based authentication for a template.	
	page-suite *file-name*	Customizes a page suite for Ruijie iPortal web-based authentication.
Customizing a Page Suite	(Optional)	
	N/A	Complies with the page suite specifications.
Configuring the Advertisement Pushing Mode	(Optional) It is used to configure an iPortal web-based authentication advertisement URL in template configuration mode.	
	login-popup *url*	Configures the login pop-up URL.

	online-popup *url*	Configures the pop-up URL after successful authentication.
Configuring a Custom URL Format	(Optional) It is used to configure the redirection URL format for a template.	
	fmt custom encry { [**none** | **md5** | **des** | **des_ecb | des_ecb3**] } { [**user-ip** *userip-str*] [**user-mac** *usermac-str* **mac-format** [**dot | line | none | 5colon**]] [**user-vid** *uservid-str*] [**user-id userid-str**] [**nas-ip** *nasip-str*] [**nas-id** nasid-str] **[nas-id2** *nasid2-str*] [**ac-name** *acname-str*] [**ap-mac** *apmac-str* **mac-format** [**dot** | **line** | **none | 5colon**]] [**url** *url-str*] [**ssid** *ssid-str*] [**port** *port-str*] [**ac-serialno** *ac-sno-str*] [**ap-serialno** *ap-sno-str*] [**additional** *extern-str*] }	Configures the format of the web-based authentication URL.
Configuring the Redirection HTTP Port	(Optional) It is used to configure the TCP interception port for redirection, so that packets on the specified port can be redirected when interception is enabled.	
	http redirect port *port-num*	Configures the redirection TCP port.
Configuring Rate Limiting for Logging in Web-based Authentication	(Optional) It is used to configure the syslog function in web-based authentication.	
	web-auth logging enable *num*	Configures the logging rate limit for web-based authentication.
Configuring the Maximum Number of HTTP Sessions for Non-authenticated Clients	(Optional) It is used to adjust the HTTP session limit. The limit value needs to be increased when there are many sessions in the background.	
	http redirect session-limit *session-num* [**port** *port-session-num*]	Configures the maximum number of HTTP sessions for non-authenticated clients.
Configuring the HTTP Redirection Timeout	(Optional) It is used to modify the timeout interval for redirection connections. The timeout interval needs to be increased to complete redirection when the network is unstable.	
	http redirect timeout *seconds*	Configures the HTTP redirection timeout interval.
Configuring the Authentication-Free Network Resource	**http redirect direct-site**	Configures the authentication-free network resource.

Configuring the Authentication-Free ARP Resource	(Optional) It is used to permit packets from the specified authentication-free ARP resource. Packets from the gateway ARP resource must be permitted to pass when ARP check is enabled.	
	http redirect direct-arp *ip-address* [*ip-mask*]	Configures the authentication-free ARP resource.
Configuring the Authentication-Free Address Range	(Optional) It is used to configure clients to access the Internet without authentication.	
	web-auth direct-host *ipv4-address* [*ip-mask*] [**arp**] [**port** *interface-name*]	Configures the range of IP or MAC addresses of clients without authentication.
Configuring the Interval for Updating Online User Information	(Optional) It is used to configure the interval for updating online user information.	
	web-auth update-interval *seconds*	Configures the interval for updating online user information.
Configuring Portal Server Detection	(Optional) It is used to detect availability of the portal server. If it is unavailable, services are switched to the standby portal server. The active and standby portal servers must be configured.	
	web-auth portal-check [**interval** *intsec* [**timeout** *tosec*] [**retransmit** retries]	Configures the portal server detection interval, timeout interval, and timeout retransmission count.
	web-auth ping [**interval** *minutes*] [**retry** *times*]	Configures the ping detection interval and timeout retransmission count.
Configuring Portal Escape	(Optional) It is used to allow new clients to access the Internet without authentication when the portal server is unavailable.	
	web-auth portal-escape	Configures portal escape.
Enabling DHCP Address Check	(Optional) It is used to check whether the IP address of a client is allocated by the DHCP server. If not, the client's authentication request is denied.	
	web-auth dhcp-check	Checks whether the IP address of a client is assigned by the DHCP server.
Disabling Link Detection	(Optional) It is used for anti-jitter. This prevents web-based authentication entries from being deleted when a link of a client is disconnected, so that the client can access the Internet again without authentication.	
	no web-auth sta-leave detection	Disables link detection.

Disabling Portal Extension	(Optional) It is used to disable portal extension in order to interwork with CMCC standard portal server. Portal extension must be enabled for interworking with Ruijie portal server software.	
	no web-auth portal extension	Disables portal extension.
Configuring an Allowlist and a Blocklist	(Optional) It is used to configure a blocklist to prevent authenticated clients from accessing some network resources, and to configure an allowlist to allow non-authenticated clients to access some network resources.	
	web-auth acl	Configures an allowlist and a blocklist.
Configuring Anti-jitter Accounting	(Optional) It is used to configure whether the anti-jitter duration is included into the online duration, in order to improve accounting precision. The anti-jitter duration depends on the anti-jitter configuration of a specific product.	
	web-auth accounting jitter-off	Configures the jitter-off duration. (Use the **no** form of this command to disable this function.)
	web-auth user-flow-control by-radius-class { **format-16bytes** | **format-32bytes** }	Configures client-based rate limiting.
Configuring the Source Port for Communication with the Portal Server	(Optional) It is used to configure the source port used for communication between the NAS and portal server.	
	ip portal source-interface *interface-type interface-num*	Specifies the port used for communication between the NAS and portal server.
Configuring the Anti-Noise Function	(Optional) Packets sent to the configured IP address and port will not be filtered by the device enabled with the noise reduction function.	
	web-auth anti-noise ip *ip-addr* **port** *port*	Configures the specified IP address and port, so that the corresponding packets will not be filtered by the device enabled with the anti-noise function.
Configuring an NDKEY-Compatible Web-based Authentication URL	(Optional) It is used to configure the web-based authentication URL used in web-based authentication to support the Shanghai NDKEY system.	
	web-auth dkey-compatible url-parameter *string*	Configures compatibility between the Shanghai NDKEY system and redirection web-based authentication URL.

Configuring Multi-Portal Mapping	**web-auth portal** { **eportalv2** | **eportalv1** | **iportal** | *name* } **ip-mapping** *ipv4 mask*	Configuring Multi-Portal Mapping
Enabling NAT for Ruijie iPortal Web-based Authentication	⚠ (Optional) It is used to configure Ruijie iPortal web-based authentication to support Network Address Translation (NAT).	
	iportal nat enable	Enables NAT for Ruijie iPortal web-based authentication.
Configuring the iPortal HTTP Retransmission Count	⚠ (Optional) It is used to configure the iPortal HTTP retransmission count.	
	iportal retransmit *count*	Configures the iPortal HTTP retransmission count.
Configuring Service Selection in Ruijie iPortal Web-based Authentication	⚠ (Optional) It is used to configure the service type used by Ruijie iPortal web-based authentication.	
	iportal service { **internet** *internet-name* | **local** *local-name* }	Configures the service type used by Ruijie iPortal web-based authentication.
Configuring the UA Field for iPortal Web-based Authentication User	⚠ (Optional) It is used to configure STA name corresponding to the UA field of the user.	
	iportal user-agent *ua-name* **type mobile** *ua-string*	Configures the STA name corresponding to the UA field of the user.
Customizing a Page Suite for Ruijie iPortal Web-based Authentication	**web-auth import-page-suite tftp:***path*	Imports a page suite for Ruijie iPortal web-based authentication.
Configuring the Accounting Method List of Web-based Authentication	⚠ (Optional) It is used to configure an accounting method for web-based authentication in global configuration mode.	
	web-auth accounting { **v2** | **intra** | **cpweb** } { **default** | *name* }	Configures an accounting method for web-based authentication in global configuration mode.
Configuring a Web-based Authentication Method List	⚠ (Optional) It is used to configure a web-based authentication method in global configuration mode.	
	web-auth authentication { **v2** | **intra** | **cpweb** } { **default |** *name*}	Configures a web-based authentication method in global configuration mode.
Configuring Upgrade Compatibility	**http redirect** *ip-address*	Configures the IP address of the portal server for first-generation web-based authentication.
	⚠ (Optional)	

Configuring RADIUS Authentication Escape	**web-auth radius-escape**	Configures RADIUS authentication escape.
Configuring Built-in Logo Replacement	**web customized-logo enable**	Configures the logo replacement function for iPortal web-based authentication.
Configuring Noise Reduction in Wireless Web-based Authentication	**web-auth noise** [**aging** *agmin*] [**hit** *times*]	Configures the anti-noise reduction policy for wireless web-based authentication.
Enabling iOS Automatic Pop-up Window Control in WeChat Web-based Authentication	**http redirect adapter ios**	Enables iOS automatic pop-up window control in WeChat authentication.
Enabling Smart WeChat Web-based Authentication	**web-auth sta-perception enable**	Enables MAB authentication for WeChat authentication.
Enabling IPFIX Traffic Upload	**web-auth acct-mtehod ipfix**	Enables IPFIX traffic upload.
Configuring Transparent Transmission of the 0x05 Attribute of the Portal Protocol	(Optional) It is used to configure transparent transmission of the 0x05 attribute of the portal protocol.	
	web-auth portal-attribute [**5** | **textinfo**]	Configures transparent transmission of the 0x05 attribute of the portal protocol.
Configuring Uniqueness Check of Portal Authentication Accounts	(Optional) It is used to configure uniqueness check of portal authentication accounts.	
	web-auth portal-valid unique-name	Configures uniqueness check of portal authentication accounts.
Enabling the One-click Configuration Through WeChat	(Optional) It is used to enable one-click wireless configuration through Wechat connection to Wi-Fi.	
	web-auth wechat-template wlan-range portal-ip nas-ip [**ios-adapter** | **perception**]	Enables one-click wireless configuration through WeChat connection to Wi-Fi.
Configuring NAS-PORT-ID for an AP	**nas-port-id** *string*	Configures NAS-PORT-ID for an AP.
Enabling the Device to Automatically Add a Domain Name to the Authentication Username	**domain** *domain-string*	Configures the device to automatically add a domain name to the username.
Configuring the App Authentication Template	**web-auth template** { **app** | *portal-name* **app** }	Creates an app authentication template.
	web-auth portal { **app |** *name* }	Applies an app authentication template.
Configuring ISE Authentication	(Mandatory) It is used to configure Identity Service Engine (ISE) authentication parameters.	

	aaa new-model	Enables AAA.
	aaa authentication cpweb { **default** | *list-name* } *method1* [*method2*...]	Configures the web-based authentication method list (ClearPass authentication).
	web-auth template cpweb	Creates a template (ClearPass authentication).
	ip *ip-address*	Configures the IP address of the ISE server.
	url *url-string*	Configures the Uniform Resource Locator (URL) of the ISE server.
	web-auth auth-server ip *ip-address*	Configures the access service IP address of the device that performs ISE authentication.
	web-auth auth-server http [*port*]	Configures the TCP port used by a STA for initiating ISE authentication.
	web-auth auth-server submit-url *url-string*	Configures the URL used by a STA for initiating ISE authentication.
	webauth	Enables web-based authentication on an interface.
Configuring the Role-based Portal Redirection Template	**web-auth template** *template-name* **rdweb**	Creates a template.
	ip *ip-address*	Configures a Server IP Address.
	url *url-string*	Configures a Server URL.
Configuring the Default Role upon Authentication Success	**web-auth default-role** *name*	Configures the default client role after the web authentication succeeds.
Configuring Second-Generation Web-based Authentication to Support Direct Access to the Authentication Page	⚠ (Optional) It is used to configure second-generation web-based authentication to support direct access to the authentication page for authentication.	
	web-auth portal direct-auth	Configures second-generation web-based authentication to support direct access to the authentication page for authentication.
Importing and Enabling an SSL Certificate	**web-auth import-ssl** [**auth-server**] { **cert ftp:***path* | **cert tftp:***path* } { **key ftp:***path* | **key tftp:***path* }	IImports a Secure Sockets Layer (SSL) certificate.

	web-auth ssl-policy { **https-redirect** | **auth-server** }	Enables an SSL certificate.
Configuring the Lowest TLS Version	**web-auth ssl-minimum-version tls1.2**	Sets the lowest TLS version for interaction between the device and STA to TLS 1.2.

1.4.1 Configuring First-Generation Web-based Authentication

Configuration Effect

Redirect non-authenticated clients to the web-based authentication URL to perform authentication.

Notes

N/A

Configuration Steps

Configuring the Portal Server

- Mandatory. To enable web-based authentication successfully, you must configure and apply the portal server.
- When the NAS or aggregation device finds a non-authenticated client attempting to access network resources through HTTP, the device redirects the access request to the specified web-based authentication URL. Then the client can initiate authentication to the portal server through this URL. If the IP address of the portal server is configured as an authentication-free network resource, non-authenticated clients can directly visit this IP address through HTTP.

Configuring the Communication Key Between the NAS and Portal Server

- Mandatory. To enable web-based authentication successfully, you must configure the key used for communication between the NAS or aggregation device and portal server.
- When the NAS finds a non-authenticated client attempting to access network resources through HTTP, the device redirects the access request to the specified web-based authentication URL. Then the client can initiate authentication to the portal server through this URL. During authentication, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.

Setting the SNMP Parameters Between the NAS and Portal Server

- Mandatory. To enable web-based authentication successfully, you must set SNMP management parameters used for communication between the NAS and portal server.
- The access or aggregation device and portal server manage authenticated clients through SNMP or MIB. The MIB is used to manage a table of authenticated clients on the NAS. The portal server accesses the MIB to obtain client statistics so as to control client login and logout. When a client logs out, the NAS or aggregation device will inform the portal server by sending SNMP-Inform packets.

Enabling Ruijie First-Generation Web-based Authentication on an Interface

- Mandatory.

- When first-generation web-based authentication is enabled in WLAN security configuration mode, web-based authentication is not enabled on any port by default. The users connecting to the port do not need to perform web-based authentication.

Verification

- Verify that non-authenticated clients are required to perform authentication.
- Verify that authenticated clients can access the Internet normally.

Related Commands

Creating a Web-based Authentication Template

Command	**web-auth template eportalv1**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	**eportalv1** is the default template of Ruijie first-generation web-based authentication.

Configuring the IP Address of the Portal Server

Command	**ip** *ip-address*
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the Context ID and IP Address of the Hot Standby Server

Command	**context** *ctx-id peer-ip-address*
Parameter Description	*ctx-id*: Configures the context ID of the hot standby server. *peer-id-address*: Configures the IP address of the hot standby server.
Command Mode	Web authentication template configuration mode
Usage Guide	N/A

Configuring the Web-based Authentication URL of the Portal Server

Command	**url** *url-string*
Parameter Description	*url-string*: Indicates the Web-based authentication URL of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The URL starts with **http://** or **https://**.

Configuring the URL Format of the Portal Server

Command	**fmt** { **ace** | **default** }

Parameter Description	Indicates the URL format of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	When the **fmt** parameter is set to **ace**, association with ACEs is supported.

Specifying the Web-based Authentication Binding Mode

Command	**bindmode** { **ip-mac-mode** | **ip-only-mode** }
Parameter Description	Indicates the web-based authentication binding mode.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Specifying the Redirection Method

Command	**redirect** { **http** | **js** }
Parameter Description	Indicates the encapsulation format of redirected packets.
Command Mode	Web-based authentication template configuration mode
Usage Guide	For JavaScript-incapable Apps, you need to specify the HTTP encapsulation format to trigger redirection.

Configuring the Web-based Authentication Communication Key

Command	**web-auth portal key** [**0** | **1** | **7**] *key-string*
Parameter Description	**0**: Configures the server key encryption type as cleartext, that is, the server key is input, saved, and displayed in cleartext. **1**: Configures the server key encryption type to ciphertext storage, that is, the cleartext input and ciphertext storage and display. **7**: Configures the server key encryption type as full ciphertext, that is, ciphertext input, ciphertext storage, and ciphertext display. *key-string:* Indicates the web-based authentication communication key used for communication between the NAS and portal server. The key contains up to 255 characters.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the SNMP Server Community String

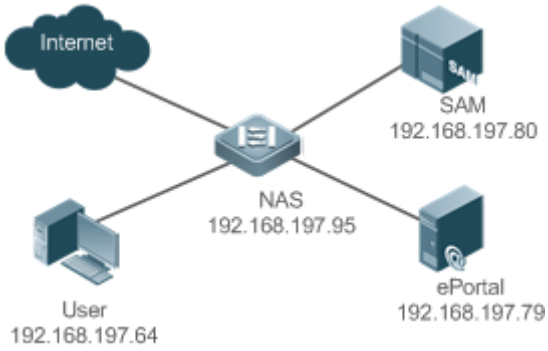
Command	**snmp-server community** *community-string* **rw**
Parameter Description	*community-string*: Indicates the community string. **rw**: Is used for read and write operations required by the Set operation in the MIB.
Command Mode	Global configuration mode

Usage Guide	The SNMP server community string is used by the portal server to manage online clients on the NAS or aggregation device.

Configuring the SNMP Server

Command	**snmp-server host** *ip-address* **inform version 2c** *community-string* **web-auth**
Parameter Description	*ip-address*: Indicates the IP address of the SNMP server, that is, portal server. *community-string*: Configures the community string used to send an SNMP Inform message.
Command Mode	Global configuration mode
Usage Guide	Configure the SNMP server to receive web-based authentication messages, including the type, version, community string, and other parameters. **inform:** Enables the SNMP Inform function. The NAS or aggregation device will send a message to the portal server when a client logs out. The message type is set to Inform instead of Trap to avoid message loss. **version 2c**: Indicates that later versions of SNMPv2 support SNMP Inform. It cannot be set to SNMPv1. **web-auth**: Indicates the preceding parameters to be used for web-based authentication. For details about SNMP configuration, see *Configuring SNMP*. SNMPv2 is used as an example here. SNMPv3 is recommended if higher security is required for SNMP communication between the NAS and portal server. To use SNMPv3, change **SNMP Community** to **SNMP User**, **version 2c** to **SNMPv3**, and set SNMPv3-related security parameters. For details, see *Configuring SNMP*.

Enabling the Device to Send Trap or Inform Messages for Web-based Authentication



Command	**snmp-server enable traps web-auth**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure the NAS or aggregation device to send Trap and Inform messages for web-based authentication. web-auth: Indicates web-based authentication messages.

Enabling Ruijie First-Generation Web-based Authentication on an Interface

Command	**webauth**
Parameter Description	N/A
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Configuration Example

Configuring First-Generation Web-based Authentication

Scenario **Figure 1-8**	
Configuration Steps	● On the NAS, configure the IP address of the ePortal server and the key (webkey) used for communicating with the ePortal server. ● Configure the web-based authentication URL on the NAS. ● Set SNMP parameters (community string: public) used for communication between the NAS and ePortal server. ● Enable web-based authentication on the WLAN of the NAS.

	`Hostname# config`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#web-auth template eportalv1`
	`Hostname(config.tmplt.eportalv1)#ip 192.168.197.79`
	`Hostname(config.tmplt.eportalv1)#exit`
	`Hostname(config)# web-auth portal key webkey`

	`Hostname(config)# web-auth template eportalv1`
	`Hostname(config.tmplt.eportalv1)#url`
	`http://192.168.197.79:8080/eportal/index.jsp`
	`Hostname(config.tmplt.eportalv1)#exit`

	`Hostname(config)# snmp-server community public rw`
	`Hostname(config)# snmp-server enable traps web-auth`
	`Hostname(config)# snmp-server host 192.168.197.79 inform version 2c public web-auth`
	`Hostname(config)# exit`

	`Hostname(config)# wlansec 1`
	`Hostname(config-wlansec)# web-auth portal eportalv1`
	`Hostname(config-wlansec)# webauth`

Verification	● Check whether web-based authentication is configured successfully.

	`Hostname(config)#show running-config`
	`...`
	`snmp-server host 192.168.197.79 inform version 2c public web-auth`
	`snmp-server enable traps web-auth`
	`snmp-server community public rw`
	`...`
	`web-auth template eportalv1`
	` ip 192.168.197.79`

```
 url http://192.168.197.79:8080/eportal/index.jsp
!
web-auth portal key webkey
...
wlansec 1
 web-auth portal eportalv1
 webauth
```

Common Errors

- SNMP parameters used for communication between the portal server and NAS are configured incorrectly, causing authentication failures.
- Specify the IP-MAC binding mode to deploy web-based authentication across the Layer 3 network, causing authentication failures.
- When web-based authentication is used with VRRP, run the **snmp-server trap-source ip** command to specify the VRRP address; otherwise, the portal server cannot process Trap packets correctly.

1.4.2 Configuring Second-Generation Web-based Authentication

Configuration Effect

Redirect non-authenticated clients to the web-based authentication URL to perform authentication.

Notes

- Second-generation web-based authentication complies with *CMCC WLAN Service Portal Specification*. Furthermore, it is extended to support Ruijie portal server. Perform compatibility configuration based on the server performance in actual deployment.
- When you configure the URL of the second-generation portal server, if the URL contains an IPv6 address, enclose it with a pair of square brackets, for example, http://[2001::1]/index.jsp. In addition, the **fmt** configuration is not supported in the IPv6 template.
- The **cmcc-normal** and **cmcc-ext1** parameters in the **fmt** command support only IPv4. If IPv6 is used, the configuration of the portal server is invalid.

Configuration Steps

Enabling AAA

- Mandatory. To enable Ruijie second-generation web-based authentication, you must enable AAA.
- The NAS is responsible for initiating authentication to the portal server through AAA in Ruijie second-generation web-based authentication.

Configuring the RADIUS Server and Communication Key

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure the RADIUS server.
- Clients' account information is stored on the RADIUS server. The NAS needs to connect to the RADIUS server to validate a client.

Configuring an AAA Method List for Web-based Authentication

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure an AAA authentication method list.
- An AAA authentication method list associates web-based authentication requests with the RADIUS server. The NAS selects an authentication method and server based on the method list.

Configuring an AAA Method List for Web-based Accounting

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure an AAA method list for web-based accounting.
- An accounting method list is used to associate an accounting method and server. In web-based authentication, accounting is implemented to record client fees.

Configuring the Portal Server

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure and apply the portal server.
- When the NAS or aggregation device finds a non-authenticated client attempting to access network resources through HTTP, it redirects the access request to the specified web-based authentication URL, where the client can initiate authentication to the portal server. If the IP address of the portal server is configured as a free network resource, non-authenticated clients can directly visit this IP address through HTTP.

Configuring the Communication Key Between the NAS and Portal Server

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure the key used for communication between the NAS or aggregation device and portal server.
- When the NAS finds a non-authenticated client attempting to access network resources, it redirects the client to the specified web-based authentication URL, where the client can initiate authentication to the portal server. During authentication, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.

Configuring the Portal Server in Global or Interface Configuration Mode

- Mandatory. To enable Ruijie second-generation web-based authentication, you must specify the use of the second-generation portal server in global or interface configuration mode.
- The NAS first selects the portal server in interface configuration mode. If such a portal server does not exist, the NAS selects the portal server in global configuration mode. If such a portal server does not exist, eportalv1 is used by default. The NAS redirects users to the selected portal server.

Enabling Ruijie Second-Generation Web Authentication on an Interface

- Mandatory.
- When Ruijie second-generation web-based authentication is enabled in interface configuration mode, web-based authentication is not enabled on any port by default. The users connecting to the port do not need to perform web-based authentication.

Verification

- Check whether non-authenticated clients are required to perform authentication.
- Check whether authenticated clients can access the Internet normally.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	You can configure the AAA authentication and accounting method lists only after AAA is enabled.

Configuring the RADIUS Server and Communication Key

Command	**radius-server host** *ip-address* [**auth-port***port-number1*] [**acct-port** *port-number 2*] **key** *string*
Parameter Description	*ip-address*: Indicates the IP address of the RADIUS server. *port-number1:* Indicates the authentication port. *port-number2:* Indicates the accounting port. *string*: Indicates the key string.
Command Mode	Global configuration mode
Usage Guide	By default, the authentication port number is 1812 and the accounting port number is 1813.

Configuring an AAA Method List for Web Authentication

Command	**aaa authentication web-auth** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	*list-name*: Creates a method list. *method1*: Configures method 1. *method2*: Configures method 2.
Command Mode	Global configuration mode
Usage Guide	Ruijie second-generation web-based authentication adopts RADIUS authentication.

Configuring an AAA Method List for Web Accounting

Command	**aaa accounting network** { **default** | *list-name* } **start-stop** *method1* [*method2*...]
Parameter Description	*list-name*: Creates a method list. *method1*: Configures method 1. *method2*: Configures method 2.
Command Mode	Global configuration mode
Usage Guide	Ruijie second-generation web-based authentication adopts RADIUS accounting.

Configuring the Second-Generation Web-based Authentication Template

Command	**web-auth template** { **eportalv2** | *portal-name* **v2** }

Parameter Description	*portal-name*: Indicates the customized portal server name.
Command Mode	Global configuration mode
Usage Guide	**eportalv2** indicates the default template of Ruijie second-generation web-based authentication.

Configuring the IP Address of the Portal Server

Command	**ip** { *ip-address* | *ipv6-address* }
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the Context ID and IP Address of the Hot Standby Server

Command	**context** *ctx-id peer-ip-address*
Parameter Description	*ctx-id*: Configures the context ID of the hot standby server. *peer-id-address*: Configures the IP address of the hot standby server.
Command Mode	Web authentication template configuration mode
Usage Guide	N/A

Configuring the Web-based Authentication URL of the Portal Server

Command	**url** *url-string*
Parameter Description	Indicates the web-based authentication URL of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The URL starts with **http://** or **https://**.

Configuring the Format of the Web-based Authentication URL

Command	**fmt** { **cmcc-ext1** | **cmcc-ext2** | **cmcc-mtx** | **cmcc-normal** | **ct-jc** | **cucc** | **default** | **custom** }
Parameter Description	Indicates the format of the web-based authentication URL.
Command Mode	Webauth template configuration mode
Usage Guide	The **cmcc-normal** and **cmcc-ext1** parameters in the **fmt** command support only IPv4. The **default** parameter indicates the default format. The **custom** parameter indicates the custom format. The **cmcc-ext2** parameter is supported for Liaoning CMCC. When **fmt** is set to **cmcc-mtx**, the URL format of mobile AC vendors is supported. The **ct-jc** format is supported for China Telecom. The **cucc** format is supported for Shandong China Telecom.

Configuring a User Binding Mode

Command	**bindmode** { **ip-mac-mode** | **ip-only-mode** }
Parameter Description	Indicates a user binding mode.
Command Mode	Webauth template configuration mode
Usage Guide	N/A

Specifying the Encapsulation Format of the Webauth URL

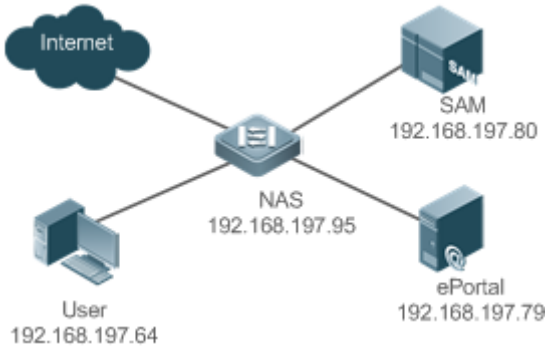
Command	**redirect** { **http** | **js** }
Parameter Description	Indicates the encapsulation format of redirected packets.
Command Mode	Web-based authentication template configuration mode
Usage Guide	For JavaScript-incapable Apps, you need to specify the HTTP encapsulation format to trigger redirection.

Configuring a Specific Attribute at the Beginning of a Portal Packet

Command	**pack-attr** { **session-id** | **bas-ip** | **nas-id** } **position first**
Parameter Description	**session-id**: Configures the session ID attribute at the beginning of a Portal packet. **bas-ip**: Configures the BAS IP attribute at the beginning of a Portal packet. **nas-id**: Configures the NAS ID attribute at the beginning of a Portal packet.
Command Mode	Second-generation web authentication template configuration mode
Usage Guide	

Configuring the Web-based Authentication Communication Key

Command	**web-auth portal key** [**0** | **1** | **7**] *key-string*
Parameter Description	**0**: Configures the server key encryption type as cleartext, that is, the server key is input, saved, and displayed in cleartext. **1**: Configures the server key encryption type to ciphertext storage, that is, the cleartext input and ciphertext storage and display. **7**: Configures the server key encryption type as full ciphertext, that is, ciphertext input, ciphertext storage, and ciphertext display. *key-string*: Indicates the Web-based authentication communication key used for the communication between the NAS and portal server. The key contains up to 255 characters.
Command Mode	Global configuration mode
Usage Guide	N/A



Enabling Ruijie Second-Generation Web-based Authentication

Command	**webauth**

Parameter Description	N/A
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Configuration Example

Configuring Second-Generation Web-based Authentication

Scenario **Figure 1-9**	
Configuration Steps	● Enable AAA on the NAS. ● Configure the RADIUS server and communication key on the NAS. ● Configure the default AAA method lists for web-based authentication and accounting on the NAS. ● Configure the IP address of the portal server and the web-based authentication communication key (webkey) used for communicating with the portal server on the NAS. ● Configure the web-based authentication URL on the NAS. ● Configure Ruijie second-generation web-based authentication in global configuration mode on the NAS. ● Enable web-based authentication on the WLAN.

	`Hostname#configure`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#aaa new-model`

	`Hostname(config)#radius-server host 192.168.197.79 key webkey`
	`Hostname(config)#aaa authentication web-auth default group radius` `Hostname(config)#aaa accounting network default start-stop group radius`

	`Hostname(config)#web-auth template eportalv2`
	`Hostname(config.tmplt.eportalv2)#ip 192.168.197.79`
	`Hostname(config.tmplt.eportalv2)#exit`
	`Hostname(config)#web-auth portal key webkey`

	`Hostname(config)# web-auth template eportalv2`
	`Hostname(config.tmplt.eportalv2)#url http://192.168.197.79:8080/eportal/index.jsp`
	`Hostname(config.tmplt.eportalv2)#exit`

	Hostname(config)# wlansec 1 Hostname(config-wlansec)# web-auth portal eportalv2 Hostname(config-wlansec)# webauth Hostname(config-wlansec)# exit
Verification	● Check whether web-based authentication is configured successfully.
	Hostname(config)#show running-config ... aaa new-model aaa authentication web-auth default group radius aaa accounting network default start-stop group radius ... radius-server host 192.168.197.79 key webkey ... web-auth template eportalv2 ip 192.168.197.79 url http://192.168.197.79:8080/eportal/index.jsp ! web-auth portal key webkey ... wlansec 1 web-auth portal eportalv2 webauth
	Hostname#show web-auth control Port Control Server Name Online User Count ------------------------- -------- -------------------- ------------- ---- wlansec 1 On eportalv2 0
	Hostname#show web-auth template Webauth Template Settings: --- Name: eportalv2 BindMode: ip-mac-mode Type: v2 Port: 50100 Ip: 192.168.197.79 Url: http://192.168.197.79:8080/eportal/index.jsp Wechat enable: 0 Temporary permit:0

Common Errors

- The communication key between the portal server and NAS is configured incorrectly or only on the portal server or NAS, causing authentication errors.
- The communication parameters of the RADIUS server and NAS are set incorrectly, causing authentication errors.

- The portal server does not support *CMCC WLAN Service Portal Specification*, causing compatibility failures.

1.4.3 Configuring iPortal Web-based Authentication

Configuration Effect

Redirect non-authenticated clients to the web-based authentication URL to perform authentication. No external portal server is required.

Notes

- Some devices, such as AP110, do not have a built-in page suite. You need to import a page suite before use. For details about the page suite support on a device, see the corresponding product description.
- Ruijie iPortal web-based authentication is configured on EG devices in global configuration mode.
- The customized page suite must comply with the relevant specification.

Configuration Steps

↘ Enabling AAA

- Mandatory. To enable Ruijie second-generation web-based authentication, you must enable AAA.
- The iPortal NAS is responsible for initiating authentication to the portal server through AAA in Ruijie iPortal web-based authentication.

↘ Configuring the RADIUS Server and Communication Key

- (Mandatory) To enable Ruijie iPortal Web Authentication, you must configure the RADIUS-server host.
- Clients' account information is stored on the RADIUS server. The NAS needs to connect to the RADIUS server to validate a client.

↘ Configuring an AAA Method List for Ruijie iPortal Web-based Authentication

- Mandatory. To enable Ruijie iPortal web-based authentication, you must configure the RADIUS server.
- Clients' account information is stored on the RADIUS server. The NAS needs to connect to the RADIUS server to validate a client.

↘ Configuring an AAA Method List for Ruijie iPortal Web-based Accounting

- Optional. Some servers require that authentication and accounting be enabled. Configure web-based accounting based on characteristics of the server in use.
- An AAA accounting method list associates an accounting method and server. In web-based authentication, accounting is implemented to record client fees.

↘ Configuring the iPortal Web-based Authentication Template

- Mandatory.
- If any non-default authentication and accounting method lists are configured, you need to specify the name of a method list in template configuration mode; otherwise, the default method list is used.

↘ Enabling Ruijie iPortal Web-based Authentication Globally or on an Interface

- Mandatory.

Verification

- Check whether non-authenticated clients are redirected to the web-based authentication URL to perform authentication, and the web-based authentication URL displayed is that in the page suite.
- Check whether authenticated clients can access the Internet normally.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	You can configure the AAA authentication and accounting method lists only after AAA is enabled.

Configuring the RADIUS Server and Communication Key

Command	**radius-server host** *ip-address* [**auth-port** *port-number1*] [**acct-port** *port-number 2*] **key** *string*
Parameter Description	*ip-address*: Indicates the IP address of the RADIUS server. *port-number1:* Indicates the authentication port. *port-number2:* Indicates the accounting port. *string*: Indicates the key string.
Command Mode	Global configuration mode
Usage Guide	By default, the authentication port number is 1812 and the accounting port number is 1813.

Configuring an AAA Method List for Ruijie iPortal Web-based Authentication

Command	**aaa authentication iportal** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	*list-name*: Creates a method list. *method1*: Indicates method 1. *method2*: Indicates method 2.
Command Mode	Global configuration mode
Usage Guide	The specified AAA method should exist in the AAA configuration.

Configuring an AAA Method List for Web-based Accounting

Command	**aaa accounting network** { **default** | *list-name* } **start-stop** *method1* [*method2*...]
Parameter Description	*list-name*: Creates a method list. *method1*: Indicates method 1. *method2*: Indicates method 2.
Command Mode	Global configuration mode
Usage Guide	The specified AAA method should exist in the AAA configuration.

Configuring the iPortal Web-based Authentication Template

Command	**web-auth template iportal**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Specifying the Advertisement Mode Before Authentication

Command	**login-popup** *url-string*
Parameter Description	Indicates the advertisement URL.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The URL starts with **http://** or **https://**.

Specifying the Advertisement Mode After Authentication

Command	**online-popup** url-string
Parameter Description	Indicates the advertisement URL.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The URL starts with **http://** or **https://**.

Customizing a Page Suite

Command	**page-suit** *filename*
Parameter Description	Indicates the file name of a page suite.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the iPortal Advertisement Interval

Command	**time-interval** *hour*
Parameter Description	Indicates the advertisement interval.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Enabling Ruijie iPortal Web-based Authentication

Command	**webauth**
Parameter Description	N/A
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Configuration Example

Configuring Ruijie iPortal Web-based Authentication

Configuration Steps	● Enable AAA on the NAS. ● Configure the RADIUS server and communication key on the NAS. ● Configure the default AAA authentication and accounting method lists on the NAS. ● Configure iPortal web-based authentication globally on the NAS. ● Enable web-based authentication on the WLAN of the NAS.
	Hostname#configure Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#aaa new-model
	Hostname(config)#radius-server host 192.168.197.79 key webkey
	Hostname(config)#aaa authentication iportal default group radius Hostname(config)#aaa accounting network default start-stop group radius
	Hostname(config)#web-auth template iportal
	Hostname(config.tmplt.iportal)#exit
	Hostname(config.tmplt.iportal)# accounting default Hostname(config.tmplt.iportal)# authentication default Hostname(config.tmplt.iportal)# page-suite defaul Hostname(config.tmplt.iportal)# exit
	Hostname(config)# wlansec 1 Hostname(config-wlansec)# web-auth portal iportal Hostnameconfig-wlansec)# webauth
Verification	● Check whether Ruijie iPortal web-based authentication is configured successfully.
	Hostname(config)#show running-config ... aaa new-model aaa authentication web-auth default group radius aaa accounting network default start-stop group radius ... radius-server host 192.168.197.79 key Hostname ... web-auth template iportal page-suite default authentication default accounting default ! ... wlansec 1 web-auth portal iportal webauth
	Hostname#show web-auth control Port Control Server Name Online User Count ------------------------- -------- ---------------------- ----------- -------

	wlansec 1 On iportal 0...
	Hostname#show web-auth template Webauth Template Settings: ---------- Name: iportal BindMode: ip-mac-mode Type: intra Port: 8081 time_interval: 1 Login_popup: (null) Online_popup: (null) Suitename: default Authentication: default Accounting: default

Common Errors

- The page suite does not comply with the relevant specification.
- A page suite is specified, but is not downloaded to the flash memory or the specified directory.

1.4.4 Configuring MAC Address-Based SMS Authentication

Configuration Effect

Allow non-authenticated STAs connected to the WLAN to access network resources. When a STA uses up the traffic during a given period of time, the NAS initiates a MAC address binding query to the bound portal server. If the STA is bound to a MAC address, the portal server initiates an authentication request. If the STA is not bound to a MAC address, the STA needs to perform authentication on the portal server before accessing the Internet.

Notes

The configured URL of the portal server must adopt the **cmcc-ext1** format.

Configuration Steps

↘ Enabling AAA

- Mandatory. To enable Ruijie second-generation web-based authentication, you must enable AAA.
- The NAS is responsible for initiating authentication to the portal server through AAA in Ruijie second-generation web-based authentication.

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	You can configure the AAA authentication and accounting method lists only after AAA is enabled.

Configuring the RADIUS Server and Communication Key

- Mandatory. To enable MAC address-based SMS authentication, you must configure the RADIUS server.
- Clients' account information is stored on the RADIUS server. The NAS needs to connect to the RADIUS server to validate a client.

Command	**radius-server host** *ip-address* [**auth-port***port-number1*] [**acct-port** *port-number 2*] **key** *string*
Parameter Description	*ip-address*: Indicates the IP address of the RADIUS server. *port-number1:* Indicates the authentication port. *port-number2:* Indicates the accounting port. *string*: Indicates the key string.
Command Mode	Global configuration mode
Usage Guide	By default, the authentication port number is 1812 and the accounting port number is 1813.

Configuring an AAA Method List for Web-based Authentication

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure an AAA authentication method list on the AAA module.
- A web-based authentication method list associates web-based authentication requests with the RADIUS server. The NAS selects an authentication method and server based on the Web authentication method list.

Command	**aaa authentication web-auth** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	*list-name*: Indicates a method list name. *method1*: Indicates method 1. *method2*: Indicates method 2.
Command Mode	Global configuration mode
Usage Guide	Ruijie second-generation web-based authentication adopts RADIUS authentication.

Configuring an AAA Method List for Web-based Accounting

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure a network accounting method on the AAA module.
- A network accounting method is used to associate an accounting method and server. In web-based authentication, accounting is implemented to record user information or fees.

Command	**aaa accounting network** { **default** | *list-name* } **start-stop** *method1* [*method2*...]
Parameter Description	*list-name*: Indicates a method list name. *method1*: Indicates method 1. *method2*: Indicates method 2.
Command Mode	Global configuration mode
Usage Guide	Ruijie second-generation web-based authentication adopts RADIUS accounting.

Configuring the Second-Generation Web-based Authentication Template

- Mandatory. To enable second-generation web-based authentication, you must configure and apply the portal server.

- When the NAS or aggregation device finds a non-authenticated client attempting to access network resources through HTTP, it redirects the access request to the specified web-based authentication URL, where the client can initiate authentication to the portal server. If the IP address of the portal server is configured as a free network resource, non-authenticated clients can directly visit this IP address through HTTP.

Command	**web-auth template** { **eportalv2** | *portal-name* **v2** }
Parameter Description	Indicates the customized portal server name.
Command Mode	Global configuration mode
Usage Guide	**eportalv2** indicates the default template of Ruijie second-generation web-based authentication.

Configuring the IP Address of the Portal Server

Command	**ip** { *ip-address* | *ipv6-address* }
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the Web-based Authentication URL of the Portal Server

Command	**url** *url-string*
Parameter Description	Indicates the web-based authentication URL of the portal server.
Command Mode	Webauth template configuration mode
Usage Guide	The URL starts with **http://** or **https://**.

Configuring the Format of the Web-based Authentication URL

Command	**fmt** { **cmcc-ext1** | **cmcc-normal** | **default** }
Parameter Description	Indicates the format of the web-based authentication URL.
Command Mode	Web-based authentication template configuration mode
Usage Guide	**fmt** must be set to **cmcc-ext1**.

Configuring the Web-based Authentication Communication Key

- Mandatory. To enable Ruijie second-generation web-based authentication, you must configure the key used for communication between the NAS or aggregation device and portal server.
- When the NAS finds a non-authenticated client attempting to access network resources, it redirects the client to the specified web-based authentication URL, where the client can initiate authentication to the portal server. During authentication, the communication key is used to encrypt some data exchanged between the NAS and portal server to improve security.

Command	**web-auth portal key** [**0** | **1** | **7**] *key-string*
Parameter Description	**0**: Configures the server key encryption type as cleartext, that is, the server key is input, saved, and displayed in cleartext. **1**: Configures the server key encryption type to ciphertext storage, that is, the cleartext input and ciphertext storage and display. **7**: Configures the server key encryption type as full ciphertext, that is, ciphertext input, ciphertext storage, and ciphertext display. *key-string*: Indicates the web-based authentication communication key used for communication between the NAS and portal server. The key contains up to 255 characters.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Detection Interval and Traffic Threshold for MAC Address-based SMS Authentication

- After a STA is associated with the WLAN enabled with MAC address-based SMS authentication, a free data quota is allocated to the STA. When the STA uses up the traffic allowed during a given period of time, a MAC address binding status query is triggered.

Command	**web-auth sms-flow interval** *interval* **threshold** *flows*
Parameter Description	*interval*: Indicates the detection interval, in minutes. *flows*: Indicates the flow threshold, in the unit of KB.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Portal Server Bound for MAC Address-based SMS Authentication

- Mandatory.

Command	**web-auth bind-portal** *string* [**type** { *local-spec* | *group-spec* }]
Parameter Description	*string*: Indicates a web-based authentication template.
Command Mode	WLAN security configuration mode
Usage Guide	N/A

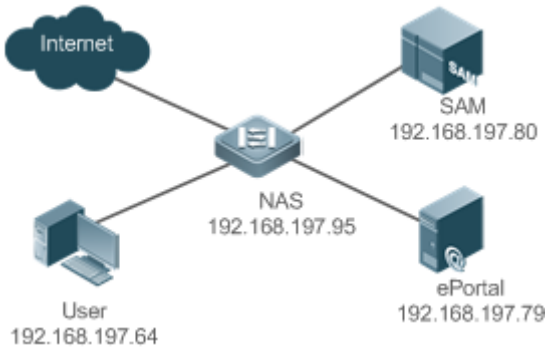
Setting the winterface Field in the Redirection URL

- China Mobile's MAC address-based specification requires that the redirection URL carry the **winterface** field, which must be configurable based on a WLAN.

Command	**web-auth winterface** *string*
Parameter Description	*string*: Indicates the **winterface** field.
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Setting the AC IP Field in the Redirection URL

- China Mobile's MAC address-based specification requires that the redirection URL carry the **AC IP** field. Because an AC may have multiple IP addresses, a configuration command is provided to configure an IPv4 address on the specified WLAN, and the IPv4 address specifies the value of the **AC IP** field in the redirection URL.



Command	**web-auth wlan-ac-ip** *ipv4*
Parameter Description	*ipv4:* Indicates the **AC IP** field.
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Verification

- Check that non-authenticated clients can access the Internet before the traffic threshold is reached.
- Check that authentication is triggered when the traffic threshold is reached.

Configuration Example

Configuring MAC Address-Based SMS Authentication

Scenario **Figure 1-10**	
Configuration Steps	● Enable AAA on the NAS. ● Configure the RADIUS server and communication key on the NAS. ● Configure the default AAA method lists for web-based authentication and accounting on the NAS. ● Configure the IP address of the portal server and the web-based authentication communication key (webkey) used for communicating with the portal server on the NAS. ● Configure the web-based authentication URL on the NAS. ● Configure the detection interval and traffic threshold for MAC address-based SMS authentication, and set the **winterface** and **AC IP** fields on the NAS. ● Enable MAC address-based SMS authentication for WLANSEC1 on the NAS.

	`Hostname#configure`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#aaa new-model`

	`Hostname(config)#radius-server host 192.168.197.79 key webkey`
	`Hostname(config)#aaa authentication web-auth default group radius`

	Hostname(config)#aaa accounting network default start-stop group radius
	Hostname(config)#web-auth template eportalv2 Hostname(config.tmplt.eportalv2)#ip 192.168.197.79 Hostname(config.tmplt.eportalv2)#exit Hostname(config)#web-auth portal key ruijie
	Hostname(config)# web-auth template eportalv2 Hostname(config.tmplt.eportalv2)#url http://192.168.197.79:8080/eportal/index.jsp Hostname(config.tmplt.eportalv2)#fmt cmcc-ext1 Hostname(config.tmplt.eportalv2)#exit

Verification	● Check whether web-based authentication is configured successfully.
	Hostname(config)#show running-config ... aaa new-model aaa authentication web-auth default group radius aaa accounting network default start-stop group radius ... radius-server host 192.168.197.79 key webkey ... web-auth template eportalv2 ip 192.168.197.79 url http://192.168.197.79:8080/eportal/index.jsp fmt cmcc-ext1 ! web-auth portal key ruijie web-auth sms-flow interval 5 threshold 10 ... wlansec 1 web-auth bind-portal eportalv2 type group-spec web-auth accounting v2 default web-auth authentication v2 default webauth

Common Errors

- The communication key between the portal server and NAS is configured incorrectly or only on the portal server or NAS, causing authentication errors.
- The communication parameters of the RADIUS server and NAS are set incorrectly, causing authentication errors.
- The portal server does not support *CMCC WLAN Service Portal Specification*, causing compatibility failures.

1.4.5 Configuring WiFiDog Authentication

Configuration Effect

Redirect non-authenticated clients to the web-based authentication URL to perform authentication.

Notes

N/A

Configuration Steps

Configuring the Portal Server

- Mandatory. To enable web-based authentication, you must configure and apply the portal server.
- When the NAS finds a non-authenticated client attempting to access network resources through HTTP, it redirects the client's access requests to the specified web-based authentication URL, where the client can initiate authentication to the portal server. The IP address of the portal server is configured as a network resource which clients can access without authentication. Non-authenticated clients can directly access this IP address through HTTP.

Configuring the IP Address of the NAS

- Mandatory.
- By default, the IP address of the NAS is not configured.
- Ensure that the configured IP address is accessible by clients.

Enabling Web-based Authentication on an Interface

- Mandatory.
- Web-based authentication is not enabled by default. The users connecting to the port do not need to perform web-based authentication.

Verification

- Check whether non-authenticated clients are required to perform authentication.
- Check whether authenticated clients can access the Internet normally.

Related Commands

Configuring a WiFiDog Web-based Authentication Template

Command	**web-auth template wifidog**
Parameter Description	N/A

Command Mode	Global configuration mode
Usage Guide	**wifidog** means the default WiFiDog Webauth template.

Configuring the IP Address of the Portal Server

Command	**ip** *ip-address*
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the Web-based Authentication URL of the Portal Server

Command	**url** *url-string*
Parameter Description	Indicates the web-based authentication URL of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The URL starts with **http://**.

Configuring the IP Address of the NAS

Command	**nas-ip** *ip-address*
Parameter Description	Indicates the IP address of the NAS.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The access service IP address of the NAS cannot be configured as the passthrough address. When the access service IP address is configured as the IP address of the NAS and a STA in the authentication template accesses this IP address, the NAS intercepts the request of the STA and forwards it to the server. As a result, the STA fails to access the web management page of the NAS. If a STA in the authentication template accesses this IP address for device management, configure the access service IP address as the unused virtual service IP address, for example, 1.1.1.1 and 2.2.2.2.

Configuring WiFiDog MAB Authentication

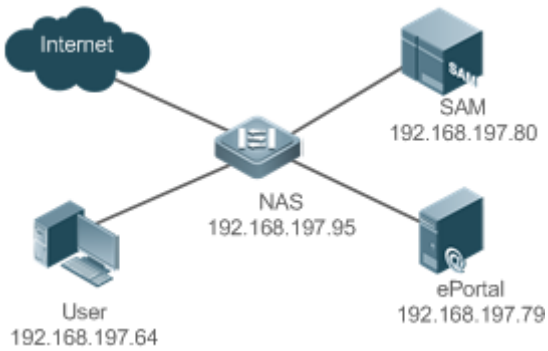
- Optional.

Command	**web-auth sta-perception enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	This function must be used with DHCP snooping.

Configuring the Gateway ID

Command	**gateway-id** *string*
Parameter Description	*string*: Indicates the gateway ID used in WiFiDog. It is the serial number of the device by default.
Command Mode	Web authentication template configuration mode
Usage Guide	This parameter is carried in the WiFiDog packets and provided for the interconnected third-party portal. It is mandatory in hot standby and VAC scenarios.

Specifying the WiFiDog Authentication Template



Command	**web-auth portal wifidog**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The default WiFiDog authentication template is **wifidog**.

Enabling WiFiDog Web-based Authentication

Command	**webauth**
Parameter Description	N/A
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Configuration Example

Configuring WiFiDog Web-based Authentication

Scenario **Figure 1-11**	
Configuration Steps	● Configure the IP address of the portal server on the NAS. ● Configure the web-based authentication URL on the NAS. ● Configure the IP address used for external communication on the NAS. ● Enable WiFiDog web-based authentication for WLAN10 on the NAS.
	`Hostname# config`

	Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#web-auth template wifidog Hostname(config.tmplt.wifidog)#ip 192.168.197.79
	Hostname(config.tmplt.wifidog)#url http://192.168.197.79/auth/wifidogAuth Hostname(config.tmplt.wifidog)#nas-ip 192.168.197.95 Hostname(config.tmplt.wifidog)#exit
	Hostname(config)# wlansec 10
	Hostname(config-wlansec)#web-auth portal wifidog Hostname(config-if-range)# webauth Hostname(config-if-range)# exit
Verification	● Check whether WiFiDog web-based authentication is configured successfully.
	Hostname(config)#show running-config ... web-auth template wifidog ip 192.168.197.79 nas-ip 192.168.197.95 url http://192.168.197.79/auth/wifidogAuth ... wlansec 10 web-auth portal wifidog webauth
	Hostname#show web-auth control Port Control Server Name Online User Count ------------------------- -------- --------------------- ------------- ---- wlansec 10 On wifidog 0 ...
	Hostname#show web-auth template Webauth Template Settings: --- Name: wifidog Type: wifidog Ip: 192.168.197.79 Url: http://192.168.197.79/auth/wifidogAuth NasIp: 192.168.197.95 ...

Common Errors

- The IP address of the NAS is not configured, causing a redirection failure.

1.4.6 Configuring WeChat Web-based Authentication

Configuration Effect

- Redirect non-authenticated mobile phone users associated with a WLAN to a WeChat-based one-click Wi-Fi connection page displayed on the mobile phone browser. A user can tap a link on the page to wake up the WeChat client and use it to perform Wi-Fi connection authentication.
- Allow non-authenticated mobile phone users to scan a QR code to perform Wi-Fi connection authentication through WeChat.
- Redirect non-authenticated PC users associated with a WLAN to a WeChat-based one-click Wi-Fi connection page displayed on the PC browser. A user can scan a QR code on the page by using the mobile phone associated with the same WLAN as the PC to enable the PC to perform authentication to access the Internet.

Notes

N/A

Configuration Steps

Creating a Wechat Web-based Authentication Template

- Mandatory. To enable WeChat web-based authentication, you must create a template.

Command	**web-auth template** { **wechat** | *portal-name* **wechat** }
Parameter Description	Indicates the name of the customized template for WeChat web-based authentication
Command Mode	Global configuration mode
Usage Guide	**wechat** is the name of the default template of WeChat web-based authentication.

Configuring the IP Address of the Portal Server

- (Mandatory) To enable WeChat web-based authentication, you must configure the IP address of the portal server.

Command	**ip***ip-address*
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the WeChat Web-based Authentication URL

- (Mandatory) To enable WeChat web-based authentication, you must configure the WeChat web-based authentication URLof the portal server.

Command	**service-url** *url-string*
Parameter Description	Indicates the WeChat web-based authentication URL.
Command Mode	Web-based authentication template configuration mode
Usage Guide	Configure only the domain name. The domain name cannot start with **http://** or **https://**.

Configuring the Authentication Page Address for the Portal Server

- The function is mandatory for devices of 11.1(5)B9 and the default configuration can be used.

Command	**url** *url-string*
Parameter Description	**url**: Indicates the URL of the server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The authentication page address starts with **http://** or **https://**.

Configuring the Web-based Authentication Communication Key

- (Mandatory) To enable WeChat web-based authentication, you must configure the communication key of the portal server.

Command	**key** *key-string*
Parameter Description	*key-string*: Indicates the communication key of the portal server. You need to configure a key used for communication between the NAS and authentication server. The key contains up to 255 characters.
Command Mode	Web-based authentication template configuration mode
Usage Guide	Ensure that the communication keys configured on the portal server and the NAS are the same; otherwise, interworking will fail.

Configuring the IP Address of the NAS

Command	**nas-ip** *ip-address*
Parameter Description	Indicates the IP address of the NAS.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The access service IP address of the NAS cannot be configured as the passthrough address. When the access service IP address is configured as the IP address of the NAS and a STA in the authentication template accesses this IP address, the NAS intercepts the request of the STA and forwards it to the server. As a result, the STA fails to access the web management page of the NAS. If a STA in the authentication template accesses this IP address for device management, configure the access service IP address as the unused virtual service IP address, for example, 1.1.1.1 and 2.2.2.2.

Enabling Smart WeChat Web-based Authentication

- Optional.

Command	**web-auth sta-perception enable**
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	Enable smart authentication based on customer's requirements. Run the **ip dhcp snooping** command before smart authentication takes effect.

Enabling the Escape Function

- With the escape function enabled, if the server is unreachable or the server allows STAs to escape, subsequently connected STAs are permitted to pass without authentication. The escape duration is specified by the **interval** *minutes* parameter.
- The configuration in WLAN security configuration mode takes precedence. If this function is not configured in WLAN security configuration mode, the configuration in global configuration mode takes effect.
- To cancel this function, run the **web-auth wechat-escape recover** command in global configuration mode.

Command	**web-auth wechat-escape interval** *minutes*
Parameter Description	*minutes*: Indicates the maximum online time for escape users, in minutes. The default value is 60 minutes.
Command Mode	Global configuration mode and WLAN security configuration mode
Usage Guide	N/A

Configuring Server Detection

- Optional. After the function is configured, the device detects the server. If it fails to receive the server response or the response is unavailable within a certain interval and the collective escape function is configured on the device, all users who gain access later are permitted to pass without authentication.
- To cancel server detection, run the **no web-auth wechat-check** command in global configuration mode.

Command	**web-auth wechat-check interval** *minutest*
Parameter Description	*minutes*: Indicates the timer interval for server detection, in minutes. There is no default value.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring Smart IP Address Check

- Optional. After smart IP address check is configured, the STAs that fail to obtain IP addresses after the specified time has elapsed are disconnected forcibly.

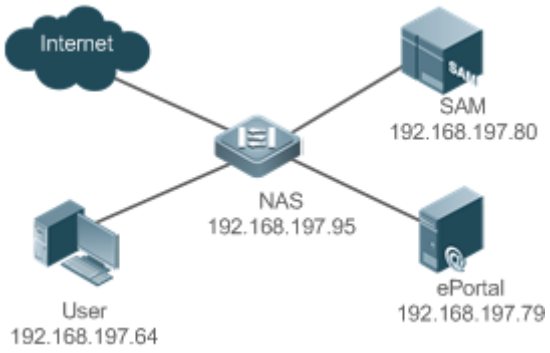
Command	**web-auth valid-ip-acct** [**timeout** *seconds*]
Parameter Description	*seconds*: Indicates the time during which STAs can attempt to obtain IP addresses, in seconds. The default value is 30s.
Command Mode	Global configuration mode
Usage Guide	N/A

Specifying the WeChat Web-based Authentication Template

Command	**web-auth portal wechat**

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The default WeChat web-based authentication template is **webchat**.

Enabling Web-based Authentication



Command	**webauth**
Parameter Description	N/A
Command Mode	WLAN security mode
Usage Guide	N/A

Verification

- Check whether non-authenticated clients are required to perform authentication.
- Check whether authenticated clients can access the Internet normally.

Configuration Example

Configuring WeChat Web-based Authentication

Scenario **Figure 1-12**	
Configuration Steps	● Configure the IP address 192.168.58.110 of the domain name server on the NAS. ● Configure the WeChat web-based authentication template on the NAS. ● Configure the IP address and web-based authentication URL on the NAS. ● Configure the communication key (webkey) used for communicating with the portal server on the NAS. ● Configure the IP address used for external communication on the NAS. ● Apply the template to WLANSEC1 and enable WeChat web-based authentication.

	`Hostname#configure`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#ip name-server 192.168.58.110`

	`Hostname(config)#web-auth template wechat`
	`Hostname(config.tmplt.wechat)#ip 192.168.197.79` `Hostname(config.tmplt.wechat)#service-url wmc.ruijie.com.cn`

	Hostname(config.tmplt.wechat)#key ruijie
	Hostname(config.tmplt.wechat)#nas-ip 1.1.1.1
	Hostname(config.tmplt.wechat)#exit
	Hostname(config)# wlansec 1 Hostname(config-wlansec)# web-auth portal wechat Hostname(config-wlansec)# webauth
Verification	● Check whether web-based authentication is configured successfully.
	Hostname(config)#show running-config ... ip name-server 192.168.58.110 ... web-auth template wechat ip 192.168.197.79 service-url wmc.ruijie.com.cn http://192.168.197.79:8080/eportal/index.jsphttp://192.168.197.79:8080 /eportal/index.jsp key ruijie nas-ip 1.1.1.1 !... wlansec 1 web-auth portal wechat webauth !

Common Errors

- The key used for communication between the portal server and NAS is configured incorrectly, or encryption is configured only on the portal server or NAS, causing abnormal authentication.
- The IP address of the NAS is configured as the authentication-free address, and authentication packets cannot be received, causing an authentication failure.
- The IP address of the domain name server is not configured, causing an allowlist resolution failure. The IP address of the WeChat server is not permitted to pass.
- The **ip dhcp snooping**, **ip dhcp snooping trust**, and **web-auth sta-perception enable** commands are not executed when smart authentication is enabled, causing a failure of smart authentication during second authentication.

1.4.7 Configuring ClearPass Authentication

Configuration Effect

Redirect non-authenticated clients to the web-based authentication URL to perform authentication.

Notes

N/A

Configuration Steps

Configuring the Portal Server

- Mandatory. To enable web-based authentication, you must configure and apply the portal server.
- When the NAS finds a non-authenticated client attempting to access network resources through HTTP, it redirects the client's access requests to the specified web-based authentication URL, where the client can initiate authentication to the portal server. The IP address of the portal server is configured as a network resource which clients can access without authentication. Non-authenticated clients can directly access this IP address through HTTP.

Configuring a Response Mode After Successful Authentication

- Optional.
- It is configured as needed.

Configuring a Response Mode Upon an Authentication Failure

- Optional.
- It is configured as needed.

Configuring a Mode for the Device to Resolve Authentication Requests

- Optional.
- It is configured according to the requirements of the server to be connected.

Configuring Whether to Pop Up a Window for Proactive Logout After Successful Authentication

- Optional.
- It is configured as needed.

Configuring the Device's IP Address

- Mandatory. It is not configured by default.
- This IP address should be configured so that users can access the device.

Configuring the Device's Port

- Mandatory. It is not configured by default.
- This port should be configured for user access and should not conflict with the ports used by built-in web management of the device.

Configuring the URL for Initiating Authentication from a STA

- Optional. The URL is http://*ip*:*port*/login by default, where *ip* is the device IP and *port* is the device port.
- The URL is used for access and should be configured to be consistent with the address configured on ClearPass.

Enabling Web-based Authentication on an Interface

- Mandatory.

- It is used to enable web-based authentication on an interface. Web-based authentication is disabled on an interface by default. In this case, users connected to this interface will not experience web-based authentication.

Verification

- Check whether non-authenticated clients are required to perform authentication.
- Check whether authenticated clients can access the Internet normally.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Commands such as **aaa method-list** can only be entered after AAA is enabled.

Configuring the RADIUS Server and Key

Command	**radius-server host** *ip-address* [**auth-port** *port-number1*] [**acct-port** *port-number 2*] **key** *string*
Parameter Description	*ip-address*: Indicates the IP address of the server. *port-number1*: Indicates the authentication port number. *port-number2*: Indicates the accounting port number. *string*: Indicates the key string.
Command Mode	Global configuration mode
Usage Guide	By default, the authentication port number is 1812 and the accounting port number is 1813.

Configuring the Web-based Authentication Method List on AAA

Command	**aaa authentication cpweb** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	*list-name*: Indicates the list name. *method1*: Indicates method 1. *method2*: Indicates method 2.
Command Mode	Global configuration mode
Usage Guide	ClearPass authentication uses RADIUS authentication.

Configuring the Method List for Network Accounting

Command	**aaa accounting network** { **default** | *list-name* } **start-stop** *method1* [*method2*...]
Parameter Description	*list-name*: Indicates the list name. *method1*: Indicates method 1. *method2*: Indicates method 2.
Command Mode	Global configuration mode
Usage Guide	ClearPass authentication uses RADIUS accounting.

Creating a Template

Command	**web-auth template cpweb**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The ClearPass authentication template is **cpweb** by default.

Configuring the Server IP Address

Command	**ip** *ip-address*
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the Context ID and IP Address of the Hot Standby Server

Command	**context** *ctx-id peer-ip-address*
Parameter Description	*ctx-id*: Configures the context ID of the hot standby server. *peer-id-address*: Configures the IP address of the hot standby server.
Command Mode	Web authentication template configuration mode
Usage Guide	N/A

Configuring the Server URL

Command	**url** *url-string*
Parameter Description	Indicates the web-based authentication URL of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The URL starts with **http://**.

Configuring a Response Mode After Successful Authentication

Command	**login-success response** { **redirect-init-url** [**default-url** *def-string*] | **msg** *msg-string* | **redirect-url** *url-string* }
Parameter Description	*def-string*: Indicates the default URL when the server does not provide a URL. *msg-string*: Indicates the text to be displayed after successful authentication. *url-string*: Indicates the URL to be redirected to after successful authentication.
Command Mode	Web-based authentication template configuration mode
Usage Guide	Optional.

Configuring Response Mode After Authentication Failure

Command	Configures the message displayed after the ClearPass authentication fails. **login-fail response msg** *msg-string*

	Configures the URL that redirects to the login page when the ClearPass authentication fails. **login-fail response redirect-login-url** Configures the redirect URL after the ClearPass authentication fails. **login-fail response redirect-url** *url-string* [**err-msg** *msg-key*] Configures the redirect URL in the format of http://xxx/xx?ap_mac=6c:8b:d3:37:e2:60&wlan=Guest&statusCode=5 after the ClearPass authentication fails. The **wlan** field indicates the SSID. **login-fail response redirect-url** *url-string* [**fmt ntes** [**errmsg-key** *key-string*]] Configures the redirect URL after the ClearPass authentication fails. The URL can be customized. **login-fail response redirect-url** *url-string* [**fmt custom encry** { **md5** | **des** | **des_ecb** | **des_ecb3** | **none** } { **additional** *extern-str* | **ap-mac** *ap-mac-str* **mac-format** { **dot** | **line** | **5colon** | **none** } | **ssid** *ssid-str* | **errmsg-key** *key-string* }]
Parameter Description	*msg-string*: Indicates the text to be displayed after authentication failure. **redirect-login-url**: Redirects the browser to the login page after the authentication fails. *url-string*: Indicates the URL to be redirected to after authentication failure. **ntes**: Indicates the customized URL format. *key-string*: Indicates the parameter name for error message in the URL. **custom**: Customizes the redirect URL after the authentication fails. **encry**: Configures the encryption method, including the following options: md5, des, des_ecb, des_ecb3, and none. *extern-str*: Indicates the customized extra information strings. *ap-mac-str*: Indicates the AP MAC address. **mac-format**: Configures the format of MAC addresses, including the following options: dot, line, 5colon, and none. *ssid-str*: Indicates the SSID.
Command Mode	Web authentication template configuration mode
Usage Guide	Optional.

Configuring a Mode for the Device to Resolve Authentication Requests

Command	**http-method post** [**username-key** *usrkey-string*] [**password-key** *pswkey-string*] [**init-url-key** *urlkey-string*] [**password-encrypt** { **none** | **uam** }]
Parameter Description	*usrkey-string*: Indicates the username in the authentication request. *pswkey-string*: Indicates the password in the authentication request. *urlkey-string*: Indicates the URL in the authentication request.

Command Mode	Web-based authentication template configuration mode
Usage Guide	(Optional) It is used to configure authentication request according to the requirements of the server.

Configuring Whether to Pop Up a Window for Proactive Logout After Successful Authentication

Command	**logout-popup-window**
Parameter Description	N/A
Command Mode	Web-based authentication template configuration mode
Usage Guide	(Optional) It is enabled when proactive logout is required. Note that the proactive logout window may be blocked by the STA's browser.

Configuring the Device's IP Address

Command	**web-auth auth-server ip** *ip-address*
Parameter Description	Sets the device access service IP address for ClearPass, which is used for communication from the server to this IP address.
Command Mode	Global configuration mode
Usage Guide	The access service IP address of the NAS cannot be configured as the passthrough address. When the access service IP address is configured as the IP address of the NAS and a STA in the authentication template accesses this IP address, the NAS intercepts the request of the STA and forwards it to the server. As a result, the STA fails to access the web management page of the NAS. If a STA in the authentication template accesses this IP address for device management, configure the access service IP address as the unused virtual service IP address, for example, 1.1.1.1 and 2.2.2.2.

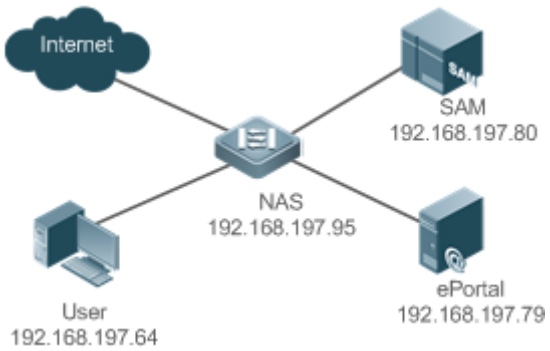
Configuring the Device Port

Command	**web-auth auth-server http** [*port*]
Parameter Description	Indicates the TCP port used by the ClearPass STA that initiates authentication.
Command Mode	Global configuration mode
Usage Guide	It is the TCP port used by the ClearPass STA that initiates authentication. It should not conflict with the ports used by built-in web management of the device.

Configuring the URL for Initiating Authentication from a STA

Command	**web-auth auth-server submit-url** *url-string*
Parameter Description	Indicates the URL used by the ClearPass STA that initiates authentication.
Command Mode	Global configuration mode
Usage Guide	It is the URL used by the STA to initiate authentication, and must start with **http://**.

Enabling Web-based Authentication



Command	**webauth**

Parameter Description	N/A
Command Mode	WLAN security mode
Usage Guide	N/A

Configuration Example

The following configuration example describes the configuration related to web-based authentication only.

Enabling ClearPass Authentication

Scenario **Figure 1-13**	
Configuration Steps	● Set the IP address of the authentication server on the network device. ● Set the URL of the authentication page on the network device. ● Set the IP address of the network device. ● Set the port of the network device. ● Set the URL for STA authentication on the network device. ● Enable web-based authentication on WLAN 10 of the network device.

	`Hostname# config`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#web-auth auth-server http port 8082`
	`Hostname(config)#web-auth auth-server ip 1.1.1.1`
	`Hostname(config)#web-auth auth-server submit-url http://1.1.1.1:8082/login`
	`Hostname(config)#web-auth template cpweb`
	`Hostname(config.tmplt.cpweb)#ip 192.168.197.79`

	`Hostname(config.tmplt.cpweb)#url http://192.168.197.79/web_login.php` `Hostname(config.tmplt.cpweb)#exit`
	`Hostname(config)# wlansec 10`

	`Hostname(config-wlansec)# web-auth portal cpweb`
	`Hostname(config-if-range)# webauth`
	`Hostname(config-if-range)# exit`

Verification	● Check whether web-based authentication is configured successfully.

	`Hostname(config)#show running-config`
	`...`
	`web-auth auth-server ip 1.1.1.1`

	web-auth auth-server http web-auth auth-server submit-url http://1.1.1.1:8082/login web-auth template cpweb ip 192.168.197.79 url http://192.168.197.79/web_login.php ... wlansec 10 web-auth portal cpweb webauth
	Hostname#show web-auth control Port Control Server Name Online User Count ------------------------- -------- -------------------- ------------- ---- wlansec 10 On cpweb 0 ...
	Hostname#show web-auth template Webauth Template Settings: --- Name: cpweb Type: cpweb Ip: 192.168.197.79 Url: http://192.168.197.79/web_login.php

Common Errors

The device IP address is not configured, causing redirection failures.

1.4.8 Specifying an Authentication Method List

Configuration Effect

- The portal server sends an authentication request to the NAS when a user submits authentication information. The NAS resolves authentication server information and other information based on the configured authentication method list name before initiating authentication
- The NAS selects the authentication server based on the specified authentication method list.

Notes

- Before you configure an authentication method list name, ensure that the authentication methods in the list have been configured on the AAA module. The command used to configure authentication methods on the AAA module is **aaa authentication web-auth** { *default* | *list-name* }*method1 [method2*...].
- Different authentication methods for IPv4 authentication and IPv6 authentication are not supported.

Configuration Steps

- Optional.

- The default authentication method is used if no authentication method list is configured. Run the **authentication** { *mlist-name* } command to configure an authentication method list name when the authentication method list name on the AAA module needs to be modified or multiple method lists exist.

Verification

- Configure two authentication method lists on the AAA module. Apply list 1 to server 1 and list 2 to server 2.
- Create user a and configured a password for the user on server 1. Create user b on server 2.
- Configure the device to use list 1.
- Perform authentication as user b and check that authentication fails.
- Perform authentication as user a and check that authentication is successful.

Related Commands

Specifying an Authentication Method List

Command	**authentication** *mlist-name*
Parameter Description	Indicates a method list name.
Command Mode	Web-based authentication template configuration mode
Usage Guide	Ensure that the configured authentication method list name is consistent with that on the AAA module.

Configuration Example

Specifying an Authentication Method List

Configuration Steps	● Specify the authentication method list **mlist1**.
	`Hostname(config.tmplt.iportal)#authentication mlist1`
Verification	● Check whether the configuration is successful.

	`Hostname#show web-auth template`
	`Webauth Template Settings:`
	`----------`
	`Name: eportalv2`
	`Url: http://17.17.1.21:8080/eportal/index.jsp`
	`Ip: 17.17.1.21`
	`BindMode: ip-only-mode`
	`Type: v2`
	`Port: 50100`
	`State: Active`
	`Acctmlist: default`
	`Authmlist: mlist1`

1.4.9 Specifying an Accounting Method List

Configuration Effect

- The NAS sends an accounting request when a user passes authentication. The recipient of the request depends on the configuration of the accounting method list and is usually the portal server.
- Specify an accounting method list for the NAS to perform accounting.

Notes

- Ensure that the accounting method list has been configured on the AAA module. The command used to configure accounting methods on the AAA module is **aaa accounting network** {**default** | *list-name* }start-stop method1 [method2...].
- Different accounting methods for IPv4 authentication and IPv6 authentication are not supported.

Configuration Steps

- Optional.
- The default accounting method is used if no accounting method list is configured. Run the **accounting** {*mlist-name* } command to configure an accounting method list name when the accounting method list name on the AAA module needs to be modified or multiple method list names exist.

Verification

- Configure two accounting method lists on the AAA module. Apply list 1 to server 1 and list 2 to server 2.
- Configure the device to use list 1.
- Use a valid account to perform authentication to access the Internet.
- View user accounting information on server1 and server2. Check that the user accounting information exists only on server1.

Related Commands

↘ Specifying an Accounting Method List

Command	**accounting** *mlist-name*
Parameter Description	Indicates a method list name.
Command Mode	Web-based authentication template configuration mode
Usage Guide	Ensure that the configured accounting method list name is consistent with that on the AAA module.

Configuration Example

↘ Specifying an Accounting Method List

Configuration Steps	● Specify the accounting method list **mlist1**.
	`Hostname(config.tmplt.eportalv2)#accounting mlist1`

Verification	● Check whether the configuration is successful.
	Hostname#show web-auth template Webauth Template Settings: ---------- Name: eportalv2 Url: http://17.17.1.21:8080/eportal/index.jsp Ip: 17.17.1.21 BindMode: ip-mac-mode Type: v2 Port: 50100 State: Active Acctmlist: mlist1 Authmlist: mlist1

1.4.10 Configuring the Communication Port of the Portal Server

Configuration Effect

- When the NAS detects that a user logs out, it notifies the portal server. The NAS interacts with the portal server through the portal protocol, which specifies the port number used to listen to and send/receive packets.
- When the listening port of the portal server is changed, the communication port of the portal server must be modified on the NAS to enable the NAS to interact with the portal server.
- In Ruijie iPortal web-based authentication, this function is used to configure the HTTP listening port of the NAS. The default port number is 8081.

Notes

- The configured port number must be consistent with the port used by the portal server.
- This function is applicable to Ruijie second-generation web-based authentication and iPortal web-based authentication. The two authentication modes use different default port numbers. In Ruijie second-generation web-based authentication, the configured port number is used for interaction between the NAS and portal server through the portal protocol. In Ruijie iPortal web-based authentication, the configured port number is used for packet listening on the NAS.

Configuration Steps

- Optional.
- Run the **port** *port-num* command to configure the port number when the portal server does not use the default port number or the listening port of the NAS conflicts with other port and needs to be adjusted.

Verification

- Configure Ruijie second-generation web-based authentication.
- Change the listening port of the server to 10000.
- Run the **port** *port-num* command to configure port number 10000.

- Simulate the scenario where a user performs authentication to access the Internet.
- Disconnect the user on the NAS, refresh the online page, and check that a user logout notification is displayed.

Related Commands

Configuring the Communication Port of the Portal Server

Command	**port** *port-num*
Parameter Description	*port-num*: Indicates the port number.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Communication Port of the Portal Server

Configuration Steps	● Configure the communication port of the portal server as port 10000.
	`Hostname(config.tmplt.eportalv2)#port 10000`
Verification	● Check whether the configuration is successful.

	`Hostname#show web-auth template`
	`Webauth Template Settings:`

	`BindMode: ip-only-mode`
	`Type: v2`
	`Port: 10000`
	`Acctmlist:`
	`Authmlist:`

1.4.11 Specifying the Web-based Authentication Binding Mode

Configuration Effect

When a user goes online, the user's entry needs to be written to a forwarding rule. The forwarding rule mapping method can be modified by specifying different binding modes, which further affects the Internet access rules applied to users. In IP-only mode, all the packets carrying the specified IP address are permitted to pass, and the STAs who send the packets can access the Internet. In IP+MAC mode, only the packets carrying both the specified IP address and MAC address are permitted to pass, and the STAs who send the packets can access the Internet.

Notes

In Layer 3 authentication, the MAC addresses that can be queried on the NAS are gateway addresses of STAs. Because these MAC addresses are inaccurate, the IP-only mode should be used.

Configuration Steps

- (Optional) The default web-based authentication binding mode is IP+MAC.
- Determine a binding mode based on the accuracy of user information obtained by the NAS. When IP and MAC addresses of STAs are accurate (for example, Layer 2 network deployment), IP+MAC is recommended. When the IP and MAC addresses are inaccurate, select IP-only.

Verification

- Change the binding mode to IP-only.
- Simulate the scenario where a user performs authentication to access the Internet.
- Modify the MAC address of the user, or use a client with the same IP address but a different MAC address to access the Internet.
- Check that the user accesses the Internet normally.

Related Commands

Specifying the Web-based Authentication Binding Mode

Command	**bindmode** { **ip-mac-mode** | **ip-only-mode** }
Parameter Description	**ip-mac-mode**: Indicates the IP-MAC binding mode. **ip-only-mode**: Indicates the IP-only binding mode.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuration Example

Specifying the Web-based Authentication Binding Mode

Configuration Steps	● Set the binding mode to IP-only.
	`Hostname(config.tmplt.eportalv2)#bindmode ip-only-mode`
Verification	● Check whether the configuration is successful.

	`Hostname#show web-auth template`
	`Webauth Template Settings:`
	`----------`
	`Name: eportalv2`
	`Url: http://17.17.1.21:8080/eportal/index.jsp`
	`Ip: 17.17.1.21`
	`BindMode: ip-only-mode`
	`Type: v2`
	`Port: 10000`
	`Acctmlist:`
	`Authmlist:`

1.4.12 Customizing a Page Suite

Configuration Effect

- Configure a page suite to be used on the iPortal server and add special content or information to the page suite, for example, a logo or notice.

Notes

- A page suite must be downloaded manually to the flash memory of the NAS and saved to the ./portal directory. If the page suite is not saved or is saved to an incorrect directory, the page fails to be pushed, causing web-based authentication failures. The default page suite can be used if there are no special requirements.
- For details, see Customizing a Page Suite.

Configuration Steps

(Optional) By default, the default page suite is used.

Verification

- Configure iPortal web-based authentication.
- Download a page suite.
- Specify the page suite.
- Check whether the page suite is applied to the login page.

Related Commands

Customizing a Page Suite

Command	**page-suit** *filename*
Parameter Description	*filename*: Indicates the file name of a page suite.
Command Mode	Web-based authentication template configuration mode
Usage Guide	Download the page suite to be used to the **./porta/zipl** directory of the flash memory in advance.

Configuration Example

Customizing a Page Suite

Configuration Steps	● Customize a page suite.
	`Hostname(config.tmplt.iportal)#page-suit hostpage`
Verification	● Check whether the configuration is successful.

	`Hostname#show web-auth template`
	`Webauth Template Settings:`
	`----------`

	Name: iportal Page-suit: hostpage Advertising url: default Advertising mode: online-popup Type: Intral Portal Acctmlist:default Authmlist:default

1.4.13 Configuring the Advertisement Pushing Mode

Configuration Effect

Optional. Advertisements are pushed before or after authentication.

Notes

- The advertisement URL must be configured in advance.
- By default, advertisements are pushed after successful authentication.
- To ensure that only advertisements are pushed in the case that users are not authenticated, select the advertising function. For details, see the advertising configuration manual.

Configuration Steps

(Optional) By default, advertisements are pushed after successful authentication.

Verification

- Configure iPortal web-based authentication.
- Configure a URL that can access the Internet.
- When a user accesses the network, check whether a new window is displayed after successful authentication and whether information on a page of a specific URI is displayed.

Related Commands

Configuring the Advertisement Pushing URL

Command	**login-popup** *url*
Parameter Description	*url*: Indicates the URL popping up before authentication or upon login.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Command	**online-popup** *url*
Parameter Description	*url*: Indicates the URL popping up after successful authentication.

Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Advertisement Pushing Mode

Configuration Steps	● Configure the advertisement pushing mode as advertisement pushing before authentication.
	`Hostname(config.tmplt.iportal)#login-popup http://www.host.com`
Verification	● Check whether the advertisement pushing mode is configured successfully.

	`Hostname#show web-auth template`
	`Webauth Template Settings:`
	`----------`
	`Name: iportal`
	`BindMode: ip-mac-mode`
	`Type: intra`
	`Port: 8081`
	`time_interval: 1`
	`Login_popup: http://www.host.com`
	`Online_popup: (null)`
	`Suitename: default`
	`Authentication:`
	`Accounting:`

1.4.14 Configuring a Custom URL Format

Configuration Effect

Configure the URL used for redirecting users to the portal server based on customized parameters.

Notes

The parameter sequence of the customized URL may be different from the parameter sequence of the actual URL.

Configuration Steps

Optional.

Verification

- Configure a custom URL.
- A non-authenticated PC accesses the Internet through the port using a browser.
- The access request is redirected. The redirection URL follows the same format as the custom URL.

Related Commands

Configuring a Custom URL Format

Command	**fmt custom** [**encryp** { **md5** | **des** | **des_ecb** | **des_ecb3** | **none** }] [**user-ip** *userip-str*] [**user-mac** *usermac-str***mac-format** [**dot** | **line** | **none** | **5colon**]] [**user-vid** *uservid-str*] [**user-id** *userid-str*] [**nas-ip** *nasip-str*] [**nas-id** *nasid-str*] [**nas-id2** *nasid2-str*] [**ac-name** *acname-str*] [**ap-mac** *apmac-str* **mac-format** [**dot** | **line** | **none**]] [**url** *url-str*] [**ssid** *ssid-str*] [**port** *port-str*] [**ac-serialno** *ac-sno-str*] [**ap-serialno** *ap-sno-str*] [**additional** *extern-str*]
Parameter Description	*userip-str*: Indicates the IP address of a STA. *usermac-st*: Indicates the MAC address of a STA. *uservid-str*: Indicates the VID of a STA. *userid-str*: Indicates the ID of a STA. *nasip-st*: Indicates the NAS IP address. *nasid-str*: Indicates the NAS ID. *nasid2-str*: Indicates the NAS ID (two NAS IDs are supported). *ac-name*: Indicates the NAS name. *apmac-str*: Indicates the AP's MAC address. *apmac-str*: Indicates the original URL. *ssid-str*: Indicates the SSID. *port-str*: Indicates the authentication port. *ac-sno-st*: Indicates the AC serial number. *ap-sno-st*: Indicates the AP serial number. *extern-st*: Indicates the fixed string, which is required by some portal servers. *md5*: Indicates MD5 encryption. *des*: Indicates DES encryption. *des_ecb*: Indicates the DES_ECB mode. *des_ecb3*: Indicates the DES_ECB3 mode. *none*: Indicates no-encryption and cleartext transmission.
Command Mode	Template configuration mode
Usage Guide	You can add or delete any parameter.

Configuration Example

Configuring a Custom URL Format

Configuration Steps	● Configure redirection URL parameters including the IP address, MAC address, NAS' IP address, SSID, and URL in cleartext.
	`Hostname(config.tmplt.eportalv2)# fmt custom encry none user-ip userip user-mac usermac mac-format none nas-ip nasip ssid ssid url firstu`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`fmt custom encry none user-ip userip user-mac usermac mac-format none nas-ip nasip ssid ssid url firsturl`

1.4.15 Configuring the Redirection HTTP Port

Configuration Effect

- When a STA accesses network resources (for example, the user accesses the Internet using a browser), the STA sends HTTP packets. The NAS or aggregation device intercepts these HTTP packets to determine whether the STA is accessing network resources. If the NAS or aggregation device detects that the STA is not authenticated, it prevents the STA from accessing network resources and displays an authentication page to the STA. By default, the NAS intercepts the HTTP packets that STAs send to port 80 to determine whether STAs are accessing network resources.
- After a redirection HTTP port is configured, the HTTP requests that STAs send to the specified destination port can be redirected.

Notes

The commonly used management ports on the NAS or aggregation device, such as ports 22, 23, and 53, and ports reserved by the system are not allowed to be configured as the redirection ports. All ports except port 80 with numbers smaller than 1000 are seldom used by HTTP. To avoid a conflict with the well-known TCP port, do not configure a port with a small number as the redirection port unless necessary.

Configuration Steps

- Optional.
- To enable the NAS configured with automatic client acquisition to intercept the HTTP packets that STAs send to the specified destination port, configure a redirection HTTP port.

Verification

- Configure an interception port.
- Open the browser of a PC and access the Internet through the port without performing authentication.
- Check whether access requests are redirected to an authentication page.

Related Commands

↘ Configuring the Redirection HTTP Port

Command	**http redirect port** *port-num*
Parameter Description	*port-num*: Indicates the port number.
Command Mode	Global configuration mode
Usage Guide	A maximum of 10 different destination port numbers can be configured, excluding default ports 80 and 443.

Configuration Example

↘ Configuring the Redirection HTTP Port

Configuration Steps	● Configure port 8080 as the redirection HTTP port.
	`Hostname(config)#http redirect port 8080`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show web-auth rdport`
	`Rd-Port:`
	`80 443 8080`

1.4.16 Configuring Rate Limiting for Logging in Web-based Authentication

Configuration Effect

- The web-based authentication module sends syslog messages to the administrator to display user login and logout information and events. By default, syslog messages are shielded.
- After syslog output rate limiting is configured, syslog messages are sent at the specified rate.

Notes

When the login or logout rate is high, syslog messages are output frequently, which affects device performance and results in too much information displayed.

Configuration Steps

- Optional.
- Configure syslog output rate limiting when you need to view the syslog messages about user login or logout.

Verification

- Configure rate limiting for logging in web-based authentication.
- Check whether users log in and out at the specified rate.
- Check that syslog messages are generated at the rate limit.

Related Commands

↘ **Configuring Rate Limiting for Logging in Web-based Authentication**

Command	**web-auth logging enable** *num*
Parameter Description	*num*: Indicates the syslog output rate (entry/second).
Command Mode	Global configuration mode
Usage Guide	When the syslog output rate is set to **0**, syslog messages are output without limit. The output of syslog messages of the critical level and syslog messages indicating errors is not limited.

Configuration Example

↘ **Configuring Rate Limiting for Logging in Web-based Authentication**

Configuration Steps	● Disable rate limiting for logging in web-based authentication.
	`Hostname(config)#web-auth logging enable 0`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth logging enable 0`
	`...`

1.4.17 Configuring the Maximum Number of HTTP Sessions for Non-authenticated Clients

Configuration Effect

- When a non-authenticated user accesses network resources, the user's PC sends requests for an HTTP session connection. The NAS or aggregation device intercepts the HTTP packets and redirects the user to a web-based authentication page. To prevent a non-authenticated user from initiating too many HTTP connection requests and save resources on the NAS, it is necessary to limit the maximum number of HTTP sessions that the non-authenticated user can initiate on the NAS.
- A user occupies an HTTP session when performing authentication, and the other applications of the user may also occupy HTTP sessions. It is recommended that the maximum number of HTTP sessions for a non-authenticated user be not set to 1. By default, each non-authenticated user can initiate 255 HTTP sessions globally, and each port supports up to 300 HTTP sessions initiated by non-authenticated clients.

Notes

If the authentication page cannot be displayed during web-based authentication, the maximum number of HTTP sessions may be reached. In this case, close the applications that may occupy HTTP sessions and then perform web-based authentication again.

Configuration Steps

- Optional.
- Perform this configuration when you need to change the maximum number of HTTP sessions that each non-authenticated user can initiate and the maximum number of HTTP sessions that non-authenticated clients can initiate on each port.
- Perform this configuration when you configure automatic SU client acquisition.

Verification

- Change the maximum number of HTTP sessions that a non-authenticated user can initiate.
- Simulate the scenario where a non-authenticated user constructs identical sessions to connect to the NAS continuously.

- Simulate the scenario where the non-authenticated user accesses the Internet using a browser. Check whether the access requests are redirected, and check that the NAS notifies the user that the maximum number of sessions is reached.

Related Commands

Configuring the Maximum Number of HTTP Sessions for Non-authenticated Clients

Command	**http redirect session-limit** *session-num* [**port** *port-session-num*]
Parameter Description	*session-num*: Indicates the maximum number of HTTP sessions for non-authenticated clients. The value range is from 1 to 255. The default value is 255. *port-session-num*: Indicates the maximum number of HTTP sessions on each port for authenticated clients. The value range is from 1 to 65,535. The default value is 300.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Maximum Number of HTTP Sessions for Non-authenticated Clients

Configuration Steps	● Set the maximum number of HTTP sessions for non-authenticated clients to 3.
	`Hostname(config)#http redirect session-limit 3`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show web-auth parameter`
	`HTTP redirection setting:`
	`  session-limit: 3`
	`  timeout:      3`
	`Hostname(config)#`

1.4.18 Configuring the HTTP Redirection Timeout Interval

Configuration Effect

Configure the HTTP redirection timeout interval to maintain redirection connections. When a non-authenticated user tries to access network resources through HTTP, the TCP connection requests sent by the user will be intercepted (a connection is established with the NAS or aggregation device). Then the NAS or aggregation device waits for the HTTP GET/HEAD packets from the user and responds with HTTP redirection packets to close the connection. The redirection timeout interval is intended to prevent the user from occupying the TCP connection for a long time without sending GET/HEAD packets. By default, the timeout interval for maintaining a redirection connection is 3s.

Notes

N/A

Configuration Steps

- Optional.
- Perform this configuration to change the timeout interval for maintaining redirection connections.

Verification

- Change the timeout interval.
- Use a network packet sending tool to set up a TCP connection.
- View the status of the TCP connection on the NAS. Check whether the TCP connection is closed when the timeout interval is reached.

Related Commands

Configuring the HTTP Redirection Timeout Interval

Command	**http redirect timeout** *seconds*
Parameter Description	*seconds*: Indicates the timeout interval for maintaining redirection connections, in seconds. The value range is from 1 to 10. The default value is 3s.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the HTTP Redirection Timeout Interval

Configuration Steps	● Set the HTTP redirection timeout interval to 5s.
	`Hostname(config)#http redirect timeout 5`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show web-auth parameter`
	`HTTP redirection setting:`
	`  session-limit: 255`
	`  timeout:      5`

1.4.19 Configuring the Authentication-Free Network Resource

Configuration Effect

- After web-based authentication or 802.1X authentication is enabled on a port, the users connecting to the port need to pass web-based authentication or 802.1X authentication before accessing network resources.
- You can configure authentication-free network resources so that the non-authenticated user can access the authentication-free network resources.
- If a website is configured as the authentication-free network resource, all users including non-authenticated clients can access the website. By default, authentication-free network resources are not configured, and non-authenticated clients are not allowed to access network resources.
- IPv6 is supported.

Notes

- The maximum number of authentication-free network resources or the maximum number of non-authenticated clients cannot exceed 1000. The actual number of available resources may be reduced because security functions occupies resources. Therefore, it is recommended that network segments be configured if many addresses need to be set.
- **http redirect direct-site** is used to configure the authentication-free URL, and **http redirect** is used to configure the authentication-free IP address of the web-based authentication server. The addresses configured using the two commands can be accessed without authentication, but they have different usages. You are not advised to configure the IP address of the web-based authentication server by using **http redirect direct-site**.
- When IPv6 addresses are used, configure the device to allow packets from the local-link address. If this function is not configured, the NAS cannot learn the MAC addresses of clients.

Configuration Steps

- Optional.
- Run the **http redirect direct-site** command to enable non-authenticated clients to access network resources.

Verification

- Configure authentication-free network resources.
- Check whether non-authenticated clients can access configured network resources using PCs.

Related Commands

Configuring the Authentication-Free Network Resource

Command	**http redirect direct-site** { *ipv6-address* | *ipv4-address* [*ip-mask*] [**arp**] | *port-number&<1-8>* }
Parameter Description	*ipv6-address*: Indicates the IPv6 address of the authentication-free network. *ipv4-address*: Indicates the IPv4 address of the authentication-free network. *ip-mask*: Indicates the IPv4 subnet mask of the authentication-free network. *port-number*: Layer 4 port number. The parameter can be entered for a maximum of eight times. The value range is from 1 to 65535.
Command Mode	Global configuration mode
Usage Guide	To configure the authentication-free ARP resource, use the **http redirect direct-arp** command preferentially.

Configuration Example

Configuring the Authentication-Free Network Resource

Configuration Steps	● Configure the authentication-free network resources as 192.168.0.0/16. `Hostname(config)#http redirect direct-site 192.168.0.0 255.255.0.0`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show web-auth direct-site`
	`Direct sites:`
	`  Address  Mask  ARP Binding Group`

```
Hostname(config)#show web-auth direct-site
Direct sites:
  Address        Mask           ARP Binding Group      Description
  ---------------- ---------------- ----------- ----------- -------------
  192.168.0.0     255.255.0.0     Off        N/A        N/A
```

1.4.20 Configuring the Authentication-Free ARP Resource Range

Configuration Effect

When ARP check or similar functions are enabled, ARP learning of clients is controlled. As a result, clients cannot learn ARP entries of the gateway and other devices, which affects user experience. You can configure the authentication-free ARP resource range to permit packets destined for the specified address to pass.

Notes

- When ARP check is enabled, you need to configure the gateway of the PCs connecting to the Layer 2 access device as the authentication-free ARP resource. When you configure authentication-free websites and ARP resources in the same address or network segment, the **http redirect direct-arp** command automatically combines the websites and ARP resources. If no ARP option is specified for the configured websites, an ARP option will be automatically added after the combination.
- When ARP check is enabled, if the egress address of the PCs connecting to the Layer 2 access device is not the gateway address, configure the egress address as the authentication-free ARP resource. If multiple egresses addresses exist, configure the addresses as authentication-free ARP resources.

Configuration Steps

- Optional.
- If ARP check is enabled on the NAS, you must configure the authentication-free resources and gateway address as authentication-free ARP resources.

Verification

- Configure authentication-free ARP resources.
- Run the **arp -d** command in the Windows operating system to clear the ARP cache of the PC of a non-authenticated user.
- Run the **ping** command on the PC to access the authentication-free ARP resources.
- run the **arp -a** command in the Windows operating system to check the ARP cache on the PC and check whether the PC learns the ARP address of the authentication-free ARP resources.

Related Commands

Configuring the Authentication-Free ARP Resource Range

Command	**http redirect direct-arp** *ip-address* [*ip-mask*]
Parameter Description	*ip-address*: Indicates the IP address of authentication-free resources. *ip-mask*: Indicates the mask of authentication-free resources.

Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Authentication-Free ARP Resource Range

Configuration Steps	● Configure the authentication-free ARP resource as 192.168.0.0/16.
	`Hostname(config)#http redirect direct-arp 192.168.0.0 255.255.0.0`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show web-auth direct-arp`
	`Direct arps:`
	`  Address  Mask`
	`  --------------- ---------------`
	`  192.168.0.0  255.255.0.0`
	`Hostname(config)#`

1.4.21 Configuring the Authentication-Free Address Range

Configuration Effect

- Users in the authentication-free address range do not need to pass web-based authentication when accessing reachable network resources. By default, no authentication-free address range is configured. All users must pass web-based authentication before accessing network resources.
- The authentication-free address range can be configured as an IP or MAC address range.

Notes

N/A

Configuration Steps

- Optional.
- Perform this configuration to allow non-authenticated clients to access network resources.

Verification

- Configure an authentication-free user.
- Check whether the user can access the Internet without authentication.

Related Commands

Configuring the Authentication-Free Address Range

Command	**web-auth direct-host** { *ipv4-address* [*ipv4-mask*] [**arp**] [**port** *interface-name interface-port*] | *ipv6-address* | *mac-address* }

Parameter Description	*ipv6-address*: Indicates the IPv6 address of the authentication-free network. *ipv4-address*: Indicates the IPv4 address of the authentication-free network. *ip-mask*: Indicates the IPv4 subnet mask of the authentication-free network. *mac-address*: Indicates the MAC address of the authentication-free network.
Command Mode	Global configuration mode
Usage Guide	The **arp** field is used for configuring the device to allow ARP packets to pass. This field must be set when ARP check is enabled. After the **port** field is set, non-authentication takes effect only on the configured interface.

Configuration Example

↘ Configuring the Authentication-Free Address Range

Configuration Steps	Configure the authentication-free address range.
	`Hostname(config)# web-auth direct-host 192.168.197.64`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show web-auth direct-host`
	`Direct hosts:`
	`  Address  Mask  Port  ARP Binding  Group  Description`
	`  ---------- ---------- ---------- ---------- -------- ----------`
	`  192.168.197.64  255.255.255.255  Off  N/A  N/A`

1.4.22 Configuring the Interval for Updating Online User Information

Configuration Effect

The NAS or aggregation device maintains and periodically updates information of online users, including users' online duration, to monitor the usage of network resources. When the online duration threshold is reached, users will be prevented from using network resources.

Notes

The interval for updating online user information must be configured as a multiple of 60. Otherwise, the actual configuration will automatically round up to the nearest multiple of 60 for it to take effect.

Configuration Steps

- Optional.
- Perform this configuration to allow non-authenticated clients to access network resources.

Verification

- Configure the interval for updating online user information.
- View information about online users after the update interval has elapsed.

Related Commands

Configuring the Interval for Updating Online User Information

Command	**web-auth update-interval** *seconds*
Parameter Description	*seconds*: Indicates the interval for updating online user information, in seconds. The value range is from 30 to 3,600. The default value is 180s.
Command Mode	Global configuration mode
Usage Guide	To restore the default interval, run the **no web-auth update-interval** command in global configuration mode.

Configuration Example

Configuring the Interval for Updating Online User Information

Configuration Steps	● Set the interval for updating online user information to 60s.
	`Hostname(config)# web-auth update-interval 60`
Verification	● Check whether the configuration is successful.
	`Hostname(config)#show run | include web-auth update-interval` `web-auth update-interval 60`

1.4.23 Configuring Portal Server Detection

Configuration Effect

- Detect the availability of the active portal server periodically. When the active portal server is unavailable, the standby portal server takes over the services.
- Ruijie second-generation web authentication provides two detection methods. One is that the NAS constructs and sends portal packets to the portal server. If the portal server returns response packets, the NAS determines that the portal server is available. Another is the NAS sends ping packets to the portal server. If the portal server returns response packets, the NAS determines that the portal server is available. Because some servers or intermediate network segments filter ping packets, the first method is commonly used. The ping detection method is only used based on special requirements. In Ruijie first-generation web authentication and ClearPass authentication, the NAS connects to a port of the portal server and checks whether the port is reachable. If the portal is reachable, the NAS determines that the portal server is available.
- For the first method in second-generation authentication, the interval of server availability detection is specified by the **interval** parameter, and the maximum number of packets that can be sent during each time of detection is specified by the **retransmit** parameter. If the portal server does not respond, the NAS determines that the portal server is unavailable. The timeout interval for each packet is specified by the **timeout** parameter. The parameter settings are also supported by Ruijie first-generation web-based authentication.
- Portal server detection takes effect for Ruijie first-generation web authetntication, ClearPass authentication, and Ruijie second-generation web authentication.
- If multiple portal servers are configured, they work in active/standby mode.

Notes

- Multiple portal servers must be configured to realize failover when an error is detected on one server.
- Only one of the two detection methods can be used at a time in case of collision. If both detection methods are configured, a detection algorithm conflict will occur or detection results will be inaccurate.
- The system will automatically select a detection method based on whether Ruijie first- or second-generation web-based authentication is used.

Configuration Steps

- Optional.
- Configure multiple portal server templates applicable to Ruijie first- or second-generation web-based authentication.

Verification

- Configure two portal server templates for Ruijie first- or second-generation web-based authentication: one server is unavailable server and the other is available in the templates.
- When the console displays a log indicating that the portal server is unavailable, simulate the scenario where a user opens a browser to perform login authentication. Check whether the user is redirected to the second portal server.

Command	**web-auth portal-check** [**interval** *intsec* [**timeout** *tosec*] [**retransmit** retries]
Parameter Description	*intsec*: Indicates the detection interval. The default value is 10s. *tosec:* Indicates the packet timeout interval. The default value is 5s. *intsec*: Indicates the retransmission count. The default value is 3 (times).
Command Mode	Global configuration mode
Usage Guide	In most network environments, only one portal server is deployed, and portal server detection does not need to be configured. If multiple portal servers exist, it is recommended that parameters of portal server detection be not set to small values; otherwise, the NAS will send many packets within a short time, affecting performance. This command cannot be used with the **fmt** command. Before using this command, use the **fmt** command to configure the URL format.

Command	**web-auth ping** [**interval** *minutes*] [**retry** *times*]
Parameter Description	*minutes*: Indicates the detection interval. The default value is 1 minute. *times*: Indicates the retransmission count. The default value is 3 (times).
Command Mode	Global configuration mode
Usage Guide	In most network environments, only one portal server is deployed, and portal server detection does not need to be configured. If multiple portal servers exist, it is recommended that parameters of portal server detection be not set to small values; otherwise, the NAS will send many packets within a short time, affecting performance. This command cannot be used with the **fmt** command. Before using this command, use the **fmt** command to configure the URL format.

Configuration Example

Configuring Portal Server Detection

Configuration Steps	● Configure portal server detection.
	`Hostname(config)#web-auth portal-check interval 20 timeout 2 retransmit 2`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth portal-check interval 20 timeout 2 retransmit 2`
	`...`

1.4.24 Configuring Portal Escape

Configuration Effect

Allow new users to access the Internet without authentication when the portal server is unavailable.

Notes

- To use the portal escape function, you must configure portal server detection.
- If multiple portal servers are configured, the escape function takes effect only when all the portal servers are unavailable.
- The escape function is intended only for the portal server but not the RADIUS server.

Configuration Steps

- Optional.
- Configure portal server detection.
- Configure portal escape.
- (Optional) Configure the nokick attribute.

Verification

- Configure a portal server and disable the server.
- Configure portal server detection and the escape function.
- When the NAS detects that the portal server is unavailable, check whether a client accesses the Internet without authentication.

Related Commands

Configuring Portal Escape

Command	**web-auth portal-escape** [**nokick**]
Parameter Description	N/A

Command Mode	Global configuration mode
Usage Guide	Configure portal escape if the continuity of some critical services on the network needs to be maintained when the portal server is faulty. You must configure portal detection when you use this function. If the nokick attribute is configured, the system does not force users offline when the escape function takes effect. If the nokick attribute is deleted, the system forces users offline.

Configuration Example

Configuring Portal Escape

Configuration Steps	● Configure portal escape.
	`Hostname(config)#web-auth portal-escape`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth portal-escape`
	`...`

1.4.25 Enabling DHCP Address Check

Configuration Effect

Allow only the clients that are allocated with IP addresses through DHCP to perform authentication.

Notes

- To use the DHCP address check function, you must configure DHCP snooping.
- DHCP address check is supported only for IPv4.
- DHCP address check is applicable only to Ruijie second-generation web-based authentication and iPortal web-based authentication.
- The requirement that clients obtain IP addresses through DHCP must be specified during network deployment. Those clients cannot use static IP addresses; otherwise, the existing clients that use static IP addresses will be affected.
- If a few clients need to use static IP addresses, configure these IP addresses as authentication-free addresses.
- If DHCP address check needs to be enabled only on some interfaces or some VLANs of interfaces, disable global DHCP address check and configure the VLAN range in which DHCP address check needs to be enabled on each interface.

Configuration Steps

- Optional.
- Enable DHCP snooping.
- Enable DHCP address check.

Verification

- Enable DHCP address check.
- Configure a static IP address that is not allocated by the DHCP server for a client.
- Connect the client to the Internet and check that the client cannot perform authentication.

Related Commands

Enabling Global DHCP Address Check

Command	**web-auth dhcp-check**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure DHCP address check to allow only the clients who obtain IP addresses through DHCP to access the Internet. This function prevents clients with private IP addresses from performing authentication to access the Internet.

Enabling Interface-based DHCP Address Check

Command	**web-auth dhcp-check {vlan [**vlan-list**]}**
Parameter Description	vlan-list: Indicates the range of VLANs that require DHCP address check on an interface.
Command Mode	Interface configuration mode
Usage Guide	If DHCP address check is only required on certain interfaces or VLANs on an interface, you need to disable DHCP address check globally, and then configure the VLAN range to be effective on each interface separately.

Configuration Example

Enabling DHCP Address Check

Configuration Steps	● Enable global DHCP address check.
	`Hostname(config)#web-auth dhcp-check`
	● Enable interface-based DHCP address check.
	`Hostname(config-if-TenGigabitEthernet 3/1)# web-auth dhcp-check vlan 1,3-4`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth dhcp-check`
	`...`
	`interface TenGigabitEthernet 3/1`
	`web-auth dhcp-check vlan 1,3-4`
	`...`

1.4.26 Disabling Link Detection

Configuration Effect

- Authentication entries of clients are kept when links are disconnected. The clients can access the Internet again without authentication if the IP addresses remain unchanged.
- You can disable link detection in scenarios where mobile office is required or wireless web-based authentication is deployed but wireless signals are bad.

Notes

- Do not disable link detection if clients obtain IP addresses through DHCP and the number of IP addresses in the DHCP address pool is smaller than the number of clients. If link detection is disabled, the IP address of a client that has logged out may be obtained by another client, causing a user information error.
- If link detection is disabled, client logout is triggered only when the user clicks the logout button on the online page, the server disconnects the client, or the NAS detects low traffic on the client. It is recommended that you enable low traffic detection if you need to disable link detection. For details, see *Configuring SCC*.
- It is recommended that you disable link detection and enable low traffic detection in a wireless environment. The reason is that the offline rate is high in a wireless environment where wireless connections are easily affected by signal interference, and disabling link detection helps improve wireless experience.

Configuration Steps

- Optional.
- Configure web-based authentication.
- Disable link detection.

Verification

- Configure Ruijie second-generation web-based authentication and disable link detection.

- Connect a client to the Internet and perform authentication. When the client passes authentication, disconnect from and then reconnect to the Internet with the same IP address. Check whether the client can access the Internet again without authentication.

Related Commands

Disabling Link Detection

Command	**no web-auth sta-leave detection**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	You can disable link detection in a wireless or wired environment with the need for mobile office. To disable link detection, you must enable low traffic detection.

Configuration Example

Disabling Link Detection

Configuration Steps	● Disable link detection.
	`Hostname(config)#no web-auth sta-leave detection`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`no web-auth sta-leave detection`
	`...`

1.4.27 Disabling Portal Extension

Configuration Effect

- Enable portal extension to support Ruijie portal server and portal servers that comply with *CMCC WLAN Service Portal Specification*.
- You can select multiple redirection URL formats when the device interworks with the servers in compliance with *CMCC WLAN Service Portal Specification*.

Notes

- Only Ruijie second-generation web-based authentication supports portal extension.
- Ruijie second-generation web-based authentication extends *CMCC WLAN Service Portal Specification*. You need to determine whether to use the extension mode based on server performance.
- If the portal server of Ruijie is used, use the default mode, that is, extension mode. If the portal server complies with *CMCC WLAN Service Portal Specification*, disable portal extension.

- *CMCC WLAN Service Portal Specification* supports multiple redirection URL formats. If the portal server complies with *CMCC WLAN Service Portal Specification*, select a redirection URL format supported by the server.

Configuration Steps

- Optional.
- Determine whether to disable portal extension based on the server type.
- Select a redirection URL format supported by the server if portal extension is disabled.

Verification

- Select Ruijie portal server and a portal server complying with *CMCC WLAN Service Portal Specification* to be used in Ruijie second-generation web-based authentication.
- Connect a client to the Internet. Check whether the client performs authentication normally on the two servers and can access the Internet.

Related Commands

Disabling Portal Extension

Command	**no web-auth portal extension**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	The portal server that complies with *CMCC WLAN Service Portal Specification* is deployed. If Ruijie portal server is used, enable portal extension.

Configuration Example

Disabling Portal Extension

Configuration Steps	• Disable portal extension.
	`Hostname(config)#no web-auth web-auth portal extension`
	`Hostname(config)# http redirect url-fmt ext1`
Verification	• Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`no web-auth web-auth portal extension`
	`http redirect url-fmt ext1`
	`...`

1.4.28 Configuring an Allowlist and a Blocklist

Configuration Effect

- Configure an allowlist to allow non-authenticated clients to access some network resources, and configure a blocklist to prevent authenticated clients from accessing some network resources.
- Allowlists and blocklists are supported based on ports, URLs, and IP addresses.

Notes

- Up to 1,000 blocklists and allowlists can be configured.
- If blocklists and allowlists are configured in domain name format, DNS must be configured on the NAS so that the NAS can resolve IP addresses correctly.
- A domain name can map up to eight IP addresses.

Configuration Steps

- Optional.
- Configure DNS.
- Configure an allowlist and a blocklist.

Verification

- Configure an allowlist and a blocklist.
- Check whether non-authenticated STAs can access the allowlisted addresses.
- Check whether authenticated STAs cannot access the blocklisted addresses.

Related Commands

Configuring an Allowlist and a Blocklist

Command	**web-auth acl** { **black-ip** *ip* | **black-port** *port* | **black-url** *name* | **white-port** *port* | **white-url** *name* }
Parameter Description	*ip*: Indicates an IP addresses blocklisted. *port*: Indicates a port numbers blocklisted or allowlisted. *name*: Indicates a URL blocklisted or allowlisted.
Command Mode	Global configuration mode (Blocklists can be configured in WLAN security configuration mode on wireless devices.)
Usage Guide	Configure an allowlist to allow non-authenticated clients to access some network resources, and configure a blocklist to prevent authenticated clients from accessing some network resources.

Configuration Example

Configuring an Allowlist and a Blocklist

Configuration Steps	● Configure an allowlist and a blocklist.
	`Hostname(config)#web-auth acl black-ip 192.168.1.2` `Hostname(config)#web-auth acl white-url www.host.com`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth acl black-ip 192.168.1.2`
	`web-auth acl white-url www.host.com`
	`...`

1.4.29 Configuring Anti-jitter Accounting

Configuration Effect

If anti-jitter or low traffic detection is configured on the NAS, the time of anti-jitter or low traffic detection will be counted into the online duration. Anti-jitter accounting is used to reduce the accounting error. Configure this function if the accounting policy does not allow the deduction of the anti-jitter time or low traffic detection time from the online duration.

Notes

- The NAS needs to support anti-jitter or low traffic detection.
- A client logs out when the link is disconnected for a long time or the NAS detects its low traffic.
- When anti-jitter and low traffic detection functions are enabled, the time of the function that first triggers logout is counted. For example, the anti-jitter duration is set to 5 minutes and the low traffic detection duration is set to 10 minutes. If the client is disconnected from the network, the anti-jitter function first triggers web-based authentication to disconnect the client. In this case, only the 5-minute duration is deducted from the online duration in the accounting packet.

Configuration Steps

- Optional.
- Configure the accounting function.
- Configure anti-jitter or low traffic detection.
- Configure anti-jitter accounting.

Verification

- Simulate the scenario where a client goes online after authentication and then go offline because the low traffic threshold is reached.
- Capture the stop-accounting packet sent by the NAS and check whether the time of low traffic detection is deducted from the online duration.

Related Commands

↘ **Configuring Anti-jitter Accounting**

Command	**web-auth accounting jitter-off**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Run this command to include the anti-jitter duration or low traffic detection time into the online duration in the accounting-stop packet based on the server accounting policy. By default, the time is not included.

Configuration Example

Configuring Anti-jitter Accounting

Configuration Steps	● Configure anti-jitter accounting.
	`Hostname(config)#web-auth accounting jitter-off`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth accounting jitter-off`
	`...`

1.4.30 Configuring the Source Port for Communication with the Portal Server

Configuration Effect

Configure the source port used for communication between the NAS and portal server.

Notes

Only one port can be configured for communication between the NAS and portal server.

Configuration Steps

Configure a port as the source port for communication with the portal server.

Verification

After web-based authentication is enabled, obtain a packet on the portal server during authentication and check whether the source IP address of the packet is the IP address of the specified port.

Related Commands

Configuring the Source Port for Communication with the Portal Server

Command	**ip portal source-interface** *interface-type interface-num*
Parameter Description	*interface-type*: Indicates the interface type. *interface-num*: Indicates the interface number.

Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the Source Port for Communication with the Portal Server

Configuration Steps	● Configure an aggregate port as the source port for communication with the portal server.
	`Hostname(config)#ip portal source-interface Aggregateport 1`
Verification	● Check whether the configuration is successful.
	`Hostname(config)#show running-config` `ip portal source-interface Aggregateport 1`

1.4.31 Configuring the Anti-Noise Function

Configuration Effect

Packets sent to the configured IP address and port are not filtered by the anti-noise function.

Notes

If there are too many packets of this type, normal authentication packets may be discarded.

Configuration Steps

Configuring the Anti-Noise Function

In global configuration mode, configure the IP address and port number to be configured with the anti-noise function.

Command	**web-auth anti-noise ip** *ip-addr* **port** *port*
Parameter Description	*ip-addr*: Indicates the destination address of a packet. *port*: Indicates the Layer 4 port number of a packet.
Command Mode	Global configuration mode
Usage Guide	Multiple IP addresses can be configured.

Verification

Send packets that comply with the configuration and packets that do not. The packets that comply with the configuration are not discarded by the line card.

Configuration Example

Configuring the Anti-Noise Function

Configuration Steps	● Configure the IP address and port with the anti-noise function.
	`Hostname(config)# web-auth anti-noise ip 192.168.1.1 port 80`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth anti-noise ip 192.168.1.1 port 80`

1.4.32 Configuring an NDKEY-Compatible Web-based Authentication URL

Configuration Effect

Configure the web-based authentication URL used in web-based authentication to support Shanghai NDKEY system.

Notes

N/A

Configuration Steps

Configuring an NDKEY-Compatible Web-based Authentication URL

Set the post parameter in global configuration mode.

Command	**web-auth dkey-compatible url-parameter** *string*
Parameter Description	*string*: Indicates the value of the **post** parameter.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Execute redirection after the configuration and check that the redirection URL contains the post parameter.

Configuration Example

Configuring Anti-noise Suppression

Configuration Steps	● Configure compatibility parameters.
	`Hostname(config)#web-auth dkey-compatible url-parameter login`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth dkey-compatible url-parameter login`

1.4.33 Configuring Multi-Portal Mapping

Configuration Effect

Users from different network segments can be configured to use different portals for authentication.

Notes

- Multiple mappings can be configured. If a user is out of the mapping range, the default portal is used for authentication.
- Different mapping ranges cannot overlap.

Configuration Steps

Configuring Multi-Portal Mapping

Configure mapping parameters in global configuration mode.

Command	**web-auth portal** { **eportalv2** | **eportalv1** | **iportal** | *name* }
Parameter Description	*name*: Indicates the name of the template in use.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Use different network segments for authentication. Users can authenticate using different portals.

Configuration Example

Configuring Multi-Portal Mapping

Configuration Steps	● Configure network segment mappings.

	`Hostname(config)# web-auth portal eportalv2 ip-mapping 192.168.1.0 255.255.255.0`
	`Hostname(config)# web-auth portal eportalv1 ip-mapping 192.168.2.0 255.255.255.0`
	`Hostname(config)# web-auth portal eportalv2`

Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`web-auth portal eportalv2`
	`web-auth portal eportalv2 ip-mapping 192.168.1.0 255.255.255.0`
	`web-auth portal eportalv1 ip-mapping 192.168.2.0 255.255.255.0`

1.4.34 Enabling NAT for Ruijie iPortal Web-based Authentication

Configuration Effect

Configure Ruijie iPortal web-based authentication to support NAT.

Notes

NAT takes effect only in Ruijie iPortal web-based authentication.

Configuration Steps

Enabling NAT for Ruijie iPortal Web-based Authentication

Enable NAT in global configuration mode.

Command	iportal nat enable
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Check whether Ruijie iPortal Web-based authentication can be implemented after NAT is enabled.

Configuration Example

Enabling NAT for Ruijie iPortal Web-based Authentication

Configuration Steps	● Enable NAT for Ruijie iPortal web-based authentication.
	`Hostname(config)#iportal nat enable`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`iportal nat enable`

1.4.35 Configuring the iPortal HTTP Retransmission Count

Configuration Effect

Configure the iPortal HTTP retransmission count.

Notes

The retransmission count takes effect only for the HTTP connections pushed by an iPortal page.

Configuration Steps

Configuring the iPortal HTTP Retransmission Count

Set the retransmission count in global configuration mode.

Command	**iportal retransmit** *count*
Parameter Description	*count*: Indicates the retransmission count.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Configure the device to send an iPortal web-based authentication request and disconnect the device from the network. Check whether the NAS resends an HTTP connection request.

Configuration Example

Configuring the Retransmission Count

Configuration Steps	● Configure the retransmission count.
	`Hostname(config)#iportal retransmit 5`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`iportal retransmit 5`

1.4.36 Configuring Service Selection in Ruijie iPortal Web-based Authentication

Configuration Effect

Configure the service type used by Ruijie iPortal web-based authentication.

Notes

N/A

Configuration Steps

Configuring the Service Type Used by Ruijie iPortal Web-based Authentication

Configure a service type in global configuration mode.

Command	**iportal service** { **internet** *internet-name* | **local** *local-name* }
Parameter Description	*internet-name*: Indicates the external service name to be used. *local-name*: Indicates the internal service name to be used.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring a Service Type

Configuration Steps	● Configure a service type.
	`Hostname(config)#iportal service local local-srv`
Verification	● Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	`...`
	`iportalservice local local-srv`

1.4.37 Configuring the UA Field for iPortal Web-based Authentication Users

Configuration Effect

It is used to configure the STA name corresponding to the UA field of a user.

Notes

This command is invalid because STA recognition should be used instead.

Configuration Steps

Configuring the UA Field for iPortal Web-based Authentication Users

Configure the UA field in global configuration mode

Command	**iportal user-agent** *ua-name* **type mobile** *ua-string*
Parameter Description	*ua-name*: Indicates the name of the UA field. *ua-string*: Indicates the content of the UA string.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

N/A

Configuration Example

N/A

1.4.38 Importing a Page Suite for Ruijie iPortal Web-based Authentication

Configuration Effect

- Import a page suite used by Ruijie iPortal web-based authentication.

Notes

- N/A

Configuration Steps

Importing a Page Suite for Ruijie iPortal Web-based Authentication

Command	**web-auth import-page-suite tftp:***path*
Parameter Description	*path*: Indicates the file path
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	Enable the TFTP server and store the file to be imported on the server.

Verification

- After a page suite is imported, run the **page-suite** command in template configuration mode to check whether the configuration is successfu.

Configuration Example

Importing a Page Suite

Configuration Steps	● Import a page suite. `Hostname# web-auth import-page-suite tftp://10.104.8.66/custom.zip`
Verification	● Check whether the configuration is successful. `Hostname#show running-config`

1.4.39 Configuring the Accounting Method List of Web-based Authentication

Configuration Effect

In global configuration mode, specify an accounting method for web-based authentication.

Notes

If no accounting method is configured for web-based authentication, the default method is used.

Configuration Steps

Configuring an Accounting Method

Configure an accounting method in global configuration mode.

Command	**web-auth accounting** { **v2** | **intra** | **cpweb** } { **default** | *name* }
Parameter Description	*name*: Indicates the name of the accounting method list to be used.
Command Mode	Global configuration mode

Usage Guide	N/A

Verification

View the destination IP address of accounting packets.

Configuration Example

Configuring an Accounting Method

Configuration Steps	● Configure an accounting method.

	`Hostname(config)#web-auth accounting v2 test`
	`Hostname(config)# web-auth accounting intra test`
	`Hostname(config)# web-auth accounting cpweb test`

Verification	● Check whether the configuration is successful.

	`Hostname#show running-config`
	`...`
	`web-auth accounting v2 test`
	`web-auth accounting intra test`
	`web-auth accounting cpweb test`

1.4.40 Configuring a Web-based Authentication Method List

Configuration Effect

In global configuration mode, specify a web-based authentication method.

Notes

If no Web authentication method is configured, the default method is used.

Configuration Steps

Configuring a Web-based Authentication Method List

Configure a web-based authentication method in global configuration mode.

Command	**web-auth authentication** { **v2** | **intra** | **cpweb** } { **default** | *name* }
Parameter Description	name: Indicates authentication method list name. The value can contain up to 63 characters.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

View the destination IP address of authentication packets.

Configuration Example

Configuring a Web-based Authentication Method

Configuration Steps	● Configure a web-based authentication method.

	`Hostname(config)#web-auth authentication v2 test`
	`Hostname(config)# web-auth authentication intra test`
	`Hostname(config)# web-auth authentication cpweb test`

Verification	● Check whether the configuration is successful.

	`Hostname#show running-config`
	`...`
	`web-auth authentication v2 test`
	`web-auth authentication intra test`
	`web-auth authentication cpweb test`

1.4.41 Customizing a Page Suite

Configuration Effect

- Customize a webpage to display logos or advertisements in Ruijie iPortal web-based authentication.
- A single page suite supports two page sets to adapt to the screen sizes of terminals, for example, mobile terminals with a small screen.

Notes

- The preparation of a page suite must comply with the relevant specification; otherwise, the customized page suite cannot be used.
- The maximum number of files in a page suite (including the files displayed on PCs and mobile terminals) is 50, and the maximum length of the file name of each page is 32 bytes.
- A new page suite must be downloaded to the ./portal directory and the name must not be the same as that of the default page suite; otherwise, the default page suite will be overwritten.
- Some NASs do not have a default page suite. When Ruijie iPortal web-based authentication is implemented, prepare a page suite in accordance with the relevant specification and import the page suite to the flash memory.

Configuration Steps

N/A

Verification

Simulate the scenario where a STA connects to the Internet and opens the browser to perform authentication. Check that the customized page is displayed.

Related Commands

Page File Naming Specification

Page File Name (with a File Name Extension)	Usage

login.htm	Login page
online.htm	Online page (which is displayed when users pass authentication)
offline.htm	Offline page
login_mobile.htm	Login page for mobile terminals
online_mobile.htm	Online page for mobile terminals (which is displayed when users pass authentication)
offline_mobile.htm	Offline page for mobile terminals

Login Page Preparation Specification

According to the page file naming specification, the file name of the login page for PCs is **login.htm**, and that for mobile terminals is **login_mobile.htm**. The login page content specification is described as follows.

- Form elements

The login page must contain a form, and the form submission method has a fixed value of POST. The PC login page is used as an example. Assume that the PC login page is stored in the **/portal** directory. The HTML code of the form is as follows (the HTML code of the form of the mobile terminal login page is similar):

```
<form method="post" action="/portal/login.htm">
...
</form>
```

The form of the login page must contain the following page elements:

1 (Mandatory) User name text box: allows a user to enter the user name. The text box ID is username.

2 (Mandatory) Password text box: allows a user to enter the password (which is not displayed in cleartext mode). The text box ID is password.

3 (Mandatory) Login button: allows a user to submit a form using the POST method.

4 (Optional) Tab showing an authentication failure cause: The ID of the tab is errormsg. The tab is displayed on the login page to show why the current user fails authentication. When the login page is loaded, an error message request is sent using the GET method, and the request results will be displayed on the errormsg tab. You can configure whether to display the errormsg tab on the login page as required. The following script is used to request the error message content from the server (the script is only one example):

```
< script language="javascript">
//Request the error message content from the server.
function requestErrorMsg() {
   var _errormsg=document.getElementById("errormsg");
    var script=document.createElement("script");
script.src="errormessage"+location.search;
_errormsg.appendChild(script);
}

//Call the init function when the login page is loaded.
function init() {
```

```
...
requestErrorMsg();
}
...
</script>
```

- Form submission

A form is submitted in the format of username=[AAAA]&password=[BBBB]&lang=[CCCC]. The meanings of the fields are described in the following:

[AAAA]: (Optional) Indicates the user name that the user enters in the user name text box.

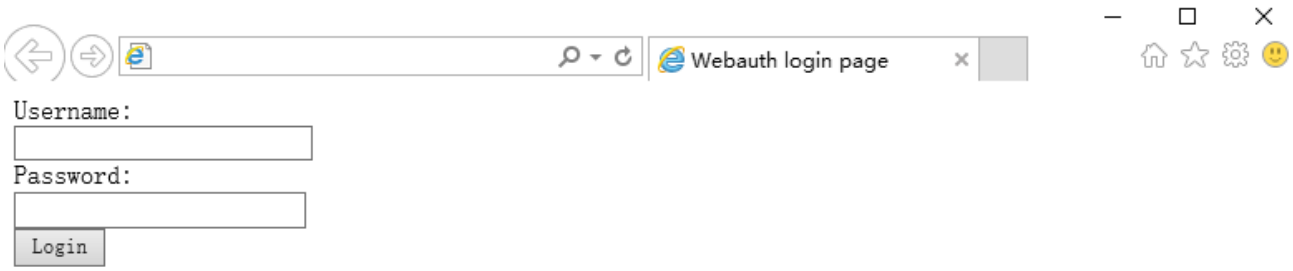
[BBBB]: (Optional) Indicates the password that the user enters in the password text box.

[CCCC]: (Optional) Indicates the language environment. The value **1** indicates Simplified Chinese, and the value **2** indicates English. Other languages are not defined. The default language environment is Simplified Chinese. When English is used, the submitted form must contain the language environment information; otherwise, the content of the errormsg tab is in Chinese.

The form of the login page must contain at least the following three input fields (tabs): username, password, and login button. If the login page provides the Chinese and English language options, the form may also contain the language input field, which is invisible.

The HTML source code of the login page is as follows:

```
<html>
<head>
<title>Web-based authentication login page</title>
</head>
<script language="javascript">
//Request errormsg. Errormsg is empty and not displayed when a user passes authentication
or the login page is loaded for the first time.
   function requestErrorMsg() {
   var _errormsg=document.getElementById("errormsg");
    var script=document.createElement("script");
script.src="errormessage"+location.search;
_errormsg.appendChild(script);
   }



function init() {
...
requestErrorMsg();
}

//Script that is executed when a user clicks the login button
function login() {
  document.getElementById('loginForm').action = "./login.htm"+location.search;
    document.getElementById('loginForm').submit();
    window.onbeforeunload = null;
```

```
    window.onunload = null;
}
...

</script>
<body onload="init()">
<form method="post" id="loginForm">
User name:<br>
<input type="text" name="username" accesskey="u" size="25" value="" id="usrename">
<br>
Password:<br>
<input type="password" name="password" accesskey="p" size="25"
       value="" id="password">
<br>
<input type="button" onclick="login()" value="Login" id="loginButton">
<input type="hidden" name="lang" value="" id="lan">
    <p name="errormsg" id="errormsg"></p>
</form>
</body>
</html>
```

The following figure shows the login page that the iPortal server pushes to users.

The login page shows only the mandatory elements. Other functions can be added. For example, you can add a background and set the styles of page elements.

Online Page Preparation Specification

The online page is designed to inform a user that the user has passed authentication and can use network resources normally. The file name of the login page for PCs is **login.htm**, and that for mobile terminals is **login_mobile.htm**.

- Form elements

The online page must contain a form, which is used to submit an offline request. For this reason, the form must contain the logout button. The form submission method has a fixed value of POST. The PC online page is used as an example. Assume that the PC online page is stored in the /portal directory. The HTML code of the form is as follows (the HTML code of the form of the mobile terminal online page is similar):

```
<form method="post" action="/portal/online.htm">
...
</form>
```

The form of the online page must contain the following page elements:

1 (Optional) Tab with the username ID: displays information about the online user.

2 (Optional) Tab with the userip ID: displays the IP address of the online user.

3 (Optional) Tab with the usermac ID: displays the MAC address of the online user.

4 (Optional) Tab with the ssid ID: displays the SSID of the online user.

5 (Optional) Tab with the availtime ID: displays the available time during which the user can access the Internet.

6 (Mandatory) Logout button: allows the user to go offline and requests the display of the offline page.

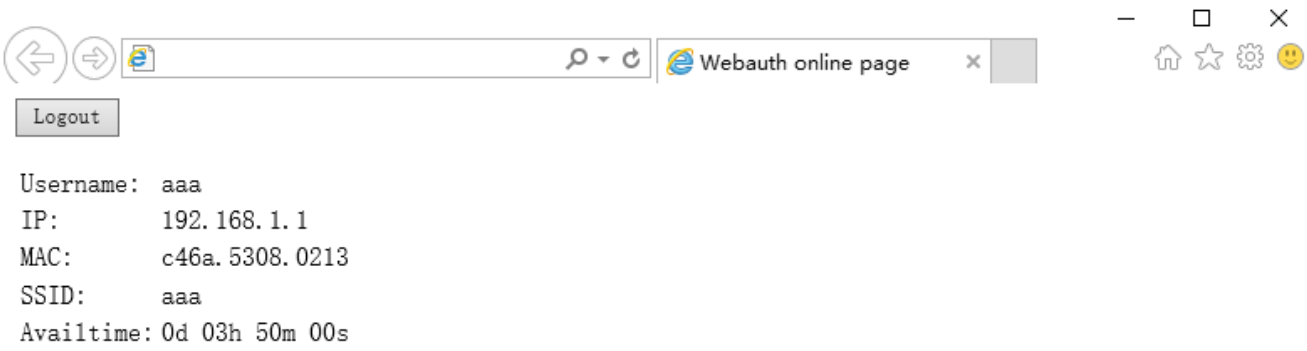
When the online page is loaded, a request is sent using the GET method to retrieve user information from the server, including the user name, IP address, MAC address, and associated SSID of the online user, and available time. The URI is getonlineinfo. The onload method of the body in the HTML code must be used. The following script is used to request user information from the server (the script is only one example):

```
<script language="javascript">
//Obtain information about the online user, including the user name, IP address, MAC
address, and associated SSID of the online user, and available time.
   function requestOnlineInfo() {
        var _availTime=document.getElementById("availtime");
        var script=document.createElement("script");
        script.src="getonlineinfo"+location.search;
        _availTime.appendChild(script);
    }

    function init() {
        requestOnlineInfo();
    }
</script>
<body onload="init()">
...
</body>
```

The HTML source code of the online page is as follows:

```
<html>
<head>
```



```
<title>Web-based authentication online page</title>
</head>
<script language="javascript">
//Obtain information about the online user, including the user name, IP address, MAC
address, and associated SSID of the online user, and available time.
   function requestOnlineInfo() {
        var _availTime=document.getElementById("availtime");
        var script=document.createElement("script");
        script.src="getonlineinfo"+location.search;
        _availTime.appendChild(script);
    }

    function init() {
        requestOnlineInfo ();
    }
    //Script that is executed when the user clicks the logout button. The request URI is
offline.htm.
    function logout() {
       document.logoutform.action = "./offline.htm"+location.search;
       document.logoutform.submit();
       window.onbeforeunload = null;
        window.onunload = null;
    }

</script>

<body onload="init()">
<form method="post" action="/portal/offline.htm" id="logoutform">
<input type="button" onclick="logout()" value="Logout" id="logoutButton">
</form>
    <table>
    <tr><td>User name:</td><td id="username"></td></tr>
    <tr><td>IP address:</td><td id="userip"></td></tr>
    <tr><td>MAC address:</td><td id="usermac"></td></tr>
    <tr><td>Associated SSID:</td><td id="ssid"></td></tr>
    <tr><td>Available time:</td><td id="availtime"></td></tr>
    </table>
</body>
</html>
```

The following figure shows the login page that the iPortal server pushes to users.

The login page shows only the mandatory elements. Other functions can be added. For example, you can add a background and set the styles of page elements.

Offline Page Preparation Specification

The offline page is displayed when a user clicks the logout button on the online page. The offline page is designed to inform the user that the user logs out successfully. If the user needs to access the Internet after logout, the user must perform authentication. The file name of the offline page for PCs is **offline.htm**, and that for mobile terminals is **offline_mobile.htm**.

The offline page has the following elements:

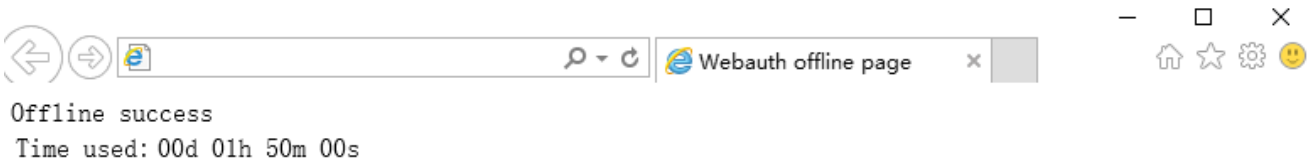
1 (Optional) Tab with the timeused ID: displays the time that has used by the user to access the Internet.

2 When the offline page is loaded, a request is sent using the GET method to retrieve the used-time information from the server. The request URI is getofflineinfo. The onload method of the body in the HTML code must be used. To obtain the used-time information, you can create a dynamic script. For example, you can create **script.src="getofflineinfo"** to include the field information to be sent in the **src** of the script. The following script is used to request the used time from the server (the script is only one example):

```
<script language="javascript">
//Obtain the used time information.
   function requestOfflineInfo() {
   var _timeused =document.getElementById("timeused");
      var script=document.createElement("script");
      script.src="getofflineinfo"+location.search;
    _timeused.appendChild(script);
    }

    function init() {
        requestUserInfo();
    }
</script>
<body onload="init()">
...
</body>
```

The HTML source code of the offline page is as follows:



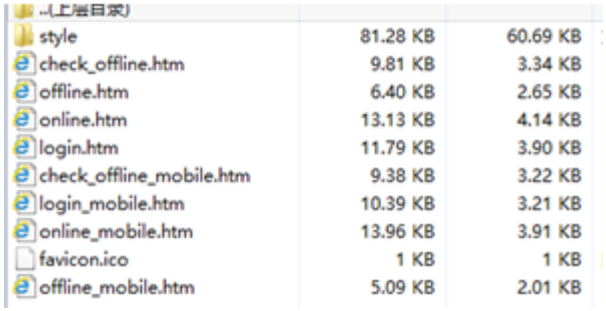
```
<html>
```

```
<head>
<title>Web authentication offline page</title>
</head>
<script language="javascript">
//Obtain the used time information.
   function requestOfflineInfo() {
        var _timeused=document.getElementById("timeused");
        var script=document.createElement("script");
        script.src="getofflineinfo"+location.search;
        _timeused.appendChild(script);
    }

    function init() {
        requestOfflineInfo();
    }
</script>

<body onload="init()">
Logout succeeded<br>
    <table>
    <tr><td>Used time:</td><td id="timeused"></td></tr>
    </table>
</body>
</html>
```

The following figure shows the offline page that the iPortal server pushes to users.



The offline page shows only the mandatory elements. Other functions can be added. For example, you can add a background and set the styles of page elements.

Page Compression Specification

After you prepare the login page, online page, and offline page in accordance with the preceding specification, you need to compress the pages and related elements and upload them to the NAS. Then you can apply the page suite. The page compression specification is as follows:

1 Compress the prepared pages and related element files (such as image files and style sheet files) into a **.zip** package, for example, **portal1_page.zip**.

2 You can create directories in a page suite. For example, the **portal1_page.zip** package shown in the following figure has the **style** directory, which contains the CSS files of pages and other image files.

After you compress the pages into a page suite, use TFTP or other tools to upload the page suite to **/portal/zip/** of the flash memory on the NAS. Then configure the portal server to use the page suite (that is, associate the portal server with the page suite). For details, see the configuration manual related to web-based authentication. A directory named after the page suite package is created in **/portal/ext_zip/** of the flash memory. For example, if the page suite package is named **portal1_page.zip**, **/portal/ext_zip/protal1_page/** of the flash memory is created, and the package is automatically decompressed in the directory. The portal server can push web-based authentication pages to users based on the page suite.

Configuration Example

Customizing a Page Suite

Configuration Steps	● Customize a page suite.
	`Hostname(config.tmplt.iportal)#page-suit hostepage`
Verification	● Check whether the configuration is successful.

	`Hostname#show web-auth template`
	`Webauth Template Settings:`
	`----------`
	`Name: iportal`
	`Page-suit: hostpage`
	`Advertising url: default`
	`Advertising mode: online-popup`
	`Type: Intral Portal`
	`Acctmlist:default`
	`Authmlist:default`

1.4.42 Configuring Upgrade Compatibility

Configuration Effect

- Some configuration commands have been optimized in the software of 11.X, resulting in format changes.
- The software of 10.X can be upgraded smoothly without any loss of functionality. However, after the upgrade, some old commands will be converted into new commands.
- For the software of 11.X, executing the **no** form of old commands will fail. You need to use the new format of commands.

Notes

N/A

Configuration Steps

You are advised to use new formats of commands with format changes.

Verification

- When the software of 10.X is upgraded to 11.X, there is no loss of functionality. Some old commands will be converted into new commands, which are displayed and saved.
- The functions of commands in new formats are the same as those of old commands.

Related Commands

Configuring the IP Address of the Portal Server for First-generation Web-based Authentication

Command	**http redirect** *ip-address*
Parameter Description	*ip-address*: Configures the IP address of the ePortal server for first-generation web-based authentication.
Command Mode	Global configuration mode
Usage Guide	When the device version is upgraded to 11.X, this command is automatically converted into the command format supported by 11.X.

Configuring the URL of the ePortal Server for First-generation Web-based Authentication

Command	**http redirect homepge** *url*
Parameter Description	*url*: Configures the URL of the ePortal server for first-generation web-based authentication.
Command Mode	Global configuration mode
Usage Guide	When the device version is upgraded to 11.X, this command is automatically converted into the command format supported by 11.X.

Configuring the Portal Server

Command	**portal-server** [**eportal1** | **eportalv2**]

Parameter Description	**eportav1**: indicates portal information about first-generation web-based authentication. **eportav2**: indicates portal information about second-generation web-based authentication.
Command Mode	Global configuration mode
Usage Guide	When the device version is upgraded to 11.X, this command is automatically converted into the command format supported by 11.X.

Configuring Interface Control for Web-based Authentication

Command	**web-auth port-control**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	In 11.X, this command is changed to **web-auth enable <type>**. **type** refers to first-generation or second-generation web-based authentication. The value is first-generation web-based authentication by default.

Configuring the Binding Mode as IP-Only

Command	**web-auth port-control ip-only-mode**
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	When the device version is upgraded to 11.X, this command is automatically converted into the command format supported by 11.X.

Configuring Web-based Authentication for VLANs

Command	**web-auth allow-vlan** *list*
Parameter Description	*list*: Configures a VLAN list for web-based authentication.
Command Mode	Global configuration mode
Usage Guide	In 11.X, this command is changed to a command without SCC.

Display the Configuration of First-generation Web-based Authentication

Command	**show http redirect**
Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	In 11.X, the old command is unavailable. It is changed to **show web-auth template**.

Displaying Interface Control Information

Command	**show web-auth port-control**

Parameter Description	N/A
Command Mode	Privileged EXEC mode
Usage Guide	In 11.X, the old command is unavailable. It is changed to **show web-auth control**.

Configuration Example

Configuring First-generation Web-based Authentication

Configuration Steps	● Configure the device to use 10.X and allocate the IP address of the first-generation web-based authentication server. `Hostname(config)# http redirect 192.168.197.64`

Verification	● Upgrade the software version to 11.X.
	● Run the **show running-config** command. Check that the new command format is used.
	`Hostname#sh running-config`
	`web-auth template eportalv1`

1.4.43 Configuring RADIUS Authentication Escape

Configuration Effect

After RADIUS authentication escape is enabled, web-based authentication users can still perform authentication to access the Internet in the case of a RADIUS server failure.

Notes

This function must be used with the RADIUS server detection command.

Configuration Steps

Configuring RADIUS Authentication Escape

Command	**web-auth radius-escape**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

After configuring RADIUS server detection, use an inaccurate username and password to pass authentication in the case of a RADIUS server failure.

Configuration Example

Configuring RADIUS Authentication Escape

Configuration Steps	● Enable RADIUS authentication escape. `Hostname(config)# web-auth radius-escape`
Verification	● Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.44 Configuring Built-in Logo Replacement

Configuration Effect

Configure the built-in logo replacement function, which allows for replacement of the logo on all pages of the built-in portal.

Notes

The logo upload directory is **/data/portal/logo** and the filename must be **free_login_logo.jpg**.

Configuration Steps

Configuring the Built-in Logo Replacement Function

Command	**web customized-logo enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Upload an image and check whether the logo on the built-in portal pages has been replaced.

Configuration Example

Configuring the Logo Replacement Function

Configuration Steps	● Enable the logo replacement function. ● (Optional) You can enable this function only when the logo on the built-in authentication page needs to be replaced. `Hostname(config)# web customized-logo enable`
Verification	● Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.45 Configuring Noise Reduction in Wireless Web-based Authentication

Configuration Effect

When the number of times a STA accesses an IP address reaches the configured threshold, the subsequent packets that the STA sends to the IP address will be dropped, achieving noise reduction.

Notes

Configure the aging time and hit count for noise reduction based on the network situation to avoid dropping of normal packets, which will affect redirection.

Configuration Steps

Configuring Noise Reduction in Wireless Web-based Authentication

Command	**web-auth noise**[**aging** *agmin*] [**hit** *times*]
Parameter Description	*agmin*: Indicates the aging time of noise reduction. The default value is 1 minute. *times*: Indicates the number of times a STA accesses an IP address. If the number of times a STA accesses an IP address reaches the the value specified by this parameter, noise is considered to occur. The default value is 3.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Simulate the scenario where a STA accesses an IP address repeatedly during redirection until the maximum number of access times is reached. Check whether the subsequent packets that the STA sends to the IP address are redirected or not. After the aging time of noise reduction has elapsed, check whether the packets that the STA sends to the IP address are redirected again.

Configuration Example

Configuring Noise Reduction in Wireless Web-based Authentication

Configuration Steps	● Set parameters of noise reduction in wireless web-based authentication. `Hostname(config)#web-auth noise aging 1 hit 3`
Verification	● Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.46 Enabling iOS Automatic Pop-up Window Control in WeChat Web-based Authentication

Configuration Effect

Enable iOS clients to support automatic display of pop-up windows and display Wi-Fi signal reception during WeChat-based authentication (including WeChat follow-up authentication and WeChat-based Wi-Fi connection authentication). iOS clients can use the WeChat app without login when the device is configured to allow WeChat traffic.

Notes

- iOS automatic pop-up window control must be used on the device that is configured to allow WeChat traffic (run the **web-ctrl free-auth weixin** command to enable this function).
- Redirection performance will deteriorate after iOS automatic pop-up window control is enabled.

- iOS automatic pop-up window control will be invalid when the device is configured to allow traffic from Apple Inc. website by running the following commands:
  - web-ctrl free-auth iphone
  - **web-auth acl white-url** http://www.apple.com.cn
- **web-auth acl white-url** http://captive.apple.com

Configuration Steps

Enabling iOS Automatic Pop-up Window Control in WeChat Web-based Authentication

Command	**http redirect adapter ios**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Check that iOS clients show pop-up windows and display Wi-Fi signal reception during WeChat web-based authentication (including WeChat follow-up authentication and WeChat-based Wi-Fi connection authentication). iOS clients can use the WeChat app without login when the device is configured to allow WeChat traffic.

Configuration Example

Enabling iOS Automatic Pop-up Window Control in WeChat Web-based Authentication

Configuration Steps	• Enable iOS automatic pop-up window control. • (Optional) The configuration is valid for the WeChat web-based authentication scenario (configured with the **web-ctrl free-auth weixin** command). `Hostname(config)#http redirect adapter ios`
Verification	• Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.47 Enabling Smart WeChat Web-based Authentication

Configuration Effect

When a STA is associated with an SSID for the second time during WeChat web-based authentication (including WeChat follow-up authentication and WeChat-based Wi-Fi connection authentication), the STA goes online without authentication.

Notes

You need to run the **ip dhcp snooping** command before the smart authentication function takes effect.

Configuration Steps

Enabling the Smart WeChat Web-based Authentication

Command	**web-auth sta-perception enable**

Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Simulate the scenario where a STA is associated with an SSID for the second time during WeChat web-based authentication (including WeChat follow-up authentication and WeChat-based Wi-Fi connection authentication). Check whether the STA goes online without authentication.

Configuration Example

Enabling Smart WeChat Web-based Authentication

Configuration Steps	● Enable smart WeChat web-based authentication. ● The configuration is optional.
	`Hostname(config)#web-auth sta-perception enable`
Verification	● Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.48 Enabling IPFIX Traffic Upload

Configuration Effect

Configure IPFIX traffic upload. If it is enabled, traffic packets are encapsulated using IPFIX and uploaded to the server.

Notes

This function needs to be used with the IPFIX function.

Configuration Steps

Enabling IPFIX Traffic Upload

Command	**web-auth acct-mtehod ipfix**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Users can be successfully authenticated and go online. Traffic will be encapsulated into IPFIX packets and sent to the server.

Configuration Example

Configuring IPFIX Traffic Upload

Configuration Steps	● Enable IPFIX traffic upload. `Hostname(config)# web-auth acct-method ipfix`
Verification	● Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.49 Configuring Transparent Transmission of the 0x05 Attribute of the Portal Protocol

Configuration Effect

Configure transparent transmission of the 0x05 attribute of the portal protocol. After this function is enabled, the web-based authentication server supports transparent transmission of the 0x05 attribute in the following scenarios:

- When the device interworks with a third-party device through the portal protocol of China Mobile, the web-based authentication server encapsulates the error flag into the 0x05 attribute (ErrID) and transparently transmits it to the portal server.
- When the device interworks with a third-party device through Huawei portal protocol 2.0, the web-based authentication server encapsulates information from the third-party authentication device such as the RADIUS server to the 0x05 attribute (TextInfo) and transparently transmits it to the portal server.

Notes

This function is disabled by default.

Configuration Steps

- Optional.
- Configure this function when the ErrID (0x05) attribute specified in the portal protocol of China Mobile is required.
- Configure this function when the TextInfo (0x05) attribute specified in Huawei portal protocol 2.0 is required.

Related Commands

↘ Configuring Transparent Transmission of the 0x05 Attribute of the Portal Protocol

Command	**web-auth portal-attribute 5**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Enable this function on the portal server when a device needs to upload the error flag (ErrID).

Command	**web-auth portal-attribute textinfo**
Parameter Description	N/A
Command Mode	Global configuration mode

Usage Guide	Enable this function on the portal server (using Huawei portal protocol 2.0) when a device needs to upload information (TextInfo) from a third-party authentication device such as the RADIUS server.

Verification

Check that the 0x05 attribute is contained in the ACK packet responded to the portal server.

Configuration Example

Configuring Transparent Transmission of the 0x05 Attribute of the Portal Protocol

Configuration Steps	● Configure transparent transmission of the 0x05 attribute.
	`Hostname(config)# web-auth portal-attribute 5`
	`Or:`
	`Hostname(config)# web-auth portal-attribute textinfo`

Verification	● Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.50 Configuring Uniqueness Check of Portal Authentication Accounts

Configuration Effect

Configure uniqueness check of portal authentication accounts. After this function is enabled, the web-based authentication server checks account information in the user authentication request. If finding that the account has been used by another user and is online, the web-based authentication server directly responds to the portal server with ErrCode 2-contained ACK_AUTH. After receiving such response, some portal servers push information about terminal preemption to users.

Notes

This function is disabled by default.

Configuration Steps

- Optional.
- Configure the function when the portal server needs to push information about terminal preemption to users.

Related Commands

Configuring Uniqueness Check of Portal Authentication Accounts

Command	**web-auth portal-valid unique-name**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Configure the function when the portal server needs to push information about terminal preemption to users.

Verification

When finding that the same account is used by another user and is online, the web-based authentication server with this function enabled directly responds to the portal server with ErrCode 2-contained ACK_AUTH.

Related Commands

Configuring Uniqueness Check of Portal Authentication Accounts

Configuration Steps	● Configure uniqueness check of portal authentication accounts. `Hostname(config)# web-auth portal-valid unique-name`
Verification	● Check whether the configuration is successful. `Hostname(config)#show running-config`

1.4.51 Enabling the One-click Configuration Through WeChat

Configuration Effect

Use one command to configure WeChat template information, port control, iOS window display, and MAB authentication.

Notes

The **no** form of this command can delete template information and controlled ports, but is not globally valid.

Configuration Steps

Enabling the One-click Configuration Through WeChat

- Optional.

Command	**web-auth wechat-template** *template-name* **wlan-range** *wlanid-start wlanid-end* **portal-ip** *portal-ip-address* **nas-ip nas-ip-address** [**nas-id** *nas-id-string*] [**perception** | **ios-adapter**]
Parameter Description	*name*: Indicates the template name. *wlanid-start*: Indicates the start WLAN ID. *wlanid-end*: Indicates the end WLAN ID. *portal-ip-addr*: Indicates the IP address of the portal server. *nas-ip-addr:* Sets the IP address for a device with WeChat configured to access a service, so that the server sends packets to this IP address for communication.*nas-id-string*: Applies to the hot standby or VAC scenario, which is often the serial number of the active AC. It is not required in standalone scenarios. **perception**: Configures MAB authentication. **ios-adapter**: Configures the automatic window display function.
Command Mode	Global configuration mode
Usage Guide	Before performing one-click configuration, you must enter the security configuration mode. Otherwise, the device monitoring and management configuration fails to be performed.

Verification

Run the **show run** command to check whether the configuration is normal.

Configuration Example

Enabling the One-click Configuration Through WeChat

Configuration Steps	● Enable the one-click configuration through WeChat.
	`Hostname(config)# web-auth wechat-template aaa interface tenGigabitEthernet 3/2 portal-ip 172.21.6.78 nas-ip 192.168.197.227`
Verification	● Run the **show running-config** command to check whether the configuration is successful.

1.4.52 Configuring NAS-PORT-ID for an AP

Configuration Effect

The Guangdong branch of China Mobile requires that the **NAS-PORT-ID** parameter be configured for each AP. The **NAS-PORT-ID** parameter is carried in portal and RADIUS packets sent to portal and RADIUS servers.

Notes

The **NAS-PORT-ID** parameter can be configured only for single APs.

Configuration Steps

Configuring NAS-PORT-ID for an AP

- Optional.

Command	**nas-port-id** *string*
Parameter Description	*string*: Indicates the NAS-PORT-ID name allocated to an AP.
Command Mode	AP configuration mode
Usage Guide	This command sets the **NAS-PORT-ID** parameter only for single APs. To cancel the configuration, run the **no nas-port-id** command.

Verification

Run the **show ap-config running** command to check whether the configuration is normal.

Configuration Example

Configuring NAS-PORT-ID for an AP

Configuration Steps	● Configure the **NAS-PORT-ID** parameter.
	`Hostname(config)# ap-config ap740` `Hostname(config-ap)# nas-port-id guangdongyidong`
Verification	● Run the **show ap-config running** command to check whether the configuration is successful.

1.4.53 Enabling the Device to Automatically Add a Domain Name to the Authentication Username

Configuration Effect

If second-generation web-based authentication and iPortal web-based authentication are configured with a domain name in the template, the domain name will be automatically added to the authentication username and sent to the AAA server.

Notes

A domain name contains up to 63 bytes. The domain name is directly added to the username from the portal server. If the new username consisting of the original username and the domain name exceeds 253 bytes, the exceeding part will be truncated.

Configuration Steps

- Optional.
- The portal server does not add the domain name to the authentication username by default. If the domain name is required by the RADIUS server, configure this function.

Verification

Run the **show running-config command** to display the configuration.

Related Commands

↘ Configuring the Device to Add a Domain Name to the Authentication Username

Command	**domain** *domain-string*
Parameter Description	*domain-string:* Indicates the domain name to be added.
Command Mode	Web-based authentication template configuration mode
Usage Guide	The authentication userame from the portal server is **host**. After you configure domain name **@wifi**, the username sent to the RADIUS server is **host@wifi**.

Configuration Example

↘ Configuring the Device to Automatically Add a Domain Name to the Authentication Username

Configuration Steps	● Configure the device to automatically add domain name **@wifi** to the eportalv2 template.
	`Hostname(config.tmplt.eportalv2)#domain @wifi`

Verification	● Check whether the configuration succeeds.
	`Hostname(config)#show run`
	`web-auth template eportalv2`
	` domain @wifi`
	` Hostname(config)#`

1.4.54 Configuring the App Authentication Template

Configuration Effect

After the template is configured, authentication through WeChat, WeChat Work, and DingTalk can be implemented.

Notes

The configuration commands in template configuration mode are the same as those for WeChat authentication.

Configuration Steps

- Optional.
- This configuration can be performed when authentication through WeChat, WeChat Work, and DingTalk is configured.

Verification

- Run the **show run** command to check whether the configuration is normal.
- Perform authentication through WeChat, WeChat Work, and DingTalk, and check whether the authentication is normal.

Related Commands

↘ Configuring the App Authentication Template

Command	**web-auth template** { **app** | *portal-name* **app** }
Parameter Description	Indicates the name of the user-defined portal server.
Command Mode	Global configuration mode
Usage Guide	The app authentication template is **app** by default.

↘ Applying the App Authentication Template

Command	**web-auth portal** { **app** | *name* }
Parameter Description	Indicates the user-defined template name.
Command Mode	Global configuration mode or WLAN security configuration mode
Usage Guide	The app authentication template is **app** by default.

Configuration Example

Configuring App Authentication

Configuration Steps	● Configure app authentication template on the network device. ● Configure the IP address and service URL of the server on the network device. ● Configure the encryption key (**ruijie**) for communication with the server on the network device. ● Configure the IP address of the device on the network device. ● Apply the app authentication template to WLANSEC1 and enable app authentication.
	Hostname#configure Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)#web-auth template app Hostname(config.tmplt.app)#ip 192.168.197.79 Hostname(config.tmplt.app)#service-url wmc.ruijie.com.cn Hostname(config.tmplt.app)#key ruijie Hostname(config.tmplt.app)#nas-ip 1.1.1.1 Hostname(config.tmplt.app)#exit Hostname(config)# wlansec 1 Hostname(config-wlansec)# web-auth portal app Hostname(config-wlansec)# webauth
Verification	● Check whether the web-based authentication configuration is successful.
	Hostname(config)#show running-config web-auth template app ip 192.168.197.79 service-url wmc.ruijie.com.cn http://192.168.197.79:8080/eportal/index.jsp key ruijie nas-ip 1.1.1.1 !... wlansec 1 web-auth portal app webauth !

1.4.55 Configuring ISE Authentication

Configuration Effect

Redirect non-authenticated users to the authentication page for authentication.

Notes

N/A

Configuration Steps

Configuring the Portal Server

- Mandatory. To implement web-based authentication, you must configure and apply a portal server.
- When a device detects that a non-authenticated user attempts to access network resources through HTTP, the device redirects the user's access request to the specified portal authentication page. In this way, the user can initiate an authentication request to the authentication server. The portal server address is configured as a special network resource that does not require authentication. Non-authenticated users can communicate over this address directly through HTTP.

Configuring a Response Mode Used After Successful Authentication

- Optional.
- It is configured as needed.

Configuring the Response Mode Used Upon an Authentication Failure

- Optional.
- It is configured as needed.

Configuring a Mode for the Device to Parse Authentication Requests

- Optional.
- It is configured according to requirements of the interconnected server.

Configuring Whether to Pop Up a Page for Proactive Logout After Successful Authentication

- Optional.
- It is configured as needed.

Configuring the Device's IP Address

- Mandatory. No IP address is configured by default.
- An IP address accessible by users needs to be configured.

Configuring the Device's Port

- Mandatory. No port is configured by default.
- As the port is configured for user access, it must not conflict with the port used by the built-in or web network management system (NMS).

Configuring the URL Used by a STA for Initiating Authentication

- Mandatory. The default URL is **http://***ip***:***port***/login http://ip:port/login**, where *ip* is the device's IP address, and *port* is the device's port.

Enabling Web-based Authentication on a Port

- Mandatory.
- When web-based authentication is enabled on a port, STAs connected to the port will not undergo web-based authentication. Web-based authentication is disabled on a port by default.

Verification

- Non-authenticated users need to be authenticated.
- Authenticated users can use the network normally.

Related Commands

Enabling AAA

Command	**aaa new-model**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	Commands related to the AAA method list can be entered only after the function is enabled.

Configuring the Web-based Authentication Method List on AAA

Command	**aaa authentication cpweb** { **default** | *list-name* } *method1* [*method2*...]
Parameter Description	*list-name*: Indicates the name of a method list. *method1*: Indicates method 1. *method2*: Indicates method 2.
Command Mode	Global configuration mode
Usage Guide	ISE authentication is performed by using the ClearPass authentication method. For details, see ClearPass authentication.

Creating a Template

Command	**web-auth template cpweb**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	ISE authentication is performed by using the ClearPass authentication template. For details, see ClearPass authentication.

Configuring the Server's IP Address

Command	**ip** { *ip-address* }
Parameter Description	Indicates the IP address of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	N/A

Configuring the Server's URL

Command	**url** *url-string*

Parameter Description	Indicates the URL of the authentication page of the portal server.
Command Mode	Web-based authentication template configuration mode
Usage Guide	Log in to the ISE server and click **Portal test URL** on the portal page to obtain the portal page URL in the format similar to https://192.168.197.79:8443/portal/PortalSetup.action?portal=401e25d0-2e02-11e8-ba71-005056872c7f. Replace the question mark (?) in the URL with a pound sign (#). In the **Authentication Success Settings** area, set the URL to that of any valid page to prevent a login success page from being displayed when a STA fails to be authenticated. By default, it is set to **http://www.cisco.com**.

Configuring the Device's IP Address

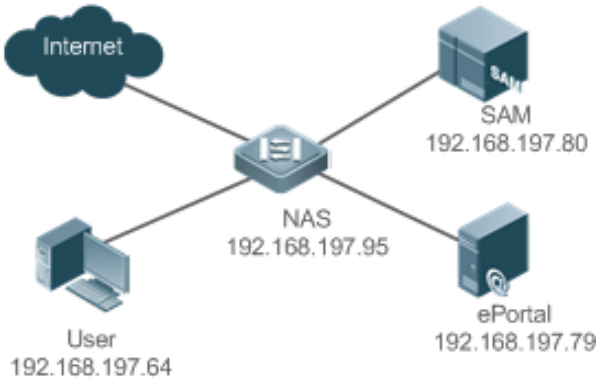
Command	**web-auth auth-server ip** *ip-address*
Parameter Description	*ip-address*: Configure the access service IP address of the device that performs ISE authentication. The server initiates communication to the IP address.
Command Mode	Global configuration mode
Usage Guide	The access service IP address of the NAS cannot be configured as the passthrough address. When the access service IP address is configured as the IP address of the NAS and a STA in the authentication template accesses this IP address, the NAS intercepts the request of the STA and forwards it to the server. As a result, the STA fails to access the web management page of the NAS. If a STA in the authentication template accesses this IP address for device management, configure the access service IP address as the unused virtual service IP address, for example, 1.1.1.1 and 2.2.2.2.

Configuring the Device's Port

Command	**web-auth auth-server** { **http** | **https** } [**port** *port*]
Parameter Description	Configures the TCP port used by a STA for initiating ISE authentication.
Command Mode	Global configuration mode
Usage Guide	This command configures the TCP port used by a STA for initiating ISE authentication. The port cannot conflict with the port used by the built-in or web NMS.

Configuring the URL Used by a STA for Initiating Authentication

Command	**web-auth auth-server submit-url** *url-string*
Parameter Description	Configures the URL used by a STA for initiating ISE authentication.
Command Mode	Global configuration mode
Usage Guide	This command configures the URL used by a STA for initiating authentication, and the URL must start with **http://**.



Enabling Web-based Authentication on an Interface

Command	webauth
Parameter Description	N/A
Command Mode	Interface configuration mode
Usage Guide	N/A

Configuration Example

The following configuration example describes the configuration related to web-based authentication only.

ISE Authentication

Scenario Figure 1-14	
Configuration Steps	● Configure the IP address of the authentication server on the network device. ● Configure the homepage address of the authentication page on the network device. ● Configure the IP address of the network device. ● Configure the port of the network device. ● Configure the URL for STA authentication on the network device. ● Enable web-based authentication for WLAN 10 on the network device.

	`Hostname# config`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#web-auth auth-server http port 8082`
	`Hostname(config)#web-auth auth-server ip 1.1.1.1`
	`Hostname(config)#web-auth auth-server submit-url`
	`http://1.1.1.1:8082/login`
	`Hostname(config)#web-auth template cpweb`
	`Hostname(config.tmplt.cpweb)#ip 192.168.197.79`

	`Hostname(config.tmplt.cpweb)#url`
	`https://192.168.197.79:8443/portal/PortalSetup.action#portal=401e25d0`

Common Errors

The device's IP address is not configured, causing a redirection failure.

1.4.56 Configuring the Role-based Portal Redirection Template

Configuration Effect

The role-based portal redirection template redirects the clients associated with a certain role when they go online.

Notes

N/A

Configuration Steps

Configuring the Portal Redirection Template

- Mandatory. Configure an available portal redirection template before you bind the role to the portal redirection template.
- When the device finds that the client associated with the role with restricted network access attempts to visit network resources through HTTP, it redirects the access request to the specified portal page. The portal server IP address will be set as an authentication-free network resource, which the clients associated with the role with restricted network access can directly access.

Binding the Role with the Portal Redirection Template

- Mandatory.
- The client associated with the role will be redirected upon access only when the role is bound with the portal redirection template,

Verification

- The client associated with the role with restricted network access is redirected upon access.
- The client associated with the role with no restriction can log in normally.

Related commands

Creating the Template

Command	**web-auth template** *template-name* **rdweb**
Parameter Description	N/A
Command Mode	Global configuration mode

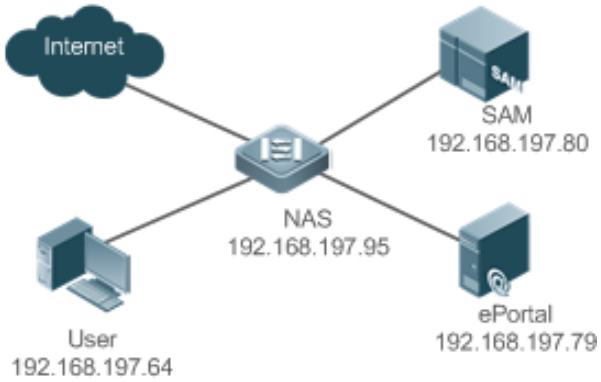
Configuring the Server IP Address

Command	**ip** *ip-address*
Parameter Description	*ip-address*: Indicates the portal server IP address.
Command Mode	Portal template configuration mode
Usage Guide	N/A

Configuring the Server URL



Command	**url** *url-string*
Parameter Description	*url-string*: Indicates the redirect URL of the portal server.
Command Mode	Portal template configuration mode
Usage Guide	N/A

Configuration Example

The following configuration example describes the configuration related to roles only.

Configuring Role-based Portal Redirection Template

Scenario Figure 1-9

Configuration Steps

- Configure the IP address of the redirection server for redirection template **rdweb** on the NAS.
- Configure the URL of the portal page for the redirection template on the NAS.
- Bind role **limit** with redirection template **rdweb**.

```
Hostname# config terminal

Enter configuration commands, one per line.  End with CNTL/Z.

Hostname(config)# web-auth template rdweb

Hostname(config.tmplt.rdweb)# ip 192.168.197.79
```

```
Hostname(config.tmplt.rdweb)# url
http://192.168.197.79:8443/portal/login Hostname(config.tmplt.rdweb)#
exit
```

```
Hostname(config)# user-role limit
```

```
Hostname(config.user-role)# captive-portal rdweb

Hostname(config-if-range)# exit
```

Verification

Run the **show running-config** command to verify the configuration result.

```
Hostname(config)# show running-config

...

web-auth template rdweb

 ip 192.168.197.79

 url http://192.168.197.79:8443/portal/login
```

```
...
user-role limit
 captive-portal rdweb
```

```
Hostname# show web-auth template
Webauth Template Settings:
-------------------------------------------------------------
  Name:          rdweb
  Type:          rdweb
  Ip:            192.168.197.79
  Url:           http://192.168.197.79:8443/portal/login
```

Common Errors

N/A

1.4.57 Configuring the Default Role upon Authentication Success

Configuration Effect

- The client is assigned with the default role after the web authentication succeeds.

Notes

- Create a role before configuring it as the default role.

Configuration Steps

Configuring the Default Role of the Client after the Web Authentication Succeeds

Command	**web-auth default-role** *name*
Parameter Description	*name*: Indicates the role name.
Defaults	No default role is configured by default.
Command Mode	WLAN security configuration mode
Usage Guide	Create a role before configuring it as the default role.

Verification

- Check whether the client is assigned with the default role after the client authentication succeeds.

Configuration Example

Configuring the Default Role

Configuration Steps

- Configure the default role.

```
Hostname(config)# wlansec 1

Hostname(config-wlansec)# web-auth default-role teacher
```

Verification

- Run the following command to verify the configuration result.

```
Hostname(config)# show running-config
```

1.4.58 Configuring Second-Generation Web-based Authentication to Support Direct Access to the Authentication Page

Configuration Effect

When a client accesses the network, the client is allowed to directly access the portal page for authentication, eliminating the need to proactively initiate an HTTP request for redirection.

Notes

- This command applies only to second-generation web-based authentication. After this command is configured, clients are allowed to directly access the authentication page for authentication only in second-generation web-based authentication.
- After this function is enabled in a VAC scenario, if user information of a client associated with a non-active AC is lost when the client accesses the network (for example, run the **clear web-auth user** command to clear user information or user entries time out), the client cannot directly access the authentication page and needs to be redirected to the authentication page by sending a HTTP request.

Configuration Steps

Configuring Second-Generation Web-based Authentication to Support Direct Access to the Authentication Page

Command	**web-auth portal direct-auth**
Parameter Description	N/A
Defaults	Direct access to the authentication page for authentication is not supported by Rijie second-generation web-based authentication.
Command Mode	Global configuration mode
Usage Guide	1. In a VAC scenario, when a client associated with a non-active AC access the network, the client needs to be redirected to the authentication page by sending a HTTP request if user information is deleted due to user entry timeout. Otherwise, the authentication fails. 2. This command takes effect only when second-generation web authentication is used.

Verification

If specified end users do not exist on the AC or fat AP (that is, no specified user is displayed in the output of the **show web-auth user all** command), the user can directly access the authentication page to implement authentication after associating with the network.

Configuration Examples

Configuring Second-Generation Web-based Authentication to Support Direct Access to the Authentication Page

Configuration Steps	Configure second-generation web-based authentication to support direct access to the authentication page for authentication. `Hostname(config)# web-auth portal direct-auth`

Verification	Check whether the configuration is successful.
	`Hostname(config)#show running-config`
	`...`
	`web-auth portal direct-auth`
	`...`
	`!`
	`end`

1.4.59 Importing and Enabling an SSL Certificate

Configuration Effect

- After configuration, the browser will not prompt alarms when the HTTPS protocol is used for redirection in web-based authentication or upon interconnection with the ClearPass server.

Notes

- N/A

Configuration Steps

Importing an SSL Certificate

Command	**web-auth import-ssl** [**auth-server**] { **cert ftp:***path* | **cert tftp:***path* } { **key ftp:***path* | **key tftp:***path* }
Parameter Description	*path*: Indicates the path of the certificate and key.
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Enabling the SSL Certificate

Command	**web-auth ssl-policy** { **https-redirect** | **auth-server** }
Parameter Description	**https - redirect:** Enables the HTTPS redirection certificate. **auth-server:** Enables the ClearPass authentication certificate.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- When a user accesses the HTTPS page for redirection in web-based authentication, the browser does not prompt an alarm. When a user submit the username and password to the ClearPass server to initiate authentication, the browser will not prompt an alarm either.

Configuration Examples

Importing and Enabling an SSL Certificate

Configuration Steps	• Import the certificate key. • Enable the certificate.

	`Hostname# web-auth import-ssl auth-server cert tftp://10.104.8.66/cpwebsrv.pem key tftp://10.104.8.66/cpwebkey.pem`
	
	`Hostname(config)# web-auth ssl-policy auth-server`

Verification	• Check whether the configuration is successful.

	`Hostname(config)#show running-config`
	
	`web-auth ssl-policy auth-server`

1.4.60 Configuring the Lowest TLS Version

Configuration Effect

- After configuration, the lowest TLS version for interaction between the device and STA is TLS 1.2 during web authentication redirection for access to the HTTPS page or when the device is connected to the ClearPass server.

Notes

- N/A

Configuration Steps

- Optional.

- Perform the operation based on user requirements.

Verification

- The lowest TLS version for interaction between the device and STA is TLS 1.2 during web authentication redirection for access to the HTTPS page. When the device is connected to the ClearPass server, the lowest TLS version for interaction between the device and STA is TLS 1.2 after the username and password are submitted to initiate authentication.

Related Commands

Setting the Lowest TLS Version for Interaction Between the Device and STA to TLS 1.2

Command	**web-auth ssl-minimum-version tls1.2**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Configuring the TLS Version for Interaction Between the Device and STA

Configuration Steps

- Set the lowest TLS version for interaction between the device and STA to TLS 1.2.

```
Hostname(config)# web-auth ssl-minimum-version tls1.2
```

Verification

- Check whether the configuration is successful.

```
Hostname(config)#show running-config

web-auth ssl-minimum-version tls1.2
```

1.5 Monitoring

Clearing

Command	Description
clear web-auth user { **all** | **id** *session-id* | **ip** *ip-address* | **mac** *mac-address* | **name** *name-string g* | **id** *id-num* }	Disconnects users.
clear web-auth direct-site	Clears all the authentication-free network resources.
clear web-auth direct-host	Clears all the authentication-free users.
clear web-auth acl [**white-url**]	Clears the web-based authentication blocklist and allowlist configuration.
clear web-auth free-acct ip	Clears all authentication-free IP addresses.

Command	Description
clear web-auth free-acct url	Clears all authentication-free URLs.
clear web-auth direct-arp	Clears all authentication-free ARP resources.
clear web-auth user diag	Clears all user tracks.

Displaying

Command	Description
show web-auth acl	Displays the web-based authentication blocklist and allowlist configuration.
show web-auth parameter	Displays basic parameters of web-based authentication.
show web-auth template	Displays the web-based authentication template configuration.
show web-auth direct-host	Displays the authentication-free host range.
show web-auth direct-site	Displays the authentication-free address range.
show web-auth direct-arp	Displays the authentication-free ARP resource range.
show web-auth rdport	Displays the TCP interception port.
show web-auth control	Displays the web-based authentication configuration on a port.
show web-auth user { **all** | **ip** *ip-address* | *ipv6-address* | **mac** *mac-address* **| name** *name-string* | **by-ap** *ap-name* | **by-ap-group** *ap-group-name* }	Displays online information about all users or specified users.
show web-auth portal-check	Displays the web-based authentication portal check information.
show web-auth noise	Displays the noise reduction configuration of web-based authentication.
show web-auth syslog ip *ip-address*	Displays user login and logout records.
show web-auth authmng [**statistic** | **abnormal**]	Displays authentication experience data.
show web-auth auth-server	Displays basic information about the local HTTP server.
show web-auth user diag { **all** | **ip** *ip-address* | **mac** *mac-address* }	Displays track information of all users or a specified user.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug web-auth all	Debugs web-based authentication.
debug web-auth dump memory	Displays memory usage statistics.
debug web-auth dump msg-rate	Displays the processing rate of redirection and authentication requests.

1 Configuring ROLE-MGMT

1.1 Overview

ROLE-MGMT is a component used for user role management on access controllers (ACs)/access points (APs). It is responsible for creating roles on the device. When a wireless client is connected to the network and is assigned a user role, this component maintains the role entries for the client and binds specific policies to the role.

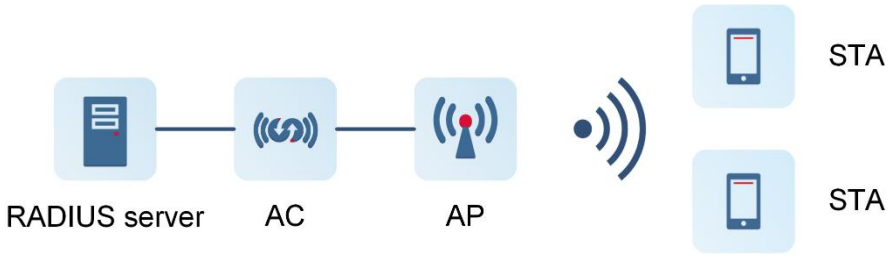
1. Create roles.
2. Assign roles.
3. Bind policies to roles (as described in the *Policy Component Configuration Guide*).

Protocols and Standards

- N/A

1.2 Applications

Application	Description
Role-based Portal Redirection	Controls network access permissions of a client based on its role.
Role-based Key Service Assurance	Configures the key service assurance feature for roles.
Role-based Uplink DSCP Priority Policy Control	Configures DSCP marking for uplink packets from clients under a specific role upon reaching the AP.
Role-based ACL Policies	Configures ACL-based packet filtering for roles.
Role-based Preferred Network Access Policies	Configures role-based QoS policy for wireless applications under a role.
Role-based QoS Policy Control for Wireless Application Recognition	Configures role-based QoS policy for wireless applications under a role.
Role-based VLAN Redirection	Configures role-based VLAN redirection. On a wireless network, different clients access the network and are assigned different roles after successful authentication. If a client access the network after being authenticated through 802.1X authentication (the account and password are correct), the server delivers role information and specifies a VLAN for redirection based on the VLAN information configured in the role.



1.2.1 Role-based Portal Redirection

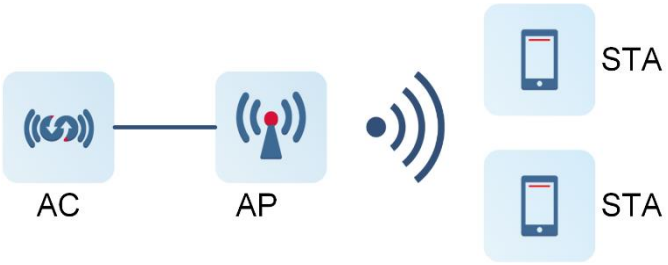
Scenario

On a wireless network, different clients access the network and are assigned different roles after successful authentication. If the role assigned to a client has restricted network access, the client will be redirected to a specified page based on the

configured portal redirection. For example, if a wireless client access the network after being authenticated through 802.1X authentication (the account and password are correct), but the number of accounts exceeds the limit, the client will be prohibited from accessing the Internet. HTTP service requests are redirected to a specified page, and a prompt will be displayed on the page.

The typical topology is as follows:

Deployment



- Configure a portal redirection template (including the URL address and IP address).
- Create a role on the AC for portal redirection. Bind the portal redirection template to the role.
- When a client is connected to the wireless network after being authenticated, the server assign a role to the client (the role name is the name of the role that has been configured with the portal redirection template on the device).

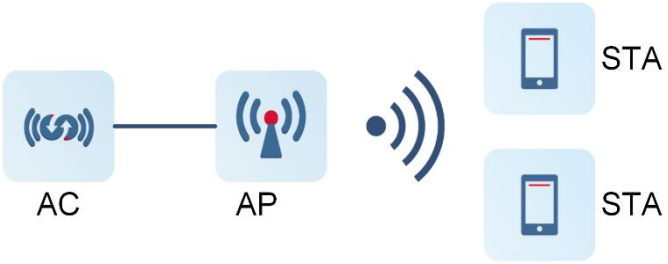
1.2.2 Role-based Key Service Assurance

Scenario

On a wireless network, multiple users may simultaneously contend for air interface resources, causing air interface congestion. The dynamic rate limiting feature can be enabled to restrict client traffic. When a role is configured with key service assurance, users under this role will be guaranteed with higher bandwidth.

The typical topology is as follows:

Deployment



- Enable the Wireless Quality of Service (WQoS) dynamic rate limiting feature.
- Configure role-based key service assurance for a user role.
- Key users will be guaranteed with higher bandwidth when the wireless air interface is congested.

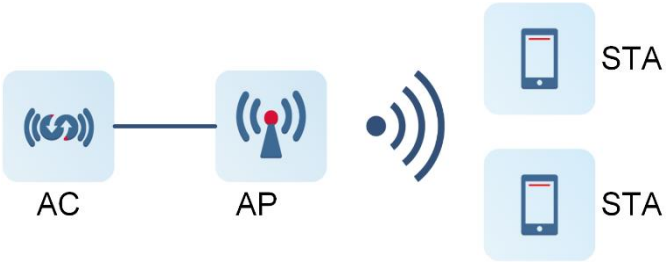
1.2.3 Role-based Uplink DSCP Priority Policy Control

Scenario

A client's uplink traffic reaches an AP through the Wireless Local Area Network (WLAN) and is subsequently forwarded through the wired network. The client's uplink traffic is tagged with a specific DSCP mark when passing through the AP over the WLAN and can be scheduled based on the DSCP priority queue at the core layer of the wired network, thereby ensuring the uplink wired network experience of key users and restricting unnecessary uplink wired forwarding of non-key users.

The typical topology is as follows:

Deployment



- Configure role-based DSCP priority policy control for a role.
- Configure DSCP marking for uplink packets from clients under this role upon reaching the AP.

1.2.4 Role-based ACL Policies

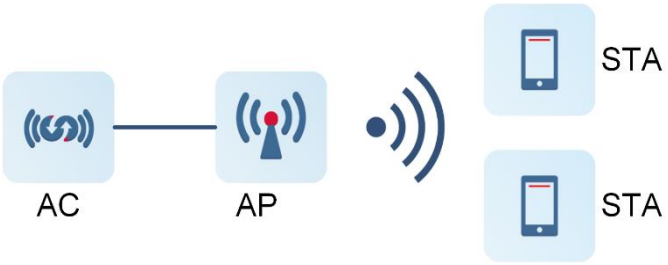
Scenario

After a client is connected to the network, if the ACL policy has been applied to the associated user role, the client's packets will be filtered and will be either permitted or discarded. Client network access control can be achieved through the ACL policy, such as allowing access only to specified services (for example, allowing access only to WWW and email services while prohibiting others like Telnet), allowing access only within a specified period, or only allowing specific clients to access the Internet.

The typical topology is as follows:

Deployment

- Configure an ACL policy used for filtering packets.



- Apply the created ACL policy to a role.
- When a client is connected to the wireless network and obtains the role's ACL policy, the client is only allowed to access network resources permitted by the ACL.

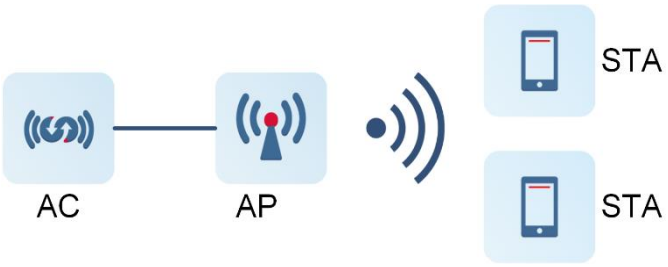
1.2.5 Role-based Preferred Network Access Policies

Scenario

When a client is connected to the network, if the number of online clients connected to the Radio, AP, WLAN, or AC reaches any of the configured thresholds, the client is allowed to access the network successfully only if the role associated with the client is configured with the preferred network access policy. At the same time, since the number of connected clients has reached the upper limit, the system will force the first user to go offline in order of MAC addresses among non-VIP-FIRST users with poor communication quality or role users not configured with the high-priority access policy.

The typical topology is as follows:

Deployment



- Configure the role-based preferred network access policy for a role.
- When a user with high-priority network access permissions connects to the Radio, AP, WLAN, or AC under which the number of connected clients has reached the upper limit, the client will be allowed to successfully access the network, and the system will force a user to go offline among non-VIP-FIRST users with poor communication quality or role users not configured with the high-priority network access policy.

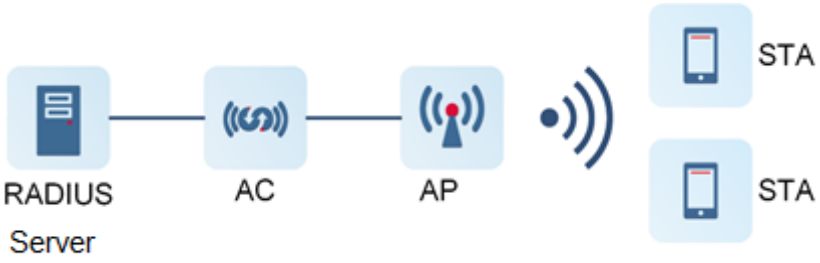
1.2.6 Role-based QoS Policy Control for Wireless Application Recognition

Scenario

The application recognition component on the AC can identify applications based on the characteristics of data flows. For different applications of role users, you can set the downlink DSCP value. When packets reach the AP, the WMM function on the AP converts the DSCP value of the packets to the corresponding 802.11e priority, and then schedules the packets based on the priority to implement priority control for different applications. You can configure the device to discard packets of specific applications of a role to block the traffic of unauthorized applications of the role. You can set different rate limits for different applications of a role user. For example, you can limit the rate of download applications to prevent them from occupying excessive bandwidth.

The typical topology is as follows:

Deployment



- Configure QoS policy control for wireless applications of the role.
- Perform downlink DSCP priority control, application traffic blocking, and application rate limiting for specified applications on STAs of this role.

1.2.7 Role-based VLAN Redirection

Scenario

On a wireless network, different clients access the network and are assigned different roles after successful authentication. If a client access the network after being authenticated through 802.1X authentication (the account and password are correct), the server delivers role information and specifies a VLAN for redirection based on the VLAN information configured in the role.

The typical topology is as follows:

Deployment

- Create a role on the AC and bind the VLAN to be redirected to the role.
- When a client passes 802.1X authentication and accesses the wireless network, the server assigns a role to the client (the role name is the name of the role configured on the AC).

1.3 Features

Basic Concepts

↘ **User Role**

- Create a user role on the device. The client permission is controlled based on different roles. Up to 256 roles can be created.

Overview

Feature	Description
Role Management	Creates a role on the device and binds a policy to the role.

1.3.1 Role Management

Create a role on the device and maintain role entries for the clients under the role.

Working Principle

The administrator creates a role on the AC and binds a policy (such as a portal template) to the role. When a client accesses the wireless network and is assigned a role, the client will be controlled by the policy bound to the role when accessing the network.

Related Configuration

Configuring a User Role

Use the **user-role** *name* command to create a role.

Use the **captive-portal** { *portal-name* } command to bind a portal template to the role.

Use the **critical-business guarantee enable** command to configure key service assurance for the role.

Use the **user-upstream-dscp** *dscp-value* command to configure an uplink DSCP priority policy for the role.

Use the **access-group** { *acl-id* | *acl-name* } [**priority** *value*] command to configure a role-based ACL policy.

Use the **user-priority-assoc high** command to configure a preferred access policy for the role.

Use the **vlan-id vlan-id** command to configure role-based VLAN redirection.

1.4 Configuration

Configuration	Description and Command	
Role Management	(Mandatory) It is used to create a role.	
	user-role	Creates a role.
	captive-portal	Binds a portal template.
	critical-business guarantee enable	Enables key service assurance.
	user-upstream-dscp	Configures an uplink DSCP priority policy for a role.
	access-group	Configures a role-based ACL policy.
	user-priority-assoc high	Configures a role-based preferred access policy.
	app-profile	Configures a role-based QoS policy profile for wireless application recognition.

	vlan-id	Configures role-based redirection to a specified VLAN.

1.4.1 Role Management

Configuration Effect

- A role should be created first before it is assigned to the client connected to the wireless network.

Precautions

- The assigned role name must have been created on the device.

Configuration Steps

↘ Creating a User Role

- Mandatory.

Command	**user-role** *name*
Parameter Description	*name*: Indicates the name of a role.
Defaults	No custom role exists.
Command Mode	Global configuration mode
Usage Guide	A role needs to be created on the AC before the authentication server assigns the role information.

↘ Binding a Portal Template to a Role

- Mandatory.

Command	**captive-portal** { *portal-name* }
Parameter Description	*portal-name*: Indicates the name of a portal template.
Defaults	No template is bound.
Command Mode	User role configuration mode
Usage Guide	A portal template needs to be created before binding.

↘ Configuring Key Service Assurance

- Mandatory.

Command	**critical-business guarantee**
Parameter Description	N/A
Defaults	Key service assurance is disabled.

Command Mode	User role configuration mode
Usage Guide	1. Before key service assurance is configured, the WQoS dynamic rate limiting feature needs to be enabled. 2. After key service assurance is configured for a role, users associated with this role will be guaranteed with higher bandwidth.

Configuring an Uplink DSCP Priority Policy for a Role

- Mandatory.

Command	**user-upstream-dscp** *dscp-value*
Parameter Description	*dscp-value*: Configures an uplink DSCP value for a role.
Defaults	No uplink DSCP value is configured.
Command Mode	User role configuration mode
Usage Guide	After an uplink DSCP policy is configured for a user role, the uplink packets of the clients associated with this role will be tagged with a specific DSCP value upon reaching the AP. Services of key users are guaranteed through the DSCP policy.

Configuring a Role-based ACL Policy

- Mandatory.

Command	**access-group** { *acl-id* | *acl-name* } [**priority** *value*]
Parameter Description	*acl-id*: Indicate the ID of an ACL. *acl-name*: Indicate the name of an ACL. *value*: Indicates the priority of an ACL. The value range is from 1 to 16. **1** indicates the highest priority, whereas **16** indicates the lowest priority. This parameter is optional. The default value is 16.
Defaults	No ACL is configured.
Command Mode	User role configuration mode
Usage Guide	1. Up to 16 different ACL policies can be configured for a single role. The priority of an ACL can be specified through the **priority** parameter. The **priority** value only specifies the order of ACLs and will not be saved as configuration. 2. Packets are filtered in descending order of the ACL policy priorities. The device stops matching the packets against ACL rules when the packets match one rule. 3. When any ACL rule is applied, it will end with a rule against which all packets will be discarded. If a packet does not match any rules in the ACL, the packet will be discarded.

Configuring a Role-based User Preferred Access Policy

- Mandatory.

Command	**user-priority-assoc high**

Parameter Description	N/A
Defaults	No high-priority network access policy is configured.
Command Mode	User role configuration mode
Usage Guide	1. The high-priority network access permissions of role users have the same priority as the network access permissions of VIP users configured with VIP-FIRST. 2. Since the user role can only be obtained after a client is authenticated, up to 500 clients can be connected to the AC when the number of associated clients has reached the upper limit. If a new user is not configured with high-priority network access permissions and is not a VIP user, the new client will fail to access the network when the number of online clients has reached the upper limit.

Configuring Role-based QoS Policy Control for Wireless Application Recognition

- Mandatory.

Command	**app-profile** *profile-name*
Parameter Description	*profile-name*: Configures the name of the application recognition policy associated with a role.
Defaults	No application recognition policy is associated.
Command Mode	User role configuration mode
Usage Guide	1. After a user role is associated with a wireless application recognition policy, the packets of clients associated with the role will be assigned to the application group of the associated policy and subject to the application group policy. 2. A role and a WLAN are associated with different wireless application recognition policies. If both the role and WLAN match the two policies, the application recognition policy associated with the role is preferentially used. 3. Before associating an application recognition policy with a role, create the application recognition policy.

Configuring Role-based VALN Redirection

- Optional. After a client is authenticated by the server and role information is delivered, the client will be redirected to the VLAN specified based on the role.
- Configure this function after 802.1X authentication is enabled.

Command	**vlan-id** *vlan-id*
Parameter Description	*vlan-id*: Indicates the ID of the VLAN to be redirected for the role.
Defaults	Role-based VLAN redirection is not configured.
Command Mode	Role configuration mode

Usage Guide	1. After this function is configured, if a client passes 802.1X authentication, the server assigns a role to the client and searches for the VLAN ID bound to the role. This VLAN ID must be configured in the VLAN group associated with the WLAN. Otherwise, redirection cannot be performed. 2. The priority of the VLAN bound to the role is lower than that of the VLAN delivered through the RADIUS attribute. 3. After VLAN redirection is enabled for the role in the Change of Authorization (CoA) message, the network is unreachable because the IP address of the client cannot be changed.

Verification

- Run the **show running-config** command to display the configuration.

Configuration Examples

Binding a Portal Template to a User Role

Configuration Steps	Use this command to configure a portal redirection template.
	Hostname(config)#web-auth template rdweb Hostname(config.tmplt.rdweb)#ip 10.10.10.10 Hostname(config.tmplt.rdweb)#url http://10.10.10.10/warning Use this command to create a user role and configure the portal redirection template for the role. Hostname(config)#user-role limit Hostname(config.user-role)#captive-portal rdweb

Configuring Key Service Assurance for a User Role

Configuration Steps	Use this command to enable the dynamic rate limiting feature.
	Hostname(config)#ap-config all Hostname (config-ap)#smart-rate-control enable Use this command to create a user role and configure key service assurance for the role. Hostname(config)#user-role teacher Hostname(config.user-role)#critical-business guarantee

Configuring an Uplink DSCP Priority Policy for a User Role

Configuration Steps	Use this command to create a user role and set the uplink DSCP priority of this role to 56. Hostname(config)#user-role teacher Hostname(config.user-role)#user-upstream-dscp 56

Configuring a Role-based ACL Policy for a User Role

Configuration Steps	Use this command to configure an ACL.

	Hostname(config)#ip access-list standard 1 Hostname (config-std-nacl)#permit host 1.1.1.1 Hostname(config-std-nacl)#exit Hostname(config)#ip access-list standard 2 Hostname (config-std-nacl)#permit host 1.1.1.1 Use this command to create a user role and apply the ACL to the role. Hostname(config)#user-role test Hostname(config.user-role)#access-group 1 Hostname(config.user-role)#access-group 2 priority 1 Use this command to display the configured ACL. Hostname(config.user-role)#show this Building configuration... ! access-group 2 access-group 1 ! end

Configuring a Preferred Access Policy for a User Role

Configuration Steps	Use this command to create a user role and configure a high-priority access policy for the role. Hostname(config)#user-role teacher Hostname(config.user-role)#user-priority-assoc high

Configuring Role-based QoS Policy Control for Wireless Application Recognition

Configuration Steps	Set the **teacher** role to associate with the **P-Tencent** application recognition policy. Hostname(config)#user-role teacher Hostname(config.user-role)#app-profile P-Tencent

Configuring Role-based VLAN Redirection

Configuration Steps	Create a user role and configure the VLAN ID to be redirected based on the role.
	Hostname(config)#user-role teacher Hostname(config.user-role)# vlan-id 2

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show user-role	Displays the role information of a client.
show access-group [**role** *role-name*]	Displays the ACL policy information of a role.
show role priority-assoc	Displays high-priority access permissions of a role.

Debugging

System resources are occupied when debugging information is output. Therefore, disable the debugging immediately after use.

Command	Description
debug role-mgmt event	Enables event debugging.
debug role-mgmt error	Enables serious error debugging.

1 Configuring SCC

1.1 Overview

The Security Control Center (SCC) provides common configuration methods and policy integration for various access control and network security services. This allows the access control and network security services to be transmitted on one device, meeting diversified access and security control requirements in various scenarios.

Typical access control services include 802.1X authentication, web-based authentication, Address Resolution Protocol (ARP) check, and IP source guard (IPSG). Network security services include Access Control List (ACL), Network Foundation Protection Policy (NFPP), ARP anti-spoofing, and others. When two or more preceding access control or network security services are simultaneously enabled on a device, the SCC coordinates these services based on policies.

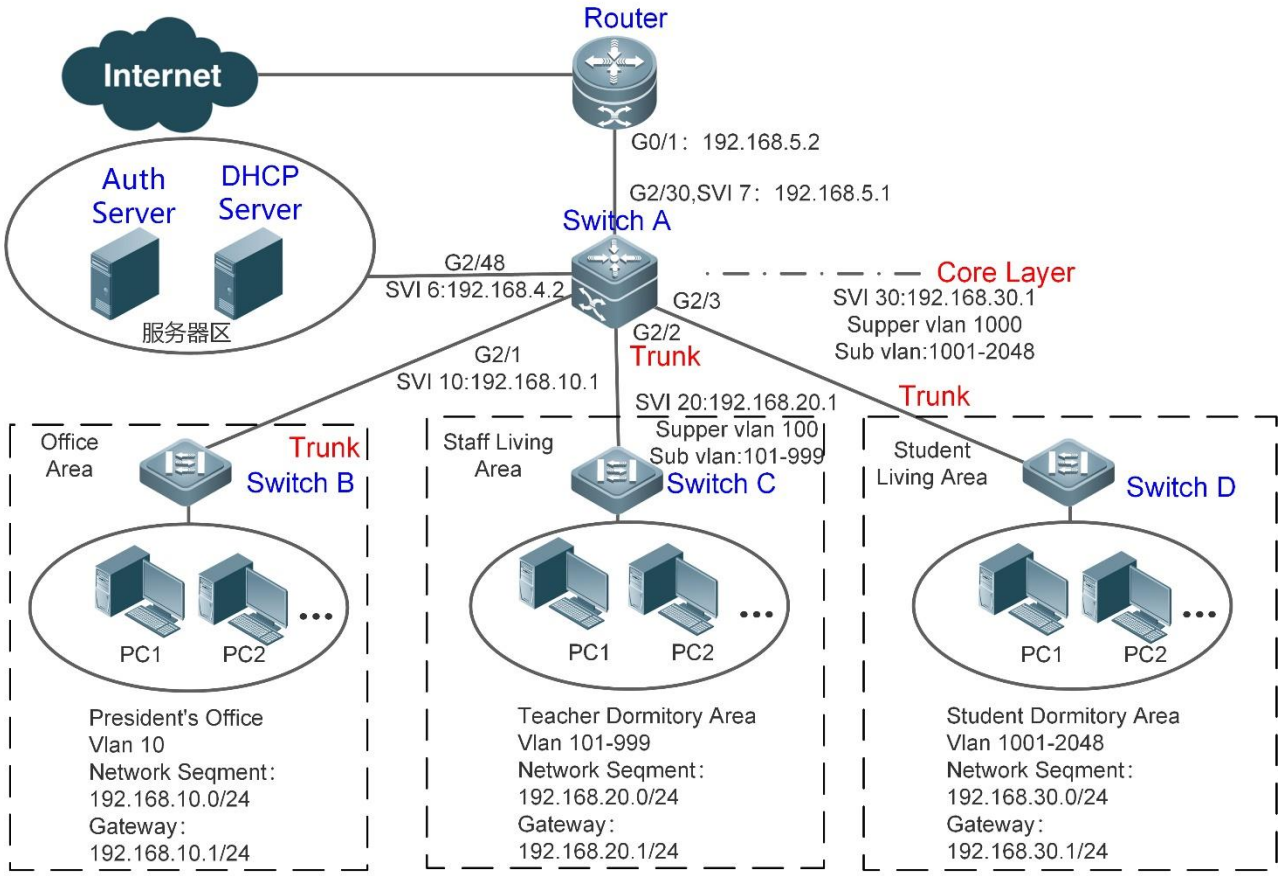
For details about the access control and network security services, see the related configuration guide. This document describes the SCC only.

Protocol and Standards

N/A

1.2 Application

Application	Scenario
Access Control of Extended Layer 2 Campus Networks	Students on a campus network can access the Internet through 802.1X client authentication or web-based authentication. ARP spoofing between the students needs to be prevented. In addition, clients of some departments (such as the principal's office) can access the Internet without authentication.



1.2.1 Access Control of Extended Layer 2 Campus Networks

Scenario

Students on a campus network usually need to pass 802.1X or web-based authentication before accessing the Internet to facilitate accounting and guarantee security of a university.

- The students can access the Internet through 802.1X client authentication or web-based authentication.
- ARP spoofing between the students needs to be prevented to guarantee network stability.
- Clients of some departments (such as the principal's office) can access the Internet without authentication.

Figure 1-1

Notes	A traditional campus network is hierarchically designed with the access layer, aggregation layer, and core layer, in which the access layer performs user access control. On an extended Layer 2 campus network, however, user access control is performed by a core switch that is directly connected to access switches without any aggregation device deployed. The ports between the core switch and access switches (switches B, C, and D in Figure 1-1) are all trunk ports. Switches B, C, and D connect to PCs of various departments through access ports, and VLANs correspond to sub-VLANs configured on the downlink ports of the core switch. Therefore, access users are located in different VLANs to prevent ARP spoofing. Core switch A connects to various servers, such as the authentication server and DHCP server. Super-VLANs and sub-VLANs are configured on the downlink ports. One super-VLAN is associated with multiple sub-VLANs, and each sub-VLAN represents an access user.

Deployment

- On the core switch, different access users are identified by VLAN and port numbers. Each access user is (or a group of access users are) allocated to one VLAN. Ports on each access switch that connect to downlink users are configured as access ports, and one VLAN is assigned to each access user based on VLAN planning. The core switch does not forward ARP request packets and replies to ARP request packets from authenticated users only to prevent ARP spoofing. On core switch A, user VLANs are configured as sub-VLANs, super-VLANs are configured, and Switched Virtual Interfaces (SVIs) corresponding to the super-VLANs are configured as user gateways.

- On downlink ports of the core switch (switch A in this example) that connect to access switches of the teachers' living area and students' living area, both 802.1X and web-based authentication are enabled. Users can freely select either authentication mode for Internet access.
- A special department (the principal's office in this example) can be allocated to a particular VLAN that is configured as an authentication-free VLAN, so users of this department can access the Internet without authentication.

1.3 Basic Concepts

IPv4 User Capacity

To ensure network stability for online users and stable operation of devices, you can limit the number of IPv4 access users.

The number of IPv4 access users is not limited by default. A large number of authenticated users are allowed to go online until the number of online users reaches the maximum value allowed by the hardware.

IPv4 access users include 802.1X authentication users (such as authorized IP users), web-based authentication users, and users with manually configured IP addresses (including IP source guard and ARP check).

User Online Status Detection

For user accounting, accounting starts immediately after the user passes authentication and goes online. The accounting process does not end until the user actively goes offline. Some users, however, forget to get offline after stopping Internet access, or cannot go offline because of client problems. Then the users suffer economic losses as the accounting process continues. To more precisely determine whether a user is online, we can preset a traffic value. When the user's traffic is lower than the preset value or no traffic is detected in a given period of time, the device considers that the user is not accessing the Internet and therefore disconnects the user.

Overview

Feature	Description
IPv4 User Capacity	Limit IPv4 user capacity on a specified interface to ensure network stability for online users.
User Online Status Detection	Specify whether to detect traffic of online users and automatically disconnect a user when the user traffic is lower than a preset value in a given period of time.
User Policy Rules	Parse the name of a control policy to obtain corresponding policy rules that will take effect after the rules are enforced.

1.3.1 IPv4 User Capacity

To ensure stable operation of the device and prevent brute-force attacks by unauthorized users, limit the total number of IPv4 access users on a specific interface.

Working Principle

If the number of IPv4 access users is limited, new users exceeding the limit are not allowed to access the network.

By default, the device does not limit the number of IPv4 access users, and the number of access users depends on the hardware capacity of the device.

The IPv4 access users in this context include IPv4 authorized users generated by 802.1X authentication, web-based authentication, and various binding functions. The limit on IPv4 access users is configured on a per-interface basis, so the limit involves both IPv4 users generated on the interface and globally generated IPv4 users. For example, if the maximum number of IPv4 access users is configured as 2 on Gi 0/1, and a command is used to bind one IPv4 user and then one global IPv4 user on the interface, the actual number of access users on this interface has reached the maximum value of 2. In this case, binding another IPv4 user on this interface or another global IPv4 user will fail.

1.3.2 User Online Status Detection

After stopping Internet access, a user may forget to go offline or cannot actively get offline due to client faults. In this case, the user will keep being charged and therefore suffer economic loss. To protect benefits of users on the Internet, the device detects whether the users are online. If the device considers that a user is not online, the device will proactively disconnect the user.

Working Principle

A specific detection interval is preset on a device. If a user's traffic is lower than a certain value in this interval, the device considers that the user is not accessing the network and therefore directly disconnects the user.

- User online status detection applies only to users that go online through 802.1X or web-based authentication.

1.3.3 User Policy Rules

After a user is successfully authenticated, a server may assign control policy names to the user. The SCC needs to parse these control policy names to obtain corresponding policy rules that will take effect after they are installed.

Working Principle

Configure a policy name on a device and configure a specific rate limit policy and filtering policy for the policy name. After a user passes authentication and the policy name is associated with the user, the corresponding rate limit policy and filtering policy will take effect.

You can also apply a filtering policy to a user group to control the user group based on the policy.

- One filtering policy can be associated with only one ACL.
- The filtering policy that is referenced by a user group cannot be modified or deleted.
- A policy can be configured only for users that go online through 802.1X or web-based authentication.

1.4 Configuration

Configuration	Description and Command	
Configuring the IPv4 User Capacity	(Optional) It is used to limit the number of access users on a specific interface.	
	[**no**] **nac-author-user maximum**	Configures the maximum number of IPv4 users that can connect to an interface.
Configuring User Online Status Detection	(Optional) It is used to specify whether to enable user online status detection.	
	offline-detect interval threshold	Configures parameters of user online status detection.
	no offline-detect	Disables user online status detection.
	default offline-detect	Restores the default user online status detection mode.
Configuring User Policy Rules	(Optional) It is used to specify a user policy rule.	
	[**no**] **rate-policy**	Enters the rate limit policy configuration mode.
	upstream average-rate burst-rate	Configures the average value and burst value for uplink traffic.
	no upstream	Deletes the uplink traffic limit configuration.
	downstream average-rate burst-rate	Configures the average value and burst value for downlink traffic.
	no downstream	Deletes the downlink traffic limit configuration.
	[**no**] **filter-policy**	Enters the filtering policy configuration mode.
	filter_acl	Configures a security ACL associated with a filtering policy.
	no filter_acl	Deletes a security ACL associated with a filtering policy.
	[**no**] **service-policy**	Enters the user policy configuration mode.
	rate-policy apply	Configures a rate limit policy to be used.
	no rate-policy	Deletes a rate limit policy in use.
	filter-policy apply	Configures a filtering policy to be used.
	no filter-policy	Deletes a filtering policy in use.

1.4.1 Configuring the IPv4 User Capacity

Configuration Effect

The maximum number of access users that can connect to an interface can be limited by configuring the IPv4 user capacity.

Notes

N/A

Configuration Steps

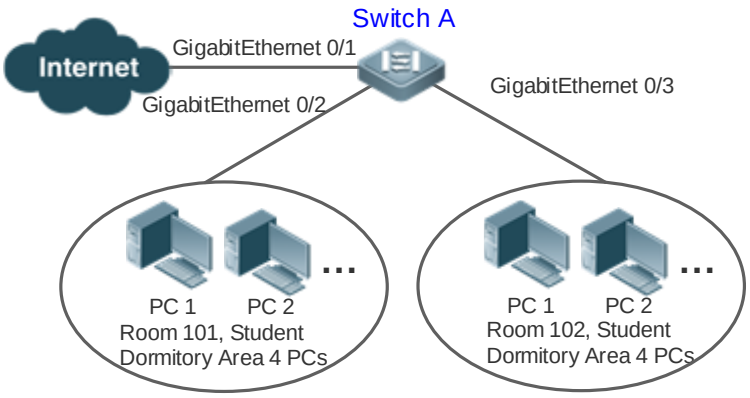
Configuring the IPv4 User Capacity

- (Optional) To limit the maximum number of access users that can connect to an interface, you must configure the IPv4 user capacity. The maximum number of access users that can connect to an interface is not limited by default. If the maximum number of access users is configured and the number of authenticated users reaches the limit on an interface, new users cannot be authenticated or go online until a user logs off.
- It is configured on the access device.

Command	**nac-author-user maximum** *max-user-num* **no nac-author-user maximum**
Parameter Description	**no**: Indicates that the IPv4 user capacity limit is canceled on an interface. *max-user-num*: Indicates the maximum number of IPv4 users on a specified interface. The value range is from 1 to 1,024.
Defaults	The maximum number of access users that can connect to an interface is not limited by default.
Command Mode	Interface configuration mode
Usage Guide	You can use this command to limit the number of IPv4 access users on a specified interface.

Verification

You can use the following methods to verify the configuration of the IPv4 user capacity on an interface:



- In 802.1X authentication mode, configure the maximum number of 802.1X authentication clients on an interface. Check whether a new user can be authenticated and go online successfully.
- In web-based authentication mode, configure the maximum number of web-based authentication clients on an interface. Check whether a new user can be authenticated and go online successfully.
- Run the **show nac-author-user** [**interface** *interface-name*] command to check the IPv4 user capacity configuration on the device.

Command	**show nac-author-user** [**interface** *interface-name*]
Parameter Description	*interface-name*: Indicates the interface name.
Command Mode	Privileged EXEC mode, global configuration mode, and interface configuration mode
Usage Guide	Global configuration mode

Configuration Example

The following configuration example describes SCC-related configuration only.

Limiting the Number of IPv4 Users on an Interface to Prevent Excessive Network Traffic Caused by Many Internet Devices

Scenario **Figure 1-2**	
Configuration Steps	● Assume that the 802.1X authentication environment on switch A has been configured. Enable 802.1X authentication on GigabitEthernet 0/2. ● Set the maximum number of IPv4 users on GigabitEthernet 0/2 to 4.
Switch A	`SwitchA(config)#int GigabitEthernet 0/2` `SwitchA(config-if-GigabitEthernet 0/2)#nac-author-user maximum 4`
Verification	● Authenticate and connect four PCs in the dormitory using 802.1X authentication. Then try to connect an additional terminal to the network and attempt to perform 802.1X authentication to check whether the terminal can be successfully authenticated. ● Run the **show nac-author-user** command to check whether the configuration takes effect.

Switch A	`SwitchA(config)#show nac-author-user`
	`Port Cur_num Max_num`
	`-------- ------- -------`
	`Gi0/1 0 4`

1.4.2 Configuring User Online Status Detection

Configuration Effect

After user online status detection is configured, if a user's traffic falls below the threshold within a given period of time, the device will automatically disconnect the user to prevent unnecessary economic loss due to continuous accounting.

Precautions

Typically, a user's client runs software such as 360 Total Security by default. The software sends packets sometime. Therefore, if you configure user logout when no traffic is detected, the user will be disconnected only when the user's client is powered off.

Configuration Method

↘ Configuring User Online Status Detection

- Optional. By default, a user will be disconnected if the user's client does not generate traffic for 8 hours.

- You can configure user online status detection on an access, aggregation, or core device based on the user distribution. This configuration takes effect only on the configured device but not other devices on the same network.

If **thredshold** is set to **0**, zero-traffic detection is performed.

Command	**offline-detect interval** *interval* **threshold** *threshold* **no offline-detect** **default offline-detect**
Parameter Description	*interval*: Indicates the offline status detection interval, in minutes. The value range is from 1 to 65,535. The default value is 8 hours, that is, 480 minutes. *threshold*: Indicates the traffic threshold, in bytes. The value range is from 0 to 4,294,967,294. The default value is 0, indicating that a user is disconnected when no traffic of the user is detected. **no offline-detect**: Disables user online status detection. **default offline-detect**: Restores the default value. That is, an online user will be disconnected if no traffic of the user is detected for 8 hours.
Defaults	8 hours
Command Mode	Global configuration mode
Usage Guide	Use this command to configure user online status detection. That is, an online user will be disconnected when its traffic is lower than a specified threshold within a specified period of time. Use the **no offline-detect** command to disable user online status detection, or use the **default offline-detect** command to restore the default detection mode.

Verification

You can use the following method to check the configuration effect of authenticated user online status detection:

- When user online status detection is configured and a user goes online on a client, power off the authenticated client. Wait for a while, and run the online user query command associated with 802.1X or web-based authentication on the device to confirm that the user is already offline.

Configuration Examples

The following configuration example describes SCC-related configuration only.

Configuring User Online Status Detection to Disconnect a User That Does Not Generate Traffic Within 5 Minutes

Scenario **Figure 1-3**	
Configuration Steps	● Enable 802.1X authentication on Gi 0/2 and configure authentication parameters. MAC address authentication is used. ● Configure user online status detection and specify that a user needs to be disconnected if the user's client does not generate traffic within 5 minutes.
Switch A	`sw1(config)# offline-detect interval 5 threshold 0`
Verification	● Perform 802.1X authentication through an SU client on a PC of the R&D department. The user gets online on the PC. Then power off the PC. Wait for 6 minutes, and run the online user query command corresponding to 802.1X authentication on switch 1 to confirm that the user on the PC is already offline.
Switch A	`sw1(config)#show running-config | include offline-detect` `offline-detect interval 5`

1.4.3 Configuring User Policy Rules

Configuration Effect

When a policy name is applied to an authenticated user, rate limiting can be performed on the user based on the configured policy rule.

Notes

An authentication server is required to assign corresponding policy attributes.

A filtering policy can be associated only with one security ACL.

Configuration Steps

↘ **Configuring User Policy Rules**

- Optional.
- Configure the rate limit policy and filtering policy first. Then specify the name of the rate limit policy in a user policy rule.

The burst limit values for uplink and downlink traffic must be larger than or equal to the average rate limits.

Command	**rate-policy** *name* { **downstream** | **upstream** } **average-rate** *avg-threshold* **burst-rate** *burst-threshold*
Parameter Description	*name*: Indicates the name of a rate limit policy. *avg-threshold*: Indicates an average rate limit, in kbps. The value ranges from 8 to 261,120. *burst-threshold*: Indicates a burst limit, in kbps. The value ranges from 8 to 261,120. The burst limit must be larger than or equal to the average rate limit.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	A rate limit policy rule must be configured first.

Command	**filter-policy** *name* **filter-acl** { *acl-name* | *acl-id* }
Parameter Description	*name*: Indicates the name of a filtering policy. *acl-name*: Indicates the name of a security ACL associated with a filtering policy. *acl-id*: Indicates the ID of a security ACL associated with a filtering policy.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	A filtering policy rule must be configured first.

Command	**service-policy** *service-name* **rate-policy** *rate-name* **apply** **filter-policy** *filter-name* **apply**
Parameter Description	*service-name*: Indicates the name of a user policy. *rate-name*: Indicates the name of a rate limit policy to be used. *filter-name*: Indicates the name of a filtering policy to be used.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	The rate limit policy rule and filtering policy rule can be used in a user policy rule only after they are configured.

Verification

You can check the configuration effect of a policy rule as follows:

- After a rate limit policy rule is configured and a user goes online after authentication, check the rate limit policy entry corresponding to Wireless Quality of Service (WQoS).

- After a filtering policy rule is configured and a user goes online after authentication, check the ACL entry applied to the user corresponding to an ACL key (ACLK).
- Run the **show running** command to display the user policy configuration.

Configuration Example

Specifying a Rate Limit Policy for an Authenticated User Through a User Policy Rule

Configuration Steps	• Enable web-based authentication on WLAN 1 and configure a user policy name on a server. • Configure a user policy rule and associate it with a specified rate limit policy.

Switch A	`AC(config)# rate-policy user-rate`
	`AC(config-rate-policy)#upstream average-rate 10 burst-rate 10`
	`AC(config-rate-policy)#downstream average-rate 10 burst-rate 10`
	`AC(config)# ip access-list extended user_2000`
	`AC(config)# filter-policy user-filter`
	`AC(config-filter-policy)#filter-acl user_2000`
	`AC(config)# service-policy user-policy`
	`AC(config-service-policy)# rate-policy user-rate apply`
	`AC(config-service-policy)# filter-policy user-filter apply`

Verification	• After a user passes authentication, display uplink and downlink rates of the user.

1.5 Monitoring

Clearing

Command	Description
clear scc event diag [**ap-mac** *mac-address*]	Clears the AP event trajectory information recorded by the SCC.

Displaying

Command	Description
show nac-author-user [**interface** *interface-name*]	Displays information about IPv4 user entries on a specified interface.

Debugging

⚠ Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug scc event	Debugs the SCC running process.
debug scc user [**mac** | **author** | **mac**]	Debugs SCC user entries.

debug scc acl-show summary	Debugs the ACL summary of all services stored in the SCC.
debug scc acl-show all	Debugs all ACLs stored in the SCC.
debug scc event diag [**ap-mac** *mac-address*] [**type** *type-id*]	Displays event tracks stored in the SCC.
debug scc dump msg-rate [**type** *type-id*]	Displays the rate of messages received by the SCC.
debug scc jemalloc	Displays SCC memory statistics.

Configuring the Number of Logs or Messages to Be Recorded

Command	Description
scc event diag { **log-num** *log-num-count* | **msg-num** *msg-num-count* }	Configures the maximum number of logs and messages that can be recorded by the SSC.

1 Configuring GSN

1.1 Overview

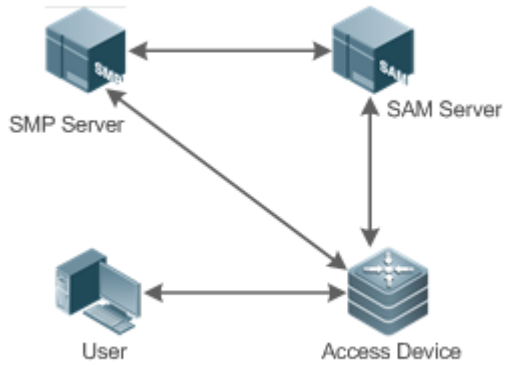
Global Security Network (GSN) is a security policy platform that provides security policy management such as access control and network security. The GSN platform involves the security switch and server. The RG Security Policy Management Platform (RG-SMP) server acts as the security policy server for GSN.

GSN accepts policies assigned by the SMP server, enforces the policies on devices, and determines whether to allow specific data packets to pass through the security device. The security policies are as follows:

- Binding: Binds the IP address and MAC address of an authenticated user on a device.
- Isolation or blocking: Allows or prevents specific data by configuring an Access Control List (ACL).

GSN is used with the SMP server, 802.1X authentication, and web-based authentication.

1.2 Applications



Application	Description
GSN Security Protection for Authenticated Users	After a user passes 802.1X authentication, the SMP server assigns security policies (such as ARP guard and device integrity) to maintain the user's network security.

1.2.1 GSN Security Protection for Authenticated Users

Scenario

After a user passes 802.1X authentication, the SMP server learns the IP-MAC binding of this user from the Security Account Manager (SAM) server and then assigns security policies to the access device.

Figure 19-1

Remarks	Process description: 1. The user passes 802.1X authentication. 2. The SAM server reports user information to the SMP server.

	3. After successful authentication, the access device determines whether to adopt the address binding policy for the user based on the configuration. 4. The user exchanges packets with the SMP server in real time, and the access device converts the packet format and forwards the packets. 5. The SMP server assigns security policies to the access device based on information reported by the user. 6. The SMP server periodically or manually synchronizes policies with the access device. If the SMP server finds that the policies maintained on itself are different from those on the access switch, it deletes all policies on the access device, and then installs all its policies onto the access device. 7. During steps 3, 5, and 6, the access device synchronizes and installs the policies based on policies of GSN.

Deployment

- Enable 802.1X authentication on the access device and deploy the SAM server.
- Deploy the SMP server and add the access device to receive security policies assigned.
- Enable GSN and address binding on the access device.

1.3 Features

Basic Concepts

Ruijie Security Solution

Ruijie security solution is composed of the following entities:

- RG-SMP platform
- RG Security Agent
- RG Restore System
- RG security switch

RG-SMP Platform

Based on the configured policies, the RG-SMP platform determines whether to allow data packets specified in a certain range to pass through the RG security switch. To install policies is to configure policies on a device, and to uninstall policies is to remove policies from a device.

RG Security Agent

RG Security Agent is a type of software running on each device connected to an enterprise network. It collects device information, identifies users' network behaviors, monitors network communication and security status of the devices, and sends collected information to the RG-SMP platform so that the administrator can make security policies accordingly. RG Security Agent automatically downloads new security policies from the RG-SMP platform and enforces specified security policies locally.

RG Restore System

RG Restore System handles abnormal behaviors as follows:

For the users that do not meet requirements of enterprise security policies, the administrator presets policies on the RG-SMP platform to shield most network access permissions of the non-authorized users and retain only one security channel. The security

channel can only connect to enterprise security policy upgrade servers, including the Windows patch upgrade server, antivirus upgrade library server for antivirus software, or other upgrade servers.

When detecting that security policies of a device do not meet the security levels defined by the RG-SMP platform, RG Security Agent immediately uploads its security logs to the RG-SMP platform. The RG-SMP platform selects one policy from the preset policy set based on the alarm logs sent by RG Security Agent, and sends this policy to all RG security switches. After accepting the latest policy configuration, RG security switches immediately apply the configuration so that the user reporting the alarm can access only the specified upgrade server based on restoration operations specified by the SMP server and automatically install patches.

When the user completes all restoration operations specified by the SMP server, RG Security Agent checks security of the RG-SMP platform again. If the user meets requirements of all security policy sets, RG Security Agent notifies the RG-SMP platform to cancel the access limitation on this user and configure the user as a common user.

RG Security Switch

As a component of Ruijie security solution, the RG security switch receives policies from the RG-SMP platform, installs policies, and controls users based on the installed policies.

1.4 Configuration

Configuration	Description and Command	
Configuring GSN Basic Functions	(Mandatory) It is used to enable GSN on an access device and communication with the SMP server.	
	security gsn enable	Globally enables GSN. GSN is disabled by default.
	security { [**v1** | **v2c**] **community** *community* | **v3 user** *username* }	Configures the name of the security authentication mechanism used for communication with the SMP server.
	smp-server host *ip-address*	Configures the IP address of the SMP server.
	(Optional) It is used to configure the minimum interval for transmitting security events.	
	security event interval *interval*	Configures the minimum interval for transmitting security events. The value range is from 1 to 65,535 seconds. The default value is 5 seconds.
Enabling WLAN-based Address Binding	(Optional) It is used to enable address binding on a WLAN.	
	gsn address-bind	Enables WLAN-based address binding. This policy is disabled by default.

1.4.1 Configuring GSN Basic Functions

Configuration Effect

- Globally enable GSN on devices.
- Enable devices to communicate with the SMP server.

Notes

- You can configure SNMPv1, SNMPv2, or SNMPv3 as the name of the security authentication mechanism for communication with the SMP server.
- **security v1 community** and **security community** are both used to configure SNMPv1 to facilitate user configuration. If SNMPv3 is selected, you must configure SNMPv3 users under the **snmp-server** command. For details about configuration commands, see *Configuring SNMP*.
- The number of entries supported by GSN cannot be exceeded.

Configuration Steps

Globally Enabling GSN

- Mandatory.
- Unless otherwise specified, enable GSN on each device that requires the security solution.

Enabling Communication with the SMP Server

- Mandatory.
- Unless otherwise specified, enable this function on each device that requires the security solution to communicate with the SMP server.

Configuring the IP Address of the SMP Server

- Mandatory.
- Unless otherwise specified, configure the IP address of the SMP server on each device that requires the security solution to communicate with the SMP server.

Configuring the Minimum Interval for Transmitting Security Events

- To prevent unauthorized users from frequently sending security events to attack the RG security switch and the SMP server by sending bogus security events, you can configure the minimum interval for transmitting security events to restrict users from reporting security events.
- To change the default minimum interval for transmitting security events, run the **security event interval** *interval* command. The default interval is 5 seconds.

Related Commands

Globally Enabling GSN

Command	**security gsn enable**
Parameter Description	N/A
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling Communication with the SMP Server

Command	**security** { [**v1** | **v2c**] **community** *community* | **v3 user** *username* }

Parameter Description	**community** *community*: Specifies the name of the security authentication mechanism for communication with the SMP server. **user** *username*: Indicates the name of an SNMPv3 user.
Command Mode	Global configuration mode
Usage Guide	**security v1 community** and **security community** are both used to configure SNMPv1 to facilitate user configuration. If SNMPv3 is selected, you must configure SNMPv3 users under the **snmp-server** command. For details about configuration commands, see *Configuring SNMP*.

Configuring the IP Address of the SMP Server

Command	**smp-server host** *ip-address*
Parameter Description	*ip-address*: Specifies the IP address of the SMP server.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Minimum Interval for Transmitting Security Events

Command	**security event interval** *interval*
Parameter Description	**interval** *interval*: Specifies the minimum interval for transmitting security events, in seconds. The value ranges from 1 to 65,535. The default value is 5s.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuration Example

Enabling GSN and Communication with the SMP Server

Configuration Steps	● Globally enable GSN on the device. ● Configure the name of the security authentication mechanism for devices to communicate with the SMP server. ● Configure the IP address of the SMP server.

	`Hostname# configure terminal`
	`Hostname(config)# security gsn enable`
	`Hostname(config)# security v1 community test-name`
	`Hostname(config)# smp-server host 192.168.30.9`
	`Hostname(config)# exit`

Verification	Run the following **show** commands: ● Run the **show smp-server** command to display the IP address of the SMP server. ● Run the **show security event interval** command to display the minimum interval for transmitting security events.
	`Hostname# show smp-server`

	SMP-Server IP:192.168.30.9 Hostname# show security event interval Event sending interval(Seconds):5

Common Errors

- Routes to the SMP server are unreachable.

1.4.2 Enabling WLAN-based Address Binding

Configuration Effect

- Enable address binding on a WLAN.

Notes

This function takes effect only when GSN is globally enabled and the WLAN security mode is set to Wi-Fi Protected Access (WPA) or WPA2.

You need to disable 802.1X-based IP address authorization before enabling GSN. GSN and 802.1X-based IP address authorization cannot be enabled simultaneously. Otherwise, security policies will be affected.

Configuration Steps

Enabling WLAN-based Address Binding

- To enable address binding based on a WLAN, run the **gsn address-bind** command.

Related Commands

Enabling WLAN-based Address Binding

Command	**gsn address-bind**
Parameter Description	N/A
Command Mode	WLAN security configuration mode
Usage Guide	N/A

Configuration Example

Enabling WLAN-based Address Binding

Configuration Steps	● Create a WLAN. ● Enter the WLAN security configuration mode. ● Enable WLAN-based address binding.
	Hostname# configure terminal Hostname(config)# wlansec 100 Hostname(config-wlansec)# gsn address-bind Hostname(config)# exit

1.5 Monitoring

Displaying

Command	Description
show smp-server	Displays the IP address of the SMP server.
show security event interval	Displays the minimum interval for transmitting security events.

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug gsn { **all** | **error** | **event** | **packet** | **server** | **detail** }	Debugs GSN.

Configuring WLAN QoS

1. Configuring WLAN QoS
2. Configuring WMM
3. Configuring Web App

1 Configuring WLAN QoS

1.1 Overview

Wireless LAN Quality of Service (WLAN QoS), also known as WQoS, is a technology for controlling wireless bandwidth. It includes rate limiting, fair scheduling, and Intranet proxy prevention.

Rate limiting is employed to limit traffic of access points (APs), WLAN, or stations (STAs), thus preventing the traffic from exceeding a specified range. It is useful in scenarios where some STAs consume excessive bandwidth, leaving others with inadequate resources.

Fair scheduling, which evenly allocates time resources, addresses issues where some nodes monopolize air interfaces for extended periods, especially low-rate nodes. This mechanism is beneficial for optimizing all types of wireless networks.

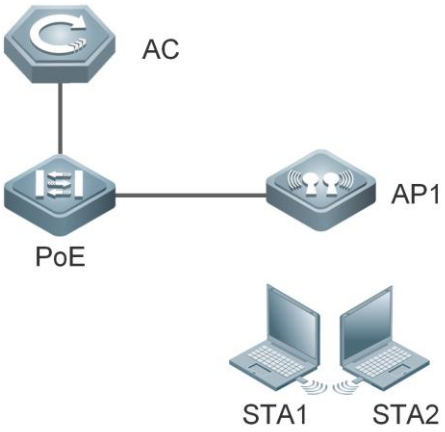
In some cases, an authorized STA connected to a wireless network may be utilized as a proxy server by unauthorized STAs, allowing them to connect without proper authorization. Intranet proxy prevention is designed to counter this behavior, ensuring that unauthorized proxy servers are excluded from the intranet environment. This feature is crucial in scenarios where unauthorized access through proxy servers needs to be mitigated.

Protocols and Standards

- IEEE 802.11e-2005: Amendment 8: Medium Access Control (MAC) Quality of Service Enhancements, IEEE Computer Society
- Wi-Fi: WMM Specification version 1.1

1.2 Applications

Application	Description
Bandwidth Control in a Fit AP Architecture	A Fit AP architecture is deployed with at least one access controller (AC) and one AP.



1.2.1 Bandwidth Control in a Fit AP Architecture

Scenario

On a wireless network, an AC is deployed to implement rate limiting on APs, WLANs, and STAs, and fair scheduling and intranet proxy prevention on APs.

As shown in Figure 1-1, the AC implements rate limiting on the AP, WLAN, and STAs, and fair scheduling and intranet proxy prevention on the AP.

Figure 1-1

Remarks	AC: wireless access controller PoE: gateway (switch)for AP1

Deployment

- Enable WQoS on the AC.

1.3 Features

Basic Concepts

Rate Limiting

In order to optimize the utilization of limited network resources and efficiently cater to a larger user base, the access device must support rate limiting. When traffic rates comply with the committed rates, packets are allowed to pass through; otherwise, they are discarded.

Traffic is evaluated based on the following parameters:

- Average data rate: It is the average flow rate that is allowed, also known as the committed information rate (CIR).
- Burst data rate: It is the maximum acceptable rate of each burst data, referred to as the committed burst size (CBS). The configured CBS must be greater than the maximum packet length, which equates to the highest data transmission rate within a 10-millisecond interval. The CBS, measured in kbps, is calculated as the maximum traffic within a period divided by 10 milliseconds.

Bypassing Rate Limiting for the Downlink Packets with the Differentiated Services Code Point (DSCP) Value in the Specified Range

To bypass rate limiting on the downlink traffic of key applications, you can mark the downlink packets of key applications with the specified DSCP value using an application-based QoS policy, thereby prioritizing forwarding of critical application traffic.

Fair Scheduling

Fair scheduling ensures that STAs within the same AP's frequency band equitably share wireless network resources provided by the AP. This function effectively prevents low-speed STAs from compromising the overall throughput of the wireless network, resulting in a smoother network experience for all connected STAs. Additionally, the fair scheduling feature intelligently monitors traffic changes for each STA and dynamically adjusts the proportion of wireless bandwidth

allocated to maintain optimal performance. Starting from software version 10.4(1T19)p1 and later, you can configure different priorities for STAs in fair scheduling, allowing specific users to enjoy preferential access to the wireless bandwidth.

Intranet Proxy Prevention

Software versions later than 10.4(1T19)p1 incorporate a mechanism specifically designed to detect STAs acting as proxy servers for other STAs within a wireless intranet. This enables accurate monitoring of the number of such STAs and their associated network traffic.

Dynamic Rate Limiting

Dynamic rate limiting is achieved based on the channel utilization, ensuring that the channel utilization remains within a proper range.

Overview

Feature	Description
Rate Limiting	Limit the rates of an AP, a WLAN, or a STA to ensure that the rate does not exceed the limit.
Bypassing Rate Limiting for the Downlink Packets with the DSCP Value in the Specified Range	Enables the downlink packets with the DSCP value in the specified range to bypass STA rate limiting.
Fair Scheduling	Allow STAs associated with an AP in the same frequency band to share wireless network resources provided by the AP, thus equitably sharing the bandwidth of the wireless network.
Intranet Proxy Prevention	Detect the STA that is used as the proxy server for other STAs on a wireless intranet, achieving accurate monitoring of the STA quantity and network traffic.
Dynamic Rate Limiting	Dynamically adjust STA rate limit based on channel utilization.
Uplink Congestion Control	When the delay of key services reaches the threshold and the packet transmission duration of heavy-traffic TCP background services in the uplink reaches the threshold, dynamic adjustment is performed to reduce the volume of the uplink data sent by STAs, ensuring user experience of key services.

1.3.1 Rate Limiting

Rate limiting is used to limit the rates of an AP, a WLAN, or a STA to ensure that the rate does not exceed the limit.

Working Principle

Rate limiting is enforced using a token bucket mechanism, which operates as follows:

- The token bucket maintains a record of the allowable number of bytes that can pass within a specific time period.
- During each interval, the permitted number of data bytes is determined based on the configured CIR and CBS, thereby adjusting the token bucket's capacity.
- Upon the arrival of a packet at the device, its byte count is compared against the token bucket size. If the packet size is smaller than the token bucket capacity, the packet is permitted to pass, and the token bucket size is

reduced. If the packet size exceeds the token bucket capacity, it can be handled in two ways: traffic shaping or traffic policing. Traffic shaping buffers the packet and continues transmission once the token bucket issues a permit notification. Conversely, traffic policing directly discards the packet. The traffic shaping algorithm ensures smoother and less volatile traffic, while the traffic policing algorithm leads to more variable traffic patterns.

- On an AP, traffic shaping is used to implement rate limiting for the AP, a STA, or a WLAN. On an AC, traffic monitoring is used to implement rate limiting for a WLAN.

1.3.2 Bypassing Rate Limiting for the Downlink Packets with the DSCP Value in the Specified Range

This function enables the downlink traffic with the DSCP value in the specified range to bypass STA rate limiting when the traffic exceeds the threshold.

Working Principle

The locally or centrally forwarded packets are marked with the specified DSCP value through the DSCP-based QoS policy on the AP. The downlink packets can also be marked with the DSCP value on the wired devices. If the DSCP value of the downlink packets is within the specified DSCP range, these downlink packets will bypass STA rate limiting.

1.3.3 Fair Scheduling

Fair scheduling, which evenly allocates time resources, addresses issues where some nodes monopolize air interfaces for extended periods, especially low-rate nodes.

Working Principle

Due to the unique characteristics of wireless networks, STAs (including APs) within the same network share air interface resources, which can become a bottleneck for STA performance. This stands as one of the key distinctions between wired and wireless networks. Traditional packet scheduling typically follows a first in, first out (FIFO) approach. On a wireless network, each STA seeking to transmit data strives to seize air interface resources whenever possible. Transmission of numerous low-rate packets can lead to prolonged occupation of the air interfaces. Consequently, persistent queue occupancy results in packet loss and degrades overall network performance.

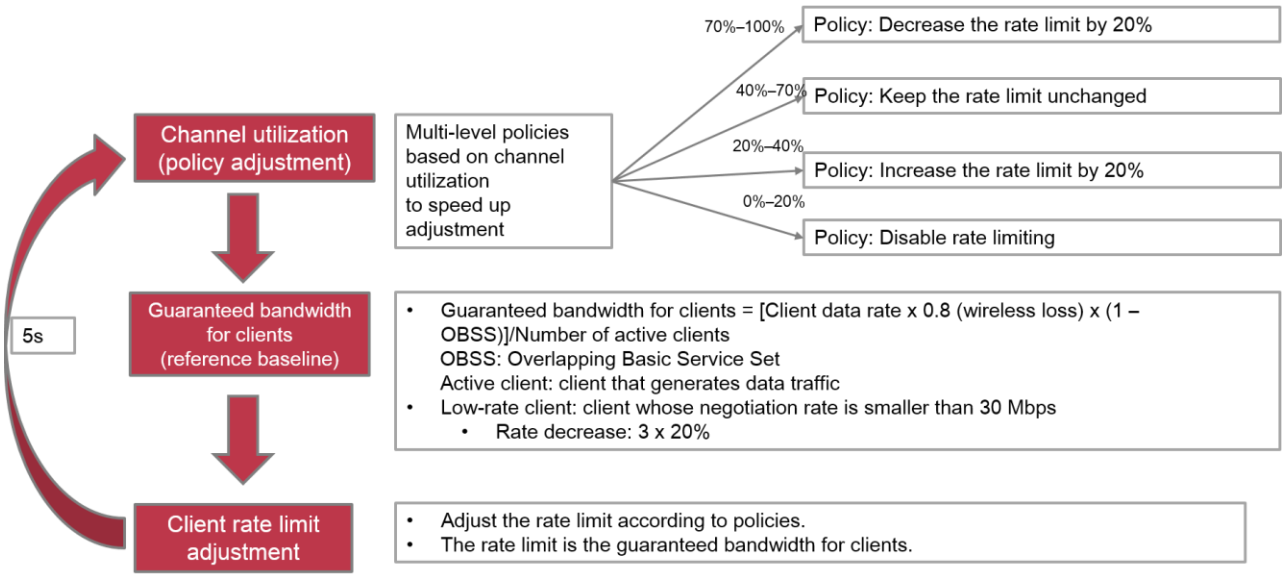
In real-world wireless scenarios, STAs often vary in type and performance. As a result, some STAs consistently struggle to obtain resources and experience significantly delayed responses. Even worse, these STAs may fail to access the network altogether, severely impacting user experience.

Addressing these issues necessitates ensuring that every STA can fairly obtain resources on the air interfaces. This means that each STA requiring data transmission should be able to occupy the air interfaces for a fair duration. Achieving fair scheduling of wireless links involves several steps: predicting the traffic of each STA based on STA-specific information (such as negotiated rates and aggregation types), converting the traffic into the number of packets that can be transmitted by each STA, adjusting the allowed packet count to allocate bandwidth to each STA over the air interfaces, and implementing traffic shaping. Through fair scheduling, each STA occupies the air interfaces for an equitable duration, effectively averting poor performance of certain STAs and thereby enhancing user experience.

1.3.4 Intranet Proxy Prevention

When an authorized STA that is connected to a wireless network, it can be used as a proxy server by other STAs, which may allow unauthorized STAs to connect to the network without permission. To address this issue, intranet proxy prevention measures can be implemented.

Working Principle



Internet proxy prevention is mainly used to determine whether a packet from a STA meets requirements of a proxy server. If not, the STA is contained. The AP supports the TTL detection policy: Detects whether the TTL in an IP packet sent by a STA to the AP is within the proper range. If the TTL is out of the range, the STA is used as a proxy server.

1.3.5 Dynamic Rate Limiting

Dynamic rate limiting, as compared to traditional rate limiting, only requires the configuration of a switch, with no need for specifying bandwidth limits for individual STAs. In a multi-STA scenario, traditional rate limiting struggles to limit rates when they are high, while air interface resources remain underutilized during idle times when rates are low. Dynamic rate limiting, on the other hand, enables stricter rate limiting to be applied to STAs when multiple users preempt air interfaces and loose rate limiting to be applied to STAs when the air interfaces are less busy. This ensures that air interface resources are appropriately allocated while maintaining a positive network experience for users.

Working Principle

Figure 1-2

The AP adopts a dynamic rate limiting policy based on channel utilization, which includes four levels:

- 70%–100%: The rate limit is decreased by 20%.
- 40%–70%: The rate limit stays unchanged.
- 20%–40%: The rate limit is increased by 20%.
- 0%–20%: Rate limiting is disabled.

The channel and client information is collected periodically to determine the guaranteed bandwidth for each client, as well as identify low-speed clients. The rate limit values are adjusted using the rate limiting algorithm.

After you specify the key clients for dynamic rate limiting, they are allocated with higher guaranteed bandwidth.

After you enable application guarantee for dynamic rate limiting, the critical application group is allocated with higher guaranteed bandwidth. When the air interface is congested, the rate of the suppression application group is limited first.

1.3.6 Uplink Congestion Control

After AP uplink congestion control is enabled, if the delay of key services reaches the threshold and the packet transmission duration of heavy-traffic TCP background services in the uplink reaches the threshold within a unit time (1s), the receiver window (RWND) in the TCP ACK packets will be dynamically adjusted. This process takes about 5s to 10s. After the adjustment is completed, the volume of the uplink data sent by STA is reduced to ensure user experience of key services.

Working Principle

The channel utilization (CU) is used to determine whether a channel is congested. It is used to measure the transmit (Tx/downlink) CU and receive (Rx/uplink) CU values of a local AP, as well as the CU values (uplink and downlink) of co-channel neighboring APs. If a CU value exceeds the threshold, it is considered that congestion is caused by greedy traffic.

Uplink congestion control is implemented based on the TCP backpressure technology. When an AP detects that uplink congestion is caused by greedy services, the AP sends a TCP ACK packet to the STA and reduces the RWND. The STA determines the volume of data to be transmitted based on the congestion window (CWND), buffer, and RWND.

1.4 Configuration

Configuration	Description and Command	
Configuring Rate Limiting	⚠ (Mandatory) It is used to enable rate limiting.	
	ap-based	Configures AP-based rate limiting on an AC.
	netuser	Configures STA-based rate limiting on an AC.
	wlan-based	Configures WLAN-based rate limiting on an AC.
Enabling the Downlink Packets with the Specified DSCP Value in the Specified Range to Bypass STA Rate Limiting	⚠ (Optional) Enables the downlink packets with the specified DSCP value in the specified range to bypass STA rate limiting.	
	wqos skip-rate-limit dscp	Configures the DSCP range of downlink packets which bypass STA rate limiting.
Configuring Fair Scheduling	⚠ (Mandatory) It is used to enable fair scheduling.	
	fair-schedule	Enables fair scheduling.
	⚠ (Optional) It is used to adjust the STA priority during fair scheduling.	
	sta-fair	Configures the fair scheduling priority of a STA.
Configuring Intranet Proxy	⚠ (Mandatory) It is used to configure an intranet proxy prevention policy and enable	

Configuration	Description and Command	
Prevention	intranet proxy prevention detection.	
	illegal-sta-check ip ttl	Enables intranet proxy prevention with the TTL detection policy.
Configuring Dynamic Rate Limiting	(Optional) It is used to configure dynamic rate limiting.	
	smart-rate-control enable	Configures dynamic rate limiting.
	smart-rate-control config low-rate-sta	Configures the associated rate threshold for low-speed STAs.
	smart-rate-control config rate-limit-step	Configures the rate limiting factor.
	smart-rate-control config sampling	Configures timer parameters.
	smart-rate-control config threshold channel-using	Configures channel utilization thresholds.
	smart-rate-control config threshold link-rate-divisor	Configuring the STA association rate factor.
	smart-rate-control config threshold rate-guard	Configures the threshold for guaranteed bandwidth.
	smart-rate-control config threshold rate-limit	Configures the rate limiting scope.
	smart-rate-control config wlan-loss	Configures wireless loss.
	smart-rate-control config user mac	Configures the MAC address of the key client for dynamic rate limiting.
	smart-rate-control config user weight	Configures the guaranteed bandwidth weights of the key clients and of the ordinary clients respectively.
	smart-rate-control config application guarantee	Configures application guarantee for dynamic rate limiting.
	smart-rate-control config application weight	Configures the guaranteed bandwidth weights of the critical application group, of the ordinary application group, and of the suppression application group respectively.
Configuring Uplink Congestion Control	(Optional) It is used to configure uplink congestion control.	
	congestion-control tcp enable	Enables uplink congestion control.
	congestion-control tcp threshold cu [up | down]	Configures the channel utilization threshold for uplink congestion control.
	congestion-control tcp threshold delay	Configures the delay threshold for uplink congestion control.
	congestion-control tcp threshold upstream	Configures the threshold of uplink traffic volume for uplink congestion control.
	congestion-control tcp window-optimize hold-time	Configures the window optimization duration for uplink congestion control.
	congestion-control tcp dscp	Configures the DSCP threshold for

Configuration	Description and Command	
		background traffic in uplink congestion control.

1.4.1 Configuring Rate Limiting

Configuration Effect

- Only the committed resource is allocated to a flow based on the network situation, which prevents network congestion caused by burst traffic.

Notes

- Rate limiting provided by the **wlan-based per-ap-limit** command configured on an AC is equivalent to that of the **wlan-qos wlan-based total-user-limit** command configured on all connected APs.
- The following types of rate limiting are available on STAs: **wlan-based per-user-limit**, **wlan-based per-ap-limit intelligent**, **ap-based per-user-limit**, **ap-based total-limit intelligent**, and **netuser**. However, only one type of rate limiting is available at a time. The following types of rate limiting are in descending order of priority: **netuser**, **wlan-based per-ap-limit intelligent**, **wlan-based per-user-limit**, **ap-based total-limit intelligent**, and **ap-based per-user-limit**.
- Rate limiting, including **wlan-based total-limit**, **wlan-based per-ap-limit**, **ap-based total-limit**, and STA-based rate limiting, can take effect on different objects simultaneously without considering priorities.

Configuration Steps

↘ Configuring AP-based Rate Limiting

- Mandatory.
- Configure rate limiting per single user on an AC in AP configuration mode.

Command	**wlan-qos ap-based** { **per-user-limit** | **total-user-limit** [**intelligent**] } { **down-streams** | **up-streams** } *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Indicates that rate limiting is implemented on every STA on the AP. **total-user-limit**: Indicates that rate limiting is implemented on all STAs on the AP. **intelligent**: Indicates whether rate limiting is implemented on all STAs on the AP intelligently. **down-streams**: Indicates that rate limiting is implemented for downlink traffic on the AP. **up-streams**: Indicates that rate limiting is implemented for uplink traffic on the AP. *average-data-rate*: Indicates the CIR. The unit is 8 kbps. The value range is from 8 to 261120. *burst-data-rate*: Indicatesthe CBS. The unit is 8 kbps. The value range is from 8 to 261120.
Defaults	By default, rate limiting is not configured. If **total-user-limit** is configured, intelligent rate limiting is disabled by default.
Command Mode	AP configuration mode
Usage Guide	N/A

- In AP configuration mode on the AC, configure rate limiting for the AP.

Command	**ap-based total-user-limit** { **down-streams** | **up-streams** } **intelligent**

Parameter Description	**total-user-limit**: Indicates that rate limiting is applied to the AP. **intelligent**: Indicates whether to enable or disable intelligent rate limiting for total users. **down-streams**: Sets the rate limit for downlink traffic on an AP. **up-streams**: Sets the rate limit for uplink traffic on an AP.
Defaults	It is disabled by default.
Command Mode	AP configuration mode
Usage Guide	N/A

Configuring STA-based Rate Limiting

- Mandatory.
- On an AC, run the **wlan-qos netuser** command in AC configuration mode to configure STA-based rate limiting.

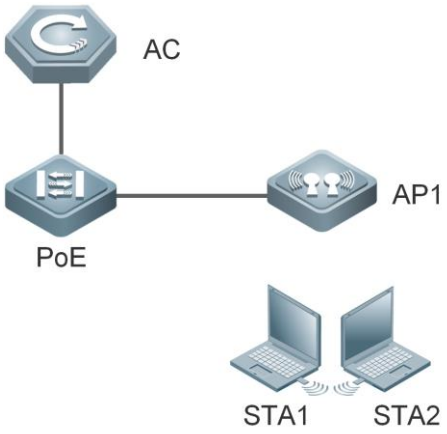
Command	**netuser** *mac-address* { **inbound** | **outbound** } **average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	*mac-address*: Indicates the MAC address of a STA. **inbound**: Indicates that rate limiting is implemented for uplink traffic on a STA. **outbound**: Indicates that rate limiting is implemented for downlink traffic on a STA. *average-data-rate*: Indicates the CIR. The unit is 8 kbps. The value range is from 8 to 261120. *burst-data-rate*: Indicates the CBS. The unit is 8 kbps. The value range is from 8 to 261120.
Defaults	By default, rate limiting is not configured.
Command Mode	AC configuration mode
Usage Guide	N/A

Configuring WLAN-based Rate Limiting

- Mandatory.
- On an AC, run the **wlan-based** command in WLAN configuration mode to configure WLAN-based rate limiting.

Command	**wlan-based** { **per-user-limit** | **total-user-limit** | **per-ap-limit** } { **down-streams** | **up-streams** } **average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Indicates that rate limiting is implemented on every STA on a WLAN. **total-user-limit**: Indicates that rate limiting is implemented on all STAs on a WLAN. **intelligent**: Indicates whether rate limiting is implemented on all STAs on a WLAN intelligently. **per-ap-limit**: Indicates that AP-based rate limiting is implemented. **down-streams**: Indicates that rate limiting is implemented for downlink traffic on a WLAN. **up-streams**: Indicates that rate limiting is implemented for uplink traffic on a WLAN. *average-data-rate*: Indicates the CIR. The unit is 8 kbps. The value range is from 8 to 261120. *burst-data-rate*: Indicates the CBS. The unit is 8 kbps. The value range is from 8 to 261120.
Defaults	By default, rate limiting is not configured.
Command Mode	WLAN configuration mode
Usage Guide	N/A

- Configure per-AP intelligent rate limiting for a WLAN.



Command	**wlan-based per-ap-limit** { **down-streams** | **up-streams** } **intelligent**
Parameter Description	**down-streams**: Sets rate limiting parameters for downlink traffic on a WLAN. **up-streams**: Sets the rate limiting parameters for uplink traffic on a WLAN. **intelligent**: Indicates whether to enable or disable intelligent rate limiting for total users.
Defaults	No rate limiting is configured by default.
Command Mode	WLAN configuration mode
Usage Guide	N/A

Verification

- Run the **show dot11 ratelimit ap** command to display AP-based rate limiting information.
- Run the **show dot11 ratelimit user** command to display STA-based rate limiting information.
- Run the **show dot11 ratelimit wlan** command to display WLAN-based rate limiting information.

Configuration Example

Configuring AP-based Rate Limiting

Scenario **Figure 1-2**	
Configuration Steps	● In AP configuration mode, configure AP-based rate limiting for downlink traffic.

AC	`Hostname#configure terminal`
	`Hostname(config)# ap-config ap1`
	`Hostname(config-ap)#ap-based per-user-limit down-streams average-data-rate 100000 burst-data-rate 120000`
	`Hostname(config-ap)# exit`

Verification	● Run the **show dot11 ratelimit ap** command to display the configuration.

AC	`AC_20_3F#show dot11 ratelimitap`
	`AP name :test, ratelimit info(unit :8kbps):`
	`Per-user-limit:`
	`  Upstream  : average rate - 0 , burst rate - 0`
	`  Downstream : average rate - 100000, burst rate - 120000`
	`Total-user-limit:`
	`  Upstream  : average rate - 0 , burst rate - 0`

	Downstream : average rate - 0 , burst rate - 0

1.4.2 Enabling the Downlink Packets with the Specified DSCP Value in the Specified Range to Bypass STA Rate Limiting

Configuration Effect

The downlink packets with the DSCP value within the specified range bypass STA rate limiting.

Notes

- Configure this function in the AP configuration mode or all-AP configuration mode on the AC.
- The DSCP range of the packet which bypasses rate limiting includes start and end values.
- The DSCP end value cannot be smaller than the start value, or the configuration fails.
- When the DSCP policy is configured in both all-AP configuration mode and AP configuration mode, the configuration in the AP configuration mode takes precedence.

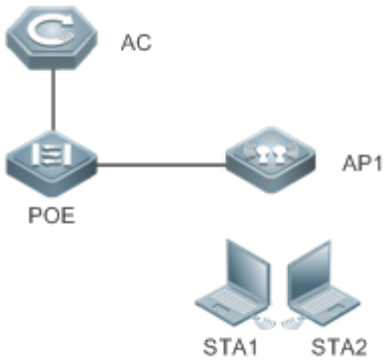
Configuration Steps

↘ Enabling the Downlink Packets with the Specified DSCP Value in the Specified Range to Bypass STA Rate Limiting

- Optional.
- Run the **wqos skip-rate-limit dscp** command on the AC.

Command	**wqos skip-rate-limit dscp** *dscp-start dscp-end*
Parameter Description	*dscp-start*: Configures the start value of the DSCP range with which the packets bypass STA rate limiting. The value ranges from 0 to 63. *dscp-end*: Configures the end value of the DSCP range with which the packets bypass STA rate limiting. The value ranges from 0 to 63.
Default	This function is disabled by default.
Command Mode	AP configuration mode and all-AP configuration mode on the AC
Usage Guide	The DSCP end value must be equal to or greater than the DSCP start value.

Verification



- Run the **show running-config** command to display the DSCP range in the all-AP configuration mode.
- Run the **show ap-config running** command to display the DSCP range in the AP configuration mode.

Configuration Example

↘ Enabling the Downlink Packets with the Specified DSCP Value to Bypass STA Rate Limiting

Network Scenario

Figure 1-74

Configuration Steps

Enable the downlink packets with the DSCP value in the range from 56 to 63 to bypass STA rate limiting.

```
Hostname# ap-config all
Hostname(config-ap)# wqos skip-rate-limit dscp 56 63
```

Verification

Run the **show running-config** command to display the DSCP range of the packet which bypasses STA rate limiting.

```
Hostname# show running-config | include skip-rate-limit
 wqos skip-rate-limit dscp 56 63
```

Common Errors

N/A

1.4.3 Configuring Fair Scheduling

Configuration Effect

- The fair scheduling function prevents low-speed STAs from compromising the overall throughput of the wireless network, resulting in a smoother network experience for all connected STAs

Notes

- In Fit AP mode, configure fair scheduling only on an AC.

Configuration Steps

↘ Enabling Fair Scheduling

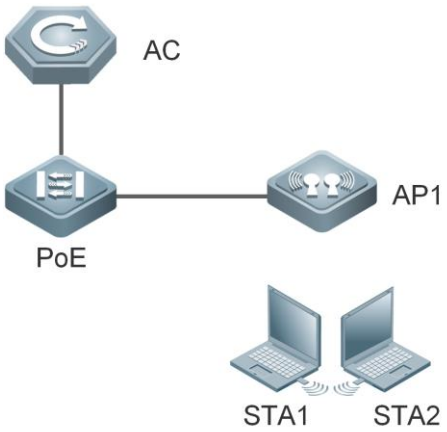
- Mandatory.
- On an AC, run the **fair-schedule** command in AP configuration mode to enable fair scheduling.
- Fair scheduling evenly allocates time resources to STAs.

Command	**fair-schedule**
Parameter Description	N/A
Defaults	By default, fair scheduling is enabled.

Command Mode	AP configuration mode
Usage Guide	N/A

Configuring the Fair Scheduling Priority

- (Optional) Perform this configuration if you need to change the fair scheduling priority of a STA.
- On an AC, run the **sta-fair** command in AC configuration mode to configure the fair scheduling priority.



Command	**sta-fair** *mac-address* **priority** *priority*
Parameter Description	*mac-address*: Indicates the MAC address of a STA. *priority*: Indicates the priority. The value range is from 1 to 6.
Defaults	By default, the priority is 1 for all STAs. A greater value indicates a higher priority, and a higher priority indicates longer time allocated to a STA.
Command Mode	AC configuration mode
Usage Guide	Whether this parameter is supported and the value range of this parameter depend on the product version.

Verification

- Run the **show ap-config run** command to display the configuration.

Configuration Example

Enabling Fair Scheduling and Configuring the Priority

Scenario **Figure 1-3**	
Configuration Steps	● In AP configuration mode, enable fair scheduling. ● In AC configuration mode, configure the fair scheduling priority of a STA.

AC	`Hostname#configure terminal`
	`Hostname(config)# ap-config ap1`
	`Hostname(config-ap)#fair-schedule`
	`Hostname(config-ap)# exit`
	`Hostname(config)#ac-controller`
	`Hostname(config-ac)#sta-fair 1111.1111.1111 priority 6`
	`Hostname(config-ac)# end`

Verification	● Run the **show ap-config running** and **show running-config** commands to display the

	configuration.

AC	`Hostname# show ap-config running`
	`!`
	`ap-configap1`
	`!`
	`Hostname# show running-config`
	`!`
	`ac-controller`
	`sta-fair 1111.1111.1111 priority 6`
	`!`

1.4.4 Configuring Intranet Proxy Prevention

Configuration Effect

- Detect the STA that is used as the proxy server for other STAs on a wireless intranet, achieving accurate monitoring of the STA quantity and network traffic.

Notes

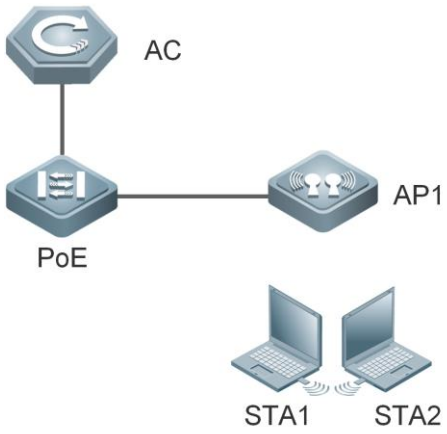
N/A

Configuration Steps

↘ Enabling Intranet Proxy Prevention

- Mandatory.
- Run the **illegal-sta-check** command to enable intranet proxy prevention.
- Enable intranet proxy prevention to detect the STA that is used as the proxy server for another STA and contain the STA.
- Enable intranet proxy prevention and use the TTL detection policy.

↘ Enabling Intranet Proxy Prevention and Using the TTL Detection Policy



Command	**illegal-sta-check ip ttl**
Parameter Description	N/A
Defaults	By default, intranet proxy prevention is disabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show running-config** command to display the configuration.

Configuration Example

↘ Enabling Intranet Proxy Prevention

Scenario **Figure 1-4**	
Configuration Steps	● Enable intranet proxy prevention in AP configuration mode.

AC	`Hostname#configure terminal`
	`Hostname(config)# ap-config ap1`
	`Hostname(config-ap)# illegal-sta-check ip ttl`
	`Hostname(config-ap)# end`

Verification	● Run the **showap-config running** command to display the configuration.

AC	`Hostname# show ap-config running ap1`
	`!`
	`ap-configap1`
	` illegal-sta-check ip ttl`
	`!`

Common Errors

N/A

1.4.5 Configuring Dynamic Rate Limiting

Configuration Effect

- Dynamic rate limiting adjusts STA rate limits based on channel utilization, keeping air interface utilization below 70%.

Notes

- In a scenario where the APs supporting dynamic rate limiting and APs not supporting dynamic rate limiting are deployed, the APs supporting dynamic rate limiting will be suppressed.

Configuration Steps

↘ Enabling Dynamic Rate Limiting Function

- Optional.
- On the AC, run the **smart-rate-control enable** command in AP configuration mode.

Command	**smart-rate-control enable**
Parameter Description	N/A
Defaults	This function is disabled by default.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring Dynamic Rate Limiting Parameters

- Configure the associated rate threshold for low-speed STAs.

Command	**smart-rate-control config low-rate-sta** *rate-num*
Parameter Description	*rate-num*: Indicates the threshold for the associated rate of a low-speed STA. The value range is from 1 to 500000, in kbps.
Defaults	The default value is 30000, which means the associated rate threshold is 30 Mbps.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	When the associated rate of a STA is lower than the threshold for low-speed STAs, the STA is considered as a low-speed STA. When the rate limiting factor is adjusted by using the **smart-rate-control config rate-limit-step** command, the adjustment result for low-speed STAs is different from that for non-low-speed STAs. 1. When you increase the rate limiting factor, for non-low-speed STAs, the percentage increase is as configured. For low-speed STAs, the actual increase factor is only one third of the configured rate limiting factor, that is, 1/3 multiplied by *increase-percent*. 2. When you reduce the rate limiting factor, for non-low-speed STAs, the percentage reduction is as configured. For low-speed STAs, the actual reduction factor is three times the configured factor, that is, 3 multiplied by *reduce-percent*.

- Configure the rate limiting factor.

Command	**smart-rate-control config rate-limit-step** { **increase** *increase-percent* | **reduce** *reduce-percent* }
Parameter Description	*increase-percent*: Indicates the value for increasing the rate limiting factor. The value range is from 1 to 100. *reduce-percent*: Indicates the value for reducing the rate limiting factor. The value range is from 1 to 100.
Defaults	By default, the value for increasing the rate limiting factor is 20 and the value for reducing the rate limiting factor is 20.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

- Configure timer parameters.

Command	**smart-rate-control config sampling** { **period** *cycle-num* | **times** *times-num* }
Parameter Description	*cycle-num*: Configures the interval for timer sampling, in milliseconds. The value range is from 1000 to 10000. *times-num*: Configures the data sampling count before rate adjustment is triggered. The value range

	is from 1 to 100.
Defaults	By default, the sampling period is 1000 ms and the data sampling count is 5.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	The timer configuration takes effect in the next scheduling period, with a waiting time of 0 to **period** multiplied by **times**.

- Configure the channel utilization threshold.

Command	**smart-rate-control config threshold channel-using** { **busy** *busy-num* | **free** *free-num* }
Parameter Description	*busy-num*: Configures the threshold percentage for busy channel utilization. The value range is from 1 to 100. *free-num*: Configures the threshold percentage for free channel utilization. The value range is from 1 to 100.
Defaults	By default, the thresholds for busy channel utilization and free channel utilization are 70 and 40 respectively.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	Ensure that the thresholds for busy channel utilization and free channel utilization are in descending order.

- Configuring the STA association rate factor.

Command	**smart-rate-control config threshold link-rate-divisor** *divisor*
Parameter Description	*divisor*: Indicates the STA association rate factor. The value range is from 16 to 256.
Defaults	64
Command Mode	AP configuration mode or all-AP configuration mode on the AC Global configuration mode on the AP
Usage Guide	After dynamic rate limiting is enabled, if the bandwidth for key users in a multi-user scenario is not effectively guaranteed, increase the STA association rate factor to compromise the minimum guaranteed bandwidth of non-key users, thereby enhancing the bandwidth for key users. This improves network experience of key users in a multi-user scenario. The minimum guaranteed bandwidth for a STA is calculated as follows: (uplink negotiation rate + downlink negotiation rate) x 0.5/*divisor.*

- Configure the threshold for guaranteed bandwidth.

Command	**smart-rate-control config threshold rate-guard** *rate-num*
Parameter Description	*rate-num*: Configures the threshold for guaranteed bandwidth, in the unit of 8 kbps. The value range is from 8 to 261120.
Defaults	By default, the threshold is not configured.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	1. After the threshold is configured, the original method of calculating guaranteed bandwidth becomes ineffective and is updated to the newly configured bandwidth. 2. Guaranteed Bandwidth = (Negotiated rate of STA * 0.8 (wireless loss) * (1 – Wireless loss))/Number of STAs

- Configure the rate limiting scope.

Command	**smart-rate-control config threshold rate-limit** { **maximum** *max-num* | **minimum** *min-num* }
Parameter Description	*max-num*: Configures the maximum rate limit, in the unit of 8 kbps. The value range is from 8 to 261120. *min-num*: Configures the minimum rate limit, in the unit of 8 kbps. The value range is from 8 to 261120.
Defaults	By default, the maximum rate limit is 25000 and the minimum rate limit is 8.
Command Mode	AP configuration mode and all-AP configuration mode
Usage Guide	1. If the rate limit is greater than the maximum value, the maximum rate limit is canceled. 2. The rate limit cannot be smaller than the minimum value.

- Configure the wireless loss.

Command	**smart-rate-control config wlan-loss** *loss-num*
Parameter Description	*busy-num*: Configures the percentage of wireless loss. The value range is from 1 to 100.
Defaults	The wireless loss is 20% by default.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

- Configure the MAC address of the key client for dynamic rate limiting.

Command	**smart-rate-control config user mac** *H.H.H*
Parameter Description	*H.H.H*: Configures the MAC address of the client whose bandwidth is to be guaranteed.
Defaults	No MAC address of the key client is configured by default.
Command Mode	AP configuration mode and all-AP configuration mode on the AC and global configuration mode on the AP
Usage Guide	N/A

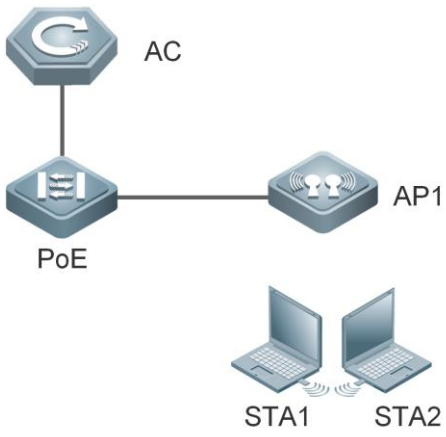
- Configure the guaranteed bandwidth weights of key clients and of ordinary clients for dynamic rate limiting respectively.

Command	**smart-rate-control config user weight key** *key-user-weight* **normal** *normal-user-weight*
Parameter Description	*key-user-weight*: Indicates the weight of key clients. The value ranges from 1 to 100 and the default value is 100. *normal-user-weight*: Indicates the weight of ordinary clients. The value ranges from 1 to 100 and the default value is 50.
Defaults	The default weights of key clients and of ordinary clients are 100 and 50 respectively.
Command Mode	AP configuration mode and all-AP configuration mode on the AC and global configuration mode on the AP
Usage Guide	The weight of key clients cannot be smaller than that of ordinary clients. The actual data rate is calculated based on the negotiated rate of the client. When the negotiated rate is relatively low, the actual data rate of key clients may be lower than that of ordinary clients though the weight of the key clients is greater.

- Configure application guarantee for dynamic rate limiting.

Command	**smart-rate-control config application guarantee enable**
Parameter Description	N/A
Defaults	The application guarantee for dynamic rate limiting is disabled by default.
Command Mode	AP configuration mode and all-AP configuration mode on the AC and global configuration mode on the AP
Usage Guide	When you enable application guarantee for dynamic rate limiting, add the critical applications into the critical application group by running the **identify-application key** command. It is optional to add the suppression applications into the suppression application group by running the **identify-application inhibitive** command.

- Configure the guaranteed bandwidth weights of the critical application group, of the ordinary application group, and of the suppression application group respectively.



Command	**smart-rate-control config application weight key** *key-group-weight* **normal** *normal-group-weight* **inhibitive** *inhibitive-group-weight*
Parameter Description	*key-group-weight*: Indicates the weight of the critical application group. The value ranges from 1 to 100 and the default value is 100. *normal-group-weight*: Indicates the weight of the ordinary application group. The value ranges from 1 to 100 and the default value is 50. *inhibitive-group-weight*: Indicates the weight of the suppression application group. The value ranges from 1 to 100 and the default value is 50.
Defaults	The default weights of the critical application group, of the ordinary application group, and of the suppression application group are 100, 50, and 50 respectively.
Command Mode	AP configuration mode and all-AP configuration mode on the AC and global configuration mode on the AP
Usage Guide	N/A

Verification

- Run the **show running-config** command to check whether dynamic rate limiting is enabled and check its parameters. By default, this information is not displayed.

Configuration Example

Configuring Dynamic Rate Limiting

Scenario Figure 1-7	

Configuration Steps	1. Enable dynamic rate control on AP1. 2. Configure the low rate for associated low-speed STAs as 1,024. 3. Set the rate limiting factor to 20%. 4. Configure the timer effective period as 2,000 ms. 5. Set the threshold percentage for busy channel utilization to 80%. 6. Set the STA association rate factor to 256. 7. Configure the guaranteed bandwidth as 100, which is equivalent to 800 kbps (100 x 8 kbps). 8. Set the minimum rate limiting to 20, which is equivalent to 160 kbps (20 x 8 kbps). 9. Set the wireless loss to **50%**. 10. Configure **STA 0a08.27c4.a8b2** as the key client for dynamic rate limiting. 11. Set the guaranteed bandwidth weights of the key clients and of the ordinary clients to **75** and **50** respectively. 12. Enable application guarantee for dynamic rate limiting. 13. Set the guaranteed bandwidth weights of the critical application group, of the ordinary application group, and of the suppression application group to **75**, **50**, and **25** respectively.

Common Errors

- N/A

1.4.6 Configuring Uplink Congestion Control

Configuration Effect

The uplink congestion control function can be configured to limit traffic by adjusting the TCP sliding window.

Notes

N/A

Configuration Steps

↘ Enabling Uplink Congestion Control

- Optional.
- On the AC, run the **congestion-control tcp enable** command to enable uplink congestion control in AP configuration mode.

Command	**congestion-control tcp enable**
Parameter Description	N/A
Defaults	Uplink congestion control is disabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

↘ Configuring Uplink Congestion Control Parameters

- Configure the channel utilization threshold.

Command	**congestion-control tcp threshold cu** [**up** | **down**] *cu*
Parameter Description	**up**: Configures the uplink channel utilization. **down**: Configures the downlink channel utilization. Currently, downlink channel utilization control is not supported. The configuration cannot take effect. Supported configuration depends on the specifications of the released version. *cu*: Configures the channel utilization threshold. The value range is from 1 to 100, in percentage.
Defaults	The channel utilization threshold is 70%.

Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	When the channel utilization of the TCP flow reaches the threshold, it is considered that there is an uplink congestion.

- Configure the delay threshold.

Command	**congestion-control tcp threshold delay** *num*
Parameter Description	*num*: Indicates the delay threshold, in μs. The value range is from 1000 to 100000.
Defaults	The delay threshold is 10000 μs.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

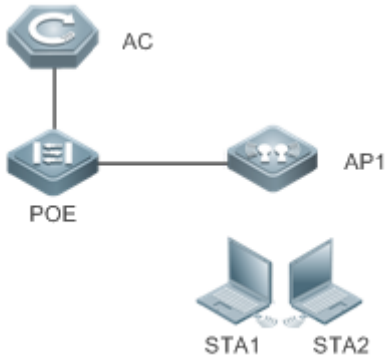
- Configure the threshold of uplink traffic volume.

Command	**congestion-control tcp threshold upstream** *num*
Parameter Description	*num:* Indicates the threshold of uplink traffic volume, in pps. The value range is from 100 to 100000.
Defaults	The threshold of uplink traffic volume is 1000 pps.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

- Configure the window optimization duration.

Command	**congestion-control tcp window-optimize hold-time** time
Parameter Description	*time*: Configures the window optimization duration, in seconds. The value range is from 1 to 100.
Defaults	The window optimization duration is 5s.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

- Configure the DSCP threshold.



Command	**congestion-control tcp dscp** *num*
Parameter Description	*num*: Configures the DSCP threshold. The value range is from 1 to 63.
Defaults	The DSCP threshold is 10.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Verification

- Run **show running-config** command to check whether uplink congestion control is enabled and whether its parameters are configured.

Configuration Examples

Configuring Uplink Congestion Control

Scenario **Figure 1-71**	
Configuration Steps	1. Enable uplink congestion control. 2. Set the window optimization duration to 8s 3. Set the DSCP threshold to 50. 4. Set the uplink CU threshold to 10%. 5. Set the delay threshold to 20 μs. 6. Set the threshold of uplink traffic volume to 30 pps.

	`Hostname(config)#congestion-control tcp enable`
	`Hostname(config)#congestion-control tcp window-optimize hold-time 8`
	`Hostname(config)#congestion-control tcp dscp 50`
	`Hostname(config)#congestion-control tcp threshold cu up 10`
	`Hostname(config)#congestion-control tcp threshold delay 20`
	`Hostname(config)#congestion-control tcp threshold upstream 30`

Verification	Run the **show running-config** command to display the uplink congestion control configurations on the AP.

	`Hostname(config)#show running-config`
	
	`Building configuration...`
	`Current configuration: 2871 bytes`
	
	`congestion-control tcp enable`
	`congestion-control tcp threshold cu up 10`
	`congestion-control tcp threshold delay 20`
	`congestion-control tcp threshold upstream 30`
	`congestion-control tcp dscp 50`

	`congestion-control tcp window-optimize hold-time 8`

Common Errors

1.5 Monitoring

Displaying

Command	Description
show dot11 ratelimit {**wlan** | **ap** | **user** }	Displays WQoS rate limiting information.

1 Configuring WMM

1.1 Overview

Wi-Fi Multimedia (WMM) is a wireless Quality of Service (QoS) protocol, which is a subset of the 802.11e protocol. WMM is utilized to prioritize high-priority packets, ensuring that voice and video applications receive preferential treatment on a wireless network.

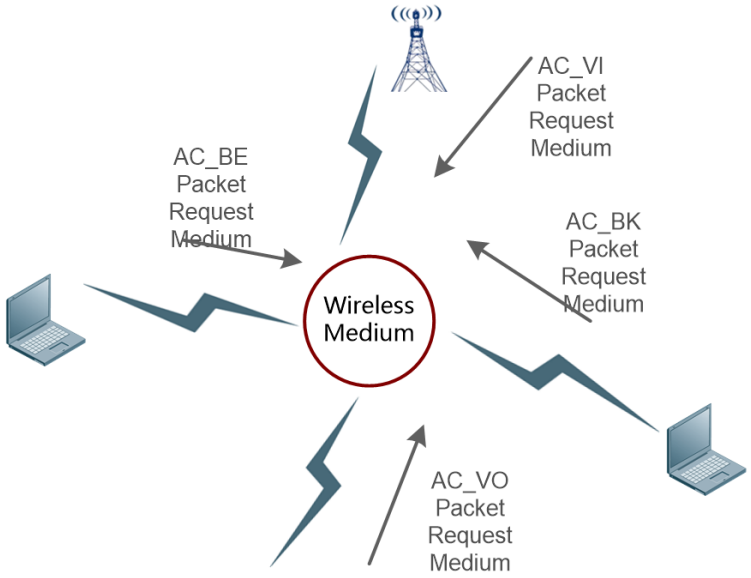
This document consists of two parts:

- WMM service: The WMM service is used to differentiate capabilities of access channels with different priorities, ensuring that channel resources are allocated based on data flow priorities. You can adjust Enhanced Distributed Channel Access (EDCA) parameters for a client or an AP based on requirements, so the AC with a higher priority can start the backoff process earlier than other ACs and preferentially access a channel.
- QoS packet priority mapping: Wireless-to-wired QoS mapping and wired-to-wireless QoS mapping help to implement end-to-end QoS on the entire network, thereby assuring the quality of high-priority service flows.

Protocols and Standards

- IEEE 802.11e-2005: Amendment 8: Medium Access Control (MAC) Quality of Service Enhancements, IEEE Computer Society
- RFC 5416: Control and Provisioning of Wireless Access Points (CAPWAP) Protocol Binding for IEEE802.11

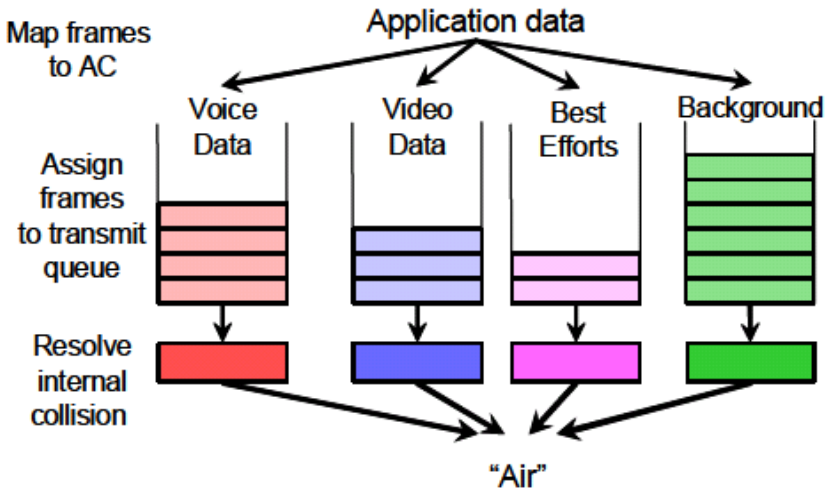
1.2 Applications



Application	Description
WMM Service	Competition process of channels with different priorities
Wireless-to-Wired Priority Mapping	Wireless-to-wired QoS packet priority mapping process
Wired-to-Wireless Priority Mapping	Wired-to-wireless QoS packet priority mapping process

1.2.1 WMM Service

Scenario



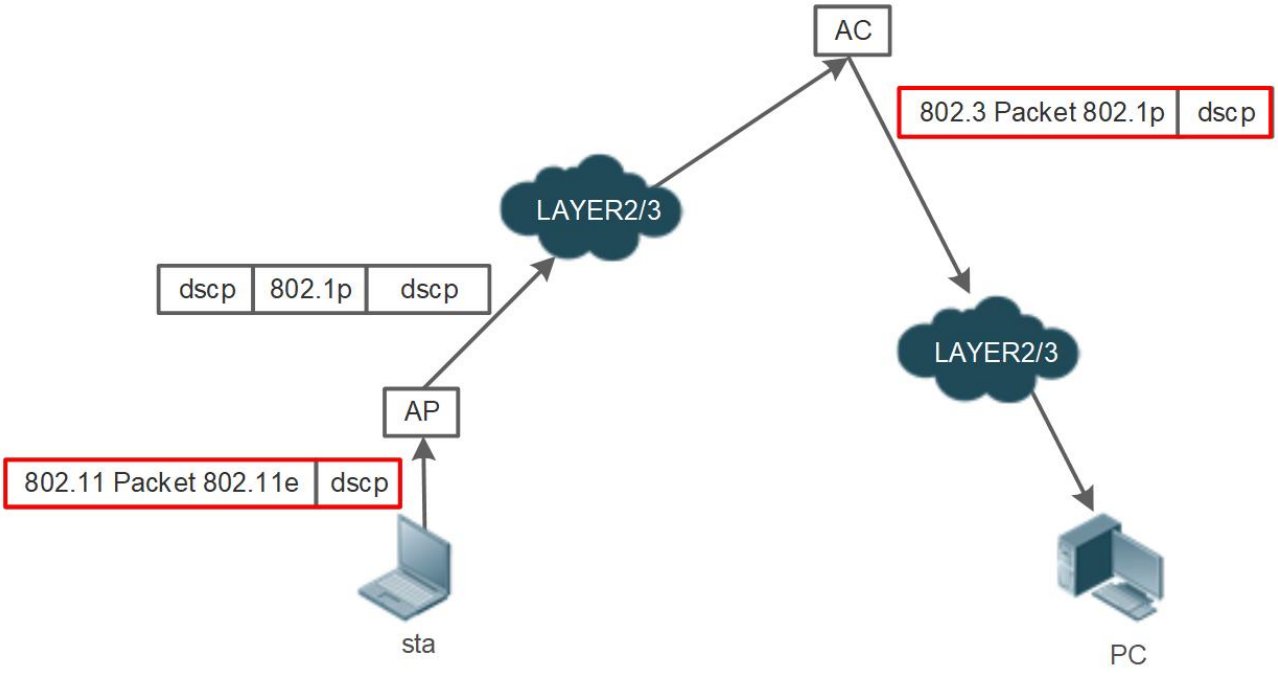
The medium for wireless communication is radio. In a specified frequency band, channels are shared during wireless network communication. In the same RF environment, uplink and downlink traffic of different sites conflicts. Therefore, it is essential to address the issue of how communication participants compete for shared channels to ensure wireless QoS. As shown in Figure 1-1, there are packets of four different priorities in the same wireless network environment (packets in descending order of priority are as follows: AC_VO > AC_VI > AC_BE > AC_BK). When multiple supplicants request access to the medium to send packets and compete for channels, a competition and coordination mechanism is employed to determine which supplicant's packet can access the medium. The higher the packet's priority is, the more likely it is to gain access to the channel.

Figure 1-1 Channel Competition

On a wireless network, the impact of packet loss and signal interference on packet integrity during transmission is significant due to the unique nature of the medium. To ensure packet delivery, retransmission of various wireless transmission parameters becomes necessary. However, it is impractical to apply optimal parameters to all packets. To cater to services with stringent reliability and timeliness requirements, packet classification becomes essential. In essence, different network services are offered based on diverse requirements, prioritizing the processing of critical data packets with high timeliness needs while assigning lower processing priority to common packets without such demands. For a network to support a variety of services, it must not only deliver a single service with top-quality QoS but also accommodate different services with varying QoS levels. As a result, the QoS of a wireless Access Point (AP) hinges on the ability to classify and identify packets to distinguish between different data flows and provide services of distinct quality.

Figure 1-2 Wireless QoS Multi-priority Queue

Deployment



Key configuration on the device:

- Enable WMM.
- Set EDCA competition parameters. Typically, default values are used.

1.2.2 Wireless-to-Wired Priority Mapping

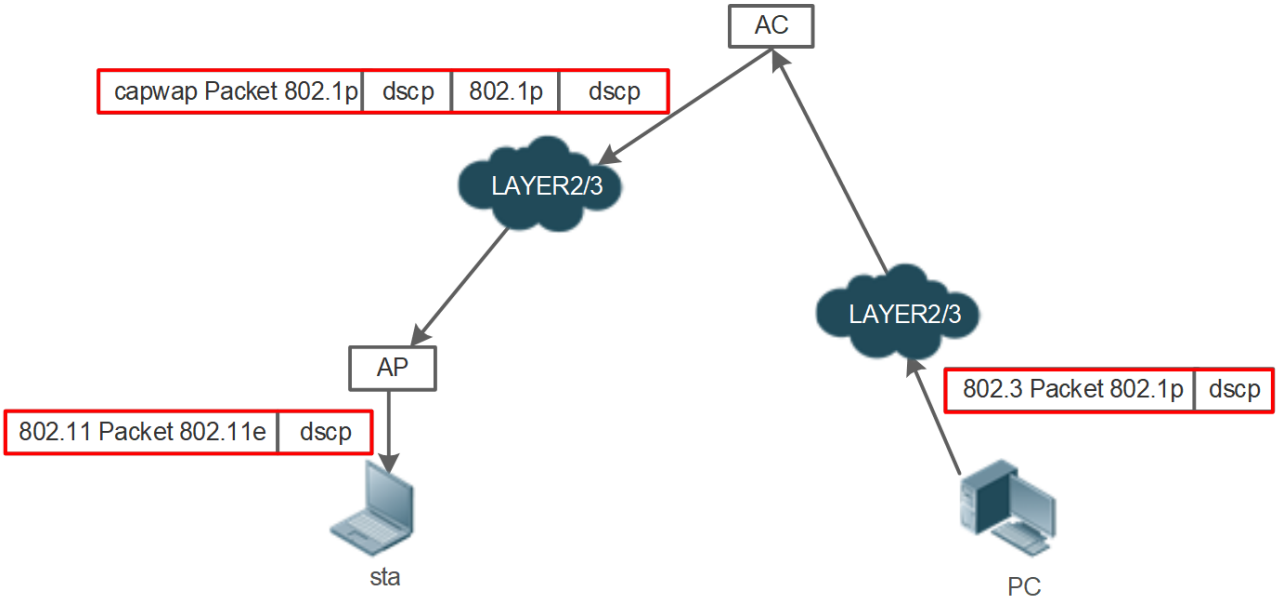
Scenario

Figure 1-3 Wireless-to-Wired Packet Priority Mapping

STA-to-PC priority mapping process:

- A STA sends an 802.11 packet carrying 802.11e and DSCP information to the AP.
- The AP sets the internal priority of the packet based on the trust mode of the wireless interface (configured on the ESS of the AC based on the BSSID). If the trusted packet carries an 802.11e priority, the AP converts the packet with the 802.11e priority into a wired packet with the 802.1p or DSCP priority and the CAPWAP packet with the 802.1p or DSCP priority. If the DSCP priority is trusted, the preceding configuration is performed based on the DSCP priority of the incoming wireless packet. By default, the DSCP priority is trusted, and the wireless end conforms to 802.11e.
- When passing Layer 2/3 network, the CAPWAP packet is processed according to the wired QoS method.
- After receiving the CAPWAP packet, the AC decapsulates the packet and then forwards the decapsulated wired packet to the Layer 2/3 network.
- When passing Layer 2/3 network, the wired packet is processed according to the wired QoS method.

Deployment



Key configuration on the device:

- Enable WMM.
- Set the wireless-to-wired priority mapping table. Typically, default values are used.

1.2.3 Wired-to-Wireless Priority Mapping

Scenario

Figure 1-4 Wired-to-Wireless Packet Priority Mapping

PC-to-STA QoS mapping process:

- The AC receives an 802.3Mac packet from the PC.
- Set the internal COS priority of the packet based on the trust mode of the physical interface. If the trusted packet has the 802.1p priority and carries a tag, set the internal CoS value of the packet based on the 802.1p priority. Otherwise, set the default priority of the packet based on the default priority of the interface. If the DSCP priority is trusted, the preceding configuration is performed based on the DSCP priority of the incoming wireless packet. By default, the DSCP priority is trusted, and the wireless end conforms to 802.11e.
- The AC encapsulates the 802.3 packet into a CAPWAP packet.
- After receiving the CAPWAP packet, the AP decapsulates the packet and performs QoS priority mapping for the wired-to-wireless packet based on the trusted priority. If the DSCP priority is trusted, the AP configures the 802.11e or DSCP priority of the wireless packet based on the DSCP priority of the 802.3 packet. If the 802.1p priority is trusted, the AP performs the configuration based on the COS value of the 802.3 packet.
- Based on the 802.11e priority of the wireless packet, the AP participates in the competition for wireless channels and sends the wireless packet to the STA.

Deployment

Key configuration on the device:

- Enable WMM.
- Set the wired-to-wireless priority mapping table. Typically, default values are used.

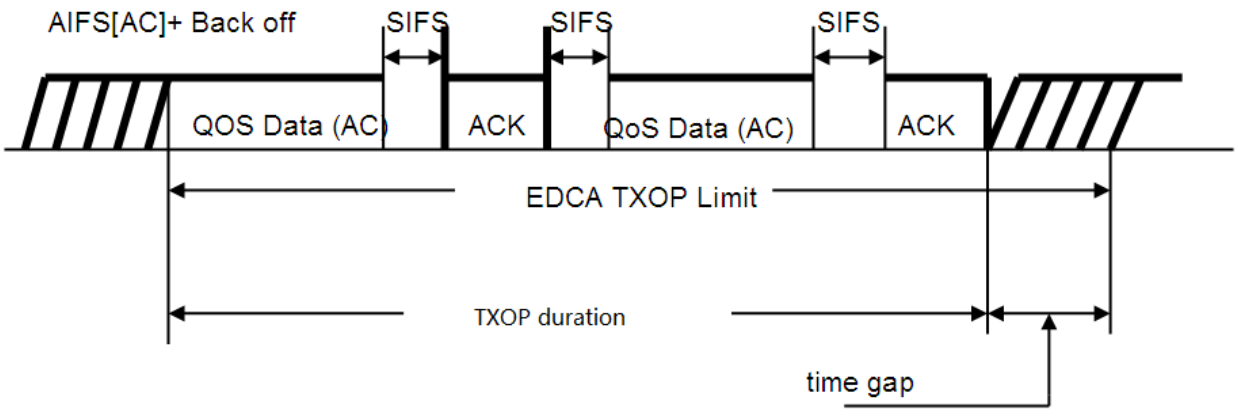
1.3 Features

Basic Concepts

Access Class

According to the WMM standard, access data flows are categorized into four priorities, each representing a class. AC_BK (background), AC_BE (best-effort), AC_VI (video data), and AC_VO (voice data) are in descending order of priority.

EDCA Competitive Mechanism



The EDCA competitive mechanism is the core of IEEE 802.11e. It differentiates access capabilities of AC channels with different priorities, ensuring that air interface resources are allocated based on data flow priorities. EDCA retains distributed channel competition between an AP and a STA, and introduces internal competition of four internal priority classes of the QoS AP (QAP) or QoS STA (QSTA). In this way, EDCA introduces the channel competition mechanism that differentiates the priority classes between different QAPs and QSTAs through the wireless air interface. Competition for channels is implemented by configuring EDCA competition parameters of different priority classes. The QAP pushes the configuration to the QSTA and controls the access capability of the QSTA. Competition parameters include the Arbitration Inter Frame Spacing Number (AIFSN), Transmission Opportunity (TXOP) limit, CWmin, and CWmax.

EDCA Parameters

The EDCA competition parameters are listed as follows:

- AIFSN: In the 802.11 protocol, the Distributed Inter-frame Spacing (DIFS) has a fixed value. However, the DIFS for different ACs of the WMM can be set to different values. A larger AIFSN value means a longer DIFS. A shorter DIFS means a higher probability of preempting channels.
- Exponent form of CWmin (ECWmin) and Exponent form of CWmax (ECWmax) determine the average backoff time. Larger ECWmin and ECWmax mean a longer backoff time.
- Transmission Opportunity (TXOP): It refers to the maximum duration for preempting channels after successful competition by a user at one time. A larger TXOP means a longer duration for a user to preempt channels. If the TXOP value is 0, only one packet is sent after channel preemption each time. If a frame is too large to be completely sent within the TXOP, this frame must be fragmented.

Figure 1-5 TXOP Successive Frame Transmission

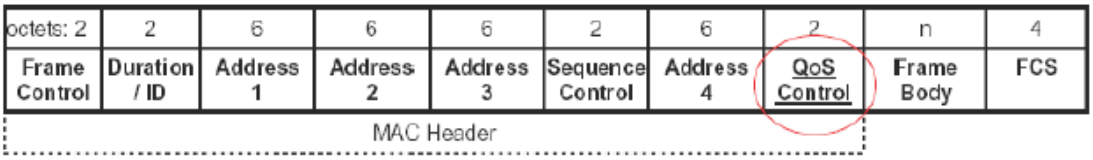
ACK Policy

Two ACK policies are available:

- Normal ACK: After receiving a unicast packet successfully, the recipient returns an ACK response.

- No ACK: In the environment with high communication quality and little interference, you can configure the device not to return an ACK packet for the flow of a certain priority, saving the channel resource. During wireless packet interaction, an ACK packet can be not used. The No ACK policy helps to improve the transmission efficiency. However, it may cause packet loss.

According to the IEEE 802.11 standard, no ACK is returned for multicast or broadcast frames.



AC Queue Depth

If the queue depth of packets of a certain priority is greater than the preset AC queue depth, subsequent packets are discarded. Otherwise, subsequent packets are added to the queue for processing.

802.11e Priority

802.11e extends the MAC header of 802.11, with the QoS Control field added, as shown in Figure 1-6.

Figure 1-6 802.11e MAC Header

The QoS Control field has 2 bytes. Among them, the first three bits are the TID field, indicating the data form identification code. TID values 0 to 7 represent QoS priorities, indicating user priorities (UP); TID values 8-15 are used for parameter-based QoS, indicating the data flow ID (TSID).

WMM maps the user priority to the corresponding access category (AC). The following table lists the mapping between the 802.11e priority and AC.

Priority	User Priority	Access Category
Lowest ↓ **Highest**	1	Background
	2	Background
	0	Best-effort
	3	Best-effort
	4	Video
	5	Video
	6	Voice
	7	Voice

Priority Mapping Table

After a packet enters a device, the device determines the packet trust mode of the interface, that is, determines which priority in the received packet is valid. In addition, the device determines the work mode (Fat AP or Fit AP) of the AP. Then the device selects a mapping table based on the preset information to perform priority mapping.

Overview

Feature	Description

Feature	Description
WMM Service	Configures the WMM service, including EDCA competition parameters, AC queue depth, and ACK policy.
QoS Packet Priority Mapping	Configures QoS packet priority mapping, including the QoS packet priority mapping table and priority mapping policy.

1.3.1 WMM Service

Configure the WMM service, including EDCA competition parameters, AC queue depth, and ACK policy.

Working Principle

WMM provides network services of different quality based on requirements. That is, it provides high-quality services for key data packets having high timeliness requirement and processes them preferentially, and assigns a low processing priority to common packets not having high timeliness requirement. According to the WMM standard, access data flows have four priorities, each representing a class. EDCA differentiates access capabilities of AC channels with different priorities, ensuring that air interface resources are allocated based on data flow priorities.

Enabling WMM

When the WMM service is enabled, the four-level priority queue is used for receiving and mapping. When the WMM service is disabled, the default priority queue is used for receiving and mapping.

EDCA Competitive Mechanism, AC Queue Depth, and NO ACK Policy

- EDCA competitive mechanism

EDCA parameters differentiate channel access capabilities of different priorities. Each AC has its own EDCA channel competition parameters. You can adjust EDCA parameters on a client or an AP based on requirements, so that the AC with a higher priority can start the backoff process earlier than other ACs and preferentially access the channel. Channel competition should be completed automatically by the hardware. The hardware will participate in channel competition after parameters such as the CWmin, CWmax, AIFSN, TXOP of each hardware queue are configured in the software.

You can choose to configure EDCA parameters on a client or an AP based on application requirements. The EDCA client mainly affects WMM competition parameters of a STA, and the EDCA radio mainly affects WMM competition parameters of an AP.

The QSTA configuration is managed and pushed by the QAP in a centralized manner. Channel competition parameters of the QAP and QSTA are independent. In most situations, the channel competition parameters of QAP can be slightly increased to ensure the competent channel control capability for the QAP. The QAP will notify EDCA parameter settings of the QAP through the EDCA Parameter Set IE of the beacon or Probe Response frame, and push the negotiated EDCA configuration to the QSTA through EDCA Parameter Set IE of the (Re)Association Response frame.

- AC queue depth

If the queue depth of packets of a certain priority is greater than the preset AC queue depth, subsequent packets are discarded. Otherwise, subsequent packets are added to the queue for processing.

- NO ACK policy

The NO ACK policy should be supported by both the recipient and sender. When the NO ACK policy is not supported for a queue, the NO ACK policy should be set in the DMA descriptor of each frame sent.

The NO ACK policy is used as an alternative for receiving confirmation (during wireless packet exchange) by using ACK packets in the environment with high communication quality and little interference. It helps to effectively improve the transmission efficiency. However, if the ACK packet for confirmation is not used and the communication quality is poor, the sender will not retransmit the packets even if the recipient has not received the packets, resulting in a higher packet loss rate.

1.3.2 QoS Packet Priority Mapping

Configure QoS packet priority mapping, including the QoS packet priority mapping table and priority mapping policy.

Working Principle

The priority mapping tables provided by the device correspond to priority mappings. Then a mapping table is selected based on the preset information to perform priority mapping, implementing end-to-end QoS for the entire network.

Packet Priority Mapping

On an IP network, IPv4 packets can carry the 802.1p priority, ToS priority, and Differentiated Services Codepoint (DSCP) priority.

For the preceding QoS priority types of wired packets, the device only needs to support 802.1p and DSCP priorities because the leftmost six bits in the ToS field correspond to the DSCP field. In addition to the preceding three priority types, the 802.11e priority is also available for wireless packets.

The device determines the packet trust mode or tag policy of an interface, that is, determines which priority in the received packet is valid. In addition, the device determines the work mode (centralized or local forwarding) of an AP. Then the device selects a mapping table based on the preset information to perform priority mapping.

1.4 Configuration

Configuration	Description and Command	
Configuring the WMM Service	(Mandatory) It is used to enable the WMM service.	
	wmm enable	Enables the WMM service.
	(Optional) It is used to configure competition parameters.	
	wmm edca-auto enable	Configures dynamic EDCA parameter adjustment.
	wmm edca-client	Configures EDCA parameters for the client.
	wmm edca-radio	Configures EDCA parameters for the AP.
Configuring QoS Packet Priority Mapping	(Optional) It is used to configure the priority mapping (mapping command for non-interworking versions).	
	wlan-qos map-table	Configures packet priority mapping of the WLAN.
	(Optional) It is used to configure the 802.11p QoS mapping policy mechanism (mapping command for interworking versions).	

Configuration	Description and Command	
	wmm dot1p enable	Enables 802.11p QoS mapping policy mechanism.
	wmm dot1p policy 1q	Configures how to apply the 802.11p QoS mapping policy mechanism for the AP.
	wmm dot1p tag	Configures the 802.1p priority.
	⚠ (Optional) It is used to configure the DSCP QoS mapping policy mechanism (mapping command for interworking versions).	
	wmm dscp enable	Enables DSCP QoS mapping policy mechanism.
	wmm dscp policy **outer-tunnel** **inner-tunnel**	Configures how to apply the DSCP QoS mapping policy mechanism for the AP.
	wmm dscp tag	Configures the DSCP priority.

1.4.1 Configuring the WMM Service

Configuration Effect

- Configure EDCA competition parameters for the client.
- Configure EDCA competition parameters for the AP.
- Configure the ACK policy.
- Configure the length of the priority queue.

Notes

- The parameter configuration takes effect after the WMM service is enabled.
- After dynamic EDCA parameter adjustment is enabled, the AP will dynamically adjust EDCA parameters. Custom configuration of EDCA parameters is not allowed.

Configuration Steps

↘ Enabling the WMM Service

- Mandatory.
- Run the **wmm enable radio** *radio-id* command in AP configuration mode to enable WMM for the Fit AP.
- When the WMM service is enabled, the four-level priority queue is used for receiving and mapping. When the WMM service is disabled, the default priority queue is used for receiving and mapping.

Command	**wmm enable radio** *radio-id*
Parameter Description	**radio** *radio-id*: Indicates that radio of the enabled/disabled WMM service is selected. The value range is from 1 to 48. This command is supported only on ACs.
Defaults	WMM is enabled by default
Command Mode	AP configuration mode for Fit APs

Usage Guide	When the WMM service is disabled, the default priority queue is used for receiving and mapping.

Configuring Dynamic EDCA Parameter Adjustment

- Optional.
- Run the **wmm edca-auto enable radio** *radio-id* command to enable dynamic EDCA parameter adjustment in AP configuration mode.
- After dynamic EDCA parameter adjustment is enabled, the AP can dynamically adjust EDCA parameters based on the number of active users. If dynamic EDCA parameter adjustment is disabled, the AP uses the static EDCA parameters.

Command	**wmm edca-auto enable radio** *radio-id*
Parameter Description	**radio** *radio-id*: Specifies the radio on which dynamic EDCA parameter adjustment is configured. The value range is from 1 to 96. This parameter is supported only on the AC.
Defaults	Dynamic EDCA parameter adjustment is disabled.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	1. Dynamic EDCA parameter adjustment takes effect only when the WMM service is enabled. 2. If static EDCA parameters are configured and dynamic EDCA parameter adjustment is enabled, the dynamic EDCA policy is used preferentially. 3. If dynamic EDCA parameter adjustment is disabled, the AP uses the static EDCA parameters. 4. Dynamic EDCA parameter adjustment is enabled by default. When dynamic EDCA parameter adjustment is disabled, EDCA parameters cannot be manually configured. To customize EDCA parameters, disable dynamic EDCA parameter adjustment.

Configuring EDCA Parameters for the Client

- Optional.
- By default, EDCA parameters on the client are as follows.

AC	aifs	cwmin	cwmax	txop
back-ground	7	4	10	0
best-effort	3	4	10	0
video	2	3	4	94
voice	2	2	3	47

- After EDCA parameters on the client and AC queue depth are set, packets are processed based on the settings. Otherwise, packets are processed based on default settings.

Command	**wmm edca-client** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin** [*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **length** [*queue-length*] } **radio** *radio-id*
Parameter Description	**back-ground**: Sets the background queue. **best-effort**: Sets the BE queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **aifsn** *aifsn-value*: Sets the AIFSN. The value range is from 1 to 15. **cwmin** *cwmin-value*: Sets the CWmin value. The value range is from 0 to 1515. **cwmax** *cwmax-value*: Sets the CWmax value. The value range is from 0 to 1515.

	txop *txop-value*: Sets the TXOP value. The value range is from 0 to 255, in the unit of 32 μs. **length** *queue-length*: Sets the AC queue length. The value range is from 1 to 255. The default is 255. **radio** *radio-id*: Sets the ID of the radio of EDCA parameters on the client. The value range is from 1 to 96. This command is supported only on ACs. Whether this parameter is supported and the value range of this parameter depend on the product version. **no**: Restores default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The CWmax value must be greater than the CWmin value. Otherwise, a configuration error message is displayed. When dynamic EDCA parameter adjustment is enabled, EDCA parameters cannot be configured for a client.

Configuring EDCA Parameters for the AP

- Optional.
- By default, the EDCA parameters on the AP side are as follows:

AC	aifs	cwmin	cwmax	txop
back-ground	7	4	10	0
best-effort	3	4	6	0
video	1	3	4	94
voice	1	2	3	47

- After non-default settings of EDCA parameters on the AP and NO ACK policy are used, packets are processed based on the settings. Otherwise, packets are processed based on the default settings.
- A smaller AIFS of a high-priority AC means earlier backoff. Smaller CWmin and CWmax values mean a shorter backoff period. TXOP limit allows an AC to transmit multi-frame packets on it continuously within the SIFS interval after the AC preempts a transmission opportunity. A larger TXOP limit means a lower packet conflict rate and a lower waste of air interface resources.

Command	**wmm edca-radio** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin** [*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **noack** } **radio** *radio-id*
Parameter Description	**back-ground**: Sets the background queue. **best-effort**: Sets the BE queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **aifsn** *aifsn-value*: Sets the AIFSN. The value range is from 1 to 15. **cwmin** *cwmin-value*: Sets the CWmin value. The value range is from 0 to 1515. **cwmax** *cwmax-value*: Sets the CWmax value. The value range is from 0 to 1515. **txop** *txop-value*: Sets the txop value. The value range is from 0 to 255, in the unit of 32 μs. **noack**: Indicates that the **no ack** policy is enabled. The **no ack** policy is disabled by default. **radio** *radio-id*: Sets the ID of the radio of EDCA parameters on the client. The value range is from 1 to

	96. This command is supported only on ACs. Whether this parameter is supported and the value range of this parameter depend on the actual product version. **no**: Restores default settings.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The CWmax value must be greater than the CWmin value. Otherwise, a configuration error message is displayed. When dynamic EDCA parameter adjustment is enabled, EDCA parameters cannot be configured.

Verification

- You can run the **show run** or **show ap-config run** command on the Fit AP to display the WMM service status. The EDCA parameters of the client that already take effect and the EDCA parameters used for the AP are not displayed when they adopt default settings.
- Obtain packets to display EDCA parameters of the client.

Configuration Example

Configuring WMM Service Parameters

Configuration Steps	● Enable or disable the WMM service on the AP. ● Configure EDCA parameters for the client. ● Configure EDCA parameters for the AP. ● Enable dynamic EDCA parameter adjustment on Radio 1 of AP002.

	`Hostname # configure terminal`
	`Hostname(config)# ap-config AP001`
	`Hostname(config-ap)# wmm enable radio 1`
	`Hostname(config-ap)# wmm edca-client voice aifsn 2 cwmin 2 cwmax 3 txop 50 radio 1`
	`Hostname(config-ap)# wmm edca-radio voice aifsn 1 cwmin 1 cwmax 3 txop 50 radio 1`

Verification	Run the **show run** or **show ap-config run** command on the Fit AP to display EDCA parameters of the client that already take effect and the EDCA parameters used for the AP. These parameters are not displayed when they adopt default settings.

Common Errors

- If no radio exists, an error message is displayed.
- The performance is affected if EDCA parameters are improperly configured. For example, if the value of a low-priority parameter is higher than that of a high-priority parameter, the performance of the high priority is affected.

1.4.2 Configuring QoS Packet Priority Mapping

Configuration Effect

- Configure packet priority mapping for the WLAN.
- Configure 802.11p mapping policy mechanism.
- Configure DSCP mapping policy mechanism.

Notes

- Packet priority mapping takes effect after the WMM service is enabled.

Configuration Steps

By default, the mapping from DSCP priorities to 802.11e priorities is as follows.

DSCP	802.11e
0-7	0
16-23	1
24-31	2
8-15	3
32-39	4
40-47	5
48-55	6
56-63	7

By default, the mapping from 802.11e priorities to DSCP priorities is as follows.

802.11e	DSCP
0	0
3	8
1	16
2	24
4	32
5	40
6	48
7	56

Configuring Packet Priority Mapping for the WLAN

- Optional.
- Unless otherwise specified, packet priority mapping of the WLAN must be configured on all APs.

After the priority mapping and the value corresponding to the mapping table are set, packets are processed based on the settings. Otherwise, packets are processed based on the default settings.

Command	**wlan-qos map-table** { **dot11e-inner-dscp** | **dot11e-tunnel-dscp** | **dscp-dot11e** } **import** *import-tag-value* **export** *export-tag-value*

Parameter Description	**dot11e-inner-dscp**: Sets priority mapping from 802.11e priorities to internal DSCP priorities. **dot11e-tunnel-dscp**: Sets priority mapping from 802.11e priorities to CAPWAP DSCP priorities. **dscp-dot11e**: Sets priority mapping from DSCP priorities to 802.11e priorities. **import** *import-tag-value*: Sets the priority of the incoming original packet. **export** *export-tag-value*: Sets the priority of the outgoing packet. **no**: Restores default settings.
Command Mode	WLAN configuration mode
Usage Guide	This command is for non-interworking versions. The parameter configuration takes effect only when the WMM service is enabled.

Enabling the 802.11p Mapping Policy Mechanism

- Optional.
- Unless otherwise specified, the DSCP mapping policy mechanism must be disabled on all APs.

When the 802.11p QoS policy mechanism is enabled, the mapping table related to 802.11p QoS is used. When the 802.11p QoS policy mechanism is disabled, the default mapping policy is adopted.

Command	**wmm dot1p enable radio** *radio-id*
Parameter Description	**radio** *radio-id*: Indicates the ID of the radio of the enabled/disabled 802.11p mapping policy mechanism. The value range is from 1 to 96. This command is supported only on ACs. Whether this parameter is supported and the value range of this parameter depend on the product version. **no**: Restores default settings.
Command Mode	AP configuration mode for fit APs
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled.

Applying the 802.11p QoS Mapping Policy Mechanism for the AP

- Optional configuration.
- Unless otherwise specified, the 802.11p mapping policy mechanism application shall be performed on all APs.

Determine how to obtain the 802.1Q priority based on the 802.11p mapping policy mechanism applied by the AP.

Command	**wmm dot1p policy 1q** [*1q-policy-value*] **radio** *radio-id*
Parameter Description	**1q** *1q-policy-value*: Applies the 802.11p mapping policy mechanism. The value is 0 or 1. The default value is 0. **radio** *radio-id*: Applies the radio of the 802.11p mapping policy mechanism. The value range is from 1 to 96. This command is supported only on ACs. Whether this parameter is supported and the value range of this parameter depend on the product version. **no**: Restores default settings.
Command Mode	AP configuration mode for fit APs

Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. Applying the 802.11p QoS mapping policy mechanism takes effect only when the 802.11p mapping policy mechanism is enabled.

Configuring the 802.1p Priority

- Optional.
- Unless otherwise specified, the 802.1p priority must be configured on all APs.

Command	**wmm dot1p tag** [*tag-value*] { **back-ground** | **best-effort** | **video** | **voice** } **radio** *radio-id*
Parameter Description	**tag** *tag-value*: Sets the 802.1p priority. The value range is from 0 to 7. The default values for **best-effort**, **back-ground**, **video**, and **voice** are 0, 2, 4, and 6 respectively. **back-ground**: Sets the background queue. **best-effort**: Sets the BE queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **radio** *radio-id*: Indicates the ID of the radio of the enabled/disabled 802.11p mapping policy mechanism. The value range is from 1 to 96. This command is supported only on ACs. Whether this parameter is supported and the value range of this parameter depend on the product version. **no**: Restores default settings.
Command Mode	AP configuration mode for fit APs
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The 802.1p priority configuration takes effect only when the 802.11p QoS mechanism is enabled.

Enabling DSCP QoS Mapping Policy Mechanism

- Optional.
- Unless otherwise specified, the DSCP mapping policy mechanism must be disabled on all APs.

When the DSCP policy mechanism is enabled, the mapping table related to the DSCP priority is used. When the DSCP policy mechanism is disabled, the default mode is adopted for mapping.

Command	**wmm dscp enable radio** *radio-id*
Parameter Description	**radio** *radio-id*: Indicates that ID of the radio of the enabled/disabled DSCP QoS mapping policy mechanism. The value range is from 1 to 96. This command is supported only on ACs. Whether this parameter is supported and the value range of this parameter depend on the product version. **no**: Restores default settings.
Defaults	The DSCP mapping policy mechanism is disabled by default.
Command Mode	AP configuration mode
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled.

Applying the DSCP Mapping Policy Mechanism for the AP

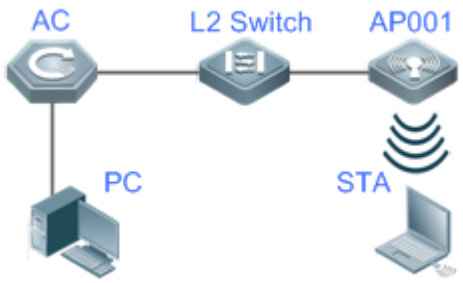
- Optional.
- Unless otherwise specified, the DSCP mapping policy mechanism must be performed on all APs.

Determine how to obtain the DSCP priority based on the DSCP mapping policy mechanism applied by the AP

Command	**wmm dscp policy outer-tunnel** *outer-tunnel-value* **inner-tunnel** *inner-tunnel-value* **radio** *radio-id*
Parameter Description	**outer-tunnel** *outer-tunnel-value*: Applies the DSCP mapping policy mechanism for the outer tunnel header. The value is 0 or 1. The default value is 0. **Inner-tunnel** *inner-tunnel-value*: Applies the DSCP mapping policy mechanism for the inner tunnel header. The value is 0 or 1. The default value is 0. **radio** *radio-id*: Applies the radio of the DSCP mapping policy mechanism. The value range is from 1 to 96. This command is supported only on ACs. **no**: Restores the default settings.
Command Mode	AP configuration mode for Fit APs
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. Applying the DSCP mapping policy mechanism takes effect only when the DSCP mechanism is enabled.

Configuring the DSCP Priority

- Optional.
- Unless otherwise specified, the DSCP priority must be configured on all APs.



Command	**wmm dscp tag** *tag-value* { **back-ground** | **best-effort** | **video** | **voice** } **radio** *radio-id*
Parameter Description	**tag** *tag-value*: Sets the DSCP priority. The value range is from 0 to 63. The default values for **best-effort**, **back-ground**, **video**, and **voice** are 0, 16, 32, and 48 respectively. **back-ground**: Sets the background queue. **best-effort**: Sets the BE queue. **video**: Sets the video queue. **voice**: Sets the voice queue. **radio** *radio-id*: Indicates the ID of the radio of the enabled/disabled DSCP mapping policy mechanism. The value range is from 1 to 96. This command is supported only on ACs. Whether this parameter is supported and the value range of this parameter depend on the product version. **no**: Restores default settings.
Command Mode	AP configuration mode for fit APs
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The DSCP priority takes effect only when the DSCP mechanism is enabled.

Verification

- You can run the **show run** or **show ap-config run** command on the Fit AP to display the mapping configuration. When the default configuration is adopted, no configuration is displayed in the command output.
- Obtain packets to check whether priority mapping is correct.

Configuration Example

Configuring QoS Packet Priority Mapping

Scenario	
	Connect the AC to the Layer 2 switch, and connect AP001 to the AC through the Layer 2 switch. Configure WLAN1 on AP001. Connect STA to AP001 in wireless mode, and connect the PC to the AC in wired mode.
Configuration Steps	Perform the following configuration on the AC: ● Enter the specified WLAN configuration mode. ● Configure packet priority mapping.

	`Hostname# configure terminal`
	`Hostname(config)# wlan-config 1`
	`Hostname(config-wlan)#wlan-qos map-table dot11e-tunnel-dscp import 7 export 50`
	`Hostname(config-wlan)# end`

Verification	Import AC_VO priority traffic from the STA to PC by using IxChariot, obtain packets on the air interface, and display the priority at the wireless end. Then obtain packets from the AC to the PC using a packet obtaining tool to display the priority at the wired end.

Common Errors

- The WMM service is disabled.

1.5 Monitoring

Debugging

Debugging occupies system resources, so disable it immediately if not required.

Command	Description
debug wlan-qos-vsp	Debugs WMM VSP.
debug wlan-qos-cli	Debugs WMM CLI.
debug wlan-qos-map	Debugs WMM mapping.

1 Configuring Web App

1.1 Overview

Web App processes and responds to Hypertext Transfer Protocol (HTTP) packets to ensure information exchange outside a device. It can process the mapping relationship for accurate projection.

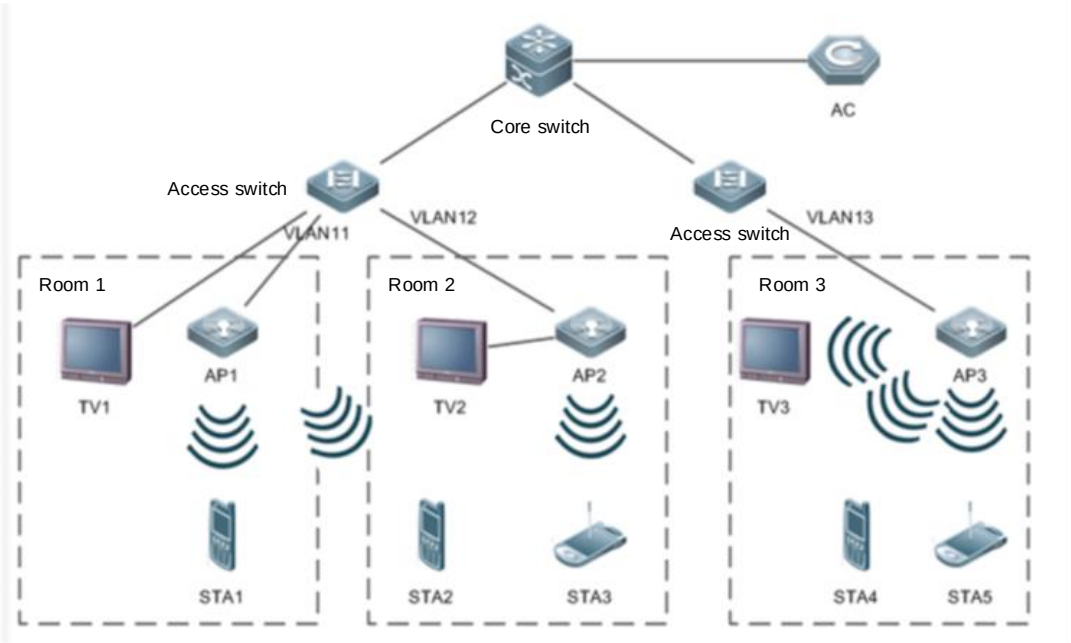
Web App provides the following function:

- Basic service configuration: Web App can be enabled or disabled, the used port can be configured, and HTTP packets can be received and handled.

Protocols and Standards

- N/A

1.2 Applications



Application	Description
Accurate Projection	The deployed TV and station (STA) that accesses a wireless network are deployed on a Layer 2 or Layer 3 network. The STA scans the QR code or enters the website address to access the projection service page and sends a request packet to Web App to add the mapping relationship. Web App receives and processes the packet and sends the mapping relationship to the Bonjour or Digital Living Network Alliance (DLNA) gateway to add the STA-TV mapping relationship.

1.2.1 Accurate Projection

Scenario

The deployed TV and the STA that accesses a wireless network are on deployed on a Layer 2 or Layer network. The STA scans the QR code or enters the website address to access the projection service page and sends a request packet to Web App to add the mapping relationship. Web App receives and processes the packet and sends the mapping relationship to the Bonjour or DLNA gateway to add the STA-TV mapping relationship. As shown in Figure 1-1, the TV can access the network through a wired port on the switch, a wired port on an access point (AP), or the wireless network of an AP. The STA accesses the network through an AP. The STA and TV may be associated with an AP in the same room or APs in different rooms.

Figure 1-1 Network Topology for Projection

Deployment

- Enable the Web App function in global configuration mode.
- Enable the Bonjour gateway function in global configuration mode and enable Bonjour fixed projection.
- Enable the DLNA gateway function in global configuration mode and set the DLNA working mode to the accurate state.
- Scan the QR code of the TV with the mobile phone to complete mapping. Then you can enjoy the accurate projection service.

1.3 Features

Basic Concepts

Bonjour Gateway

A Bonjour gateway is used to manage clients and servers that support the Bonjour protocol so that the Bonjour protocol can be applied to large-scale networks.

DLNA Gateway

A DLNA gateway is used to manage clients and servers that support the DLNA specifications so that the DLNA projection service can be applied to wireless networks.

Overview

Feature	Description
Configuring Basic Services	Enables or disables the Web App function and configures the port used by the Web App function.

1.3.1 Configuring Basic Services

The basic service configuration includes enabling or disabling the Web App function and configuring the used port.

Working Principle

After the Web App function is enabled, the device can receive and process HTTP packets.

The device supports binding requests of accurate projection. A STA scans the QR code to access the Uniform Resource Locator (URL). The URL contains the IP address and port number of the access controller (AC) to be accessed, access path, and name and media access control (MAC) address of the TV to be bound. Web App will parse the URL, obtain field information to generate binding information on the device, and push the binding result to the STA.

URL format: http://<HOSTNAME>:<PORT>/touping?tvmac=<H.H.H>&tvname=<TV-NAME>

Example: http://172.30.103.252:8080/touping?tvmac=009e.c8cf.2255&tvname=abc

URL field description:

172.30.103.252: Indicates the IP address or domain name of the device. Ensure that the STA can access the address or domain name.

8080: Indicates the port number of the accessed device. The port number is configured by running the **webapp port** command.

009e.c8cf.2255: Indicates the MAC address of the bound TV.

abc: Indicates the name of the bound TV.

1.4 Configuration

Configuration	Description and Command	
Configuring Basic Services	⚠ (Mandatory) It is used to enable the Web App function.	
	webapp enable	Enables the Web App function.
	⚠ (Optional)	
	webapp port	Configures the port used by the Web App function.

1.4.1 Configuring Basic Services

Configuration Effect

- After the Web App function is enabled, the device can receive and process HTTP packets.
- Web App modifies the port number and uses the specific port number for packet sending and receiving.

Notes

- N/A

Configuration Steps

↘ **Enabling Web App**

- Mandatory.

Command	**webapp enable**
Parameter Description	N/A
Defaults	The Web App function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Port Used by the Web App

- Optional.

Command	**webapp port** *port*
Parameter Description	*port*: Indicates the port number. The value range is from 1024 to 65535.
Defaults	8080
Command Mode	Global configuration mode
Usage Guide	Plan application port numbers of the device and on a network to prevent service unavailability due to port number conflicts. Run the **show tcp port** and **show ip udp** commands on the device to display the port usage. The port can be configured only when the Web App service is disabled.

Verification

- Run the **show running-config** or **show webapp status** command to display the Web App configuration.

Configuration Example

Enabling Web App

Configuration Steps	• Enter the global configuration mode. • Enable the Web App function.

	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#webapp enable`

Verification	• Check whether the Web App function is enabled.
	`Hostname#show run | in webapp`
	`webapp enable`

Configuring the Port Used by the Web App

Configuration Steps	• Enter the global configuration mode. • Set the port used by Web App to 8192.

	`Hostname#configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)#webapp port 8192`

Verification	Check whether the port is configured successfully.
	`Hostname#show run | in webapp`
	`webapp enable`
	`webapp port 8192`

Common Errors

N/A

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show webapp status	Displays the Web App status information.

Debugging

N/A

Configuring WLAN Distributed System

1. Configuring WDS
2. Configuring Leveled AC Configuration Synchronization

1 Configuring WDS

1.1 Overview

The Wireless Distribution System (WDS) connects multiple access points (APs) in wireless bridging or relay mode to interconnect distributed networks and extend wireless signals.

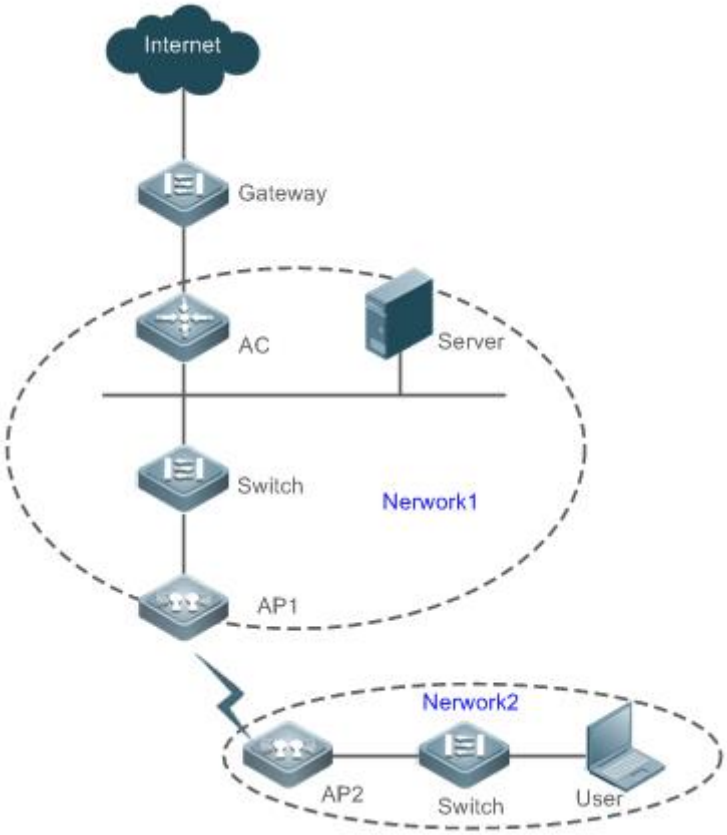
The WDS can work in either of the two following modes:

- Root bridge mode: Wired interfaces connect to wired networks, and wireless interfaces are used as wireless bridges to connect to those in non-root-bridge mode.
- Non-root-bridge mode: Wired interfaces connect to wired networks, and wireless interfaces are used as wireless bridges to connect to those in root bridge mode.

1.2 Applications

Application	Description
Static WDS Bridging	Two separate networks are interconnected through WDS bridging.
Mobile WDS Bridging	A mobile network is interconnected to a statically deployed network through WDS bridging.
Automatic Bridging of an AP Partner	Wireless signals are extended through WDS bridging between the AP partner and common APs.

1.2.1 Static WDS Bridging



Scenario

Two separate networks are interconnected through bridging.

As shown in Figure 2-1, Network1 and Network2 are interconnected through WDS bridging by AP1 and AP2.

- WDS bridging enables users on Network2 to access the server on Network1.
- WDS bridging also enables users on Network2 to access the Internet.

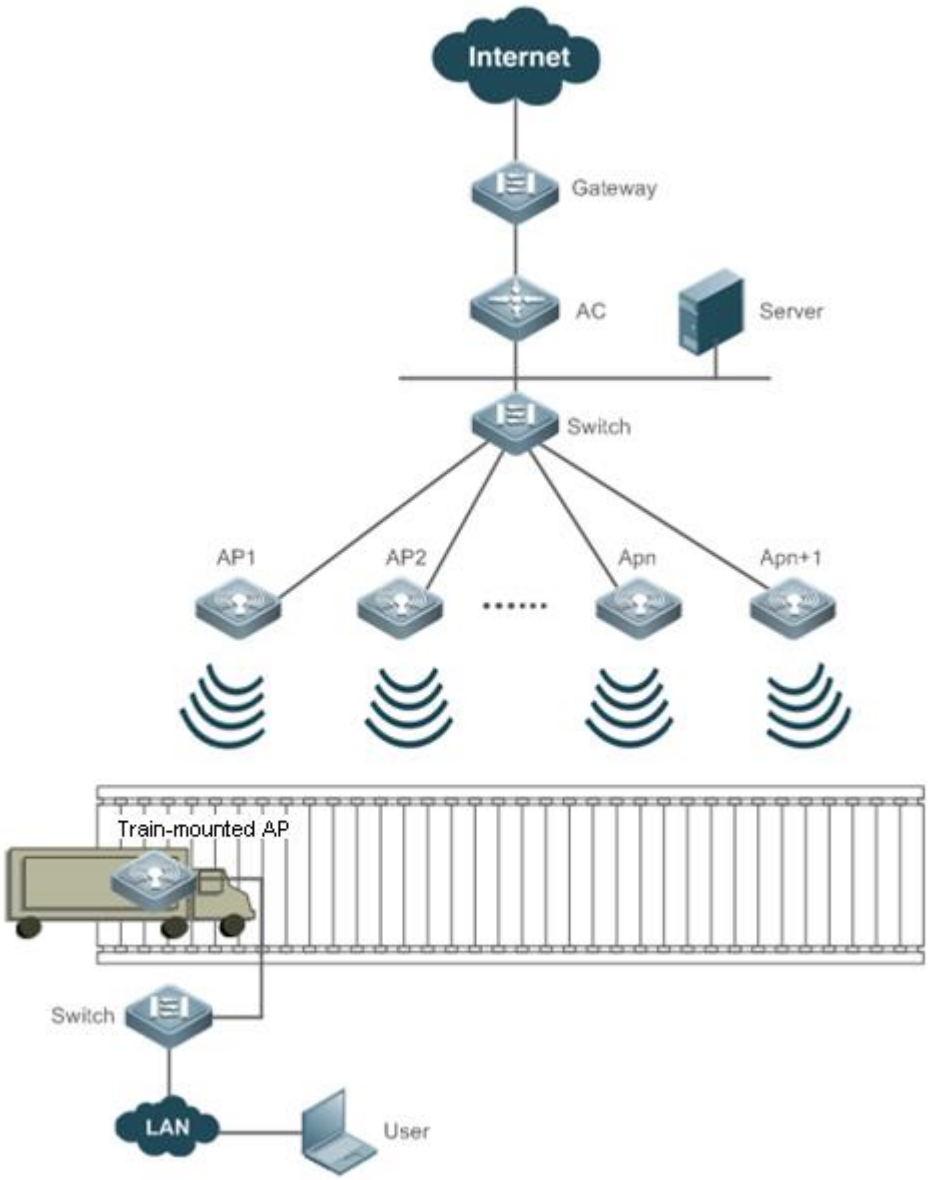
Figure 2-1

Remarks	AP1 is a root bridge and AP2 is a non-root bridge.

Deployment

- WDS bridging is Layer 2 bridging.
- WDS bridging bridges multiple VLANs transparently.

1.2.2 Mobile WDS Bridging



Scenario

A mobile network is interconnected to a static network through WDS bridging.

As shown in Figure 2-2, networks are interconnected through WDS bridging between the train-mounted AP and the APs outside the train (AP1 to AP*n*+1).

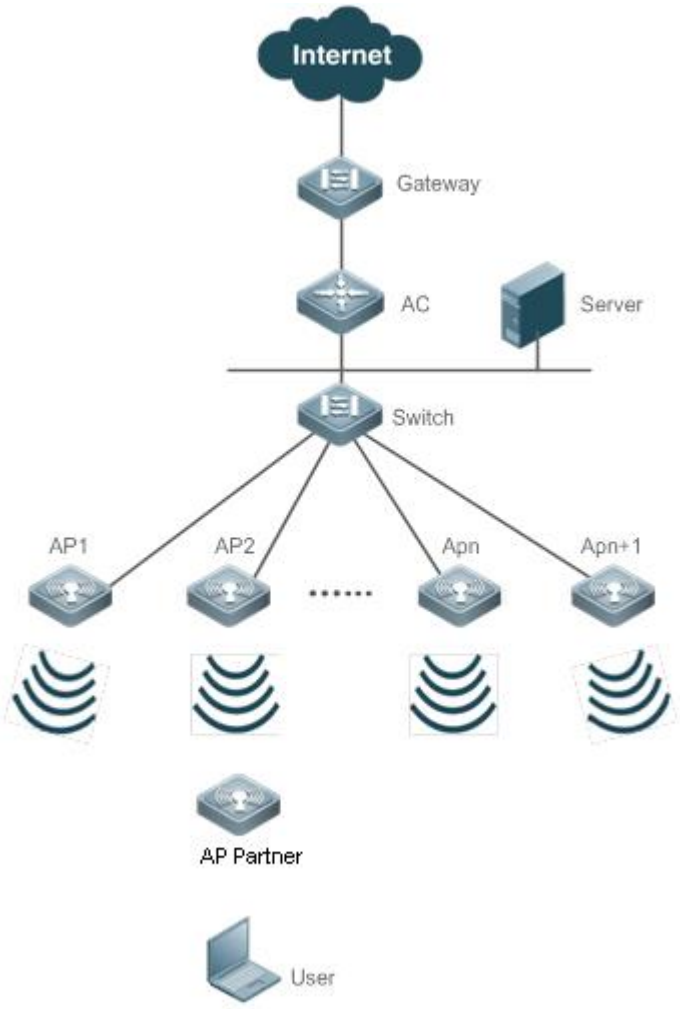
- When the train is advancing, users in the train can access the server through bridging.
- When the train is advancing, users in the train can access the Internet through bridging.

Figure 2-2

Remarks	AP1 to AP*n*+1 are root bridges. The train-mounted AP is a non-root bridge.

Deployment

- When the train is advancing, the non-root-bridge of WDS bridging can roam and switch to a root bridge.
- WDS bridging is Layer 2 bridging.
- WDS bridging can be used to transparently data from multiple VLANs.



1.2.3 Automatic Bridging of an AP Partner

Scenario

An AP partner is used to extend wireless signals.

As shown in the Figure 2-3, wireless signals are extended through bridging between the AP partner and common APs.

Figure 2-3

Deployment

- The AP partner is used to achieve a large coverage of wireless signals.
- The AP partner uses zero-configuration.
- When automatic bridging is configured, the AP partner automatically connects to the network.

1.3 Features

Basic Concepts

Root Bridge

A root bridge is the root node in WDS bridging. It allows the access of a non-root bridge to establish WDS bridging.

Non-root Bridge

A non-root bridge is a non-root node in WDS bridging. It proactively accesses the root bridge to establish WDS bridging based on user configuration.

Features

Feature	Description
Establishing WDS Bridging	Establishes WDS bridging.
Address Format of MAC Frames in the WDS	Describes the address format of MAC frames exchanged between the root bridge and non-root bridges in WDS.

1.3.1 Establishing WDS Bridging

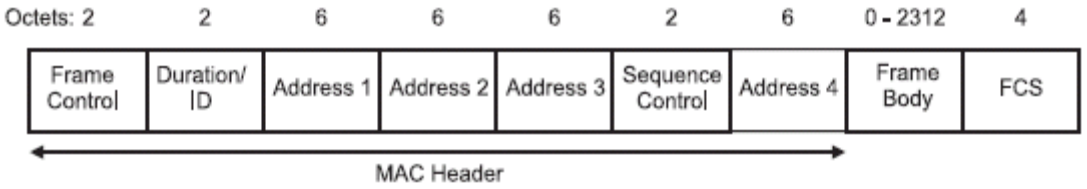
Establish WDS bridging.

Working Principle

Each AP is a Basic Service Set (BSS). Each has a BSSID (typically the MAC address of an AP). An AP regularly broadcasts Beacon frames that contain the SSID (name of a Wi-Fi network) and BSSID, and STAs listen to the Beacon frames by scanning. If the SSID of a Beacon frame is the same as the network name preset by a STA, the STA connects to the AP to access the network. If the STA listens to Beacon frames from multiple APs, the STA selects one of the APs for access. That is, the STA connects to and associates with the selected AP by identifying the BSSID of the AP.

In the WDS, the root bridge will specify a BSS used for access of non-root bridges to establish bridging. Common STAs are not allowed to access the BSS. When the BSS exists, the root bridge will accept the access request of a non-root bridge. During access, the root bridge will provide a mechanism to determine whether to allow a non-root bridge to connect to a network.

A non-root bridge searches for accessible root bridges based on the configured BSSIDs or SSIDs. A mechanism will be provided to determine whether a root bridge with a specified BSSID or SSID is accessible. The root bridge will be connected if accessible. In this way, WDS bridging is established.



1.3.2 Address Format of MAC Frames in the WDS

This section describes the address format of MAC frames exchanged between a root bridge and a non-root bridge in WDS bridging.

Working Principle

In IEEE 802.11 standards, the format of MAC frames is defined for the wireless technology. The MAC header contains four address fields.

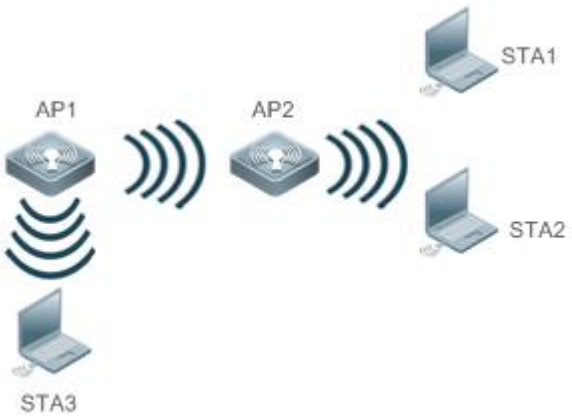


Figure 2-4

Based on transmission modes, 802.11 MAC frames can use the three-address or four-address format. The MAC frames in three-address format are transmitted between APs and STAs; while the MAC frames in four-address format are transmitted between APs.

As shown in Figure 2-5, when STA1 communicates with STA2, STA1 sends a MAC frame with three address fields of AP2, STA1 and STA2 to AP2 (See STA1->AP2 in the table). After receiving the MAC frame, AP2 forwards it to STA2, with three address fields changed into the MAC addresses of STA2, AP2 and STA1 (see AP2->STA2 in the table). When STA1 communicates with STA3, AP2 needs to forward the MAC frame received from STA1 to AP 1. The three-address format is changed to a four-address format, with the MAC addresses of AP2, AP1, STA3, and STA1 filled (see Figure 2-5). After receiving the frame, AP1 forwards it to STA3 and changes the four-address format back to a three-address format.

Figure 2-5

Transmission Mode	Address 1	Address 2	Address 3	Address 4
STA1 -> AP2	RA = AP2	TA = STA1	DA = STA2	N/A
AP2 -> STA2	RA = STA2	TA = AP2	SA = STA1	N/A
AP2 -> AP1	RA = AP1	TA = AP2	DA = STA3	SA = STA1

1.4 Configuration

Configuration	Description and Command	
Configuring WDS Basic Functions	(Mandatory) It is used to establish WDS bridging.	
	station-role root-bridge bridge-wlan	Configures a root bridge.

	station-role non-root-bridge	Configures a non-root bridge.
	parent	Specifies a root bridge for a non-root bridge.
	(Mandatory) If a non-root bridge works in Fit AP mode, it is used for WDS pre-configuration.	
	wds pre-config	Pre-configures a Fit non-root bridge.
	(Mandatory) If the non-root configuration is to be modified on the AC, it is used to submit or delete the ineffective WDS commands.	
	wds config	Submits or clears ineffective configuration of non-root bridges.
	(Optional) It is used to configure WDS parameters or enable the bridge coverage.	
	bridge roam-threshold	Configures roaming thresholds of a non-root bridge.
	bridge with-client	Configures bridge coverage.
	bridge vlan	Creates a bridge VLAN.
	bridge security	Configures bridge encryption on a non-root bridge.
	wds head-chansecurity enable	Sets whether to encrypt the head and tail channels on a non-root bridge.
	wds ctrl eth	Sets whether to control the wired interface on the non-root bridge.
	wds-mode enable	Enables WDS bridge mode.
	autowds	Enables automatic bridging of an AP partner.

1.4.1 Configuring WDS Basic Functions

Configuration Effect

- Configure WDS bridging.

Notes

- In WDS application environments, the Multiple Spanning Tree Protocol (MSTP) function must be enabled to prevent potential network loops.
- The Address Resolution Protocol (ARP) agent must be disabled.
- The WDS configuration commands can be used for establishing bridging only. They must be used with other commands to build a test environment, such as the commands for BBS creation or wireless interface configuration.
- In WDS, Fit APs need to support Control and Provisioning of Wireless Access Points (CAPWAP) through the Bridge-Group Virtual Interface (BVI) by default.

Configuration Steps

Configuring the WDS Mode

- Mandatory.
- Configure the WDS bridge mode on ACs for Fit APs.
- Run the **wds-mode enable** command to configure an AP to work in WDS bridge mode.

Command	**wds-mode {enable | disable}**
Parameter Description	**enable**: Enables the WDS bridge mode. **disable**: Disables the WDS bridge mode.
Defaults	disabled
Command Mode	AP configuration mode on the AC
Usage Guide	On the AC, run the **show ap-config wds-mode summary** command to check whether the corresponding AP has the WDS mode enabled. After this command is configured, the AP will automatically restart.

Configuring a Root Bridge

- Mandatory.
- Configure bridge coverage on ACs for Fit APs.
- Run the **station-role root-bridge bridge-wlan** *wlan-id* command to configure an AP working in WDS bridge mode.
- Specify a WLAN for the bridging BSS. If the WLAN has not been created, WDS bridging cannot work.

Command	**station-role root-bridge bridge-wlan** *wlan-id* [**radio** *radio-id*]
Parameter Description	**bridge-wlan** *wlan-id*: Specifies a WLAN for bridging. **radio** *radio-id*: Specifies the ID of a radio.
Defaults	The root AP mode means the regular AP mode but not the bridging mode.
Command Mode	AP configuration mode on the AC
Usage Guide	N/A

Configuring a Non-Root Bridge

- Mandatory.
- Configure bridge coverage on ACs for Fit APs.
- On a non-root bridge, you must specify a radio to work in non-root bridge mode.
- Run the **station-role non-root-bridge** command to configure an AP working in non-root bridge mode of WDS bridging.
- A non-root bridge starts to establish WDS bridging only after a destination root bridge is specified.

Command	**station-role non-root-bridge** [**radio** *radio-id*]
Parameter Description	**radio** *radio-id*: Specifies the ID of a radio.
Defaults	The root AP mode means the regular AP mode but not the bridging mode.

Command Mode	AP configuration mode on the AC
Usage Guide	The configurable WLAN quantity varies with the product model.

Specifying a Root Bridge for a Non-root Bridge

- Mandatory.
- Configure bridge coverage on ACs for Fit APs.
- Specify the BSSID or SSID to determine the root bridge.
- Specifying the BSSID of a root bridge, which is applicable to a static root bridge.
- Specifying the SSID of a root bridge. The non-root roaming function is enabled to select the root bridge with the best signals for access.
- Run the **parent** { **mac-address** *HHHH.HHHH.HHHH* | **ssid** *ssid* } [**channel** *channel* **chan-width**] command to specify the BSSID or SSID of a root bridge to be accessed by a non-root bridge.

Command	**parent** { **mac-address** *HHHH.HHHH.HHHH*	**ssid** *ssid* } [**radio** *radio-id*]
Parameter Description	**mac-address** *HHHH.HHHH.HHHH*: Specifies the BSSID of a root bridge for static bridging. **ssid** *ssid*: Specifies the SSID of a root bridge for roaming. **radio** *radio-id*: Specifies the ID of a radio.
Defaults	This function is not configured by default.
Command Mode	AP configuration mode
Usage Guide	Non-root bridges start searching root bridges after this command is executed. If WDS bridging is required, this command must be configured on the non-root bridges.

Configuring Roaming Thresholds of a Non-Root Bridge

- Optional.
- Configure bridge coverage on ACs for Fit APs.
- This command is configured to adjust roaming parameters.
- These thresholds are not required unless in special environments where roaming parameters need to be adjusted.
- Professionals are required to provide recommended values after measuring and analyzing the application environments. You are not advised to configure this command without the assistance of professionals; otherwise, the WDS roaming effect and even the use of WDS bridging will be affected.

Command	**bridge roam-threshold** *num1 num2 num3 num4* [*num5 num6 num7*] **radio** *radio-id*
Parameter Description	*num1*: Indicates the roaming start threshold.. The value range is from 0 to 90, and the default value is 40. *num2*: Indicates the scanning start threshold. The value range is from 0 to 30, and the default value is 15. *num3*: Indicates the roaming switch threshold. The value range is from 0 to 30, and the default value is 5. *num4*: Indicates the roaming switch time threshold. The value range is from 0 to 30, and the default value is 5. *num5*: Sets the roaming start upper threshold. The value range is from 0 to 90.

	num6: Sets the roaming switch upper threshold. The value range is from 1 to 30. *num7*: Sets the roaming pre-linking lower threshold. The value range is from 0 to 90. **radio** *radio-id*: Specifies the ID of a radio.
Defaults	This function is enabled by default.
Command Mode	AP configuration mode
Usage Guide	These thresholds are not required unless in special environments where roaming parameters need to be adjusted.

Configuring Bridge Encryption on a Non-Root Bridge

- Optional.
- Configure bridge coverage on ACs for Fit APs.
- This command is configured to adjust encryption parameters.
- This configuration is required only when bridging is required for accessing an encrypted network.
- The encryption parameters must be configured the same as those of the encrypted network to be accessed; otherwise, bridging may fail.

Command	**bridge security radio** *num* { **rsn ciphers aes akm psk key** { **ascii** | **hex** } *key* | **wpa** { **ciphers aes akm psk key** { **ascii** | **hex** } *key* | **mix pwe** { **both** | **hnp** } **passphrase ascii** *key* | **personal pwe** { **both** | **h2e** | **hnp** } **passphrase ascii** *key* } | **wpa3** { **mix pwe** { **both** | **hnp** } **passphrase ascii** *key* | **personal pwe** { **both** | **h2e** | **hnp** } **passphrase ascii** *key* } }
Parameter Description	**radio** *num*: Indicates the number of a configured RF interface. **wpa | rsn**: Configures WPA or RSN authentication. **aes**: Configures AES encryption. **psk**: Configures PSK authentication. **ascii**: Specifies the ASCII format. **hex**: Specifies the hexadecimal format. *key*: When the ASCII format is selected, the value is a string of 8 to 63 ASCII characters. When the hexadecimal format is selected, the value has 64 hexadecimal characters. **mix**: Configures mixed WPA2/WPA3-Personal authentication. **pwe**: Configures the WPA3 SAE encryption mode. **both**: Configures both HnP and H2E for WPA3 SAE authentication. **hnp**: Configures HnP for WPA3 SAE authentication. **passphrase**: Sets a key for authentication **personal**: Configures WPA3-Personal authentication. **h2e**: Configures H2E for WPA3 SAE authentication.
Defaults	No encryption parameter is configured by default.
Command Mode	AP configuration mode
Usage Guide	The encryption parameters must be configured the same as those of the encrypted network to be accessed;

	otherwise, bridging may fail.

Creating or Deleting a Bridge VLAN

- Optional.
- This is configured only on ACs in Fit AP mode.
- If you need to create a VLAN independently on an AP, you must perform this configuration on the AC.

Command	**bridge vlan** *vid*
Parameter Description	*vid*: Indicates the ID of the VLAN to be created
Defaults	This function is not configured by default.
Command Mode	AP configuration mode
Usage Guide	Use this command to create a WDS VLAN in coordination with other VLAN creation commands.

Configuring Bridge Coverage

- Optional.
- In root bridge mode: Configure bridge coverage on ACs for Fit APs. In non-root bridge mode, configure bridge coverage on APs for Fit APs through pre-configuration.
- This command is optional if the bridge coverage function is not required for the WDS. This command is mandatory if the bridge coverage function is required.
- You are not advised to enable the coverage function in bridging mode, because it may affect bridging performance, especially when there are low-speed STAs connecting to the network.

Command	**bridge with-client{ enable** | **disable** } [**radio** *radio-id*]
Parameter Description	**enable**: Enables bridge coverage. **disable**: Disables bridge coverage. **radio** *radio-id*: Specifies the ID of a radio.
Defaults	Bridge coverage is disabled by default.
Command Mode	AP configuration mode
Usage Guide	You are advised to disable bridge coverage.

Configuring Head and Tail Channels in Non-root Bridge Mode

- Optional.
- It can be configured in non-root bridge mode when you need to change AP channels based on head and tail status in metro scenarios.
- After this command is configured, the non-root bridge will switch to the corresponding channel when the status of the non-root bridge mode changes.

Command	**wds head-chan** *num1* **tail-chan** *num2* [**radio** *radio-id*]

Parameter Description	*num1*: Indicates the head channel. *num2*: Indicates the tail channel. **radio** *radio-id*: Indicates the radio ID specified on the AC.
Defaults	This function is disabled by default.
Command Mode	AP configuration mode on the AC
Usage Guide	Only the non-root bridge needs to be configured with this command. For the non-root Fit AP, this command needs to be configured on the AC and committed. Whether this configuration is supported depend on the product version.

Configuring Whether to Control the Wired Interface in Non-root Bridge Mode

- Optional.
- It can be configured in non-root bridge mode when you need to control traffic through wired interfaces in metro scenarios.
- After this command is configured, if the non-root bridge is not connected to the root bridge through bridging, the wired interface will be disconnected to control traffic.

Command	**wds ctrl eth**
Parameter Description	N/A
Defaults	The function is disabled by default.
Command Mode	AP configuration mode on the AC
Usage Guide	Only the non-root bridge needs to be configured with this command. For the non-root Fit AP, this command needs to be configured on the AC. Whether this configuration is supported depend on the product version.

Pre-configuring a Fit Non-root Bridge

- Optional.

Command	**wds pre-config delete radio** *radio-id*
Parameter Description	**delete**: Deletes the pre-configuration. **radio** *radio-id*: Specifies the ID of a radio.
Defaults	N/A
Command Mode	AP configuration mode
Usage Guide	To exit bridging mode, run the **wds pre-config delete** command to delete the non-root configuration created during pre-configuration.

Clearing or Submitting Ineffective WDS Configuration

- Optional.

- Use this command to submit inactive commands.
- Changes in the configuration of non-root bridges on the AC cannot take effect immediately. To issue the changes, you must run the **wds config commit** command.

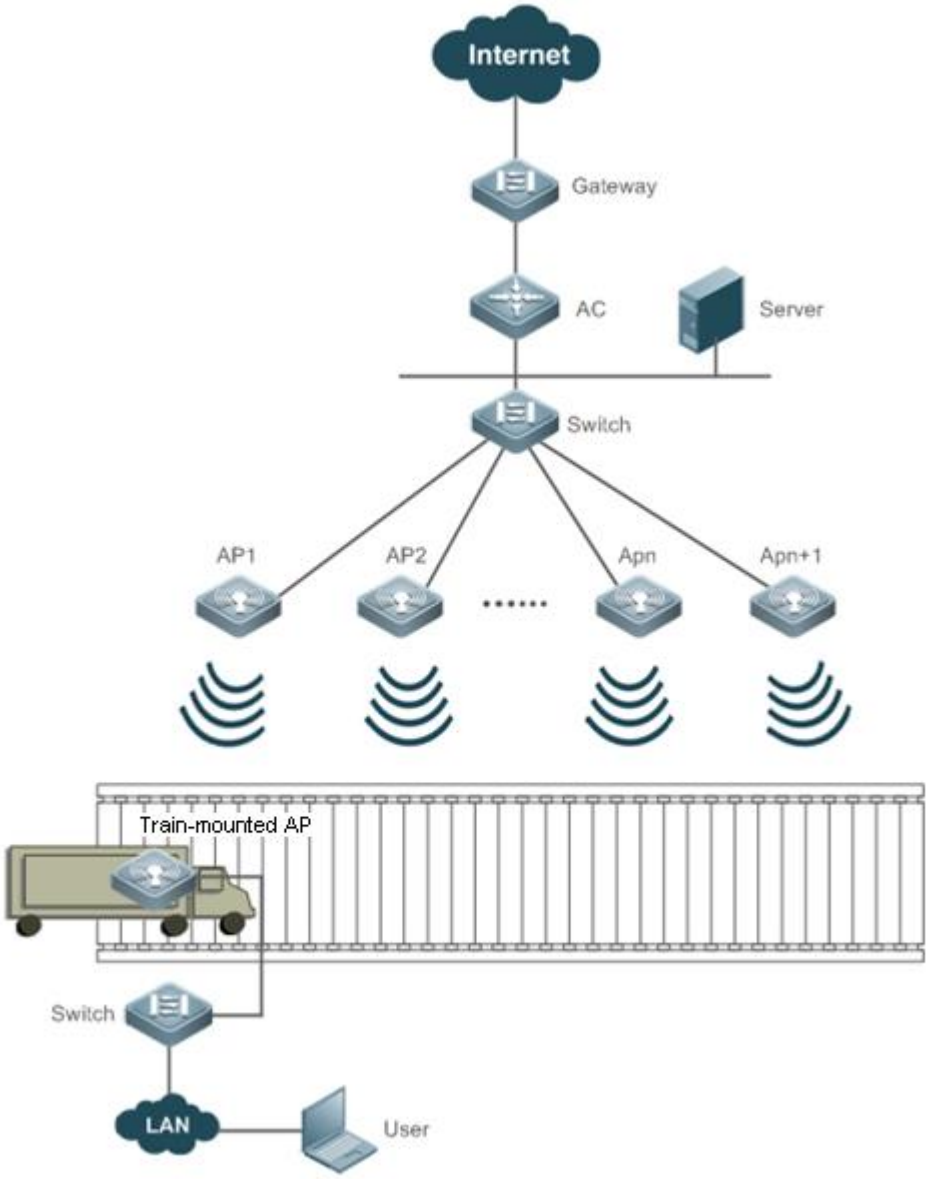
Command	**wds config**[**clear | commit**] **radio** *radio-id*
Parameter Description	**clear**: Clears ineffective WDS configuration. **commit**: Submits ineffective WDS configuration. Then bridging will be re-established. **radio** *radio-id*: Specifies the ID of a radio.
Defaults	N/A
Command Mode	AP configuration mode on the AC
Usage Guide	Whether this configuration is supported depend on the product version. If the AP is configured to work in non-root bridge mode on the AC or synchronized from the AP to non-root bridge mode, the corresponding radio will enter the WDS edit mode. In this case, most of the WDS commands will not take effect immediately. You can view the configuration using the **show ap-config wds-config** command. After confirming that the configuration is correct, use this command to commit and make it take effect.

Configuring Automatic Bridging on the AC

- Optional.
- It can be configured in AP-all configuration mode, AP group configuration mode, and AP configuration mode in ascending order of priority.
- After this command is configured, the root AP will automatically create the WDS configuration upon receiving requests from an AP partner (non-root bridge).

Command	**autowds**
Parameter Description	N/A
Defaults	This function is not configured by default.
Command Mode	AP configuration mode or AP group configuration mode
Usage Guide	This function does not need to be configured in normal non-root bridge mode, and need to be configured only when an AP partner is to be connected. Whether this configuration is supported depend on the product version.

Verification



Run the **show running-config**, **show dot11 wds-bridge-info**, or **show wds-mode** command on the AP to display the WDS information.

Run the **show ap-config running**, **show ap-config wds-bridge-info**, **show ap-config wds-config**, or **show ap-config wds-mode summary** command on the AC to display WDS information.

Configuration Example

WDS Roaming Scenario in Fit AP Mode

In this scenario, APs are required to establish a CAPWAP link through the BVI by default.

Scenario **Figure 2-6**	
Configuration Steps	● Configure the WLAN, VLAN, and channels for AP1 to AP*n*+1. Unified channel information is required. ● The preceding configuration is the same as that in common AP application scenarios. ● Configure the root bridge and specify a WLAN used for bridging. ● Configure the non-root bridge. The pre-configuration is used for the non-root bridge. Assume that the bridge WLAN is **ruijie-root** and the channel is 149 with the bandwidth of 40 MB.
ROOT **(AP1 - APn+1)**	`Hostname#configure terminal` `Hostname(config)#ap-config ap1`

	Hostname(config-ap)# station-role root-bridge bridge-wlan 1 radio 2
NONROOT (In-vehicle AP)	Hostname#configure terminal Hostname(config)#interface dot 2/0 Hostname(config-if-Dot11radio 2/0)# station-role non-root-bridge Hostname(config-if-Dot11radio 2/0)# parent ssid ruijie-root Hostname(config-if-Dot11radio 1/0)# wds pre-config create Hostname(config-if-Dot11radio 1/0)# exit Hostname(config)#ap-mode fit
Verification	Run the following command to display WDS bridging information.
In-vehicle AP	Hostname#show dot11 wds-bridge-info 1/0 WDS-MODE: NONROOT-BRIDGE MAC:00d0.f822.3304 WBI 1/0 ROOT 32d0.f822.3303
On the AC	Display WDS bridging information on the interface. Hostname#show ap-config wds-bridge-info summary Ap Name Mac Address Radio Station Role ---------- -------------- ----- ---------------- Ap-001 00d0.f822.3301 2 ROOT-BRIDGE Ap-002 00d0.f822.3304 2 NON-ROOT-BRIDGE Hostname# show ap-config wds-bridge-info Ap-001 radio 2 WDS-MODE: ROOT-BRIDGE BRIDGE-WLAN: Status OK WlanID 1, SSID ruijie_root, BSSID 32d0.f822.3303 WBI 1/0 NONROOT 00d0.f822.3304

Common Errors

N/A

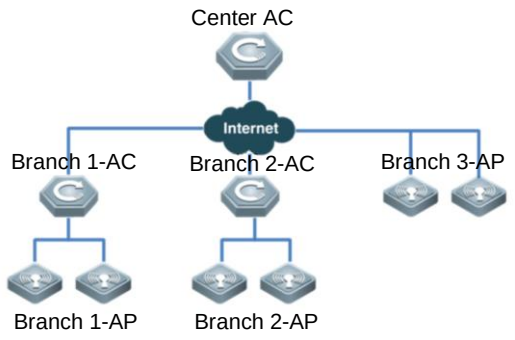
1.5 Monitoring

Displaying

Command	Description
show ap-config wds-mode summary	Displays whether WDS bridge is enabled on an AC.
show ap-config wds-mode summary	Displays the WDS bridge configuration on an AC.
show ap-config wds-bridge-info { **summary** |*ap-name* **radio** *radio-id* }	Displays WDS links on an AC.
show ap-config wds-config [*ap-name*]	Displays the WDS configuration on an AC.

1 Configuring Hierarchical AC Configuration Synchronization

1.1 Overview



In the hierarchical access controller (AC) scenario, wireless-related configurations on the center AC and branch ACs must be the same. The manual configuration requires a large number of resources and are prone to errors. The hierarchical AC configuration synchronization function ensures configuration synchronization between the center AC and branch ACs in the hierarchical AC scenario. The configuration can be synchronized through the configuration template or configuration commands. In the initial deployment phase of a hierarchical network, the center AC can use the configuration template to deliver the configurations to branch ACs uniformly. If the hierarchical network is deployed, configuration command synchronization can be performed for synchronization of configuration commands of access point (AP) groups associated with branch ACs and in AP configuration mode between the center AC and branch ACs.

Protocols and Standards

N/A

1.2 Applications

1.2.1 Scenario

Deployment

- Configure the AC planned for the headquarters as the center AC in hierarchical AC networking.
- Configure the ACs planned for the branches as the branch ACs in hierarchical AC networking.
- On the center AC and branch ACs, enable the wireless local area network (WLAN) hot standby function.
- On the center AC, add hot standby peers for Branch 1-AC and Branch 2-AC.
- On Branch 1-AC and Branch 2-AC, add the hot standby peer for the center AC.
- On the center AC and branch ACs, add the AP groups to which Branch 1-AP and Branch 2-AP belong to the hot standby instances of the corresponding branches.

- On the center AC, create two different configuration templates named **template1** and **template2**.
- In **template1**, add configuration commands delivered to Branch 1-AC. On Branch 1-AC, request **template1**.
- In **template2**, add configuration commands delivered to Branch 2-AC. On Branch 2-AC, request **template2**.

1.3 Features

Overview

Feature	Description
Configuring Configuration Template Synchronization	Synchronizes configuration commands in configuration templates of the center AC to branch ACs.
Configuring Configuration Command Synchronization	Synchronizes configuration commands of the AP groups associated with branch ACs in AP configuration mode between the center AC and branch ACs.

1.3.1 Configuring Configuration Template Synchronization

In the hierarchical AC scenario, create multiple configuration templates on the center AC. Based on the configuration command maintenance method provided by the configuration templates, create the template content. Then batch synchronize commands in the configuration templates of the center AC to the branch ACs.

Working Principle

A center AC can be configured with multiple configuration templates, and each center AC can map to multiple branch ACs. The methods for determining the configuration templates to be synchronized to the branch ACs are as follows:

1. The center AC applies different configuration templates to different branch ACs.

   After the configuration templates are created, the center AC configures different configuration templates for different branch ACs to batch synchronize configurations to all branch ACs that trigger configuration synchronization.

2. Different branch ACs request different configuration templates from the center AC.

   The center AC creates configuration templates and associates different configuration templates with different branch ACs. Branch ACs request the center AC to deliver configuration templates based on network deployment requirements. In this case, branch ACs can plan the network configuration flexibly.

On a hierarchical network with configuration templates applied, configuration template synchronization can be triggered in two modes:

1. Automatic mode

   The center AC automatically synchronizes configuration templates to branch ACs in the following scenarios:

   (1) Configuration template synchronization is deployed for the first time.

   (2) A connection is established between a branch AC and the center AC for the first time.

2. Manual mode

   After the configuration templates are modified, you can manually synchronize the configuration templates from the center AC to the branch ACs.

When configuration template synchronization is enabled, the execution result varies depending on whether the center AC and branch ACs are associated with configuration templates.

1. If both the center AC and branch ACs are associated with configuration templates, only the configuration templates applied to the center AC are delivered to the branch ACs. Requests for configuration templates from the branch ACs do not take effect.
2. If only the center AC is associated with configuration templates, the center AC synchronizes the associated configuration templates to the branch ACs.
3. If only the branch ACs are associated with configuration templates, the center AC synchronizes the configuration templates requested by the branch ACs to the branch ACs.

1.3.2 Configuring Configuration Command Synchronization

During O&M of a hierarchical wireless network, configurations on the center AC or branch ACs may be changed. If the configuration on the peer AC cannot be changed automatically in a timely manner, it becomes cumbersome to update configuration commands in the configuration templates manually. Configuration command synchronization ensures automatic synchronization of configuration commands changed in the specified configuration mode between the center AC and branch ACs, keeping configuration consistency between them. The configuration command synchronization function can be used when the following configurations are changed:

1. Configurations of AP groups associated in hot standby instance configuration mode on the center AC and branch ACs
2. Configuration commands in AP configuration mode of APs associated with the preceding AP groups

Working Principle

In the hierarchical AC scenario, after configuration command synchronization is enabled and configurations are changed on the center AC or a branch AC, configurations of AP groups in hot standby instances and configurations of APs associated with the AP groups are collected and saved as a changed configuration file on the AC. The process of configuration command synchronization is as follows:

1. When an AC detects that the configuration in the hot standby instance is changed, it sends the changed configuration to the peer AC using a file.
2. After the peer AC receives the changed configuration, it determines whether a baseline file is available.
3. If no baseline file exists, the AC runs all commands in the configuration file to ensure configuration synchronization.
4. If a baseline file exists, it compares the received configuration with the baseline file to identify any differences. It then generates a configuration file to eliminate the differences, and runs the commands in the difference configuration file using a script to ensure configuration synchronization.

1.4 Configuration

Configuration	Description and Command
Configuring Configuration	(Optional) It is used to achieve configuration command synchronization.

Template Synchronization	**cfgmg template**	Configures the center AC to apply configuration templates to a branch AC.
	request cfgmg template	Configures a branch AC to request configuration templates from the center AC.
	sync cfgmg template	Enables the center AC to synchronize commands in the configuration template.
Configuring Configuration Command Synchronization	⚠ (Optional) It is used to maintain commands in a configuration template.	
	config command sync enable	Enables configuration command synchronization.

1.4.1 Configuring Configuration Template Synchronization

Configuration Effect

- With configuration synchronization deployed, configuration template synchronization is automatically triggered when a connection is established between the center AC and a branch AC for the first time. Compare the configuration on the branch AC with that in the configuration template to ensure that commands in the configuration template are synchronized to the branch AC.
- Manually trigger configuration template synchronization on the center AC. Compare the configuration on the branch AC with that in the configuration template to ensure that commands in the configuration template are synchronized to the branch AC.

Notes

- A configuration template needs to be created before being applied.
- When configuration template synchronization is deployed, the center AC synchronizes a configuration template to a branch AC only when a connection is established between the branch AC and center AC for the first time.

↘ Applying a Configuration Template

- Apply a configuration template on the center AC.

Command	**cfgmg template** *temp-name*
Parameter Description	*temp-name*: Indicates the name of the configuration template applied to the specified branch AC on the center AC. The configuration template needs to be created on the center AC in advance. The value is a string of 1 to 31 characters.
Defaults	N/A
Command Mode	Hot standby configuration mode
Usage Guide	1. This command can be configured only on the center AC in the hierarchical AC scenario. A maximum of eight configuration templates can be applied to each hot standby instance. 2. When multiple configuration templates are applied, the sequence for synchronizing commands in these templates depends on the sequence during which the templates are applied. 3. Applied configuration templates are delivered to a branch AC only when the branch AC connects to the center AC for the first time. Subsequent template configuration changes are not proactively synchronized to the branch AC. 4. Applied configuration templates are not forcibly bound to configuration templates of the CFGMG

	module. A non-existent configuration template can be applied. However, no configuration can be synchronized. When configuration templates of the CFGMG module are deleted, applied configuration templates are not deleted.

Verification

- Run the **show this** command in hot standby configuration mode to confirm the configurations.

Requesting a Configuration Template

- Request a configuration template on a branch AC.

Command	**request cfgmg template** *temp-name*
Parameter Description	*temp-name*: Indicates the name of the configuration template requested from the center AC on a branch AC. The configuration template needs to be created on the center AC in advance. The value is a string of 1 to 31 characters.
Defaults	N/A
Command Mode	Hot standby configuration mode
Usage Guide	1. In the hierarchical AC scenario, only branch ACs can request configuration templates from the center AC. 2. A requested configuration template has a lower priority than a configuration template applied to a branch AC by the center AC. If the center AC applies a configuration template to a branch AC, the applied configuration templates are preferred. Otherwise, the configuration template requested by the branch AC takes effect. 3. The requested configuration template is delivered to a branch AC only when the branch AC connects to the center AC for the first time. Subsequent template configuration changes are not proactively synchronized to the branch AC. 4. The requested configuration template is a configuration template of the CFGMG module on the center AC instead of a configuration template of the CFGMG module on the branch AC. 5. The requested configuration template is not forcibly bound to the configuration templates of the CFGMG module on the center AC. A non-existent configuration template can be requested. However, no configuration can be synchronized. When the configuration template of the CFGMG module on the center AC is deleted, the requested configuration template is not deleted.

Verification

- Run the **show this** command in hot standby configuration mode to confirm the configurations.
- When the center AC applies a configuration template, run the **show layerac template name** command to display the branch AC to which the configuration template is applied.
- When a branch AC requests for configuration templates, run the **show layerac template peer** command to display the configuration templates that the branch AC requests from the center AC.

Triggering Configuration Template Synchronization

- Manually trigger configuration template synchronization on the center AC.

Command	**sync cfgmg template**
Parameter Description	N/A
Defaults	N/A
Command Mode	Hot standby configuration mode
Usage Guide	1. When a template configuration is changed or when the template configuration needs to be re-sent in other scenarios, you can use this command to synchronize the template configuration to a branch AC. 2. Before triggering configuration template synchronization, check whether the center AC applies a configuration template in the hot standby instance of a branch AC or the branch AC requests a configuration template. 3. The command is supported only on center ACs.

Verification

- Run the **show running** command on a branch AC to confirm that commands in the template are synchronized.

Configuration Example

Configuring Configuration Template Synchronization

Configuration Steps	Use a typical hierarchical AC case as an example. Create templates **wlan-temp1** and **wlan-temp2** on the center AC and perform WLAN configuration in the templates. On the center AC, apply **wlan-temp1** to Branch AC-1 and **wlan-temp2** to Branch AC-2. Branch AC-1 and Branch AC-2 request configuration templates **wlan-temp1** and **wlan-temp2**. First, configuration template synchronization is automatically triggered. Then the template content is modified, and configuration synchronization is manually triggered. Display the configuration template synchronization results.
	- On the center AC, create configuration templates and import configuration commands to the configuration templates.

	(1) Create the content in the **temp-test1.text** file.
	`wlan-config 10 wlan-test1`
	`tunnel local`
	`wlan-config 20 wlan-test2`
	`tunnel local`
	(2) Create configuration template **wlan-temp1** and import the content in the **temp-test1.text** file to the configuration template.
	`Center AC (config)#cfgmg template wlan-temp1`
	`Center AC (config-temp)#import temp-test1.text`
	(3) Check whether the commands in the **temp-test1.text** file are imported to the configuration template successfully.
	`Center AC (config-temp)#show cfgmg template name wlan-temp1`

```
1: wlan-config 10 wlan-test1
2: tunnel local
3: wlan-config 20 wlan-test2
4: tunnel local
```

(4) Create the content in the **temp-test2.text** file.

```
wlan-config 30 wlan-test3
tunnel local
wlan-config 40 wlan-test4
tunnel local
```

(5) Create configuration template **wlan-temp2** and import the content in the **temp-test2.text** file to the configuration template.

```
Center AC (config)#cfgmg template wlan-temp2
Center AC (config-temp)#import temp-test2.text
```

(6) Check whether the commands in the **temp-test2.text** file are imported to the configuration template successfully.

```
Center AC (config-temp)#show cfgmg template name wlan-temp2
1: wlan-config 30 wlan-test3
2: tunnel local
3: wlan-config 40 wlan-test4
4: tunnel local
```

- On the center AC, apply configuration templates.

(1) On the center AC, apply configuration template **wlan-temp1** to the hot standby instance of Branch AC-1.

```
Center AC (config)#wlan hot-backup 100.100.102.72
Center AC (config-hotbackup)#cfgmg template wlan-temp1
```

(2) On the center AC, apply configuration template **wlan-temp2** to the hot standby instance of Branch AC-2.

```
Center AC (config)#wlan hot-backup 63.254.254.47
Center AC (config-hotbackup)#cfgmg template wlan-temp2
```

- On a branch AC, request configuration templates.

(1) Apply configuration templates **wlan-temp1** and **wlan-temp2** to Branch AC-1.

```
Branch AC-1 (config)#wlan hot-backup 89.2.1.78
Branch AC-1 (config-hotbackup)#request cfgmg template wlan-temp1
Branch AC-1 (config-hotbackup)#request cfgmg template wlan-temp2
```

(2) Check whether Branch AC-1 requests **wlan-temp1** and **wlan-temp2** successfully.

```
Branch AC-1 (config-hotbackup)#show layerac template peer 89.2.1.78
Apply in center:
1. wlan-temp1

Request in branch:
1. wlan-temp1
2. wlan-temp2
```

(3) On Branch AC-2, request configuration templates **wlan-temp1** and **wlan-temp2**.

```
Branch AC-2 (config-hotbackup)#request cfgmg template wlan-temp1
Branch AC-2 (config-hotbackup)#request cfgmg template wlan-temp2
```

(4) Check whether Branch AC-2 requests **wlan-temp1** and **wlan-temp2** successfully.

```
Branch AC-2 (config-hotbackup)#show layerac template peer 89.2.1.78
Apply in center:
1. wlan-temp1

Request in branch:
1. wlan-temp1
2. wlan-temp2
```

- Automatic configuration template synchronization

(1) Establish a hot standby channel between a branch AC and the center AC. If the following syslog is displayed on the branch AC, configuration template synchronization is complete.

```
Branch AC-1#
*Apr 26 17:18:39: %LAYERAC-6-CONFIG_SYNC: The template configuration has been
successfully synchronized from the center ac(89.2.1.78).
```

(2) Run the **show running** command on Branch AC-1 to confirm that commands in the template are synchronized.

```
Branch AC-1#show running | beggning wlan-config
wlan-config 10 wlan-test1
 ssid-code utf-8
 tunnel local
!
wlan-config 20 wlan-test2
 ssid-code utf-8
 tunnel local
!
```

(3) Run the **show layerac template peer** command on Branch AC-1 to display the configuration templates requested by Branch AC-1 and applied by the center AC.

```
Branch AC-1 (config-hotbackup)#show layerac template peer 89.2.1.78
Apply in center:
1. wlan-temp1

Request in branch:
1. wlan-temp1
2. wlan-temp2
```

(4) Run the **show running** command on Branch AC-2 to confirm that commands in the template are synchronized.

```
Branch AC-1#show running | begging wlan-config
wlan-config 30 wlan-test3
 ssid-code utf-8
 tunnel local
```

```
!
wlan-config 40 wlan-test4
 ssid-code utf-8
 tunnel local
!
```

(5) Run the **show layerac template peer** command on Branch AC-2 to display the configuration templates requested by Branch AC-2 and applied by the center AC.

```
Branch AC-2 (config-hotbackup)#show layerac template peer 89.2.1.78
Apply in center:
1. wlan-temp2

Request in branch:
1. wlan-temp1
2. wlan-temp2
```

- Modify commands in a configuration template on the center AC.

(1) Modify commands in the configuration template **wlan-temp1** on the center AC and display the modification result.

```
Center AC (config)#cfgmg template wlan-temp1
Center AC (config-temp)#line 1 wlan-config 11 wlan-test11
Center AC (config-temp)#line 3 wlan-config 22 wlan-test22
Center AC (config-temp)#show this

Building configuration...
!
 line 1 wlan-config 11 wlan-test11
 line 2 tunnel local
 line 3 wlan-config 22 wlan-test22
 line 4 tunnel local
!
end
```

(2) Modify commands in the configuration template **wlan-temp2** on the center AC and display the modification result.

```
Center AC (config)#cfgmg template wlan-temp2
Center AC (config-temp)#line 1 wlan-config 33 wlan-test33
Center AC (config-temp)#line 3 wlan-config 44 wlan-test44
Center AC (config-temp)#show this

Building configuration...
!
 line 1 wlan-config 33 wlan-test33
 line 2 tunnel local
 line 3 wlan-config 44 wlan-test44
 line 4 tunnel local
```

```
!
end
```

- Manual triggering of configuration template synchronization

(1) Run the following commands in hot standby configuration mode of Branch AC-1 on the center AC.

```
Center AC (config)#wlan hot-backup 100.100.102.72
Center AC (config-hotbackup)#sync cfgmg template
```

(2) Run the following commands in hot standby configuration mode of Branch AC-2 on the center AC.

```
Center AC (config)#wlan hot-backup 63.254.254.47
Center AC (config-hotbackup)#sync cfgmg template
```

(3) Run the following command on Branch AC-1 to check whether the commands in the template are synchronized.

```
Branch AC-1#sh run | b wlan-config
wlan-config 10 wlan-test1
 ssid-code utf-8
 tunnel local
!
wlan-config 11 wlan-test11
 ssid-code utf-8
 tunnel local
!
wlan-config 20 wlan-test2
 ssid-code utf-8
 tunnel local
!
wlan-config 22 wlan-test22
 ssid-code utf-8
 tunnel local
```

(4) Run the show running command on Branch AC-2 to check whether the commands in the template are synchronized.

```
Branch AC-2#sh run | b wlan-config
wlan-config 30 wlan-test3
 ssid-code utf-8
 tunnel local
!
wlan-config 33 wlan-test33
 ssid-code utf-8
 tunnel local
!
wlan-config 40 wlan-test4
 ssid-code utf-8
 tunnel local
!
wlan-config 44 wlan-test44
 ssid-code utf-8
```

	tunnel local !

Common Errors

A non-existent template is applied on the center AC or requested by a branch AC. Because the template does not exist, no content is synchronized to the branch AC.

1.4.2 Configuring Configuration Command Synchronization

Configuration Effect

- The configuration of the center AC can be synchronized to a branch AC only when configuration synchronization is enabled on the center AC.
- The configuration on a branch AC can be synchronized to the center AC only when configuration synchronization is enabled on the branch AC.

Notes

N/A

↘ Enabling Configuration Command Synchronization

- Enable configuration command synchronization.

Command	**config command sync enable**
Parameter Description	N/A
Defaults	Configuration command synchronization is enabled by default.
Command Mode	Global configuration mode
Usage Guide	1. When configuration synchronization is disabled on a branch AC, the branch AC cannot synchronize configuration to the center AC. However, the center AC can synchronize configuration to the branch AC. 2. When configuration synchronization is disabled on the center AC, the center AC cannot synchronize configuration to the branch AC. However, the branch AC can synchronize configuration to the center AC. 3. Configuration command synchronization takes effect only in the hierarchical AC scenario. The synchronized commands are configurations of AP groups in the hot standby instance and configurations of APs associated with the AP groups. 4. Synchronization of commands that depend on other commands or files may fail. For example, the **interface-mapping** command depends on the WLAN. Therefore, the WLAN needs to be configured at both ends in advance. The file specified by the **auto-cfg file** *filename* command must be uploaded to the AC in advance. 5. After commands are configured through the NMS software, such as the Simple Network Management Protocol (SNMP) network management platform or smart network controller (SNC), configuration command synchronization is not triggered by default. You need to manually run this command in configuration mode to trigger configuration collection.

Verification

- Run the **show running** command to display the configuration.

Configuration Example

Configuring Configuration Command Synchronization

Configuration Steps	Use a typical hierarchical AC case as an example. Create group **branch1** on the center AC and add **branch1** to the hot standby instance of Branch AC-1. Add configuration to **branch1** and confirm that configuration of **branch1** can be synchronized to Branch AC-1. Add an AP to **branch1** and confirm that configuration of the AP can be synchronized to Branch AC-1. After configuration of **branch1** is synchronized to Branch AC-1, Branch AC-1 deletes or modifies configuration of b**ranch1** and can synchronize the configuration to the center AC.
	● Enable configuration command synchronization on the center AC and a branch AC.

	(1) Enable configuration command synchronization on the center AC.
	`Center AC (config)#config command sync enable`
	`Check whether configuration command synchronization is enabled on the center AC.`
	`Center AC #show run | in config command sync enable`
	`config command sync enable`
	(2) Enable configuration command synchronization on Branch AC-1.
	`Branch AC (config)#config command sync enable`
	(3) Check whether configuration command synchronization is enabled on Branch AC-1.
	`Branch AC-1 #show run | in config command sync enable`
	`config command sync enable`

	● Synchronize configuration commands of the AP groups in the hot standby instance.

	(1) Create **branch1** on the center AC and add commands.
	`Center AC (config)#ap-group branch1`
	`Center AC (config-group)#interface-mapping 10 10 ap-wlan-id 1`
	`Center AC (config-group)#interface-mapping 20 20 ap-wlan-id 2`
	`Center AC (config-group)#sh th`
	
	`Building configuration...`
	`!`
	` interface-mapping 10 10 ap-wlan-id 1`
	` interface-mapping 20 20 ap-wlan-id 2`
	`!`
	`end`
	(2) On the center AC, add branch1 to the hot standby instance of Branch AC-1.
	`Center AC (config)#wlan hot-backup 100.100.102.72`
	`Center AC (config-hotbackup)#context 0`
	`Center AC (config-hotbackup-ctx)#ap-group branch1`
	(3) On the center AC, check whether **branch1** is added to the hot standby instance of Branch AC-1 successfully.
	`Center AC (config-hotbackup-ctx)#show this`

```
Building configuration...
!
  ap-group branch1
  peer-ip 100.100.102.72
!
end

Center AC (config-group)#ap-group branch1
Center AC (config-group)#sh th

Building configuration...
!
end
```

(4) On Branch AC-1, check whether **branch1** is added to the hot standby instance.

```
Branch AC-1#show run | b wlan hot-backup
wlan hot-backup branch
!
wlan hot-backup 89.2.1.78
 local-ip 100.100.102.72
 !
 context 0
  ap-group branch1
  peer-ip 89.2.1.78
 !
 wlan hot-backup enable
!
```

(5) On Branch AC-1, check whether the configuration of **branch1** is synchronized.

```
Branch AC-1#show run | b ap-group branch1
ap-group branch1
 interface-mapping 10 10 ap-wlan-id 1
 interface-mapping 20 20 ap-wlan-id 2
!
```

- Synchronize configuration commands of APs in the hot standby instance.

(1) On the center AC, add AP **sync-test** to **branch1**.

```
Center AC (config)#ap-config sync-test
You are going to config AP(sync-test), which is online now.
Center AC (config-ap)#ap-group branch1
Center AC (config-ap)#show ap-config run sync-test

Building configuration...
Current configuration: 426 bytes

!
```

```
ap-config sync-test
 ap-mac 8005.880a.b557
 ap-group branch1
 ript enable

 power local 50 radio 2
 power local 50 radio 3
 channel 11 radio 1
 channel 64 radio 2
 channel 149 radio 3
 chan-width 20 radio 1
 chan-width 40 radio 2
 chan-width 20 radio 3
!
End
```

(2) On **b**ranch AC-1, check whether configuration of AP **sync-test** is synchronized.

```
Branch AC-1 #show ap-config run sync-test

Building configuration...
Current configuration: 359 bytes

!
ap-config sync-test
 ap-mac 8005.880a.b557
 ap-group branch1
 ript enable
 power local 50 radio 1
 power local 50 radio 2
 power local 50 radio 3
 channel 11 radio 1
 channel 64 radio 2
 channel 149 radio 3
 chan-width 20 radio 1
 chan-width 40 radio 2
 chan-width 20 radio 3
!
end
```

- Modify the configuration of the AP group on the branch AC and check whether the configuration on the center AC is also modified.

(1) On Branch AC-1, modify the configuration of the AP group.

```
Branch AC-1 (config)#ap-group branch1
Branch AC-1 (config-group)#no interface-mapping 20 20
Branch AC-1 (config-group)#interface-mapping 22 22
Branch AC-1 (config-group)#show this
```

```
Building configuration...
!
 interface-mapping 10 10 ap-wlan-id 1
 interface-mapping 22 22 ap-wlan-id 2
!
end
```

(2) On the center AC, check that the configuration modified on Branch AC-1 is synchronized.

```
Center AC (config)#ap-group branch1
Center AC (config-group)#show this

Building configuration...
!
 interface-mapping 10 10 ap-wlan-id 1
 interface-mapping 22 22 ap-wlan-id 2
!
end
```

Common Errors

The command or file that a command depends on is not pre-configured on the center AC and branch AC. As a result, configuration synchronization fails.

After commands are configured through the NMS software, such as the SNMP network management platform or SNC, configuration command synchronization is not manually triggered. As a result, the configuration commands cannot be synchronized.

1.5 Monitoring

Clearing

N/A

Displaying

Command	Description
show layerac config-sync summary	Displays the template synchronization status.
show layerac template name	Displays application and request of the specified configuration template in branch ACs.
show layerac cli record	Displays template commands run by the LAYERAC module in the CLI.
show layerac template peer	Displays templates applied to and requested by the specified branch AC.

Configuring WLAN Optimization and Maintenance

1. Configuring WLOG
2. Configuring WLAN Optimization
3. Configuring WIS
4. Configuring STA-TRACE
5. Configuring Broadcast Forwarding Control
6. Configuring Metric Monitoring

1 Configuring WLOG

1.1 Overview

WLAN Log (WLOG) enables the access controller (AC) to store and view the wireless network and station (STA) status in the past period of time. By collecting and storing information about the wireless network, access points (APs), and STAs in the past 24 hours and then displaying such information through CLI commands, WLOG allows users to analyze the wireless network status and troubleshoot problems.

WLOG can be used to collect and store information, but does not support automatic information analysis and diagnosis.

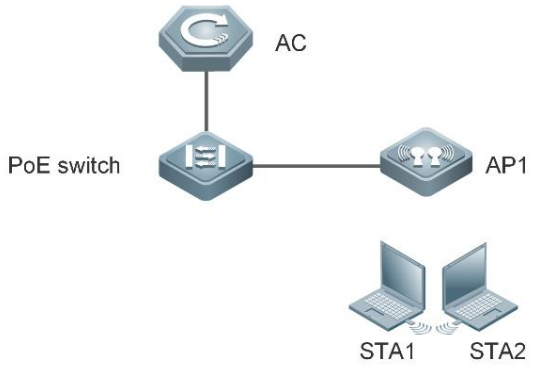
WLOG information can be installed on an AC or AP. Except that STA spatial information is stored on the AP, all other information is stored on the AC.

Protocols and Standards

N/A

1.2 Applications

Application	Description
Fit AP Networking	The Fit AP networking includes at least one AC and one AP.



1.2.1 Fit AP Networking

Scenario

Deploy an AC on a wireless network to query information on the network, and AP and STAs associated with the AC.

Figure 1-1 shows the networking topology for viewing information on the network, AP and STAs associated with the AC.

Figure 1-1

Deployment

- Enable the WLOG feature on an AC.

1.3 Features

Basic Concepts

Two Modes of Information Collection on the AC

- Periodic collection

The summary of the entire network, AP, and STA is collected and stored once or at an interval of 1 hour. The AP and STA summary covers all the information about online APs and STAs.

- Reception advertisement collection

When an AP behavior occurs, the WLOG module is informed to collect and store information about the behavior.

When a STA behavior occurs, the WLOG module is informed to collect and store information about the behavior.

Information collection on the AP covers only periodic collection of spatial information on all online STAs.

Summary of the Entire Network

- Continuous operation time of the AC
- Number of online APs
- Number of pre-configured and offline APs
- Versions of online APs (number of APs of each version)
- Information on each WLAN (SSID) includes:
- Number of online STAs which have passed web-based authentication
- Number of online STAs which have passed 802.1X authentication
- Number of online authentication-free STAs

Summary of the AP

- AP's name
- AP's MAC address
- AP's IP address
- AP's uptime
- Status of each wired interface of the AP
- Input/output rate (bits/sec) in the last 5 minutes
- Statistics on received or sent unicast, broadcast, multicast, and error frames
- Summary of each radio
- Working channel
- Transmit power (dBm, absolute value)
- Number of associated online STAs
- Number of online STAs which have passed web-based authentication
- Number of online STAs which have passed 802.1X authentication

- Intensity of the co-channel interference signal
- Number of received error frames
- Packet retransmission count

Summary of the STA

- IP address
- Signal strength
- Access rate
- Associated AP, radio, and SSID

STA's Spatial Information

- The STA's spatial information includes statistics on data frames and management frames of the STA, and statistics on each type of the rate:
- Number of data frames successfully transmitted (from the AP to the STA)/total traffic
- Number of unresponsive data frames/total traffic
- Number of management frames/total traffic
- Statistics of each type of frames with the access rate (the access rate is divided into 8 grades for statistics)

Grade	0	1	2	3	4	5	6	7
Access Type (Mbps)	1/2	5.5/11	6/9	12/18	24/36	48/54	Reserved	Reserved

- Statistics of each type of frames with the MIMO rate (the MIMO rate is divided into 8 grades for statistics)

Grade	0	1	2	3	4	5	6	7
MIMO Type	mcs0 mcs1	mcs2 mcs3	mcs4 mcs5	mcs6 mcs7	mcs8 mcs9	mcs10 mcs11	mcs12 mcs13	mcs14 mcs15

The spatial information is mainly used to check whether the STA is in low-speed state, whether there is a high proportion of frames for which no ACK frame is transmitted, and whether many management frames are transmitted and received, so as to further analyze and locate the network problems caused by low-speed STAs, management frame attacks, and poor conditions. The STA's spatial information varies in real time, and is collected every five minutes. The information is saved only on the AP due to a large data volume.

AP Behavior Type

The AP behavior type includes login, logout, and CAPWAP connection failures.

STA Behavior Type

The STA behavior type includes association, de-association, roaming, and login and logout through web-based authentication or 802.1X authentication.

Overview

Feature	Description
Enabling the WLOG Feature	Enables the WLOG feature to automatically collect AC, AP, and STA information.

Feature	Description
Synchronizing STA Login or Logout Information to the erver	Synchronizes STA login or logout information to the Elog server.
Configuring the AP Detection Function	An AP detects information about STAs and hotspots nearby.
Synchronizing Information Detected by an AP to the	An AC synchronizes STA information and hotspot information detected by an AP to the Elog server.
Generating Detected STA Information in Syslog Format	Generates STA information detected by the AP in syslog format for output.
Interconnecting with the BCR	Sends information about STAs to the BCR device.

1.3.1 Enabling the WLOG Feature

After the WLOG feature is enabled, the AC or AP automatically collects AC, AP, and STA information and records the information into memory. This helps a network administrator to have a more accurate understanding of the wireless network and STA status in the past 24 hours and analyze and troubleshoot problems.

Working Principle

After the WLOG feature is enabled, the AC or AP automatically collects AC, AP, and STA information and records the information into memory, and receives login or logout advertisement of the AP and STA and records into memory for query.

1.3.2 Synchronizing STA Login or Logout Information to the Elog Server

After the WLOG function is enabled and the URL of the Elog server is configured, the AC sends STA login or logout information to the Elog server.

Working Principle

After the WLOG function is enabled and the AC receives the STA login or logout notification, the AC sends STA information in a specific format to the Elog server.

1.3.3 Configuring the AP Detection Function

The AP detection function is used to detect STAs and hotspots around an AP. The AP detection function can be configured to detect either or both of STAs and hotspots.

Working Principle

After an AC delivers the command of enabling the AP detection function, the AP periodically reports the detected information to the AC for reprocessing.

1.3.4 Synchronizing Information Detected by an AP to the Elog Server

An AC reports information detected by an AP to the Elog server.

Working Principle

An AC reports information detected by an AP in a specific format to the Elog server.

1.3.5 Generating Detected STA Information in Syslog Format

An AC generates detected STA information in syslog.

Working Principle

Generate STAs information detected by an AP in a specified syslog format for output.

1.3.6 Interconnecting with the BCR Server

After the WLOG function is enabled, configure the URL and type of the BCR server. When a STA goes online or offline, relevant information about the STA will be sent to the BCR server.

Working Principle

On the AC enabled with WLOG, when a STA goes online or offline, relevant information about the STA will be sent to the BCR server, and STA login or logout log will be generated on the local device.

1.4 Configuration

Configuration	Description and Command	
Enabling the WLOG Feature	(Mandatory) It is used to enable the WLOG feature.	
	wlan diag enable	Enables the WLOG feature.
Synchronizing STA Login or Logout Information to the	(Optional) It is used to synchronize STA login or logout information to the Elog server.	
	web-server enable api-path assoc-sta url *url*	Configures the address of the Elog server.
Configure the AP Detection Function	(Optional) It is used to enable the detection function of an AP.	
	ap-probe ap enable	Enables the hotspot information detection function of an AP.
	ap-probe sta enable	Enables the STA information detection function of an AP.
	ap-probe cache-time	Configures the time for caching detection information (aging) for an AP.
	ap-probe upload-time	Configures the interval for periodically reporting detection information for an AP.
	ap-probe limit	Configures the number of non-repeated detection information records that can be received within aging period for the AP.
Synchronizing Information Detected by an AP to the	(Optional) It is used to synchronize information detected by an AP to the Elog server.	
	web-server enable api-path probe-ap url *url*	Configures the Elog address to which the hotspot information detected by an AP is synchronized.

Configuration	Description and Command	
	web-server enable api-path probe-sta url *url*	Configures the Elog address to which the STA information detected by an AP is synchronized.
Generating Detected STA Information in Syslog	(Optional) It is used to generate detected STAs in syslog format.	
	web-server enable api-path probe-sta syslog	Generates detected STAs in syslog format.
Interconnecting with the BCR Device	(Optional) It is used to interconnect with the BCR device.	
	web-server enable api-path auth-sta url ***url***	Configures the URL to interconnect with the BCR server.
	web-server enable api-path auth-sta type ***type***	Configures the authentication type to interconnect with the BCR server.

1.4.1 Enabling the WLOG Feature

Configuration Effect

- After the WLOG feature is enabled, the AC or AP automatically records the AC, AP, and STA information.

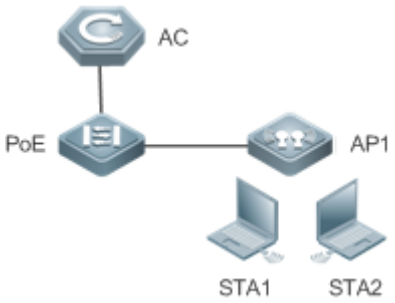
Notes

- Enabling the WLOG will result in memory pre-allocation. If the memory is insufficient, the WLOG feature cannot be enabled. Disabling the WLOG feature frees all memory for information storage and pre-allocated memory.

Configuration Steps

↘ Enabling the WLOG Feature

- Mandatory. Run the **wlog diag enable** command to enable the WLOG feature.
- Enable the WLOG feature in global configuration mode of the AC.
- After the WLOG feature is enabled, information is collected and recorded into the memory periodically.



Command	**wlan diag enable**
Parameter Description	N/A
Defaults	By default, the WLOG feature is disabled on the AC and AP.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

- Run the **show wlan diag network** command to check whether the entire network information can be viewed on the AC.
- Run the **show wlan diag sta** command to check whether the STA information can be viewed on the AC.

Configuration Example

Enabling the WLOG Feature

Scenario **Figure 8-2**	
Configuration Steps	● Enable the WLOG feature in global configuration mode.
AC	`Hostname# configure terminal` `Hostname(config)# wlan diag enable`
Verification	● Use the **show wlan diag network** command to display the summary of the entire network.

AC	`Hostname# show wlan diag network`
	`Time: 2017-05-05 14:57:07`
	`AC uptime: 10 h`
	`Online AP: 1`
	`Offline AP:0`
	`Online AP Version:`
	`PID HwVer SwVer AP Number`
	`--- ---`
	`--- ---`
	`AP520 1.00 AP_RGOS 11.1(5)B9P2, Release(04162423) 1`
	
	`Wlan information:`
	`WLAN ID SSID Active STA WEB Auth 1X Auth Other`
	
	`--- --- --- --- --- ---`
	`4 wlan-guest 2 2 0 0`
	
	`5 wlan-802.1x 6 0 6 0`

1.4.2 Synchronizing STA Login or Logout Information to the Elog Server

Whether this function is supported depends on the actual product version.

Configuration Effect

- After the WLOG function is enabled and the URL of the Elog server is configured, the AC sends the STA login or logout information to the Elog server.

Notes

- This function is triggered by the STA login or logout action. Before the function is enabled, the STA login or logout information is not sent to the Elog server.

Configuration Steps

Configuring the URL of the Elog Server

- The complete address of the Elog server needs to be configured.

Command	**web-server enable api-path assoc-sta url** *url*
Parameter Description	*url*: indicates the URL of the Elog server.
Defaults	By default, the URL of the Elog server is not configured, that is, the AC does not interwork with the Elog server.
Command Mode	Global configuration mode
Usage Guide	To ensure smooth data transmission, the WLOG function needs to be enabled. In local forwarding scenarios, if the AC does not obtain the STA's IP address (which can be queried by running the **show ac-config client** command) after the STA goes online, run the **ip dhcp snooping** command in global configuration mode to ensure that the AC can obtain the STA's IP address. Up to eight Elog servers are supported. Whether this configuration is supported depends on the actual product version.

Verification

- Run the **show running-config** command to display the configuration.

Configuration Example

Configuring the URL of the Elog Server

Configuration Steps	● In global configuration mode, configure two URLs of Elog servers.

AC	`Hostname# configure terminal`
	`Hostname(config)#web-server enable api-path assoc-sta url http://172.18.155.14:8080/elog/service/dc/updateSta`
	`Hostname(config)# web-server enable api-path assoc-sta url http://172.18.155.15:8080/elog/service/dc/updateSta`

Verification	● Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config`
	`!`
	`web-server enable api-path assoc-sta url http://172.18.155.14:8080/elog/service/dc/updateSta`

	http://172.18.155.14:8080/elog/service/dc/updateSta web-server enable api-path assoc-sta url http://172.18.155.15:8080/elog/service/dc/updateSta !

Common Errors

- Only an IP address but not a complete URL is specified in *url*.

Common Errors

- N/A

1.4.3 Configure the AP Detection Function

Whether this function is supported depends on the actual product version.

Configuration Effect

After an AC delivers the command of enabling the AP detection function, the AP periodically reports detected STA information and hotspot information to the AC.

Configuration Steps

Enabling the Hotspot Information Detection Function of an AP

- Optional. After the function is enabled, an AP can detect hotspot information.

Command	**ap-probe ap enable**
Parameter Description	N/A
Defaults	This function is not configured by default.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Enabling the STA Information Detection Function of an AP

- Optional. After the function is enabled, an AP can detect STA information.

Command	**ap-probe sta enable**
Parameter Description	N/A
Defaults	This function is not configured by default.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring the Time for Caching Detected Information (Aging) for an AP

- Optional. Configure the time for caching detected information on the AP.

Command	**ap-probe cache-time** *time*
Parameter Description	*time*: Indicates the cache time (aging time). The value range is from 0 to 3600, in seconds.
Defaults	The default value is 120s.
Command Mode	AP configuration mode, AP group configuration mode, or all-AP configuration mode
Usage Guide	When the cache time is set to 0 seconds, the AP does not cache data, resulting in a large amount of duplicate information being reported to the AC. A high packet sending frequency may cause the high CPU load of the AP and potentially impact wireless services. It is recommended that this configuration be performed only during debugging, and you are not advised to set the cache time to 0 seconds in normal situations.

Configuring the Interval for Periodically Reporting Detected Information for an AP

- Optional. Configure the interval for periodically reporting detected information for an AP.

Command	**ap-probe upload-time** *time*
Parameter Description	*time*: Indicates the interval for periodically reporting detected information. The value range is from 1 to 300, in seconds.
Defaults	The default value is 5s.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	N/A

Configuring the Maximum Number of Detected Information Records That Can Be Cached on an AP

- Optional. Configure the number of non-repeated detected information records that can be received within the aging period for the AP.

Command	**ap-probe limit** *num*
Parameter Description	*num*: Indicates the number of detected information records that can be cached on an AP. The value range is from 1 to 65535. The actual number of records that can be cached on an AP depends on the AP's memory.
Defaults	The default value is 100.
Command Mode	AP configuration mode or all-AP configuration mode
Usage Guide	If the configured value of *num* exceeds the maximum number of information records supported by an AP, the maximum number of information records supported by the AP is used. Cached information occupies memory resources, so do not set it to a large number.

Verification

- Run the **show running-config** command to display the detection configuration in all-AP configuration mode.
- Run the **show ap-config running** command to display the configuration in AP configuration mode.

Configuration Example

Enabling the Detection Function of AP 1

Configuration Steps	● Enable the hotspot and STA detection function in AP configuration mode. Set the cache time to 60s, report interval to 6s, and the number of non-repeated detected information that can be cached to 200.

AC	`Hostname# configure terminal`
	`Hostname(config)#ap-config AP1`
	`You are going to config AP(AP1), which is online now.`
	`Hostname(config-ap)#ap-probe ap enable`
	`Hostname(config-ap)#ap-probe sta enable`
	`Hostname(config-ap)#ap-probe cache-time 60`
	`Hostname(config-ap)#ap-probe upload-time 6`
	`Hostname(config-ap)#ap-probe limit 200`
	`Hostname(config-ap)#`

Verification	● Run the **show ap-config running** command to display the configuration.

AC	`Hostname# show ap-config running`
	`!`
	`ap-config AP1`
	` ap-mac 1234.1234.5656`
	` ap-probe sta enable`
	` ap-probe ap enable`
	` ap-probe upload-time 6`
	` ap-probe cache-time 60`
	` ap-probe limit 200`
	`!`

1.4.4 Synchronizing Information Detected by an AP to the Elog Server

Whether this function is supported depends on the actual product version.

Configuration Effect

- After the hotspot information detection function of an AP is enabled and the URL of the Elog server to which the detected hotspot information is synchronized is configured, the AC sends the detected hotspot information reported by the AP to the Elog server.
- After the STA information detection function of an AP is enabled and the URL of the Elog server to which the detected STA information is synchronized is configured, the AC sends the detected STA information reported by the AP to the Elog server.

Configuration Steps

Configuring the URL of the Elog Server to Which Hotspot Information Detected by an AP Is Synchronized

- The complete address of the Elog server needs to be configured.

Command	**web-server enable api-path probe-ap url** *url*
Parameter Description	*url*: Indicates the complete address of the Elog server for storing detected hotspot information.

Defaults	By default, The Elog server's URL is not configured, that is, an AC is not connected to the Elog server.
Command Mode	Global configuration mode
Usage Guide	A maximum of eight Elog servers can be configured.

Configuring the URL of the Elog Server to Which STA Information Detected by an AP Is Synchronized

- The complete address of the Elog server needs to be configured.

Command	**web-server enable api-path probe-sta url** *url*
Parameter Description	*url*: Indicates the complete address of the Elog server for storing detected STA information.
Defaults	By default, The Elog server's URL is not configured, that is, an AC is not connected to the Elog server.
Command Mode	Global configuration mode
Usage Guide	A maximum of eight Elog servers can be configured.

Verification

- Run the **show running-config** command to display the configuration.

Configuration Example

Configuring the URL of the Elog Server to Which Information Detected by an AP Is Synchronized

Configuration Steps	• In global configuration mode, set the URL of the first Elog server for storing detected hotspot information to http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSsid and the URL of the second Elog server to http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSsid. • In global configuration mode, set the URL of the first Elog server for storing detected STA information to http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSta and the URL of the second Elog server to http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSta.

AC	`Hostname# configure terminal`
	`Hostname(config)# web-server enable api-path probe-ap url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSsid`
	`Hostname(config)# web-server enable api-path probe-ap url http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSsid`
	`Hostname(config)# web-server enable api-path probe-sta url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSta`
	`Hostname(config)# web-server enable api-path probe-sta url http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSta`

Verification	• Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config`
	`!`
	`web-server enable api-path probe-ap url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSsid`

	http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSsid web-server enable api-path probe-sta url http://172.21.155.131:8080/elog/service/dc/updateAcCapturedSta http://172.21.155.132:8080/elog/service/dc/updateAcCapturedSta!

1.4.5 Generating Detected STA Information in Syslog Format

Whether this function is supported depends on the actual product version.

Configuration Effect

After this function is enabled, information about detected STAs will be generated in syslog format.

Notes

This command cannot be used with the **web-server enable api-path probe-sta url** *url* command.

Configuration Steps

Generating Detected STA Information in Syslog Format

Command	**web-server enable api-path probe-sta syslog**
Parameter Description	N/A
Defaults	This function is disabled by default.
Command Mode	Global configuration mode
Usage Guide	This command cannot be used with the **web-server enable api-path probe-sta url** *url* command.

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Generating Detected STA Information in Syslog Format

Configuration Steps	● Enable the device to generate information about detected STAs in global configuration mode.
AC	Hostname# configure terminal Hostname(config)# web-server enable api-path probe-sta syslog
Verification	● Run the **show running-config** command to display the configuration.
AC	Hostname# show running-config ! web-server enable api-path probe-sta syslog !

1.4.6 Interconnecting with the BCR Server

Configuration Effect

- When the AC is enabled with WLOG and configured with the URL and type of the BCR server for interconnection, the AC sends STA login or logout information to the BCR server.

Notes

N/A

Configuration Steps

↘ Configuring the URL for the BCR Server Where STA Login or Logout Information Will Be Sent

- To configure the URL, enter the http:// prefix and the part of the web address following it, such as proline/Msg. You only need to enter information preceding the question mark (?).

Command	**web-server enable api-path auth-sta url** *url*
Parameter Description	*url*: Indicates the prefix of the BCR server address.
Defaults	The URL is not configured by default. That is, the AC does not interconnect with the BCR server by default.
Command Mode	Global configuration mode
Usage Guide	In global configuration mode, first enable WLOG, and then configure the URL of the BCR server for interconnection (enter the http:// prefix and the part of the web address following it, such as proline/Msg). You only need to enter information preceding the question mark (?).

↘ Configuring the Authentication Type for the BCR Server Where STA Login or Logout Information Will Be Sent

- The type value depends on the corresponding input authentication type value.

Command	**web-server enable api-path auth-sta type** *type*
Parameter Description	*type*: Indicates the authentication type.
Defaults	The default type is 1020004.
Command Mode	Global configuration mode
Usage Guide	In global configuration mode, first enable WLOG, and then u configure the authentication type for interconnection with the BCR server.

Verification

- Run the **show running-config** command to display the configuration.

Configuration Example

↘ Configuring the URL for the BCR Server Where STA Login or Logout Information Will Be Sent

Configuration	● For example, in global configuration mode, configure the URL of the BCR server as

Steps	http://10.18.78.149:19900/pronline/Msg.
AC	`Hostname# configure terminal` `Hostname(config)#web-server enable api-path auth-sta url http://10.18.78.149:19900/pronline/Msg`
Verification	● Run the **show running-config** command to display the configuration.
AC	`Hostname# show running-config` `web-server enable api-path auth-sta url http://10.18.78.149:19900/pronline/Msg`

Configuring the Authentication Type Value for the BCR Server Where STA Login or Logout Information Will Be Sent

Configuration Steps	● For example, in global configuration mode, configure the authentication type of the BCR server as 1020002.
AC	`Hostname# configure terminal` `Hostname(config)#web-server enable api-path auth-sta type 1020002`
Verification	● Run the **show running-config** command to display the configuration.
AC	`Hostname# show running-config` `web-server enable api-path auth-sta type 1020002`

Common Errors

N/A

1.5 Monitoring

Displaying

Command	Description
show wlan diag network Whether this configuration is supported depends on the actual product version.	Displays the general information on the whole network
show wlan diag ap [**ap-mac** *ap-mac*] [**number** *number*]	Displays the AP information on the AC
show wlan diag sta [**sta-mac** *sta-mac*] [**ip-range** *ip-prefix*] [**action** *action* [**result** *result*]] [**number** *number*]	Displays the STA information on the AC
show wlan diag sta [**sta-mac** *sta-mac*] [**number** *number*]	Displays STA information on the AP.

1 Configuring WLAN Optimization

1.1 Overview

Wireless network optimization is to optimize the wireless network and enhance the experience of wireless users by adjusting the WLAN configuration.

WLAN configuration optimization can achieve the following effects:

- Reduce co-channel interference and adjacent-channel interference and enhance signal coverage.
- Increase the channel bandwidth.
- Improve the channel utilization.
- Improve the available channel bandwidth for wireless users.
- Decrease network attacks and multicast packet bandwidth usage.
- Improve the downlink throughput of an access point (AP).
- Reduce weak-signal terminals and overall wireless network performance.
- Reduce the impact of the power-saving network adapter.
- Limit the number of access users.

Different WLAN optimization methods are applicable to different application scenarios.

WLAN Optimization Method	Application Scenario
Channel planning and adjustment	This method is used as required.
Power planning and adjustment	This method is used as required.
Terminating low-rate applications	This method is applicable to the high-density deployment scenario (school and building).
Establishing a pure 802.11n wireless network	This method is used as required.
Adjusting Beacon sending interval	This method is applicable to the high-density deployment scenario where many service set identifiers (SSIDs) are configured for the AP.
Enabling Layer 2 isolation for wireless users in a VLAN	This function is mandatory for the network where Layer 2 mutual access is not required.
Enabling the RTS/CTS protection mechanism	This method is applicable to the network involving indoor coverage.
Enhancing the AP's packet sending priority and suppressing packet sending by a STA	It is recommended that you determine whether to use this method based on actual effects.
Reducing the influence of weak-signal terminals	This method is applicable to the high-density deployment scenario (school and building).
Band selection	This method is applicable to the high-density deployment scenario where an AP supports dual bands.
Power-saving STA processing optimization	This method is applicable to all scenarios.
802.11n A-MPDU aggregation frame sending protection	This method is applicable to all scenarios.

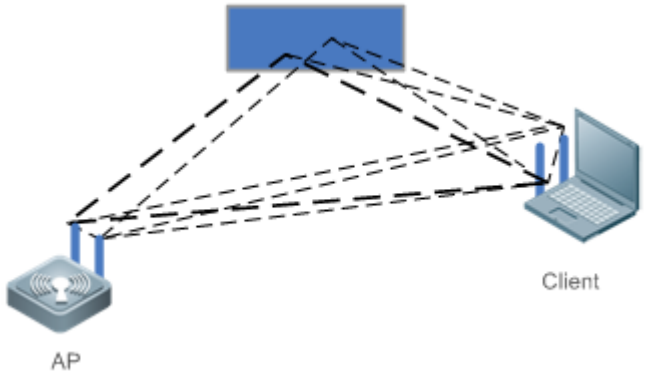
WLAN Optimization Method	Application Scenario
Limiting the number of STAs connected to an AP	This method is applicable to the high-density deployment scenario (school and building) with lots of wireless users.

Protocol Specification

IEEE Std 802.11-2012: Wireless LAN Medium Access Control (MAC) and Physical Layer (PHY) Specifications

1.2 Applications

Application	Description
802.11n	Both the AP and STA support the 802.11n network.
Spectrum Navigation for a WLAN Composed of Fit APs	In the Fit AP architecture, spectrum navigation is enabled for the WLAN composed of multiple dual-band APs.



1.2.1 802.11n

Scenario

As a new protocol of the 802.11 protocol suite, 802.11n supports two frequency bands, that is, 2.4 GHz and 5 GHz. 802.11n aims to provide WLAN access users with higher access rate. It improves the communication rate by using the MIMO technology or by increasing the bandwidth and improving the channel utilization.

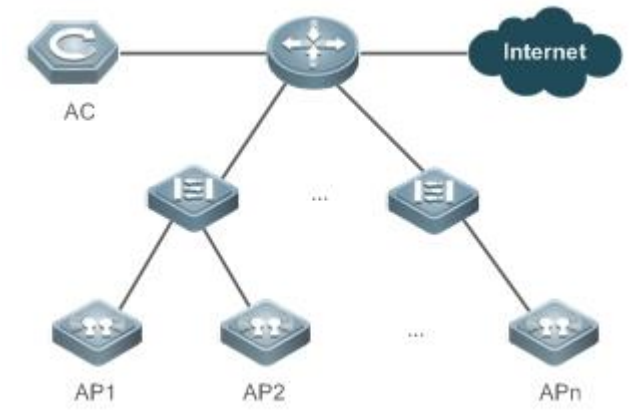
As shown in Figure 1-1, the client accesses the wired network through the AP; the client and AP communicate with each other in wireless mode; and there are multiple transmission paths between the client and AP.

Figure 1-1

Deployment

Enable the IEEE802.11 protocol on the AP and client to implement access and authentication of the client.

1.2.2 Spectrum Navigation for a WLAN Composed of Fit APs



Scenario

In the Fit AP architecture, spectrum navigation is enabled for the WLAN composed of multiple dual-band APs.

In Figure 1-2:

- One access controller (AC) is associated with many dual-band APs. The AC and APs are connected by the Layer 2 switching device and Layer 3 routing device.
- The WLAN is mapped to the two radio frequency (RF) interfaces of all dual-band APs.

Figure 1-2

Deployment

- Manage operating parameters of the spectrum navigation function on the AC.
- Enable the spectrum navigation function on the AP to identify the STA type and guide STA access.

1.3 Features

Basic Concepts

WLAN

A Wireless Local Area Network (WLAN) interconnects computers by using the wireless communication technology to form a network system that supports mutual communication and resource sharing. It uses the wireless mode but not communication cables, making it flexible to build a network and migrate a terminal.

AP

An AP is used for a wireless terminal to access a wired network. It serves as the communication bridge between a wireless terminal and a wired network.

STA

A station (STA) refers to the user who accesses the Internet by using a wireless terminal.

RSSI

The Received Signal Strength Indication (RSSI) is used to indicate the quality of a wireless link.

Overview

Feature	Description

Feature	Description
Terminating Low-Rate Applications	Terminates low-rate applications by configuring the rate set.
Increasing the Beacon Frame Period Appropriately	Increases the Beacon frame period; reduces the frequency of sending Beacon frames; reduces the channel utilization for packet management; increases the available channel bandwidth for wireless users.
Configuring Layer 2 Isolation of Wireless Users in a VLAN	Configures this function for the network not requiring Layer 2 mutual access to decrease network attacks and multicast packet bandwidth usage.
Configuring the Rate Limit for Wireless Users	Makes full use of network resources.
Improving the Anti-Interference Capability	Decreases the RTS threshold appropriately to improve the anti-interference capability when there is co-channel interference.
Improving the Capability of Competing for Channels	Adjusts of EDCA parameters on the STA or AP as needed to make the AC with a higher priority to start the backoff process earlier than other ACs and preferentially access the channel.
Reducing Weak-Signal STAs	Limits the number of wireless access users to control the network coverage of the AP and improve the transmission quality of wireless signals.
Configuring the Maximum Number of STAs Connected to an AP	Limits the STA number on the AP to implement load balancing, avoiding uneven distribution of connected STAs.
Establishing a Pure 802.11n Network	Configures a pure 802.11n network to prohibit access of non-802.11n devices so that all the 802.11n devices to use pure HT header for transmission. This reduces the size of the packet header and increases the available channel bandwidth for wireless users.
Spectrum Navigation	Guides access of the dual-band STA to the 5G frequency band that has stronger access capacity by means of band selection to reduce the pressure of the 2.4G frequency band, thereby improving user experience.
One-Click Network Optimization	Is required to address the following issues on a wireless network that has been running for a period of time: ● The network speed is slow. ● Signal or interference problems exist. ● The authentication page cannot be displayed. ● STAs equipped with 2.4 GHz/5 GHz network adapters are usually associated the network at the 2.4 GHz band. ● A large number of low-rate packets exist. ● Multicast packets are lost or retransmitted.
Intelligent Network Optimization	Performs wireless network optimization intelligently based on real-time network running.
Mcell Configuration	Enables dense deployment optimization.
Roaming Stickiness	Determines whether a STA is associated with the AP with the optimal signal quality based on STA detection information. If the AC detects that a STA associates with an AP with poor signal quality, a notification is reported to the WIS client. Based on collected remote association information, the WIS client performs coverage optimization for APs.

Feature	Description
Remote Association Information Collection	Determines whether a STA is associated with the AP with the optimal signal quality based on STA detection information. If the AC detects that a STA associates with an AP with poor signal quality, a notification is reported to the WIS client. Based on collected remote association information, the WIS client performs coverage optimization for APs.
Automatic Device Information Upload	Configures automatic upload of software and hardware version numbers of the AC and AP.

1.3.1 Terminating Low-Rate Applications

Working Principle

Terminate low-rate applications by configuring the rate set.

1.3.2 Increasing the Beacon Frame Period Appropriately

Working Principle

Increase the Beacon frame period; reduce the frequency of sending Beacon frames; reduce the channel usage for packet management; increase the available channel bandwidth for wireless users.

1.3.3 Configuring Layer 2 Isolation of Wireless Users in a VLAN

Working Principle

Configure this function for the network not requiring Layer 2 mutual access to reduce network attacks and multicast packet bandwidth usage.

1.3.4 Configuring the Rate Limit for Wireless Users

Working Principle

To make full use of network resources, ensure that the device supports the traffic rate limit function. When data traffic accords with the committed rate, data packets are allowed to pass. When data traffic does not accord with the committed rate, data packets are discarded.

1.3.5 Improving the Anti-Interference Capability

Working Principle

To avoid data transmission failures caused by conflicts between channels, the IEEE 802.11 MAC protocol provides a Request to Send/Clear to Send (RTS/CTS) handshake protocol, that is, requests to send/allow sending protocol. The following description assumes that workstation A needs to send data to workstation B. First of all, workstation A sends a RTS request frame. If workstation B allows workstation A to send the request frame, workstation B replies a CTS permission frame. After receiving this permission frame, workstation A begins to sending data. If multiple workstations send RTS requests to the same workstation, only the workstations receiving CTS are allowed to send data. For the workstation not receiving CTS, it is regarded that channel conflict occurs. In this case, this workstation waits for a given period of time and sends an RTS request again.

If RTS/CTS handshake needs to be performed when a workstation sends data each time, excessive RTS frames will occupy much channel bandwidth. You can set the RTS threshold to specify the length of the data frame to be sent. RTS/CTS handshake is not performed when a workstation sends a data frame with a length smaller than the RTS threshold.

1.3.6 Improving the Capability of Competing for Channels

Working Principle

EDCA parameters differentiate access capabilities of channels with different priorities. Each AC has its own EDCA channel competition parameters. You can adjust values of EDCA parameters on the STA or AP as needed to make the AC with a higher priority to start the backoff process earlier than other ACs and preferentially access the channel.

In real-world applications, you can choose to configure EDCA parameters on the STA or AP based on application requirements. Configuring EDCA parameters on the STA and AP affects downlink and uplink data traffic respectively.

1.3.7 Reducing Weak-Signal STAs

Working Principle

STAs search for the AP in proactive or passive scanning mode:

- Proactive scanning: A STA sends a Probe Request for accessing the AP. After confirming the request frame, the AP returns a Probe Response frame.
- Passive scanning: The AP periodically broadcasts Beacon frames. A STA attempts to connect to the AP after listening Beacon frames.

To control the network coverage of the AP and improve the transmission quality of wireless signals, limit the number of STAs. You can control the Beacon frame broadcast coverage of the AP to prevent access of remote STAs. You can also limit the minimum value of the RSSI for STAs. When the RSSI of the request frame sent from a STA is smaller than the minimum value, access of the STA is not allowed.

1.3.8 Configuring the Maximum Number of STAs Connected to an AP

↘ Working Principle

On a WLAN, one AP allows access of multiple wireless users, and an administrator can specify the maximum number of wireless users. The number of STAs connected to the AP can be limited to implement load balancing, avoiding uneven distribution of AP access users.

1.3.9 Establishing a Pure 802.11n Network

↘ Working Principle

Configure a pure 802.11n network to prohibit access of non-802.11n devices; make all the 802.11n devices of the network to use pure HT header for transmission; reduce the size of the packet header; increase the available channel bandwidth for wireless users.

1.3.10 Spectrum Navigation

Working Principle

IEEE802.11 mainly has three communication frequency bands:

- 2.4 GHz (2.412 to 2.4835 GHz) (IEEE 802.11b/g operates in this frequency band)
- 5 GHz (5.15 to 5.35 and 5.725 to 5.825 GHz) (IEEE 802.11a operates in this frequency band)
- 6 GHz (5925 MHz to 7125 MHz) (IEEE 802.11ax operates in this frequency band)

With the popularization of WLAN, most clients are capable of both 2.4 GHz and 5 GHz radios. The publish of Wi-Fi 6E standard ushers in the brand new 6 GHz radio, which is supported by many countries worldwide. The 6 GHz radio provides 59 available channels, 5 GHz radio provides 25 available channels, and 2.4 GHz radio provides 3 non-overlapping channels. The wireless clients should be steered to the 6 GHz and 5 GHz radios preferentially which offer a greater access capacity.

1.3.11 One-Click Network Optimization

Working Principle

One-click network optimization is required to address the following issues on a wireless network that has been running for a period of time:

- The network speed is slow.
- Signal or interference problems exist.
- The authentication page cannot be displayed.
- STAs equipped with 2.4 GHz/5 GHz network adapters are usually associated the network at the 2.4 GHz band.
- A large number of low-rate packets exist.
- Multicast packets are lost or retransmitted.

1. The network speed is slow.

The possible causes are as follows:

- No rate limit is configured. Some users occupy large bandwidth for downloading or playing videos. As a result, the network speed of other users is slow.
- A rate limit is configured but the rate is high, without achieving the rate limit effect.
- A rate limit is configured but the rate is low, resulting in slow network speed.
- The rate limit solution can be used. Rate limiting is performed for all STAs by WLAN to ensure that the average uplink or downlink rate is 256 kbit/s and the burst traffic rate is 300 kbit/s.

2. Signal or interference problems exist.

For example, the signal is poor, roaming frequently occurs, or intra-frequency or inter-frequency interference occurs. To address this issue, use the RRM function. After the RRM function is enabled, channel or power adjustment is performed for online APs or new APs to ensure signal coverage and channel different from those of neighboring APs. If the poor signal or intra-frequency/inter-frequency interference problem does not exist, disable the RRM function to improve the device performance.

3. The authentication page cannot be displayed.

This is because few sessions are configured. Restore the default number of sessions to ensure that each STA supports 255 sessions and each interface supports 1000 sessions by default.

4. STAs equipped with 2.4 GHz/5 GHz network adapters are usually associated the network at the 2.4 GHz band.

For this problem, band steering can be used. If only few 5 GHz/6 GHz-capable clients exist in the environment, it is recommended that band steering be disabled.

5. A large number of low-rate packets exist.

The low-rate packet forbidding function can be used to forbid packets complying with 802.11b, 802.11g, or 802.11a and with a rate lower than 11 Mbps.

6. Multicast packets are lost or retransmitted.

This is because a high multicast rate is set. To solve this problem, restore the default multicast rate to ensure user experience.

1.3.12 Intelligent Network Optimization

Perform wireless network optimization intelligently.

Working Principle

Perform wireless network optimization intelligently based on real-time network running.

1.3.13 Mcell Configuration

Enable dense deployment optimization.

Working Principle

Enable dense deployment optimization.

1.3.14 Roaming Stickiness

Working Principle

Monitor STAs with low RSSI and poor user experience on the entire wireless network in real time and determine whether more suitable APs exist for STAs to access the network based on STA detection information collected by each AP. If such STAs with sticky roaming exist, the AP sends a deauthentication frame to disassociate with the terminal to ensure that the STA is associated with an AP with better signal quality.

1.3.15 Remote Association Information Collection

Working Principle

Determine whether a STA is associated with the AP with the optimal signal quality based on STA detection information. If the AC detects that a STA associates with an AP with poor signal quality, a notification is reported to the WIS client. Based on collected remote association information, the WIS client performs coverage optimization for APs.

1.3.16 Automatic Device Information Upload

Working Principle

Configure automatic upload of software and hardware version numbers of the AC and AP.

1.4 Configuration

Configuration Item	Configuration Suggestion & Relevant Command	
Configuring the Rate Set	(Optional) It is used to terminate low-rate applications.	
	802.11a network rate	Configures the 802.11a rate set.
	802.11b network rate	Configures the 802.11b rate set.
	802.11g network rate	Configures the 802.11g rate set.
Configuring the Beacon Frame Period	(Optional) It is used to increase the Beacon frame period.	
	beacon period	Configures the Beacon frame period.
Configuring Layer 2 Isolation of Wireless Users in a VLAN	(Optional) It is used to enable Layer 2 isolation of wireless users in a VLAN.	
	user-isolation ssid_ap enable	Configures WLAN-based user isolation for an AP.
	user-isolation ap enable	Configures user isolation for an AP.
	user-isolation ssid_ac enable	Configures WLAN-based user isolation for an AC.
	user-isolation ac enable	Configures user isolation for an AC.
Configuring the Rate Limit for Wireless Users	(Optional) It is used to configure rate limit for wireless users.	
	ap-based	Configures AP-based rate limit.
	netuser	Configures STA-based rate limit.
	wlan-based	Configures WLAN-based rate limit.
Configuring the RTS/CTS Protection Mechanism	(Optional) It is used to configure the RTS/CTS protection mechanism.	
	rts-threshold	Configures the RTS threshold.
Configuring EDCA Parameters	(Optional) It is used to configure EDCA parameters.	
	wmm edca-client	Configures EDCA parameters on the STA.
	wmm edca-radio	Configures EDCA parameters on the AP.
Configuring the Allowed Access Signal Strength	(Optional) It is used to configure the allowed access signal strength.	
	response-rssi	Configures the minimum RSSI for wireless user access.
	coverage-area-control	Configures the management frame transmit power.
Configuring the Maximum Number of STAs Connected to an AP	(Optional) It is used to configure the maximum number of STAs connected to the AP.	
	sta-limit	Configures the maximum number of STAs connected to the AP.
Configuring a Pure 802.11n Network	(Optional) It is used to configure a pure 802.11n network.	
	11asupport	Configures whether to support 802.11a or not.

Configuration Item	Configuration Suggestion & Relevant Command	
	11bsupport	Configures whether to support 802.11b or not.
	11gsupport	Configures whether to support 802.11g or not.
	11nasupport	Configures whether to support 802.11na or not.
	11ngsupport	Configures whether to support 802.11ng or not.
Configuring Spectrum Navigation	⚠ (Mandatory) It is used to enable the spectrum navigation function of the WLAN.	
	band-select enable	Enables the spectrum navigation function.
	⚠ (Optional) It is used to configure the operating parameters of the spectrum navigation function.	
	band-select acceptable-rssi	Configures the lower limit of STA signal strength accepted by spectrum navigation.
	band-select access-denial	Configures the number of times for which dual-band STA access to 2.4G band is denied.
	band-select age-out	Configures the STA information aging time.
	band-select probe-count	Configures the detection period count of suppression STA.
	band-select scan-cycle	Configures the threshold of STA detection scanning period.
Configuring One-Click Network Optimization	⚠ (Optional) It is used to configure network optimization options.	
	wopt choose	Configures network optimization options.
	⚠ (Optional) It is used to configure one-click network optimization.	
	wopt enable	Configures one-click network optimization.
Configuring Intelligent Network Optimization	⚠ (Optional) It is used to configure network optimization options.	
	wis enable	Enables intelligent network optimization.
Configuring Mcell	⚠ (Optional) It is used to configure network optimization options.	
	mcell enable	Enables dense deployment optimization.
Configuring Roaming Stickiness	⚠ (Optional) It is used to configure network optimization options.	
	sticky-steering monitor-only	Enables roaming stickiness monitoring.
	⚠ (Optional) It is used to configure one-click network optimization.	
	sticky-steering enable	Enables roaming stickiness navigation.
Configuring Automatic Device Information Upload	**wis devinfo enable**	Enables the automatic device information upload function.

1.4.1 Configuring the Rate Set

Configuration Effect

Configure the rate set to terminate low-rate applications; prohibit packet transmission at low rate between the STA and AP; improve the channel usage.

Notes

- If you disable a rate, this rate can no longer be used.
- If you disable all rates, wireless users cannot access the WLAN.
- If you disable all 802.11b rates, 802.11b wireless users cannot access the WLAN.

Configuration Steps

Configuring the 802.11a Rate Set

- Mandatory.
- Unless otherwise specified, the configuration is performed in AC configuration mode on the AC.

Command	**802.11a network rate** { **6** | **9** | **12** | **18** | **24** | **36** | **48** | **54** } { **disable** | **mandatory** | **supported** }
Parameter Description	**6**: The rate is 6 Mbps. **9**: The rate is 9 Mbps. **12**: The rate is 12 Mbps. **18**: The rate is 18 Mbps. **24**: The rate is 24 Mbps. **36**: The rate is 36 Mbps. **48**: The rate is 48 Mbps. **54**: The rate is 54 Mbps. **disable**: Disables the rate. **mandatory**: Specifies the mandatory rate. **supported**: Specifies the supported rate.
Command Mode	AC configuration mode
Defaults	The rates of 6 Mbps, 12 Mbps, and 24 Mbps are mandatory, and the rates of 9 Mbps, 18 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps are optional.
Usage Guide	N/A

Configuring the 11b Rate Set

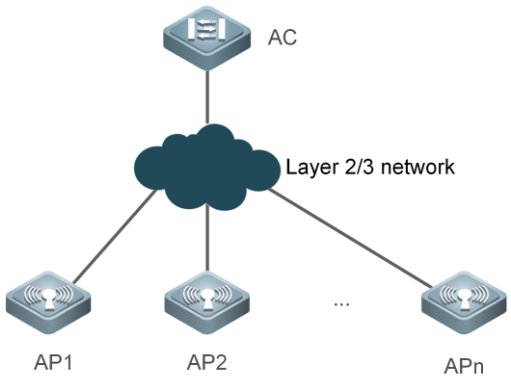
- Optional.
- Unless otherwise specified, the configuration is performed in AC configuration mode on the AC.

Command	**802.11b network rate** { **1** | **2** | **5** | **11** } { **disable** | **mandatory** | **supported** }
Parameter Description	**1**: The rate is 1 Mbps. **2**: The rate is 2 Mbps. **5**: The rate is 5.5 Mbps. **11**: The rate is 11 Mbps. **disable**: Disables the rate. **mandatory**: Specifies the mandatory rate. **supported**: Specifies the supported rate.
Command	AC configuration mode

Mode	
Defaults	By default, the rates of 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps are mandatory.
Usage Guide	N/A

Configuring the 11g Rate Set

- Optional.
- Unless otherwise specified, the configuration is performed in AC configuration mode on the AC.



Command	**802.11g network rate** { **1** | **2** | **5** | **6** | **9** | **11** | **12** | **18** | **24** | **36** | **48** | **54** } { **disable** | **mandatory** | **supported** }
Parameter Description	**1**: The rate is 1 Mbps. **2**: The rate is 2 Mbps. **5**: The rate is 5.5 Mbps. **6**: The rate is 6 Mbps. **9**: The rate is 9 Mbps. **11**: The rate is 11 Mbps. **12**: The rate is 12 Mbps. **18**: The rate is 18 Mbps. **24**: The rate is 24 Mbps. **36**: The rate is 36 Mbps. **48**: The rate is 48 Mbps. **54**: The rate is 54 Mbps. **disable**: Disables the rate. **mandatory**: Specifies the mandatory rate. **supported**: Specifies the supported rate.
Command Mode	AC configuration mode
Defaults	The rates of 1 Mbps, 2 Mbps, 5.5 Mbps, and 11 Mbps are mandatory, and the rates of 6 Mbps, 9 Mbps, 12 Mbps, 18 Mbps, 24 Mbps, 36 Mbps, 48 Mbps, and 54 Mbps are optional.
Usage Guide	N/A

Verification

- You can run the **show running-config** command to display the configuration of the rate set.

Configuration Examples

Configuring the Rate Set

Scenario **Figure 1-3**	
Configuration Steps	● Disable the 6 Mbps rate for 802.11a users on the AC. ● Disable the 1 Mbps and 2 Mbps rates for the 802.11b users on the AC. ● Disable the 1 Mbps, 2 Mbps, and 5.5 Mbps rates for 802.11g users on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ac-controller`
	`Hostname(config-ac)# 802.11a network rate 6 disabled`
	`Hostname(config-ac)# 802.11b network rate 1 disabled`
	`Hostname(config-ac)# 802.11b network rate 2 disabled`
	`Hostname(config-ac)# 802.11g network rate 1 disabled`
	`Hostname(config-ac)# 802.11g network rate 2 disabled`
	`Hostname(config-ac)# 802.11g network rate 5 disabled`

Verification	After configuring the rate set, you can display the configuration of the rate set. ● You can run the **show running** command to display the configuration of the rate set.

	`Hostname# show running`
	`!`
	`ac-controller`
	` country CN`
	` country US`
	` 802.11g network rate 1 disabled`
	` 802.11g network rate 2 disabled`
	` 802.11g network rate 5 disabled`
	` 802.11g network rate 11 mandatory`
	` 802.11g network rate 6 supported`
	` 802.11g network rate 9 supported`
	` 802.11g network rate 12 supported`
	` 802.11g network rate 18 supported`
	` 802.11g network rate 24 supported`
	` 802.11g network rate 36 supported`
	` 802.11g network rate 48 supported`
	` 802.11g network rate 54 supported`
	` 802.11b network rate 1 disabled`
	` 802.11b network rate 2 disabled`

```
 802.11b network rate 5 mandatory
 802.11b network rate 11 mandatory

 802.11a network rate 18 supported
 802.11a network rate 24 mandatory
 802.11a network rate 36 supported
 802.11a network rate 48 supported
 802.11a network rate 54 supported
!
```

Common Errors

None.

1.4.2 Configuring the Beacon Frame Period

Configuration Effect

Increase the Beacon frame period; reduce the frequency of sending Beacon frames; reduce the channel usage for packet management; increase the available channel bandwidth for wireless users.

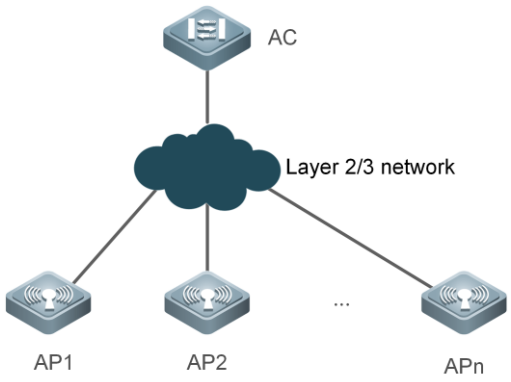
Notes

If a long Beacon frame period is used, users may be disconnected from the WLAN or detect the WLAN frequently.

Configuration Steps

↘ Configuring the Beacon Frame Period

- Optional.
- Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.



Command	**beacon period** *milliseconds* **radio** *radio-id*
Parameter Description	*milliseconds*: Specifies the Beacon frame period, in milliseconds. The value range is from 20 to 1,000. *radio-id*: Specifies the RF interface index. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	The Beacon frame period is 100 milliseconds.
Usage Guide	The configuration for all APs is not supported.

Verification

You can run the **show ap-config running** command to display the configuration of the Beacon frame period.

Configuration Examples

↘ Configuring the Beacon Frame Period

Scenario **Figure 1-4**	
Configuration Steps	Set the Beacon frame period of radio 1 of AP1 to 300 milliseconds on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# beacon period 300 radio 1`

Verification	● After configuring the Beacon frame period, you can display the configuration of the Beacon frame period. ● You can run the **show ap-config running** command to display the configuration of the Beacon frame period.

	`Hostname# show ap-config running AP1`
	`!`
	`ap-config AP1`
	` no 11acsupport enable radio 1`
	` no 11acsupport enable radio 2`
	` 802.11n mcs support 15 radio 1`
	` 802.11n mcs support 15 radio 2`
	` antenna receive 3 radio 1`
	` antenna receive 3 radio 2`
	` antenna transmit 3 radio 1`
	` antenna transmit 3 radio 2`
	` radio-type 1 802.11b`
	` radio-type 2 802.11a`
	` beacon period 300 radio 1`
	` beacon period 100 radio 2`
	` ap-mac 001a.a9c5.3f49`
	` no enable-radio 1`
	` no enable-radio 2`
	`!`

Common Errors

None.

1.4.3 Configuring Layer 2 Isolation of Wireless Users in a VLAN

Configuration Effect

Configure this function for the network not requiring Layer 2 mutual access to decrease network attacks and multicast packet bandwidth usage.

Notes

None.

Configuration Steps

Configuring WLAN-Based User Isolation for an AP

- Optional. Unless otherwise specified, the configuration is performed in WIDS configuration mode on the AC.

Command	**user-isolation ssid-ap enable**
Parameter Description	N/A
Defaults	WLAN-based user isolation on the AP is disabled.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring User Isolation for an AP

Optional. Unless otherwise specified, the configuration is performed in WIDS configuration mode on the AC.

Command	**user-isolation ap enable**
Parameter Description	*N/A*
Defaults	User isolation on the AP is disabled.
Command Mode	WIDS configuration mode
Usage Guide	N/A

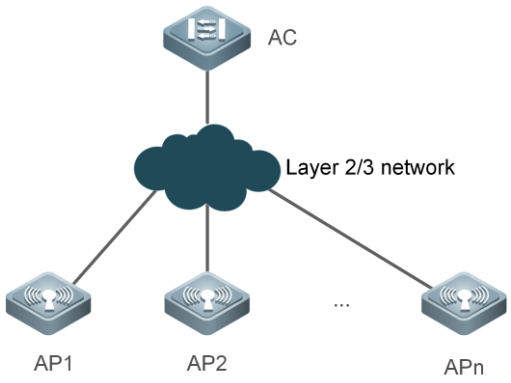
Configuring WLAN-Based User Isolation for an AC

- Optional configuration. By default, WLAN-based user isolation is disabled for the AC.
- Unless otherwise specified, the configuration shall be performed in WIDS configuration mode on the AC device.

Command	**user-isolation ssid-ac enable**
Parameter Description	N/A
Defaults	WLAN-based user isolation on the AC is disabled.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Configuring User Isolation for an AC

Optional. Unless otherwise specified, the configuration is performed in WIDS configuration mode on the AC.



Command	user-isolation ac enable
Parameter Description	*N/A*
Defaults	User isolation on the AC is disabled.
Command Mode	WIDS configuration mode
Usage Guide	N/A

Verification

You can run the **show running-config** command to display the configuration of Layer 2 isolation of wireless users in a VLAN.

Configuration Examples

Configuring Layer 2 Isolation of Wireless Users in a VLAN

Scenario Figure 1-5	
Configuration Steps	● Enable WLAN-based user isolation for an AP on the AC. ● Enable user isolation for an AP on the AC. ● Enable WLAN-based user isolation for an AC on the AC. ● Enable user isolation for an AC on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# wids`
	`Hostname(config-wids)# user-isolation ssid-ap enable`
	`Hostname(config-wids)# user-isolation ap enable`
	`Hostname(config-wids)# user-isolation ssid-ac enable`
	`Hostname(config-wids)# user-isolation ac enable`

Verification	● After configuring Layer 2 isolation of wireless users in a VLAN, you can display the configuration on Layer 2 isolation of wireless users in a VLAN. ● You can run the **show running-config** command to display the configuration on Layer 2 isolation of wireless users in a VLAN.
	`Hostname# show running-config` `!`

	wids user-isolation ap enable user-isolation ac enable user-isolation ssid-ac enable user-isolation ssid-ap enable !

1.4.4 Configuring the Rate Limit for Wireless Users

Configuration Effect

To make full use of network resources, ensure that the device supports the traffic rate limit function. When data traffic accords with the committed rate, data packets are allowed to pass. When data traffic does not accord with the committed rate, data packets are discarded.

Notes

When data traffic does not accord with the committed rate, data packets are discarded.

Configuration Steps

Configuring AP-Based Rate Limit

- Optional.
- Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.

Command	**ap-based { per-user-limit | total-user-limit } { up-streams | down-streams } average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Limits the rates of all users on the AP. **total-user-limit**: Limits the rate of the AP. **up-streams**: Limits the rate of uplink traffic. **down-streams**: Limits the rate of downlink traffic. *average-data-rate*: Specifies the average rate limit, in the unit of 8 kbps. The value range is from 8 to 261120. *burst-data-rate*: Specifies the burst rate limit, in the unit of 8 kbps. The value range is from 8 to 261120.
Command Mode	AP configuration mode
Defaults	AP-based rate limit is disabled.
Usage Guide	N/A

Configuring STA-Based Rate Limit

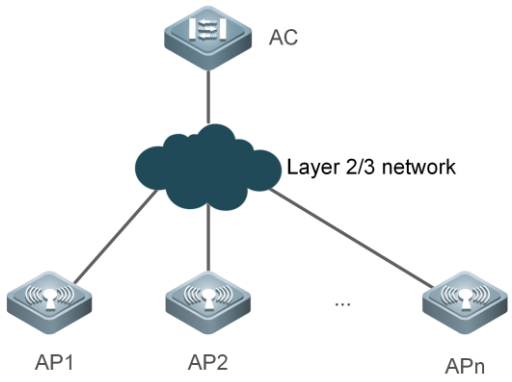
Optional. Unless otherwise specified, the configuration is performed in AC configuration mode on the AC.

Command	**netuser** *mac-address* **{ inbound | outbound } average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	*mac-address*: Specifies the MAC address of a STA. **inbound**: Limits the rate of uplink traffic.

	outbound: Limits the rate of downlink traffic. *average-data-rate*: Specifies the average rate limit, in the unit of 8 kbps. The value range is from 8 to 261120. *burst-data-rate*: Specifies the burst rate limit, in the unit of 8 kbps. The value range is from 8 to 261120.
Command Mode	AC configuration mode
Defaults	STA-based rate limit is disabled.
Usage Guide	N/A

Configuring WLAN-Based Rate Limit

- Optional.
- Unless otherwise specified, the configuration is performed in WLAN configuration mode on the AC.



Command	**wlan-based { per-user-limit | total-user-limit | per-ap-limit } { up-streams | down-streams } average-data-rate** *average-data-rate* **burst-data-rate** *burst-data-rate*
Parameter Description	**per-user-limit**: Limits the rates of all users on the WLAN. **total-user-limit**: Limits the rate of the WLAN. **per-ap-limit**: Limits the rate of the WLAN for each AP separately. **up-streams**: Limits the rate of uplink traffic. **down-streams**: Limits the rate of downlink traffic. *average-data-rate*: Specifies the average rate limit, in the unit of 8 kbps. The value range is from 8 to 261120. *burst-data-rate*: Specifies the burst rate limit, in the unit of 8 kbps. The value range is from 8 to 261120.
Command Mode	WLAN configuration mode
Defaults	WLAN-based rate limit is disabled.
Usage Guide	N/A

Verification

You can run the **show running-config** command to display the configuration of the rate limit for wireless users.

Configuration Examples

Configuring Rate Limit for Wireless Users

Scenario **Figure 1-6**	
Configuration Steps	● Limit the maximum uplink average rate and maximum uplink burst rate of each user on AP1 to 256*8 kbps and 1024*8 kbps respectively on the AC. ● Limit the maximum uplink average rate and maximum uplink burst rate of wireless user 14cf.920b.bfce on the AC to 256* 8 kbps and 1024*8 kbps respectively on the AC. ● Limit the maximum uplink average rate and maximum uplink burst rate of each user in WLAN 12 to 256*8 kbps and 1024*8 kbps respectively on the AC.
	Hostname# configure terminal Hostname(config)# ap-config AP1 Hostname(config-ap)# ap-based per-user-limit up-streams average-data-rate 256 burst-data-rate 1024 Hostname(config-ap)# end Hostname#configure terminal Hostname(config)# ac-controller Hostname(config-ac)# netuser 14cf.920b.bfce inbound average-data-rate 256 burst-data-rate 1024 Hostname(config-ap)# end Hostname# configure terminal Hostname(config)# wlan-config 12 Hostname(config-wlan)# wlan-based per-user-limit up-streams average-data-rate 256 burst-data-rate 1024
Verification	● After configuring the rate limit for wireless users, you can display the configuration of the rate limit for wireless users. ● You can run the **show running-config** command to display the configuration of the rate limit for wireless users.

Common Errors

None.

1.4.5 Configuring the RTS/CTS Protection Mechanism

Configuration Effect

When co-channel interference exists, a smaller RTS threshold means a higher anti-interference capability. However, more RTS/CTS packets require higher channel usage for packet control, reducing the available channel bandwidth for wireless users. You can set the RTS threshold to specify the length of the data frame to be sent. RTS/CTS handshake is not performed when a workstation sends a data frame with the length smaller than the RTS threshold.

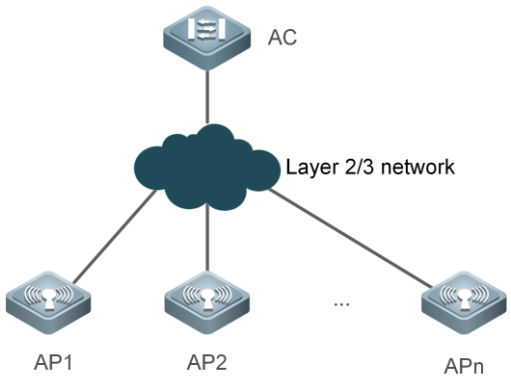
Notes

None.

Configuration Steps

↘ Configuring the RTS Threshold

Optional. Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.



Command	**rts-threshold** *value* **radio** *radio-id*
Parameter Description	*value*: Specifies the RTS threshold, in bytes. The value range is from 257 to 2347. *radio-id*: Specifies the RF interface index. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	The RTS threshold is 2347 bytes.
Usage Guide	N/A

Verification

You can run the **show ap-config running** command to display the configuration of the RTS threshold.

Configuration Examples

↘ Configuring the RTS Threshold

Scenario **Figure 1-7**	
Configuration Steps	Set the RTS threshold of Radio1 on AP1 to 800 bytes on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# rts-threshold 800 radio 1`

Verification	● After configuring the RTS threshold, you can display the configuration of the RTS threshold. ● You can run the **show ap-config running** command to display the configuration of the RTS threshold.

	`Hostname# show ap-config running AP1`
	`!`
	`ap-config AP1`

1.4.6 Configuring EDCA Parameters

Configuration Effect

In real-world situations, you can choose to configure EDCA parameters on a STA or an AP as needed. EDCA parameters on the STA and AP respectively affect downlink data traffic and uplink data traffic.

Notes

None.

Configuration Steps

Configuring EDCA Parameters on a STA

- Optional.
- Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.

Command	**wmm edca-client** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin** [*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **length** [*queue-length*] } **radio** [*radio-id*]
Parameter Description	**back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort (BE) queue. **video**: Sets the video queue. **voice**: Sets the voice queue. *aifsn-value*: Sets the AIFSN value. The value range is from 1 to 15. *cwmin-value*: Sets the CWmin value. The value range is from 0 to 15. *cwmax-value*: Sets the CWmax value. The value range is from 0 to 15. *txop-value*: Sets the TXOP value. The value range is from 0 to 255, in the unit of 32 microseconds. *queue-length*: Sets the AC queue length. The value range is from 1 to 255. The default is 255. *radio-id*: Sets the ID of a radio on the STA. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The CWmax value must be greater than the CWmin value. Otherwise, a message indicating a configuration failure is displayed.

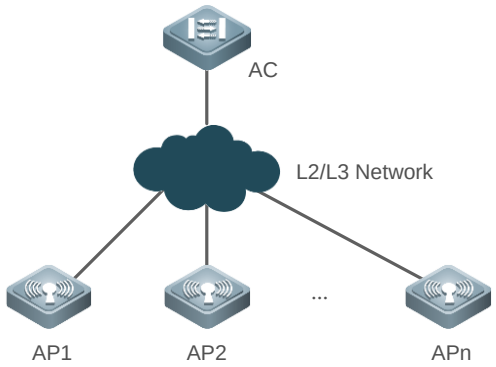
AC	AIFSN	CWmin	CWmax	TXOP
back-ground	7	4	10	0
best-effort	3	4	10	0
video	2	3	4	94
voice	2	2	3	47

Configuring the EDCA Parameters on an AP

- Optional.
- Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.

Command	**wmm edca-radio** { **back-ground** | **best-effort** | **video** | **voice** } { **aifsn** [*aifsn-value*] **cwmin**

	[*cwmin-value*] **cwmax** [*cwmax-value*] **txop** [*txop-value*] | **noack** } **radio** [*radio-id*]
Parameter Description	**back-ground**: Sets the back-ground queue. **best-effort**: Sets the best-effort queue. **video**: Sets the video queue. **voice**: Sets the voice queue. *aifsn-value*: Sets the AIFSN value. The value range is from 1 to 15. *cwmin-value*: Sets the CWmin value. The value range is from 0 to 15. *cwmax-value*: Sets the CWmax value. The value range is from 0 to 15. *txop-value*: Sets the TXOP value. The value range is from 0 to 255, in the unit of 32 microseconds. **noack**: Enables the no ack policy. The no ack policy is not enabled by default. *radio-id*: Sets the ID of a radio on the STA. The value range is from 1 to 48.
Command Mode	AP configuration mode
Defaults	
Usage Guide	The parameter configuration takes effect only when the WMM service is enabled. The CWmax value must be greater than the CWmin value. Otherwise, a message indicating a configuration failure is displayed.



AC	AIFSN	CWmin	CWmax	TXOP
back-ground	7	4	10	0
best-effort	3	4	6	0
video	1	3	4	94
voice	1	2	3	47

Verification

You can run the **show ap-config running** command to display the configuration of EDCA parameters.

Configuration Examples

Configuring EDCA Parameters

Scenario **Figure 1-8**	
Configuration Steps	● Configure EDCA parameters of the STA for Radio1 of AP1 on the AC. ● Configure EDCA parameters of the AP for Radio1 of AP1 on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# wmm edca-client voice aifsn 2 cwmin 2 cwmax 3 txop 50 radio 1`

	`Hostname(config-ap)# wmm edca-radio voice aifsn 1 cwmin 1 cwmax 3 txop 50 radio 1`
Verification	● After configuring EDCA parameters, you can display the configuration of EDCA parameters. ● You can run the **show ap-config running** command to display the configuration of EDCA parameters.

	`Hostname# show ap-config running AP1`
	`!`
	`ap-config AP1`
	` wmm edca-client voice aifsn 2 cwmin 2 cwmax 3 txop 50 radio 1`
	` wmm edca-radio voice aifsn 1 cwmin 1 cwmax 3 txop 50 radio 1`
	` no 11acsupport enable radio 1`

	` ap-mac 001a.a9c5.3f49`
	` no enable-radio 1`
	` no enable-radio 2`
	`!`

Common Errors

None.

1.4.7 Configuring the Allowed Access Signal Strength

Configuration Effect

You can control the Beacon frame broadcast coverage of an AP to prevent access of remote wireless users. You can also limit the minimum value of the RSSI for wireless users. When the RSSI of the request frame sent from a wireless user is smaller than the minimum value, access of the wireless user is prohibited.

Notes

- If a large value of the minimum RSSI for wireless user access is used, many wireless users may fail to access the WLAN.
- If a large management frame transmit power is used, many remote wireless users may fail to discover the network.

Configuration Steps

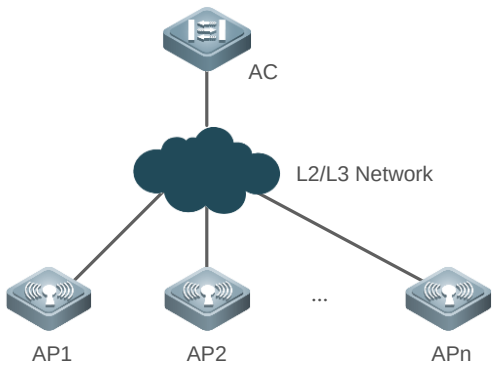
Configuring the Minimum RSSI for Wireless User Access

- Optional.
- Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.

Command	**response-rssi** *rssi* **radio** *radio-id*
Parameter Description	*rssi*: Specifies the minimum RSSI for wireless user access. The value range is from 0 to 100, in dB. *radio-id*: Specifies the ID of a radio to be configured. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	The default RSSI is 0. That is, all users are allowed to access the WLAN regardless of the RSSI.
Usage Guide	N/A

Configuring the Management Frame Transmit Power

- Optional.
- Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.



Command	**coverage-area-control** *power* **radio** *radio-id*
Parameter Description	*power*: Specifies the management frame transmit power. The value range is from 0 to 32, in dBm. *radio-id*: Specifies the ID of a radio to be configured. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	The default power is 0. That is, the management frame transmit power is not configured.
Usage Guide	N/A

Verification

You can run the **show ap-config running** command to display the configuration of the allowed access signal strength.

Configuration Examples

Configuring the Allowed Access Signal Strength

Scenario **Figure 1-9**	
Verification	● Set the minimum RSSI for wireless user access of Radio1 on AP1 to 20 dB on the AC. ● Set the management frame transmit power of Radio1 on AP1 to 30 dBm on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# response-rssi 20 radio 1`
	`Hostname(config-ap)# coverage-area-control 30`

Configuration Steps	● After configuring the allowed access signal strength, you can display the configuration of the allowed access signal strength. ● You can run the **show ap-config running** command to display the configuration of the allowed access signal strength.

	`Hostname# show ap-config running AP1`
	`!`
	`ap-config AP1`
	` ap-based per-user-limit up-streams average-data-rate 256 burst-data-rate 1024`
	` no 11acsupport enable radio 1`
	` no 11acsupport enable radio 2`
	` 802.11n mcs support 15 radio 1`
	` 802.11n mcs support 15 radio 2`
	` rts-threshold 800 radio 1`
	` coverage-area-control 30`
	` response-rssi 20 radio 1`
	` antenna receive 3 radio 1`
	` antenna receive 3 radio 2`
	` antenna transmit 3 radio 1`
	` antenna transmit 3 radio 2`
	` radio-type 1 802.11b`
	` radio-type 2 802.11a`
	` beacon period 300 radio 1`
	` beacon period 100 radio 2`
	` ap-mac 001a.a9c5.3f49`

Common Errors

None.

1.4.8 Configuring the Maximum Number of STAs Connected to an AP

Configuration Effect

Configure the maximum number of STAs connected to an AP to implement load balancing, avoiding uneven distribution of STAs of an AP.

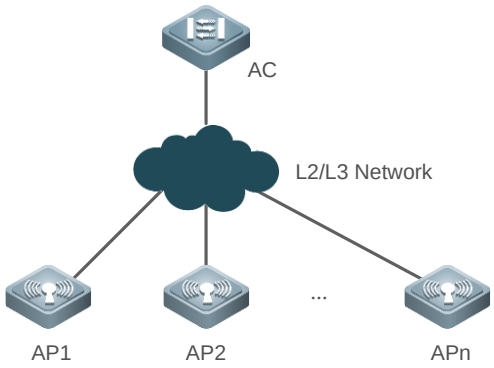
Notes

None.

Configuration Steps

Configuring the Maximum Number of STAs Connected to an AP

- Optional.
- Unless otherwise specified, the configuration is performed in AP configuration mode on the AC.



Command	**sta-limit** *client-max-num*
Parameter Description	*client-max-num*: Specifies the maximum number of STAs connected to an AP. The value range is from 1 to 512.
Command Mode	AP configuration mode
Defaults	The default value is 512.
Usage Guide	N/A

Verification

You can run the **show ap-config running** command to display the maximum number of STAs connected to an AP.

Configuration Examples

Configuring the Maximum Number of STAs Connected to an AP

Scenario **Figure 1-10**	
Configuration Steps	● Set the maximum number of STAs connected to AP1 to 12 on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# sta-limit 12`

Verification	● After configuring the maximum number of STAs connected to an AP, you can display the maximum value. ● You can run the **show ap-config running** command to display the maximum number of STAs connected to.
	`Hostname# show ap-config running AP1` `!`

```

!
```

Common Errors

None.

1.4.9 Configuring a Pure 802.11n Network

Configuration Effect

Configure a pure 802.1n network to prohibit access of non-802.11n devices; make all the 802.11n devices of the network to use pure HT header for transmission; reduce the size of the packet header; increase the available channel bandwidth for the wireless users.

Notes

Pure 802.11n network does not allow access of non-802.11n devices.

Configuration Steps

↘ Configuring Whether to Support 802.11a or Not

- Optional.
- This configuration takes effect only when the radio of the AP operates at 5 GHz.

Command	**11asupport enable radio** *radio-id*
Parameter	*radio-id*: Specifies the ID of a radio to be configured. The value range is from 1 to 96.

Description	
Command Mode	AP configuration mode
Defaults	802.11a is supported.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 5 GHz. The configuration for all APs is not supported.

Configuring Whether to Support 802.11b or Not

- Optional.
- This configuration takes effect only when the radio of the AP operates at 2.4 GHz.

Command	**11bsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio to be configured. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	802.11b is supported.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 2.4 GHz. The configuration for all APs is not supported.

Configuring Whether to Support 802.11g or Not

- Optional. By default, access of 11g users at 2.4 GHz is supported.
- This configuration takes effect only when the radio of the AP operates at 2.4 GHz.

Command	**11gsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio to be configured. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	802.11g is supported.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 2.4 GHz. The configuration for all APs is not supported.

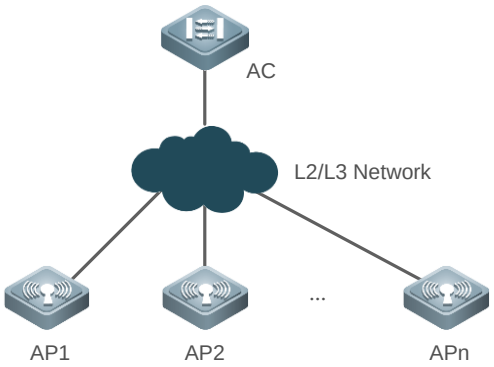
Configuring Whether to Support 802.11na or Not

- Optional.
- This configuration takes effect only when the radio of the AP operates at 5 GHz.

Command	**11nasupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio to be configured. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	802.11n at 5 GHz is supported.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 5 GHz. The configuration for all APs is not supported.

Configuring Whether to Support 802.11ng or Not

- Optional.
- This configuration takes effect only when the radio of the AP operates at 2.4 GHz.



Command	**11ngsupport enable radio** *radio-id*
Parameter Description	*radio-id*: Specifies the ID of a radio to be configured. The value range is from 1 to 96.
Command Mode	AP configuration mode
Defaults	802.11n at 2.4 GHz is supported by default.
Usage Guide	This configuration takes effect only when the radio of the AP operates at 2.4 GHz. The configuration for all APs is not supported.

Verification

You can run the **show ap-config running** command to display the configuration of the pure 802.11n network.

Configuration Examples

Configuring a Pure 802.11n Network

Scenario **Figure 1-11**	 ● Radio1 of AP1 operates at 2.4 GHz. ● Radio2 of AP2 operates at 5.8 GHz.
Configuration Steps	● Configure Radio1 of AP1 as a pure 802.11n network on the AC. ● Configure Radio2 of AP2 as a pure 802.11n network on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# no 11bsupport enable radio 1`
	`Hostname(config-ap)# no 11gsupport enable radio 1`

1.4.10 Configuring Spectrum Navigation

Configuration Effect

The spectrum navigation function of the WLAN is enabled, steering the dual-band STA to the 5G frequency band.

Configuration Steps

↘ Enabling the Spectrum Navigation Function of the WLAN

- Mandatory.
- Unless otherwise specified, this configuration is performed on the AC or Fat AP.

Command	**band-select enable**
Parameter Description	N/A

Command Mode	WLAN configuration mode
Defaults	Spectrum navigation is disabled.
Usage Guide	N/A

Configuring the Lower Limit of STA Signal Strength Accepted by Spectrum Navigation

- Optional. This configuration is performed when the spectrum navigation coverage needs to be adjusted.
- Unless otherwise specified, this configuration is performed on the AC.

Command	**band-select acceptable-rssi** *value*
Parameter Description	*value*: Lower limit of STA RSSI accepted by spectrum navigation. The value range is from -100 to -50, in dBm.
Command Mode	Global configuration mode
Defaults	The lower limit of STA RSSI accepted by spectrum navigation is -80 dBm.
Usage Guide	N/A

Configuring the Number of Times for Which the Dual-Band STA's Access to 2.4G Band is Denied

- Optional. This configuration is performed when the dual-band STA's access to 2.4G band needs to be denied. If access of many dual-band STAs lasts for a long time or fails after the configuration, you need to set a lower value or remove the configuration.
- Unless otherwise specified, this configuration is performed on the AC.

Command	**band-select access-denial** *value*
Parameter Description	*value*: Number of times for which the dual-band STA's access to 2.4G band is denied. The value range is from 0 to 10.
Command Mode	Global configuration mode
Defaults	0
Usage Guide	N/A

Configuring the STA Information Aging Time

- Optional. If no dual-band STA switches to a single-band 2.4G STA on a network, you can configure a long aging time. Otherwise, you can configure a short aging time. If you cannot determine whether this type of switching occurs on the network, use the default configuration.
- Unless otherwise specified, this configuration is performed on the AC.

Command	**band-select age-out** { **dual-band** *value* **| suppression** *value* }
Parameter Description	**dual-band** *value*: Aging time of dual-band STA information. The value range is from 20 to 120, in seconds. **suppression** *value*: Aging time of dual-band STA information. The value range is from 10 to 60, in seconds.
Command Mode	Global configuration mode
Defaults	**dual-band** *value:* 60 seconds

	suppression *value:* 20 seconds
Usage Guide	It is recommended that the aging time of dual-band STA information be set to twice to three times the aging time of suppression STA information.

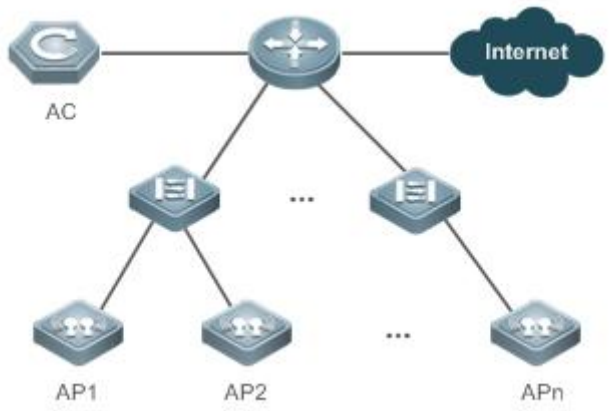
Configuring the Detection Period Count Value of Suppression STA

- Optional. If a single-band 2.4G STA cannot discover the WLAN for a long time, decrease the value.
- Unless otherwise specified, this configuration is performed on the AC.

Command	**band-select probe-count** *value*
Parameter Description	*value*: Detection period count of suppression STA. The value range is from 1 to 10.
Command Mode	Global configuration mode
Defaults	2
Usage Guide	N/A

Configuring the Threshold of STA Detection Scanning Period

- Optional. If a single-band 2.4G STA cannot discover the WLAN for a long time, decrease the value. The default setting is recommended if the network situation is not clear.
- Unless otherwise specified, this configuration is performed on the AC.



Command	**band-select scan-cycle** *value*
Parameter Description	*value*: Threshold of STA detection scanning period. The value range is from 1 to 1000, in milliseconds.
Command Mode	Global configuration mode
Defaults	200
Usage Guide	N/A

Verification

- Run the **show band-select configuration** command to display the spectrum navigation parameter configuration on the device.
- Run the **show running-config** command to display whether the spectrum navigation function is enabled for the WLAN.
- After the device operates for a period of time, run the **show band-select statistics** command to display the running statistics on the device.
- Obtain packets to check whether spectrum navigation has controlled the active detection process.

Configuration Examples

Configuring WLAN Spectrum Navigation for the Fit AP Architecture

Scenario **Figure 1-12**	 In the typical Fit AP architecture: ● The AC represents a wireless access controller. ● AP1, AP2… and AP*n* are all dual-band APs. ● The AC and APs are connected through the Layer 2 switching device and Layer 3 routing device. ● To configure spectrum navigation WLAN as WLAN 99 with SSID **wlan-bandselect**, map the WLAN to the two RF interfaces to all dual-band APs.
Configuration Steps	● Configure spectrum navigation parameters on the AC (optional). ● Enable the spectrum navigation function of WLAN 99 on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# wlan-config 99`
	`Hostname(config-wlan)# band-select enable`

Verification	Use a dual-band STA to access WLAN **wlan-bandselect**. ● Make the STA access the 5G frequency band. (Navigation may fail, and the STA may access the 2.4G frequency band.) ● Display the running statistics of spectrum navigation on the AC, and verify that the count increases.

AC	`Hostname# show band-select statistics`
	`Band Select Statistics`
	`  Number of dual band client.............................. 1`
	`  Number of dual band client added.......................... 1`
	`  Number of dual band client expired....................... 0`
	`  Number of suppressed client.............................. 0`
	`  Number of suppressed client added........................ 0`
	`  Number of suppressed client expired...................... 0`

Common Errors

- Spectrum navigation parameters are improperly configured.
- The spectrum navigation function is not enabled.

- One of the two RF interfaces of the dual-band AP is disabled.

1.4.11 Configuring One-Click Network Optimization

Configuration Effect

Improve the network performance.

Configuration Steps

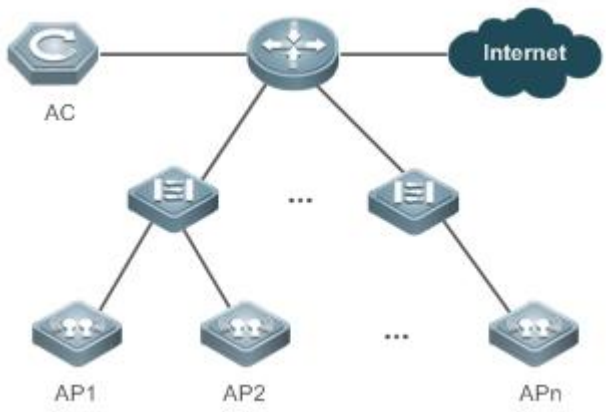
Configuring Network Optimization Options

- Optional.
- Enable network optimization on the AC unless otherwise specified.
- Run the **wopt choose** command to configure network optimization options. At least one option is selected.
- Network optimization options can be configured through the network optimization function to improve network performance. You can select network optimization options based on recommended configurations and actual network conditions. The **no** form is not supported to restore the configurations before optimization. Therefore, if the configurations are incorrect, change configurations in corresponding mode.

Command	**wopt choose** { **band-select-disable** | **band-select-enable** | **low-rate-disable** | **multicast-speed** | **rrm-disable** | **rrm-enable** | **session-limit** | **speed-limit** }
Parameter Description	**band-select-disable**: Disables the band steering function. If only few 5 GHz/6 GHz-capable STAs exist in the environment, it is recommended that banding steering be disabled. **band-select-enable**: Enables the band steering function. If a large number of 5 GHz/6 GHz-capable STAs exist in the environment, it is recommended that banding steering be enabled. **low-rate-disable**: Forbids low-rate packets. Packets with a rate lower than 11 Mbps are forbidden. **multicast-speed**: Restores the default multicast rate (24 Mbps). **rrm-disable**: Disables the RRM function. If no intra-frequency or inter-frequency interference exists in the environment, it is recommended that the RRM function be disabled. **rrm-enable**: Enables the RRM function. If intra-frequency or inter-frequency interference exists in the environment, it is recommended that the RRM function be enabled to perform channel or power adjustment. **session-limit**: Restores the default number of sessions. The number of sessions affects the authentication page pushing by iPortal. It is recommended that the default number of sessions be used. The default number of sessions is 255 for each STA and 1000 for each interface. **speed-limit**: Limits the rate. (Rate limiting is performed for all STAs by WLAN. The average uplink and downlink rate is 256 kbit/s and the burst traffic rate is 300 kbit/s.)
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	Select network optimization options as required. Restoring to the configurations before network optimization is not supported. Therefore, exercise caution when selecting network optimization options. If incorrect configurations are optimized, change configurations in corresponding configuration mode manually.

Configuring One-Click Network Optimization

- Optional.
- Enable network optimization on the AC unless otherwise specified.
- Run the **wopt enable** command to configure one-click network optimization.
- One-click network optimization can be configured through the network optimization function to improve network performance. The **no** form is not supported to restore the configurations before optimization. Therefore, if the configurations are incorrect, change configurations in corresponding mode.



Command	**wopt enable**
Parameter Description	N/A
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	One-click network optimization can be configured if low-rate packets need to be forbidden. Restore default multicast rates for WLANs, restore the default number of sessions, and limit rates for WLANs (average uplink and downlink rate is 256 kbit/s and abrupt rate is 300 kbit/s). Restoring to the configurations before network optimization is not supported. Therefore, exercise caution when configuring one-click network optimization. If incorrect configurations are optimized, change configurations in corresponding configuration mode manually.

Verification

Run the **show wopt** command to display network optimization information.

Configuration Example

Configuring Network Optimization Options in a Fit AP Architecture

Scenario **Figure 1-13**	 In the Fit AP architecture: ● The AC is the wireless network controller. ● AP1, AP2, ….APn are dual-band APs. ● The AC and AP are connected through a Layer 2 switch and a Layer 3 router. ● Many STAs supporting 5 GHz exist. Therefore, it is recommended that the band steering function be enabled, that is, the spectrum navigation function be enabled.

	● Low-rate packets are forbidden.
Configuration Steps	Configure network optimization options on the AC.
AC	`Hostname# configure terminal` `Hostname(config)# wopt choose band-select-enable low-rate-disable`
Verification	● After network optimization options are configured, display network optimization information. ● Run the **show wopt** command to display network optimization information.

AC	`Hostname# show wopt`

1.4.12 Configuring Intelligent Network Optimization

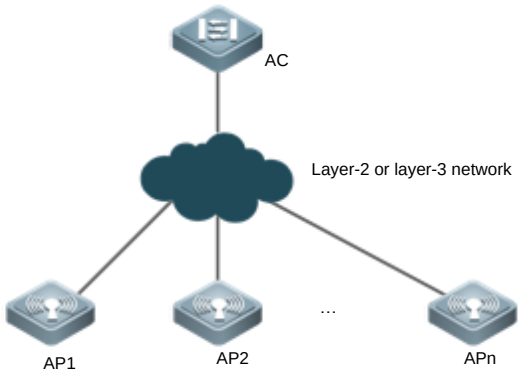
Configuration Effect

Perform intelligent network optimization based on network conditions.

Configuration Steps

Run the **wis enable** command in configuration mode.

Command	**wis enable**
Parameter Description	N/A
Defaults	Intelligent network optimization is not configured.
Command	AC global configuration mode



Mode	
Usage Guide	After this command is run on a running network, intelligent optimization can be performed for the network. In normal cases, this command is used by network administrators.

Verification

Run the **show running-config** command to display the configuration.

Configuration Examples

Configuring Intelligent Network Optimization

Scenario Figure1-15	
Configuration Steps	Enable intelligent network optimization on the AC.
AC	`Hostname# configure terminal` `Hostname(config-ac)# wis enable`
Verification	● After intelligent network optimization is configured, display the configuration. ● Run the **show running-config** command to display information about intelligent network optimization.

	`Hostname# show running-config`
	`!`
	`wis enable`
	`!`

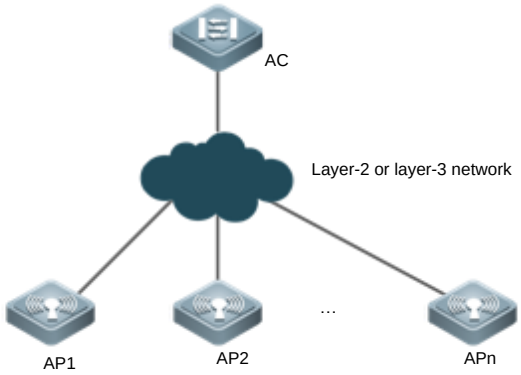
1.4.13 Configuring Mcell

Configuration Effect

Enable dense deployment optimization.

Configuration Steps

Run the **mcell** command in AP configuration mode.



Command	mcell enable **radio** *radio-id*
Parameter Description	*radio-id*: Indicates the index of an RF port. The value range is from 1 to 96.
Defaults	Mcell is disabled.
Command Mode	AP configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Configuring Mcell

Scenario Figure 1-16	
Configuration Steps	Enable the Mcell function on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config AP1`
	`Hostname(config-ap)# mcell enable radio 1`

Verification	● After the Mcell function is configured, display the configuration. ● Run the **show running-config** command to display information about the Mcell function.

	`Hostname# show ap-config running-config`
	`ap-config AP1`
	` mcell enable radio 1`

1.4.14 Configuring Roaming Stickiness

Configuration Effect

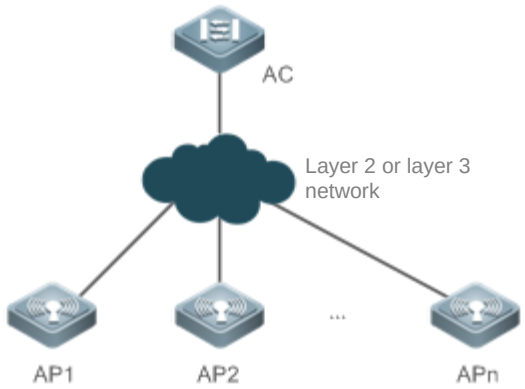
Configure this function to enable roaming stickiness monitoring or navigation.

Notes

WIS must be enabled.

Configuration Steps

Configure roaming stickiness in AP-all configuration or AP group configuration mode.



Command	**sticky-steering** { **monitor-only** | **enable** }
Parameter Description	**monitor-only**: Indicates the monitoring mode, that is, only roaming stickiness is monitored. **enable**: Indicates the navigation mode, that is, roaming stickiness navigation is performed if roaming stickiness is detected.
Defaults	Roaming stickiness is disabled.
Command Mode	Configure roaming stickiness for all AP groups in ap-all configuration mode, and configure roaming stickiness for a single AP group in AP group configuration mode.
Usage Guide	N/A

Verification

Run **show running-config** to query the corresponding configuration.

Configuration Example

Configuring Roaming Stickiness

Scenario **Figure 1-17**	
Configuration Steps	● Configure roaming stickiness monitoring on the AC. ● Configure roaming stickiness navigation on the AC.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-config all`
	`Hostname(config-ap)# sticky-steering monitor-only`
	`Hostname(config-ap)# ap-group test1`
	`Hostname(config-group)# sticky-steering enable`

Verification	Run **show running-config** to query the roaming stickiness configuration.

	`Hostname# show running-config`
	`ap-group test1`
	` sticky-steering enable`
	`!`

	ap-group test2 sticky-steering monitor-only ! ap-group test3 sticky-steering monitor-only !

1.4.15 Configuring Automatic Device Information Upload

Configuration Effect

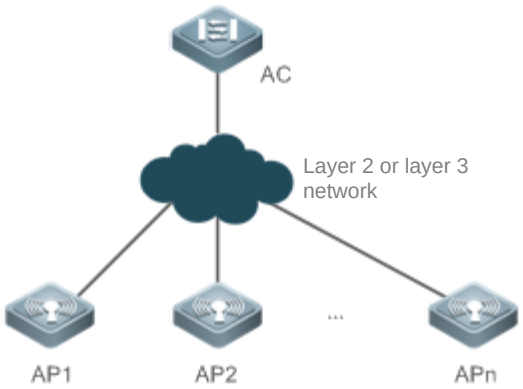
Enable automatic upload of AC and AP software and hardware version information to the WIS cloud.

Notes

- If WIS is not enabled, AC and AP software and hardware version information will also be automatically uploaded after this function is enabled.
- If the WIS client address is configured, the information is uploaded to the WIS client.
- If the WIS client is not configured but the device can access to the WIS public cloud, the information will be uploaded to the WIS public cloud.
- If the WIS client is not configured and the device cannot access to the WIS public cloud, the device information is not uploaded.

Configuration Steps

Perform this operation in global configuration mode.



Command	**wis devinfo enable**
Parameter Description	**enable**: Indicates that device information is automatically uploaded.
Defaults	By default, automatic device information upload is enabled.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run **show running-config** to query the configuration.

Configuration Example

↘ **Configuring Automatic Device Information Upload**

Scenario **Figure 1-19**	
Configuration Steps	Disable automatic device information upload on the AC.
AC	`Hostname# configure terminal` `Hostname(config)# no wis devinfo enable`
Verification	Run **show running-config** to query the configuration of automatic device information upload.

	`Hostname# show running-config`
	`no wis devinfo enable!`
	`!`

1.5 Monitoring

Displaying

Command	Function
show running-config	Display all configuration information.
show ap-config running *ap-name*	Display the configuration information of a specified AP.
show ap-config radio	Display the radio information of all APs.
show ap-config radio *radio-id* **config** *ap-name*	Display the configuration information of a specified AP's specified radio.
show ap-config radio *radio-id* **status** *ap-name*	Display the detailed status information of an AP's specified radio.
show ap-config radio status *ap-name*	Display the radio list of an AP.
show band-select statistics	Display the running statistics of band selection.
show wopt	Display the network optimization information.

1 Configuring WIS

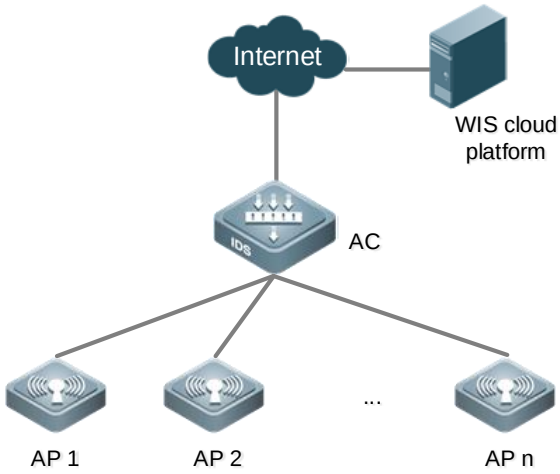
1.1 Overview

If a large number of access points (APs) connect to a wireless network and the network configuration is improperly planned, the wireless network quality deteriorates easily or the STA experience is poor. In this situation, you can connect the wireless access controller (AC) to the Wireless Intelligent Service (WIS) cloud platform. The AC collects network data of a wireless network, such as version information, basic AP information, and radio frequency (RF) information, analyzes the data, and sends the data analysis result to WIS. Based on the data analysis result, WIS delivers a proper network optimization policy to improve the wireless network quality. In addition, WIS enables network administrators to quickly learn about the network running status.

Protocols and Standards

N/A

1.2 Applications



Application	Description
Configuring Intelligent Network Optimization	Enable intelligent wireless network optimization.
Configuring STA Diagnosis	Enable STA diagnosis.

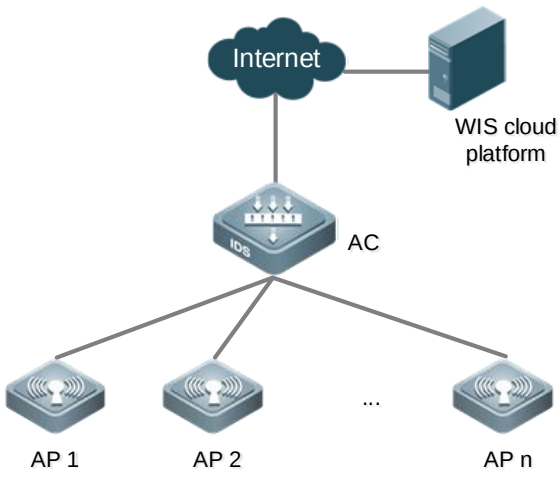
1.2.1 Configuring Intelligent Network Optimization

Scenario

Enable intelligent network optimization on a wireless local area network (WLAN) formed by multiple Fit APs. In Figure 1-1, AP 1, AP 2, ….AP n are Fit APs.

Figure 1-1

Deployment



- Connect the AC to WIS.
- Enable intelligent network optimization on the AC.
- The AC periodically reports network data to WIS, and WIS delivers a proper network optimization policy based on the data analysis result.

1.2.2 Configuring STA Diagnosis

Scenario

Enable STA diagnosis on a WLAN formed by multiple Fit APs.

Figure 1-2

Deployment

- Enable STA diagnosis on the AC. The AC sends STA running data, such as association packets, disassociation packets, and diagnosis results to WIS.
- Enable Dynamic Host Configuration Protocol (DHCP) packet parsing on the AC. APs send DHCP packets of STAs to the AC, and the AC forwards them to WIS.
- Display STA diagnosis information on the AC.
- Display STA diagnosis result on WIS.

1.3 Features

Basic Concepts

↘ WIS

WIS is a wireless intelligent service system deployed on the cloud. It receives network data from the AC and delivers network optimization policies.

Overview

Feature	Description

Feature	Description
Configuring Intelligent Network Optimization	Automatically performs network optimization.
Configuring Periodic Version Information Reporting	Configures automatic upload of the AC and AP software and hardware version numbers.
Configuring STA Diagnosis	Enables the diagnosis function. When a STA is faulty, key packet information can be diagnosed to help locate the fault.
Data Reporting of High-Frequency Telemetry	Configures key indicator reporting for APs and STAs.

1.3.1 Configuring Intelligent Network Optimization

Working Principle

The AC periodically reports network data to WIS. Based on the real-time network running status displayed on WIS, a network administrator selects a proper network optimization policy.

Data that the AC sends to WIS periodically includes:

- Wireless network scale data

  Number of APs and STAs

- Wireless network configuration data

  Parameter configuration of network devices

- STA experience data

  MAC address, wireless access status, delay, packet loss, rate, signal strength, load, traffic, STA capability, STA features, and STA type of a certain user or users of a certain area accessing the network

  Wireless network access or disconnection of STAs

Network optimization policies include:

- One-click network optimization

  A network administrator enables automatic network optimization through one-click network optimization on WIS. WIS automatically delivers network optimization policies to the AC.

- Access optimization

  A network administrator can also manually plan proper network configurations and deliver them to the AC, such as reducing the signal strength of APs in areas with serious interference and adjusting the working channels of APs.

1.3.2 Configuring Periodic Version Information Reporting

Working Principle

The AC sends software and hardware version numbers of the AC and AP to WIS using the Hypertext Transfer Protocol (HTTP) or HTTP Secure (HTTPS) protocol to enable network administrators to view version information about managed devices.

1.3.3 Configuring STA Diagnosis

Working Principle

APs report processed control service flows to the AC. Based on the reported service data, the AC analyzes the STA running status and reports it to WIS. A network administrator can view the STA diagnosis result on WIS and quickly learn about STA fault causes.

Control network data that APs report to the AC does not include DHCP packets of STAs. After APs periodically send DHCP packets to the AC, the AC can analyze DHCP packets to diagnose STA fault causes in the IP address obtaining phase.

1.3.4 Data Reporting of High-Frequency Telemetry

Working Principle

To achieve real-time visualized monitoring of network-wide wireless experience and locate problems within 5 minutes, key indicators of APs and wireless STAs need to be monitored in real time at second level, and historical records can be traced. APs collect all indicators and write the indicators into metrics. Then, APs periodically report specified indicators in metrics to the cloud.

1.4 Configuration

Configuration	Description and Command	
Configuring Intelligent Network Optimization	⚠ (Mandatory)	
	wis enable	Enables intelligent network optimization.
Configuring Periodic Version Information Reporting	⚠ (Optional)	
	wis devinfo enable	Enables the AC to report version information periodically.
Configuring STA Diagnosis of the WIS	⚠ (Optional)	
	wis tsr enable	Enables STA diagnosis of WIS.
	wis tsr packet-parser enable	Enables APs to send DHCP packets to the AC.
Configuring Data Reporting of High-frequency Telemetry	⚠ (Optional)	
	wis hfmg app-upload enable *apg_nam*	Enables indicator reporting for a specified application group.
	wis hfmg app-upload interval *value*	Configures the indicator reporting period for an application.
	wis hfmg ap-upload enable *ap_mac*	Enables indicator reporting for a specified AP.
	wis hfmg ap-upload interval *value*	Configures the indicator reporting period for an AP.
	wis hfmg radio-upload enable *ap_mac radio_id*	Enables indicator reporting on a specified radio of a specified AP.

Configuration	Description and Command	
	wis hfmg radio-upload interval *value*	Configures the indicator reporting period for a radio.
	wis hfmg sta-upload enable *sta_mac*	Enables indicator reporting for a specified STA.
	wis hfmg sta-upload interval *value*	Configures the indicator reporting period for a STA.

1.4.1 Configuring Intelligent Network Optimization

Configuration Effect

After intelligent network optimization is enabled, the AC periodically reports network data to WIS. A network administrator performs intelligent network optimization through WIS.

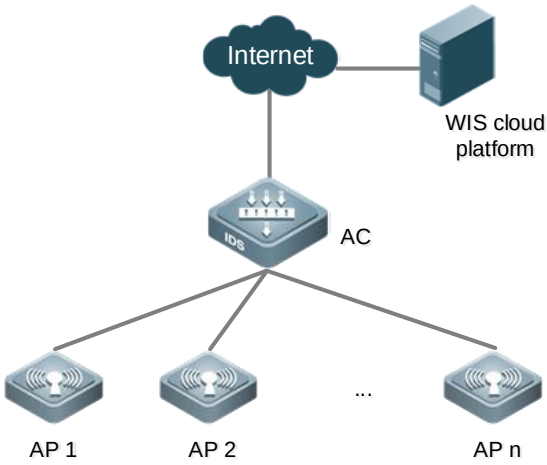
Notes

Before enabling the intelligent network optimization function, connect the AC to WIS.

Configuration Steps

↘ Enabling Intelligent Network Optimization

- Mandatory.
- Run the **wis enable** command in global configuration mode.



Command	**wis enable**
Parameter Description	N/A
Defaults	Intelligent network optimization is disabled by default.
Command Mode	Global configuration mode
Usage Guide	1. After this function is enabled, all APs on a network will send network data to the AC. The function will consume the performance of CAPWAP channels between the APs and AC. It is recommended that this function be used only by network administrators and enabled when the network is idle. 2. In hot standby networking, this function needs to be configured on both the active and standby devices. 3. In AC virtualized networking, this function only needs to be configured on the active AC.

Verification

- Run the **show running-config** command to display the configuration.

Configuration Example

↘ Configuring Intelligent Network Optimization

Scenario **Figure 1-3**	
Configuration Steps	Enable intelligent network optimization on the AC.
AC	`Hostname#configure terminal` `Hostname(config)# wis enable`
Verification	After intelligent network optimization is enabled, run the **show running-config** command to display the configuration on the AC.

	`Hostname#show running-config`
	`!`
	`wis enable`
	`!`

Common Errors

N/A

1.4.2 Configuring Periodic Version Information Reporting

Configuration Effect

Software and hardware version information of the AC and AP is uploaded to WIS periodically.

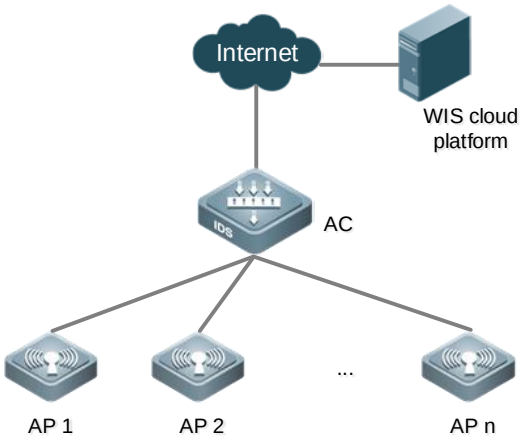
Notes

N/A

Configuration Steps

- In global configuration mode of the AC, enable the AC to periodically report version information to WIS. Version information includes the software and hardware version information.
- Optional.

Command	**wis devinfo enable**
Parameter Description	N/A



Defaults	Periodic information reporting is enabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Configuring Automatic Upload of Device Information to WIS

Scenario Figure 1-4	
Configuration Steps	Disable automatic version information upload to WIS on the AC.
AC	`Hostname# configure terminal` `Hostname(config)# no wis devinfo enable`
Verification	Run the **show running-config** command to display the configuration.

	`Hostname# show running-config`
	`no wis devinfo enable!`
	`!`

Common Errors

N/A

1.4.3 Configuring STA Diagnosis of the WIS

Configuration Effect

After the STA diagnosis function of WIS is enabled, the AC diagnoses the STA fault causes based on the network data sent by APs and sends the diagnosis results to WIS.

Notes

- STA diagnosis is enabled by default.

- APs periodically send DHCP packets to the AC.

Configuration Steps

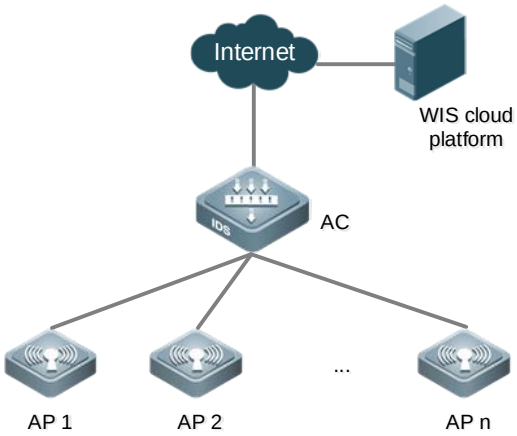
Configuring STA Diagnosis

- STA diagnosis is enabled by default.
- Optional.

Command	**wis tsr enable**
Parameter Description	N/A
Defaults	STA diagnosis is enabled by default.
Command Mode	Global configuration mode
Usage Guide	STA diagnosis information on the AC will be aged periodically. A network administrator can view all diagnosis information on WIS.

Configuring APs to Send DHCP Packets to the AC

- APs send DHCP packets to the AC by default.
- Optional.



Command	**wis tsr packet-parser enable**
Parameter Description	N/A
Defaults	APs send DHCP packets to the AC by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show wis tsr status** command to display the STA diagnosis function.

Configuration Example

Enabling STA Diagnosis of WIS

Scenario **Figure 1-5**	

Configuration Steps	Disable STA diagnosis of WIS on the AC.
AC	`Hostname#configure terminal` `Hostname(config)# no wis devinfo enable`
Verification	Run the **show running-config** command to display the configuration.

	`Hostname#show running-config`
	`no wis devinfo enable!`
	`!`

Common Errors

N/A

1.4.4 Configuring Data Reporting of High-frequency Telemetry

Configuration Effect

Data reporting of high-frequency telemetry can be used to control the reporting period and reporting status (enabled/disabled) of indicators related to apps, APs, STAs, and radios.

Notes

- The default period of reporting all types of indicators is 20 seconds.
- By default, no indicator is reported.
- This function can be used only after the **wis enable** command is enabled.
- When you configure the period, the parameter represents n times 5 seconds, and the actual configuration effect is n x 5 seconds.

Configuration Steps

Enabling Indicator Reporting for a Specified Application Group

Command	**wis hfmg app-upload enable** *apg_name*
Parameter Description	*apg_name*: Indicates the name of the application group.
Defaults	Disabled
Command Mode	Global configuration mode
Usage Guide	Up to 114 entries can be configured.

Configuring the Indicator Reporting Period for an Application

Command	**wis hfmg app-upload interval** *value*
Parameter Description	*value*: Indicates the value in the unit of 5 seconds. When value is 1, the effective period is 5 seconds.
Defaults	20 seconds
Command	Global configuration mode

Mode	
Usage Guide	N/A

Enabling Indicator Reporting on a Specified AP

Command	**wis hfmg ap-upload enable** *ap_mac*
Parameter Description	*ap_mac*: Indicates the MAC address of the AP.
Defaults	Disabled
Command Mode	Global configuration mode
Usage Guide	Up to 500 entries can be configured.

Configuring the Indicator Reporting Period for an AP

Command	**wis hfmg ap-upload interval** *value*
Parameter Description	*value*: Indicates the value in the unit of 5 seconds. When value is 1, the effective period is 5 seconds.
Defaults	20 seconds
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling Indicator Reporting on a Specified Radio of a Specified AP

Command	**wis hfmg radio-upload enable** *ap_mac radio_id*
Parameter Description	*ap_mac radio_id*: Indicates the MAC address of the AP and the ID of the radio on the AP respectively.
Defaults	Disabled
Command Mode	Global configuration mode
Usage Guide	Up to 500 entries can be configured.

Configuring the Indicator Reporting Period for a Radio

Command	**wis hfmg radio-upload interval** *value*
Parameter Description	*value*: Indicates the value in the unit of 5 seconds. When value is 1, the effective period is 5 seconds.
Defaults	20 seconds
Command Mode	Global configuration mode
Usage Guide	N/A

Enabling Indicator Reporting on a Specified STA

Command	**wis hfmg sta-upload enable** *sta_mac*
Parameter Description	*sta_mac*: Indicates the MAC address of the STA.
Defaults	Disabled
Command	Global configuration mode

Mode	
Usage Guide	Up to 500 entries can be configured.

Configuring the Indicator Reporting Period for a STA

Command	**wis hfmg sta-upload interval** *value*
Parameter Description	*value*: Indicates the value in the unit of 5 seconds. When value is 1, the effective period is 5 seconds.
Defaults	20 seconds
Command Mode	Global configuration mode
Usage Guide	N/A

Displaying

Command	Description
show wis tsr status	Displays the STA diagnosis function.
show wis tsr [*sta-mac-address*]	Displays STA diagnosis information.

1 Configuring STA-TRACE

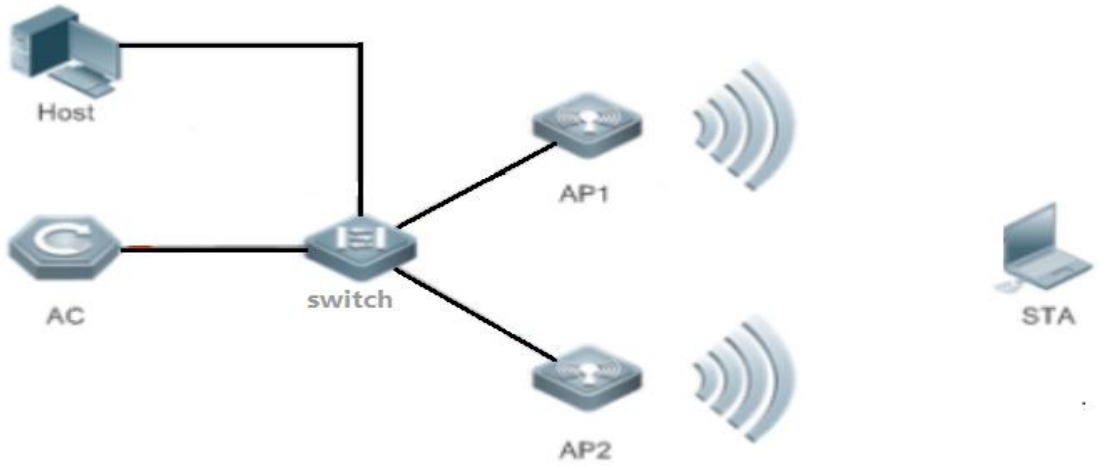
1.1 Overview

As a tool for tracing key stations (STAs) and obtaining key packets, STA-TRACE identifies key packets, parses key fields in packets, and analyzes the field meaning to determine whether the protocol exchange process is normal. It helps users collect STA online fault information conveniently, quickly locate STA faults, and improve the user experience.

With STA-TRACE enabled, access points (APs) controlled by an access controller (AC) obtain key packets of key STAs. This function makes full use of APs on a network and can collect complete fault information onsite at a time. Fault reproduction is not required for fault processing. STA-TRACE can automatically identify network exceptions and collect key information onsite to facilitate fault analysis and locating and improve the fault processing efficiency.

Protocols and Standards

N/A



1.2 Applications

Application	Description
Enabling STA-TRACE in Fit AP Mode	In a Fit AP environment, enable STA-TRACE on the AC. A remote host can download packet files through Wireless Intelligent Service (WIS) Cloud or Eweb.

1.2.1 Enabling STA-TRACE in Fit AP Mode

Scenario

In Fit AP mode, APs controlled by the AC trace key STAs, obtain packets on a network, and report them to the AC, as shown in the following figure.

Deployment

- Enable STA-TRACE.
- Configure the media access control (MAC) address of the STA to be traced.

1.3 Features

Basic Concepts

STA, AP, AC

- STA: indicates a wireless station equipped with network interface cards (NICs), for example, portable computer or mobile phone
- AP: provides wireless signals for STAs to access a network.
- AC: provides wireless connections and services.

Fast Forwarding Channel

A fast forwarding channel refers to the communication channel between the kernel and processes. The fast forwarding method of the fast forwarding framework is used for communication.

CAPWAP Tunnel

In the Fit AP architecture, the AC centrally manages all APs through a Control and Provisioning of Wireless Access Points (CAPWAP) tunnel. Control policies sent to APs do not need to be independently configured on the APs. The CAPWAP protocol is used for establishing control and data channels between the APs and AC. The control channels are used by the AC to configure APs and by APs to send event advertisements to the AC, and the data channels are used to send data packets between the APs and AC.

Control Channel and Data Channel

- Control channel: is used by the AC to configure APs and APs to send event advertisements to the AC.
- Data channel: is used to send data packets between the APs and AC.

Overview

Feature	Description
Enabling STA-TRACE	The AC obtains key packets sent and received by APs during the STA login process.

1.3.1 Enabling STA-TRACE

The STA-TRACE function enables the AC to control APs and obtain key packets sent and received by APs during the online process of key STAs. This ensures key packet tracing of key STAs on the entire network and real-time packet analysis remotely.

Working Principle

The STA-TRACE function obtains key packets during the STA online process to monitor the STA online behavior. APs filter wired or wireless packets sent by STAs to trace the STA online behavior and use the CAPWAP data channels to send the data to the AC. The AC stores the data to the Redis database and periodically sends it to the WIS in file format.

Key packets include the management frames, four-way handshake packets, DHCP packets, AR packets, and ICMP packets.

The AC controls APs to enable STA-TRACE.

1 APs filter out key packets from wired or wireless packets.

2 APs add required fields for key packets and transparently forward them to the AC through the CAPWAP tunnel.

3 The AC stores the packets in the Redis database, adds the PCAP header to the packet files, and sends the packet files to the WIS module or Eweb of the remote host.

4 The remote host uses a tool that can parse custom packet protocols (such as WireShark) to analyze and process the packets.

1.4 Configuration

Configuration	Description and Command	
Enabling STA-TRACE	(Mandatory) It is used to enable the STA-TRACE service on APs controlled by the AC. Perform either of the following configurations.	
	sta-trace enable all-trace	Enables the STA-TRACE service to filter out all key packets.
	sta-trace enable wireless	Enables the STA-TRACE service to filter out wireless packets.
Configuring STA Information	(Mandatory) It is used to configure the device to monitor STA information.	
	sta-trace sta	Configures the MAC address of a STA.
Configuring the Limited Number of Packets	(Optional) It is used to configure the number of packets captured.	
	sta-trace pkt-count	Configures the number of packets stored in the Redis database.
Configuring the Size of a Stored File	(Optional) It is used to configure the size of a stored file.	
	sta-trace file-size	Configures the size of a stored file.

1.4.1 Enabling STA-TRACE

Configuration Effect

- To trace key packets, the STA-TRACE service must be enabled.
- You can select whether to filter out all packets or wireless packets only.

Notes

- After the STA-TRACE service is enabled, the MAC address of the STA needs to be configured to start packet obtaining.

Configuration Steps

Enabling STA-TRACE

- Mandatory.
- To trace key packets, enable the STA-TRACE service on the AC.
- Run the **sta-trace enable all-trace** command to enable the STA-TRACE service.
- Run the **sta-trace enable wireless-trace** command to enable the STA-TRACE service on the wireless end.

Command	sta-trace enable all-trace/wireless-trace
Parameter Description	N/A
Defaults	The STA-TRACE service is disabled by default.
Command Mode	Global configuration mode
Usage Guide	After the STA-TRACE service is enabled, the MAC address of the STA needs to be configured.

Verification

Run the **show running-config** command to display the function and check whether the STA-TRACE service is configured.

Configuration Example

Enabling STA-TRACE in a Fit AP Environment

Configuration Steps	

AC	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# sta-trace enable`

Verification	● Display the function.

AC	`Hostname# show running-config`
	`!`
	`sta-trace enable all-trace`
	`!`

Common Errors

N/A

1.4.2 Configuring STA Information

Configuration Effect

After STA information is entered on the AC, APs automatically obtain packets of associated STAs.

Notes

N/A

Configuration Steps

Configuring STA Information

- Mandatory.
- To trace key packets on an AP, STA information needs to be configured on the AC.
- Run the **sta-trace sta** *H.H.H* command to configure the STAs to be traced.
- Configure STA information and enable STA-TRACE.

Command	**sta-trace sta** *H.H.H*
Parameter Description	*H.H.H*: MAC address of a STA.
Defaults	N/A
Command Mode	Global configuration mode
Usage Guide	Only online APs that support STA-TRACE will trace STA packets.

Verification

- Display STA information. Configured STA information is displayed.
- Run the **show running-config** command to display configured STA information.

Configuration Example

Configuring STA Information in a Fit AP Environment

Configuration Steps	● Configure the STA whose MAC address is 1032.7e5d.6ecf as a key STA.

AC	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# sta-trace enable all-trace`
	`Hostname(config)# sta-trace sta 1032.7e5d.6ecf`

Verification	● Display the STA configuration.

AC	`Hostname# show sta-trace sta-info`
	`Mac Address    Pkt Number File Number`
	`-------------- ---------- ------------`
	`7cc3.a19d.63fb 14371      2`
	`7cc3.a19d.63fc 11163      2`
	`7cc3.a19d.63fd 11135      2`
	`7cc3.a19d.63fe 11129      2`
	`7cc3.a19d.63ff 11104      2`
	`1032.7e5d.6ecf 11096      2`
	
	`Send Fail ToAP Add Fail ToREDIS`
	`-------------- ----------------`
	`0              0`

Common Errors

N/A

1.4.3 Configuring the Limited Number of Packets

Configuration Effect

Configure the number of packets that can be stored for each STA to restrict the number of packets stored in the Redis database.

Notes

N/A

Configuration Steps

Configuring the Number of Packets Obtained

- Optional.
- Perform this configuration on the AC.
- Run the **sta-trace pkt-count pktnum** command on the AC to configure the number of packets stored.

Command	**sta-trace pkt-count** *pktnum*
Parameter Description	*pktnum*: Number of packets that can be stored for each STA. The value range is from 0 to 1000000. The default value is 5000.
Defaults	The default number of packets stored for each STA is 5000.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Configuring the Number of Packets on the AC

Configuration Steps	Enter the global configuration mode on the AC.

AC	`Hostname# configure terminal`
	`Enter configuration commands, one per line.  End with CNTL/Z.`
	`Hostname(config)# sta-trace pkt-count 1000`

Verification	Display the configuration on the AC.

AC	`Hostname#show running-config`
	`mac-address-table filtering 1032.7e5d.6ecf vlan 5`
	`!`
	`sta-trace enable all-trace`

	sta-trace sta 1032.7e5d.6ecf sta-trace pkt_count 1000 ! wlan-cap forward central

1.4.4 Configuring the Size of a Stored File

Configuration Effect

Configure the size of an STA packet file to restrict the storage capacity of a file.

Notes

N/A

Configuration Steps

Configuring the Size of a Stored File

- Optional.
- Perform the configuration on the AC.
- Run the **sta-trace file-size size** command on the AC to configure the number of packets stored.

Command	**sta-trace file-size** *size*
Parameter Description	*size*: Size of each STA packet file, in MB. The value is 1, 2, or 3.
Defaults	The default file size is 1 MB.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Configuring the Number of Packets on the AC

Configuration Steps	Enter the global configuration mode on the AC.
AC	Hostname# configure terminal Enter configuration commands, one per line. End with CNTL/Z. Hostname(config)# sta-trace file-size 2
Verification	Display the configuration on the AC.
AC	Hostname#show running-config mac-address-table filtering 1032.7e5d.6ecf vlan 5

```
!
sta-trace enable all-trace
sta-trace sta 1032.7e5d.6ecf

1 Configuring Broadcast Forwarding Control

1.1 Overview

Broadcast forwarding control includes weight-based broadcast forwarding control and broadcast forwarding control in wireless mode.

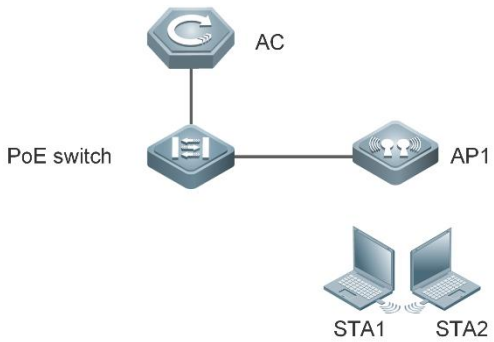
- Weight-based broadcast forwarding control means restricting weights of packet types for broadcast forwarding, so as to prevent stations (STAs) from being affected when a certain type of packets occupy all resources. This mode is applicable to all packets to be flooded.
- Broadcast forwarding control in wireless mode means forwarding only required packets to a wireless network, so as to prevent some useless broadcast packets from occupying substantial radio frequency (RF) resources. This mode is applicable to all packets to be sent to the air interface.

Protocols and Standards

N/A

1.2 Applications

Application	Description
Broadcast Forwarding Control	The Fit AP networking contains at least one access controller (AC) and one Fit access point (AP).



1.2.1 Broadcast Forwarding Control

Scenario

An AC is deployed on a wireless network and enabled with broadcast forwarding control in wireless mode.

The AC controls wireless forwarding of broadcast packets, as shown in Figure 1-1.

Figure 1-1

Deployment

Enable broadcast forwarding control in wireless mode on the AC.

1.3 Features

Basic Concepts

Weight-based Broadcast Forwarding Control

A network switching device may need to flood broadcast packets, multicast packets, and some unicast packets. A weight can be set for each type of packets to prevent a certain type of broadcast packets from exhausting all broadcast forwarding capabilities, thereby improving STAs' network experience.

Broadcast Forwarding Control in Wireless Mode

This function is used to forward only required broadcast packets to a wireless network, so as to prevent certain broadcast packets from occupying substantial air interface resources and improve network rates of STAs.

ARP Broadcast Control

In some scenarios, intra-LAN ARP discovery is prevented. That is, users on a LAN do not respond to ARP request packets from an external network, thereby achieving isolation and preventing ARP scanning (host discovery). Users on the LAN are also mutually isolated.

ARP or ND Broadcast Isolation Between CAPWAP Tunnel Interfaces

CAPWAP tunnel interfaces do not broadcast ARP or ND packets to each other by default. CAPWAP tunnel interfaces can be enabled to mutually broadcast ARP or ND packets.

Allowing mDNS Packets to Pass Through

For broadcast forwarding control in wireless mode, Multicast DNS (mDNS) packets are not allowed to pass through by default. In some scenarios such as screen mirroring, mDNS keepalive packets from the screen end to a terminal are blocked by the AC, causing a mirroring disconnection. To restore mirroring, configure the AC to allow mDNS packets to pass through.

Allowing SSDP Packets to Pass Through

For broadcast forwarding control in wireless mode, Simple Service Discovery Protocol (SSDP) packets are not allowed to pass through by default. The AC can be configured to allow SSDP packets to pass through as required.

Allowing OSPF Packets to Pass Through

For broadcast forwarding control in wireless mode, Open Shortest Path First (OSPF) packets are not allowed to pass through by default. In some scenarios, an AP may be connected to an OSPF network instead of an end STA. In this case, The AC can be configured to allow OSPF packets to pass through.

Allowing VRRP Packets to Pass Through

For broadcast forwarding control in wireless mode, Virtual Router Redundancy Protocol (VRRP) packets are not allowed to pass through by default. The AC can be configured to allow VRRP packets to pass through as required.

Broadcast and Multicast Packet Optimization on Air Interfaces

On wireless networks, data is transmitted over air interfaces. Both APs and STAs need to compete for air interface channels. On the same channel, only one device can transmit data at a time. In this case, broadcast or multicast packets compete for air interface resources, which will affect the quality of the service network.

- To ensure stable transmission of broadcast or multicast packets over air interfaces, the protocol stipulates that broadcast or multicast packets are transmitted at the lowest rate on wireless networks. However, the competition of for air interface resources by broadcast and multicast packets will reduce the overall rate on the service network.
- Broadcast or multicast packets are used to request a service, and many STAs on the network will receive these packets. Typically, only one STA needs to respond, while the unnecessary broadcast or multicast packets consume wireless network and device resources.
- On wireless networks, numerous protocols (such as ARP and DHCP) require the transmission of broadcast or multicast packets over air interfaces, which will occupy a large number of air interface resources. This may cause network congestion and results in a decrease in Wi-Fi performance.

Therefore, it is necessary to identify and analyze broadcast and multicast packets, and implement a series of measures to reduce the forwarding of broadcast and multicast packets.

- Respond to only specific devices in the network topology by proxy or by converting broadcast or multicast packets into unicast packets.
- Discard broadcast and multicast packets that are not allowed to be transmitted over air interfaces.
- Implement rate limiting for broadcast and multicast packets transmitted over air interfaces.

Overview

Feature	Description
Weight-based Broadcast Forwarding Control	Restricts weights of packet types for broadcast forwarding, so as to protect broadcast forwarding resources from being occupied by a certain type of packets and thereby guarantee normal forwarding of other packets.
Broadcast Forwarding Control in Wireless Mode	Controls whether to forward broadcast packets to a wireless network, so as to prevent useless broadcast packets from occupying substantial RF resources.
ARP Broadcast Control	Prevents ARP discovery and ARP scanning on a LAN.
ARP or ND Broadcast Isolation	Configures the AC to mutually broadcast ARP or ND packets between CAPWAP tunnel interfaces.
mDNS Packet Control	Configures the AC to allow mDNS packets to pass through.
SSDP Packet Control	Configures the AC to allow SSDP packets to pass through.
OSPF Packet Control	Configures the AC to allow OSPF packets to pass through.
VRRP Packet Control	Configures the AC to allow VRRP packets to pass through.
Intra-VLAN STA isolation	Enables intra-VLAN STA isolation.
Prohibition of Downstream Broadcast and Multicast Packets on Air Interfaces	Prohibits the device from sending downstream broadcast or multicast packets to air interfaces.
Control over Broadcast and Multicast Packets of Different Types	Configures forwarding policies and rate limit for different types of broadcast and multicast packets.
Rate Limiting on Broadcast and Multicast Packets	Configures a rate limit for broadcast and multicast packets of different types or different protocols as required.

Intelligent ARP Packet Forwarding	Configures intelligent ARP packet forwarding.
Intelligent DHCP Packet Forwarding	Configuring intelligent DHCP packet forwarding.

1.3.1 Weight-based Broadcast Forwarding Control

This function is used to restrict a certain type of packets, so that the ratio of this type of packets is no greater than the specified weight during broadcast forwarding.

Working Principle

- Classify packets. Packets can be classified into unicast packets, multicast packets, broadcast packets, unknown multicast packets, and unknown unicast packets.
- Allocate a token bucket to each type of packets, and record the number of packets permitted to pass at this moment.
- According to the configured broadcast forwarding weights, calculate the number of packets permitted to pass within each interval, and adjust the sizes of the token buckets accordingly.
- When a packet arrives, determine the type of the packet and check whether there is any token in the token bucket corresponding to the packet type. If the token bucket contains a token, the packet is permitted to pass; otherwise, the packet is discarded.

1.3.2 Broadcast Forwarding Control in Wireless Mode

This function is used to forward only some packets that affect STAs to the wireless network, so as to prevent useless broadcast packets from occupying substantial air interface resources.

Working Principle

Wireless networks differ from wired networks in performance. On a wireless network, air interface resources are shared by STAs and APs which often becomes a bottleneck for STAs. Broadcast packets are sent at low rates, which occupies more air interface resources.

In practice, some broadcast packets are useless for STAs. Forwarding these packets to a wireless network will result in fewer air interface resources and lowered user experience.

One solution is to classify broadcast packets for forwarding control. Only the packets of specified types are forwarded to the wireless network.

1.3.3 ARP Broadcast Control

Parse ARP packets to control uplink and downlink ARP packet forwarding.

Principles

In some scenarios, ARP discovery and ARP scanning on a LAN are not allowed.

On the AC, ARP broadcast packets are parsed to disallow STA from sending gratuitous ARP, sending ARP spoofing packets pretending to be the gateway, or forwarding ARP packets with non-trusted destination IPs for uplink ARP. Only ARP packets with trusted source IPs are allowed to be forwarded for downlink ARP.

1.3.4 ARP or ND Broadcast Isolation

ARP or ND broadcast isolation between CAPWAP tunnel interfaces are enabled by default. ARP or ND packets are not broadcast to CAPWAP tunnel interfaces directly. Instead, the gateway responds the APR and ND broadcast packets through ARP or ND proxy. In some scenarios with ARP or ND proxy disabled, STAs in a VLAN may fail to ping each other due to broadcast isolation.

Working Principle

In some scenarios with ARP or ND proxy disabled, to allow successful ping among STAs in a VLAN, you can run the command to disable ARP or ND broadcast isolation between CAPWAP tunnel interfaces.

1.3.5 mDNS Packet Control

When wireless broadcast forwarding is disabled, mDNS packets are not sent to the CAPWAP tunnel interface by default. You can run the command to send mDNS packets to the CAPWAP tunnel interface.

Working Principle

In some scenarios where broadcast forwarding control in wireless mode is disabled, you can run the command to send mDNS packets to the CAPWAP tunnel interface.

1.3.6 SSDP Packet Control

When broadcast forwarding control in wireless mode is disabled, SSDP packets are not sent to the CAPWAP tunnel interface by default. You can run the command to send SSDP packets to the CAPWAP tunnel interface.

Working Principle

In some scenarios where broadcast forwarding control in wireless mode is disabled, you can run the command to send SSDP packets to the CAPWAP tunnel interface.

1.3.7 OSPF Packet Control

OSPF packets are not sent to the CAPWAP and roaming tunnel interfaces by default. You can run the command to send OSPF packets to the CAPWAP and roaming tunnel interfaces.

Working Principle

In some scenarios where broadcast forwarding control in wireless mode is disabled, you can run the command to send OSPF packets to the CAPWAP and roaming tunnel interfaces.

1.3.8 VRRP Packet Control

VRRP packets are not sent to the CAPWAP and roaming tunnel interfaces by default. You can run the command to send VRRP packets to the CAPWAP and roaming tunnel interfaces.

Principles

In some scenarios where broadcast forwarding control in wireless mode is disabled, you can run the command to send VRRP packets to the CAPWAP and roaming tunnel interfaces.

1.3.9 Intra-VLAN STA isolation

By default, STAs in a VLAN are isolated from each other and can communicate with their gateways only. However, you can add devices to an allowlist to allow them to communicate with STAs in the VLAN.

Working Principle

If intra-VLAN STA isolation is enabled on a Fat AP, the AP forwards DHCP and ARP packets of STAs to discover their gateways. That is, STAs can communicate with their gateways by default but cannot communicate with each other. You can also add devices to an allowlist to enable them to communicate with STAs in the VLAN.

1.3.10 Prohibition of Downstream Broadcast and Multicast Packets on Air Interfaces

Working Principle

The AC and AP are prohibited from sending broadcast and multicast packets, which reduces the number of broadcast and multicast packets sent to air interfaces and alleviate the competition for air interface resources.

1.3.11 Control over Broadcast and Multicast Packets of Different Types

Working Principle

In scenarios where you need to configure the AC and AP to control broadcast and multicast packets of different types, configure forwarding policies for specified broadcast and multicast packets.

By default, the AC and AP are allowed to forward all broadcast and multicast packets.

To specify the type of packets that are not allowed to be forwarded, configure the device to block specified broadcast and multicast packets.

To specify the type of packets that can be forwarded, disable the forwarding of all broadcast and multicast packets and then permit specified broadcast and multicast packets, or permit specified broadcast and multicast packets directly.

1.3.12 Rate Limiting on Broadcast and Multicast Packets

Working Principle

You can limit the rate of broadcast and multicast packets of different types or different protocols as required.

Broadcast and multicast types include well-known multicast, unknown multicast, broadcast, and unknown unicast. You can limit the rate of packets based on the broadcast and multicast types. If the broadcast and multicast packets of a specific protocol are configured to be forwarded, you can also limit the rate of the broadcast and multicast packets of different protocols. This effectively reduces resource competition and improves air interface performance.

1.3.13 Intelligent ARP Packet Forwarding

On an IPv4 network, the most common broadcast and multicast packets are ARP and DHCP packets. These packets usually require a specific server or client to respond, but are broadcast on Layer 2 WLANs. Intelligent ARP packet forwarding can be used to intelligently identify ARP packets and forward only the ARP packets required by clients.

Working Principle

The AP processes the broadcast ARP request packet received by the air interface as follows:

- Proxy ARP is configured so that the AC or AP can respond to the ARP request packet.
- If the STA corresponding to the IP address in the ARP request packet is not connected to the AP, the AP considers that the STA is connected to another AP and discards the ARP request packet.

1.3.14 Intelligent DHCP Packet Forwarding

Working Principle

When a STA goes online, it sends a DHCP broadcast request packet that needs to be forwarded to the DHCP server, not to other STAs. Therefore, the AP does not need to forward the DHCP broadcast request packet over the air interface to prevent other wireless STAs from receiving the packet.

Some STAs require the DHCP server to respond to DHCP broadcast request packets. Therefore, DHCP broadcast response packets exist on the network. These packets need to be sent only to specific STAs. The AP can intelligently identify the STA addresses in DHCP broadcast response packets:

- If the STA is connected to the AP, the AP converts the DHCP response packet into a unicast packet and sends it to the client.
- If the STA is not connected to the AP, the AP discards the DHCP response packet.

1.4 Configuration

Configuration	Description and Command	
Configuring	⚠ (Optional) It is used to set the weights of packet types for broadcast forwarding.	
	data-plane queue-weight	Configures the weights of packet types for broadcast forwarding on the AC or AP.
	data-plane token	Configures the refresh interval of the broadcast token bucket and bucket-based rate on the AC or AP.
Configuring Broadcast Forwarding	⚠ (Optional) It is used to enable the broadcast wireless forwarding function.	
	data-plane wireless-broadcast	Enables or disables broadcast forwarding control in wireless mode on the AC or AP.
Configuring ARP Broadcast Control	⚠ (Optional) It is used to enable ARP broadcast control to prevent ARP discovery on a LAN.	
	data-plane arp-control enable	Enables or disables ARP broadcast control.
	data-plane arp-control vlan	Configures a trusted host for ARP broadcast control.
Configuring ARP or ND Broadcast Isolation	⚠ (Optional) It is used to control ARP or ND broadcast between CAPWAP tunnel interfaces.	
	data-plane close-arp-filter	Broadcasts ARP packets to the CAPWAP tunnel interface.
	data-plane close-nd-filter	Broadcasts ND packets to the CAPWAP

		tunnel interface.
Configuring the Device to Allow Specified Packets to Pass Through	(Optional) It is used to allow mDNS, SSDP, OSPF, or VRRP packets to pass through.	
	data-plane close-mdns-filter	Allows mDNS packets to pass through when broadcast forwarding control in wireless mode is disabled.
	data-plane close-ssdp-filter	Allows SSDP packets to pass through when broadcast forwarding control in wireless mode is disabled.
	data-plane close-ospf-filter	Allows OSPF packets to pass through when broadcast forwarding control in wireless mode is disabled.
	data-plane close-vrrp-filter	Allows VRRP packets to pass through when broadcast forwarding control in wireless mode is disabled.
Enabling Intra-VLAN STA Isolation	(Optional) It is used to forbid communication between STAs in a VLAN, ensuring network isolation between the STAs.	
	data-plane user-isolation vlan	Enables or disables intra-VLAN user isolation.
	data-plane user-isolation trusted-mac	Adds or deletes a trusted MAC address.
	data-plane user-isolation trusted-ip	Adds or deletes a trusted IPv4 address.
Configuring a Forwarding Policy for Broadcast or Multicast Packets	Optional. It is used to configure forwarding policies for broadcast and multicast packets.	
	data-plane bcmc deny all	Disables the AC and AP from sending broadcast and multicast packets to air interfaces.
	data-plan bcmc { **arp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **ssdp** | **ospf** | **vrrp** | **igmp** | **mld** | **other-broadcast** | **other-multicast** } **disable**	Disables the AC and AP from forwarding broadcast and multicast packets of different protocols.
	data-plane bcmc { **arp** | **igmp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **ssdp** | **other-broadcast** | **other-multicast** } **packets**	Configures a rate limit for broadcast and multicast packets of different protocols on the AC and AP.
	data-plane bcmc [**broadcast** | **multicast** | **unicast** | **unknown-multicast** | **unknown-unicast**] **packets**	Configures a rate limit for broadcast, multicast, and unknown unicast packets on the AC and AP.
Configuring Intelligent ARP Packet Forwarding	Optional. It is used to configure intelligent ARP packet forwarding. This function needs to be used with proxy ARP.	
	data-plane bcmc smart arp forward	Configures the AP to discard ARP broadcast packets of STAs not associated with the AP.
Configuring Intelligent	Optional. It is used to configure intelligent DHCP packet forwarding.	

DHCP Packet Forwarding	**data-plane bcmc smart dhcp forward**	Configures the AP to discard DHCP broadcast response packets for STAs not associated with the AP.

1.4.1 Configuring Weights for Broadcast Forwarding

Networking Requirements

You can control the weight of a packet type for forwarding according to the network situation, so as to avoid network congestion due to excessive burst traffic.

Notes

N/A

Configuration Steps

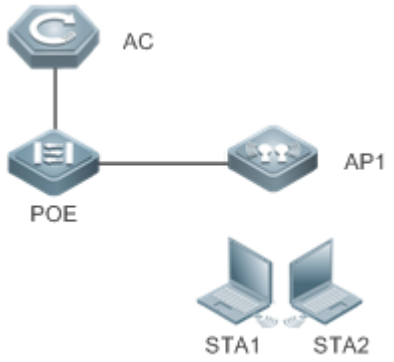
Configuring Weights for Broadcast Forwarding

- Optional. Run the **data-plane queue-weight** command to configure the broadcast forwarding weights.
- For centralized forwarding, configure this command in global configuration mode on the AC.
- For local forwarding, configuration this command in AP configuration mode on the AC.

Command	**data-plane queue-weight** *unicast-packet-weight multicast-packet-weight broadcast-packet-weight unknown-multicast-packet-weight unknown-unicast-packet-weight*
Parameter Description	*unicast-packet-weight*: Sets the weight for forwarding unicast packets. The value range is from 1 to 100. The default weight is 16. *multicast-packet-weight*: Sets the weight for forwarding multicast packets. The value range is from 1 to 50. The default weight is 4. *broadcast-packet-weight*: Sets the weight for forwarding broadcast packets. The value range is from 1 to 50. The default weight is 2. *unknown-multicast-packet-weight*: Sets the weight for forwarding unknown multicast packets. The value range is from 1 to 25. The default weight is 1. *unknown-unicast-packet-weight*: Sets the forwarding weight of unknown unicast packets. The value range is from 1 to 25. The default weight is 1.
Defaults	Default weights are applied.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Refresh Interval of Broadcast Token Bucket and Bucket-based Rate

- Optional. Run the **show run** command to display the configuration.
- For centralized forwarding, configure this command in global configuration mode on the AC.
- For local forwarding, configuration this command in AP configuration mode on the AC.



Command	**data-plane token** *token-interval token-base-rate*

Parameter Description	*token-interval*: Indicates the refresh interval of broadcast token bucket, in 10 ms. The default interval is 1. The value range is from 1 to 10,000. *token-base-rate*: Indicates the token bucket-based rate. The default rate is 64 for the AC and 5 for the AP. The value range is from 1 to 1,000,000.
Defaults	Default parameters are applied.
Command Mode	Global configuration mode
Usage Guide	Broadcast rate per second = Packet weight × (1s/Refresh Interval) x Token bucket-based rate Example: Broadcast rate per second for the AC = 1 x (1 / 0.01) x 64 = 6400 pps

Configuration Example

Configuring Weights for Broadcast Forwarding

Figure 7-1

Configuration Steps	Configure weights of packet types for broadcast forwarding in global configuration mode.

AC	`Hostname#configure terminal`
	`Hostname(config)#data-plane queue-weight 100 50 50 25 25`
	`Hostname(config)#data-plane token 10 10`
	`Hostname(config)#exit`

Verification	Run the **show running-config** command to display the configuration.

AC	`Hostname#show running-config`
	`…`
	`!`
	`cwmp`
	`!`
	`data-plane queue-weight 100 50 50 25 25`
	`data-plane token 10 10`
	`!`
	`…`

Common Errors

N/A

1.4.2 Configuring Broadcast Forwarding Control in Wireless Mode

Networking Requirements

Useless broadcast packets are not forwarded to the air interface.

Notes

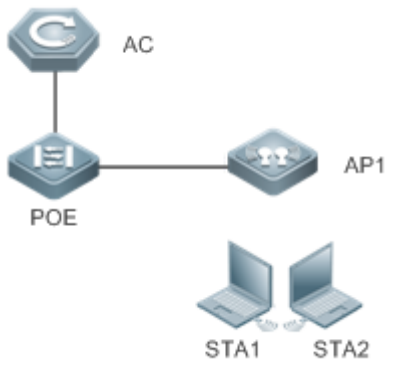
N/A

Configuration Steps

Configuring Broadcast Forwarding

- Optional.
- Broadcast packets on a network are limited by default.
- You can configure this function accordingly if you want to remove the limitation on broadcast packets on the network.

Command	**data-plane wireless-broadcast** { **enable** | **disable** }
Parameter Description	**enable**: Permits all broadcast packets to be forwarded to the air interface. **disable**: Prevents all broadcast packets from being forwarded to the air interface.
Defaults	Broadcast forwarding control in wireless mode is disabled; that is, broadcast packets are not forwarded to the wireless network.
Command Mode	Global configuration mode
Usage Guide	N/A



Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Enabling Broadcast Forwarding Control in Wireless Mode

Figure 7-2

Configuration	Enable broadcast forwarding control in wireless mode in global configuration mode.

Steps	
AC	Hostname#configure terminal Hostname(config)#data-plane wireless-broadcast enable
Verification	Run the **show running-config** command to display the configuration.
AC	Hostname# show ap-config running ! cwmp ! data-plane wireless-broadcast enable !

Common Errors

N/A

1.4.3 Configuring ARP Broadcast Control

Configuration Effect

Prevent ARP discovery and ARP scanning on a LAN.

Notes

N/A

Configuration Steps

Enabling ARP Broadcast Control

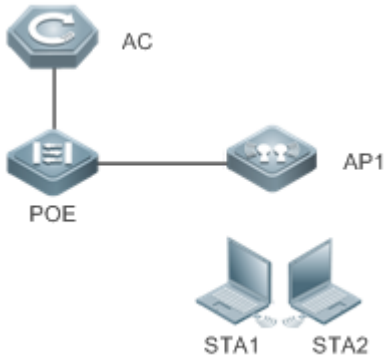
- Optional.
- Configure this function if you want to prevent ARP discovery and ARP scanning on a LAN.
- Configure this command in AC global configuration mode.

Command	**data-plane arp-control enable**
Parameter Description	**enable**: Enables ARP broadcast control to prevent ARP discovery and ARP scanning on a LAN.
Defaults	ARP broadcast control is disabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring the Trusted Host for ARP Broadcast Control

- Optional.
- Configure this command if you want to allow the specified host to discover the device on the LAN.
- In Ruijie Cloud scenarios, configure this command in AC global configuration mode.

Command	**data-plane arp-control vlan** *vlan-id* **trusted-host** *ipv4-address*



Parameter Description	*vlan-id*: Indicates the ID of the VLAN to be enabled with ARP broadcast control. The value range is from 1 to 4094. *ipv4-address*: Indicates the trusted IP address. Up to 64 IP addresses are allowed.
Defaults	No trusted IP address is configured by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Enabling ARP Broadcast Control

Scenario Figure1-1	
Configuration Steps	● Enable ARP broadcast control in global configuration mode.
AC	`Hostname#configure terminal` `Hostname(config)# data-plane arp-control enable`
Verification	● Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config`
	`!`
	`cwmp`
	`!`
	`data-plane arp-control enable`
	`!`

Common Errors

N/A

1.4.4 Configuring ARP or ND Broadcast Isolation

Configuration Effect

Control whether to broadcast ARP or ND packets to the CAPWAP tunnel interface.

Notes

N/A

Configuration Steps

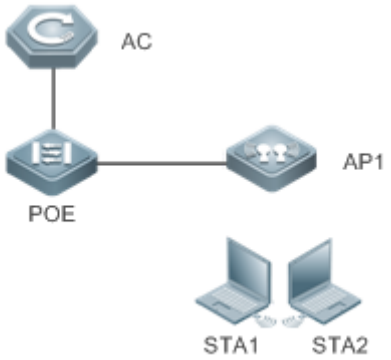
Disabling ARP Broadcast Isolation

- Optional.
- Configure this function if you want to broadcast ARP packets to the CAPWAP tunnel interface.
- Configure this command in global configuration mode.

Command	**data-plane close-arp-filter** { **enable** | **disable** }
Parameter Description	**enable**: Allows ARP packets to be broadcast to the CAPWAP tunnel interface. **disable**: Prevents ARP packets from being broadcast to the CAPWAP tunnel interface.
Defaults	ARP packets are not broadcast to the CAPWAP tunnel interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Disabling ND Broadcast Isolation

- Optional.
- Configure this function if you want to broadcast ND packets to the CAPWAP tunnel interface.
- Configure this command in global configuration mode.



Command	**data-plane close-nd-filter** { **enable** | **disable** }
Parameter Description	**enable**: Allows ND packets to be broadcast to the CAPWAP tunnel interface. **disable**: Prevents ND packets from being broadcast to the CAPWAP tunnel interface.
Defaults	ND packets are not broadcast to the CAPWAP tunnel interface.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Disabling ARP Broadcast Isolation

Scenario **Figure 1-2**	
Configuration Steps	Disable ARP broadcast isolation in global configuration mode.
AC	`Hostname#configure terminal` `Hostname(config)#data-plane close-arp-filter enable`
Verification	Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config`
	`!`
	`cwmp`
	`!`
	`data-plane close-arp-filter enable`
	`!`

Common Errors

N/A

1.4.5 Configuring the Device to Allow Specified Packets to Pass Through

Configuration Effect

When wireless broadcast forwarding is disabled, allow mDNS, SSDP, OSPF, or VRRP packets to pass through.

Notes

N/A

Configuration Steps

↘ Configuring mDNS Packet Control

- Optional.
- Configure this function if you want to allow mDNS packets to pass through.
- Configure this command in global configuration mode.

Command	**data-plane close-mdns-filter** { **enable** | **disable** }
Parameter	**enable**: Allows mDNS packets to be forwarded to the air interface.

Description	**disable**: Prevents mDNS packets from being forwarded to the air interface.
Defaults	mDNS packets are not forwarded to the wireless network.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring SSDP Packet Control

- Optional.
- Configure this function if you want to allow SSDP packets to pass through.
- Configure this command in global configuration mode.

Command	**data-plane close-ssdp-filter** { **enable** | **disable** }
Parameter Description	**enable**: Allows SSDP packets to be forwarded to the air interface. **disable**: Prevents SSDP packets from being forwarded to the air interface.
Defaults	SSDP packets are not forwarded to the wireless network.
Command Mode	Global configuration mode
Usage Guide	N/A

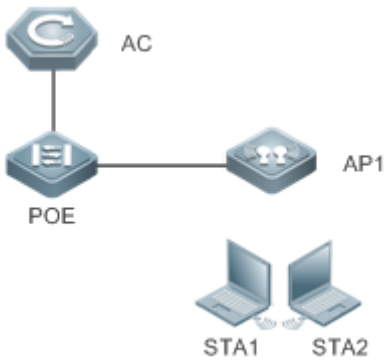
Configuring OSPF Packet Control

- Optional.
- Configure this function if you want to allow OSPF packets to pass through.
- Configure this command in global configuration mode.

Command	**data-plane close-ospf-filter** { **enable** | **disable** }
Parameter Description	**enable**: Allows OSPF packets to be forwarded to the air interface. **disable**: Prevents OSPF packets from being forwarded to the air interface.
Defaults	OSPF packets are not forwarded to the wireless network.
Command Mode	Global configuration mode
Usage Guide	N/A

Configuring VRRP Packet Control

- Optional.
- Configure this function if you want to allow VRRP packets to pass through.
- Configure this command in global configuration mode.



Command	**data-plane close-vrrp-filter** { **enable** | **disable** }
Parameter Description	**enable**: Allows VRRP packets to be forwarded to the air interface. **disable**: Prevents VRRP packets from being forwarded to the air interface.
Defaults	VRRP packets are not forwarded to the wireless network.
Command Mode	Global configuration mode
Usage Guide	N/A

Verification

Run the **show running-config** command to display the configuration.

Configuration Example

Configuring the Device to Allow OSPF Packets to Pass Through

Scenario **Figure 1-3**	
Configuration Steps	Configure the device to allow OSPF packets to pass through in global configuration mode.
AC	`Hostname#configure terminal` `Hostname(config)#data-plane close-ospf-filter enable`
Verification	Run the **show running-config** command to display the configuration.

AC	`Hostname# show running-config`
	`!`
	`cwmp`
	`!`
	`data-plane close-ospf-filter enable`
	`!`

Common Errors

N/A

1.4.6 Enabling Intra-VLAN STA Isolation

Configuration Effect

By default, STAs in a VLAN cannot communicate with each other and can communicate with their gateways only. You can add the MAC addresses of devices that need to communicate with STAs in the VLAN to an allowlist.

Notes

- The IP DHCP snooping function must be enabled.
- STAs must obtain IP addresses through DHCP, and only IPv4 addresses are supported.
- The default gateway IP address must be configured for the DHCP address pool.

- When intra-VLAN user isolation is enabled, STAs will be brought offline and wired STAs can access the network only after they obtain IP addresses through DHCP.

Configuration Steps

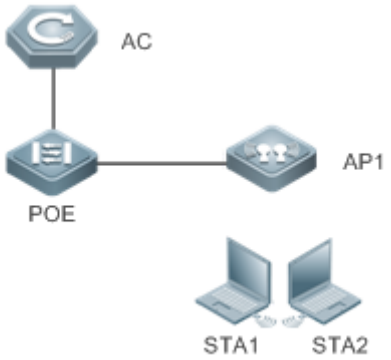
Enabling Intra-VLAN STA Isolation

Optional.

Command	**data-plane user-isolation vlan** *vid*
Parameter Description	*vid*: Indicates the ID of the VLAN for which STA isolation is enabled. The value range is from 1 to 4094.
Defaults	STAs in a VLAN are not isolated by default.
Command Mode	AP group configuration mode
Usage Guide	1. To enable intra-VLAN STA isolation, you must enable IP DHCP snooping first. 2. The default gateway IP address must be configured for the DHCP address pool. 3. STA isolation can be enabled for a maximum of 16 VLANs on an AP group.

Configuring an Allowlist

Optional.



Command	**data-plane user-isolation** { **trusted-mac** *H.H.H* | **trusted-ip** *ipv4_address* } **vlan** *vid*
Parameter Description	*H.H.H*: Indicates the MAC address of a STA to be allowed to communicate with other STAs in the VLAN. *ipv4_address*: Indicates the IPv4 address of a STA to be allowed to communicate with other STAs in the VLAN. *vid*: Indicates the ID of the VLAN for which STA isolation is enabled.
Defaults	STAs in a VLAN are not isolated by default.
Command Mode	AP group configuration mode
Usage Guide	A maximum of 64 allowlists can be configured for intra-VLAN STA isolation on an AP group.

Verification

Run the **show data-plane user-isolation ap-group** *ap_group_name* command to display the configuration.

Configuration Example

Enabling STA Isolation for VLAN 10

Scenario **Figure 1-9**	
Configuration Steps	Configure the default gateway of AP1 on the PoE switch. In AP group configuration mode of the AC, add the STA whose MAC address is 0010.1111.2222 to the allowlist.

AC	`Hostname# configure terminal`
	`Hostname(config)# ap-group ap1`
	`Hostname(config-group)# data-plane user-isolation vlan 10`
	`Hostname(config-group)# data-plane user-isolation trusted-mac 0010.1111.2222 vlan 10`

Verification	Run the **show data-plane user-isolation ap-group** *ap_group_name* command to display the configuration.

AC	`Hostname# show show data-plane user-isolation ap-group ap1`
	`!`
	`data-plane user-isolation vlan 10`
	`data-plane user-isolation trusted-mac 0010.1111.2222 vlan 10`
	`!`

Common Errors

IP DHCP snooping is not configured.

1.4.7 Configuring a Forwarding Policy for Broadcast or Multicast Packets

Configuration Effect

After this function is configured, the number of broadcast and multicast packets forwarded to wireless STAs will be reduced, alleviating the competition for air interface resources and improving network quality.

Notes

- N/A

Configuration Steps

↘ Disabling the Forwarding of Broadcast and Multicast Packets to Air Interfaces

- Optional.
- Configure this function to prevent all broadcast and multicast packets from being sent to wireless STAs.

Command	data-plane bcmc deny all
Parameter Description	N/A
Defaults	All broadcast and multicast packets can be forwarded.
Command Mode	Global configuration mode, AP configuration mode, or all-AP configuration mode
Usage Guide	On a large Layer 2 wireless network where numerous broadcast and multicast packets affect normal services, run this command to prevent all broadcast and multicast packets from being sent to air interfaces. To permit specified packets, configure the forwarding of broadcast and multicast packets of different types.

Disabling the Forwarding of Broadcast and Multicast Packets of Different Protocols

- Optional.
- All broadcast and multicast packets can be forwarded by default on the network.
- Configure this function to prevent specific broadcast and multicast packets from being forwarded on the network.

Command	**data-plan bcmc** { **arp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **ssdp** | **ospf** | **vrrp** | **igmp** | **mld** | **other-broadcast** | **other-multicast** } **disable**
Parameter Description	**disable**: Disables the forwarding of broadcast and multicast packets to air interfaces.
Defaults	All broadcast and multicast packets can be forwarded.
Command Mode	Global configuration mode, AP configuration mode, or all-AP configuration mode
Usage Guide	1. By default, all broadcast and multicast packets are allowed to be sent to air interfaces. 2. In a service scenario where only packets of a specified type need to be forwarded on the network, run the **data-pane bcmc deny all** command to disable the forwarding of all broadcast and multicast packets, and then enables the forwarding of specified packets. For example, in a scenario where only printers and speakers require support, run the **data-pane bcmc deny all** command to disable the forwarding of all packets, and then run the **no data-plane bcmc arp disable** and **no data-plane bcmc mdns disable** commands to enable the forwarding of ARP and MDNS packets. 3. In service scenarios where you need to disable the forwarding of broadcast and multicast packets of a specified type, run this command. If you need to disable the forwarding of SSDP packets, run the **data-plane bcmc ssdp disable** command**.** 4. The **other-broadcast** and **other-multicast** parameters indicates other broadcast or multicast packets not predefined in this command. 5. The forwarding configuration for all packets takes priority over the forwarding configuration for specific packets. For example, run the **data-plane bcmc deny arp disable** command to disable ARP packet forwarding, and then run the **no data-plane bcmc deny all** command to enable the forwarding of all broadcast and multicast packets so that ARP packets can be also forwarded. Or run the **data-plane bcmc deny all** command to disable the forwarding of broadcast and multicast packets, then run the **no data-plane bcmc deny arp disable** command to enable ARP packet forwarding, and then run the **data-plane bcmc deny all** command to prevent ARP packets from being forwarded.

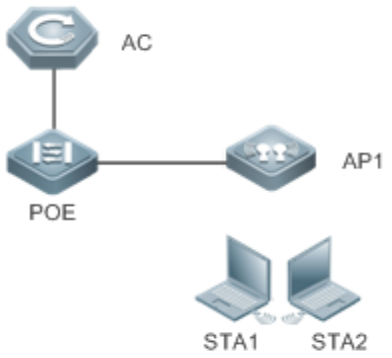
Configuring a Rate Limit for Broadcast and Multicast Packets of Different Protocols

- Optional.
- Configure this function to limit the rate of broadcast or multicast packets of a specific protocol on the network.

Command	**data-plan bcmc** { **arp** | **nd** | **dhcp** | **dhcpv6** | **mdns** | **ssdp** | **ospf** | **vrrp** | **igmp** | **mld** | **other-broadcast** | **other-multicast** } **packets** *packets-rate*
Parameter Description	*packets-rate*: Indicates the rate limit, in pps. The value range is from 1 to 1000000.
Defaults	The rate limiting function for packet forwarding is disabled.
Command Mode	Global configuration mode, AP configuration mode, or all-AP configuration mode
Usage Guide	N/A

Configuring a Rate Limit for Broadcast and Multicast Packets of Different Types

- Optional.
- Configure this function to limit the rate of broadcast packets, multicast packets, unicast packets, unknown unicast packets, and unknown multicast packets on the network.



Command	**data-plan bcmc** { **broadcast** | **multicast** | **unicast** | **unknown-multicast** | **unknown-unicast** } **packets** *packets-rate*
Parameter Description	*packets-rate*: Indicates the rate limit, in pps. The value range is from 1 to 1000000.
Defaults	The rate limiting function for packet forwarding is disabled.
Command Mode	Global configuration mode, AP configuration mode, or all-AP configuration mode
Usage Guide	1. Supported packet types include broadcast, multicast, unicast, unknown unicast, and unknown multicast. 2. This function can be used together with the rate limiting function for broadcast and multicast packets of specified protocols to implement multi-level rate limit control. For example, the rate limit for broadcast packets is set to 1000 pps, and the rate limit for ARP packets is set to 200 pps.

Verification

Run the **show running-config** or **show ap-config running** command to display the configuration.

Configuration Examples

Configuring a Forwarding Policy for Downstream Broadcast or Multicast Packets on Air Interfaces

Scenario	
Configuration Steps	1. On the AC, disable AP1 from forwarding downstream broadcast and multicast packets to the air interface. 2. Disable AP2 from forwarding downstream MDNS broadcast and multicast packet to the air interface. 3. Set the rate limit of downstream SSDP packets on the air interface of AP2 to 100 pps. **4.** Set the rate limit of broadcast packets for AP2 to 1000 pps.

AC	`Hostname(config)#ap-config AP1`
	`Hostname(config-ap)#data-plane bcmc deny all`
	`Hostname(config-ap)#exit`
	`Hostname(config)#ap-config AP2`
	`Hostname(config-ap)#data-plane bcmc mdns disable`
	`Hostname(config-ap)#data-plane bcmc ssdp packets 100`
	`Hostname(config-ap)#data-plane bcmc broadcast packets 1000`

Verification	Run the **show ap-config running** command to display the configuration.

AC	`Hostname# show ap-config running`
	`!`
	`cwmp`
	`!`
	`ap-config AP1`
	` data-plane bcmc arp disable`
	` data-plane bcmc nd disable`
	` data-plane bcmc dhcp disable`
	` data-plane bcmc dhcpv6 disable`
	` data-plane bcmc mdns disable`
	` data-plane bcmc ssdp disable`
	` data-plane bcmc igmp disable`
	` data-plane bcmc mld disable`
	` data-plane bcmc ospf disable`
	` data-plane bcmc vrrp disable`

	data-plane bcmc other-multicast disable data-plane bcmc other-broadcast disable ap-config AP2 data-plane bcmc mdns disable data-plane bcmc ssdp packets 100 data-plane bcmc broadcast packets 1000

Common Errors

N/A

1.4.8 Configuring Intelligent ARP Packet Forwarding

Configuration Effect

If the STA corresponding to the IP address in the ARP request packet is not connected to the AP, the AP determines that the STA is connected to another AP and discards the ARP request packet.

Notes

- To enable intelligent ARP packet forwarding, enable DHCP snooping first. Otherwise, other STAs and management devices cannot learn the MAC address of the current STA.
- User IP addresses must be obtained through DHCP. Currently, only IPv4 addresses are supported. If user IP addresses are not obtained through DHCP, user IP addresses need to be added to the intelligent ARP forwarding allowlist.
- The default gateway IP address needs to be configured for the DHCP address pool.
- Proxy ARP needs to be configured on the AC or AP.

Configuration Steps

↘ Configuring Intelligent ARP Packet Forwarding

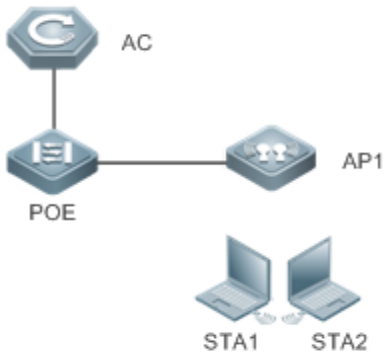
- Optional.
- Configure this function for the AP to discard ARP broadcast packets of STAs that are not connected to the AP on the network.

Command	**data-plane bcmc smart arp forward**
Parameter Description	N/A
Defaults	This function is disabled. That is, ARP broadcast packets of STAs not connected to the AP are not discarded.
Command Mode	Global configuration mode, AP configuration mode, or all-AP configuration mode
Usage Guide	1. If the STA corresponding to the IP address in the ARP request packet is not connected to the AP, the AP determines that the STA is connected to another AP. In this case, the AP discards the ARP request packet.

	2. STA lookup is implemented through proxy ARP and DHCP snooping. If proxy ARP and DHCP snooping are not configured, enabling this function will cause other devices to fail to learn the MAC address of the STA. 3. Use IP addresses must be obtained through DHCP. If user IP addresses are not obtained through DHCP, you need to add them to the intelligent ARP forwarding allowlist.

Configuring an Allowlist for Intelligent ARP Packet Forwarding

- Optional.
- To forward the ARP request packet from the STA that is not connected to the AP, add the IP address of the STA to the the intelligent ARP forwarding allowlist.



Command	**data-plane bcmc smart arp forward permit-ip**
Parameter Description	N/A
Defaults	No allowlist is configured.
Command Mode	Global configuration mode, AP configuration mode, or all-AP configuration mode
Usage Guide	1. To forward the ARP request packet from the STA that is not connected to the AP, add the IP address of the STA to the intelligent ARP forwarding allowlist. 2. Intelligent ARP packet forwarding takes effect only for users who obtain IP addresses through DHCP. To enable intelligent ARP packet forwarding for users with static IP addresses, add the user IP addresses to the intelligent ARP forwarding allowlist.

Verification

Run the **show running-config** and **show ap-config running** commands to display the configurations.

Configuration Examples

Configuring Intelligent ARP Packet Forwarding

Scenario	
Configuration Steps	● Configure DHCP snooping and proxy ARP on the AC. ● Configure intelligent ARP packet forwarding for AP1 on the AC.

AC	`Hostname(config)#ip dhcp snooping`
	`Hostname(config)#proxy-arp enable`
	`Hostname(config)#ap-config AP1`

	`Hostname(config-ap)#data-plane bcmc smart arp forward`
Verification	Run the **show running** and **show ap-config running** commands to display the configurations.

AC	`Hostname# show running`
	`!`
	`ip dhcp snooping`
	`proxy-arp enable`
	
	`Hostname# show ap-config running`
	`!`
	`cwmp`
	`!`
	`ap-config ap`
	`data-plane bcmc smart arp forward`

Common Errors

- Proxy ARP is not configured.
- The user IP address is not configured to be obtained through DHCP, and the user IP address is not added to the intelligent ARP forwarding allowlist.
- DHCP snooping is not enabled.

1.4.9 Configuring Intelligent DHCP Packet Forwarding

Configuration Effect

When a STA goes online, it sends a DHCP broadcast request packet that needs to be forwarded to the DHCP server, not to other STAs. Therefore, the AP does not need to forward the DHCP broadcast request packet over the air interface to prevent other wireless STAs from receiving the packet.

Some STAs require the DHCP server to respond to DHCP broadcast request packets. Therefore, DHCP broadcast response packets exist on the network. These packets need to be sent only to specific STAs. The AP intelligently identifies and checks the STA addresses in the received DHCP broadcast response packets.

- If the STA is connected to the AP, the AP converts the DHCP response packet into a unicast packet and sends it to the STA.
- If the STA is not connected to the AP, the AP discards the DHCP response packet.

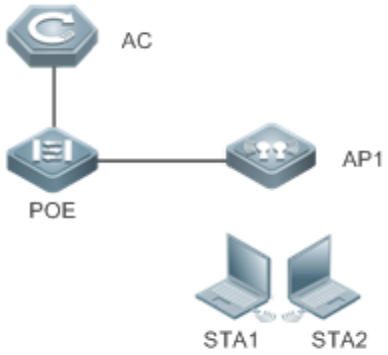
Notes

- By default, the DHCP request packet from a wireless STA is not forwarded to other wireless STAs.
- By default, the DHCP broadcast packets replied by the DHCP server are converted into unicast packets for forwarding.

Configuration Steps

Configuring Intelligent DHCP Packet Forwarding

- Optional.
- Configure this function for the AP to intelligently discard broadcast packets replied by the DHCP server to STAs that are not connected to the AP.



Command	data-plane bcmc smart dhcp forward
Parameter Description	N/A
Defaults	This function is disabled. That is, the AP does not discard broadcast packets replied by the DHCP server to STAs that are not connected to the AP.
Command Mode	Global configuration mode, AP configuration mode, or all-AP configuration mode
Usage Guide	N/A

Verification

Run the **show ap-config running** command to display the configuration.

Configuration Examples

Configuring Intelligent DHCP Packet Forwarding

Scenario	
Configuration Steps	• On the AC, disable AP1 from converting DHCP broadcast response packets into unicast packets for STAs. • On the AC, configure intelligent DHCP packet forwarding for AP1.
AC	`Hostname(config)#ap-config AP1` `Hostname(config-ap)#data-plane bcmc smart dhcp forward`
Verification	Run the **show ap-config running** command to display the configuration.

AC	`Hostname# show ap-config running`
	`!`
	`cwmp`
	`!`
	`ap-config ap`
	`data-plane bcmc smart dhcp forward`

1 Configuring Metric Monitoring

1.1 Overview

Metric monitoring is developed to collect and monitor key data on an access controller (AC) or access point (AP), to improve the information collection and fault locating efficiency.

Protocols and Standards

N/A

1.2 Features

Overview

Feature	Description
Metric Monitoring	Commands can be run to display and clear data of a specified metric on a specified device.

1.2.1 Metric Monitoring

Working Principle

Wireless devices collect and record data of metrics defined in the system. CLI commands provided by the metrics module can display or clear data by metric group or metric name.

1.3 Configuration

Configuration	Description and Command	
Displaying and Clearing Metric Data	⚠ (Optional) It is used to enable the broadcast wireless forwarding function.	
	metrics monitor enable	Enables metric monitoring on the device.
	clear metrics all	Clears all metric data.
	clear metrics group *group-name*	Clears data of all metrics in a specified metric group.
	clear metrics group *group-name metrics-name*	Clears data of a specified metric in a specified metric group.

1.3.1 Displaying and Clearing Metric Data

Configuration Effect

Clear metric data collected by the device. The range of data to be cleared can be configured and may include all data, data of a specified group, and data of a specified metric in a specified group.

Notes

N/A

Configuration Steps

Enabling Metric Monitoring on the Device

- Optional.
- In global configuration mode, enable metric monitoring on the device.

Command	**metrics monitor enable**
Parameter Description	N/A
Defaults	It is enabled by default.
Command Mode	Global configuration mode
Usage Guide	N/A

Clearing All Metric Data

- Optional.
- In global configuration mode, clear all metric data collected by the device.

Command	**clear metrics all**
Parameter Description	N/A
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Clearing Data of All Metrics in a Specified Metric Group

- Optional.
- In global configuration mode, clear data of all metrics in a specified metric group on the device.

Command	**clear metrics group** *group-name*
Parameter Description	*group-name*: Indicates the name of a specified metric group.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Clearing Data of a Specified Metric in a Specified Metric Group

- Optional.
- In global configuration mode, clear data of a specified metric in a specified metric group.

Command	**clear metrics group** *group-name metrics-name*
Parameter	*group-name*: Indicates the name of a specified metric group.

Description	*metrics-name*: Indicates the name of a specified metric.
Defaults	N/A
Command Mode	Privileged EXEC mode
Usage Guide	N/A

Verification

- Run the **show metrics summary** command to display collected data.
- Run the **show metrics summary group** *group-name* command to display data of all metrics in a metric group.
- Run the **show metrics detail** *group-name metrics-name* command to display data of a specified metric in a metric group.

Configuration Example

Clearing Specified Data

Configuration Steps	• 1. Clear all metric data. • 2. Clear data of all metrics in a metric group named **sys**. • 3. Clear data of a metric named **memory** in a metric group named **sys**.

	`Hostname# clear metrics all`
	`Hostname# clear metrics group sys`
	`Hostname# clear metrics group sys memory`

Verification	1. Run the **show metrics summary** command to display collected data. 2. Run the **show metrics summary group** *group-name* command to display data of all metrics in a specified metric group. 3. Run the **show metrics detail** *group-name metrics-name* command to display data of a specified metric in a specified metric group. 4. The following uses the **show metrics summary** command as an example. Run this command immediately after clearing metric data.

	`Hostname# clear metrics all`
	`Hostname# show metrics summary`
	`group  name  unit  tags`
	`value  LastUpdTime`
	`Hostname#`

Common Errors

N/A

1.4 Monitoring

Clearing

N/A

Displaying

Command	Description
show metrics define summary	Displays the summary of existing metrics.
show metrics define summary group *group-name*	Displays the summary of existing metrics in a specified metric group.
show metrics detail *group-name metrics-name*	Displays metric details.
show metrics summary	Displays the summary of all metrics.
show metrics summary group *group-name*	Displays the summary of all metrics in a specified metric group.

1 Configuring the ACL

1.1 Overview

An access control list (ACL) is also called access list. The ACL defines rules to determine whether to forward or drop data packets arriving at a network interface.

ACLs are classified into two types by function:

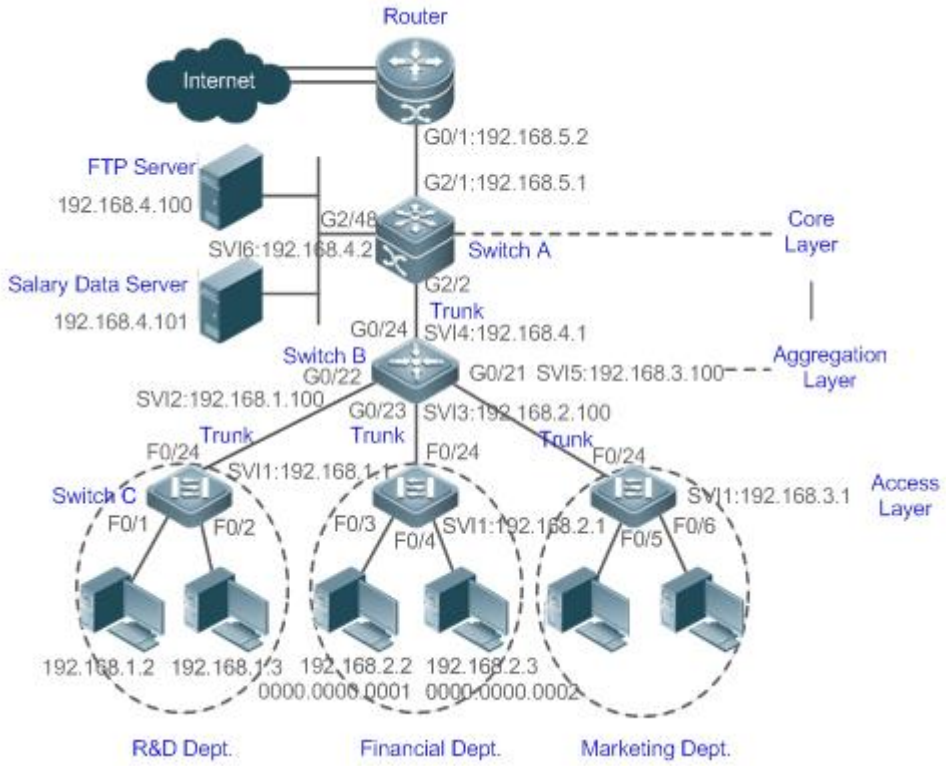
- Security ACLs: are used to control data flows that are allowed to pass through a network device.
- Quality of service (QoS) ACLs: are used to classify and process data flows by priority.

ACLs are typically used in the following situations:

- Network access control: To ensure network security, define rules to limit users' access to some services (for example, only access to web and email services is permitted, and access to other services such as Telnet is prohibited), to allow users to access services in a specified period of time, or to allow only specified hosts to access a network.
- QoS: QoS ACLs are used to preferentially classify and process important data flows. For details about QoS ACLs, see *Configuring QoS*.

1.2 Applications

Application	Description
Access Control of an Enterprise Network	On an enterprise network, network access rights of each department, for example, access rights of servers and use permissions of chatting tools such as Facebook Messenger, must be controlled as needed.



1.2.1 Access Control of an Enterprise Network

Scenario

Internet viruses can be found everywhere. Therefore, it is necessary to block interfaces that are often attacked by viruses to ensure security of an enterprise network:

- Allow only internal PCs to access the server.
- Prohibit PCs of a non-financial department from accessing PCs of the financial department, and prohibit PCs of a non-R&D department from accessing PCs of the R&D department.
- Prohibit the staff of the R&D department from using chatting tools such as Facebook Messenger during working hours from 09:00 to 18:00.

Figure 1-1

Remarks	Switch C at the access layer: is connected to PCs of each department and to Switch B at the aggregation layer through the 1000M optical fiber (trunk mode). Switch B at the aggregation layer: Is connected to the Switch A at the core layer through the 10GE optical fiber (trunk mode). Multiple virtual local area networks (VLANs) are divided, and a VLAN is allocated to each department. Switch A at the core layer: is connected to various servers, such as the File Transfer Protocol (FTP) server and Hypertext Transfer Protocol (HTTP) server, and to the Internet through firewalls.

Deployment

- Configure extended ACLs on G2/1 to filter data packets, protecting the network against viruses. This interface is located on Switch A and connects Switch A to G2/1 of a router.
- Allow only internal PCs to access servers, and prohibit external PCs from accessing servers. Define and apply the extended IP ACLs on G2/2 or switch virtual interface (SVI) 2 that is used to connect Switch A to an aggregation layer device or server.
- Prohibit mutual access between specified departments. Define and apply the extended IP ACLs on G0/22 and G0/23 of Switch B.
- Configure and apply the time-based extended IP ACLs on SVI 2 of Switch B to prohibit the R&D department from using chatting tools such as Facebook Messenger in a specified period of time.

1.3 Features

Basic Concepts

ACL

ACLs include basic and dynamic ACLs.

You can select basic or dynamic ACLs as required. In most situations, basic ACLs can meet security requirements. However, attackers may use certain software to access a network by means of IP address spoofing. If dynamic ACLs are used, users are requested to pass identify authentication before accessing a network, which prevents attackers from intruding the network. Therefore, you can use dynamic ACLs in some sensitive areas to guarantee network security.

ACLs cannot eliminate IP address spoofing. Attackers may use forged IP addresses to access a network during the validity period of authenticated user identities. Two methods are available to resolve this problem. One is to set the idle time of user access to a smaller value, which increases the difficulty for attackers to attack a network. The other is to encrypt network data using IP Security (IPsec), which ensures that all data is encrypted when arriving at a device.

ACLs are configured on the following network devices:

- Devices between the internal network and the external network (such as the Internet)
- Devices on the border of two network segments
- Devices connected to controlled interfaces

ACL statements must be executed in strict compliance with their sequence in the ACL. The device matches packets with the ACL starting from the first statement. Once the header of a data packet matches a statement in the ACL, the subsequent statements are ignored and no longer checked.

Input/Output ACLs, Filtering Field Template, and Rules

When receiving a packet on an interface, the device checks whether the packet matches any access control entry (ACE) in the input ACL of this interface. Before sending a packet through an interface, the device checks whether the packet matches any ACE in the output ACL of this interface.

When different filtering rules are defined, all or only some rules may be applied simultaneously. If a packet matches an ACE, this packet is processed according to the action policy (permit or deny) defined in this ACE. ACEs in an ACL identify Ethernet packets based on the following fields in the Ethernet packets:

Layer 2 fields:

- 48-bit source MAC address (containing all 48 bits)
- 48-bit destination MAC address (containing all 48 bits)
- 16-bit Layer 2 type field

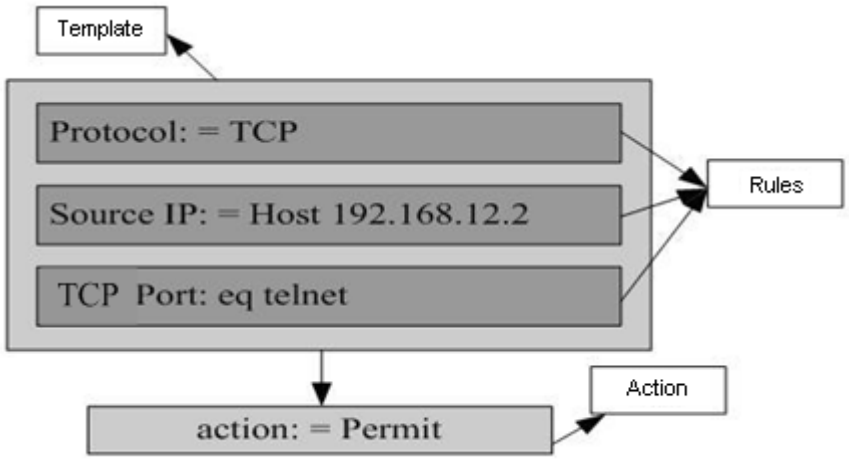
Layer 3 fields:

- Source IP address field (All source IP addresses can be specified, or the subnet can be used to define a type of data flows.)
- Destination IP address field (All destination IP addresses can be specified, or the subnet can be used to define a type of data flows.)
- Protocol type field

Layer 4 fields:

- Either a TCP source or destination port is specified, both TCP source and destination ports are specified, or the range of the source or destination port is specified.
- Either a UDP source or destination port is specified, both UDP source and destination ports are specified, or the range of the source or destination port is specified.

Filtering fields refer to the fields in packets that can be used to identify or classify packets when an ACE is generated. A filtering field template is a combination of these fields. For example, when an ACE is generated, packets are identified and classified based on the destination IP address field in each packet; when another ACE is generated, packets are identified and classified based on the source IP address field and UDP source port field in each packet. The two ACEs use different filtering field templates.



Rules refer to values of fields in the filtering field template of an ACE. For example, the content of an ACE is as follows.

```
permit tcp host 192.168.12.2 any eq telnet
```

In this ACE, the filtering field template is a combination of the following fields: source IP address field, IP protocol field, and TCP destination port field. The corresponding values (rules) are as follows:

- Source IP address = Host 192.168.12.2
- IP protocol = TCP
- TCP destination port = Telnet

Figure 1-2 Analysis of the ACE: permit tcp host 192.168.12.2 any eq telnet

- A filtering field template can be a combination of Layer 3 and Layer 4 fields, or a combination of multiple Layer 2 fields. The filtering field template of a standard or an extended ACL, however, cannot be a combination of Layer 2 and Layer 3 fields, a combination of Layer 2 and Layer 4 fields, or a combination of Layer 2, Layer 3, and Layer 4 fields. To use a combination of Layer 2, Layer 3, and Layer 4 fields, you can use the expert ACLs.
- An SVI associated with ACLs in the outbound direction supports the standard IP, extended IP, extended MAC, and expert ACLs.
- If an extended MAC or expert ACL is configured to match the destination MAC address and is applied to the outbound direction of an SVI, the ACEs containing the destination MAC address can be configured but cannot take effect. If an ACE in a standard IP ACL, extended IP ACL, or expert ACL is configured to match the destination IP address, and the destination IP address is not in the subnet IP address range of the associated SVI, the ACE cannot take effect. For example, the subnet IP address range of VLAN 1 is 192.168.64.1 255.255.255.0, and an IP extended ACL is created and contains the ACE of **deny udp any 192.168.65.1 0.0.0.255 eq 255**. If the ACL is applied to the outbound interface of VLAN 1, the ACL cannot take effect because the destination IP address is not within the subnet IP address range of VLAN 1. If the ACE is **deny udp any 192.168.64.1 0.0.0.255 eq 255**, the ACL can take effect because the destination IP address is within the subnet IP address range of VLAN 1.
- The ACL applied to the outbound direction of a physical interface or aggregate interface can match only well-known unicast and multicast packets but not unknown unicast packets. That is, such an ACL is ineffective for the unknown or broadcast packets.
- When the input ACL, 802.1X, global IP-MAC binding, port security, and IP source guard are all configured, the ACEs with permit statements and default deny statement do not take effect but other ACEs with deny statements take effect.
- When both the input ACL and QoS ACL are configured, the ACEs with permit statements do not take effect, but ACEs with deny statements except the default deny statement take effect. The QoS ACL takes precedence over the ACL that contains the default deny statement.
- An ACE is added to the ACL that has been applied to the inbound direction of multiple SVIs, and the device is restarted after the configuration is saved. In this case, the ACL may fail to be configured on several SVIs due to limitation on the hardware.
- If an expert ACL is configured and applied to the outbound direction of an interface, and some ACEs in this ACL contain Layer 3 matching information (for example, IP address and Layer 4 port), non-IP packets sent to the device from this interface cannot be controlled by the permit and deny ACEs in this ACL.
- If ACEs of an ACL (IP ACL or extended expert ACL) are configured to match non-Layer 2 fields (such as SIP and DIP), the ACL is invalid for tagged MPLS packets.

Overview

Feature	Description

Feature	Description
IP ACL	Control incoming or outgoing IPv4 packets of a device based on Layer 3 or Layer 4 information in the IPv4 packet header.
Extended MAC ACL	Control incoming or outgoing Layer 2 packets of a device based on Layer 2 information in the Ethernet packet header.
Extended Expert ACL	Combine the IP ACL and extended MAC ACL into an expert extended ACL, which controls (permits or denies) incoming or outgoing packets of a device using the same rule based on the Layer 2, Layer 3, and Layer 4 information in the packet header.
IPv6 ACL	Control incoming or outgoing IPv6 packets of a device based on Layer 3 or Layer 4 information in the IPv6 packet header.
Security Channel	Allow packets to bypass the check of access control applications, such as 802.1X and web authentication, to meet requirements of some special scenarios.

1.3.1 IP ACL

The IP ACL implements refined control on incoming and outgoing IPv4 packets of a device. You can configure the device to permit or deny specific IPv4 packets to control IP users' access to network resources.

Working Principle

Define a series of IP access rules in an IP ACL, and then apply the IP ACL in the inbound or outbound direction of an interface or globally. The device checks whether the incoming or outgoing IPv4 packets match the rules and accordingly forwards or blocks these packets.

To configure an IP ACL, you must specify a unique name or ID for the ACL of a protocol so that the protocol can uniquely identify each ACL. The following table lists the protocols that can use IDs to identify ACLs and the range of IDs.

Protocol	ID Range
Standard IP	1–99, 1300–1999
Extended IP	100–199, 2000–2699

Basic ACLs include the standard and extended IP ACLs. Typical rules defined in an ACL contain the following matching fields:

- Source IP address
- Destination IP address
- IP protocol number
- Layer 4 source port ID or ICMP type
- Layer 4 destination port ID or ICMP code

The standard IP ACL is used to forward or block packets based on the source IP address, whereas the extended IP ACL is used to forward or block packets based on a combination of the preceding matching fields.

For an individual ACL, multiple independent ACL statements can be used to define multiple rules. All statements reference the same ID or name so that these statements are bound to the same ACL. However, more statements increase the difficulty in reading and understanding the ACL.

For routing products, the ICMP code field in an ACE is ineffective for ICPM packets whose ICPM type is 3. If the ICPM code of ICMP packets to be matched is configured in an ACE, the ACL matching result of incoming ICMP packets of a device whose ICPM type is 3 may be different from the expected result.

Implicit Statement of Deny All Traffic

At the end of every IP ACL is an implicit statement of deny all traffic. Therefore, if a packet does not match any rule, the packet will be denied.

Example:

```
access-list 1 permit host 192.168.4.12
```

This ACL permits only packets sent from the source host at 192.168.4.12, and denies packets sent from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 1 deny any**.

If the ACL contains only the following statement, packets sent from any host will be denied when passing through this interface.

```
access-list 1 deny host 192.168.4.12
```

When defining an ACL, you must consider the routing update packets. As the implicit statement of deny all traffic exists at the end of an ACL, all routing update packets may be blocked.

Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence in which rule statements were created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and denies all traffic, all subsequent statements will not be checked.

Example:

```
access-list 101 deny ip any any

access-list 101 permit tcp 192.168.12.0 0.0.0.255  eqtelnetany
```

The first rule statement denies all IP packets. Therefore, Telnet packets from the host on the network 192.168.12.0/24 will be denied. After the device finds that packets match the first rule statement, it does not check subsequent rule statements any more.

Related Configuration

Configuring an IP ACL

By default, no IP ACL is configured on a device.

Run the **ip access-list** { **standard** | **extended** } { ***acl-name*** | ***acl-id*** } command in global configuration mode to create a standard or an extended IP ACL and enter the standard or extended IP ACL mode.

Adding ACEs to an IP ACL

By default, a created IP ACL contains an implicit ACE that denies all IPv4 packets. This ACE is hidden, but takes effect when the ACL is applied to an interface. That is, all IPv4 packets will be discarded. Therefore, if the device needs to receive or send some specific IPv4 packets, add some ACEs to the ACL.

For a standard IP ACL, add ACEs as follows:

- Regardless of whether the standard IP ACL is a named or numbered ACL, you can run the following command in standard IP ACL mode to add an ACE:

  [*sn*] { **permit** | **deny** } { **host** *source* | **any** | *source source-wildcard* } [**time-range** *time-range-name*] [**url-group** *url-group-id*]

- For a numbered standard IP ACL, you can also run the following command in global configuration mode to add an ACE:

  access-list *acl-id* { **permit** | **deny** } { **host** *source* | **any** | *source source-wildcard* } [**time-range** *tm-rng-name*] [**url-group** *url-group-id*]

For an extended IP ACL, you can add ACEs as follows:

- Regardless of whether the extended IP ACL is a named or numbered ACL, you can run the following command in extended IP ACL mode to add an ACE:
  [*sn*] { **deny** | **permit** } *protocol* { *source source-wildcard* | **any** | **host** *source* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any** | **host** *destination* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**url-group** *url-group-id*]

- For a numbered extended IP ACL, you can also run the following command in global configuration mode to add an ACE:

  access-list *acl-id* { **deny** | **permit** } *protocol* { *source source-wildcard* | **any** | **host** *source* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any** | **host** *destination* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**url-group** *url-group-id*]

Applying an IP ACL

By default, an IP ACL is not applied to any interface, that is, the IP ACL does not filter incoming or outgoing IP packets of the device.

Run the **ip access-group** { *acl-id* | *acl-name* } { **in** | **out** } command in interface configuration mode to apply a standard or an extended IP ACL to a specified interface.

1.3.2 Extended MAC ACL

The MAC extended ACL implements refined control on incoming and outgoing packets based on the Layer 2 header of packets. You can permit or deny specific Layer 2 packets on a network, thus protecting network resources against attacks or control users' access to network resources.

Working Principle

Define a series of MAC access rules in the extended MAC ACL, and then apply the ACL to the inbound or outbound direction of an interface. The device checks whether the incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an extended MAC ACL, you must specify a unique name or ID for this ACL to uniquely identify the ACL. The following table lists the range of IDs that identify extended MAC ACLs.

Protocol	ID Range
Extended MAC ACL	700–799

Typical rules defined in an extended MAC ACL include the following items:

- Source MAC address
- Destination MAC address
- Ethernet protocol type

The extended MAC ACL is used to filter packets based on the source or destination MAC address and the Ethernet type in the packets.

For an individual extended MAC ACL, define multiple independent ACL statements in multiple rules. All statements reference the same ID or name so that these statements are bound to the same ACL. However, more statements increase the difficulty in reading and understanding the ACL.

If ACEs in an extended MAC ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the extended MAC ACL does not filter IPv6 packets. To filter IPv6 packets, use the extended IPv6 ACL.

Implicit Rule Statement of Deny All Traffic

At the end of every extended MAC ACL is an implicit rule statement of deny all traffic. Therefore, if a packet does not match any rule, the packet will be denied.

Example:

```
access-list 700 permit host 00d0.f800.0001 any
```

This ACL permits only packets from the host with the MAC address of 00d0.f800.0001, and denies packets from all other hosts. This is because the following statement exists at the end of this ACL: **access-list 700 deny any any**.

Related Configuration

Configuring an Extended MAC ACL

By default, no extended MAC ACL is configured on a device.

Run the **mac access-list extended {*acl-name* | *acl-id* }** command in global configuration mode to create an extended MAC ACL and enter the extended MAC ACL mode.

Adding ACEs to an Extended MAC ACL

By default, a created extended MAC ACL contains an implicit ACE that denies all Layer 2 packets. This ACE is hidden, but takes effect when the ACL is applied to an interface. That is, all Layer 2 packets will be discarded. Therefore, if the device needs to receive or send some specific Layer 2 packets, add some ACEs to the ACL.

You can add ACEs to an extended MAC ACL as follows:

- Regardless of whether the extended MAC ACL is a named or numbered ACL, you can run the following command in MAC extended ACL mode to add an ACE:

  [*sn*] { **deny** | **permit** } { *source-mac-address source-mac-mask* | **any** | **host** *source-mac-address* } { *destination-mac-address destination-mac-mask* | **any** | **host** *destination-mac-address* } [*ethernet-type*] **[cos** [*cos*] [**inner** *cos* **]**

- For a numbered MAC extended ACL, you can also run the following command in global configuration mode to add an ACE:

  access-list *acl-id* { **deny** | **permit** } { *source-mac-address source-mac-mask* | **any** | **host** *source-mac-address* } { *destination-mac-address destination-mac-mask* | **any** | **host** *destination-mac-address* } [*ethernet-type*] **[cos** [*cos*] [**inner** *cos* **]**

Applying an Extended MAC ACL

By default, the extended MAC ACL is not applied to any interface, that is, the created MAC extended ACL does not filter incoming or outgoing Layer 2 packets of a device.

Run the **mac access-group** { ***acl-id*** | ***acl-name*** } { **in** | **out** } command in interface configuration mode to apply an MAC extended ACL to a specified interface.

1.3.3 Extended Expert ACL

You can create an extended expert ACL to match Layer 2 and Layer 3 information in packets using the same rule. The extended expert ACL can be treated as a combination and enhancement of the IP ACL and extended MAC ACL because the extended expert ACL can contain ACEs in both the IP ACL and extended MAC ACL. In addition, the VLAN ID can be specified in the extended expert ACL to filter packets.

Working Principle

Define a series of access rules in the extended expert ACL, and then apply the ACL in the inbound or outbound direction of an interface. The device checks whether incoming or outgoing packets match the rules and accordingly forwards or blocks these packets.

To configure an extended expert ACL, you must specify a unique name or ID for this ACL so that the protocol can uniquely identify each ACL. The following table lists the ID range of the extended expert ACL.

Protocol	ID Range
Extended expert ACL	2700–2899

When an extended expert ACL is created, defined rules can be applied to all packets. The device determines whether to forward or block packets by checking whether packets match these rules.

Typical rules defined in an extended expert ACL include the following items:

- All information in the basic ACL and extended MAC ACL
- VLAN ID

The extended expert ACL is a combination of the basic ACL and extended MAC ACL, and can filter packets based on the VLAN ID.

For an individual extended expert ACL, define multiple independent statements in multiple rules. All statements reference the same ID or name so that these statements are bound to the same ACL.

If rules in an extended expert ACL are not defined specifically for IPv6 packets, that is, the Ethernet type is not specified or the value of the Ethernet type field is not 0x86dd, the expert extended ACL does not filter IPv6 packets. If you want to filter IPv6 packets, use the IPv6 extended ACL.

Implicit Rule Statement of Deny All Traffic

At the end of every expert extended ACL is an implicit rule statement of deny all traffic. Therefore, if a packet does not match any rule, the packet will be denied.

Example:

```
access-list 2700permit 0x0806 any any any any any
```

This ACL permits only ARP packets whose Ethernet type is 0x0806, and denies all other types of packets. This is because the following statement exists at the end of this ACL: **access-list 2700 deny any any any any**.

Related Configuration

Configuring an Extended Expert ACL

By default, no extended expert ACL is configured on a device.

Run the **expert access-list extended** { ***acl-name*** | ***acl-id*** } command in global configuration mode to create an extended expert ACL and enter the extended expert ACL mode.

Adding ACEs to an Extended Expert ACL

By default, a created extended expert ACL contains an implicit ACE that denies all packets. This ACE is hidden, but takes effect when the ACL is applied to an interface. That is, all Layer 2 packets will be discarded. Therefore, if the device needs to receive or send some specific Layer 2 packets, add some ACEs to the ACL.

You can add ACEs to an extended expert ACL as follows:

- Regardless of whether the extended expert ACL is a named or numbered ACL, you can run the following command in extended expert ACL mode to add an ACE:

  [*sn*] { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos*] [**inner** *cos*]]] [**VID** [*vid*] [**inner** *vid*]] { *source source-wildcard* | **any** | **host** *source* } { *source-mac-address source-mac-mask* | **any** | **host** *source-mac-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any** | **host** *destination* } { **any** | **host** *destination-mac-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*]

- For an extended expert ACL with a numeric index, in addition to configuring an ACE by using the preceding command in extended MAC ACL mode, you can add an ACE to the extended expert ACL in configuration mode by using **access-list** *acl-id* { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos*] [**inner** *cos*]]] [**VID** [*vid*] [**inner** *vid*]] { *source source-wildcard* | **any** | **host** *source* } { *source-mac-address source-mac-mask* | **any** | **host** *source-mac-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination destination-wildcard* | **any** | **host** *destination* } { **any** | **host** *destination-mac-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*].

Applying an Extended Expert ACL

By default, an extended expert ACL is not applied to any interface, that is, the created extended expert ACL does not filter incoming or outgoing Layer 2 or Layer 3 packets of a device.

Run the **expert access-group** { ***acl-id*** | ***acl-name*** } { **in** | **out** } command in interface configuration mode to apply an extended expert ACL to a specified interface.

1.3.4 IPv6 ACL

The IPv6 ACL implements refined control on incoming and outgoing IPv6 packets of a device. You can permit or deny specific IPv6 packets on a network as needed to control IPv6 users' access to network resources.

Working Principle

Define a series of IPv6 access rules in an IPv6 ACL, and then apply the ACL in the inbound or outbound direction of an interface. The device checks whether the incoming or outgoing IPv6 packets match the rules and accordingly forwards or blocks these packets.

To configure an IPv6 ACL, you must specify a unique name for this ACL.

Unlike the IP ACL, extended MAC ACL, and extended expert ACL, you can specify only a name but not an ID for the IPv6 ACL.

Only one IP ACL, or one extended MAC ACL, or one extended expert ACL can be applied to the inbound or outbound direction of an interface. Besides, one more IPv6 ACL can be applied.

Implicit Rule Statement of Deny All Traffic

At the end of every IPv6 ACL is an implicit rule statement of deny all IPv6 traffic. Therefore, if a packet does not match any rule, the packet will be denied.

Example:

```
ipv6 access-list ipv6_acl
 10 permit ipv6 host 200::1 any
```

This ACL permits only IPv6 packets from the source host 200::1, and denies IPv6 packets from all other hosts. This is because the following statement exists at the end of this ACL: **deny ipv6 any any**.

Although the IPv6 ACL contains the implicit rule statement of deny all IPv6 traffic by default, it does not filter ND packets.

Input Sequence of Rule Statements

Every new rule is added to the end of an ACL and in front of the default rule statement. The input sequence of statements in an ACL determines the priority of each statement in the ACL. When determining whether to forward or block packets, a device compares packets with rule statements based on the sequence in which rule statements were created. After locating a matched rule statement, the device does not check any other rule statement.

If a rule statement is created and permits all IPv6 traffic, all subsequent statements will not be checked.

For example:

```
ipv6 access-list ipv6_acl
10 permit ipv6 any any
20 deny ipv6 host 200::1 any
```

As the first rule statement permits all IPv6 packets, all IPv6 packets sent from the host 200::1 does not match the subsequent deny rule with the serial number of 20, and therefore will not be denied. After the device finds that packets match the first rule statement, it does not check subsequent rule statements any more.

Related Configuration

Configuring an IPv6 ACL

By default, no IPv6 ACL is configured on a device.

Run the **ipv6 access-list *acl-name*** command in global configuration mode to create an IPv6 ACL and enter the IPv6 ACL mode.

Adding ACEs to an IPv6 ACL

By default, a created IPv6 ACL contains an implicit ACE that denies all IPv6 packets. This ACE is hidden, but takes effect when the ACL is applied to an interface. That is, all IPv6 packets will be discarded. Therefore, if the device needs to receive or send some specific IPv6 packets, add some ACEs to the ACL.

Run the following command in IPv6 ACL mode to add an ACE:

[*sn*] { **deny** | **permit** } *protocol* { *source-ipv6-prefix/prefix-length* | **any** | **host** *source-ipv6-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix/prefix-length* | **any** | **host** *destination-ipv6-address* } [**lt** *port* | **eq** *port* | **gt** *port* | **neq** *port* | **range** *lower upper*] [**flow-label** *flow-label*] [**time-range** *time-range-name*]

Applying an IPv6 ACL

By default, the IPv6 ACL is not applied to any interface, that is, the IPv6 ACL does not filter incoming or outgoing IPv6 packets of a device.

Run the **ipv6 traffic-filter *acl-name*** { **in** | **out** } command in interface configuration mode to apply an IPv6 ACL to a specified interface.

1.3.5 Security Channel

In some application scenarios, packets matching some characteristics need to be not checked by access control applications. For example, before 802.1X authentication, users are allowed to log in to a specified website to download the 802.1X authentication client. The security channel can be used. When the security channel configuration command is executed to apply a secure ACL globally or to an interface, this ACL becomes a security channel.

Working Principle

The security channel is also an ACL, and can be configured globally or for a specified interface. When arriving at an interface, packets are checked on the security channel. If the packets meet matching conditions of the security channel, they enter a switch without access control, such as port security, web-based authentication, 802.1X, and IP+MAC binding check. A globally applied security channel takes effect on all interfaces except excluded interfaces.

- The deny ACEs in an ACL that is applied to a security channel do not take effect. In addition, this ACL does not contain an implicit rule statement of deny all traffic at the end of the ACL. If packets do not meet matching conditions of the security channel, the device checks the packets against access control rules.
- You can configure up to eight excluded interfaces for the global security channel. In addition, you cannot configure interface-based security channel on these exclusive interfaces.
- If both interface-based migratable authentication mode and security channel are applied to an interface, the security channel does not take effect.
- An IPv6 ACL cannot be configured as a security channel.

Related Configuration

Configuring an ACL

Before configuring the security channel, configure an ACL. For details, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.

Adding ACEs to an ACL

For details about how to add ACEs to an ACL, see 1.3.1 IP ACL, 1.3.2 Extended MAC ACL, 1.3.3 Extended Expert ACL, or 1.3.4 IPv6 ACL.

Configuring a Security Channel for an Interface

By default, no security channel is configured for an interface on a device.

Run the **security access-group** { *acl-id* | *acl-name* } command in interface configuration mode to configure a security channel.

Configuring a Global Security Channel

By default, no global security channel is configured on a device.

Run the **security global access-group** { *acl-id* | ***acl-name*** } command in global configuration mode to configure a global security channel.

Configuring an Excluded Interface for the Global Security Channel

By default, no excluded interface is configured for the global security channel on a device.

Run the **security uplink enable** command in interface configuration mode to configure a specified interface as the excluded interface of the global security channel.

1.4 Configuration

Configuration	Description and Command	
Configuring an IP ACL	⚠ (Optional) It is used to filter IPv4 packets.	
	ip access-list standard	Configures a standard IP ACL.
	ip access-list extended	Configures an extended IP ACL.
	permit host any time-range	Adds a permit ACE to a standard IP ACL.
	deny host any time-range	Adds a deny ACE to a standard IP ACL.
	permit host any host any time-range	Adds a permit ACE to an extended IP ACL.
	deny host any host any time-range	Adds a deny ACE to an extended IP ACL.

Configuration	Description and Command	
	ip access-list resequence	Rearranges sequence numbers of ACEs for an IP standard or extended ACL.
Configuring an Extended MAC ACL	(Optional) It is used to filter Layer 2 packets.	
	mac access-list extended	Configures an extended MAC ACL.
	permit any host any host cos inner time-range	Adds a permit ACE to an extended MAC ACL.
	deny any host any host cos inner time-range	Adds a deny ACE to an extended MAC ACL.
	mac access-list resequence	Rearranges sequence numbers of ACEs for an extended MAC ACL.
	mac access-group in out	Applies an extended MAC ACL.
Configuring an Extended Expert ACL	(Optional) It is used to filter Layer 2 and Layer 3 packets.	
	expert access-list extended	Configures an extended expert ACL.
	permit cos inner VID inner host any host any host any host any precedence tos fragment range time-range	Adds a permit ACE to an extended expert ACL.
	deny cos inner VID inner host any host any host any host any precedence tos fragment range time-range	Adds a deny ACE to an extended expert ACL.
	expert access-list resequence	Rearranges sequence numbers of ACEs for an extended expert ACL.
	expert access-group in out	Applies an extended expert ACL.
Configuring an IPv6 ACL	(Optional) It is used to filter IPv6 packets.	
	ipv6 access-list	Configures an IPv6 ACL.
	permit host any host any range dscp flow-label fragment time-range	Adds a permit ACE to an IPv6 ACL.
	deny host any host any range dscp flow-label fragment time-range	Adds a deny ACE to an IPv6 ACL.
	ipv6 access-list resequence	Rearranges sequence numbers of ACEs for an IPv6 ACL.
	ipv6 traffic-filter in out	Applies an IPv6 ACL.
Configuring a Security Channel	(Optional) It is used to enable packets matching some characteristics not to be checked by access control applications, such as 802.1X and web-based authentication.	

Configuration	Description and Command	
	security access-group	Enables the security channel in interface configuration mode.
	security global access-group	Enables the security channel in global configuration mode.
	security uplinkenable	Configures an interface as the excluded interface of the global security channel in interface configuration mode.
Configuring ACEs Based on the Time Range	(Optional) It is used to configure an ACE based on the time range.	
	time-range	Configures rules based on the time range.
Configuring Comments for ACLs	⚠ (Optional) It is used to configure comments for an ACL or ACE so that users can easily identify the functions of the ACL or ACE.	
	list-remark	Configures a comment for an ACL in ACL configuration mode.
	access-list list-remark	Configures a comment for an ACL in global configuration mode.
	access-list remark	Configures a comment for an ACE in global configuration mode.
	remark	Configures a comment for an ACE in ACL configuration mode.

1.4.1 Configuring an IP ACL

Configuration Effect

Configure and apply an IP ACL to an interface to control all incoming and outgoing IPv4 packets of this interface/VXLAN. You can permit or deny the entry of specific IPv4 packets to a network to control access of IP users to network resources.

Notes

N/A

Configuration Step

↘ **Configuring an IP ACL**

- Mandatory. Configure an IP ACL to control access of IPv4 users to network resources.

- You can configure this ACL on an access device, an aggregation device, or a core device based on user distribution. The IP ACL takes effect only on the local device, and does not affect other devices on the network.

Adding ACEs to an IP ACL

- Optional. An ACL may contain no ACE or multiple ACEs. If no ACE is configured, all incoming IPv4 packets of the device are denied by default.

Rearranging Sequence Numbers of ACEs

- Optional. Rearrange sequence numbers of ACEs in an ACL to regularize them.

Applying an IP ACL

- Mandatory. You must apply an IP ACL to a specified interface so that the IP ACL can take effect.
- Based on user distribution, you can apply an extended IP ACL to a specified interface of the access, aggregation, or core device.
- Mandatory. You must apply an IP ACL to a specified interface so that the IP ACL can take effect.
- You can apply an IP ACL on a specified interface of the access, aggregation, or core device based on user distribution.

Verification

Use the following methods to verify the configuration of the IP ACL:

- Run the **ping** command to verify that the IP ACL takes effect on the specified interface. For example, if an IP ACL is configured to prohibit a host with a specified IP address or hosts in a specified IP address range from accessing the network, run the **ping** command to verify that the host(s) cannot be successfully pinged.
- Access related network resources to verify that the IP ACL takes effect on the specified interface. For example, access the Internet or FTP resources on the network through FTP.

Related Commands

Configuring an IP ACL

Command	**ip access-list** { **standard** | **extended** } { *acl-name* | *acl-id* }
Parameter Description	**standard**: Indicates that a standard IP ACL is created. **extended**: Indicates that an extended IP ACL is created. *acl-id*: Indicates the ID that uniquely identifies a standard or extended IP ACL. If this parameter is specified, a numbered ACL is created. If a standard IP ACL is created, the value range of *acl-id* is 1–99 and 1300–1999. If an extended IP ACL is created, the value range of *acl-id* is 100–199 and 2000–2699. *acl-name*: Indicates the name of a standard or an extended IP ACL. If this parameter is specified, a named ACL is created. The value is a string of 1 to 99 characters. It cannot

	start with numerals (0–9), or cannot be **in** or **out**.
Command Mode	Global configuration mode
Usage Guide	Run this command to configure a standard or an extended IP ACL and enter the standard or extended IP ACL configuration mode. To control users' access to network resources by checking the source IP address of each packet, configure a standard IP ACL. To control users' access to network resources by checking the source or destination IP address, protocol number, and TCP/UDP source or destination port, configure an extended IP ACL.

Adding ACEs to an IP ACL

- Add ACEs to a standard IP ACL.

Use either of the following methods to add ACEs to a standard IP ACL.

Command	[*sn*] { **permit** | **deny** } { **host** *source* | **any** | *source source-wildcard* } [**time-range** *time-range-name*] [**url-group** *url-group-id*]
Parameter Description	*sn*: Indicates the sequence number of an ACE. The value range is from 1 to 2,147,483,647. The sequence number determines the priority of the ACE in the ACL. A smaller sequence number indicates a higher priority. An ACE with a higher priority will be preferentially used to match packets. If you do not specify the sequence number when adding an ACE, the system automatically allocates a sequence number, which is equal to an increment (10 by default) plus the sequence number of the last ACE in the ACL. For example, if the sequence number of the last ACE is 100, the sequence number of a new ACE will be 110 by default. You can adjust the increment using a command. **permit**: Indicates that the ACE is a permit ACE. **deny**: Indicates that the ACE is a deny ACE. **host** *source*: Indicates that IP packets sent from a host with the specified source IP address are filtered. **any**: Indicates that IP packets sent from any host are filtered. *source source-wildcard:* Indicates that IP packets sent from hosts in the specified IP network segment are filtered. **time-range** *time-range-name:* Indicates that this ACE is associated with a time range. The ACE takes effect only within this time range. **url-group** *url-group-id*: Indicates that this ACE is associated with the URL group of a packet. For details about the URL group, see the configuration guide of application identification.
Command Mode	Standard IP ACL configuration mode
Usage Guide	Run this command to add ACEs in standard IP ACL configuration mode. The ACL can be a named or numbered ACL.

Command	**access-list** *acl-id* { **permit** | **deny** } { **host** *source* | **any** | *source source-wildcard* } [**time-range** *tm-rng-name*] [**url-group** *url-group-id*]
