Run the **no** form of this command to configure an OSPF-enabled interface to disable the BFD function.

The BFD function is disabled on an interface by default.

Syntax

ip ospf bfd [**disable**]

no ip ospf bfd

Parameter Description

disable: Disables BFD link detection on the OSPF-enabled interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Once a link is faulty, OSPF can quickly detect the failure of the route. Configuring this command helps shorten the traffic interruption time.

The **ip ospf bfd** command configured on an interface takes precedence over the **bfd all-interfaces** command used in process configuration mode.

In light of the actual environment, you can run the **ip ospf bfd** command to configure BFD link detection on the specified interface, or run the **bfd all-interfaces** command in OSPF process configuration mode to configure BFD for link detection on all the interfaces of the OSPF process. You can run the **ip ospf bfd disable** command to disable BFD for link detection on the specified interface.

Examples

The following example configures the OSPF-enabled GigabitEthernet 0/1 interface to conduct BFD link detection.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf bfd
```

1.37 ip ospf cost

Function

Run the **ip ospf cost** command to configure the cost value for an OSPF interface to send a packet.

Run the **no** form of this command to restore the default value.

By default, the cost value of an OSPF interface is automatically calculated.

Syntax

ip ospf cost *cost*

no ip ospf cost

Parameter Description

cost: Cost value of an OSPF interface. The value range is from 0 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

By default, the cost of an OSPF interface is equal to the reference value of the interface bandwidth divided by the actual interface bandwidth.

You can run the **auto-cost** command to configure the bandwidth reference value of an interface. The default value is 100 Mbps.

Run the **bandwidth** command to set the interface bandwidth.

The default costs of OSPF interfaces on several typical lines are as follows:

- For the 64 Kbps serial line, the cost is 1562.
- For the E1 line, the cost is 48.
- For the 10 Mbps Ethernet, the cost is 10.
- For the 100 Mbps Ethernet, the cost is 1.

Configuring the cost value of an OSPF interface through the **ip ospf cost** command will overwrite the default configuration.

Examples

The following command configures the cost for the OSPF-enabled GigabitEthernet 0/1 interface to send a packet as **100**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip ospf cost 100
```

1.38 ip ospf cost-fallback

Function

Run the **ip ospf cost-fallback** command to configure the cost fallback of an aggregation port (AP).

Run the **no** form of this command to disable the cost fallback of an AP.

The cost fallback function is disabled on an AP by default.

Syntax

ip ospf cost-fallback *cost* **threshold** *bandwith*

no ip ospf cost-fallback

Parameter Description

cost: Cost fallback value. The value range is from 1 to 65535.

threshold *bandwith*: Indicates the bandwidth threshold, in bytes per second. When the AP bandwidth is smaller than this value, the cost fallback value takes effect. The value range is from 1 to 4294967.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The bandwidth of an AP is equal to the sum of the bandwidths of all the valid member ports. When a member port fails, the bandwidth of the AP will be reduced. You can set a cost fallback value for the AP to enable OSPF to select other paths preferably. When the failed member port recovers, the cost fallback value becomes invalid, and the metric of the AP returns to normal.

Examples

The following example configures the cost fallback value for an AP, and sets the metric to 100 when the bandwidth is smaller than 1,000 Mbps.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# interface AggregatePort 1
Hostname(config-if-AggregatePort 1)# ip ospf cost-fallback 100 threshold 1000
```

Notifications

When a cost fallback value is configured for a non-AP, the following notification will be displayed:

```
%OSPF: Warning: Only aggregate ports are suitable for this command
```

Common Errors

Cost fallback is enabled on a non-AP.

Platform Description

1.39 ip ospf database-filter all out

Function

Run the **ip ospf database-filter all out** command to prevent an interface from diffusing LSA packets to the outside, that is, LSA update packets are not sent from the interface.

Run the **no** form of this command to restore the default value.

By default, the function of not diffusing LSA packets to the outside is disabled on an interface, that is, any LSA update packet can be sent from the interface.

Syntax

ip ospf database-filter all out

no ip ospf database-filter

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To prevent an interface from sending LSA update packets, you can enable this function on the interface. After this function is enabled, the local device does not advertise the LSA update packet to neighbors, but still sets up a neighbor relationship with neighbors and receives LSAs from neighbors.

Examples

The following example prevents the GigabitEthernet 0/1 interface from diffusing LSA packets to the outside.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.10.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf database-filter all out
```

1.40 ip ospf dead-interval

Function

Run the **ip ospf dead-interval** command to configure the interval for OSPF to determine the failure of a specified interface neighbor.

Run the **no** form of this command to restore the default configuration.

By default, the fast hello function is disabled, and the neighbor dead interval is four times the sending interval of hello packet.

Syntax

ip ospf dead-interval { *dead-interval* | **minimal hello-multiplier** *multiplier* }

no ip ospf dead-interval

Parameter Description

Dead-interval: Interval for determining failure of a neighbor, in seconds. The value range is from 0 to 2147483647.

minimal: Enables the fast hello function and sets the interval for determining failure of a neighbor to 1s.

hello-multiplier *multiplier*: Specifies the number of hello packets sent per second in the fast hello function. The value range is from 3 to 20.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The failure determining interval of an OSPF neighbor is contained in the hello packet. If OSPF does not receive a hello packet from a neighbor within the neighbor dead interval, it declares that the neighbor is invalid and deletes this neighbor record from the neighbor list. The neighbor dead interval is four times the sending interval of hello packet. If the hello interval is modified, the neighbor dead interval is modified automatically.

You can run this command to manually modify the interval for OSPF to judge failure of a neighbor. However, note the following points:

(1) The neighbor dead interval cannot be smaller than the hello packet sending interval.

(2) The neighbor dead interval must be the same on all routers in the same network segment.

After the OSPF fast hello function is enabled, OSPF finds neighbors and detects neighbor failures faster. You can enable the OSPF fast hello function by specifying the **minimal** and **hello-multiplier** keywords and the *multiplier* parameter. The **minimal** keyword indicates that the neighbor dead interval is set to 1s, and **hello-multiplier** indicates the number of hello packets sent per second. In this way, the interval at which the hello packet is sent decreases to less than 1s.

If the fast hello function is configured for an interface, the hello interval field of the hello packet advertised on the interface is set to 0, and the hello interval field of the hello packet received on this interface is ignored.

No matter whether the fast hello function is enabled, the neighbor dead interval must be always consistent in the same network segment. The **hello-multiplier** value can be inconsistent provided that at least one hello packet can be received within the neighbor dead interval. The **dead-interval minimal hello-multiplier** and **hello-interval** parameters introduced for the fast hello function cannot be configured simultaneously.

Run the **show ip ospf interface** command to monitor the neighbor dead interval and the fast hello interval configured for an interface.

Examples

The following example configures the interval for OSPF to judge failure of a neighbor on the GigabitEthernet 0/1 interface as **30**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.10.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf dead-interval 30
```

The following example enables the fast hello function of the GigabitEthernet 0/1 interface and configures Hello-multiplier as **3**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.10.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf dead-interval minimal
hello-multiplier 3
```

Notifications

1.41 ip ospf disable all

Function

Run the **ip ospf disable all** command to prevent a specified interface from generating OSPF packets.

Run the **no** form of this command to restore the default state.

By default, an interface is allowed to generate OSPF packets.

Syntax

ip ospf disable all

no ip ospf disable all

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The interface configured with this command ignores whether **network area** is matched. After this command is configured, even if the interface belongs to the network segment range advertised by the **network** command, it will not generate OSPF packets any more. Therefore, the interface will neither send/receive any OSPF packet, nor participate in OSPF computation.

Examples

The following example prevents the GigabitEthernet 0/1 interface from generating LSA packets any more.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.10.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf disable all
```

1.42 ip ospf fast-reroute protection

Function

Run the **ip ospf fast-reroute protection** command to enable the loop-free alternate (LFA) protection mode of a specified interface.

Run the **no** form of this command to restore the default configuration.

The LFA link protection function is enabled by default.

Syntax

ip ospf fast-reroute protection { **node** | **link-node** | **disable** }

no ip ospf fast-reroute protection

Parameter Description

node: Enables the LFA node protection.

link-node: Enables the LFA link node protection.

disable: Disables LFA protection.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After you run the **fast-reroute lfa** command in OSPF routing process configuration mode, OSPF fast reroute calculation will be enabled, and a standby route will be generated for the primary route based on the LFA protection mode specified in interface configuration mode. By default, LFA protection is enabled on each OSPF interface, and the failure of the active link does not affect data forwarding on the standby route.

- Run the **node** parameter to enable node protection for the interface, that is, data forwarding on the standby route will not be affected by the failure of a neighbor node corresponding to the active link.
- Run the **link-node** parameter to protect both the link and neighbor node corresponding to the primary route.
- Run the **disable** parameter to disable the LFA protection function of the interface, that is, no backup entry will be generated for the route whose next hop is the interface.

This command does not take effect if **fast-rerotue route-map** is configured.

Examples

The following example enables LFA link node protection on the GigabitEthernet 0/1 interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.10.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf fast-reroute protection link-node
```

1.43 ip ospf fast-reroute no-eligible-backup

Function

Run the **ip ospf fast-reroute no-eligible-backup** command to exclude an OSPF interface that cannot be used as a backup interface in the OSPF fast reroute calculation.

Run the **no** form of this command to restore the default configuration.

By default, an interface can be used as a backup interface of OSPF fast reroute.

Syntax

ip ospf fast-reroute no-eligible-backup

no ip ospf fast-reroute no-eligible-backup

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the remaining bandwidth of an interface is small or an interface may fail with the primary interface at the same time, the interface is not suitable for a backup interface. This command needs to be enabled in interface configuration mode of this interface. In the fast reroute calculation of OSPF, this interface is excluded and cannot be used as a backup interface, and a backup interface is selected from other interfaces. This command does not take effect if **fast-rerotue route-map** is configured.

Examples

The following example excludes GigabitEthernet 0/1 from being a backup interface in the fast reroute calculation of OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.10.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf fast-reroute no-eligible-backup
```

1.44 ip ospf hello-interval

Function

Run the **ip ospf hello-interval** command to configure the interval for OSPF to send hello packets.

Run the **no** form of this command to restore the default configuration.

By default, the hello packet interval is 10s for Ethernet, PPP, HDLC encapsulation interface, and frame relay point-to-point sub-interface. The hello packet interval is 30s for non-frame relay point-to-point sub-interface and X.25 interface.

Syntax

ip ospf hello-interval *hello-interval*

no ip ospf hello-interval

Parameter Description

hello-interval: Interval for OSPF to send hello packets, in seconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The hello packet interval is contained in the hello packet. A shorter hello interval indicates that OSPF can detect topology changes more quickly, but the network traffic increases. The hello packet interval must be the same on all routers in the same network segment. If you want to manually modify the neighbor dead interval, ensure that the neighbor dead interval is longer than the hello packet interval.

Examples

The following example sets the interval for OSPF to send hello packets to 15s on the GigabitEthernet 0/1 interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 172.16.10.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip ospf hello-interval 15
```

Notifications

N/A

Common Errors

The hello packet intervals configured on different interfaces in the same area are inconsistent.

Platform Description

N/A

Related Commands

- **show ip ospf interface**

1.45 ip ospf message-digest-key

Function

Run the **ip ospf message-digest-key** command to configure a cipher text authentication key of OSPF packets.

Run the **no** form of this command to delete a configured cipher text authentication key of OSPF packets.

By default, no cipher text authentication key is configured.

Syntax

ip ospf message-digest-key *key-id* **md5** [**0** | **7**] *key*

no ip ospf message-digest-key *key-id*

Parameter Description

key-id: ID of the authentication key. The value range is from 1 to 255.

md5: Uses the MD5 cipher text authentication.

0: Indicates that the key is displayed in plain text.

7: Indicates that the key is displayed in cipher text.

key: The key, a string of up to 16 characters.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command configures a key of cipher text authentication, which takes effect only after the **area authentication** or **ip ospf authentication** command is used to configure the authentication type as **message-digest**. Authentication succeeds only when both *key-id* and key are matched.

Multiple *key-id* values are configured for the same interface, and the last *key-id* configured takes effect when packets are sent, but all *key-id* values can participate in the authentication when packets are received.

Examples

The following example configures the cipher text authentication of OSPF packets on the GigabitEthernet 0/1 interface as MD5, and key as hello.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip ospf message-digest-key 10 md5 hello
```

Notifications

When a key not configured is deleted, the following notification will be displayed:

```
OSPF: Key 1 does not exist
```

When a configured key is configured again, the following notification will be displayed:

```
OSPF: Key 1 already exists
```

When a key is too long and will be truncated to 16 characters, the following notification will be displayed:

```
%OSPF: Warning: The password/key will be truncated to 16 characters
```

Common Errors

1.46 ip ospf mtu-ignore

Function

Run the **ip ospf mtu-ignore** command to disable MTU verification when an interface receives database description packets.

Run the **no** form of this command to enable MTU verification when an interface receives database description packets.

The MTU verification function is disabled by default.

Syntax

ip ospf mtu-ignore

no ip ospf mtu-ignore

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When receiving a database description packet, OSPF verifies whether the MTU of the neighbor's interface is the same as that of its own interface. If the interface MTU specified in the received database description packet is greater than the MTU of the local interface, the neighbor relationship cannot be set up. To resolve this problem, you can disable MTU verification.

Examples

The following example disables MTU verification when the GigabitEthernet 0/1 interface receives database description packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip ospf mtu-ignore
```

1.47 ip ospf network

Function

Run the **ip ospf network** command to configure the OSPF network type of an interface.

Run the **no** form of this command to restore the default configuration.

By default, the interface type of OSPF is not configured. No interface is set to P2MP type by default.

Syntax

ip ospf network { **broadcast** | **non-broadcast** | **point-to-multipoint** [**non-broadcast**] | **point-to-point** }

no ip ospf network

Parameter Description

broadcast: Sets the interface network type to **broadcast**.

non-broadcast: Sets the interface network type to non-broadcast multiple access (NBMA).

point-to-multipoint [**non-broadcast**]: Sets the interface network type to P2MP. If the interface does not have the broadcast capability, the **non-broadcast** parameter must be set.

point-to-point: Sets the interface network type to P2P.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The command is used to set a network type of OSPF according to the network topology. Ethernet and fiber distributed data interface (FDDI) fall into the broadcast type, X.25, frame relay, and ATM fall into the NBMA type, and PPP, HDLC, and LAPB fall into the P2P type. Each network type is restricted as follows:

- The broadcast type requires that the interface must have the broadcast capability.
- The P2P type requires that the interfaces are interconnected in one-to-one manner.
- The NBMA type requires full-meshed connections, and all interconnected routers can directly communicate with each other.
- The P2MP type does not raise any requirement.

Examples

The following example configures the OSPF network type of the GigabitEthernet 0/1 interface as P2P type.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-GigabitEthernet 0/1)#ip address 172.16.24.4 255.255.255.0
Hostname(config-GigabitEthernet 0/1)# encapsulation frame-relay
Hostname(config-GigabitEthernet 0/1)# ip ospf network point-to-point
```

The following example configures the OSPF network type of the GigabitEthernet 0/1 interface as NBMA.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-GigabitEthernet 0/1)# ip address 172.16.24.4 255.255.255.0
Hostname(config-GigabitEthernet 0/1)# encapsulation frame-relay
Hostname(config-GigabitEthernet 0/1)# ip ospf network non-broadcast
Hostname(config-GigabitEthernet 0/1)# exit
```

1.48 ip ospf priority

Function

Run the **ip ospf priority** command to configure the OSPF priority value of an interface.

Run the **no** form of this command to restore the default configuration.

The priority value is 1 by default.

Syntax

ip ospf priority *priority*

no ip ospf priority

Parameter Description

priority: OSPF priority value of an interface. The value range is from 0 to 255. A device with the priority 0 does not participate in the designated router (DR)/backup designated router (BDR) election.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The priority value of an OSPF interface is contained in the hello packet. When the DR/BDR election occurs on the OSPF broadcast network, the router with the highest priority becomes the DR or BDR. If the priorities are the same, the router with the largest router ID becomes the DR or BDR. A router with the priority set to 0 does

not participate in the DR/BDR election. This command is applicable only to the OSPF broadcast and NBMA interfaces.

Examples

The following example configures the priority value of the GigabitEthernet 0/1 interface as **0**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip ospf priority 0
```

1.49 ip ospf retransmit-interval

Function

Run the **ip ospf retransmit-interval** command to configure the retransmission interval of LSU packets on an interface.

Run the **no** form of this command to restore the default configuration.

The retransmission interval of LSU packets on an interface is 5s by default.

Syntax

ip ospf retransmit-interval *retransmit-interval*

no ip ospf retransmit-interval

Parameter Description

retransmit-interval: Retransmission interval of LSU packets, in seconds. This interval must be longer than the round-trip transmission delay of data packets between two neighbors. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After a router finishes sending an LSU packet, this packet is still kept in the transmit buffer queue. If an acknowledgment from the neighbor is not received within the time defined by the **ip ospf retransmit-interval** command, the router retransmits the LSU packet.

The retransmission interval can be set to a greater value on a serial line or virtual link to prevent unwanted retransmission. The LSU packet retransmission interval of a virtual link is defined using the **retransmit-interval** keyword in the **area virtual-link** command.

Examples

The following example sets the LSU packet retransmission interval on the GigabitEthernet 0/1 interface to 10s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip ospf retransmit-interval 10
```

1.50 ip ospf source-check-ignore

Function

Run the **ip ospf source-check-ignore** command to disable the source address verification function for the packets received on a P2P link.

Run the **no** form of this command to restore the default configuration.

The source address verification function for the packets received on a P2P link is enabled by default.

Syntax

ip ospf source-check-ignore

no ip ospf source-check-ignore

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Generally, the source address of a packet received by OSPF is in the same network segment as the receiving interface. The addresses at both ends of a P2P link are configured separately and are not necessarily in the same network segment. In this scenario, as the peer address information is notified during the P2P link negotiation, OSPF checks whether the source address of the packet is the address advertised by the peer end during negotiation. If not, OSPF determines that the packet is invalid and discards it. OSPF never verifies the address of an interface not configured with an IP address.

In some scenarios, the source address of a packet received by OSPF may not be in the same network segment as the receiving interface, and therefore OSPF address verification fails. For example, the negotiated peer address cannot be obtained on a P2P link. In this scenario, source address verification must be disabled to ensure that the OSPF adjacency can be properly set up.

Examples

The following example configures that the Gigabit Ethernet 0/1 interface on the P2P link does not verify the source address of the received packet.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip ospf source-check-ignore
```

1.51 ip ospf subvlan

Function

Run the **ip ospf subvlan** command to enable the OSPF function on a super VLAN.

Run the **no** form of this command to restore the default configuration.

By default, the OSPF function is disabled on a super VLAN.

Syntax

ip ospf subvlan [**all** | *vid*]

no ip ospf subvlan

Parameter Description

all: Allows sending packets to all sub VLANs.

vid: ID of the sub VLAN. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

In normal cases, a super VLAN contains multiple sub VLANs. The corresponding OSPF multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when OSPF multicast packets are sent over a super VLAN containing multiple sub VLANs, the OSPF multicast packets are replicated multiple times, and the device processing capability is insufficient. As a result, a large number of packets are discarded, causing protocol flapping.

In most scenarios, the OSPF function does not need to be enabled on a super VLAN. However, in some scenarios, the OSPF function must be run on the super VLAN, but packets only need to be sent to one sub VLAN. In this case, you can decide to send multicast packets to a certain sub VLAN or to all sub VLANs as actually needed. Usually packets need to be sent to only one sub VLAN. In this case, run this command to specify a particular sub VLAN. You must be cautious when configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor flapping.

Examples

The following example enables the OSPF function on Super VLAN 300 and allows sending packets to Sub VLAN 1024.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface vlan 300
Hostname(config-if-VLAN 300)# ip ospf subvlan 1024
```

Notifications

N/A

Common Errors

The function is configured on a non-super VLAN.

The specified sub VLAN on the super VLAN cannot implement interworking with its neighbors.

1.52 ip ospf transmit-delay

Function

Run the **ip ospf transmit-delay** command to configure the delay for an OSPF interface to transmit LSU packets.

Run the **no** form of this command to restore the default configuration.

The LSU packet transmission delay is 1s by default.

Syntax

ip ospf transmit-delay *transmit-delay*

no ip ospf transmit-delay

Parameter Description

transmit-delay: Delay for an OSPF interface to transmit LSU packets, in seconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Before an LSU packet is transmitted, the **Age** fields in all LSAs in this packet will increase based on the amount specified by the **ip ospf transmit-delay** command. Considering the transmission delay and line propagation delay on the interface, you need to set the LSU transmission delay to a greater value for a low-speed line or interface. The LSU packet transmission delay of a virtual link is configured through the **transmit-delay** option in the **area virtual-link** command.

If the value of the **Age** field of an LSA reaches 3600, the packet will be retransmitted or a retransmission will be requested. If the LSA is not updated in time, the expired LSA will be deleted from the LSDB.

Examples

The following example sets the LSU packet transmission delay on the GigabitEthernet 0/1 interface to 10s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip ospf transmit-delay 10
```

1.53 ispf enable

Function

Run the **ispf enable** command to enable the incremental shortest path first (iSPF) feature and run the iSPF algorithm to calculate the network topology.

Run the **no** form of this command to disable the iSPF feature.

The iSPF feature is disabled by default.

Syntax

ispf enable

no ispf enable

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

OSPF uses the classic shortest path first (SPF) algorithm to calculate the network topology information and routing information. Calculation of the topology information is based on the area, and the SPF algorithm runs independently in each area.

The iSPF algorithm is improved and optimized on the basis of SPF algorithm, and its calculation is still based on the area. However, after the network topology changes, the iSPF algorithm corrects only the nodes affected by the topology change, instead of re-building the entire shortest path tree (SPT). This accelerates OSPF convergence to a certain extent, and effectively relieves the load pressure of the device processor. Normally a larger network scale and a more complex structure show more significant advantages brought by the iSPF algorithm.

The iSPF algorithm does not involve interoperability with other devices, and devices on the same network can be configured differently. To speed up convergence of the entire network as much as possible, enable the iSPF feature for the devices throughout the network.

Enabling the iSPF feature influences only OSPF's selection of a network topology calculation algorithm. Therefore, the backoff time of route computation configured using the **timers spf** command and **timers throttle spf** command also takes effect for the iSPF algorithm.

Examples

The following example enables the iSPF feature.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# ispf enable
```

The following example enables the iSPF feature under VRF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1 vrf vpn1
Hostname(config-router)# ispf enable
```

1.54 log-adj-changes

Function

Run the **log-adj-changes** command to record the log of adjacency state changes.

Run the **no** form of this command to remove this configuration.

The log recording function is enabled by default, without the **detail** parameter.

Syntax

log-adj-changes [**detail**]

no log-adj-changes [**detail**]

Parameter Description

detail: Records all the state change information.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The log records the log information of the following four types of events only:

- The adjacency reaches the full state;
- The adjacency leaves the full state;
- The adjacency reaches the down state;
- The adjacency leaves the down state.

Examples

The following example records the log of adjacency state changes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# log-adj-changes detail
```

1.55 max-concurrent-dd

Function

Run the **max-concurrent-dd** command to configure the maximum number of neighbors with which the current OSPF process can concurrently initiate or accept interaction.

Run the **no** form of this command to restore the default configuration.

The maximum number of neighbors is 5 by default.

Syntax

max-concurrent-dd *neighbor-num*

no max-concurrent-dd

Parameter Description

neighbor-num: Maximum number of neighbors that concurrently interact with the OSPF process. The value range is from 1 to 65535.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

When the performance of a router is affected because the router exchanges data with multiple neighbors, you can configure this command to restrict the maximum of neighbors with which each OSPF process can concurrently initiate or accept interaction.

Examples

The following example configures the maximum number of neighbors with which the current OSPF process can concurrently initiate or accept interaction as 4.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 10
Hostname(config-router)# max-concurrent-dd 4
```

1.56 max-metric router-lsa

Function

Run the **max-metric router-lsa** command to configure the maximum advertisement metric of an OSPF-enabled device so that other routers will not preferably regard this router as a transmission node in SPF calculation.

Run the **no** form of this command to cancel the maximum advertisement metric.

By default, the LSAs of normal metric are advertised.

Syntax

max-metric router-lsa [**external-lsa** [*max-metric-value*] | **include-stub** | **on-neighborup** [*full-interval-time*] | **on-startup** [*startup-interval-time*] | **summary-lsa** [*max-metric-value*]] *

no max-metric router-lsa [**external-lsa** [*max-metric-value*] | **include-stub** | **on-neighborup** [*full-interval-time*] | **on-startup** [*startup-interval-time*] | **summary-lsa** [*max-metric-value*]] *

Parameter Description

router-lsa: Sets the metric of non-stub links in the router LSA to the maximum value (0xFFFF).

external-lsa: Allows a router to replace the metrics of external LSAs (including Type-5 and Type-7 LSAs) with the maximum metric.

max-metric-value: Maximum metric of the external LSA. The value range is from 1 to 16777215, and the default value is **16711680**.

include-stub: Sets the metrics of stub links in the router LSA advertised by the router to the maximum value.

on-startup: Allows a router to advertise the maximum metric when started.

startup-interval-time: The interval at which the maximum metric is advertised, in seconds. The value range is 5 to 86400, and the default value is **600**.

on-neighborup: Allows a router to advertise the maximum routing when its neighbor enters the full state.

full-interval-time: Interval at which the maximum metric is advertised, in seconds. The value range is 5 to 1800, and the default value is **120**.

summary-lsa: Allows a router to replace the metrics of summary LSAs (including Type-3 and Type-4 LSAs) with the maximum metric.

max-metric-value: Maximum metric of the summary LSA. The value range is from 1 to 16777215, and the default value is **16711680**.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

After the **max-metric router-lsa** command is executed, the metrics of the non-stub links in the router LSAs generated by the router will be set to the maximum value (0xFFFF). If you cancel this configuration or the timer expires, the normal metrics of the links are restored.

By default, if this command is configured, the stub links still advertise the common metrics, that is, the costs of outbound interfaces. If the **include-stub** parameter is configured, the stub links will advertise the maximum metric.

- If an ABR does not wish to transfer inter-area traffic, run the **summary-lsa** parameter to set the metric of the summary LSA to the maximum metric.
- If an ASBR does not wish to transfer external traffic, run the **external-lsa** parameter to set the metric of the external LSA to the maximum metric.

The **max-metric router-lsa** command is generally used in the following scenarios:

- Restart a device. After the device is restarted, IGP generally converges faster, and other devices attempt to forward traffic through the restarted device. If the current device is still building the BGP routing table and some BGP routes are not learned yet, packets sent to these networks are discarded. In this case, you can use the **on-startup** parameter to set a delay after which the restarted device acts as the transmission mode.
- Add a device to the network but the device is not used to transfer traffic. The device is added to the network. If a candidate path exists, the current device is not used to transfer traffic. If a candidate path does not exist, the current device is still used to transfer traffic.
- Delete a device gracefully from the network. After the **max-metric router-lsa** command is configured, the

current device advertises the maximum metric among all the routes. In this way, other devices on the network can select the backup path for data transmission before the device is shut down.

- In the earlier OSPF version (RFC1247 or earlier), the links with the maximum metric (0xFFFF) in the LSAs do not participate in the SPF computation, that is, no traffic is sent to routers that generate these LSAs.

Examples

The following example configures the maximum metric of non-stub links in the router LSAs as 100s when an OSPF-enabled router starts.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 20
Hostname(config-router)# max-metric router-lsa on-startup 100
```

1.57 neighbor

Function

Run the **neighbor** command to configure an OSPF neighbor.

Run the **no** form of this command to delete a specified neighbor.

An OSPF neighbor is disabled by default.

Syntax

neighbor *ipv4-address* [**cost** *cost* | [**poll-interval** *poll-interval* | **priority** *priority*] *]

no neighbor *ipv4-address* [**cost** | [**poll-interval** | **priority**] *]

Parameter Description

ipv4-address: IP address of an interface on the neighbor.

cost *cost*: Indicates the cost required to reach each neighbor. This parameter is applicable only to the P2MP interface. The value range is from 0 to 65535.

poll-interval *poll-interval*: Indicates the neighbor polling interval, in seconds. This parameter is applicable only to the NBMA interface. The value range is 0 to 2147483647, and the default value is **120**.

priority *priority*: Indicates the neighbor priority value. This parameter is applicable only to the NBMA interface. The value range is from 0 to 255, and the default value is **0**.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Neighbors must be specified for the NBMA or P2MP (non-broadcast) interfaces. The neighbor IP address must be the primary IP address of this neighbor interface.

If a neighbor router becomes inactive on the NBMA network, OSPF still sends hello packets to this neighbor even if no hello packet is received within the router failure time. The interval at which the hello packet is sent is called polling interval. When running for the first time, OSPF sends hello packets only to neighbors whose priorities are not 0. In this way, neighbors with priorities set to 0 do not participate in the DR/BDR election. After a DR/BDR is elected, the DR/BDR sends the hello packets to all neighbors to set up a neighbor relationship.

The P2MP (non-broadcast) network cannot dynamically discover neighbors because it does not have the broadcast capability. Therefore, you must run this command to manually configure neighbors for the P2MP (non-broadcast) network. In addition, you can use the **cost** parameter to specify the cost to reach each neighbor on the P2MP network.

Examples

The following example configures the IP address of an OSPF neighbor as 172.16.24.2, priority value as 1, and polling interval as 150s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 20
Hostname(config-router)# network 172.16.24.0 0.0.0.255 area 0
Hostname(config-router)# neighbor 172.16.24.2 priority 1 poll-interval 150
```

Notifications

When the configured neighbor address is the local address, the following notification will be displayed:

```
%OSPF: Warning: OSPF neighbor address 192.168.1.1 is our address
```

Common Errors

1.58 network area

Function

Run the **network area** command to configure which interfaces will run OSPF and which OSPF area they belong to.

Run the **no** form of this command to delete the OSPF area definition of an interface.

No interface IP address is configured to join the OSPF area by default.

Syntax

network *ipv4-address wildcard* **area** *area-id*

no network *ipv4-address wildcard* **area** *area-id*

Parameter Description

ipv4-address: IP address corresponding to the interface.

wildcard: IP address comparison bit. 0 indicates accurate matching, and 1 indicates that no comparison is performed.

area-id: ID of the OSPF area. The parameter can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

To run OSPF on an interface, you can include the primary IP address of the interface in the IP address range defined by the **network area** command. By defining the *ipv4-address* and *wildcard* parameters, you can use one command to associate multiple interfaces with one OSPF area. If the interface address matches the IP address ranges defined in the **network area** command of multiple OSPF processes, the OSPF process that the interface is associated with is determined based on the optimal matching method.

If the IP address range defined by the **network area** command contains only the secondary IP address of the interface, OSPF does not run on this interface. You can also add an interface to an OSPF process using the **ip ospf area** command on the interface. If the **network area** command for the instance and the **ip ospf area** command on the interface are configured at the same time, the configuration on the interface takes effect first.

Examples

The following example configures three areas: 0, 1, and 172.16.16.0. The interface with an IP address in the range of 192.168.12.0/24 is defined to area 1, the interface with an IP address in the range of 172.16.16.0/20 is defined to Area 172.16.16.0, and the remaining interfaces are defined to Area 0.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 20
Hostname(config-router)# network 172.16.16.0 0.0.15.255 area 172.16.16.0
```

```
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 1
Hostname(config-router)# network 0.0.0.0 255.255.255.255 area 0
```

Notifications

When an invalid address/mask combination is detected, the following notification will be displayed:

```
OSPF: Invalid address/mask combination
```

1.59 nsr

Function

Run the **nsr** command to configure the current OSPF process to support the non-stop routing (NSR) function.

Run the **no** form of this command to restore the default configuration.

The NSR function is disabled by default.

Syntax

nsr

no nsr

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

During NSR, OSPF-related information is backed up from the active supervisor module of a distributed device to the standby supervisor module, or from the active host of a virtual switching unit (VSU) to the standby host. In this way, the device can automatically recover the link state and re-generate routes without the help of the neighbor devices during the active/standby switchover. Information that should be backed up includes the neighbor relationship and link state.

For the same OSPF process, either NSR or GR is enabled because they are mutually exclusive. Nevertheless, when NSR is enabled, the GR helper capability is still supported.

The switchover of devices in distributed or VSU mode takes a period of time. If the OSPF neighbor keepalive duration is shorter than the switchover duration, the OSPF neighbor relationship with the neighbor device is removed, and services are interrupted during the switchover. Therefore, you are advised to set the OSPF neighbor keepalive duration not less than the default value. When fast hello is enabled, the OSPF neighbor keepalive duration is less than 1s and the OSPF neighbor relationship times out during the switchover, causing NSR failures. Therefore, you are advised to disable fast hello when NSR is enabled.

Examples

The following example configures the current OSPF process 1 to support the NSR function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# nsr
```

Notifications

N/A

Common Errors

The neighbor keepalive duration is short. When fast hello is enabled, the OSPF neighbor relationship is removed during a switchover, causing forwarding interruption.

1.60 overflow database

Function

Run the **overflow database** command to configure the maximum number of LSAs supported by the current OSPF process.

Run the **no** form of this command to restore the default configuration.

The maximum number of LSAs is not configured by default.

Syntax

overflow database *max-lsa* [**hard** | **soft**]

no overflow database

Parameter Description

max-lsa: Maximum number of LSAs. The value range is from 1 to 4294967294.

hard: Indicates that the OSPF process will be stopped if the number of LSAs exceeds the limit.

soft: Indicates that a warning is generated when the number of LSAs exceeds the limit.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

You can configure the maximum number of LSAs supported by an OSPF process on a low performance device.

Examples

The following example configures the maximum number of LSAs supported by the current OSPF process as **10**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 10
Hostname(config-router)# overflow database 10 hard
```

1.61 overflow database external

Function

Run the **overflow database external** command to configure the maximum number of external LSAs and the waiting time for recovery from the overflow state to the normal state.

Run the **no** form of this command to restore the default configuration.

The maximum number of external LSAs is not configured by default.

If the maximum number of external LSAs is set, when the number of external LSAs exceeds the maximum, the normal state will not be restored.

Syntax

overflow database external *max-dbsize wait-time*

no overflow database external

Parameter Description

max-dbsize: Maximum number of external LSAs. This value must be the same on all the routers in the same AS. The value range is from 0 to 2147483647.

wait-time: Waiting time for a router in the overflow state to attempt to restore the normal state. The value range is from 0 to 2147483647.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

You can configure the maximum number of external LSAs on a low performance device. When the number of external LSAs of a device exceeds the configured *max-dbsize* value, the device enters the overflow state. In this state, the router no longer loads external LSAs and deletes external LSAs that are generated locally. After the set time of *wait-time* elapses, the device restores the normal state, and loads external LSAs again.

When using the **overflow database external** command, ensure that the same *max-dbsize* value is configured on all devices in the OSPF backbone area and common areas; otherwise, the following problems may occur:

- The LSDBs throughout the network are inconsistent, and the neighbor relationship fails to reach the full state.
- Routes are incorrect, including routing loops.
- AS external LSAs are frequently retransmitted.

Examples

The following example configures the maximum number of external LSAs as 10 and the waiting time for recovery from the overflow state to the normal state as 3s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 10
Hostname(config-router)# overflow database external 10 3
```

1.62 overflow memory-lack

Function

Run the **overflow memory-lack** command to allow the OSPF process to enter the overflow state when the memory is insufficient.

Run the **no** form of this command to prevent the OSPF process from entering the overflow state when the memory is insufficient.

By default, the OSPF process is allowed to enter the overflow state when the memory is insufficient.

Syntax

overflow memory-lack

no overflow memory-lack

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The OSPF process enters the overflow state to discard newly-learned external routes. This behavior can effectively prevent the memory usage from increasing.

After the overflow function is enabled, the OSPF process enters the overflow state and discards newly-learned external routes, which may cause a routing loop on the entire network. To reduce the occurrence probability of this problem, the OSPF process generates a default route to the null interface, and this route always exists in the overflow state.

You can run the **clear ip ospf process** command to reset the OSPF process so that the OSPF process can exit the overflow state.

You can run the **no** form of the command to prevent the OSPF process from entering the overflow state when the memory is insufficient. This, however, may lead to over-consumption of the memory resource, after which the OSPF process will stop and delete all the learned routes.

Examples

The following example prevents the OSPF process from entering the overflow state when the memory is insufficient.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# no overflow memory-lack
```

1.63 passive-interface

Function

Run the **passive-interface** command to configure a network interface specified for the local router as a passive interface.

Run the **no** form of this command to restore the default configuration.

By default, the passive modes of all interfaces are disabled, and all interfaces are allowed to send and receive OSPF packets.

Syntax

passive-interface { **default** | *interface-type interface-number* | *interface-type interface-number ipv4-address* }

no passive-interface { **default** | *interface-type interface-number* | *interface-type interface-number ipv4-address* }

Parameter Description

interface-type interface-number: Interface to be configured as a passive interface.

Default: Configures all interfaces as passive interfaces.

interface-type interface-number ipv4-address: Address of an interface as passive address.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

To prevent other routers on the network from learning the routing information of the local router, you can configure a specified network interface of the local router as the passive interface, or the specified IP address of a network interface as a passive address. The loopback interface and the interface of the unconnected OSPF neighbor can be set to passive interfaces.

Examples

The following example configures the GigabitEthernet 0/1 interface as a passive interface, and specifies the IP address 1.1.1.1 under the interface as a passive IP address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 30
Hostname(config-router)# passive-interface GigabitEthernet 0/1
Hostname(config-router)# passive-interface GigabitEthernet 0/1 1.1.1.1
```

Notifications

1.64 redistribute

Function

Run the **redistribute** command to enable the function of redistributing the external routing information.

Run the **no** form of this command to disable the redistributing function.

The route redistribution function is not configured by default.

Syntax

redistribute { **arp-host** | **bgp** | **connected** | **isis** [*area-tag*] [**level-1** | **level-1-2** | **level-2**] | **ospf** *process-id* [**match** { **external** [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**] } *] | **rip** | **static** } [**metric** *metric-value* | **metric-type** { **1** | **2** } | **route-map** *route-map-name* | **subnets** | **tag** *tag-value*] *

no redistribute { **arp-host** | **bgp** | **connected** | **isis** [*area-tag*] [**level-1** | **level-1-2** | **level-2**] | **ospf** *process-id* [**match** { **external** [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**] } *] | **rip** | **static** } [**metric** | **metric-type** | **route-map** | **subnets** | **tag**] *

Parameter Description

arp-host: Indicates redistribution from host routes converted by ARP.

bgp: Indicates redistribution from BGP.

connected: Indicates redistribution from direct routes.

isis [*area-tag*]: Indicates redistribution from IS-IS. Here, *area-tag* specifies an IS-IS instance.

level-1 | **level-2** | **level-1-2**: Used only when IS-IS routes are redistributed. Only the routes of the specified level are redistributed. By default, only Level-2 IS-IS routes can be redistributed.

ospf *process-id*: Indicates redistribution from OSPF. Here, *process-id* specifies an OSPF process. The value range is from 1 to 65535.

match: Used only when OSPF routes are redistributed. Only the routes that match the specified criteria are redistributed. By default, all OSPF routes can be redistributed.

external [**1** | **2**]: Redistributes E1, E2, or all external routes.

internal: Redistributes internal routes and inter-area routes.

nssa-external [**1** | **2**]: Redistributes N1, N2, or all external routes of all NSSAs.

rip: Indicates redistribution from RIP.

static: Indicates redistribution from static routes.

metric *metric-value*: Sets the metric of an OSPF external LSA. The value range is from 0 to 16777214.

metric-type { **1** | **2** }: Sets the external route type to **E-1** or **E-2**.

route-map *route-map-name*: Sets the redistribution filtering rules. Here, the value of *route-map-name* cannot exceed 32 characters.

subnets: Specifies the non-standard networks for redistribution.

tag *tag-value*: Specifies the tag value of the route that is redistributed into the OSPF routing domain. The value range is from 0 to 4294967295.

Command Modes

Routing configuration mode

Default Level

14

Usage Guidelines

After this command is configured, the router becomes an ASBR, imports related routing information to the OSPF domain, and advertises the routing information as Type 5 LSAs to other OSPF routers in the domain.

If the **level** parameter is not carried when IS-IS route redistribution is configured, only Level-2 routes can be redistributed by default. The **level** parameter is carried during initial configuration of redistribution, the routes configured with the **level** parameter can be redistributed. If both **level 1** and **level 2** are configured, the two levels are combined and saved as **level-1-2**.

If you configure redistribution of OSPF routes without specifying the **match** parameter, OSPF routes of all sub-types can be distributed by default. The latest setting of the **match** parameter is used as the initial **match** parameter. Only routes that match the sub-types can be redistributed. You can run the **no** form of the command to restore the default value of **match**.

If **route-map** is specified, the **match** filtering rules specified in **route-map** are applicable to the original parameters of redistribution. For redistribution of OSPF or IS-IS routes, **route-map** is used for filtering only when the redistributed routes meet the criteria specified by **match** or **level**.

The **set metric** value of the associated **route-map** should fall into the range of 0 to 16777214. If the value exceeds this range, routes cannot be introduced.

The configuration rules for the **no** form of the **redistribute** command are as follows:

- If some parameters are specified in the **no** form of this command, default values of these parameters will be restored.
- If no parameter is specified in the **no** form of this command, the entire command will be deleted.

For example, if **redistribute isis 112 level-2** is configured, you can run the **no redistribute isis 112 level-2** command to restore the default value of level 2. As **level-2** itself is the default value of the parameter, the configuration saved is still **redistribute isis 112 level-2** after the preceding **no** form of the command is executed. To delete the entire command, run the **no redistribute isis 112** command.

Examples

The following example configures to redistribute OSPF 2 and IS-IS isis-001 to OSPF1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# redistribute ospf 2 subnets
Hostname(config-router)# redistribute ospf 2 match external 1 internal
Hostname(config-router)# redistribute isis isis-001
Hostname(config-router)# redistribute isis isis-001 level-1
```

Notifications

When redistribution of this instance's routes is not allowed, the following notification will be displayed:

```
% Redistribution of "ospf 1" via "ospf 1" not allowed
```

When only classful network segments are redistributed, the following notification will be displayed:

```
% Only classful networks will be redistributed
```

Common Errors

The routes of the same OSPF process are redistributed.

Platform Description

N/A

Related Commands

- **show ip ospf database**

1.65 router ospf

Function

Run the **router ospf** command to create an OSPF routing process and enter routing configuration mode of OSPF.

Run the **no** form of this command to delete a created OSPF routing process.

The OSPF routing process is disabled by default.

Syntax

router ospf *process-id* [**vrf** *vrf-name*]

no router ospf *process-id*

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535, and the default value is **1**.

vrf-name: VRF to which the OSPF process belongs.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Based on the original implementation, the process ID parameter is added to the device software to realize expansion to a multi-instance OSPF process. Different OSPF processes are independent of each other, and can be treated as different routing protocols that run independently.

Examples

The following example creates an OSPF routing process in vrf vpn_1 and enters routing configuration mode of OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 10 vrf vpn_1
Hostname(config-router)#
```

Notifications

When no router ID can be allocated and the corresponding OSPF process cannot be started, the following notification will be displayed:

```
%OSPF-NORTRID: OSPF process 1 failed to allocate unique router-id and cannot start.
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **show ip ospf**

1.66 router ospf max-concurrent-dd

Function

Run the **router ospf max-concurrent-dd** command to configure the maximum number of neighbors with which all the OSPF routing processes can concurrently initiate or accept interaction.

Run the **no** form of this command to restore the default configuration.

The maximum number of neighbors is **10** by default.

Syntax

router ospf max-concurrent-dd *max-neighbor*

no router ospf max-concurrent-dd

Parameter Description

max-neighbor: Maximum number of neighbors that concurrently interact with the OSPF process. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the performance of a router is affected because the router exchanges data with multiple neighbors, you can configure this command to restrict the maximum number of neighbors with which all OSPF processes can concurrently initiate or accept interaction.

Examples

The following example configures the maximum number of neighbors with which all OSPF processes can concurrently initiate or accept interaction as **4**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf max-concurrent-dd 4
```

1.67 router-id

Function

Run the **router-id** command to configure the ID of a router.

Run the **no** form of this command to delete the configured router ID and restore the default router ID.

By default, the OSPF routing process elects the largest IP address among the IP addresses of all the loopback interfaces as the router ID. If the loopback interfaces configured with IP addresses are not available, the OSPF process elects the largest one among the IP addresses of all its physical interfaces as the router ID.

Syntax

router-id *router-id*

no router-id

Parameter Description

router-id: Router ID to be configured, expressed in the form of an IP address.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

You can configure any IP address as the ID of the router, and ensure that the router ID is unique in an AS. After the router ID changes, OSPF performs a lot of internal processing. Therefore, you are advised to set the router ID before generating an LSA. When an attempt is made to modify the router ID, a prompt is displayed, requesting you to confirm the modification.

Examples

The following example configures the router ID as **0.0.0.36**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 20
Hostname(config-router)# router-id 0.0.0.36
```

Notifications

When you configure the router ID as **0.0.0.0** and this operation will stop the OSPF process, the following notification will be displayed:

```
% OSPF: router-id set to 0.0.0.0, process will not run.
```

When the configured router ID is duplicate with that of another process, the following notification will be displayed:

```
% OSPF: router-id 192.168.1.1 is in use by process 1
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **show ip ospf**

1.68 show ip ospf

Function

Run the **show ip ospf** command to display the summary of an OSPF process.

Syntax

show ip ospf [*process-id*]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the summary of an OSPF process.

```
Hostname> enable
Hostname# show ip ospf
Routing Process "ospf 1" with ID 1.1.1.1
  Domain ID type 0x0105, value 0x010101010101
Process uptime is 4 minutes
Process bound to VRF default
Memory Overflow is enabled.
Router is not in overflow state now.
Conforms to RFC2328, and RFC1583Compatibility flag isenabled
Supports only single TOS(TOS0) routes
Enable two-way-maintain
Enable ispf
Supports opaque LSA
Supports Graceful Restart
This router is an ASBR (injecting external routing information)
Originating router-LSAs with maximum metric
   Condition: on startup for 100 seconds, State: inactive
   Advertise stub links with maximum metric in router-LSAs
   Advertise summary-LSAs with metric 16711680
   Advertise external-LSAs with metric 16711680
   Unset reason: timer expired, Originated for 100 seconds
   Unset time: 00:02:02.080, Time elapsed: 00:23:54.656
SPF schedule delay 5 secs, Hold time between two SPFs 10 secs
Initial LSA throttle delay 0 msecs
```

```
Minimum hold time for LSA throttle 5000 msecs
Maximum wait time for LSA throttle 5000 msecs
Lsa Transmit Pacing timer 40 msecs, 1 LS-Upd
Minimum LSA arrival 1000 msecs
Pacing lsa-group: 30 secs
Number of incomming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 4. Checksum 0x0278E0
Number of opaque AS LSA 0. Checksum 0x000000
Number of non-default external LSA 4
External LSA database is unlimited.
Number of LSA originated 6
Number of LSA received 2
Log Neighbor Adjency Changes : Enabled
Graceful-restart disabled
Graceful-restart helper support enabled
Number of areas attached to this router: 1
BFD enabled
Area 0 (BACKBONE)
Number of interfaces in this area is 1(1)
Number of fully adjacent neighbors in this area is 1
Area has no authentication
SPF algorithm last executed 00:01:26.640 ago
SPF algorithm executed 4 times
iSPF algorithm executed 0 timesNumber of LSA 3. Checksum 0x0204bf
Area 1 (NSSA)
Number of interfaces in this area is 1(1)
Number of fully adjacent neighbors in this area is 0
Number of fully adjacent virtual neighbors through this area is 0
Area has no authentication
SPF algorithm last executed 02:09:23.040 ago
SPF algorithm executed 4 times
iSPF algorithm executed 0 times
Number of LSA 6. Checksum 0x028638
NSSA Translator State is disabled, Stability Interval expired in 00:00:03
```

Table 1-1 Output Fields of the show ip ospf Command

Field	Description
Router ID	Indicates the ID of a router.
Process uptime	Indicates the time when this OSPF process takes effect (the process is invalid when the router ID is 0.0.0.0).
Bound to VRF	Indicates the VRF to which the OSPF process belongs.
Conforms to RFC2328	Indicates conformity to RFC2328.

Field	Description
RFC1583Compatibility flag	Indicates whether the RFC1583 rule or RFC2328 rule is used in the external route computation; this rule will be used during selection of the optimal ASBR and route comparison.
Support Tos	Indicates that only TOS0 is supported.
Supports opaque LSA	Indicates that Opaque-LSA is supported.
Graceful-restart	Indicates the GR capability described by RFC3623 Graceful Restart.
Graceful-restart Helper	Indicates the GR helper capability described by RFC3623 Graceful Restart.
Router Type	Indicates that the OSPF router type is Normal, ABR, or ASBR.
SPF Delay	Indicates the required delay time before calling the SPF computation when a topology change is received.
SPF-holdtime	Indicates the minimum time of holding between two SPF calculations.
LsaGroupPacing	Indicates the interval between the LSA update, verification, computation, and aging operations.
Incomming current DD exchange neighbors	Indicates the number of neighbors in interaction. Incomming means that the neighbor enters the Exstart state for the first time.
Outgoing current DD exchange neighbors	Indicates the number of neighbors in interaction. Outgoing means that the neighbor returns from a higher state to the Exstart state for re-interaction.
Number of external LSA	Indicates the number of external LSAs stored in the database.
External LSA Checksum Sum	Indicates the sum of checksums of external LSAs stored in the database.
Number of opaque LSA	Indicates the number of Opaque-LSAs stored in the database.
Opaque LSA Checksum Sum	Indicates the sum of checksums of Opaque-LSAs stored in the database.
Number of non-default external LSA	Indicates the number of external LSAs of non-default routes.
External LSA database limit	Indicates the quantity limit of external LSAs.
Exit database overflow state interval	Judges the waiting time for a router to attempt to return to normal state from the overflow state.
Database overflow state	Indicates whether the current OSPF process is in the overflow state.
Number of LSA originated	Indicates the number of generated LSAs.

Field	Description
Number of LSA received	Indicates the number of received LSAs.
Log Neighbor Adjency Changes	Indicates whether the neighbor state change recording switch is enabled.
Number of areas attached to this router	Indicates the number of areas on this router.
Area type	Indicates the area type. The value can be Default, Stub, or NSSA.
Number of interfaces in this area	Indicates the number of interfaces in this area.
Number of fully adjacent neighbors in this area	Indicates the number of neighbors in full neighbor relationship in this area.
Number of fully adjacent virtual neighbors through this area	Indicates the number of neighbors of virtual links with two neighbors already in the full state in this area. This field is valid only for the non-backbone area of default type.
Area authentication	Indicates the area authentication method.
SPF algorithm last executed	Indicates the duration from the last SPF computation to the present time.
SPF algorithm executed times	Indicates the SPF computation times.
Number of LSA	Indicates the total number of LSAs in this area.
Checksum Sum	Indicates the sum of the checksums of LSAs in this area.
NSSA Translator State	Indicates whether the NSSA LSA is converted to an external LSA. This field is valid only for the OSPF process that is an ABR in the NSSA.
BFD enabled	Indicates that correlating OSPF with BFD is enabled.

1.69 show ip ospf border-routers

Function

Run the **show ip ospf border-routers** command to display the OSPF internal routing table to an ABR/ASBR.

Syntax

show ip ospf [*process-id*] **border-routers**

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command can be used to display the OSPF internal route to an ABR or ASBR. The OSPF internal routing table is different from the routing table displayed using the **show ip route** command. The target address of the OSPF internal routing table is the OSPF router ID, not the target network.

Examples

The following example displays the OSPF internal routing table to an ABR/ASBR.

```
Hostname> enable
Hostname# show ip ospf border-routers
OSPF internal Routing Table
Codes: i - Intra-area route, I - Inter-area route
i 1.1.1.1 [2] via 10.0.0.1, GigabitEthernet 0/1, ABR, ASBR, Area 0.0.0.1 select
```

Table 1-2 Output Fields of the show ip ospf border-routers Command

Field	Description
Codes	Indicates the route type code definition. Here, i indicates an internal route of the area, and I indicates a route between areas.
i	Indicates that this route is an internal route of the area.
1.1.1.1	Displays the OSPF ID of the boundary router.
[2]	Displays the cost value to the boundary router.
via 10.0.0.1	Displays the next hop gateway to the boundary router.
GigabitEthernet 0/1	Displays the interface to the boundary router.
ABR, ASBR	Displays the type of the boundary router: ABR or ASBR, or both.
Area 0.0.0.1	Displays the area where the route is learned.
select	Indicates the optimum path currently selected when multiple paths are available to the ASBR.

1.70 show ip ospf database

Function

Run the **show ip ospf database** command to display the information of an OSPF LSDB.

Syntax

show ip ospf [*process-id* [*area-id* [*ipv4-address*]]] **database** [{ **asbr-summary** | **external** | **network** | **nssa-external** | **opaque-area** | **opaque-as** | **opaque-link** | **router** | **summary** }] [{ **adv-router** *ipv4-address* | **self-originate** } | *link-state-id* | **brief**] [**database-summary** | **max-age** | **detail**]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

area-id: ID of the OSPF area, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

ipv4-address: ID of the OSPF area, which is an IP address, for example, 0.0.0.1.

adv-router: Displays the link state description information generated by the specified adverting router.

link-state-id: Link state description information of the specified OSPF link state ID to be displayed.

self-originate: Displays the link state description information generated by the local router.

max-age: Displays the LSA whose aging time expires.

router: Displays the link state description information of the OSPF router.

network: Displays the link state description information of the OSPF network.

summary: Displays the link state description summary of the OSPF link.

asbr-summary: Displays the link state description summary of the ASBR.

external: Displays the external link state description of the OSPF process.

nssa-external: Displays the Type-7 external link state description of the OSPF process.

opaque-area: Displays the Type-10 LSA.

opaque-as: Displays the Type-11 LSA.

opaque-link: Displays the Type-9 LSA.

database-summary: Displays the statistical summary of each type of LSA in the OSPF LSDB.

detail: Displays the details about all LSAs of the OSPF process.

brief: Displays the summary of the specified type of LSA.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

When the OSPF LSDB is large, itemized display is necessary. Correct use of these commands is helpful to the troubleshooting of OSPF faults.

Examples

The following example displays the information about the OSPF LSDB.

```
Hostname> enable
Hostname# show ip ospf database

```

Table 1-3 Output Fields of the show ip ospf database Command

Field	Description
OSPF Router with ID	Displays the process ID of the OSPF LSDB's router ID that corresponds to this OSPF process.
Router Link States	Indicates that the following content is the link state description of the router.
Net Link States	Indicates that the following content is the network link state description.
Summary Net Link States	Indicates that the following content is the network link state description summary.
NSSA-external Link States	Indicates that the following content is the external link state description of Type-7 AS.
AS External Link States	Indicates that the following content is the external link state description of Type-5 AS.
Link ID	Indicates the link ID.
ADV Router	Indicates the ID of the router that advertises the link state description.
Age	Displays the keeping time of the link state description.
Seq#	Displays the sequence number of the link state description, used to detect the old or duplicate LSA.
Cksum	Displays the checksum of the link state description.
Link-Count	Displays the number of links in the link state description information of the router.
Route	Displays the route information contained in the LSA.
Tag	Displays the tag of the link state description.

The following example displays the link state description summary of an ASBR.

```
Hostname> enable
Hostname# show ip ospf database asbr-summary
OSPF Router with ID (1.1.1.35) (Process ID 1)
ASBR-Summary Link States (Area 0.0.0.1)
LS age: 47
Options: 0x2 (*|-|-|-|E|-)
LS Type: ASBR-summary-LSA
Link State ID: 3.3.3.3 (AS Boundary Router address)
Advertising Router: 1.1.1.1
LS Seq Number: 80000001
Checksum: 0xbe8c
Length: 28
Network Mask: /0
```

```
TOS: 0  Metric: 1
```

Table 1-4 Output Fields of the show ip ospf database asbr-summary Command

Field	Description
OSPF Router with ID	Indicates the router ID corresponding to the following information and the corresponding ID of this OSPF process.
AS Summary Link States	Indicates that the following content displays the link description summary of the AS.
LS age	Displays the keeping time of the link state description.
Options	Indicates the options.
LS Type	Displays the type of the link state description.
Link State ID	Displays the link ID of the link state description.
Advertising Router	Indicates the advertising router of the link state description.
LS Seq Number	Displays the sequence number of the link state description.
Checksum	Displays the checksum of the link state description.
Length	Displays the length of the link state description, in bytes.
Network Mask	Displays the subnet mask of the route corresponding to the link state description.
TOS	Indicates the TOS value, which can only be 0 at present.
Metric	Displays the metric value of the route corresponding to the link state description.

The following example displays the external link state description of the OSPF process.

```
Hostname> enable
Hostname# show ip ospf database external
OSPF Router with ID (1.1.1.35) (Process ID 1)
AS External Link States
LS age: 752
Options: 0x2 (*|-|-|-|E|-)
LS Type: AS-external-LSA
Link State ID: 20.0.0.0 (External Network Number)
Advertising Router: 1.1.1.1
LS Seq Number: 8000000a
Checksum: 0x7627
Length: 36
Network Mask: /24
Metric Type: 2 (Larger than any link state path)
TOS: 0
Metric: 20
```

```
Forward Address: 0.0.0.0
External Route Tag: 0
```

Table 1-5 Output Fields of the show ip ospf database external Command

Field	Description
OSPF Router with ID	Indicates the router ID corresponding to the following information and the corresponding ID of this OSPF process.
Type-5 AS External Link States	Indicates that the following content is the external link state description of the AS.
LS age	Displays the keeping time of the link state description.
Options	Indicates the options.
LS Type	Displays the type of the link state description.
Link State ID	Displays the link ID of the link state description.
Advertising Router	Indicates the advertising router of the link state description.
LS Seq Number	Displays the sequence number of the link state description.
Checksum	Displays the checksum of the link state description.
Length	Displays the length of the link state description, in bytes.
Network Mask	Displays the subnet mask of the route corresponding to the link state description.
Metric Type	Indicates the external link type.
TOS	Indicates the TOS value, which can only be 0 at present.
Metric	Displays the metric value of the route corresponding to the link state description.
Forward Address	Indicates that the data traffic to the target network will be forwarded to this IP address. If the address is 0.0.0.0, the data traffic will be forwarded to the router that generates this link state.
External Route Tag	Indicates the external route tag. Every external route has a 32-bit route tag. The OSPF process does not use this route tag, which will be used when other routing processes redistribute OSPF routes.

The following example displays the link state description of the OSPF network.

```
Hostname> enable
Hostname# show ip ospf database network
OSPF Router with ID (1.1.1.1) (Process ID 1)
Network Link States (Area 0.0.0.0)
LS age: 572
```

```
Options: 0x2 (*|-|-|-|E|-)
LS Type: network-LSA
Link State ID: 192.88.88.27 (address of Designated Router)
Advertising Router: 1.1.1.1
LS Seq Number: 80000001
Checksum: 0x5366
Length: 32
Network Mask: /24
Attached Router: 1.1.1.1
Attached Router: 3.3.3.3
```

Table 1-6 Output Fields of the show ip ospf database network Command

Field	Description
OSPF Router with ID	Indicates the router ID corresponding to the following information and the corresponding ID of this OSPF process.
Network Link States	Indicates that the following content is the network link state description.
LS age	Displays the keeping time of the link state description.
Options	Indicates the options.
LS Type	Displays the type of the link state description.
Link State ID	Displays the link ID of the link state description.
Advertising Router	Indicates the advertising router of the link state description.
LS Seq Number	Displays the sequence number of the link state description.
Checksum	Displays the checksum of the link state description.
Length	Displays the length of the link state description, in bytes.
Network Mask	Displays the subnet mask of the network corresponding to the link state description.
Attached Router	Displays the routers connected on the network.

The following example displays the link state description of the OSPF router.

```
Hostname> enable
Hostname# show ip ospf database router
OSPF Router with ID (1.1.1.1) (Process ID 1)
Router Link States (Area 0.0.0.0)
LS age: 322
Options: 0x2 (*|-|-|-|E|-)
Flags: 0x3 : ABR ASBR
LS Type: router-LSA
Link State ID: 1.1.1.1
```

```
Advertising Router: 1.1.1.1
LS Seq Number: 80000012
Checksum: 0x6d3a
Length: 48
Number of Links: 2
Link connected to: Stub Network
(Link ID) Network/subnet number: 100.0.1.1
(Link Data) Network Mask: 255.255.255.255
Number of TOS metrics: 0
TOS 0 Metric: 0
```

Table 1-7 Output Fields of the show ip ospf database router Command

Field	Description
OSPF Router with ID	Indicates the router ID corresponding to the following information and the corresponding ID of this OSPF process.
Router Link States	Indicates that the following content is the link state description of the router.
LS age	Displays the keeping time of the link state description.
Options	Indicates the options.
Flag	Indicates the router flag.
LS Type	Displays the type of the link state description.
Link State ID	Displays the link ID of the link state description.
Advertising Router	Indicates the advertising router of the link state description.
LS Seq Number	Displays the sequence number of the link state description.
Checksum	Displays the checksum of the link state description.
Length	Displays the length of the link state description, in bytes.
Number of Links	Displays the number of links associated with the router.
Link connected to	Displays the device to which the link is connected and the type of the network.
(Link ID)	Indicates the link ID.
(Link Data)	Indicates the link data.
Number of TOS metrics	Indicates the TOS value, which is 0.
TOS 0 Metrics	Indicates the metric value of TOS 0.

The following example displays the link state description summary of the OSPF process.

```
Hostname> enable
```

```
Hostname# show ip ospf database summary
OSPF Router with ID (1.1.1.1) (Process ID 1)
Summary Link States (Area 0.0.0.0)
LS age: 499
Options: 0x2 (*|-|-|-|E|-)
LS Type: summary-LSA
Link State ID: 10.0.0.0 (summary Network Number)
Advertising Router: 1.1.1.1

Checksum: 0x330e
Length: 28
Network Mask: /24
TOS: 0  Metric: 11
```

Table 1-8 Output Fields of the show ip ospf database summary Command

Field	Description
OSPF Router with ID	Indicates the router ID corresponding to the following information and the corresponding ID of this OSPF process.
Summary Net Link States	Indicates that the following content is the network link state description summary.
LS age	Displays the keeping time of the link state description.
Options	Indicates the options.
LS Type	Displays the type of the link state description.
Link State ID	Displays the link ID of the link state description.
Advertising Router	Indicates the advertising router of the link state description.
LS Seq Number	Displays the sequence number of the link state description.
Checksum	Displays the checksum of the link state description.
Length	Displays the length of the link state description, in bytes.
Network Mask	Displays the subnet mask of the route corresponding to the link state description.
TOS	Indicates the TOS value, which can only be 0 at present.
Metric	Displays the metric value of the route corresponding to the link state description.

The following example displays the Type-7 external link state description of the OSPF process.

```
Hostname> enable
Hostname# show ip ospf database nssa-external
OSPF Router with ID (1.1.1.1) (Process ID 1)
NSSA-external Link States (Area 0.0.0.1 [NSSA])
```

```
LS age: 1
Options: 0x0 (*|-|-|-|-)
LS Type: AS-NSSA-LSA
Link State ID: 20.0.0.0 (External Network Number For NSSA)
Advertising Router: 1.1.1.1
LS Seq Number: 80000001
Checksum: 0x033c
Length: 36
Network Mask: /24
Metric Type: 2 (Larger than any link state path)
TOS: 0
Metric: 20
NSSA: Forward Address: 100.0.2.1
External Route Tag: 0
```

Table 1-9 Output Fields of the show ip ospf database nssa-external Command

Field	Description
OSPF Router with ID	Indicates the router ID corresponding to the following information and the corresponding ID of this OSPF process.
NSSA-external Link States	Indicates that the following content is the external link state description of the Type-7 AS.
LS age	Displays the keeping time of the link state description.
Options	Indicates the options.
LS Type	Displays the type of the link state description.
Link State ID	Displays the link ID of the link state description.
Advertising Router	Indicates the advertising router of the link state description.
LS Seq Number	Displays the sequence number of the link state description.
Checksum	Displays the checksum of the link state description.
Length	Displays the length of the link state description, in bytes.
Network Mask	Displays the subnet mask of the route corresponding to the link state description.
Metric Type	Indicates the external link type.
TOS	Indicates the TOS value, which can only be 0 at present.
Metric	Displays the metric value of the route corresponding to the link state description.
NSSA:Forward Address	Indicates that the data traffic to the target network will be forwarded to this IP address. If the address is 0.0.0.0, the data traffic will be forwarded to the router that generates this link state.

Field	Description
External Route Tag	Indicates the external route tag. Every external route has a 32-bit route tag. The OSPF process does not use this route tag, which will be used when other routing processes redistribute OSPF routes.

The following example displays the statistical summary of each type of LSA in the OSPF LSDB.

```
Hostname> enable
Hostname# show ip ospf database database-summary
OSPF process 1:
Router Link States      : 4
Network Link States     : 2
Summary Link States     : 4
ASBR-Summary Link States : 0
AS External Link States  : 4
NSSA-external Link States: 2
```

Table 1-10 Output Fields of the show ip ospf database database-summary Command

Field	Description
OSPF Process	Displays the routing process ID corresponding to the following information.
Router Link	Indicates the number of OSPF router LSAs in this area.
Network Link	Indicates the number of OSPF network LSAs in this area.
Summary Link	Indicates the number of OSPF network summary LSAs in this area.
ASBR-Summary Link	Indicates the number of OSPF ASBR summary LSAs in this area.
AS External Link	Indicates the number of OSPF external LSAs in this area.
NSSA-external Link	Indicates the number of OSPF NSSA LSAs in the router.

1.71 show ip ospf interface

Function

Run the **show ip ospf interface** command to display the information about an interface associated with an OSPF process.

Syntax

show ip ospf [*process-id*] **interface** [*interface-type interface-number* | **brief**]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

interface-type interface-number: Specified interface.

brief: Displays the brief information of the interface.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command can display the interfaces where OSPF runs, and the configuration information of these interfaces that related to the OSPF process.

Examples

The following example displays the information about the interface associated with the OSPF process.

```
Hostname> enable
Hostname# show ip ospf interface GigabitEthernet 0/1
GigabitEthernet 0/1 is up, line protocol is up
Internet Address 192.88.88.27/24, Ifindex 4, Area 0.0.0.0, MTU 1500
Matching network config: 192.88.88.0/24
Process ID 1, Router ID 1.1.1.1, Network Type BROADCAST, Cost: 1
Transmit Delay is 1 sec, State DR, Priority 1,
BFD enabled
Designated Router (ID) 1.1.1.1, Interface Address 192.88.88.27
Backup Designated Router (ID) 3.3.3.3, Interface Address 192.88.88.72
Timer intervals configured,Hello 10,Dead 40,Wait 40,Retransmit 5
Hello due in 00:00:03
Neighbor Count is 1, Adjacent neighbor count is 1
Crypt Sequence Number is 70784
Hello received 1786 sent 1787, DD received 13 sent 8
LS-Req received 2 sent 2, LS-Upd received 29 sent 53
LS-Ack received 46 sent 23, Discarded 1
```

Table 1-11 Output Fields of the show ip ospf interface GigabitEthernet 0/1 Command

Field	Description
GigabitEthernet 0/1 State	Indicates the state of the network interface: Up indicates normal operation, and Down indicates a fault.
Internet Address	Indicates the IP address of the interface.
Area	Indicates the OSPF area to which the interface belongs.
MTU	Indicates the corresponding MTU.
Matching network config	Indicates the configuration for the **network area** command corresponding to the OSPF process.
Process ID	Indicates the corresponding process ID.
Router ID	Indicates the ID of the OSPF router.
Network Type	Indicates the OSPF network type.
Cost	Indicates the cost of the OSPF interface.
Transmit Delay is	Indicates the transmission delay of the OSPF interface.
State	Indicates the DR/BDR state ID.
Priority	Indicates the priority of this interface.
Designated Router(ID)	Indicates the ID for the DR of this interface.
DR's Interface address	Indicates the interface address for the DR of this interface.
Backup designated router(ID)	Indicates the ID for the BDR of this interface.
BDR's Interface address	Indicates the interface address for the BDR of this interface.
Time intervals configured	Indicates the Hello, Dead, Wait, and Retransmit time corresponding to this interface.
Hello due in	Indicates the last time of sending a hello packet.
Neighbor count	Indicates the total number of neighbors.
Adjacent neighbor count	Indicates the number of neighbors in full neighbor relationship.
Crypt Sequence Number	Indicates the sequence number of MD5 authentication corresponding to this interface.
Hello received send	Indicates the statistics of the received and sent hello packets.
DD received send	Indicates the statistics of the received and sent DD packets.
LS-Req received send	Indicates the statistics of the received and sent LS request packets.

Field	Description
LS-Upd received send	Indicates the statistics of the received and sent LS update packets.
LS-Ack received send	Indicates the statistics of the received and sent LS response packets.
Discard	Indicates the statistics of the discarded OSPF packets.
BFD enabled	Indicates that correlating OSPF with BFD is enabled.

1.72 show ip ospf ispf

Function

Run the **show ip ospf ispf** command to display the times of route computation through iSPF in the OSPF area.

Syntax

show ip ospf [*process-id*] **ispf**

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the times of route computation through iSPF in the OSPF area in the last 30 minutes, as well as the total times of computation using the iSPF algorithm up to now.

Examples

The following example displays the times of iSPF computation in the OSPF area.

```
Hostname> enable
Hostname# show ip ospf 1 ispf
OSPF process 1:
Area_id     30min_counts   Total_counts
```

```
0           32          1235
1           6           356
```

Table 1-12 Output Fields of the show ip ospf 1 ispf Command

Field	Description
Area_id	Indicates the OSPF area ID.
30min_counts	Indicates the times of iSPF computation in the last 30 minutes.
Total_counts	Indicates the total times of iSPF computation up to now.

1.73 show ip ospf neighbor

Function

Run the **show ip ospf neighbor** command to display the neighbor table of an OSPF process.

Syntax

show ip ospf [*process-id*] **neighbor** [[*interface-type interface-number* | *neighbor-id*] * [**detail**] | **statistics**]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

interface-type interface-number: Neighbor information of a specified interface.

neighbor-id: Information about a specified neighbor.

detail: Displays the neighbor details.

statistics: Displays the statistics of neighbors.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command can be used to display the neighbor information and confirm whether the OSPF process is running normally.

Examples

The following example displays the neighbor list of an OSPF process.

```
Hostname> enable
Hostname# show ip ospf neighbor
OSPF process 1, 1 Neighbors, 1 is Full:
Neighbor ID   Pri   State    BFD State   Dead Time   Address       Interface
3.3.3.3      1    Full/BDR  Up        00:00:32   192.88.88.72   GigabitEthernet
0/1
Hostname# show ip ospf neighbor detail
Neighbor 3.3.3.3, interface address 192.88.88.72
In the area 0.0.0.0 via interface GigabitEthernet 0/1
Neighbor priority is 1, State is Full, 11 state changes
DR is 192.88.88.27, BDR is 192.88.88.72
Options is 0x52 (*|O|-|EA|-|E|-)
Dead timer due in 00:00:32
Neighbor is up for 05:11:27
Database Summary List 0
Link State Request List 0
Link State Retransmission List 0
Crypt Sequence Number is 0
Thread Inactivity Timer on
Thread Database Description Retransmission off
Thread Link State Request Retransmission off
Thread Link State Update Retransmission off
Thread Poll Timer on
Graceful-restart helper disabled
BFD session state up
```

Table 1-13 Output Fields of the show ip ospf neighbor Command

Field	Description
Neighbor ID	Indicates the ID of the neighbor router.
Pri	Indicates the priority (used to elect a DR) of the neighbor.
State	Indicates the state of the neighbor.
Dead Time	Indicates the time before the neighbor enters the dead state.
Address	Indicates the IP address of the interface corresponding to the neighbor.
Interface	Indicates the interface corresponding to the neighbor.
interface address	Indicates the interface address of the neighbor router.
In the area	Displays the area where the neighbor is learned.
via interface	Displays the interface where the neighbor is learned.

Field	Description
Neighbor priority	Indicates the priority value of the neighbor.
State	Indicates the connection state of the OSPF neighbor. DR or BDR is unavailable for the point-to-point network type. ● **Full** indicates the stable state. ● **DR** indicates that the neighbor is the specified router. ● **BDR** indicates that the neighbor is the specified router for backup. ● **DROTHER** indicates that the neighbor is not a DR/BDR.
State changes times	Indicates the change times of the neighbor state.
Dead Time	Displays the time when the dead state of this neighbor is declared.
DR	Indicates the interface address (namely, the DR field of the hello packet) of the DR elected by the neighbor router.
BDR	Indicates the interface address (namely, the BDR field of the hello packet) of the BDR elected by the neighbor router.
Options	Indicates the option for the E bit of the hello packet: ● **0** indicates that the area is a stub area. ● **2** indicates that the area is not a stub area.
Dead timer due in	Indicates the time before the neighbor router enters the dead state.
Neighbor up time	Indicates the duration from the time of discovering the neighbor router to the current time.
Database Summary List	Indicates the DD packet statistics of the neighbor.
Link State Request List	Indicates the LS request packet statistics of the neighbor.
Link State Retransmission List	Indicates the retransmitted packet statistics of the neighbor.
Crypt Sequence Number	Indicates the MD5 authentication code of the area.
Thread Inactivity Timer	Indicates the inactivity timer state of the neighbor.
Thread Database Description Retransmission	Indicates the DD packet timer state of the interface.
Thread Link State Request Retransmission	Indicates the LS request packet timer state of the interface.
Thread Link State Update Retransmission	Indicates the LS update packet timer state of the interface.
Thread Poll Timer	Indicates the poll timer startup state of the statically configured neighbor.

Field	Description
Graceful-restart Helper	Indicates whether the local router can become a GR helper for the specified neighbor.

1.74 show ip ospf route

Function

Run the **show ip ospf route** command to display an OSPF route.

Syntax

show ip ospf [*process-id*] **route** [**count** | *ipv4-address mask*]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

count: Displays the statistics of all kinds of OSPF routes.

ipv4-address mask: Routing information of the specified prefix and mask.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays an OSPF route.

```
Hostname> enable
Hostname# show ip ospf route
OSPF process 1:
Codes: C - connected, D - Discard, B – Backup, O - OSPF,
IA - OSPF inter area  N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type
2
```

```
E1 - OSPF external type 1, E2 - OSPF external type 2
E2 100.0.0.0/24 [1/20] via 192.88.88.126, GigabitEthernet 0/1
B                  via 192.88.89.126, GigabitEthernet 0/2
C  192.88.88.0/24 [1] is directly connected,GigabitEthernet 0/1,Area 0.0.0.1
```

Table 1-14 Output Fields of the show ip ospf neighbor Command

Field	Description
codes	Indicates the route type and corresponding abbreviation description.
100.0.0.0/24	Indicates the corresponding prefix of the route.
[1/20]	Indicates the management distance and cost value corresponding to the route.
via	Indicates the next hop and interlace of the route.

1.75 show ip ospf sham-links

Function

Run the **show ip ospf sham-links** command to display the sham link information of an OSPF process.

Syntax

show ip ospf [*process-id*] **sham-links** [**area** *area-id*]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

area *area-id*: Indicates the ID of the OSPF area where the sham link is, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the sham link information of an OSPF process.

```
Hostname> enable
Hostname# show ip ospf sham-links
Sham Link SLINK1 to address 8.8.8.8 is up
  Area 0.0.0.0 source address 7.7.7.7, Cost: 10
  Output interface is GigabitEthernet 0/8
  Nexthop address 192.168.1.2
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:07
    Adjacency state Full
```

Table 1-15 Output Fields of the show ip ospf sham-links Command

Field	Description
Area	Indicates the domain ID.
source address	Indicates the source IP address of the sham link.
Cost	Indicates the cost value of the sham link.
Output interface	Indicates the actual outbound interface of the sham link.
Nexthop address	Indicates the actual next-hop address of the sham link.
Transmit Delay	Indicates the transmission delay of the sham link.
State	Indicates the state of the sham link.
Time intervals configured	Indicates the Hello, Dead, Wait, and Retransmit time corresponding to the sham link.
Adjacency State	Indicates the adjacency state. **Full** indicates the stable state.

Notifications

If the specified OSPF process does not exist (for example, when the sham link information of OSPF 1 is checked), the following notification will be displayed:

```
%OSPF: No router process 1
```

1.76 show ip ospf spf

Function

Run the **show ip ospf spf** command to display the times of route computation in the OSPF area.

Syntax

show ip ospf [*process-id*] **spf**

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the times of route computation in the OSPF area in the last 30 minutes, as well as the total times of route computation up to now.

Examples

The following example displays the times of route computation in the OSPF area.

```
Hostname> enable
Hostname# show ip ospf 1 spf
OSPF process 1:
Area_id     30min_counts   Total_counts
0           32             1235
1           6              356
```

Table 1-16 Output Fields of the show ip ospf 1 spf Command

Field	Description
Area_id	Indicates the OSPF area ID.
30min_counts	Indicates the times of route computation in the OSPF area in the last 30 minutes.
Total_counts	Indicates the total times of route computation in the OSPF area up to now.

1.77 show ip ospf summary-address

Function

Run the **show ip ospf summary-address** command to display the summarized route of all the redistributed routes of an OSPF process.

Syntax

show ip ospf [*process-id*] **summary-address**

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

Currently this command takes effect only on an ABR of NSSA, and it displays only the route that is summarized on the local device.

Examples

The following example displays the summarized route of all the redistributed routes of an OSPF process.

```
Hostname> enable
Hostname# show ip ospf summary-address
OSPF Process 1, Summary-address:
172.16.0.0/16, Metric 20, Type 2, Tag 0, Match count 3, advertise
```

Table 1-17 Output Fields of the show ip ospf summary-address Command

Field	Description
Summary Address	Indicates the address of the route to be summarized.
Summary Mask	Indicates the subnet mask of the route to be summarized.
Advertise	Indicates whether to advertise the summarized route.
Status	Indicates whether the range of the route to be summarized takes effect.
Aggregated subnets	Indicates how many external routes are summarized in this range.

1.78 show ip ospf topology

Function

Run the **show ip ospf topology** command to display the topology information of SPF computation of an OSPF process.

Syntax

show ip ospf [*process-id* [*area-id*]] **topology**

[**adv-router** *adv-router-id* [*router-id*] | **self-originate** [*router-id*]]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

area-id: Area ID, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

topology: Displays the topology summary of a specified OSPF process and area.

adv-router: Displays the topology information of a specified device, which must be a direct neighbor of the current device.

adv-router-id: Root node router ID of the shortest path tree.

router-id: Information about a specified node on the shortest path tree.

self-originate: Displays the topology information of the current device.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command helps users to learn the topology information of OSPF SPF computation, and locate the faults caused by topology planning. If a user has enabled fast reroute calculation, the command displays the information about fast reroute calculation.

Examples

The following example displays the topology summary of a specified OSPF process and area.

```
Hostname> enable
Hostname# show ip ospf topology
```

```
OSPF Router with ID (1.1.1.1) (Process ID 1)
Router Topology States (Area 0.0.0.0)
+1.1.1.1
  +2.2.2.2
    +4.4.4.4
  +3.3.3.3
    +4.4.4.4
+2.2.2.2
  +1.1.1.1
    +3.3.3.3
  +4.4.4.4
    +3.3.3.3
+3.3.3.3
  +1.1.1.1
    +2.2.2.2
  +4.4.4.4
    +2.2.2.2
```

The following example displays the topology information of the current device.

```
Hostname> enable
Hostname# show ip ospf topology self-originate
OSPF Router with ID (1.1.1.1) (Process ID 1)
Router Topology States (Area 0.0.0.0)
1.1.1.1
  Self to Destination Metric: 0
Parent Node:
Child Node:2.2.2.2
  Primary next-hop:
  Backup next-hop:
  Backup Neighbor:
2.2.2.2
  Self to Destination Metric: 1
Parent Node: 1.1.1.1
Child Node:
  Primary next-hop: GigabitEthernet 0/1 via 10.0.0.1
  Backup next-hop: GigabitEthernet 0/2 via 10.0.1.1
  Backup Neighbor: 2.2.2.2
Neighbor to Destination Metric: 0
Neighbor to Self Metric: 10
Neighbor to Primary Neighbor: 0
Self to Neighbor Metric: 1
```

Table 1-18 Output Fields of the show ip ospf topology Command

Field	Description
Self to Destination Metric	Indicates the metric from the root node to the current destination node.

Field	Description
Parent Node	Indicates the parent node of the current destination node.
Child Node	Indicates the child node of the current destination node.
Primary next-hop	Reaches the primary next hop of the current destination node.
Backup next-hop	Reaches the backup next hop of the current destination node.
Backup Neighbor	Reaches the backup neighbor of the current destination node.
Neighbor to Destination Metric	Indicates the metric from the backup neighbor to the current destination node.
Neighbor to Self Metric	Indicates the metric from the backup neighbor to the root node.
Neighbor to Primary Neighbor	Indicates the metric from the backup neighbor to the primary neighbor.
Self to Neighbor Metric	Indicates the metric from the root node to the backup neighbor.

1.79 show ip ospf virtual-links

Function

Run the **show ip ospf virtual-links** command to display the information about a virtual link of an OSPF process.

Syntax

show ip ospf [*process-id*] **virtual-links** [*ipv4-address*]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

ipv4-address: Router ID of the neighbor of a virtual link.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If a virtual link is configured, the neighbor state and other related information can be displayed only by running this command. The **show ip ospf neighbor** command does not display the neighbors of the virtual link.

Examples

The following example displays the information about a virtual link of an OSPF process.

```
Hostname> enable
Hostname# show ip ospf virtual-links
Virtual Link VLINK0 to router 1.1.1.1 is up
Transit area 0.0.0.1 via interface GigabitEthernet 0/1
Local address 10.0.0.37/32
Remote address 10.0.0.27/32
Transmit Delay is 1 sec, State Point-To-Point,
Timer intervals configured,Hello 10,Dead 40,Wait 40,Retransmit 5
Hello due in 00:00:05
Adjacency state Full
```

Field description:

Field	Description
Virtual Link VLINK0 to router	Displays the neighbor and neighbor state of the virtual link.
Virtual Link state	Displays the state of the virtual link.
Transit area	Displays the transit area of the virtual link.
via interface	Displays the interface associated with the virtual link.
Local address	Indicates the address of the local interface.
Remote Address	Indicates the address of the peer interface.
Transmit Delay	Displays the transit delay of the virtual link.
State	Indicates the link state.
Time intervals configured	Indicates the Hello, Dead, Wait, and Retransmit time corresponding to this interface.
Adjacency State	Indicates the adjacency state. **Full** indicates the stable state.

1.81 summary-address

Function

Run the **summary-address** command to configure a summarized route for the external routes of the OSPF routing domain.

Run the **no** form of this command to delete the definition of summarized route.

The route summarization function is disabled by default.

Syntax

summary-address *ipv4-address mask* [[**cost** *cost* | **distribute-delay** *interval* | **nssa-only** | **tag** *tag-value*] * | **not-advertise**]

no summary-address *ipv4-address mask* [[**cost** | **distribute-delay** | **nssa-only** | **tag**] * | **not-advertise**]

Parameter Description

ipv4-address: IP address of the summarized route.

mask: Subnet mask of the summarized route.

cost *cost*: Set the cost value of the summarized route. The value range is from 0 to 16777214. If no cost value is configured, the default metric of the summarized route is related to compatibility with RFC1583. If the RFC1583 compatibility mode is configured, the default metric is the minimum cost value of the summarized route; otherwise, the default metric is the maximum cost value of the summarized route.

distribute-delay *interval*: Specifies the delay time after which the summarized route is advertised, in seconds. The value range is 1 to 65535, and the default value is **2**.

nssa-only: Specifies that the summarized route cannot be converted to a Type-5 route. By default, the summarized route can be converted to a Type-5 route.

tag *tag-value*: Sets the tag value of the summarized route. The value range is from 0 to 4294967295.

not-advertise: Indicates that the summarized route is not advertised. If this parameter is not specified, the summarized route is advertised.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

When routes are redistributed from other routing processes and injected to the OSPF routing process, each route is advertised to the OSPF routers using an external LSA. If the injected routes are a continuous address space, the ABR can advertise only one summarized route to reduce the size of the routing table.

When configured on the NSSA ABR translator, the **summary-address** command summarizes the redistributed routes and routes obtained based on the LSAs that are converted from Type 7 to Type 5. When configured on the ASBR (not an NSSA ABR translator), this command summarizes only the redistributed routes. The **area range** command summarizes the routes between OSPF areas, while the **summary-address** command summarizes the external routes of the OSPF routing domain.

Examples

The following example configures a summarized route for the external routes of the OSPF routing domain as 100.100.0.0/16.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# router ospf 20
Hostname(config-router)# summary-address 100.100.0.0 255.255.0.0
Hostname(config-router)# redistribute static subnets
Hostname(config-router)# network 200.2.2.0 0.0.0.255 area 1
Hostname(config-router)# network 172.16.24.0 0.0.0.255 area 0
Hostname(config-router)# area 1 nssa
```

Notifications

When an invalid mask is configured, the following notification will be displayed:

```
OSPF: Invalid mask input
```

1.82 timers lsa arrival

Function

Run the **timers lsa arrival** command to configure the delay for receiving a duplicate LSA.

Run the **no** form of this command to restore the default configuration.

By default, the delay for receiving a duplicate LSA is 1000 ms.

Syntax

timers lsa arrival *arrival-time*

no timers lsa arrival

Parameter Description

arrival-time: Delay after which a duplicate LSA is received, in milliseconds. The value range is from 0 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Using this command can avoid consuming the device resource and the duplicate LSA received within a specified time does not need to be processed.

Examples

The following example configures the delay after which a duplicate LSA is received as 2s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# timers lsa arrival 2000
```

1.83 timers pacing lsa-group

Function

Run the **timers pacing lsa-group** command to configure a group pacing interval of LSA.

Run the **no** form of this command to restore the default configuration.

The group pacing interval of LSA is 30s by default.

Syntax

timers pacing lsa-group *pacing-interval*

no timers pacing lsa-group

Parameter Description

update-time: Group pacing interval of LSA, in seconds. The range is from 10 to 1800.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Every LSA has its time to live (LSA age). When the LSA age reaches 3,600s, a refreshment is needed to prevent normal LSAs from being cleared because their ages reaching the maximum. If LSA update and aging computation are performed for every LSA, the device will consume a lot of CPU resources. To use CPU resources effectively, you can refresh LSAs by group on the device. The interval of group refreshment is called

group pacing interval. The group refreshment operation is to organize the LSAs generated within a group pacing interval into a group and refresh the group as a whole.

If the total number of LSAs does not change, a larger group pacing interval indicates that more LSAs need to be processed after timeout. For CPU stability, the number of LSAs processed upon each timeout cannot be too large. If the number of LSAs is large, you are advised to reduce the group pacing interval. For example, if there are 10,000 LSAs in the database, you can reduce the pacing interval. If there are 40 to 100 LSAs only, you can set the pacing interval to 10-20 minutes.

Examples

The following example configures the group pacing interval of LSA as 120s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 20
Hostname(config-router)# timers pacing lsa-group 120
```

1.84 timers pacing lsa-transmit

Function

Run the **timers pacing lsa-transmit** command to configure an interval for sending LSA group and a number of LS-UPD packets in each group.

Run the **no** form of this command to restore the default configuration.

By default, the interval for sending LSA group is 40 ms, and the number of LS-UPD packets in each group is 1.

Syntax

timers pacing lsa-transmit *transmit-interval transmit-count*

no timers pacing lsa-transmit

Parameter Description

transmit-interval: Interval of sending LSA group packets, in milliseconds. The value range is from 10 to 1000.

transmit-count: Number of LS-UPD packets in each group. The value range is from 1 to 200.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

When the number of LSAs is large and the device load is heavy in an environment, configuring an appropriate interval of sending LSA group and an appropriate number of LS-UPD packets in each group can limit the number of LS-UPD packets flooded on a network.

If the CPU usage is not high and the network bandwidth load is not heavy, reducing the interval of sending LSA group and increasing the number of LS-UPD packets in each group can accelerate the environment convergence.

Examples

The following example configures the interval for sending LSA group as 50 ms, and the number of LS-UPD packets in each group as 20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# timers pacing lsa-transmit 50 20
```

1.85 timers spf

Function

Run the **timers spf** command to configure the delay time for SPF computation after an OSPF process receives the topology change information and the time interval between two SPF computations.

Run the **no** form of this command to restore the default configuration.

By default, the **timers spf** command does not take effect, and the delay for SPF computation is subject to the default configuration of the **timers throttle spf** command. Refer to the description of the **timers throttle spf** command.

Syntax

timers spf *spf-delay spf-holdtime*

no timers spf

Parameter Description

spf-delay: Delay for SPF computation, in seconds. After receiving the topology change information, the OSPF routing process must wait for the specified time before performing SPF computation. The range is from 0 to 2147483647.

spf-holdtime: Interval between two SPF computations, in seconds. If the waiting time expires, but the interval between two computations does not time out, the SPF computation cannot start. The range is from 0 to 2147483647.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Changes to LSDB trigger SPF computation. Frequent network jitter consumes a lot of CPU resources. Setting a reasonable delay for SPF computation can avoid occupying excessive device memory and bandwidth resources.

A smaller value set for *spf-delay* and *spf-holdtime* indicates that the OSPF can adapt to topology changes more quickly. In other words, a shorter network convergence time means that more CPU time of the router will be occupied.

The configurations of **timers spf** and **timers throttle spf** are mutually overwritten.

Examples

The following example configures the delay time for SPF computation after an OSPF process receives the topology change information as 3s and the time interval between two SPF computations as 9s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 20
Hostname(config-router)# timers spf 3 9
```

1.86 timers throttle lsa all

Function

Run the **timers throttle lsa all** command to configure an exponential backoff algorithm of LSA packet generation.

Run the **no** form of this command to restore the default configuration.

By default, the minimum delay of LSA generation is 0 ms, the minimum interval between the first update and the second update of LSA is 5,000 ms, and the maximum interval between consecutive LSA updates is 5,000 ms.

Syntax

timers throttle lsa all *delay-time hold-time max-wait-time*

no timers throttle lsa all

Parameter Description

delay-time: Minimum delay for LSA generation, in milliseconds. The first LSA in the database is always generated instantly. The value range is from 0 to 600000.

hold-time: Minimum interval between the first LSA update and the second LSA update, in milliseconds. The value range is from 1 to 600000.

max-wait-time: Maximum interval between two LSA updates when the LSA is updated continuously, in milliseconds. This interval is also used to determine whether the LSA is updated continuously. The value range is from 1 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If a high convergence requirement is raised when a link changes, you can set *delay-time* to a smaller value. To reduce the CPU usage, you can set *delay-time, hold-time* and *max-wait-time* to larger values.

When this command is configured, the value of *hold-time* cannot be smaller than the value of *delay-time*, and the value of *max-wait-time* cannot be smaller than the value of *hold-time*.

Examples

The following example configures the first delay as 10 ms, the minimum interval between the first update and the second update of LSA as 1s, and the maximum interval between two LSA updates as 5s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# timers throttle lsa all 10 1000 5000
```

Notifications

When the configured value of *max-wait-time* is smaller than that of *hold-time*, the following notification will be displayed:

```
% Warning: max-wait-time should be no less than hold-time, set to (5).
```

When the configured value of *hold-time* is smaller than that of *delay-time*, the following notification will be displayed:

```
% Warning: hold-time should be no less than delay-time, set to (5).
```

Common Errors

The configured value of *hold-time* is smaller than that of *delay-time*, or the configured value of *max-wait-time* is smaller than that of *hold-time*.

Platform Description

1.87 timers throttle route

Function

Run the **timers throttle route** command to configure the delay time for route computation when an OSPF process receives changed inter-area and external LSAs.

Run the **no** form of this command to restore the default configuration.

By default, the waiting time for inter-area route computation is 0 ms, and that of external route computation is 0 ms.

Syntax

timers throttle route { **inter-area** *ia-delay* | **ase** *ase-delay* }

no timers throttle route { **inter-area** | **ase** }

Parameter Description

inter-area: Indicates inter-area route computation.

ia-delay: Delay for inter-area route computation, in milliseconds. When an inter-area LSA change is detected, the route computation triggered by the OSPF process is performed at least after the delay for inter-area route computation elapses. The value range is from 0 to 600000.

ase: Indicates the external route computation.

ase-delay: Delay for external route computation, in milliseconds. When an external LSA change is detected, the route computation triggered by the OSPF process is performed at least after the delay for external route computation elapses. The value range is from 0 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If a strict requirement is raised for the network convergence time, use the default value. If a lot of inter-area or external routes exist on the network and the network is not stable, adjust the corresponding delays and optimize route computation to reduce the load on the device.

Examples

The following example configures the delay time for route computation when an OSPF process receives changed inter-area and external LSAs as 1s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# timers throttle route inter-area 1000
```

1.88 timers throttle spf

Function

Run the **timers throttle spf** command to configure the delay time for SPF computation, and the minimum interval and maximum interval for two SPF computations after an OSPF process receives the topology change information.

Run the **no** form of this command to restore the default configuration.

By default, the delay for SPF computation is 1000 ms, the minimum interval for two SPF computations is 5000 ms, and the maximum interval between two SPF computations is 10,000 ms.

Syntax

timers throttle spf *spf-delay spf-holdtime spf-max-waittime*

no timers throttle spf

Parameter Description

spf-delay: Delay for SPF computation, in milliseconds. When a topology change is detected, the SPF computation triggered by the OSPF process is performed at least after the delay for SPF computation elapses. The value range is from 1 to 600000.

spf-holdtime: Minimum interval between two SPF computations, in milliseconds. The value range is from 1 to 600000.

spf-max-waittime: Maximum interval between two SPF computations, in milliseconds. The value range is from 1 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Here, *spf-delay* indicates the minimum time between the occurrence of a topology change and the start of SPF computation. The minimum interval between the first SPF computation and the second SPF computation is *spf-holdtime*. After that, the interval between two SPF computations must be at least twice of the previous interval. When the interval reaches *spf-max-waittime*, the interval cannot increase again. If the interval between two SPF computations already exceeds the required minimum value, the interval for SPF computation is calculated starting from *spf-holdtime*.

You can set *spf-delay* and *spf-holdtime* to smaller values to accelerate topology convergence. Set *spf-max-waittime* to a larger value to reduce SPF computation. Flexible settings can be used based on stability of the network topology.

Compared with the **timers spf** command, this command supports more flexible settings to accelerate the convergence speed of SPF computation and further reduce the system resources consumed by SPF computation when the topology continuously changes. Therefore, you are advised to run the **timers throttle spf** command for configuration.

- The value of *spf-holdtime* cannot be smaller than that of *spf-delay*; otherwise, *spf-holdtime* will be automatically set to the value of *spf-delay*.
- The value of *spf-max-waittime* cannot be smaller than that of *spf-holdtime*; otherwise, *spf-max-waittime* will be automatically set to the value of *spf-holdtime*.
- The configurations of **timers throttle spf** and **timers spf** are mutually overwritten.
- When neither **timers spf** nor **timers throttle spf** is configured, the default value of **timers throttle spf** prevails.

Examples

The following example configures the SPF computation delay, minimum interval and maximum interval of an OSPF process as 5 ms, 1,000 ms, and 90,000 ms in turn. If the topology changes continuously, the SPF computation time is as follows: 5 ms, 1s, 3s, 7s, 15s, 31s, 63s, 89s, 179s, 179+90.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# router ospf 20
Hostname(config-router)# timers throttle spf 5 1000 90000
```

Notifications

When the configured value of **max-wait-time** is smaller than that of **hold-time**, the following notification will be displayed:

```
% Warning: max-wait-time should be no less than hold-time, set to (5).
```

When the configured value of **hold-time** is smaller than that of **delay-time**, the following notification will be displayed:

```
% Warning: hold-time should be no less than delay-time, set to (5).
```

Common Errors

The configured value of *hold-time* is smaller than that of *delay-time* or the configured value of *max-wait-time* is smaller than that of *hold-time*.

1.89 two-way-maintain

Function

Run the **two-way-maintain** command to enable the two-way maintenance function of an OSPF process.

Run the **no** form of this command to disable the two-way maintenance function of an OSPF process.

By default, the two-way maintenance function is enabled for an OSPF process.

Syntax

two-way-maintain

no two-way-maintain

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

On a large network, a lot of packets may be sent or received, occupying a great proportion of CPU and memory. As a result, some packets are delayed or discarded. If the time required for processing hello packets exceeds the neighbor dead interval, the corresponding adjacency times out and is removed. If the two-way maintenance

function is enabled, in addition to the hello packets, the DD, LSU, LSR, and LSAck packets from a neighbor can also be used to maintain the bidirectional communication between neighbors when a large number of packets exist on the network. This prevents termination of the adjacency caused by delayed or discarded hello packets.

Examples

The following example enables the two-way maintenance function of an OSPF process.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf 1
Hostname(config-router)# no two-way-maintain
```

1 OSPFv3 Commands

Command	Function
area authentication	Enable OSPFv3 area authentication.
area default-cost	Configure the cost of the default route in a stub area or not-so-stubby area (NSSA) on the ABR that resides in the stub area or NSSA.
area encryption	Enable OSPFv3 area encryption and authentication.
area nssa	Configure an OSPFv3 area as NSSA.
area range	Configure a range of summarized inter-area routes.
area stub	Configure an area as a stub or totally stub area.
area virtual-link	Create a virtual link or set virtual link parameters.
asbr enable	Configure a device as an ASBR.
auto-cost reference-bandwidth	Enable metric computation or reference bandwidth value modification for an interface based on bandwidth.
bfd all-interfaces	Enable bidirectional forwarding detection (BFD) on all OSPFv3 interfaces for link detection.
clear ipv6 ospf process	Clear and reset an OSPFv3 process.
default-information originate	Generate a default route and inject the route to an OSPFv3 routing domain.
default-metric	Configure the default metric of a redistributed route.
distance	Configure the administrative distances corresponding to different types of OSPFv3 routes.
distribute-list in	Enable the function of filtering routes that are computed based on the received LSAs.
distribute-list out	Enable the function of filtering redistributed routes.
enable mib-binding	Bind an MIB to a specified OSPFv3 process.
enable traps	Enable sending of the specified trap message.
graceful-restart	Enable the OSPFv3 GR capability.

graceful-restart helper	Enable the OSPFv3 GR helper function and configure a topology detection method of the OSPFv3 GR helper.
ipv6 ospf area	Enable an interface to join in an OSPFv3 routing process.
ipv6 ospf authentication	Enable OSPFv3 authentication on an interface.
ipv6 ospf bfd	Enable BFD on a specified OSPFv3 interface for link detection.
ipv6 ospf cost	Configure cost of an interface.
ipv6 ospf dead-interval	Configure the neighbor dead interval of an interface.
ipv6 ospf encryption	Enable OSPFv3 encryption on an interface.
ipv6 ospf hello-interval	Configure the hello packet sending interval on an interface.
ipv6 ospf mtu-ignore	Disable MTU verification for an interface that receives database description packets.
ipv6 ospf neighbor	Configure OSPFv3 neighbors.
ipv6 ospf network	Configure an OSPF network type of an interface.
ipv6 ospf priority	Configure the priority of an interface.
ipv6 ospf retransmit-interval	Configure the LSA retransmission interval on an interface.
ipv6 ospf subvlan	Enable the OSPFv3 function in a super VLAN.
ipv6 ospf transmit-delay	Configure the LSU transmission delay on an interface.
ipv6 router ospf	Enable an OSPFv3 routing process.
ipv6 router ospf max-concurrent-dd	Configure the maximum number of neighbors with which all the OSPFv3 routing processes can concurrently initiate or accept interaction.
log-adj-changes	Record the log of adjacency state changes.
max-concurrent-dd	Configure the maximum number of neighbors with which the current OSPFv3 instance can concurrently initiate or accept interaction.
nsr	Enable the nonstop routing (NSR) function.
passive-interface	Configure a passive interface.

redistribute	Enable route redistribution and inject routing information of other routing protocols to an OSPFv3 routing process.
router-id	Configure the ID of a router.
show ipv6 ospf	Display information of an OSPFv3 process.
show ipv6 ospf database	Display the database information of an OSPFv3 process.
show ipv6 ospf interface	Display the information of an OSPFv3 interface.
show ipv6 ospf neighbor	Display neighbor information of an OSPFv3 process.
show ipv6 ospf restart	Display the information related to OSPFv3 GR.
show ipv6 ospf route	Display the routing information of OSPFv3.
show ipv6 ospf summary-prefix	Display external route summarization information of OSPFv3.
show ipv6 ospf topology	Display the topological information of an OSPFv3 area.
show ipv6 ospf virtual-links	Display virtual link information of an OSPFv3 process.
summary-prefix	Configure a summarized route for the external routes of an OSPFv3 routing domain.
timers lsa arrival	Configure the delay for receiving same LSAs.
timers pacing lsa-group	Configure a group update time of LSAs.
timers pacing lsa-transmit	Configure the LSA group sending interval.
timers spf	Configure the delay time for SPF computation after an OSPFv3 process receives the topological change information and the interval between two SPF computations.
timers throttle lsa all	Configure an exponential backoff algorithm of LSA packet generation.
timers throttle route	Configure the delay time for route computation when an OSPFv3 process receives changed inter-area and external LSAs.
timers throttle spf	Configure the delay time for SPF computation when an OSPFv3 process receives topological change information, and the minimum and maximum intervals for two SPF computations.

two-way-maintain	Enable the two-way maintenance function of OSPFv3.

1.1 area authentication

Function

Run the **area authentication** command to enable OSPFv3 area authentication.

Run the **no** form of this command to disable this function.

The OSPFv3 area authentication function is disabled by default.

Syntax

area *area-id* **authentication ipsec spi** *sip* { **md5** [**string-key**] | **sha1** } [**0** | **7**] *key*

no area *area-id* **authentication**

Parameter Description

area-id: Area ID, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

spi *spi*: Specifies a security parameter index. The value range is from 256 to 4294967295.

md5: Enables the MD5 authentication mode.

string-key: Specifies to use a string as an authentication key.

sha1: Enables the SHA1 authentication mode.

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

key: Authentication key.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

Enabling authentication can improve interaction security of OSPFv3 packets. A device supports four types of authentication:

- No authentication (when authentication is not configured)
- MD5
- SHA1

After an OSPFv3 area is configured with authentication, the configuration takes effect on all interfaces (except virtual links) in the area. If the interface authentication configuration is different from area authentication configuration, interface authentication configuration takes precedence over the area authentication configuration.

OSPFv3 area authentication and area associated SA authentication are mutually exclusive.

Examples

The following example configures MD5 for Area 1 in the OSPFv3 routing process, and sets the security parameter index to 300 and the password to aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa.

The following example configures MD5 for Area 0 in the OSPFv3 routing process, and sets the security parameter index to 606 and the key to psw@123.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# area 1 authentication ipsec spi 300 md5
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
Hostname(config-router)# area 0 authentication ipsec spi 606 md5 string-key psw@123
```

Notifications

If this SPI has been used in this module, the following notification will be displayed:

```
% OSPFv3: SPI is already in use.
```

If this SPI has been used in another module, the following notification will be displayed:

```
% OSPFv3: SPI is already in use by others.
```

If this SPI has been configured in the local area, the following notification will be displayed:

```
% OSPFv3: Area is already configured with the same SPI.
```

If authentication is configured for an area with encryption configuration, the following notification will be displayed:

```
% OSPFv3: Area is already configured with encryption so cannot configure
authentication.
```

Common Errors

1.2 area default-cost

Function

Run the **area default-cost** command to configure the cost of the default route in a stub area or not-so-stubby area (NSSA) on the ABR that resides in the stub area or NSSA.

Run the **no** form of this command to restore the default configuration.

The default cost value of the default route is **1**.

Syntax

area *area-id* **default-cost** *cost*

no area *area-id* **default-cost**

Parameter Description

area-id: ID of a stub area or an NSSA, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

cost: Cost of the default summarized route injected to the stub area or NSSA. The value range is from 0 to 16777215.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The ABR in the stub area or NSSA will advertise the default route to the devices in the area. The default cost value of the default route is **1**. To lower the routing priority of the default route, you can use this command to set the cost to a greater value.

Examples

The following example sets the cost of the default route in a stub area to 100 on the ABR that resides in the stub area.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# area 50 stub
Hostname(config-router)# area 50 default-cost 100
```

Notifications

When this command is configured in the backbone area, the following notification will be displayed:

```
% You can't configure default-cost to backbone
```

When this command is configured in a non-stub area or non-NSSA, the following notification will be displayed:

```
% The area is neither stub, nor NSSA
```

Common Errors

1.3 area encryption

Function

Run the **area encryption** command to enable OSPFv3 area encryption and authentication.

Run the **no** form of this command to disable this function.

The encryption and authentication function is disabled by default.

Syntax

area *area-id* **encryption ipsec spi** *spi* **esp** { { **3des** | **aes-cbc** { **128** | **192** | **256** } | **des** } [**0** | **7**] *des-key* | **null** } { **md5** | **sha1** } [**0** | **7**] *key*

no area *area-id* **encryption**

Parameter Description

Area-id: Area ID, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

spi *spi*: Specifies a security parameter index. The value range is from 256 to 4294967295.

esp: Enables the ESP encryption mode.

3des: Enables the 3DES encryption mode.

aes-cbc [**128** | **192** | **256**]: Enables the Advanced Encryption Standard-Cipher Block Chaining (AES-CBC) encryption mode. The encryption key length is 128, 192, or 256 bits.

des: Enables the Data Encryption Standard (DES) mode.

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

des-key: Encryption key.

null: Indicates that no encryption mode is used.

md5: Enables the MD5 authentication mode.

sha1: Enables the SHA1 authentication mode.

key: Authentication key.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

Enabling encryption and authentication can improve interaction security of OSPFv3 packets. A device supports the following types of encryption and authentication:

- Encryption modes: DES, 3DES, and AES-CBC.
- Authentication modes: MD5 and SHA1

After an OSPFv3 area is configured with encryption and authentication, the configuration takes effect on all interfaces (except virtual links) in the area, but the interface encryption and authentication configuration takes precedence over the area configuration.

Examples

The following example enables the OSPFv3 encryption and authentication function for Area 1, configures Area 1 with null encryption and MD5 authentication, and sets the password to aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# area 1 encryption ipsec spi 300 esp null md5
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
```

Notifications

If this SPI has been used in this module, the following notification will be displayed:

```
% OSPFv3: SPI is already in use.
```

If this SPI has been used in another module, the following notification will be displayed:

```
% OSPFv3: SPI is already in use by others.
```

If this SPI has been configured in the local area, the following notification will be displayed:

```
% OSPFv3: Area is already configured with the same SPI.
```

If encryption and authentication is re-configured for an area with authentication configuration, the following notification will be displayed:

```
% OSPFv3: Area is already configured with authentication so cannot configure
encryption.
```

1.4 area nssa

Function

Run the **area nssa** command to configure an OSPFv3 area as NSSA.

Run the **no** form of this command to remove this configuration.

The NSSA function is disabled by default.

Syntax

area *area-id* **nssa** [**default-information-originate** [**metric** *metric* | **metric-type** *metric-type*] * | **no-redistribution** | **no-summary** | **translator** [**always** | **stability-interval** ***stability-interval***] *] *

no area *area-id* **nssa** [**default-information-originate** [**metric** | **metric-type**] * | **no-redistribution** | **no-summary** | **translator** [**always** | **stability-interval**] *] *

Parameter Description

area-id: ID of the NSSA, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

default-information-originate: Indicates that generated default Type 7 LSAs are introduced to the NSSA. This option takes effect only on an NSSA ABR or ASBR.

metric *metric*: Indicates the metric of the generated default LSA. The value range is from 0 to 16777214, and the default value is **1**.

metric-type *metric-type*: Indicates the route type of the generated default LSA. *metric-type*: The value is **1** or **2**: **1** represents N-1, and **2** represents N-2. The default value is **2**.

no-redistribution: Select this option if the router is an NSSA ABR and you want to use the **redistribute** command to introduce the routing information only to a common area instead of an NSSA.

no-summary: Prohibits the ABR in the NSSA from sending Summary LSAs (Type 3 LSAs).

translator: Configures an ABR translator in an NSSA.

always: Enables the current NSSA ABR to always act as a translator. The default value is the standby translator.

stability-interval *stability-interval*: Configures the stability interval after the NSSA ABR is changed from a translator to a non-translator, in seconds. The value range is from 0 to 2147483647, and the default value is **40**.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If you expect to reduce the LSA number in an area and to redistribute external routes, you can configure this area as an NSSA.

Parameter configurations are used as follows:

- The **default-information-originate** parameter is used to generate a default Type 7 LSA. This parameter has different functions on the ABR and the ASBR in the NSSA. On the ABR, a Type 7 LSA default route is generated regardless of whether the default route exists in the routing table. On the ASBR (not an ABR), a Type 7 LSA default route is generated only when the default route exists in the routing table.
- If the **no-redistribution** parameter is configured on the ASBR, other external routes introduced by OSPF through the **redistribute** command cannot be distributed to the NSSA. This parameter is generally used when a router in the NSSA acts both as an ASBR and an ABR. It prevents external routing information from entering the NSSA.

- The **no-summary** parameter is used to further reduce the number of LSAs sent to the NSSA and prevent the ABR from sending Summary LSAs (Type 3 LSAs) to the NSSA.
- The **area default-cost** parameter is used on an ABR/ASBR in this NSSA. This command configures the cost of the default route sent from the ABR/ASBR to the NSSA. The default cost of the default route sent to the NSSA is 1.
- If an NSSA has two or more ABRs, the ABR with the largest router ID is elected by default as the translator for translating Type 7 LSAs to Type 5 LSAs. If you expect that the current device is always the translator ABR for translating Type 7 LSAs to Type 5 LSAs, use the **translator always** parameter.
- If the translator role of the current device is replaced by another ABR, the translation capability of the device is retained during the time specified by **stability-interval**. If the device does not become a translator again during the time, LSAs that are translated from Type 7 to Type 5 will be deleted from the AS after **stability-interval** expires.
- To prevent a routing loop, LSAs that are translated from Type 7 to Type 5 are deleted from the AS immediately after the current device loses the translator role even if **stability-interval** does not expire.
- In the same NSSA, it is recommended that **translator always** be configured on only one ABR.

Examples

The following example configures OSPFv3 Area 1 as an NSSA.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# area 1 nssa
```

Notifications

If the backbone area is configured as an NSSA, the following notification will be displayed:

```
% You can't configure NSSA to backbone
```

If a stub area is configured as an NSSA, the following notification will be displayed:

```
% The area is configured as stub area already
```

1.5 area range

Function

Run the **area range** command to configure a range of summarized inter-area routes.

Run the **no** form of this command to remove this configuration or restore the default configuration.

Inter-area route summarization is not performed by default.

Syntax

area *area-id* **range** *ipv6-prefix*/*prefix-length* [**advertise** | **not-advertise**]

no area *area-id* **range** *ipv6-prefix*/*prefix-length*

Parameter Description

area-id: ID of the OSPF area to which the summarized routes will be injected, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

ipv6-prefix/prefix-length: Range of IP addresses to be summarized.

advertise: Advertises the range of summarized routes.

not-advertise: Does not advertise the range of summarized routes.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

This command takes effect only on an ABR, and is used to summarize multiple routes in an area as a route and advertise this route to other areas. Combination of the routing information occurs only on the boundary of an area. Routers inside the area can learn specific routing information, whereas routers in other areas can learn only one summarized route. You can configure **advertise** or **not-advertise** to determine whether to advertise the range of summarized routes, which helps shield and filter routes. By default, the summarized routes are advertised.

You can configure the route summarization command for multiple areas to simplify the entire OSPF routing domain, and improve the network forwarding performance, especially for a large-sized network.

When multiple summarized routes are configured and have an inclusive relationship with each other, the range of routes to be summarized is determined based on the longest match principle.

Examples

The following example sets the IP address of the inter-area route summarization in Area 1 to 2001:DB8:1:2::/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# area 1 range 2001:db8:1:2::/64
```

Notifications

If an inexistent summarization entry is deleted, the following notification will be displayed:

```
% Can't find specified area range.
```

1.6 area stub

Function

Run the **area stub** command to configure an area as a stub or totally stub area.

Run the **no** form of this command to remove this configuration or restore the default configuration.

The stub area function is disabled by default.

Syntax

area *area-id* **stub** [**no-summary**]

no area *area-id* **stub** [**no-summary**]

Parameter Description

area-id: ID of a stub area, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

no-summary: This option is valid only on the ABR in a stub area. If this option is specified, the ABR only advertises one Type 3 LSA indicating the default route to the stub area, and does not advertise other Type 3 LSAs.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

An area located on the stub of a network can be configured as a stub area. You must run the **area stub** command on all routers in the stub area. Devices in a stub area cannot learn external routes (Type 5 LSAs) of the AS. In actual application, external routes take up a large proportion of the LSDB. Therefore, devices in a stub area can learn only a small amount of routing information, which reduces the amount of system resources required to run the OSPFv3 protocol.

By default, an ABR in a stub area will generate a Type 3 LSA indicating the default fault and advertise the LSA to the stub area. In this way, devices in the stub area can access devices outside the AS.

To configure a totally stub area, add the **no-summary** keyword when you are running the **area stub** command on the ABR.

Examples

The following example creates a stub area 10 and enables the ABRs in stub area 10 to advertise only default routes to the stub area.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# area 10 stub
Hostname(config-router)# area 10 stub no-summary
```

Notifications

If the backbone area is configured as a stub area, the following notification will be displayed:

```
% You can't configure stub to backbone
```

If an NSSA is configured as a stub area, the following notification will be displayed:

```
% The area is configured as NSSA area already
```

If a stub area is configured with a virtual link, the following notification will be displayed, indicating that the virtual link must be deleted to validate the configuration:

```
% First deconfigure all virtual link through this area
```

1.7 area virtual-link

Function

Run the **area virtual-link** command to create a virtual link or set virtual link parameters.

Run the **no** form of this command to remove this configuration or restore the default configuration.

No virtual link is configured by default.

Syntax

area *area-id* **virtual-link** *router-id* [**dead-interval** *dead-interval* | **hello-interval** *hello-interval* | **instance** *instance-id* | **retransmit-interval** *retransmit-interval* | **transmit-delay** *transmit-delay*] * [**authentication ipsec spi** *spi* { **md5** | **sha1** } [**0** | **7**] *key* | **encryption ipsec spi** *spi* **esp** [**3des** | **aes-cbc** { **128** | **192** | **256** } [**0** | **7**] *des-key* | **des** [**0** | **7**] *des-key* | **null**] { **md5** | **sha1** } [**0** | **7**] *key*]

no area *area-id* **virtual-link** *router-id* [**dead-interval** | **hello-interval** | **instance** | **retransmit-interval** | **transmit-delay**] * [**authentication** | **encryption**]

Parameter Description

area-id: ID of an area where a virtual link exists, which can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

router-id: ID of a neighboring router of the virtual link.

dead-interval *dead-interval*: Indicates the time that the local interface of the virtual link detects the failure of the neighbor, in seconds. The value range is from 0 to 2147483647, and the default value is **40**.

hello-interval *hello-interval*: Indicates the time consumed to send a Hello packet on the local interface of the virtual link, in seconds. The value range is from 1 to 65535, and the default value is **10**.

instance *instance-id*: Specifies the instance of a virtual link. The value range is from 0 to 255.

retransmit-interval *retransmit-interval*: Indicates the retransmission time of an LSA on the local interface of the virtual link, in seconds. The value range is from 0 to 65535, and the default value is **5**.

transmit-delay *transmit-delay*: Indicates the delay after which the LSA is sent on the local interface of the virtual link, in seconds. The value range is from 0 to 65535, and the default value is **1**.

authentication ipsec spi *spi* { **md5** | **sha1** | **sha2-256** } [**0** | **7**] *key*: Defines OSPFv3 authentication.

Note

Authentication between neighbors must be consistent. The **service password-encryption** command enables a configured key to be displayed in ciphertext mode.

spi *spi*: Specifies a security parameter index. The value range is from 256 to 4294967295.

md5: Specifies the MD5 authentication mode.

sha1: Specifies the SHA1 authentication mode.

sha2-256: Specifies the sha2-256 authentication mode.

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

key: Authentication key.

encryption ipsec spi *spi* **esp** [**3des** | **aes-cbc** { **128** | **192** | **256** } [**0** | **7**] *des-key* | **des** [**0** | **7**] *des-key* | **null**] { **md5** | **sha1** } [**0** | **7**] *key*: Defines OSPFv3 encryption and authentication.

Note

Encryption and authentication between neighbors must be consistent. The **service password-encryption** command enables a configured key to be displayed in ciphertext mode.

spi *spi*: Specifies a security parameter index. The value range is from 256 to 4294967295.

3des: Specifies the 3DES encryption mode.

aes-cbc 128: Specifies 128-bit AES-CBC authentication mode.

aes-cbc 192: Specifies 192-bit AES-CBC authentication mode.

aes-cbc 256: Specifies 256-bit AES-CBC authentication mode.

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

des-key: Encryption key.

des: Specifies the DES encryption mode.

null: Indicates that no encryption mode is used.

md5: Specifies the MD5 authentication mode.

sha1: Specifies the SHA1 authentication mode.

key: Authentication key.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

In an OSPFv3 AS, all areas must be connected to the backbone area to properly learn the routing information of the entire OSPFv3 AS. If an area cannot be directly connected to the backbone area, the virtual link can be used to connect this area to the backbone area.

The area where the virtual link is located cannot be a stub area or NSSA.

The **hello-interval**, **dead-interval**, and **instance** parameters configured for neighbors connected by a virtual link must be consistent; otherwise, the adjacency cannot be set up properly.

Examples

The following example creates a virtual link and sets the router ID of the virtual link to 192.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# area 1 virtual-link 192.1.1.1
```

Notifications

If a virtual link is configured in the backbone area, the following notification will be displayed:

```
% You can't configure virtual-link transit to backbone
```

If a virtual link is configured in a stub area or an NSSA, the following notification will be displayed:

```
% Area is a stub or NSSA so virtual links are not allowed
```

1.8 asbr enable

Function

Run the **asbr enable** command to configure a device as an ASBR.

Run the **no** form of this command to restore the default configuration.

No device is an ASBR by default.

Syntax

asbr enable

no asbr enable

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

After the **redistribute** or **default-information** command is executed, an OSPF router automatically becomes an ASBR. If you want the device to become an ASBR without configuring the above command, run the **asbr enable** command. If the **asbr enable** command is deleted, but the **redistribute** or **default-information** command configuration remains valid, the device is still an ASBR.

Examples

The following example configures a device as an ASBR.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# asbr enable
```

1.9 auto-cost reference-bandwidth

Function

Run the **auto-cost reference-bandwidth** command to enable metric computation or reference bandwidth value modification for an interface based on bandwidth.

Run the **no** form of this command to disable this function or restore the default configuration.

The default reference bandwidth value computed based on the metric of an interface is **100** Mbps.

Syntax

auto-cost reference-bandwidth *ref-bw*

no auto-cost reference-bandwidth

Parameter Description

reference-bandwidth *reference-bandwidth*: Specifies the reference bandwidth value, in Kbps. The value range is from 1 to 4294967.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The cost value of an OSPFv3 interface is equal to the reference bandwidth value/interface bandwidth. To enable OSPFv3 on a 100M link, it is recommended that the *ref-bw* value be adjusted to a greater value based on actual network bandwidth. For a 1000M network, the reference bandwidth value can be set to a value greater than 1000; for a 10G network, the reference bandwidth value can be set to a value greater than 10000.

You can run the **ipv6 ospf cost** command in interface configuration mode to specify the cost of the specified interface. The priority of this cost is higher than that of the metric computed based on the reference bandwidth value.

Examples

The following example sets the reference bandwidth value to 10 Mbps.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# auto-cost reference-bandwidth 10
```

Notifications

If the reference bandwidth value is modified, the following notification will be displayed:

```
% OSPFv3: Reference bandwidth is changed.
Please ensure reference bandwidth is consistent across all routers
```

1.10 bfd all-interfaces

Function

Run the **bfd all-interfaces** command to enable bidirectional forwarding detection (BFD) on all OSPFv3 interfaces for link detection.

Run the **no** form of this command to restore the default configuration.

The BFD function is disabled on all interfaces by default.

Syntax

bfd all-interfaces

no bfd all-interfaces

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The OSPFv3 protocol dynamically discovers a neighbor by using hello packets. After BFD is enabled, OSPFv3 establishes a BFD session with a neighbor in the full neighbor relationship. The neighbor state is detected using the BFD mechanism. When the BFD neighbor fails, OSFPv3 immediately performs network convergence.

You can also run the **ipv6 ospf bfd** [**disable**] command in interface configuration mode to enable or disable the BFD function on a specified interface, and this configuration takes precedence over the configuration made using the **bfd all-interfaces** command in process configuration mode.

Examples

The following example enables BFD on all OSPFv3 interfaces for link detection.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# bfd all-interfaces
```

Notifications

If BFD is enabled on all interfaces for link detection, the following notification will be displayed:

```
% Warning: The BFD for OSPFv3 neighbor shall be enabled, or it would affect the route
learning.
```

Common Errors

1.11 clear ipv6 ospf process

Function

Run the **clear ipv6 ospf process** command to clear and reset an OSPFv3 process.

Syntax

clear ipv6 ospf [*process-id*] **process**

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535. When this parameter is specified, the specified OSPF process will be cleared and reset. When this parameter is not specified, all the running OSPF processes will be cleared and reset.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

Resetting the whole OSPFv3 process will reestablish all the neighbors, which has a great impact on the entire protocol.

When running this command, you need to make confirmation.

Use the *process-id* parameter to specify to clear an OSPFv3 instance. If the *process-id* parameter is not specified, all OSPFv3 instances are cleared.

Examples

The following example clears and resets an OSPFv3 instance.

```
Hostname> enable
Hostname# clear ipv6 ospf process
```

Notifications

If the specified process ID is incorrect, the following notification will be displayed:

```
% OSPFv3: No router process 1.
```

Platform Description

N/A

Related Commands

N/A

1.12 default-information originate

Function

Run the **default-information originate** command to generate a default route and inject the route to an OSPFv3 routing domain.

Run the **no** form of this command to remove this configuration or restore the default configuration.

No default route is generated by default.

Syntax

default-information originate [**always** | **metric** *metric* | **metric-type** *type* | **route-map** *map*] *

no default-information originate [**always** | **metric** | **metric-type** | **route-map** *map*] *

Parameter Description

always: Enables OSPFv3 to generate a default route even if a default route exists locally.

metric *metric*: Indicates the initial metric of the default route. The value range is from 0 to 16777214, and the default value is **1**.

metric-type type: Indicates the type of the default route. The value is 1 or 2, and the default value is **2**.

route-map *map*: Indicates the name of the associated route map. No route map is associated by default.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

When the **redistribute** or **default-information** command is executed, an OSPFv3 router automatically becomes an ASBR. The ASBR, however, does not automatically generate or advertise a default route to all

routers in the OSPF routing domain. To enable an ASBR to generate a default route, run the **default-information originate** command.

If the **always** parameter is specified, the OSPFv3 process advertises an external default route to neighbors no matter whether a default route exists in the core routing table. This default route, however, is not displayed on the local router. To confirm whether the default route is generated, run the **show ipv6 ospf database** command to display the OSPFv3 LSDB. On an OSPFv3 neighbor, you can run the **show ipv6 route** command to display the default route.

The metric of the external default route can be defined only by the **default-information originate** command, instead of the **default-metric** command.

OSPFv3 has two types of external routes. The metric of the Type 1 external route changes, but the metric of the Type 2 external route is fixed. If two parallel paths to the same destination network have the same route metric, the priority of the Type 1 route is higher than that of the Type 2 route. Therefore, the **show ipv6 route** command displays only the Type 1 route.

This command generates a default route of Type 5 LSA, which will not be flooded to an NSSA. If you want to generate a default route in the NSSA, use the **area nssa default-information-originate** command. A router in the stub area cannot generate an external default route.

Examples

The following example generates a default route and injects the route to an OSPFv3 routing domain.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# default-information originate always
```

1.13 default-metric

Function

Run the **default-metric** command to configure the default metric of a redistributed route.

Run the **no** form of this command to restore the default configuration.

The default metric of a redistributed route is **20**.

Syntax

default-metric *metric-value*

no default-metric

Parameter Description

metric-value: Default metric of a redistributed route. The value range is from 1 to 16777214.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

This command is used with the **redistribute** command to configure the default metric of a redistributed route. This command does not take effect to two types of routes:

- Default route generated by the **default-information originate** command.
- Redistributed direct route. The default metric of a redistributed direct route is always **20**.

Examples

The following example sets the default metric of a redistributed route to **10**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# default-metric 10
```

1.14 distance

Function

Run the **distance** command to configure the administrative distances corresponding to different types of OSPFv3 routes.

Run the **no** form of this command to restore the default configuration.

The default administrative distance is **110** for all the OSPF routes.

Syntax

distance { *distance* | **ospf** { **external** *distance* | **inter-area** *distance* | **intra-area** *distance* } * }

no distance [**ospf**]

Parameter Description

distance: Administrative distance of a route. The value range is from 1 to 255.

distance: Configures an administrative distance of OSPFv3.

external *distance*: Indicates the administrative distance of an external route. The value range is from 1 to 255.

inter-area *distance*: Indicates the administrative distance of an inter-area route. The value range is from 1 to 255.

intra-area *distance*: Indicates the administrative distance of an internal route. The value range is from 1 to 255.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

To compare the priorities of routes generated by different OSPF processes, use this command to specify the administrative distances corresponding to different types of OSPF routes.

The administrative distances of routes allow different routing protocols to compare route priorities. A smaller administrative distance indicates a higher route priority.

If the administrative distance of a route entry is set to 255, the route entry is not trustworthy and does not participate in packet forwarding.

Examples

The following example sets the administrative distance of an OSPFv3 external route to **160**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# distance ospf external 160
```

1.15 distribute-list in

Function

Run the **distribute-list in** command to enable the function of filtering routes that are computed based on the received LSAs.

Run the **no** form of this command to disable this function.

By default, the function of filtering routes computed based on the received LSAs is disabled, that is, all these routes get passed.

Syntax

distribute-list { *acl-name* | **prefix-list** *prefix-list-name* } **in** [*interface-type interface-number*]

no distribute-list { *acl-name* | **prefix-list** *prefix-list-name* } **in** [*interface-type interface-number*]

Parameter Description

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list *prefix-list-name*: Uses a prefix list for filtering.

interface-type interface-number: Type and number of an interface on which LSA routes are filtered.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

This command filters the routes that are computed based on received LSAs. Only the routes meeting the filtering conditions can be forwarded. The command does not affect the LSDB or the routing tables of neighbors. The ACL and prefix list filtering rules are mutually exclusive in the configuration. In other words, if an ACL is used for filtering routes of a specified interface, prefix list cannot be configured for the same interface.

This command affects forwarding of local routes, but does not affect route computation based on LSAs. Therefore, if route filtering is configured on the ABR, Type 3 LSAs will still be generated and advertised to other areas because routes can still be computed based on LSAs. As a result, black-hole routes are generated. In this case, you can run the **area range** (containing the **not-advertise** parameter) command on the ABR to prevent generation of black-hole routes.

Examples

The following example filters routes (that are computed based on the received LSAs) based on the prefix list aaa.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 prefix-list aaa seq 10 permit 2001::/64
Hostname(config)# ipv6 router ospf 25
Hostname(config-router)# redistribute rip metric 100
Hostname(config-router)# distribute-list prefix-list aaa in gigabitethernet 0/1
```

Notifications

If the configured interface is invalid, the following notification will be displayed:

```
% Interface is invalid.
```

If the configured ACL name is invalid, the following notification will be displayed:

```
% ACL name abc-acl is invalid
```

If routes imported by this instance are filtered, the following notification will be displayed:

```
% Distribute-list of "ospf 1" via "ospf 1" not allowed
```

Common Errors

1.16 distribute-list out

Function

Run the **distribute-list out** command to enable the function of filtering redistributed routes.

Run the **no** form of this command to disable this function.

By default, the filtering function of redistributed routes is disabled, that is, all the redistributed routes pass the filtering rules.

Syntax

distribute-list { *acl-name* | **prefix-list** *prefix-list-name* } **out** [**bgp** | **connected** | **isis** [*area-tag*] | **ospf** *process-id* | **rip** | **static**]

no distribute-list { *name* | **prefix-list** *prefix-list-name* } **out** [**bgp** | **connected** | **isis** [*area-tag*] | **ospf** *process-id* | **rip** | **static**]

Parameter Description

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list prefix-*list-name*: Uses a prefix list for filtering.

bgp: Filters BGP routes.

connected: Filters direct routes.

isis [*area-tag*]: Filters IS-IS routes.

ospf *process-id*: Filters OSPF routes.

rip: Filters RIP routes.

static: Filters static routes.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

As with the **redistribute route-map** command, the **distribute-list out** command filters routes that are redistributed from other protocols to OSPFv3. The **distribute-list out** command does not redistribute routes, and is generally used together with the **redistribute** command. The ACL and prefix list are mutually exclusive in the configuration. In other words, if an ACL is used for filtering routes of a source, prefix list cannot be configured for the same source.

Examples

The following example filters redistributed static routes based on the prefix list jjj.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# redistribute static
Hostname(config-router)# distribute-list prefix-list jjj out static
```

1.17 enable mib-binding

Function

Run the **enable mib-binding** command to bind an MIB to a specified OSPFv3 process.

Run the **no** form of this command to restore the default configuration.

The MIB is bound to the OSPFv3 process with the minimum process ID by default.

Syntax

enable mib-binding

no enable mib-binding

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The OSPFv3 MIB does not contain OSPFv3 process information. Therefore, SNMP operations take effect on one OSPFv3 process only.

If you wish to perform operations on a specified OSPFv3 process through SNMP, run this command to bind the MIB with the process.

Examples

The following example binds an MIB to a specified OSPFv3 process.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 100
Hostname(config-router)# enable mib-binding
```

1.18 enable traps

Function

Run the **enable traps** command to enable sending of the specified trap message.

Run the **no** form of this command to disable this function.

The trap function is disabled by default.

Syntax

enable traps [**error** [**IfConfigError** | **IfRxBadPacket** | **VirtIfConfigError** | **VirtIfRxBadPacket**] * | **state-change** [**IfStateChange** | **NbrStateChange** | **NssaTranslatorStatusChange** | **VirtIfStateChange** |

VirtNbrStateChange | **RestartStatusChange** | **NbrRestartHelperStatusChange** | **VirtNbrRestartHelperStatusChange**] *]

no enable traps [**error** [**IfConfigError** | **IfRxBadPacket** | **VirtIfConfigError** | **VirtIfRxBadPacket**] * | **state-change** [**IfStateChange** | **NbrStateChange** | **NssaTranslatorStatusChange** | **VirtIfStateChange** | **VirtNbrStateChange** | **RestartStatusChange** | **NbrRestartHelperStatusChange** | **VirtNbrRestartHelperStatusChange**] *]

Parameter Description

error: Configures all the trap switches related to Error. This parameter can also configure the following specific error trap switches:

IfConfigError: Indicates interface parameter configuration error.

IfRxBadPacket: Indicates that the interface receives an error packet.

VirtIfConfigError: Indicates virtual interface parameter configuration error.

VirtIfRxBadPacket: Indicates that the virtual interface receives an error packet.

state-change: Configures all the trap switches related to State-change. This parameter can also configure the following specific state-change trap switches:

IfStateChange: Indicates that the interface state changes.

NbrStateChange: Indicates that the neighbor state changes.

NssaTranslatorStatusChange: Indicates that the NSSA translator state changes.

VirtIfStateChange: Indicates that the virtual interface state changes.

VirtNbrStateChange: Indicates that the virtual neighbor state changes.

RestartStatusChange: Indicates that the local GR state changes.

NbrRestartHelperStatusChange: Indicates that the neighbor GR process state changes.

VirtNbrRestartHelperStatusChange: Indicates that the status of the virtual neighbor GR process changes.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The function of this command is restricted by the **snmp-server** command. The **snmp-server enable traps ospf** command must be run prior to the **enable traps** command so that OSPFv3 Trap messages can be sent correctly.

This command is not restricted by the MIB bound to the process. The trap switch can be enabled concurrently for different processes.

Examples

The following example enables sending of the specified trap message.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# ipv6 router ospf 100
Hostname(config-router)# enable traps
```

1.19 graceful-restart

Function

Run the **graceful-restart** command to enable the OSPFv3 GR capability.

Run the **no** form of this command to disable this function or restore the default configuration.

The OSPFv3 GR function is enabled by default.

Syntax

graceful-restart [**grace-period** *grace-period* | **inconsistent-lsa-checking**]

no graceful-restart [**grace-period** | **inconsistent-lsa-checking**]

Parameter Description

grace-period *grace-period*: Configures the GR time (in seconds), which starts at the time when OSPFv3 fails and ends at the time when OSPFv3 is restarted and GR is completed. The value range is from 1 to 1800, and the default value is **120**.

inconsistent-lsa-checking: Enables topology change detection. If any topology change is detected, OSPF exits the GR process to complete convergence.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

When a GR-enabled router is restarted on the control plane, data forwarding can be still guided on the forwarding plane. In addition, actions such as neighbor relationship re-forming and route computation performed on the control plane do not affect functions of the forwarding plane. In this way, service interruption caused by route flapping can be avoided, thus enhancing reliability of the entire network.

The GR function is based on OSPFv3 instance configuration, and different instances can be configured with different parameters based on actual situation.

This command is used to configure the GR restarter capability of a router. In the GR period, link state reestablishment enables OSPFv3 to restore to the original state. When a GR period expires, OSPFv3 exits the GR state and executes normal OSPFv3 operations.

Run the **graceful-restart** command to set the GR period to 120s. The **graceful-restart grace-period** command allows you to modify the GR period explicitly.

If the Fast Hello function is enabled, the GR function cannot be enabled.

The precondition for successful execution of GR and uninterrupted forwarding is that the topology remains stable. In case of a topology change, OSPFv3 converges as soon as possible and does not wait for GR execution to avoid longtime forwarding black-hole.

- Disabling topology detection: If OSPFv3 cannot converge in time when the topology changes during the hot standby process, forwarding black-hole may appear in a long time.
- Enabling topology detection: Forwarding interruption may occur, but the interruption time is far less than the forwarding black-hole time when topology detection is disabled.

In most cases, it is recommended that topology detection be enabled. In special scenarios, topology detection can be disabled if the topology changes after the hot standby process, but it can be ensured that the forwarding black-hole will not appear in a long time. This can minimize the forwarding interruption time during the hot standby process.

Examples

The following example enables the OSPFv3 restarter capability and sets the GR period to **60** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# graceful-restart
Hostname(config-router)# graceful-restart grace-period 60
```

1.20 graceful-restart helper

Function

Run the **graceful-restart helper** command to enable the OSPFv3 GR helper function and configure a topology detection method of the OSPFv3 GR helper.

Run the **no** form of this command to disable this function and remove this configuration.

The GR helper capability is enabled by default. After the GR helper is enabled on the device, LSA changes are not checked.

Syntax

graceful-restart helper { **disable** | **internal-lsa-checking** | **strict-lsa-checking** }

no graceful-restart helper { **disable** | **internal-lsa-checking** | **strict-lsa-checking** }

Parameter Description

disable: Disables a device to act as a GR helper for other devices.

internal-lsa-checking: Indicates that changes in Type 1 to Type 3 LSAs will be checked during the period that the device acts as a GR helper to determine whether the network changes. If the network changes, the device will stop acting as a GR helper.

strict-lsa-checking: Indicates that changes in Type 1 to Type 5 and Type 7 LSAs will be checked during the period that the device acts as a GR helper to determine whether the network changes. If the network changes, the device will stop acting as a GR helper.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the GR help capability of a device. When a device performs GR, it sends a Grace-LSA to notify all its neighbor devices. If the GR help capability is enabled on the local device, the local device becomes a GR helper upon receiving the Grace-LSA to help the former device complete GR. The **disable** option indicates that the GR helper is not provided for any device that implements GR.

After a device becomes a GR helper, the network changes are not detected by default. If any change takes place in the network, the network topology converges after GR is completed. If you expect that network change can be detected quickly during GR, configure the **strict-lsa-checking** or **internal-lsa-checking** option to enable detection. The former option detects any LSA (Type 1 to Type 5 and Type 7 LSAs) that indicates network information, and the latter option detects any LSA (Type 1 to Type 3 LSAs) that indicates routes in an AS domain. When the network scale is large, it is recommended that you disable the LSA checking options because regional network changes may trigger termination of GR and consequently reduce the convergence of the entire network.

Examples

The following example disables the OSPFv3 GR helper function and configures the topology detection method as **strict-lsa-checking**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# graceful-restart helper disable
Hostname(config-router)# no graceful-restart helper disable
Hostname(config-router)# graceful-restart helper strict-lsa-checking
```

1.21 ipv6 ospf area

Function

Run the **ipv6 ospf area** command to enable an interface to join in an OSPFv3 routing process.

Run the **no** form of this command to disable this function.

No interface joins in an OSPFv3 routing process by default.

Syntax

ipv6 ospf *process-id* **area** *area-id* [**instance** *instance-id*]

no ipv6 ospf *process-id* **area** [**instance** *instance-id*]

Parameter Description

process-id: OSPF process ID. The value range is from 1 to 65535.

area *area-id*: Specifies an OSPFv3 area that an interface joins in. The area ID can be a decimal integer or an IP address. The value range is from 0 to 4294967295.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Run this command in interface configuration mode to enable an interface to join in OSPFv3, and then run the **ipv6 router ospf** command to configure an OSPFv3 process. After the OSPFv3 process is configured, the interface will automatically join in the process. The adjacency can be set up only between devices with the same *instance ID*. After this command is configured, all prefix information on the interface will be used to participate in the OSPFv3 process.

The following methods can be used to disable an interface from joining in an OSPFv3 process.

- Run the **no** form of this command to disable an interface from joining an OSPFv3 process.
- Run the **no ipv6 router ospf** command to disable all interfaces from joining in an OSPFv3 process.

Examples

The following example enables an OSPFv3 process on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1))# ipv6 ospf 1 area 2 instance 2
```

1.22 ipv6 ospf authentication

Function

Run the **ipv6 ospf authentication** command to enable OSPFv3 authentication on an interface.

Run the **no** form of this command to disable this function.

By default, no authentication mode is configured on an interface. In this case, the authentication type of the area where the interface resides is used on the interface.

Syntax

ipv6 ospf authentication { **ipsec spi** *spi* { **md5** [**string-key**] | **sha1** } [**0** | **7**] *key* | **null** } [**instance** *instance-id*]

no ipv6 ospf authentication [**instance** *instance-id*]

Parameter Description

spi *spi*: Specifies a security parameter index. The value range is from 256 to 4294967295.

md5: Enables the MD5 authentication mode.

string-key: Specifies to use a string as an authentication key.

sha1: Enables the SHA1 authentication mode.

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

key: Authentication key.

null: Indicates that no authentication mode is enabled.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

Use this command to enable OSPFv3 authentication on an interface.

The device supports four authentication types:

- No authentication (when authentication is not configured)
- MD5
- SHA1

After an OSPFv3 area is configured with authentication, the configuration takes effect on all interfaces (except virtual links) in the area. If the interface authentication configuration is different from area authentication configuration, interface authentication configuration takes precedence over the area authentication configuration.

OSPFv3 interface authentication and interface associated SA authentication are mutually exclusive.

Note

OSPFv3 authentication parameters configured on interconnected interfaces must be consistent.

Examples

The following example configures an OSPFv3 interface with MD5 authentication mode and sets the password to aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf authentication ipsec spi 300 md5
aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
```

Notifications

If this SPI has been used in this module, the following notification will be displayed:

1.23 ipv6 ospf bfd

Function

Run the **ipv6 ospf bfd** command to enable BFD on a specified OSPFv3 interface for link detection.

Run the **no** form of this command to disable this function.

The BFD function is disabled on an interface by default, and the BFD configuration is subject to the configuration in the OSFPv3 process configuration mode.

Syntax

ipv6 ospf bfd [**disable**] [**instance** *instance-id*]

no ipv6 ospf bfd [**instance** *instance-id*]

Parameter Description

disable: Disables BFD on a specified OSPF interface for link detection.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Once a link is faulty, OSPF can quickly detect the failure of the route. This configuration helps shorten the traffic interruption time.

The BFD priority configured on an interface takes precedence over that configured in process configuration mode.

In light of the actual environment, you can run the **ipv6 ospf bfd** command to enable BFD on a specified OSPF interface for link detection, or run the **bfd all-interfaces** command in OSPFv3 process configuration mode to enable BFD on all OSPFv3 interfaces for link detection. Run the **ipv6 ospf bfd disable** command to disable BFD on a specified OSPF interface for link detection.

Examples

The following example enables BFD for link detection.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf bfd
```

Notifications

If BFD is enabled for link detection on an interface, the following notification will be displayed:

```
% Warning: The BFD for OSPFv3 neighbor shall be enabled, or it would affect the route
learning.
```

Common Errors

1.24 ipv6 ospf cost

Function

Run the **ipv6 ospf cost** command to configure cost of an interface.

Run the **no** form of this command to restore the default configuration.

The default cost of an interface is the reference bandwidth value/Bandwidth (the default reference bandwidth value is 100 Mbps).

Syntax

ipv6 ospf cost *cost* [**instance** *instance-id*]

no ipv6 ospf *cost* [**instance** *instance-id*]

Parameter Description

cost: Cost of an OSPFv3 interface. The value range is from 0 to 65535.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The default cost value of an OSPFv3 interface is 100 Mbps/Bandwidth. Bandwidth indicates the bandwidth of the interface and it is configured by running the **bandwidth** command in interface configuration mode.

The default interface costs of several typical OSPFv3 lines are as follows:

- For the 64 Kbps serial line, the cost is 1562.
- For the E1 line, the cost is 48.
- For the 10 Mbps Ethernet, the cost is 10.
- For the 100 Mbps Ethernet, the cost is 1.

The OSPFv3 cost configured through the **ipv6 ospf cost** command will overwrite the default configuration.

Examples

The following example sets the cost of an interface to **1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf cost 1
```

1.25 ipv6 ospf dead-interval

Function

Run the **ipv6 ospf dead-interval** command to configure the neighbor dead interval of an interface.

Run the **no** form of this command to restore the default configuration.

The fast hello function is disabled by default, and the neighbor dead interval is four times the sending interval of hello packets.

Syntax

ipv6 ospf dead-interval { *dead-interval* | **minimal hello-multiplier** *multiplier* } [**instance** *instance-id*]

no ipv6 ospf dead-interval [**instance** *instance-id*]

Parameter Description

Dead-interval: Neighbor dead interval, in seconds. The value range is from 0 to 2147483647.

minimal hello-multiplier: Enables the fast hello function and sets the neighbor dead interval to **1** second.

multiplier: Hello packet sending times per second. The value range is from 3 to 20.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The OSPFv3 neighbor dead interval is contained in hello packets. If OSPF does not receive a hello packet from a neighbor within the neighbor dead interval, it declares that the neighbor is invalid and deletes this neighbor record from the neighbor list. By default, the neighbor dead interval is four times the hello packet sending interval. If the hello packet sending interval is modified, the neighbor dead interval is modified automatically.

This command can be used to manually modify the neighbor dead interval. However, the configuration must be made with caution. Pay attention to the following two issues:

(1) The dead interval cannot be smaller than the hello packet sending interval.

(2) The dead interval must be the same on all routers in the same network segment.

OSPFv3 supports the fast hello function:

Enabling the OSPFv3 fast hello function allows OSPFv3 to find neighbors more quickly and detect neighbor failures faster. You can enable the OSPFv3 fast hello function by specifying the **minimal hello-multiplier** keyword and the *multiplier* parameter. The **minimal** keyword sets the dead interval to 1s, and the value of **hello-multiplier** specifies the hello packet sending times per second. In this way, the hello packet sending interval drops to less than 1s.

If the fast hello function is enabled on an interface, the hello-interval field of the hello packets advertised on the interface is set to 0, and the hello-interval field of the hello packets received on this interface is ignored.

Note

The *dead-interval*, *minimal hello-multiplier*, and *hello-interval* parameters introduced for the fast hello function cannot be configured simultaneously.

No matter whether the fast hello function is enabled, the neighbor dead interval must be consistent among neighbor interfaces. The **hello-multiplier** value can be inconsistent provided that at least one hello packet can be received within the neighbor dead interval.

Run the **show ipv6 ospf interface** command to display the dead interval and fast hello interval configured for an interface.

Examples

The following example sets the neighbor dead interval of an interface to **60** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf dead-interval 60
```

Notifications

If the neighbor dead interval is smaller than the hello packet sending interval, the following notification will be displayed:

```
% Warning: OSPFv3 dead interval should be higher than hello interval
```

If the hello packet sending interval is configured prior to the fast hello function, the following notification will be displayed:

```
% OSPFv3: Hello interval configured with hello-interval.
```

Common Errors

- The neighbor dead intervals configured on different ports in the same area are inconsistent.

1.26 ipv6 ospf encryption

Function

Run the **ipv6 ospf encryption** command to enable OSPFv3 encryption on an interface.

Run the **no** form of this command to disable this function.

Encryption is disabled by default.

Syntax

ipv6 ospf encryption { **ipsec spi** *spi* **esp** { { **3des** | **aes-cbc** { **128** | **192** | **256** } | **des** } [**0** | **7**] *des-key* | **null** } { **md5** | **sha1** } [**0** | **7**] *key* | **null** } [**instance** *instance-id*]

no ipv6 ospf encryption [**instance** *instance-id*]

Parameter Description

spi *spi*: Specifies a security parameter index. The value range is from 256 to 4294967295.

esp: Enables the ESP encryption mode.

des: Enables the DES encryption mode.

3des: Enables the 3DES encryption mode.

aes-cbc [**128** | **192** | **256**]: Enables the Advanced Encryption Standard-Cipher Block Chaining (AES-CBC) encryption mode. The encryption key length is 128, 192, or 256 bits.

des: Enables the DES encryption mode.

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

des-key: Encryption key.

null: Indicates that no encryption mode is used.

md5: Enables the MD5 authentication mode.

sha1: Enables the SHA1 authentication mode.

key: Authentication key.

null: Indicates that no authentication mode is enabled.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

The device supports the following types of encryption and authentication:

Encryption modes: DES, 3DES, and AES-CBC.

Authentication modes: MD5 and SHA1

Note

OSPFv3 encryption and authentication parameters configured on the interconnected interfaces must be consistent.

Examples

The following example enables OSPFv3 encryption and authentication for an interface, configures the interface with null encryption and MD5 authentication, and sets the password to aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf encryption ipsec spi 300 esp null md5 aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa
```

1.27 ipv6 ospf hello-interval

Function

Run the **ipv6 ospf hello-interval** command to configure the hello packet sending interval on an interface.

Run the **no** form of this command to restore the default configuration.

The default hello packet sending interval of the broadcast and P2P networks is **10** seconds. The default hello packet sending interval of the P2MP and NBMA networks is **30** seconds.

Syntax

ipv6 ospf hello-interval *hello-interval* [**instance** *instance-id*]

no ipv6 ospf hello-interval [**instance** *instance-id*]

Parameter Description

hello-interval: Hello packet sending interval, in seconds. The value range is from 1 to 65535.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The hello packet sending interval is contained in hello packets. A shorter interval indicates that OSPFv3 can detect topology changes more quickly, but the network traffic increases. The hello packet sending interval must be the same on all routers in the same network segment. If you want to manually modify the neighbor dead interval, ensure that the neighbor dead interval is longer than the hello packet sending interval.

Note

The *dead-interval minimal hello-multiplier* and *hello-interval* parameters introduced for the fast hello function cannot be configured simultaneously.

Examples

The following example sets the hello packet sending interval to **20** seconds on the interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf hello-interval 20
```

Notifications

If the hello packet sending interval is configured on an interface that is configured with the *dead-interval minimal hello-multiplier* parameter of the fast hello function, the following notification will be displayed:

```
% OSPFv3: Hello interval configured with hello-multiplier.
```

1.28 ipv6 ospf mtu-ignore

Function

Run the **ipv6 ospf mtu-ignore** command to disable MTU verification for an interface that receives database description packets.

Run the **no** form of this command to enable MTU verification for an interface that receives database description packets.

The MTU verification function is disabled by default.

Syntax

ipv6 ospf mtu-ignore [**instance** *instance-id*]

no ipv6 ospf mtu-ignore [**instance** *instance-id*]

Parameter Description

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

On receiving a database description packet, OSPFv3 checks whether the MTU of the neighbor interface in the database description packet is the same as the MTU of the local interface. If the interface MTU specified in the received database description packet is greater than the MTU of the local interface, the adjacency fails to be set up. To resolve this problem, you can disable MTU verification.

Examples

The following example disables MTU verification for an interface that receives database description packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf mtu-ignore
```

1.29 ipv6 ospf neighbor

Function

Run the **ipv6 ospf neighbor** command to configure OSPFv3 neighbors.

Run the **no** form of this command to restore the default configuration.

No neighbor is configured by default.

Syntax

ipv6 ospf neighbor *ipv6-address* [**cost** *cost* | [**poll-interval** *poll-interval* | **priority** *value*] *] [**instance** *instance-id*]

no ipv6 ospf neighbor *ipv6-address* [**cost** *cost* | [**poll-interval** *poll-interval* | **priority** *value*] *] [**instance** *instance-id*]

Parameter Description

cost *cost*: Configures costs required to reach each neighbor in the P2MP network. This parameter is not defined by default and applicable only to the P2MP network. The value range is from 0 to 65535.

poll-interval *poll-interval*: Indicates the neighbor polling interval, in seconds. This parameter is applicable only to the NBMA network. The value range is from 0 to 2147483647, and the default value is **120**.

priority *priority*: Configures the priority of a neighbor in the NBMA network. This parameter is applicable only to the NBMA network. The value range is from 0 to 255, and the default value is **0**.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the IPv6 address of an OSPFv3 neighbor to FE80::2D0:F8FF:FE22:3533, priority value to **1**, and polling interval to **150** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf network non-broadcast
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf neighbor fe80::2d0:f8ff:fe22:3533
priority 1 poll-interval 150
```

Notifications

If a neighbor is configured in the NBMA and P2MP networks, the following notification will be displayed:

```
% Neighbor command is allowed only on NBMA and point-to-multipoint networks.
```

If the IP address of a specified neighbor is not an IPv6 address, the following notification will be displayed:

```
% OSPFv3: Neighbor address needs to be a link-local address.
```

1.30 ipv6 ospf network

Function

Run the **ipv6 ospf network** command to configure an OSPF network type of an interface.

Run the **no** form of this command to restore the default configuration.

By default, the interface type of OSPF is not configured. No interface is set to P2MP type by default.

Syntax

ipv6 ospf network { **broadcast** | **non-broadcast** | **point-to-multipoint** [**non-broadcast**] | **point-to-point** } [**instance** *instance-id*]

no ipv6 ospf network [**broadcast** | **non-broadcast** | **point-to-multipoint** [**non-broadcast**] | **point-to-point**] [**instance** *instance-id*]

Parameter Description

broadcast: Configures the broadcast network type for an interface.

non-broadcast: Configures the non-broadcast network type for an interface.

point-to-multipoint: Configures the P2MP network type for an interface.

point-to-multipoint non-broadcast: Configures the P2MP non-broadcast network type for an interface.

point-to-point: Configures the P2P network type for an interface.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

OSPFv3 network types are configured based on the network architecture. Ethernet and FDDI belong to the broadcast type. X.25, frame relay, and ATM belong to the NBMA type. PPP, HDLC, and LAPB belong to the P2P type. Each network type is restricted as follows:

- The broadcast type requires that the interfaces must have the broadcast capability.
- The P2P type requires that the interfaces are interconnected in one-to-one manner.
- The NBMA type requires full-meshed connections, and all interconnected routers can directly communicate with each other.
- The P2MP type does not raise any requirement.

Examples

The following example configures the OSPF network type of an interface as P2P.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf network point-to-point
```

1.31 ipv6 ospf priority

Function

Run the **ipv6 ospf priority** command to configure the priority of an interface.

Run the **no** form of this command to restore the default configuration.

The priority value is **1** by default.

Syntax

ipv6 ospf priority *priority* [**instance** *instance-id*]

no ipv6 ospf priority [**instance** *instance-id*]

Parameter Description

priority: Priority of an interface. The value range is from 0 to 255.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

In a broadcast network, a DR or BDR must be elected. During the DR or BDR election, the device with a higher priority will be preferentially elected as a DR or BDR. If the priority is the same, the device with a larger router ID will be preferentially elected as a DR or BDR.

A device with the priority 0 does not participate in the DR or BDR election.

Examples

The following example sets the priority of an interface to **0** so that the interface does not participate in the DR or BDR election.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf priority 0
```

1.32 ipv6 ospf retransmit-interval

Function

Run the **ipv6 ospf retransmit-interval** command to configure the LSA retransmission interval on an interface.

Run the **no** form of this command to restore the default configuration.

The default LSA retransmission interval is **5** seconds.

Syntax

ipv6 ospf retransmit-interval *retransmit-interval* [**instance** *instance-id*]

no ipv6 ospf retransmit-interval [**instance** *instance-id*]

Parameter Description

retransmit-interval: LSU retransmission interval, in seconds. The value range is from 1 to 65535.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To ensure transmission reliability of the routing information, a router must get confirmation from a neighbor when sending LSAs to the neighbor. Users can use this command to configure the interval of waiting for confirmation from a neighbor based on the actual running environment. If no confirmation is received within the specified interval, the router retransmits LSAs.

The LSU retransmission interval must be longer than the round-trip transmission delay of data packets between two neighbors.

Examples

The following example sets the LSA transmission interval on an interface to **10** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf retransmit-interval 10
```

1.33 ipv6 ospf subvlan

Function

Run the **ipv6 ospf subvlan** command to enable the OSPFv3 function in a super VLAN.

Run the **no** form of this command to restore the default configuration.

The OSPFv3 function takes effect in super VLANs only and is disabled by default.

Syntax

ipv6 ospf subvlan [**all** | *vlan-id*]

no ipv6 ospf subvlan

Parameter Description

all: Allows sending packets to all sub VLANs.

vlan-id: Sub VLAN ID. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

In normal cases, a super VLAN contains multiple sub VLANs. The multicast packets corresponding to a super VLAN are also sent to its sub VLANs. OSPFv3 multicast packets will be replicated when they are sent in a super VLAN. If the super VLAN contains many sub VLANs, a great number of OSPF multicast packets are replicated, exceeding the processing capability of the device. This results in discarding of many packets and causes protocol flapping.

In most scenarios, the OSPFv3 function does not need to be enabled in a super VLAN, and it is disabled by default. In some other scenarios, OSPFv3 needs to be run in a super VLAN. In this case, you can decide to send multicast packets to a certain sub VLAN or to all sub VLANs as actually needed. Usually, packets need to be sent to only one sub VLAN. You can run this command to specify a sub VLAN. You must be cautious when configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor flapping.

Examples

The following example enables the OSPFv3 function on super VLAN 300 and allows sending packets to sub VLAN 1024.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface vlan 300
Hostname(config-if-VLAN 300)# ipv6 ospf subvlan 1024
```

Notifications

N/A

Common Errors

- The function is configured on a non-super VLAN.
- The specified sub VLAN on the super VLAN cannot implement interworking with its neighbors.

1.34 ipv6 ospf transmit-delay

Function

Run the **ipv6 ospf transmit-delay** command to configure the LSU transmission delay on an interface.

Run the **no** form of this command to restore the default configuration.

The LSU packet transmission time is **1** second by default.

Syntax

ipv6 ospf transmit-delay *transmit-delay* [**instance** *instance-id*]

no ipv6 ospf transmit-delay [**instance** *instance-id*]

Parameter Description

transmit-delay: Delay for an OSPF interface to transmit LSU packets, in seconds. The value range is from 1 to 65535.

instance *instance-id*: Configures a specified OSPFv3 instance of the interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The sending delay and line transmission delay of the interface must be considered when *transmit-delay* is configured. For a low-speed line, the transmission delay of the interface must be set to a value greater than the default value.

Examples

The following example sets the LSU transmission delay on an interface to **2** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 ospf transmit-delay 2
```

1.35 ipv6 router ospf

Function

Run the **ipv6 router ospf** command to enable an OSPFv3 routing process.

Run the **no** form of this command to disable this process.

No OSPFv3 routing process is enabled by default.

Syntax

ipv6 router ospf [*process-id* [**vrf** *vrf-name*]]

no ipv6 router ospf *process-id*

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535, and the default value is **1**.

vrf-name: VRF to which the OSPFv3 process belongs.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Run this command to enable an OSPFv3 routing process, and the device enters the routing process configuration mode.

A maximum of 32 OSPFv3 processes can be configured.

Examples

The following example enables an OSPFv3 process in vrf:vpn_1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1 vrf vpn_1
```

Notifications

When an OSPFv3 process fails to be configured because **ipv6 unicast-routing** is not enabled, the following notification will be displayed:

```
IPv6 unicast-routing not enabled, OSPFv3 process can't configure
```

When the corresponding OSPFv3 process cannot be enabled because it is not allocated a router ID, the following notification will be displayed:

```
%OSPFV3-NORTRID: OSPFv3 process 1 failed to allocate unique router-id and cannot start.
```

1.36 ipv6 router ospf max-concurrent-dd

Function

Run the **ipv6 router ospf max-concurrent-dd** command to configure the maximum number of neighbors with which all the OSPFv3 routing processes can concurrently initiate or accept interaction.

Run the **no** form of this command to restore the default configuration.

The maximum number of neighbors is **10** by default.

Syntax

ipv6 router ospf max-concurrent-dd *max-neighbor*

no ipv6 router ospf max-concurrent-dd

Parameter Description

max-neighbor: Maximum number of neighbors that concurrently interact with the OSPF process. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the performance of a router is affected because the router exchanges data with multiple neighbors, you can run this command to restrict the maximum of neighbors with which all OSPFv3 processes can concurrently initiate or accept interaction.

Examples

The following example sets the maximum number of neighbors with which all OSPFv3 processes can concurrently initiate or accept interaction to **4**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf max-concurrent-dd 4
```

1.37 log-adj-changes

Function

Run the **log-adj-changes** command to record the log of adjacency state changes.

Run the **no** form of this command to remove this configuration.

The log record function is enabled by default.

Syntax

log-adj-changes [**detail**]

no log-adj-changes [**detail**]

Parameter Description

detail: Displays detailed information of neighbor state changes.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

The log records the log information of the following four types of events only:

The adjacency reaches the full state;

The adjacency leaves the full state;

The adjacency reaches the down state;

The adjacency leaves the down state.

Examples

The following example records the log of adjacency state changes.

```
Hostname> enable

1.39 nsr

Function

Run the **nsr** command to enable the nonstop routing (NSR) function.

Run the **no** form of this command to restore the default configuration.

The NSR function is disabled by default.

Syntax

nsr

no nsr

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

During NSR, OSPFv3-related information is backed up from the active supervisor module of a distributed device to the standby supervisor module, or from the active host of a virtual switching unit (VSU) to the standby host. In this way, the device can automatically recover the link state and re-generate routes without the help of the neighbor devices during the active/standby switchover. Information that should be backed up includes the neighbor relationship and link state.

For the same OSPFv3 instance, either NSR or GR is enabled because they are mutually exclusive. Nevertheless, when NSR is enabled, the GR helper capability is supported.

The switchover of devices in distributed or VSU mode takes a period of time. If OSPFv3 neighbor keepalive duration is shorter than the switchover duration, the OSPFv3 neighbor relationship with the neighbor device is removed, and services are interrupted during the switchover. Therefore, you are advised to set the OSPFv3 neighbor keepalive duration not less than the default value when you are enabling the NSR function. When fast hello is enabled, the OSPFv3 neighbor keepalive duration is less than 1s and the OSPFv3 neighbor relationship times out during the switchover, causing NSR failures. Therefore, you are advised to disable fast hello when NSR is enabled.

Examples

The following example enables the NSR function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# nsr
```

Notifications

N/A

Common Errors

- The neighbor keepalive duration is short. When fast hello is enabled, the OSPFv3 neighbor relationship is removed during a switchover, causing forwarding interruption.

Platform Description

N/A

1.40 passive-interface

Function

Run the **passive-interface** command to configure a passive interface.

Run the **no** form of this command to restore the default configuration.

The passive mode of interfaces is disabled by default, and all interfaces are allowed to send and receive OSPFv3 packets.

Syntax

passive-interface { **default** | *interface-type interface-number* }

no passive-interface { **default** | *interface-type interface-number* }

Parameter Description

Default: Configures all interfaces as passive interfaces.

interface-type interface-number: Interface type and interface number.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

To prevent other routers in the network from learning the routing information of the local router, you can configure a specified network interface of the local router as the passive interface, or a specified IP address of a network interface as the passive address. The loopback interface and the interface that is not connected to any OSPF neighbor can be set to passive interfaces.

When an interface is configured as a passive interface, it no longer sends or receives hello packets.

This command takes effect only on an OSPFv3 interface, and not on a virtual link.

Examples

The following example configures all interfaces of the local router as passive interfaces and enables OSPFv3 on the interfaces of VLAN 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# passive-interface default
Hostname(config-router)# no passive-interface vlan 1
```

Notifications

If the specified interface is invalid, the following notification will be displayed:

```
% Interface is invalid.
```

Common Errors

1.41 redistribute

Function

Run the **redistribute** command to enable route redistribution and inject routing information of other routing protocols to an OSPFv3 routing process.

Run the **no** form of this command to disable this function or modify the redistribution parameters.

The route redistribution function is not enabled by default.

Syntax

redistribute { **bgp** | **connected** | **isis** [*area-tag*] [**level-1** | **level-1-2** | **level-2**] * | **ospf** *process-id* [**match** { **externa**l [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**] } *] | **rip** | **static** } [**metric** *metric-value* | **metric-type** { **1** | **2** } | **route-map** *route-map-name* | **tag** *tag-value*] *

no redistribute { **bgp** | **connected** | **isis** [*area-tag*] [**level-1** | **level-1-2** | **level-2**] * | **ospf** *process-id* [**match** { **externa**l [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**] } *] | **rip** | **static** } [**metric** | **metric**-**type** | **route**-**map** | **tag**] *

Parameter Description

bgp: Indicates redistribution from BGP.

connected: Indicates redistribution from direct routes.

isis [*area-tag*]: Indicates redistribution from IS-IS. Here, *area-tag* specifies an IS-IS instance.

level-1 | **level-2** | **level-1-2**: Redistributes IS-IS routes at the specified level.

ospf *process-id*: Indicates redistribution from OSPF. Here, *process-id* specifies an OSPF process. The value range is from 1 to 65535.

match: Redistributes specific OSPFv3 routes that meet the filtering conditions.

external [**1** | **2**]: Redistributes E1, E2, or all external routes.

internal: Redistributes internal routes and inter-area routes.

nssa-external [**1** | **2**]: Redistributes N1, N2, or all external routes of all NSSAs.

rip: Indicates redistribution from RIP.

static: Indicates redistribution from static routes.

metric *metric-value*: Configures a metric value of OSPFv3 external LSAs, which is specified based on *metric-value*. The value range is from 0 to 16777214.

metric-type { **1** | **2** }: Configures the metric type of external routes, which can be E-1 or E-2.

route-map *route-map-name*: Configures the redistribution route filtering rules. Here, the value of *route-map-name* cannot exceed 32 characters.

tag *tag-value*: Specifies the tag value of the route that is redistributed to an OSPFv3 routing domain. The value range is from 0 to 4294967295.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

When the device supports multiple routing protocols, collaboration between protocols is required. To run multiple routing protocols concurrently, the device must be able to redistribute routing information of a protocol to another protocol.

During redistribution of IS-IS routes, **level-1**, **level-2**, or **level-1-2** parameters can be configured to indicate that IS routes of the specified levels are redistributed. By default, level-2 IS-IS routes are redistributed.

During redistribution of OSPFv3 routes, *match* can be configured to indicate that OSPFv3 routes of the specified sub-type are redistributed. By default, all types of OSPFv3 routes are redistributed.

For the **level** parameter configured for redistribution of IS-IS routes and the **match** parameter configured during redistribution of OSPFv3 routes, the routes are matched against the route map only when the sub-types of the routes are correct.

The **match** parameter in the route map rule used for route redistribution is matched based on the original information of the routes. The priority of the **tag**, **metric**, and **metric-type** parameters configured for route redistribution is lower than that of the **set** rule in the route map.

The **set metric** value of the associated route map should fall into the range of 0 to 16777214. If the value exceeds this range, routes cannot be introduced.

The configuration rules for the **no** form of the **redistribute** command are as follows:

- If some parameters are specified in the **no** form of this command, default values of these parameters will be restored.
- If no parameter is specified in the **no** form of this command, the entire command will be deleted.

For example, if **redistribute isis 112 level-2** is configured, you can run the **no redistribute isis 112 level-2** command to restore the default value of level-2. As **level-2** itself is the default value of the parameter, the configuration saved is still **redistribute isis 112 level-2** after the preceding **no** form of the command is executed. To delete the entire command, run the **no redistribute isis 112** command.

Examples

The following example redistributes a direct route and associates the route with the route map **test**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# redistribute connect metric 10 route-map test
```

The following example configures the route map **test** and changes the metric value of the matched routes from **20** to **30** and the metric value of other redistributed routes from **20** to **10**.

```
Hostname(config)# route-map test permit 10
Hostname(config-route-map)# match metric 20
Hostname(config-route-map)# set metric 30
```

Notifications

If routes of this instance are redistributed, the following notification will be displayed:

```
% Redistribution of "ospf 1" via "ospf 1" not allowed
```

1.42 router-id

Function

Run the **router-id** command to configure the ID of a router.

Run the **no** form of this command to remove this configuration.

A router ID is selected from IP addresses of interfaces by default. By default, the OSPFv3 routing process elects the largest IPv4 address among all the loopback interfaces as the router ID. If the loopback interfaces configured with IP addresses are not available, the OSPFv3 process elects the largest one among the IP addresses of all its physical interfaces as the router ID.

Syntax

router-id *router-id*

no router-id

Parameter Description

router-id: ID of a router, which is expressed in the IPv4 address.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Every OSPFv3 router must be identified by using a router ID. You can configure an IPv4 address as the ID of the router, but ensure that the router ID is unique in an AS. If a router runs multiple OSPFv3 processes, ensure that the router ID of each process is unique.

After the router ID changes, OSPF performs a lot of internal processing. Therefore, you are not advised to change the router ID unless necessary. When an attempt is made to modify the router ID, a prompt is displayed, requesting you to confirm the modification. After an OSPFv3 process is enabled, you are advised to specify the router ID before configuring other parameters of the process.

Examples

The following example sets the router ID to 1.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# router-id 1.1.1.1
```

Notifications

When you set the router ID to 0.0.0.0, which stops the OSPFv3 process, the following notification will be displayed:

```
% OSPFv3: router-id set to 0.0.0.0, process will not run.
```

When the configured router ID is duplicate with that of another process, the following notification will be displayed:

```
% OSPFv3: router-id %r is in use by process %s
```

1.43 show ipv6 ospf

Function

Run the **show ipv6 ospf** command to display information of an OSPFv3 process.

Syntax

show ipv6 ospf [*process-id*]

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays information of an OSPFv3 process.

```
Hostname> enable
Hostname# show ipv6 ospf
Routing Process "OSPFv3 (1)" with ID 1.1.1.1
Process uptime is 24 minutes
Enable two-way-maintain
SPF schedule delay 5 secs, Hold time between SPFs 10 secs
Initial LSA throttle delay 0 msecs
Minimum hold time for LSA throttle 5000 msecs
Maximum wait time for LSA throttle 5000 msecs
Lsa Transmit Pacing timer 40 msecs, 1 LS-Upd
```

```
Minimum LSA arrival 1000 msecs
Pacing lsa-group: 30 secs
Number of incomming current DD exchange neighbors 0/5
Number of outgoing current DD exchange neighbors 0/5
Number of external LSA 0. Checksum Sum 0x0000
Number of AS-Scoped Unknown LSA 0
Number of LSA originated 11
Number of LSA received 4
Log Neighbor Adjency Changes : Enabled
BFD enabled
Number of areas in this router is 2
Area BACKBONE(0)
Number of interfaces in this area is 1(1)
SPF algorithm executed 4 times
Number of LSA 3. Checksum Sum 0x1DDF1
Number of Unknown LSA 0
Area 0.0.0.1 (NSSA)
Number of interfaces in this area is 1(1)
SPF algorithm executed 5 times
Number of LSA 7. Checksum Sum 0x445FE
Number of Unknown LSA 0
```

Table 1-1 Output Fields of the show ipv6 ospf Command

Field	Description
Routing Process "OSPFv3 (x)" with ID 1.1.1.1	OSPFv3 process ID and OSPFv3 router ID
Process uptime	Validation time of this OSPFv3 process (the process is invalid when the router ID is 0.0.0.0)
Enable two-way-maintain	Whether to enable two-way maintenance of OSPFv3
SPF schedule delay	Required delay time before calling the SPF computation when a topology change is received
SPF Hold time	Minimum holding time between two SPF computations
Initial LSA throttle delay	Minimum delay time of generating LSAs
Minimum hold time for LSA throttle	Minimum interval between two SPF computations
Maximum wait time for LSA throttle	Maximum interval between two SPF computations
Lsa Transmit Pacing timer	LSA group update frequency
Minimum LSA arrival	Minimum receiving delay time of LSAs

Field	Description
Pacing lsa-group	Group pace interval
Incomming current DD exchange neighbors	Number of neighbors in interaction. Incoming means that a neighbor enters the Exstart state for the first time.
Outgoing current DD exchange neighbors	Number of neighbors in interaction. Outgoing means that a neighbor returns from a higher state to the Exstart state for re-interaction.
Number of external LSA	Number of external LSAs stored in the database
External LSA Checksum Sum	Sum of checksums of external LSAs stored in the database
Number of AS-Scoped Unknown LSA	Number of unknown LSAs in the flooding scope
Number of LSA originated	Number of generated LSAs
Number of LSA received	Number of received LSAs
Log Neighbor Adjency Changes	Whether the neighbor state change recording is enabled
BFD enabled	Whether to associate OSPFv3 with BFD
Number of areas in this router	Number of areas on this router
Number of interfaces in this area	Number of interfaces in this area
SPF algorithm executed	SPF computation times
Number of LSA	Total number of LSAs in this area
Checksum Sum	Sum of the checksums of LSAs in this area
Number of Unknown LSA	Number of LSAs of unknown types received in this area
NSSA Translator State	Whether an NSSA LSA is translated to an external LSA. This field is valid only for the OSPFv3 process that is an ABR in the NSSA.

1.44 show ipv6 ospf database

Function

Run the **show ipv6 ospf database** command to display the database information of an OSPFv3 process.

Syntax

show ipv6 ospf [*process-id*] **database** [**database-summary** | *lsa-type* [**adv-router** *router-id*]]

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

lsa-type: LSA type, including

NSSA-external-LSA, AS-external-LSAs, Link-LSAs, Inter-Area-Prefix-LSAs, Inter-Area-Router-LSAs,

Intra-Area-Prefix-LSAs, Network-LSAs, and Router-LSAs.

If this parameter is not specified, all LSA information is displayed.

adv-route*r router-id*: Displays LSA information generated by a specified OSPFv3 neighbor.

database-summary: Displays the statistical information of each type of LSAs in the OSPFv3 LSDB.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the database information of an OSPFv3 process.

```
Hostname> enable
Hostname# show ipv6 ospf database
OSPFv3 Router with ID (1.1.1.1) (Process 1)
Link-LSA (Interface GigabitEthernet 0/1)

1.45 show ipv6 ospf interface

Function

Run the **show ipv6 ospf interface** command to display the information of an OSPFv3 interface.

Syntax

show ipv6 ospf [*process-id*] **interface** [**brief** | *interface-type interface-number*]

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

brief: Displays the brief information of an interface.

interface-type interface-number: Interface type and interface number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays information of an OSPFv3 interface.

```
Hostname> enable
Hostname# show ipv6 ospf interface
GigabitEthernet 0/1 is up, line protocol is up
Interface ID 2
IPv6 Prefixes
fe80::2d0:22ff:fe22:2223/64 (Link-Local Address)
OSPFv3 Process (1), Area 0.0.0.0, Instance ID 0
Router ID 1.1.1.1, Network Type BROADCAST, Cost: 1
Transmit Delay is 1 sec, State BDR, Priority 1,
BFD enabled
Designated Router (ID) 2.2.2.2
Interface Address fe80::c800:eff:fe84:1c
Backup Designated Router (ID) 1.1.1.1
Interface Address fe80::2d0:22ff:fe22:2223
Timer interval configured,Hello 10,Dead 40,Wait 40,Retransmit 5
Hello due in 00:00:02
Neighbor Count is 1, Adjacent neighbor count is 1
Hello received 26 sent 26, DD received 5 sent 4
LS-Req received 1 sent 1, LS-Upd received 3 sent 6
LS-Ack received 6 sent 2, Discarded 0
```

Table 1-3 Output Fields of the show ipv6 ospf interface Command

Field	**Description**
GigabitEthernet 0/1 is up, line protocol is up	Link and protocol state
Interface ID	Interface index
IPv6 Prefixes	IPv6 prefix information of an interface
OSPFv3 Process (1)	OSPFv3 process where an interface resides
Area	Area to which an interface belongs
Instance ID	Instance to which an interface belongs
Router ID	ID of an OSPFv3 router
Network Type	OSPFv3 network type
Cost	Cost of an OSPFv3 interface
Transmit Delay	Transmission delay of an OSPFv3 interface
State	DR/BDR state
Priority	Priority of an OSPFv3 interface
BFD enabled	Whether to associate OSPFv3 with BFD
Designated Router (ID)	ID for the DR of this interface
DR's Interface address	Interface address for the DR of this interface
Backup Designated Router (ID)	ID for the BDR of this interface
BDR's Interface address	Interface address for the BDR of this interface
Time intervals configured	Hello, Dead, Wait, and Retransmit time corresponding to this interface
Hello due in	Hello packet sending duration last time
Neighbor Count	Total number of neighbors
Adjacent neighbor count	Number of neighbors in full neighbor relationship
Hello received sent	Statistics of the received and sent hello packets
DD received send	Statistics of the received and sent DD packets
LS-Req received send	Statistics of the received and sent LS request packets
LS-Upd received send	Statistics of the received and sent LS update packets
LS-Ack received send	Statistics of the received and sent LS response packets

Field	Description
Discard	Statistics of the discarded OSPFv3 packets

1.46 show ipv6 ospf neighbor

Function

Run the **show ipv6 ospf neighbor** command to display neighbor information of an OSPFv3 process.

Syntax

show ipv6 ospf [*process-id*] **neighbor** [**detail** | *interface-type interface-number* [**detail**] | *neighbor-id* | **statistics**]

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

detail: Displays the neighbor details.

interface-type interface-number: Interface type and interface number.

neighbor-id: Route ID of a specified neighbor.

statistics: Displays the statistics of neighbors.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the brief information of an OSPFv3 neighbor.

```
Hostname> enable
Hostname# show ipv6 ospf neighbor
OSPFv3 Process (1) , 1 Neighbors, 1 is Full:
Neighbor ID  Pri  State    Dead Time   Interface       Instance ID
```

```
2.2.2.2     1    Full/DR   00:00:33    GigabitEthernet 0/1  0
Hostname# show ipv6 ospf neighbor detail
Neighbor 2.2.2.2, interface address fe80::c800:eff:fe84:1c
In the area 0.0.0.0 via interface GigabitEthernet 0/1
Neighbor priority is 1, State is Full, 6 state changes
DR is 2.2.2.2 BDR is 1.1.1.1
Options is 0x000013 (-|R|-|E|V6)
Dead timer due in 00:00:36
Database Summary List 0
Link State Request List 0
Link State Retransmission List 0
BFD session state up
```

Table 1-4 Output Fields of the show ipv6 ospf neighbor Command

Field	Description
OSPFv3 Process (1), 1 Neighbors, 1 is Full:	Process ID, number of neighbors, and number of neighbors in full neighbor relationship
Neighbor ID	Router ID of a neighbor
Pri	Priority of a neighbor

Field	Description
State	Neighbor states, including Down—Initial status of a neighbor in a session Attempt—When the interface of a device in the NBMA qualified for DR election becomes valid, the neighbor state is reset to Attempt. This state is applicable to neighbors in the NBMA. Init—The neighbor receives a hello packet that does not contain the neighbor ID. 2-Way—The hello packet received from the neighbor contains the local router ID, indicating that 2-way communication has been established. Exstart—An active/standby relationship is established between a router and its neighbors and the sequence number of DD packets is determined, which is ready for DD packet exchange. Exchange—A router sends DD packets that describe local LSDB information to its neighbors. Loading—A router sends LSR packets to a neighbor to request the latest LSA. Full—A router establishes full adjacency relationship with neighbors. OSPF routers play the following roles in broadcast and NBMA networks: DR—A DR exists in only broadcast and NBMA networks. BDR—A BDR exists in only broadcast and NBMA networks. DRother—Indicates all other devices except the DR and BDR in broadcast and NBMA networks. In P2P and P2MP networks, the preceding roles do not exist, and this field is displayed as a hyphen (-).
Dead Time	Time before the neighbor enters the dead state
Instance ID	ID of a neighbor instance
Interface	Interface connected to neighbors
Interface address	Interface address of the neighbor router
In the area	Area that learns this neighbor
via interface	Interface that learns this neighbor
Neighbor priority	Priority value of the neighbor
State changes times	Change times of the neighbor state
DR	Interface address (namely, the DR field in the hello packet) of the DR elected by the neighbor router
BDR	Interface address (namely, the BDR field in the hello packet) of the BDR elected by the neighbor router

Field	Description
Options	Options for the hello packet
Dead Time due in	Time when the dead state of this neighbor is declared
Database Summary List	DD packet statistics of the neighbor
Link State Request List	LSR packet statistics of the neighbor
Link State Retransmission List	Retransmitted packet statistics of the neighbor
BFD session state up	BFD association state

1.47 show ipv6 ospf restart

Function

Run the **show ipv6 ospf restart** command to display the information related to OSPFv3 GR.

Syntax

show ipv6 ospf [*process-id*] **restart**

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the current status of the restarter.

```
Hostname> enable
```

```
Hostname# show ipv6 ospf restart
Routing Process is ospf 1
Graceful-restart enabled
Restart grace period 120 secs
Current Restart status is plannedRestart
Current Restart remaining time 50 secs
Graceful-restart helper support enabled
```

Table 1-5 Output Fields of the show ipv6 ospf restart Command

Field	Description
Routing Process is ospf	ID of a process that starts GR
Graceful-restart enabled	Whether to enable the GR function
Restart grace period	GR period
Current Restart status	Current GR status
Current Restart remaining time	Remaining GR time
Graceful-restart helper support enabled	Whether to support restart helper

The following example displays the current status of the restart helper.

```
Hostname> enable
Hostname# show ipv6 ospf restart
Routing Process is ospf 1
Neighbor 10.1.1.2, interface addr 10.1.1.2
In the area 0.0.0.0 via interface GigabitEthernet 6/0/0
Graceful-restart helper enabled
Current helper status is helping
Current helper remaining time 50 secs
```

Table 1-6 Output Fields of the show ipv6 ospf restart Command

Field	Description
Neighbor	Router ID of the neighbor of the helper
interface addr	IP address of the interface corresponding to the helper
In the area	Area in which the helper resides
interface GigabitEthernet	Interface corresponding to the helper
Graceful-restart helper enabled	Whether to enable the helper function
Current helper status	Current helper status
Current helper remaining time	Remaining time of a router in the helper state

1.48 show ipv6 ospf route

Function

Run the **show ipv6 ospf route** command to display the routing information of OSPFv3.

Syntax

show ipv6 ospf [*process-id*] **route** [**count**]

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

count: Displays the number of OSPFv3 routes.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the routing information of OSPFv3.

```
Hostname> enable
Hostname# show ipv6 ospf route
OSPFv3 Process (1)
Codes: C - connected, D - Discard, B – Backup O - OSPF, IA - OSPF inter area
      N1 - OSPF NSSA external type 1, N2 - OSPF NSSA external type 2
      E1 - OSPF external type 1, E2 - OSPF external type 2Destination        Metric
Next-hop
E2 2001:DB8:1::/64   1/20    via fe80::c800:eff:fe84:1c, GigabitEthernet 0/1
B                        via fe80::c800:eff:fe84:1d, GigabitEthernet 0/2
O  2001:DB8:2::/64   11      via fe80::c800:eff:fe84:1c, GigabitEthernet 0/1, Area
0.0.0.0
```

Table 1-7 Output Fields of the show ipv6 ospf route Command

Field	Description
OSPFv3 Process (1)	OSPFv3 process ID
Destination	Type and destination network of OSPFv3 routes OSPFv3 supports the following four types of routes: **C**: Direct route **D**: Black-hole route **O**: Internal route of OSPFv3 **IA**: Inter-area route of OSPFv3 **N1**: NSSA external type 1 route of OSPFv3 **N2**: NSSA external type 2 route of OSPFv3 **E1**: External type 1 route of OSPFv3 **E2**: External type 2 route of OSPFv3

1.49 show ipv6 ospf summary-prefix

Function

Run the **show ipv6 ospf summary-prefix** command to display external route summarization information of OSPFv3.

Syntax

show ipv6 ospf [*process-id*] **summary-prefix**

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the external route summarization information of OSPFv3.

```
Hostname> enable
Hostname# show ipv6 ospf summary-prefix
OSPFv3 Process 1, Summary-prefix:
2001:1::/64, Metric 20, Type 2, Tag 0, Match count 5, advertise
```

Table 1-8 Output Fields of the show ipv6 ospf summary-prefix Command

Field	Description
Summary-prefix	Prefix of a summarized route
Metric	Metric of a summarized route
Type	Type of a summarized route
Match count	Number of summarized routes
Advertise	Advertisement after summarization
Tag	Tag of a summarized route

1.51 show ipv6 ospf virtual-links

Function

Run the **show ipv6 ospf virtual-links** command to display virtual link information of an OSPFv3 process.

Syntax

show ipv6 ospf [*process-id*] **virtual-links**

Parameter Description

process-id: OSPFv3 process ID. The value range is from 1 to 65535.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays virtual link information of OSPFv3.

```
Hostname> enable
Hostname# show ipv6 ospf virtual-links
Virtual Link VLINK1 to router 1.1.1.1 is up
  Transit area 0.0.0.1 via interface GigabitEthernet 0/1, instance ID 0
  Local address 2001::2/128
  Remote address 2001::1/128
  Transmit Delay is 1 sec, State Point-To-Point,
  Timer intervals configured, Hello 10, Dead 40, Wait 40, Retransmit 5
    Hello due in 00:00:08
Adajcency state Full
```

Table 1-10 Output Fields of the show ipv6 ospf virtual-links Command

Field	Description
Virtual Link VLINK1 to router	Neighbor and neighbor state of a virtual link
Transit area	Transmission area of a virtual link
via interface	Interface associated with a virtual link
Local address	Address of the local interface

Field	Description
Remote address	Address of the peer interface
Transmit Delay	Transmission delay of a virtual link
State	Network type of a virtual link
Timer intervals configured	Timer of a virtual link, including Hello, Dead, and Retransmit
Hello due in	Hello packet sending interval
Adjacency state	Neighbor state of a virtual link

1.52 summary-prefix

Function

Run the **summary-prefix** command to configure a summarized route for the external routes of an OSPFv3 routing domain.

Run the **no** form of this command to restore the default configuration.

Route summarization is disabled by default.

Syntax

summary-prefix *ipv6-prefix*/*prefix-length* [[**cost** *cost* | **tag** *tag-value*] * | **not-advertise**]

no summary-prefix *ipv6-prefix*/*prefix-length* [[**cost** | **tag**] ***** | **not-advertise**]

Parameter Description

ipv6-prefix/prefix-length: Range of IP addresses to be summarized.

cost *cost*: Configures a cost value of the summarized routes. The value range is from 0 to 16777214. The default metric value is the minimum cost value of the summarized routes.

tag *tag-value*: Specifies the tag value of the route that is redistributed to an OSPFv3 routing domain. The value range is from 0 to 4294967295.

not-advertise: Does not advertise this summarized route to neighbors. If this parameter is not specified, this summarized route is advertised.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

When routes are redistributed from other routing processes and injected to the OSPFv3 routing process, each route is advertised to the OSPFv3 routers using an external LSA. If the injected routes are a continuous address space, the ASBR can advertise only one summarized route to reduce the size of the routing table.

While **area range** summarizes the routes between OSPFv3 areas, **summary-prefix** summarizes external routes of the OSPFv3 routing domain.

When configured on the NSSA ABR translator, **summary-prefix** summarizes redistributed routes and routes obtained based on the LSAs that are translated from Type 7 to Type 5. When configured on the ASBR (not an NSSA ABR translator), **summary-prefix** summarizes only redistributed routes.

Examples

The following example summarizes external routes of the OSPFv3 routing domain as 2001:DB8::/64 and advertises the routes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# summary-prefix 2001:db8::/64
```

1.53 timers lsa arrival

Function

Run the **timers lsa arrival** command to configure the delay for receiving same LSAs.

Run the **no** form of this command to restore the default configuration.

By default, the delay for receiving a duplicate LSA is **1000** ms.

Syntax

timers lsa arrival *arrival-time*

no timers lsa arrival

Parameter Description

arrival-time: Delay for receiving same LSAs, in milliseconds. The value range is from 0 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

No processing is performed if the same LSAs are received within the specified time to avoid resource consumption.

Examples

The following example sets the delay for receiving the same LSAs to **2** seconds at least.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# timers lsa arrival 2000
```

1.54 timers pacing lsa-group

Function

Run the **timers pacing lsa-group** command to configure a group update time of LSAs.

Run the **no** form of this command to restore the default configuration.

The default group refresh time of LSAs is **30** seconds.

Syntax

timers pacing lsa-group *update-time*

no timers pacing lsa-group

Parameter Description

update-time: Group update time of LSAs, in seconds. The value range is from 10 to 1800.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Every LSA has a time to live (LSA age). When the LSA age reaches 1800s, the LSA age must be updated to prevent LSAs from being cleared because their age reaches the maximum time to live. If LSA update and aging computation are performed for every LSA, the device will consume a lot of CPU resources.

To use CPU resources effectively, you can refresh LSAs by group on the device. The interval of group refreshment is called group pacing interval. The group refreshment operation is to organize the LSAs generated within a group pacing interval into a group and refresh the group as a whole.

If the total number of LSAs does not change, a larger group pacing interval indicates that more LSAs need to be processed after timeout. To maintain the CPU stability, the number of LSAs to be processed upon each timeout cannot be too large. If the number of LSAs is large, you are advised to reduce the group pacing interval. For example, if there are 10,000 LSAs in the database, you can reduce the pacing interval; if there are 40 to 100 LSAs, you can set the pacing interval to 10-20 minutes.

Examples

The following example sets the LSA group refresh time to 120 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# timers pacing lsa-group 120
```

1.55 timers pacing lsa-transmit

Function

Run the **timers pacing lsa-transmit** command to configure the LSA group sending interval.

Run the **no** form of this command to restore the default configuration.

The default LSA group sending interval is **40** ms, and the number of LS-UPD packets in each group is **1**.

Syntax

timers pacing lsa-transmit *transmit-time transmit-count*

no timers pacing lsa-transmit

Parameter Description

transmit-time: LSA group sending interval, in milliseconds. The value range is from 10 to 1000.

transmit-count: Number of LS-UPD packets in each group. The value range is from 1 to 200.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If the number of LSAs is large and the device load is heavy in an environment, properly configuring *transimit-time* and *transimit-count* can limit the number of LS-UPD packets flooded in the network.

If the CPU usage is not high and the network bandwidth load is not heavy, reducing the value of *transimit-time* and increasing the value of *transimit-count* can accelerate the environment convergence.

Examples

The following example sets the LSA group sending interval to **50** ms and the number of LS-UPD packets in each group to **20**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# timers pacing lsa-transmit 50 20
```

1.56 timers spf

Function

Run the **timers spf** command to configure the delay time for SPF computation after an OSPFv3 process receives the topological change information and the interval between two SPF computations.

Run the **no** form of this command to restore the default configuration.

By default, the **timers spf** command does not take effect, and the delay for SPF computation is subject to the default configuration of the **timers throttle spf** command. Refer to the description of the **timers throttle spf** command.

Syntax

timers spf *spf-delay spf-holdtime*

no timers spf

Parameter Description

spf-delay: Delay for SPF computation, in seconds. After receiving the topological change information, the OSPF routing process must wait for the specified time before performing SPF computation. The value range is from 0 to 2147483647.

spf-holdtime: Interval between two SPF computations, in seconds. If the delay time expires but the interval between two SPF computations does not expire, SPF computation still cannot be performed. The value range is from 0 to 2147483647.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Changes to LSDB will trigger SPF computation. Frequent network jitter will consume a lot of CPU resources. Setting a proper delay for SPF computation can avoid occupying excessive device memory and bandwidth resources.

Smaller values of *spf-delay* and *spf-holdtime* mean that the OSPF can adapt to topological changes more quickly. In other words, a shorter network convergence time means that more CPU time of the router will be occupied.

The configurations of **timers spf** and **timers throttle spf** are mutually overwritten.

Examples

The following example sets the delay time for SPF computation to **3** seconds after an OSPFv3 process receives the topological change information, and sets the interval between two SPF computations to **9** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 20
Hostname(config-router)# timers spf 3 9
```

1.57 timers throttle lsa all

Function

Run the **timers throttle lsa all** command to configure an exponential backoff algorithm of LSA packet generation.

Run the **no** form of this command to restore the default configuration.

The default minimum delay of LSA generation is **0** ms, the minimum interval between the first update and the second update of LSA is **5000** ms, and the maximum interval between consecutive LSA updates is **5000** ms.

Syntax

timers throttle lsa all *delay-time hold-time max-wait-time*

no timers throttle lsa all

Parameter Description

delay-time: Minimum delay for LSA generation, in milliseconds. The first LSA in the database is always generated instantly. The value range is from 0 to 600000.

hold-time: Minimum interval between the first LSA update and the second LSA update, in milliseconds. The value range is from 0 to 600000.

max-wait-time: Maximum interval between two LSA updates when the LSA is updated continuously, in milliseconds. This interval is also used to determine whether the LSA is updated continuously. The value range is from 0 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If a high convergence requirement is raised when a link changes, you can set *delay-time* to a smaller value. You can also appropriately increase the values of the preceding parameters to reduce the CPU usage. When this command is used for configuration, the value of *hold-time* cannot be smaller than the value of *delay-time*, and the value of *max-wait-time* cannot be smaller than the value of *hold-time*.

Examples

The following example sets the minimum delay of LSA generation to **10** ms, the minimum interval between the first update and the second update to **1** second, and the maximum interval between two LSA updates to **5** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# timers throttle lsa all 10 1000 5000
```

Notifications

If the configured value of *max-wait-time* is smaller than that of *hold-time*, the following notification will be displayed:

```
% Warning: max-wait-time should be no less than hold-time, set to (5)
```

If the configured value of *hold-time* is smaller than that of *delay-time*, the following notification will be displayed:

```
% Warning: hold-time should be no less than delay-time, set to (5).
```

Common Errors

- The configured value of *hold-time* is smaller than that of *delay-time* or the configured value of *max-wait-time* is smaller than that of *hold-time*.

1.58 timers throttle route

Function

Run the **timers throttle route** command to configure the delay time for route computation when an OSPFv3 process receives changed inter-area and external LSAs.

Run the **no** form of this command to restore the default configuration.

The default delay for inter-area route computation and external route computation is **0** ms.

Syntax

timers throttle route { **ase** *ase-delay* | **inter-area** *ia-delay* }

no timers throttle route { **ase** | **inter-area** }

Parameter Description

ase: Indicates external route computation.

ase-delay: Delay for external route computation, in milliseconds. When the OSPF process receives external LSA change information, the route computation triggered should be performed at least after the ase-delay for external route computation elapses. The value range is from 0 to 600000.

inter-area: Indicates inter-area route computation.

ia-delay: Delay for inter-area route computation, in milliseconds. When the OSPF process receives inter-area LSA change information, the route computation triggered should be performed at least after the ia-delay for inter-area route computation elapses. The value range is from 0 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

If a strict requirement is raised for the network convergence time, use the default value.

If a lot of inter-area or external routes exist in the network and the network is not stable, adjust the delays and optimize route computation to reduce the load on the device.

Examples

The following example sets the delay for inter-area route computation to **1** second.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# timers throttle route inter-area 1000
```

1.59 timers throttle spf

Function

Run the **timers throttle spf** command to configure the delay time for SPF computation when an OSPFv3 process receives topological change information, and the minimum and maximum intervals for two SPF computations.

Run the **no** form of this command to restore the default configuration.

The default delay for SPF computation is **1000** ms, the minimum interval for two SPF computations is **5000** ms, and the maximum interval between two SPF computations is **10000** ms.

Syntax

timers throttle spf *spf-delay spf-holdtime spf-max-waittime*

no timers throttle spf

Parameter Description

spf-delay: Delay for SPF computation, in milliseconds. When the OSPF process receives topological change information, the SPF computation triggered should be performed at least after the spf-delay for SPF computation elapses. The value range is from 1 to 600000.

spf-holdtime: Minimum interval between two SPF computations, in milliseconds. The value range is from 1 to 600000.

spf-max-waittime: Maximum interval between two SPF computations, in milliseconds. The value range is from 1 to 600000.

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

Here, *spf-delay* indicates the minimum time between the occurrence of a topology change and the start of SPF computation. *spf-holdtime* indicates the minimum interval between the first and second SPF computations. After that, the interval between two SPF computations must be at least twice of the previous interval. When the interval reaches *spf-max-waittime*, the interval cannot increase again. If the interval between two SPF computations already exceeds the required minimum value, the interval for SPF computation is computed starting from *spf-holdtime*.

You can set *spf-delay* and *spf-holdtime* to values smaller than the default values to accelerate topology convergence. The value of *spf-max-waittime* can be set to a larger value to reduce SPF computation. Flexible settings can be used based on stability of the network topology.

Compared with the **timers spf** command, this command supports more flexible settings to accelerate SPF computation convergence and further reduce the system resources consumed by SPF computation when the topology continuously changes. Therefore, you are advised to use the **timers throttle spf** command for configuration.

Notes:

- The value of *spf-holdtime* cannot be smaller than that of *spf-delay*; otherwise, the value of *spf-holdtime* will be automatically set to the value of *spf-delay*.
- The value of *spf-max-waittime* cannot be smaller than that of *spf-holdtime*; otherwise, *spf-max-waittime* will be automatically set to the value of *spf-holdtime*.
- The configurations of **timers throttle spf** and **timers spf** are mutually overwritten.
- When both **timers throttle spf** and **timers spf** are not configured, the default values of **timers throttle spf** prevail.

Examples

The following example sets the delay for SPF computation, hold time, and maximum interval for two SPF computations to 5 ms, 1000 ms, and 90000 ms, respectively. If the topology continuously changes, the delay for SPF computation is set to 5 ms, 1s, 3s, 7s, 15s, 31s, 63s, 89s, 179s, and (179+90)s..., respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 20
Hostname(config-router)# timers spf 5 1000 90000
```

Notifications

If the configured value of *max-wait-time* is smaller than that of *hold-time*, the following notification will be displayed:

```
% Warning: max-wait-time should be no less than hold-time, set to (5).
```

If the configured value of *hold-time* is smaller than that of *delay-time*, the following notification will be displayed:

```
% Warning: hold-time should be no less than delay-time, set to (5).
```

1.60 two-way-maintain

Function

Run the **two-way-maintain** command to enable the two-way maintenance function of OSPFv3.

Run the **no** form of this command to disable this function.

The two-way maintenance function of OSPFv3 is enabled by default.

Syntax

two-way-maintain

no two-way-maintain

Parameter Description

N/A

Command Modes

Routing process configuration mode

Default Level

14

Usage Guidelines

In a large network, a lot of packets may be sent or received, occupying too much CPU and memory. As a result, some packets are delayed or discarded. If the processing time of Hello packets exceeds the neighbor dead interval, the adjacency will be destroyed due to timeout. If the two-way maintenance function is enabled, in addition to the hello packets, the DD, LSU, LSR, and LSAck packets from a neighbor can also be used to maintain the bidirectional communication between neighbors when a large number of packets exist in the network. This prevents termination of the adjacency caused by delayed or discarded hello packets.

Examples

The following example enables the two-way maintenance function of an OSPF process.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf 1
Hostname(config-router)# no two-way-maintain
```

1 IS-IS Commands

Command	Function
address-family ipv6	Enter the IS-IS IPv6 address family configuration mode.
adjacency-check	Enable the neighbor supported protocol detection function in Hello packets.
area-password	Configure plaintext authentication password of Level-1 areas.
authentication key-chain	Configure a key chain for IS-IS authentication.
authentication mode	Enable an IS-IS authentication mode.
authentication send-only	Apply a specified IS-IS authentication mode to only sent packets. Received packets are not authenticated.
bandwidth-reference	Configure the reference bandwidth value of IS-IS.
bfd all-interfaces	Enable BFD for IS-IS interfaces.
clear clns neighbors	Clear all neighbor relationship tables of IS-IS.
clear isis *	Clear all data structures of IS-IS.
clear isis counter	Clear statistical information of IS-IS.
default-information originate	Generate a default route and advertise the route in LSPs.
distance	Configure the administrative distance of an IS-IS route.
domain-password	Configure plaintext authentication password of Level-2 areas.
enable mib-binding	Bind an IS-IS instance for SNMP operation.
enable traps	Enable the trap message sending function of IS-IS.
exit-address-family	Exit the IS-IS IPv6 address family configuration mode and go back to the IS-IS routing process configuration mode.
graceful-restart	Enable the GR capability of IS-IS.
graceful-restart grace-period	Configure the maximum GR interval of a device.

graceful-restart helper disable	Disable the IS-IS GR Helper capability.
hello padding	Enable padding specified IS-IS Hello packets.
hostname dynamic	Replace the system ID of a device with the host name of the destination device.
ignore-lsp-errors	Ignore LSP checksum errors.
interfaces-protocol-compatible	Pad the TLV field of the IS-IS protocol based on protocols supported by an interface.
ip router isis	Enable the IPv4 IS-IS routing function on an interface.
ipv6 router isis	Enable the IPv6 IS-IS routing function on an interface.
isis authentication key-chain	Configure a key chain for IS-IS interface authentication.
isis authentication mode	Enable an authentication mode of an IS-IS interface.
isis authentication send-only	Apply a specified IS-IS interface authentication mode to only sent packets. Received packets are not authenticated.
isis bfd	Enable IS-IS correlation with BFD on an interface.
isis circuit-type	Configure an IS-IS level on an interface.
isis csnp-interval	Specify the CSNP broadcast interval on an IS-IS interface.
isis hello padding	Enable padding IS-IS hello packets sent on an IS-IS interface.
isis hello-interval	Configure the hello packet sending interval on an interface.
isis hello-multiplier	Configure the multiplier of the hello holdtime on an interface.
isis lsp-flood	Configure the maximum number of LSP packets sent by the IS-IS interface at a time.
isis lsp-interval	Configure the LSP sending interval on an interface.
isis mesh-group	Add an IS-IS interface to a specified mesh group.
isis metric	Configure the metric for an IS-IS interface.

isis network point-to-point	Change the type of an interface from broadcast to P2P.
isis passive	Configure an interface as a passive interface.
isis password	Configure the password for plaintext authentication of hello packets on an interface.
isis priority	Configure the priority for DIS election in a LAN.
isis psnp-interval	Configure the minimum PSNP sending interval.
isis retransmit-interval	Configure the LSP retransmission interval on an IS-IS interface.
isis subvlan	Enable the IS-IS function in a super VLAN.
isis suppress on-neighbor-up	Suppress routing calculation after an IS-IS neighbor is up.
isis three-way-handshake disable	Disable three-way handshake of a P2P network.
isis wide-metric	Configure the wide metric value for an interface.
is-name	Replace the system ID of an instance with the configured name.
is-type	Specify the level at which IS-IS runs.
log-adjacency-changes	Record neighbor state changes of IS-IS without enabling the debug command.
lsp-fragments-extend	Enable fragment extension.
lsp-gen-interval	Configure an exponential backoff algorithm of LSP generation.
lsp-length originate	Configure the maximum length of sent LSPs.
lsp-length receive	Configure the maximum length of received LSPs.
lsp-refresh-interval	Configure the LSP refresh interval.
max-area-addresses	Configure the maximum number of area addresses.
maximum-paths	Configure the maximum number of IS-IS equal-cost paths to be added to a routing table.
max-lsp-lifetime	Configure the maximum LSP lifetime.
max-metric on-neighbor-up	Configure the maximum metric for the directly-connected routes after the first neighbor is up.

metric-style	Configure a metric type.
min-lsp-arrival	Configure the delay for receiving duplicate LSPs.
multi-topology	Configure IS-IS to support IPv6 unicast topologies. After that, IPv4 and IPv6 unicast routes in IS-IS will be calculated based on different topologies.
net	Configure a NET address in IS-IS.
nsr	Enable the NSR function for current IS-IS instance.
passive-interface	Configure a passive interface.
redistribute	Redistribute other routes to IS-IS.
redistribute isis level-1 into level-2	Redistribute the Level-1 reachable routing information of the specified IS-IS instance to Level-2 of the current instance.
redistribute isis level-2 into level-1	Redistribute the Level-2 reachable routing information of the specified IS-IS instance to Level-1 of the current instance.
router isis	Create an IS-IS instance.
set-overload-bit	Prevent neighbors from using the local IS-IS node as a forwarding device to forward data.
show clns is-neighbors	Display all IS-IS neighbors and provide device adjacency relationship information.
show clns neighbors	Display all IS-IS neighbors and provide device information and adjacency relationship information about terminals.
show isis counter	Display statistical information of IS-IS.
show isis database	Display the information of an LSP database.
show isis graceful-restart	Display the state information about IS-IS GR.
show isis hostname	Display the mapping of a host name to a system ID.
show isis interface	Display details of an IS-IS interface.
show isis ipv6 topology	Display the IPv6 unicast topology information of an IS-IS device.
show isis mesh-groups	Display the mesh group configuration of interfaces.
show isis neighbors	Display neighbor information of IS-IS.
show isis nsr	Display NSR information of IS-IS.

show isis protocol	Display protocol information of IS-IS.
show isis topology	Display the topology information of connected IS-IS devices.
show isis virtual-neighbors	Display virtual system neighbor information of IS-IS.
spf-interval	Configure the exponential backoff algorithm of SPF calculation.
summary-address	Configure IPv4 summarized routes.
summary-prefix	Configure IPv6 summarized routes.
two-way-maintain	Enable the two-way maintenance function of IS-IS.
virtual-system	Configure an additional system ID for fragment extension.
vrf	Bind an IS-IS instance to a VRF table.

1.1 address-family ipv6

Function

Run the **address-family ipv6** command to enter the IS-IS IPv6 address family configuration mode.

Run the **no** form of this command to remove this configuration.

A device does not enter the IPv6 address family configuration mode by default.

Syntax

address-family ipv6 [**unicast**]

no address-family ipv6 [**unicast**]

Parameter Description

unicast: Specifies to use the IPv6 unicast address prefix of the IPv6 address family. This parameter is optional and does not make any difference no matter whether it is configured.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Run this command to enter the IS-IS IPv6 address family configuration mode. Special IS-IS IPv6 configuration can be made in this mode.

To exit the IS-IS IPv6 address family configuration mode, run the **exit-address-family** command.

Examples

The following example enters the IS-IS IPv6 address family configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# address-family ipv6 unicast
```

1.3 area-password

Function

Run the **area-password** command to configure plaintext authentication password of Level-1 areas.

Run the **no** form of this command to remove this configuration.

The authentication password configuration function is disabled by default.

Syntax

area-password [**0** | **7**] *password-string* [**send-only**]

no area-password [**send-only**]

Parameter Description

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

password-string: Password string for plaintext authentication. The string can contain up to 126 characters.

send-only: Indicates that the plaintext authentication password is only used to authenticate sent Hello packets in Level-1 areas. Received Hello packets are not authenticated.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

Run this command to enable authentication of received LSPs, CSNPs, and PSNPs in Level-1 areas and include authentication information in these packets before they are sent. All IS-IS devices in an area must be configured with the same *password-string*.

This command does not take effect if the **authentication mode** command is executed. You need to first delete the previous command configuration.

To delete the password, run the **no area-password** command. If you run the **no area-password send-only** command, only the **send-only** setting is canceled. If you run the **area-password** *psw* **send-only** and **no area-password send-only** commands in sequence, the configuration is changed to **area-password** *psw*.

Examples

The following example sets the plaintext authentication password of Level-1 areas to **redgiant** and applies the password to only sent packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
```

```
Hostname(config-router)# area-password redgiant send-only
```

Notifications

If authentication is configured using the **authentication mode** command, the following notification will be displayed:

```
% Please configure password using authentication command.
```

1.4 authentication key-chain

Function

Run the **authentication key-chain** command to configure a key chain for IS-IS authentication.

Run the **no** form of this command to remove this configuration.

The authentication key chain function is disabled by default.

Syntax

authentication key-chain *name-of-chain* [**level-1** | **level-2**]

no authentication key-chain *name-of-chain* [**level-1** | **level-2**]

Parameter Description

name-of-chain: Name of a key chain. The maximum length is 255.

level-1: Indicates that the authentication key chain takes effect for Level-1.

level-2: Indicates that the authentication key chain takes effect for Level-2.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Authentication is not performed if no key chain is configured using the **key chain** command.

(1) If the **authentication mode** command is run with this command, the authentication type configured in the **authentication mode** command is used as an encryption and authentication type, and the key specified by the key-chain is used as an authentication key. You can run the **authentication mode** command to specify the authentication mode.

(2) If only this command is run, the authentication type specified by the key-chain is used as an encryption and authentication type, and the key specified by the key-chain is used as an authentication key. You can run the **key chain** command to specify the authentication mode.

For plaintext authentication, the key-string in the key chain cannot exceed 80 characters; otherwise, the key chain will be invalid.

Only one key chain can be used at a time. After you configure a new key chain, it will replace the original one.

If no Level is specified, the key chain takes effect for Level-1 and Level-2.

The key chain is applicable to LSPs, CSNPs, and PSNPs. IS-IS will send or receive passwords that belong to the key chain.

A key chain may contain multiple passwords. A password with a smaller SN is preferentially used for sending a packet. When the packet arrives at the peer device, the device will receive the packet if the packet-carried password is consistent with a password in the key chain.

If key chain authentication is configured and the authentication type specified in the key chain is SM3, the range of Algorithm-ID is 0 to 255. If the Algorithm-ID exceeds the range, IS-IS packets do not carry TLV information for authentication. In this case, local authentication and checking will fail.

Examples

The following example specifies the Level-1 key chain with the name kc for IS-IS authentication.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# authentication key-chain kc level-1
```

Function

Run the **authentication mode** command to enable an IS-IS authentication mode.

Run the **no** form of this command to disable this mode.

The authentication mode function is disabled by default.

Syntax

authentication mode { **md5** | **text** } [**level-1** | **level-2**]

no authentication mode { **md5** | **text** } [**level-1** | **level-2**]

Parameter Description

md5: Specifies the MD5 authentication mode.

text: Specifies the plaintext authentication mode.

level-1: Specifies that the authentication mode takes effect for Level-1.

level-2: Specifies that the authentication mode takes effect for Level-2.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If no Level is specified, the authentication mode will take effect for Level-1 and Level-2.

If you use the **authentication mode** command after the **area-password** or **domain-password** command is executed to configure plaintext authentication, the previous command configuration will be overwritten.

The **area-password** or **domain-password** command does not take effect if the **authentication mode** command is executed. To run the **area-password** or **domain-password** command, delete the **authentication mode** command configuration first.

Examples

The following example specifies the IS-IS authentication mode as MD5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# authentication mode md5 level-1
```

1.6 authentication send-only

Function

Run the **authentication send-only** command to apply a specified IS-IS authentication mode to only sent packets. Received packets are not authenticated.

Run the **no** form of this command to restore the default configuration.

Packets sent and received are authenticated by default.

Syntax

authentication send-only [**level-1** | **level-2**]

no authentication send-only [**level-1** | **level-2**]

Parameter Description

level-1: Applies authentication to only the sent packets on Level-1.

level-2: Applies authentication to only the sent packets on Level-2.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Use this command to enable IS-IS to set an authentication password in the Hello packets to be sent. Received packets are not authenticated. You can use this command before you deploy IS-IS authentication on all devices in the network or before you change the authentication password or authentication mode. Before using this command, you should run the **authentication send-only** command. The devices will not authenticate received packets to avoid network flapping during authentication deployment. After authentication is deployed in the entire network, run the **no isis authentication send-only** command to cancel the **send-only** setting.

This command is applicable to plaintext authentication and MD5 authentication. You can run the **authentication mode** command to specify the authentication mode.

If no Level is specified, the authentication mode will take effect for Level-1 and Level-2.

Examples

The following example specifies that IS-IS authentication is performed only on sent packets. Received packets are not authenticated.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# authentication send-only level-1
```

1.7 bandwidth-reference

Function

Run the **bandwidth-reference** command to configure the reference bandwidth value of IS-IS.

Run the **no** form of this command to remove this configuration.

The default reference bandwidth value for cost computation is **100** Mbps.

Syntax

bandwidth-reference *bandwidth*

no bandwidth-reference

Parameter Description

bandwidth: Reference bandwidth value for automatic cost computation of an IS-IS link, in Mbps. The value range is from 1 to 4294967.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If an IS-IS interface is configured with a metric value, the bandwidth value in this command does not involve in cost computation of a link.

Examples

The following example sets the reference bandwidth value of IS-IS to **200** Mbps.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# bandwidth-reference 200
```

1.8 bfd all-interfaces

Function

Run the **bfd all-interfaces** command to enable BFD for IS-IS interfaces.

Run the **no** form of this command to disable this function.

The IS-IS correlation with BFD function is disabled on all interfaces by default.

Syntax

bfd all-interfaces [**anti-congestion**]

no bfd all-interfaces [**anti-congestion**]

Parameter Description

anti-congestion: Indicates the IS-IS BFD anti-congestion option.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

You can enable or disable BFD on an IS-IS interface by using any of the following two methods:

Method 1: Run the [**no**] **bfd all-interfaces** [**anti-congestion**] command in IS-IS routing process configuration mode to enable or disable BFD on all IS-IS interfaces.

Method 2: Run the **isis bfd** [**disable** | **anti-congestion**] command in interface configuration mode to enable or disable BFD on the specified interface.

Normally, BFD sends detection packets at millisecond intervals to detect the link state. When a link exception (such as a disconnected link) occurs, BFD can quickly detect it and instruct IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Then IS-IS recalculates and generates a new route to bypass the abnormal link, thus realizing fast convergence. With many new techniques such as Multi-Service Transport Platform (MSTP) emerging, links become easily congested in peak hours of data communication. In this case, BFD can quickly detect the abnormal link and instruct IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Link switch is performed to bypass the congested link. A Hello packet for IS-IS neighbor detection is sent every 10s and its expiration time is 30s. The Hello packet can still be received normally when BFD detects an exception, and therefore an IS-IS neighbor relationship is reestablished quickly, causing the route to be restored to the congested link. Then BFD detects the abnormal link and link switch is performed again. This process is repeated, which makes the route be switched between the congested link and other links, causing repetitive flapping.

The anti-congestion option is used to avoid route flapping in case of link congestion. After the option is configured, the IS-IS neighbor state is still kept alive when link congestion occurs, but the neighbor reachability information in LSPs is deleted. The route is switched to a normal link. When the congested link is restored, the neighbor reachability information in LSPs is recovered and the route is switched back, which avoids route flapping.

When you run the **bfd all-interfaces [anti-congestion]** command, you must run the **bfd up-dampening** command on the interface. The two commands must be used together. If you run only one command, the anti-congestion feature may not take effect or other network exceptions may occur.

Note

- You must configure a BFD session on the interface before you enable IS-IS correlation with BFD.
- When you run the **bfd up-dampening** command on an interface with IS-IS correlation with BFD, you must run the **bfd all-interfaces [anti-congestion]** command.
- When you run the **bfd all-interfaces** command with the **[anti-congestion]** option selected, run the **bfd up-dampening** command on the interface.

Examples

The following example configures all interfaces running IS-IS protocol to perform BFD for link detection.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis 123
Hostname(config-router)# bfd all-interface
```

1.12 default-information originate

Function

Run the **default-information originate** command to generate a default route and advertise the route in LSPs.

Run the **no** form of this command to remove this configuration.

The default route function is disabled by default.

Syntax

default-information originate [**route-map** *route-map-name*]

no default-information originate

Parameter Description

route-map *route-map-name*: Associates a route map.

Command Modes

IS-IS routing process configuration mode

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

Because Level-2 domains do not generate any default route, use this command to allow a default route to enter a Level-2 domain.

Examples

The following example generates a default route and advertises the route in LSPs.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# default-information originate
Hostname(config-router)# address-family ipv6
Hostname(config-router-af)# default-information originate
```

1.13 distance

Function

Run the **distance** command to configure the administrative distance of an IS-IS route.

Run the **no** form of this command to restore the default configuration.

The default administrative distance of IS-IS is **115**.

Syntax

distance *distance-value*

no distance

Parameter Description

distance-value: Administrative distance of a route. The value range is from 1 to 255.

Command Modes

IS-IS routing process configuration mode

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

If the administrative distance of a route is set to a smaller value, the routing information becomes more trustworthy and the priority of the route in the routing table is higher.

Examples

The following example sets the administrative distance of an IS-IS route to **100** Mbps.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# distance 100
```

1.14 domain-password

Function

Run the **domain-password** command to configure plaintext authentication password of Level-2 areas.

Run the **no** form of this command to remove this configuration.

The Level-2 domain authentication password function is disabled by default.

Syntax

domain-password [**0** | **7**] *password-string* [**send-only**]

no domain-password [**send-only**]

Parameter Description

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

password-string: Password string for plaintext authentication. The string can contain up to 126 characters.

send-only: Indicates that the plaintext authentication password is only used to authenticate sent Hello packets in Level-2 areas. Received Hello packets are not authenticated.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

Run this command to enable authentication of received LSPs, CSNPs, and PSNPs in Level-2 areas and include authentication information in these packets before they are sent. All IS-IS devices in a Level-2 area must be configured with the same *password-string*.

This command does not take effect if the **authentication mode** command is executed. You need to first delete the previous command configuration.

To delete the password, run the **no domain-password** command. If you run the **no domain-password send-only** command, only the **send-only** setting is canceled. If you run the **domain-password** *psw* **send-only** and **no domain-password send-only** commands in sequence, the configuration is changed to **domain-password** *psw*.

Examples

The following example sets the plaintext authentication password of Level-2 domain to **redgiant**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# domain-password redgiant
```

Notifications

If authentication has been configured for Level-2 area by the **authentication mode** command, the following notification will be displayed:

```
% Please configure password using authentication command.
```

1.15 enable mib-binding

Function

Run the **enable mib-binding** command to bind an IS-IS instance for SNMP operation.

Run the **no** form of this command to remove this configuration.

By default, the SNMP operation is performed on the first displayed IS-IS instance.

Syntax

enable mib-binding

no enable mib-binding

Parameter Description

N/A

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

The latest standards stipulate that the MIB operation can be performed on a single instance. By default, the MIB operation is performed on the first displayed IS-IS instance. Because multiple IS-IS instances can be configured, the administrator can use this command to specify the instances on which the MIB operation will be performed.

Examples

The following example binds an instance for IS-IS MIB operation.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# enable mib-binding
```

1.16 enable traps

Function

Run the **enable traps** command to enable the trap message sending function of IS-IS.

Run the **no** form of this command to disable this function.

The IS-IS trap message sending function is disabled by default.

Syntax

enable traps { **all** | *traps set* }

no enable traps { **all** | *traps set* }

Parameter Description

all: Indicates all IS-IS trap messages.

traps set: Trap message type in any set.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

IS-IS packets are classified into 18 types and grouped into several sets based on characteristics, with each set containing several trap message types. To send IS-IS trap messages, run the **snmp-server enable traps isis** command to enable the global trap switch of IS-IS, specify a host to receive IS-IS trap messages, and then run this command to specify the types of IS-IS trap messages that can be sent.

Examples

The following example enables the trap message sending function and sets the IP address of the message receiving host to 10.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server enable traps isis
Hostname(config)# snmp-server host 10.1.1.1 traps version 2c public
Hostname(config)# router isis
```

```
Hostname(config-router)# enable traps all
```

1.18 graceful-restart

Function

Run the **graceful-restart** command to enable the GR capability of IS-IS.

Run the **no** form of this command to disable this capability.

The IS-IS GR capability is enabled by default.

Syntax

graceful-restart

no graceful-restart

Parameter Description

N/A

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Use this command to configure the IS-IS GR capability. As long as the network conditions remain unchanged, IS-IS can be restarted and restored to the pre-restart state without impact on data forwarding.

Examples

The following example enables the IS-IS GR capability.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# graceful-restart
```

1.21 hello padding

Function

Run the **hello padding** command to enable padding specified IS-IS Hello packets.

Run the **no** form of this command to disable this function.

Padding is enabled for hello packets of the LAN and P2P types by default.

Syntax

hello padding [**multi-point** | **point-to-point**]

no hello padding [**multi-point** | **point-to-point**]

Parameter Description

multi-point: Pads the hello packets of the LAN type.

point-to-point: Pads the hello packets of the P2P type.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

By padding hello packets, IS-IS can advertise neighbors of the MTU supported by the local device. You can use this command to enable or disable padding all hello packets sent by the local IS-IS process. You can also use this command to disable padding all hello packets of the LAN type or P2P type.

The **isis hello padding** command applies to padding in interface configuration mode. To disable padding hello packets on a specified interface, disable padding the packets in IS-IS routing process configuration mode or interface configuration mode.

Examples

The following example disables padding hello packets of the P2P type.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# no hello padding point-to-point
```

1.23 ignore-lsp-errors

Function

Run the **ignore-lsp-errors** command to ignore LSP checksum errors.

Run the **no** form of this command to remove this configuration.

LSP checksum errors are processed by default.

Syntax

ignore-lsp-errors

no ignore-lsp-errors

Parameter Description

N/A

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

After receiving an LSP, the local IS-IS router calculates its checksum and compares it with the checksum contained in the LSP. If the two checksums are inconsistent, the LSP will be discarded by default. If you run the **ignore-lsp-errors** command to ignore checksum errors, the LSP will be processed normally despite checksum inconsistency.

Examples

The following example configures to ignore LSP checksum errors.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# ignore-lsp-errors
```

1.24 interfaces-protocol-compatible

Function

Run the **interfaces-protocol-compatible** command to pad the TLV field of the IS-IS protocol based on protocols supported by an interface.

Run the **no** form of this command to restore the default configuration.

The TLV field of the IS-IS protocol is padded based on protocols supported by an interface by default.

Syntax

interfaces-protocol-compatible

no interfaces-protocol-compatible

Parameter Description

N/A

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

In single topology mode, a Ruijie device connects to a device of another vendor, a loopback interface is configured on both devices, both IS-IS IPv4 IS-IS and IPv6 IS-IS are enabled, and only a single protocol stack (IPv4 IS-IS or IPv6 IS-IS) is configured on the interconnected interfaces of the two devices. The device of the other vendor sends TLV#129 (supporting only a single protocol stack) based on interfaces whereas Ruijie device sends TLV#129 (supporting dual protocol stacks) based on instances. As a result, the displayed neighbor status on the device of the other vendor is "Init". Ruijie device failed to establish a neighbor relationship with the device of the other vendor. To solve this issue, this command can be configured to enable neighbor relationship establishment between Ruijie devices and devices of other vendors.

Examples

The following example pads the TLV field of the IS-IS protocol based on protocols supported by an interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# interfaces-protocol-compatible
```

1.25 ip router isis

Function

Run the **ip router isis** command to enable the IPv4 IS-IS routing function on an interface.

Run the **no** form of this command to disable this function.

The IPv4 IS-IS routing function is not enabled on an interface by default.

Syntax

ip router isis [*tag*]

no ip router isis [*tag*]

Parameter Description

tag: Name of an IS-IS instance.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Note

This command must be run to enable the IS-IS function on an interface in an IPv4 network.

An IS-IS instance named tag runs on an interface. If no such instance exists or will be started and initialized in the name of tag, the IS-IS routing function will not be started on this interface.

Use this command to enable an interface to participate in IS-IS IPv4 routing. Use the **no** form of this command to disable the IS-IS routing process on the interface.

If you run the **no ip routing** command in global configuration mode, IS-IS will disable IPv4 routing on all interfaces. That is, the **no ip router isis** [**tag**] command is automatically executed on all interfaces. Other IS-IS settings remain unchanged.

An instance named tag can be started on 255 broadcast network interfaces at most, whereas, it can be started on unlimited number of P2P network interfaces.

Examples

The following example enables the IPv4 IS-IS routing function on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# ip router isis
```

Notifications

If this interface has been added to another IS-IS instance, the following notification will be displayed:

```
% Interface enabled in another area
```

1.26 ipv6 router isis

Function

Run the **ipv6 router isis** command to enable the IPv6 IS-IS routing function on an interface.

Run the **no** form of this command to disable this function.

The IPv6 IS-IS routing function is not enabled on an interface by default.

Syntax

ipv6 router isis [*tag*]

no ipv6 router isis [*tag*]

Parameter Description

tag: Name of an IS-IS instance.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

> **Note**
>
> This command must be run to enable the IS-IS function on an interface in an IPv6 network.

After this command is run, an IS-IS instance named tag runs on an interface. If no such instance exists or will be started and initialized in the name of tag, the IPv6 IS-IS routing function will not be started on this interface.

If you run the **no ipv6 unicast-routing** command in global configuration mode, IS-IS will disable IPv6 routing on all interfaces.

An instance named tag can be started on 255 broadcast network interfaces at most, whereas, it can be started on unlimited number of P2P network interfaces.

Examples

The following example enables the IPv6 IS-IS routing function on an interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# ipv6 router isis
```

1.27 isis authentication key-chain

Function

Run the **isis authentication key-chain** command to configure a key chain for IS-IS interface authentication.

Run the **no** form of this command to remove this configuration.

The IS-IS interface authentication key chain function is disabled by default.

Syntax

isis authentication key-chain *name-of-chain* [**level-1** | **level-2**]

no isis authentication key-chain *name-of-chain* [**level-1** | **level-2**]

Parameter Description

name-of-chain: Name of a key chain. The maximum length is 255.

level-1: Indicates that the authentication key chain takes effect for Level-1.

level-2: Indicates that the authentication key chain takes effect for Level-2.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Authentication is not performed if no key chain is configured using the **key chain** command.

(1) If the **authentication mode** command is run with this command, the authentication type configured in the **authentication mode** command is used as an encryption and authentication type, and the key specified by the key-chain is used as an authentication key. You can run the **authentication mode** command to specify the authentication mode.

(2) If only this command is run, the authentication type specified by the key-chain is used as an encryption and authentication type, and the key specified by the key-chain is used as an authentication key. You can run the **key chain** command to specify the authentication mode.

For plaintext authentication, the key-string in the key chain cannot exceed 80 characters; otherwise, the key chain will be invalid.

Only one key chain can be used at a time. After you configure a new key chain, it will replace the original one.

If no Level is specified, the key chain takes effect for Level-1 and Level-2.

The key chain is applicable to Hello packets. IS-IS will send or receive passwords that belong to the key chain.

A key chain may contain multiple passwords. A password with a smaller SN is preferentially used for sending a packet. When the packet arrives at the peer device, the device will receive the packet if the packet-carried password is consistent with a password in the key chain.

The authentication commands (for example, **authentication key-chain**) executed in IS-IS routing process configuration mode are intended for LSPs and SNPs. They do not take effect for IS-IS interfaces.

If key chain authentication is configured and the authentication type specified in the key chain is SM3, the range of Algorithm-ID is 0 to 255. If the Algorithm-ID exceeds the range, IS-IS packets do not carry TLV information for authentication. In this case, local authentication and checking will fail.

Examples

The following example specifies the key chain with the name kc for authentication on the IS-IS interface TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
```

```
Hostname(config-if-TenGigabitEthernet 0/1)# isis authentication key-chain kc
```

Notifications

N/A

Common Errors

- The key-string in the key chain exceeds 80 characters.

Platform Description

Related Commands

- **isis authentication mode**

1.28 isis authentication mode

Function

Run the **isis authentication mode** command to enable an authentication mode of an IS-IS interface.

Run the **no** form of this command to disable this mode.

The interface authentication mode is disabled by default.

Syntax

isis authentication mode { **md5** | **text** } [**level-1** | **level-2**]

no isis authentication mode { **md5** | **text** } [**level-1** | **level-2**]

Parameter Description

md5: Specifies the MD5 authentication mode.

text: Specifies the plaintext authentication mode.

level-1: Specifies that the interface authentication mode takes effect for Level-1.

level-2: Specifies that the interface authentication mode takes effect for Level-2.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If no Level is specified, the authentication mode will take effect for Level-1 and Level-2.

Run the **authentication mode** command to specify the authentication mode before you can make the key chain configured using the **authentication key-chain** command take effect.

If you use the **isis authentication mode** command after the **isis password** command is executed to configure plaintext authentication, the previous command configuration will be overwritten.

The **isis password** command does not take effect if the **isis authentication mode** command is executed. To run the **isis password** command, delete the **isis authentication mode** command configuration first.

Examples

The following example specifies the Level-2 authentication mode on the IS-IS interface TenGigabitEthernet 0/1 as MD5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis authentication mode md5 level-2
```

1.29 isis authentication send-only

Function

Run the **isis authentication send-only** command to apply a specified IS-IS interface authentication mode to only sent packets. Received packets are not authenticated.

Run the **no** form of this command to restore the default configuration.

Packets sent and received on an interface are authenticated by default.

Syntax

isis authentication send-only [**level-1** | **level-2**]

no isis authentication send-only [**level-1** | **level-2**]

Parameter Description

level-1: Sets **send-only** for Level-1 on an interface.

level-2: Sets **send-only** for Level-2 on an interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Use this command to enable IS-IS to set an authentication password in the Hello packets sent by an interface. Received packets are not authenticated. You can use this command before you deploy IS-IS interface authentication on all devices in the network or before you change the authentication password or authentication mode. After you run the **isis authentication send-only** command, the devices will not authenticate received Hello packets to avoid network flapping when IS-IS interface authentication is deployed. After authentication is deployed in the entire network, run the **no isis authentication send-only** command to cancel the **send-only** setting.

This command is applicable to plaintext authentication and MD5 authentication. You can run the **isis authentication mode** command to specify the authentication mode for an IS-IS interface.

If no Level is specified, the authentication mode will take effect for Level-1 and Level-2 on the interface.

Examples

The following example specifies that Level-1 authentication applies to only sent packets on the IS-IS interface TenGigabitEthernet 0/1. Received packets are not authenticated.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis authentication send-only level-1
```

1.30 isis bfd

Function

Run the **isis bfd** command to enable IS-IS correlation with BFD on an interface.

Run the **no** form of this command to disable this function.

The IS-IS correlation with BFD function is enabled on an interface by default if the **bfd all-interfaces** command is run. The IS-IS correlation with BFD function is not enabled on an interface if the **bfd all-interfaces** command is not run. The anti-congestion option is disabled by default.

Syntax

isis bfd [**anti-congestion** | **disable**]

no isis bfd [**anti-congestion** | **disable**]

Parameter Description

anti-congestion: Indicates the IS-IS BFD anti-congestion option.

disable: Disables IS-IS correlation with BFD on an interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can enable or disable BFD on an IS-IS interface by using any of the following two methods:

Method 1: Run the [**no**] **bfd all-interfaces** [**anti-congestion**] command in IS-IS routing process configuration mode to enable or disable BFD on all IS-IS interfaces.

Method 2: Run the **isis bfd** [**disable** | **anti-congestion**] command in interface configuration mode to enable or disable BFD on the specified interface.

Normally, BFD sends detection packets at millisecond intervals to detect the link state. When a link exception (such as a disconnected link) occurs, BFD can quickly detect it and instruct IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Then IS-IS recalculates and generates a new route to bypass the abnormal link, thus realizing fast convergence. With the introduction of new techniques such as the Multi-Service Transport Platform (MSTP), link congestion tends to occur during peak hours of data communication. BFD quickly detects the link exception and instructs IS-IS to delete the neighbor relationship and the neighbor reachability information in LSPs. Link switch is performed to bypass the congested link. A Hello packet for IS-IS neighbor detection is sent every 10s and its expiration time is 30s. The Hello packet can still be received normally when BFD detects an exception, and therefore an IS-IS neighbor relationship is reestablished quickly, causing the route to be restored to the congested link. Then BFD detects the abnormal link and link switch is performed again. This process is repeated, which makes the route be switched between the congested link and other links, causing repetitive flapping.

The anti-congestion option is used to avoid routing flapping in case of link congestion. After the option is configured, the IS-IS neighbor state is still kept alive when link congestion occurs, but the neighbor reachability information in LSPs is deleted. The route is switched to a normal link. When the congested link is restored, the neighbor reachability information in LSPs is recovered and the route is switched back, which avoids route flapping.

When you run the **bfd all-interfaces [anti-congestion]** command, you must run the **bfd up-dampening** command on the interface. The two commands must be used together. If you run only one command, the anti-congestion feature may not take effect or other network exceptions may occur.

Note

- You must configure a BFD session on the interface before you enable IS-IS correlation with BFD.
- When you run the **bfd up-dampening** command on an interface with IS-IS correlation with BFD, you must run the **bfd all-interfaces [anti-congestion]** command.
- When you run the **bfd all-interfaces** command with the **[anti-congestion]** option selected, run the **bfd up-dampening** command on the interface.

Examples

The following example disables IS-IS correlation with BFD on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# no switchport
Hostname(config-if-TenGigabitEthernet 0/1)# isis bfd disable
```

The following example enables the IS-IS BFD anti-congestion option on TenGigabitEthernet 0/1 and runs the BFD anti-congestion option.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# no switchport
Hostname(config-if-TenGigabitEthernet 0/1)# isis bfd anti-congestion
Hostname(config-if-TenGigabitEthernet 0/1)# bfd up-dampening 60000
```

1.31 isis circuit-type

Function

Run the **isis circuit-type** command to configure an IS-IS level on an interface.

Run the **no** form of this command to restore the default configuration.

An interface runs on Level-1/Level-2 by default.

Syntax

isis circuit-type { **level-1** | **level-1-2** | **level-2-only** [**external**] }

no isis circuit-type

Parameter Description

level-1: Establishes a Level-1 neighbor relationship.

level-2-only: Establishes a Level-2 neighbor relationship.

level-1-2: Establishes a Level-1/Level-2 neighbor relationship.

external: Uses the interface as an external domain interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If **circuit-type** is set to Level-1 or Level-only, IS-IS will only send PDUs at the corresponding level.

If **is-type** is set to **level-1** or **level-only**, the IS-IS instance only processes transactions at the corresponding level. In this case, the interface only sends the PDUs of the same Level specified by the **is-type** and **circuit-type** commands.

If the interface is set to external, the interface is used as an external domain interface and IS-IS will not send PDUs at the corresponding Level.

Examples

The following example sets the level of TenGigabitEthernet 0/1 to level-2-only.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis circuit-type level-2-only
```

1.32 isis csnp-interval

Function

Run the **isis csnp-interval** command to specify the CSNP broadcast interval on an IS-IS interface.

Run the **no** form of this command to restore the default configuration.

CSNPs are sent at an interval of **10** seconds in a broadcast network by default. No CSNPs are sent in a P2P network by default.

Syntax

isis csnp-interval *interval* [**level-1** | **level-2**]

no isis csnp-interval [*interval*] [**level-1** | **level-2**]

Parameter Description

interval: CSNP transmission interval, in seconds. The value range is from 0 to 65535.

level-1: Applies transmission interval only to Level-1 CSNPs.

level-2: Applies transmission interval only to Level-2 CSNPs.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Use this command to change the CSNP interval. By default, the DIS sends CSNPs every 10s in a broadcast network.

In a P2P network, CSNPs are sent only after a neighbor relationship is established. If an interface is configured as **mesh-groups**, CSNP sending interval can be configured. If **csnp-interval** is set to 0, no CSNP is sent.

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 CSNPs.

Examples

The following example sets the CSNP broadcast interval to **20** seconds on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis csnp-interval 20
```

1.33 isis hello padding

Function

Run the **isis hello padding** command to enable padding IS-IS hello packets sent on an IS-IS interface.

Run the **no** form of this command to remove this configuration.

Padding is enabled by default for hello packets sent on an interface.

Syntax

isis hello padding

no isis hello padding

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

By padding hello packets, IS-IS can advertise neighbors of the MTU supported by the local device.

The **hello padding** command applies to padding in IS-IS routing process configuration mode. To disable padding hello packets on a specified interface, disable padding the packets in IS-IS routing process configuration mode or interface configuration mode.

Examples

The following example disables padding IS-IS hello packets on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# no isis hello padding
```

1.34 isis hello-interval

Function

Run the **isis hello-interval** command to configure the hello packet sending interval on an interface.

Run the **no** form of this command to restore the default configuration.

Hello packet are sent at an interval of **10** seconds by default.

Syntax

isis hello-interval { *interval* | **minimal** } [**level-1** | **level-2**]

no isis hello-interval { *interval* | **minimal** } [**level-1** | **level-2**]

Parameter Description

interval: Hello packet sending interval, in seconds. The value range is from 1 to 65535.

minimal: Uses the minimum holdtime **1** second.

level-1: Takes effect for Level-1 Hello packets.

level-2: Takes effect for Level-2 Hello packets.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 LSPs.

Use this command to modify the Hello packet sending interval. Hello packets are sent at an interval of **10** seconds by default. A DIS sends Hello packets at a frequency three times that by non-DIS devices in a broadcast network. If the local device is elected as the DIS on the interface, this interface sends hello packet every 3.3s by default.

The default hello multiplier of an IS-IS interface is **3**. The holdtime in hello packets is the hello-interval multiplied by this multiplier. If the keyword **minimal** is used, the holdtime in hello packets is set to **1**, the hello packet sending interval is the result of one divided by the hello multiplier. If the hello multiplier is set to **4** and the **isis hello-interval minimal** command is executed, the packet sending interval is **250** ms.

CPU protection is enabled by default. For packets sent to each destination group address (AllISSystems, AllL1ISSystems, and AllL2ISSystems), the number of packets sent to the CPU is limited to 400 per second. If a device has many neighbor relationships or sends Hello packets at short intervals, the IS-IS packets that the device receives may exceed the default limit, causing frequent flapping of neighbor relationships. To solve the problem, you can use the CPU protection command in global configuration mode to increase the limit.

Examples

The following example sets the Level-1 hello packet sending interval to **5** seconds on TenGigabitEthernet 0/1.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis hello-interval 5 level-1
```

The following example sets the minimum hello packet holdtime to **1** second on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis hello-interval minimal
```

1.35 isis hello-multiplier

Function

Run the **isis hello-multiplier** command to configure the multiplier of the hello holdtime on an interface.

Run the **no** form of this command to restore the default configuration.

The default multiplier of the hello holdtime on an interface is **3**.

Syntax

isis hello-multiplier *multiplier-number* [**level-1** | **level-2**]

no isis hello-multiplier [*multiplier-number*] [**level-1** | **level-2**]

Parameter Description

multiplier-number: Multiplier of the hello holdtime on an IS-IS interface. The value range is from 2 to 100.

level-1: Takes effect for Level-1 hello packets.

level-2: Takes effect for Level-2 hello packets.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The holdtime in hello packets is equal to the hello-interval multiplied by the hello multiplier.

Examples

The following example sets the multiplier of the hello holdtime to **5** on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis hello-multiplier 5

Function

Run the **isis lsp-flood** command to configure the maximum number of LSP packets sent by the IS-IS interface at a time.

Run the **no** form of this command to restore the default configuration.

An interface can send a maximum of 5 LSP packets at a time by default.

Syntax

isis lsp-flood *lsp-number* [**level-1** | **level-2**]

no isis lsp-flood [**level-1** | **level-2**]

Parameter Description

lsp-number: Maximum number of LSP packets sent by the IS-IS interface at a time. The value range is from 1 to 1000.

level-1: Takes effect for Level-1 LSPs.

level-2: Takes effect for Level-2 LSPs.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the maximum number of Level-2 LSP packets sent by TenGigabitEthernet 0/1 at a time to **10**.

```
Hostname> enable

1.37 isis lsp-interval

Function

Run the **isis lsp-interval** command to configure the LSP sending interval on an interface.

Run the **no** form of this command to restore the default configuration.

LSPs are sent at an interval of **33** ms by default on an IS-IS interface.

Syntax

isis lsp-interval *pdu-interval* [**level-1** | **level-2**]

no isis lsp-interval [**level-1** | **level-2**]

Parameter Description

pdu-interval: LSP sending interval, in milliseconds. The value range is from 1 to 4294967295.

level-1: Takes effect for Level-1 LSPs.

level-2: Takes effect for Level-2 LSPs.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 LSPs.

Examples

The following example sets the Level-2 LSP sending interval to **100** ms on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1

1.38 isis mesh-group

Function

Run the **isis mesh-group** command to add an IS-IS interface to a specified mesh group.

Run the **no** form of this command to remove this configuration.

No interface joins any mesh group by default.

Syntax

isis mesh-group { **blocked** | *mesh-group-id* }

no isis mesh-group

Parameter Description

blocked: Blocks all LSP forwarding on this interface.

mesh-group-id: ID of a mesh group an interface joins. The value range is from 1 to 4294967295.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Mesh-groups can control transitional and redundant LSPs in an NBMA network. In normal cases, an IS-IS device advertises LSPs from all other interfaces except the packet receiving interface. If a device is configured with multiple interfaces, LSPs will be sent from all these interfaces. In this case, neighbors will receive duplicate LSPs. This wastes a huge amount of CPU and bandwidth resources.

The IS-IS mesh group allows a device to group interfaces. If an LSP is received by any interface in a group, this LSP will not be advertised by other interfaces in the group. If the LSP is received from an interface out of the group, the LSP will be advertised from other interfaces as usual.

When you need to set **mesh-group** on an IS-IS interface, run the **isis csnp-interval** command to configure the non-0 CSNP sending interval to ensure complete LSP synchronization between neighbors in the network. After that, CNSPs will be periodically sent to synchronize LSPs.

Examples

The following example adds the IS-IS interface TenGigabitEthernet 0/1 to a specified mesh group 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis mesh-group 1
```

1.39 isis metric

Function

Run the **isis metric** command to configure the metric for an IS-IS interface.

Run the **no** form of this command to configure the metric for an IS-IS interface as a default value.

Level-1 and Level-2 use the computation result of **bandwidth-reference** by default.

Syntax

isis metric *metric* [**level-1** | **level-2**]

no isis metric [*metric*] [**level-1** | **level-2**]

Parameter Description

metric: Metric value. The value range is from 1 to 63.

level-1: Takes effect for Level-1 circuit type.

level-2: Takes effect for Level-2 circuit type.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The metric value, which is used in IP calculation, is stored in the TLV of the IP reachability information. A greater metric value indicates a greater routing consumption of this interface and a longer path of SPF calculation.

The metric belongs to the narrow type and is valid only when **metric-style** is set to Narrow.

Examples

The following example sets the metric on the IS-IS interface TenGigabitEthernet 0/1 to **1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis metric 1
```

1.40 isis network point-to-point

Function

Run the **isis network point-to-point** command to change the type of an interface from broadcast to P2P.

Run the **no** form of this command to restore the default configuration.

The default type of an interface is broadcast.

Syntax

isis network point-to-point

no isis network [**point-to-point**]

Parameter Description

point-to-point: Configures an interface as a P2P interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Use this command to change the type of an interface from broadcast to P2P. This command is valid to broadcast network interfaces.

If the current interfaces have been configured with the IS-IS protocol and the number of broadcast network interfaces configured with the same IS-IS protocol reaches 255 (for example, **ip router isis** [**tag**] or **ipv6 router isis** [**tag**] is configured, or the interfaces are passive interfaces), this configuration cannot be deleted.

Examples

The following example changes the interface type of TenGigabitEthernet 0/1 from broadcast to P2P.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis network point-to-point
```

1.42 isis password

Function

Run the **isis password** command to configure the password for plaintext authentication of hello packets on an interface.

Run the **no** form of this command to remove this configuration.

Syntax

isis password [**0** | **7**] *password-string* [**send-only**] [**level-1** | **level-2**]

no isis password [**send-only**] [**level-1** | **level-2**]

Parameter Description

0: Indicates that the key is displayed in plaintext.

7: Indicates that the key is displayed in ciphertext.

password-string: Password string for plaintext authentication. The string can contain up to 126 characters.

send-only: Indicates that the plaintext authentication password is only used to authenticate sent packets. Received packets are not authenticated.

level-1: Takes effect for Level-1 circuit type.

level-2: Takes effect for Level-2 circuit type.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If a password is a Type 7 ciphertext password, the password may not be identified when the device version does not support AES128/SHA256. Therefore, before the device version is degraded, you must reconfigure the password as plaintext or a Type 7 ciphertext password that is generated on the earlier device version.

Use this command to configure the password for Hello packet authentication on an interface. Use the **no** form of this command to clear the password.

If no Level is specified by default, the password takes effect for Level-1 and Level-2 circuit types.

This command does not take effect if the **isis authentication mode** command is executed. You need to first delete the previous command configuration.

If you include the **send-only** parameter when deleting the **isis authentication mode** command configuration, only the parameter setting is canceled.

Examples

The following example sets the password for plaintext authentication of hello packets to **redgiant** on an interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis password redgiant
```

Notifications

If authentication is configured using the **isis authentication mode** command, the following notification will be displayed:

```

Run the **isis priority** command to configure the priority for DIS election in a LAN.

Run the **no** form of this command to restore the default configuration.

The default priority of a device for Level-1 and Level-2 DIS election is **64**.

Syntax

isis priority *value* [**level-1** | **level-2**]

no isis priority [*value*] [**level-1** | **level-2**]

Parameter Description

value: Priority for DIS election in a LAN. The value range is from 0 to 127.

level-1: Takes effect for Level-1 circuit type.

level-2: Takes effect for Level-2 circuit type.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Use this command to change the priority in Hello packets in a LAN.

A lower DIS priority of an interface indicates a lower priority of being elected as a DIS.

This command is invalid on a P2P network interface.

The **no isis priority** command, with or without parameters, restores the priority to its default value. To change the configured priority, run the **isis priority** command with the priority specified to overwrite the existing configuration, or you can first restore the priority to its default value and then configure a new priority.

Examples

The following example sets the priority for Level-1 DIS election on TenGigabitEthernet 0/1 to 127.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis priority 127 level-1
```

1.44 isis psnp-interval

Function

Run the **isis psnp-interval** command to configure the minimum PSNP sending interval.

Run the **no** form of this command to remove this configuration.

The function of configuring the PSNP sending interval is disabled by default. In this case, the default minimum PSNP sending interval is **2** seconds and it takes effect for Level-1 and Level-2 PSNPs.

Syntax

isis psnp-interval *psnp-interval* [**level-1** | **level-2**]

no isis psnp-interval [**level-1** | **level-2**]

Parameter Description

psnp-interval: PSNP interval, in seconds. The value range is from 1 to 120.

level-1: Takes effect for Level-1 PSNPs.

level-2: Takes effect for Level-2 PSNPs.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 CSNPs.

PSNPs are mainly used to request LSPs that are absent locally or respond to received LSPs (in a P2P network). The PSNP interval should be minimized. If many LSPs exist and the device performance is low, you can increase the PSNP sending interval and LSP retransmission interval to reduce the device load.

Examples

The following example sets the Level-2 PSNP sending interval to 5 seconds on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis psnp-interval 5 level-2
```

1.45 isis retransmit-interval

Function

Run the **isis retransmit-interval** command to configure the LSP retransmission interval on an IS-IS interface.

Run the **no** form of this command to restore the default configuration.

The default LSP Retransmit-interval is **5** seconds, and it takes effect for Level-1 and Level-2 LSPs.

Syntax

isis retransmit-interval *retransmit-interval* [**level-1** | **level-2**]

no isis retransmit-interval [**level-1** | **level-2**]

Parameter Description

retransmit-interval: Retransmission interval, in seconds. The value range is from 0 to 65535.
level-1: Takes effect for Level-1 LSPs.

level-2: Takes effect for Level-2 LSPs.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 CSNPs.

Use this command to configure the LSP retransmission interval. In a P2P network, after a device sends an LSP, if the device receives no PSNP response within the time specified by retransmit-interval, it will resend the LSP. If the retransmission interval is set to **0**, the LSP will not be resent.

Examples

The following example sets the Level-2 LSP sending interval to **10** seconds on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis retransmit-interval 10 level-2
```

1.46 isis subvlan

Function

Run the **isis subvlan** command to enable the IS-IS function in a super VLAN.

Run the **no** form of this command to restore the default configuration.

The IS-IS function takes effect in super VLAN only and is disabled by default.

Syntax

isis subvlan [**all** | *vlan-id*]

no isis subvlan

Parameter Description

all: Allows sending packets to all sub VLANs

vlan-id: Sub VLAN ID. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

In normal cases, a super VLAN contains multiple sub VLANs. Multicast packets of a super VLAN are also sent to its sub VLANs. In this case, when IS-IS multicast packets are sent over a super VLAN containing multiple sub VLANs, the IS-IS multicast packets are replicated multiple times, which exceeds the processing capability of the device. As a result, a large number of packets are discarded, causing protocol flapping.

In most scenarios, the IS-IS function does not need to be enabled on a super VLAN, and it is disabled by default. However, in some scenarios, the IS-IS function must be run on the super VLAN, but packets need to be sent to only one sub VLAN. In this case, you can decide to send multicast packets to a certain sub VLAN or to all sub VLANs as actually needed. You can use this command to specify a particular sub VLAN. You must be cautious when configuring packet transmission to all sub VLANs, as the large number of sub VLANs may cause a device processing bottleneck, which will lead to the neighbor flapping.

Examples

The following example enables the IS-IS function on super VLAN 300 and allows sending packets to sub VLAN 1024.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface vlan 300
Hostname(config-if-VLAN 300)# isis subvlan 1024
```

Notifications

1.47 isis suppress on-neighbor-up

Function

Run the **isis suppress on-neighbor-up** command to suppress routing calculation after an IS-IS neighbor is up.

Run the **no** form of this command to remove this configuration.

The route calculation suppression function is disabled by default.

Syntax

isis suppress on-neighbor-up *delay-time*

no isis suppress on-neighbor-up

Parameter Description

delay-time: Delay time of suppressing route calculation, in seconds. The value range is from 1 to 60.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After the interface neighbor is up, this command prevents the neighbor reachability information from being added to LSP so as to delay the routing calculation. When the timer expires, the neighbor reachability information is added to LSP to start the routing calculation. This function prevents the route calculation from using the old LSP, which may lead to route flapping.

Examples

The following example suppresses route calculation after the IS-IS neighbor on TenGigabitEthernet 0/1 is up.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis suppress on-neighbor-up 10
```

1.48 isis three-way-handshake disable

Function

Run the **isis three-way-handshake disable** command to disable three-way handshake of a P2P network.

Run the **no** form of this command to enable three-way handshake of a P2P network.

Three-way handshake is performed in a P2P network by default.

Syntax

isis three-way-handshake disable

no isis three-way-handshake disable

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Neighbor establishment in a P2P network requires three-way handshake. The neighbor relationship can be established only after the three-way handshake succeeds. If you want to accelerate neighbor establishment or there is device that does not support three-way handshake, you can run this command to cancel three-way handshake.

Examples

The following example disables three-way handshake on TenGigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis network point-to-point
Hostname(config-if-TenGigabitEthernet 0/1)# isis three-way-handshake disable
```

1.49 isis wide-metric

Function

Run the **isis wide-metric** command to configure the wide metric value for an interface.

Run the **no** form of this command to configure the wide metric value of an interface as a default value.

The default wide metric value of Level-1 and Level-2 is the computation result of **bandwidth-reference**.

Syntax

isis wide-metric *metric* [**level-1** | **level-2**]

no isis wide-metric [*metric*] [**level-1** | **level-2**]

Parameter Description

metric: Metric value. The value range is from 1 to 16777214, and the default value is the computation result of **bandwidth-reference**.

level-1: Takes effect for the Level-1 links.

level-2: Takes effect for the Level-2 links.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The metric value, which is used in IP calculation, is stored in the TLV of the IP reachability information. A greater metric value indicates a greater routing consumption of this interface and a longer path of SPF calculation.

The metric is valid only when **metric-style** is set to **Wide**.

Examples

The following example sets the wide metric value of TenGigabitEthernet 0/1 to **1000**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface tenGigabitEthernet 0/1
Hostname(config-if-TenGigabitEthernet 0/1)# isis wide-metric 1000
```

1.50 is-name

Function

Run the **is-name** command to replace the system ID of an instance with the configured name.

Run the **no** form of this command to remove this configuration.

The name customization function is disabled by default.

Syntax

is-name *name*

no is-name

Parameter Description

name: Alias of an instance, which is a string of a maximum of 64 characters.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Use this command to replace the system ID of an instance with the configured name. The system IDs that can be displayed by running the **show isis database** and **show isis neighbors** commands are replaced with the configured name.

Examples

The following example replaces the system ID of an instance with dut.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# is-name dut
```

1.51 is-type

Function

Run the **is-type** command to specify the level at which IS-IS runs.

Run the **no** form of this command to restore the default configuration.

IS-IS runs at Level-1/Level-2 by default.

Syntax

is-type { **level-1** | **level-1-2** | **level-2-only** }

no is-type

Parameter Description

level-1: Indicates that IS-IS only runs at Level-1.

level-1-2: Indicates that IS-IS runs at Level-1 and Level-2.

level-2-only: Indicates that IS-IS only runs at Level-2.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Changing the IS-IS type will enable or disable the routes of the corresponding level.

Examples

The following example enables IS-IS to only run at Level-1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# is-type level-1
```

1.52 log-adjacency-changes

Function

Run the **log-adjacency-changes** command to record neighbor state changes of IS-IS without enabling the **debug** command.

Run the **no** form of this command to disable this function.

The function of recording neighbor state changes of IS-IS is enabled by default without the **debug** command.

Syntax

log-adjacency-changes

no log-adjacency-changes

Parameter Description

N/A

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Using the **debug** command to record neighbor state changes of IS-IS will consume a great amount of system resources. Run this command to record neighbor state changes of IS-IS without enabling the **debug** command.

Examples

The following example records neighbor state changes of IS-IS without enabling the **debug** command.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# log-adjacency-changes
```

1.53 lsp-fragments-extend

Function

Run the **lsp-fragments-extend** command to enable fragment extension.

Run the **no** form of this command to disable this function.

The fragment extension function is disabled by default.

Syntax

lsp-fragments-extend [**level-1** | **level-2**] [**compatible rfc3786**]

no lsp-fragments-extend [**level-1** | **level-2**] [**compatible rfc3786**]

Parameter Description

level-1: Enables LSP fragment extension on Level-1.

level-2: Enables LSP fragment extension on Level-2.

compatible: Indicates compatibility with the RFC version of extended LSPs.

rfc3786: Indicates the old version of extended LSPs.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 CSNPs.

There are up to 256 LSP fragments. When the fragments are used up, subsequent link state information, including neighbor information and IP route information, will be discarded, causing a network exception.

To solve this problem, enable fragment extension at the specified level and configure an additional system ID by using the **virtual-system** command.

When you enable or disable the **compatible** option for a network containing RFC 3786 compliant devices of other vendors, observe the LSDB of the related devices. If there are LSPs affecting network routing existing in the network, run the **clear isis *** command to clear the LSPs and trigger LSDB synchronization.

Examples

The following example enables fragment extension on Level-2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# lsp-fragments-extend level-2
```

1.54 lsp-gen-interval

Function

Run the **lsp-gen-interval** command to configure an exponential backoff algorithm of LSP generation.

Run the **no** form of this command to restore the default configuration.

The default maximum interval of two LSP generations is **5** seconds, the delay of LSP generation is **50** ms, and the maximum interval for the first and second LSP generations is **200** ms. The configuration takes effect for Level-1 and Level-2 LSPs.

Syntax

lsp-gen-interval [**level-1** | **level-2**] *maximum-interval* [*initial-interval hold-interval*]

no lsp-gen-interval [**level-1** | **level-2**]

Parameter Description

level-1: Takes effect for Level-1 IS-IS LSPs.

level-2: Takes effect for Level-2 IS-IS LSPs.

maximum-interval: Maximum interval for generating two consecutive LSPs, in seconds. The value range is from 1 to 65535.

initial-interval: Delay for generating LSPs for the first time, in milliseconds. The value range is 0 to 60000.

hold-interval: Minimum interval for the first and second LSP generations, in milliseconds. The value range is 10 to 60000.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 CSNPs.

The LSP packet generation interval refers to the interval for generating two different LSP packets. A smaller generation interval indicates faster network convergence, which, however, will be accompanied by frequent flooding in the network.

The wait time for generating an LSP packet for the first time is the *initial-interval*. If the network becomes unstable, the LSP packet regeneration interval changes to be less than the *maximum-interval*, and the interval for generating an LSP packet for the second time changes to *hold-interval*. A corresponding penalty will be added to this interval: The next interval for regenerating an LSP packet doubles the previous interval for generating the same LSP packet, until the regeneration interval reaches the *maximum-interval*. Subsequent LSP packets will be generated at the *maximum-interval*. When the network becomes stable, the LSP packet regeneration interval becomes greater than the *maximum-interval*, and the wait time for LSP packet generation is restored to the *initial interval*.

Link changes have high requirements for convergence. The *initial-interval* can be set to a small value. You can also appropriately increase the values of the preceding parameters to reduce the CPU usage.

Note

- The value of the configured *hold-interval* cannot be greater than that of *maximum-interval*. Otherwise, the value of *hold-interval* is changed to that of *maximum-interval*.
- The value of the configured *initial-interval* cannot be greater than that of *hold-interval*. Otherwise, the value of *initial-interval* is changed to that of *hold-interval*.

Examples

The following example configures an exponential backoff algorithm of LSP generation, and sets the maximum interval of two LSP generations to **10** seconds, the wait time of LSP generation for the first time to **100** ms, and the interval for the first and second LSP generations to **200** ms.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# lsp-gen-interval 10 100 200
```

The following example configures an exponential backoff algorithm of LSP generation, sets the maximum interval of two LSP generations to **5** seconds, and uses the default values of other exponential backoff parameters.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# lsp-gen-interval 5
```

Notifications

If the configured value of *hold-interval* is greater than *maximum-interval* (for example, the configured value of *hold-interval* is **1500** ms, and the *maximum-interval* is **1** second), the following notification will be displayed:

```
% ISIS: hold_interval (1500ms) should be no more than maximum_interval (1s), set to
(1000ms).
```

If the configured value of *initial-interval* is greater than *hold-interval* (for example, the configured value of *initial-interval* is **20** ms, and the *hold-interval* is **10** ms), the following notification will be displayed:

```
% ISIS: initial_interval (20ms) should be no more than hold_interval (10ms), set to
(10ms).
```

1.55 lsp-length originate

Function

Run the **lsp-length originate** command to configure the maximum length of sent LSPs.

Run the **no** form of this command to restore the default configuration.

The default maximum length of sent LSPs is **1492** bytes, and it takes effect for Level-1 and Level-2 LSPs.

Syntax

lsp-length originate *size* [**level-1** | **level-2**]

no lsp-length originate [**level-1** | **level-2**]

Parameter Description

size: Maximum length of sent LSPs, in bytes. The value range is from 512 to 16000.

level-1: Takes effect for Level-1 LSPs.

level-2: Takes effect for Level-2 LSPs.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 CSNPs.

In principle, the maximum length of LSPs and SNPs cannot be greater than the interface MTU; otherwise, the packets will be discarded when being sent.

Examples

The following example sets the maximum length of sent LSPs on Level-2 to **1498** bytes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis1
Hostname(config-router)# lsp-length originate 1498 level-2
```

1.56 lsp-length receive

Function

Run the **lsp-length receive** command to configure the maximum length of received LSPs.

Run the **no** form of this command to restore the default configuration.

The default maximum length of received LSPs is **1492** bytes.

Syntax

lsp-length receive *size*

no lsp-length receive

Parameter Description

size: Maximum length of received LSPs, in bytes. The value range is from 1492 to 16000.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Use this command to control the maximum length of LSPs received by the local device. Intermediate nodes with sufficient memory are required to receive LSPs whose maximum length is equal to the interface MTU in order to avoid a route convergence failure. From this perspective, the command is meaningless. The maximum length of received LSPs cannot be smaller than that of sent LSPs; otherwise, the former will be automatically adjusted to be equal to the latter.

Examples

The following example sets the maximum length of received LSPs to **1498** bytes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# lsp-length receive 1498
```

1.57 lsp-refresh-interval

Function

Run the **lsp-refresh-interval** command to configure the LSP refresh interval.

Run the **no** form of this command to restore the default configuration.

The default LSP refresh interval is **900** seconds.

Syntax

lsp-refresh-interval *interval*

no lsp-refresh-interval

Parameter Description

interval: LSP refresh interval, in seconds. The value range is from 1 to 65535.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

After an LSP has remained stable for the time specified by this command, it will be refreshed and then advertised.

The LSP refresh interval must be at least 300 seconds less than the maximum LSP lifetime. If the difference of the configured LSP lifetime *max-lifetime* from the LSP refresh interval *interval* is less than 300s, the value of *max-lifetime* minus 300s is used as the LSP refresh interval.

Examples

The following example sets the LSP refresh interval to **600** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# lsp-refresh-interval 600
```

Notifications

If the difference of the configured LSP lifetime from the LSP refresh interval is less than 300s, for example, the maximum LSP lifetime is 1000 and the LSP refresh interval is 900, the following notification will be displayed:

```
% ISIS: max-lsp-lifetime should be 300s greater than lsp-refresh-interval
% ISIS: set lsp-refresh-interval to 700s
```

1.58 max-area-addresses

Function

Run the **max-area-addresses** command to configure the maximum number of area addresses.

Run the **no** form of this command to restore the default configuration.

The default maximum number of area addresses is **3**.

Syntax

max-area-addresses *max-area- number*

no max-area-addresses

Parameter Description

max-area- number: Maximum number of area addresses. The value range is from 3 to 6.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Generally, an IS-IS process is configured with a Network Entry Title (NET) address. During area reallocation, an IS-IS process can be configured with multiple NET addresses to ensure routing correctness. The system ID of multiple NET addresses must be the same. For Level-1 IS-IS devices, neighbor relationship can be created between the routers only when the maximum numbers of area addresses are the same.

Examples

The following example sets the maximum number of area addresses to **5**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# max-area-addresses 5
```

1.59 maximum-paths

Function

Run the **maximum-paths** command to configure the maximum number of IS-IS equal-cost paths to be added to a routing table.

Run the **no** form of this command to restore the default configuration.

The default maximum number of equal-cost paths is **2**.

Syntax

maximum-paths *maximum*

no maximum-paths

Parameter Description

maximum: Maximum number of IS-IS equal-cost routes to be added to a routing table. The value range is from 1 to 32.

Command Modes

IS-IS routing process configuration mode

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

This command is used by IS-IS to control the number of IS-IS equal-cost paths to be added to a routing table. The routing table also has a command used to control the number of equal-cost paths. The number of effective equal-cost paths is determined by either of the two command values, whichever is smaller.

Examples

The following example sets the maximum number of IS-IS IPv4 equal-cost routes to be added to a routing table to **5**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# maximum-paths 5
```

The following example sets the maximum number of IS-IS IPv6 equal-cost routes to be added to a routing table to **6**.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# address-family ipv6
Hostname(config-router-af)# maximum-paths 6
```

1.60 max-lsp-lifetime

Function

Run the **max-lsp-lifetime** command to configure the maximum LSP lifetime.

Run the **no** form of this command to restore the default configuration.

The default maximum LSP lifetime is **1200** seconds.

Syntax

max-lsp-lifetime *max-lifetime*

no max-lsp-lifetime

Parameter Description

max-lifetime: Maximum LSP lifetime, in seconds. The value range is from 1 to 65535.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

The maximum LSP lifetime must be at least 300s greater than the LSP refresh interval. If the difference of the configured LSP lifetime *max-lifetime* from the LSP refresh interval *interval* is less than 300s, the value of *max-lifetime* minus 300s is used as the LSP refresh interval.

Examples

The following example sets the maximum LSP lifetime to **1200** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# max-lsp-lifetime 1200
```

Notifications

If the difference of the configured maximum LSP lifetime from the LSP refresh interval is less than 300s, for example, the maximum LSP lifetime is 1000 and the LSP refresh interval is 900, the following notification will be displayed:

```
% ISIS: max-lsp-lifetime should be 300s greater than lsp-refresh-interval

1.61 max-metric on-neighbor-up

Function

Run the **max-metric on-neighbor-up** command to configure the maximum metric for the directly-connected routes after the first neighbor is up.

Run the **no** form of this command to remove this configuration.

The metric of the directly-connected route is not modified by default after the first neighbor is up.

Syntax

max-metric on-neighbor-up *delay-time*

no max-metric on-neighbor-up

Parameter Description

delay-time: Delay for configuring the maximum metric for the directly-connected routes after the first neighbor is up, in seconds. The value range is from 5 to 1800.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

In the Overlay scene where IS-IS is applied to Underlay, the Overlay tunnel may rely on Underlay routing. After the IS-IS neighbor is up, the Underlay routing is reachable but the Overlay tunnel may not be created, which

may lead to traffic interruption. In this case, run this command to prevent traffic interruption. According to the metric type, the maximum metric for Narrow is 63 and for Wide is 16777214.

Examples

The following example sets the delay for configuring the maximum metric for the directly-connected routes to **100** seconds after the first neighbor is up.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# max-metric on-neighbor-up 100
```

1.62 metric-style

Function

Run the **metric-style** command to configure a metric type.

Run the **no** form of this command to restore the default configuration.

The narrow metric type is used by default.

Syntax

metric-style { **narrow** | **wide** } [**transition**] [**level-1** | **level-1-2** | **level-2**]

no metric-style { **narrow** | **wide** } [**transition**] [**level-1** | **level-1-2** | **level-2**]

Parameter Description

narrow: Uses the narrow metric type. The value range of interface metrics is from 1 to 63.

wide: Uses the wide metric type. The value range of interface metrics is from 1 to 16777214.

transition: Allows a device to send and receive narrow and wide metric types.

level-1: Takes effect for Level-1 interface.

level-1-2: Takes effect for Level-1 and Level-2 interfaces.

level-2: Takes effect for Level-2 interface.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

When the metric type is Narrow, run the **isis metric** command to configure metric values of an interface.

When the metric type is Wide or Transition, run the **isis wide-metric** command to configure metric values of an interface.

Examples

The following example configures the metric type as Wide.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# metric-style wide
```

1.63 min-lsp-arrival

Function

Run the **min-lsp-arrival** command to configure the delay for receiving duplicate LSPs.

Run the **no** form of this command to remove this configuration.

The function of delaying receiving duplicate LSPs packets is not supported on Level-1 and Level-2 by default.

Syntax

min-lsp-arrival [**level-1** | **level-2**] *minimum-interval initial-interval hold-interval*

no min-lsp-arrival [**level-1** | **level-2**]

Parameter Description

level-1: Takes effect for Level-1 IS-IS LSPs.

level-2: Takes effect for Level-2 IS-IS LSPs.

minimum-interval: Minimum interval for receiving two duplicate LSP packets, in seconds. The value range is from 1 to 120.

initial-interval: Interval for receiving duplicate LSP packets for the first time, in milliseconds. The value range is 0 to 60000.

hold-interval: Minimum interval for receiving duplicate LSP packets for the first and second times, in milliseconds. The value range is 10 to 60000.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 CSNPs.

The interval for receiving duplicate LSP packets for the first time is the *initial-interval*. When the interval for receiving duplicate LSP packets is less than the *minimum-interval*, the interval for receiving duplicate LSP packets for the second time becomes the *hold-interval*. In addition, a corresponding penalty is added to this interval: The next interval for receiving duplicate LSP packets doubles the previous interval for receiving the same LSP packets, until this interval reaches the *minimum-interval*. The interval for receiving duplicate LSP packets is changed to *minimum-interval*. When the network becomes stable, the interval for receiving duplicate LSP packets becomes greater than the *minimum-interval*, and the delay for receiving duplicate LSP packets is restored to the *initial-interval*.

Link changes have high requirements for convergence. The *initial-interval* can be set to a small value. You can also appropriately increase the values of the preceding parameters to reduce the CPU usage.

Note

- The value of the configured *hold-interval* cannot be greater than that of *minimum-interval*. Otherwise, the value of *hold-interval* is changed to that of *minimum-interval*.
- The value of the configured *initial-interval* cannot be greater than that of *hold-interval*. Otherwise, the value of *initial-interval* is changed to that of *hold-interval*.

Examples

The following example sets the minimum interval of receiving duplicate LSP packets to **10** seconds, the interval of receiving duplicate LSP packets for the first time to **100** ms, and the interval of receiving duplicate LSP packets for the first and second times to **200** ms.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# min-lsp-arrival 10 100 200
```

Notifications

If the configured value of *hold-interval* is greater than the *minimum-interval* (for example, the configured value of *hold-interval* is 1500 ms, and the *minimum-interval* is 1 second), the following notification will be displayed:

```
% ISIS: hold_interval (1500ms) should be no more than minimum_interval (1s), set to
(1000ms).
```

If the configured value of *initial-interval* is greater than the *hold-interval* (for example, the configured value of *initial-interval* is 20 ms, and the *hold-interval* is 10 ms), the following notification will be displayed:

```
% ISIS: initial_interval (20ms) should be no more than hold_interval (10ms), set to
(10ms).
```

1.64 multi-topology

Function

Run the **multi-topology** command to configure IS-IS to support IPv6 unicast topologies. After that, IPv4 and IPv6 unicast routes in IS-IS will be calculated based on different topologies.

Run the **no** form of this command to restore the default configuration.

IS-IS does not support IPv6 unicast topologies by default.

Syntax

multi-topology [**transition**]

no multi-topology [**transition**]

Parameter Description

transition: Configures the MT mode, which supports smooth migration from an IPv4/IPv6 hybrid topology to separate IPv4 and IPv6 topologies.

Command Modes

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

The configuration of this command is applied in the following scenarios:

- If this command is not configured, IPv4 and IPv6 share the same IS-IS physical topology. This is a default topology.
- If this command is configured without the **transition** parameter, the router runs in MT mode, and IS-IS IPv4 runs in the default topology and IS-IS IPv6 runs in the IPv6 unicast topology.

- If this command is configured with the **transition** parameter, the router runs in MTT mode, and IS-IS IPv6 runs in the default topology and the IPv6 unicast topology.

The routers in MTT mode can **transfer** the MT TLV or the default topology TLV. The MTT mode is applicable to incremental deployment to ensure smooth network migration. The MTT mode can cause route leaking between the default topology and IPv6 unicast topology. If the MTT mode is configured improperly, network failures such as routing black holes and loops may occur.

The metric type must be set to Wide or Transition before you run this command. The MTR feature will be disabled if the metric type is set to Narrow or only one Level is configured to support the Wide or Transition mode.

Examples

The following example configures IS-IS to support IPv6 unicast topologies.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# address-family ipv6
Hostname(config-router-af)# multi-topology
```

1.65 net

Function

Run the **net** command to configure a NET address in IS-IS.

Run the **no** form of this command to remove this configuration.

No NET address is configured in IS-IS by default.

Syntax

net *net-address*

no net *net-address*

Parameter Description

net-address: NET address, in the format of XX.XXXX.YYYY.YYYY.YYYY.00. In this format, XX.XXXX indicates the area ID and YYYY.YYYY.YYYY indicates the system ID.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Use this command to configure an area ID and a system ID in IS-IS.

Different NET addresses must have the same system ID.

Examples

The following example sets the NET address of IS-IS to 49.0000.0001.0002.0003.00.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# net 49.0000.0001.0002.0003.00
```

1.66 nsr

Function

Run the **nsr** command to enable the NSR function for current IS-IS instance.

Run the **no** form of this command to restore the default configuration.

The NSR function is disabled by default.

Syntax

nsr

no nsr

Parameter Description

N/A

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

NSR backs up relevant IS-IS information from the master Supervisor Engine to the slave Supervisor Engine of the distributed device, or from the master device to the salve device in VSU mode, so that the device can automatically recover the link state and regenerate a route upon active/standby switchover, without requiring help from neighbor devices during the recovery. Information that should be backed up includes the neighbor relationship and link state.

For the same IS-IS process, either NSP or GR is enabled, because they are exclusive.

The switchover of distributed devices and VSU devices takes a period of time. If the IS-IS neighbor keepalive duration is less than the switchover duration, IS-IS neighbor relationship with the neighbor device is removed, and the services are interrupted during the switchover. Therefore, it is recommended that the IS-IS neighbor keepalive duration be set not less than the default value. When Fast Hello is enabled, the IS-IS neighbor keepalive duration is less than 1 second and the IS-IS neighbor relationship times out during the switchover, causing NSR failures. Therefore, it is recommended that Fast Hello be disabled when NSR is enabled.

Examples

The following example enables the NSR function for current IS-IS instance.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis 1
Hostname(config-router)# nsr
```

Notifications

N/A

Common Errors

- If the neighbor keepalive duration is short, when fast hello is enabled, IS-IS neighbor relationship is disconnected during a switchover, causing forwarding interruption.

1.67 passive-interface

Function

Run the **passive-interface** command to configure a passive interface.

Run the **no** form of this command to restore the default configuration.

The passive interface function is not enabled by default.

Syntax

passive-interface { **default** | *interface-type interface-number* }

no passive-interface { **default** | *interface-type interface-number* }

Parameter Description

default: Configures all IS-IS interfaces that are not enabled as passive interfaces.

interface-type: Interface type.

interface-number: Interface number.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

This function prevents the specified interface from receiving and sending IS-IS packets, but the IP address of this interface will be flooded by other interfaces. If the number of interfaces with IS-IS not enabled exceeds 255, only the first 255 interfaces will be configured as passive interfaces. The remaining interfaces are non-passive interfaces.

Examples

The following examples configures TenGigabitEthernet 0/1 as a passive interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis 1
Hostname(config-router)# passive-interface tenGigabitEthernet 0/1
```

1.68 redistribute

Function

Run the **redistribute** command to redistribute other routes to IS-IS.

Run the **no** form of this command to remove this configuration.

Redistribution is disabled by default.

Syntax

redistribute { **bgp** | **connected** | **ospf** *process-id* [**match** { **externa**l [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**] } *] | **rip** | **static** } [[**level-1** | **level-1-2** | **level-2**] | **metric** *metric-value* | **metric-type** { **external** | **internal** } | **route-map** *route-map-name*] *

no redistribute { **bgp** | **connected** | **ospf** *process-id* [**match** { **externa**l [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**] } *] | **rip** | **static** } [[**level-1** | **level-1-2** | **level-2**] | **metric** *metric-value* | **metric-type** { **external** | **internal** } | **route-map** *route-map-name*] *

Parameter Description

bgp: Indicates redistribution from BGP.

connected: Indicates redistribution from direct routes.

ospf *process-id*: Performs redistribution from OSPF. *process-id* specifies an OSPF process. The value range is from 1 to 65535 and the default value is **1**.

match { **externa**l [**1** | **2**] | **internal** | **nssa-external** [**1** | **2**] } *: Filters route sub-types of OSPF during OSPF route redistribution. If the **match** parameter is not included, all route sub-types of OSPF are received. If **1** or **2** is not specified after **match external**, OSPF routes of **external 1** and **external 2** are redistributed. If **1** or **2** is not specified after **match nssa-external**, OSPF routes of **nssa-external 1** and **nssa-external 2** are redistributed.

match: Redistributes specific OSPFv3 routes that meet the filtering conditions.

external [**1** | **2**]: Redistributes E1, E2, or all external routes.

internal: Redistributes internal routes and inter-area routes.

nssa-external [**1** | **2**]: Redistributes N1, N2, or all external routes of all NSSAs.

rip: Indicates redistribution from RIP.

static: Indicates redistribution from static routes.

level-1 | **level-1-2** | **level-2**: Indicates the Level of redistributed routes received by IS-IS. If no Level is specified, routes are redistributed to Level-2.

level-1: Redistributes routes to Level-1.

level-1-2: Redistributes routes to Level-1 and Level-2.

level-2: Redistributes routes to Level-2.

metric *metric-value*: Sets the metric of a redistributed route. The value range is from 0 to 4261412864. The metric of external routes is used when the **metric** option is not specified.

metric-type { external | internal }: Indicates the metric type of redistributed routes. If no metric type is specified, the metric belongs to the **internal** type.

external: Indicates that the metric belongs to the external type.

internal: Indicates that the metric belongs to the internal type.

route-map *route-map-name*: Indicates the route map used for external route redistribution. It is used to filter redistributed routes or configure the attributes of the redistributed routes. The value of *route-map-name* cannot exceed 32 characters. No route map is configured by default.

Command Modes

IS-IS routing process configuration mode

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

Run the **no redistritbue** { **bgp** | **connected** | **ospf** *processs-id* | **rip** | **static** } command to cancel the redistribution of routes mapped to the specified protocol. If **no redistribute** is followed by other parameters, the command will restore the default configuration, rather than cancel route redistribution. For example: **no redistribute bgp** cancels BGP route redistribution, whereas **no redistribute bgp route-map aa** cancels the route map named **aa** associated with BGP route redistribution.

When external routes are redistributed in IPv4 mode, the routing information is stored in LSPs' IP External Reachability Information TLV.

When external routes are redistributed in IPv6 mode, the routing information is stored in LSPs' IPv6 Reachable TLV.

In the old versions of some vendors, if the metric type is set to **external**, the metric of redistributed routes is added by 64 during route calculation and routes are selected based on the metric. This practice does not comply with the related protocol. In the actual application, external routes may be preferred over internal routes. If this happens during interworking with old versions of some vendors, you can modify the related setting (such as metric value or metric type) of each device to ensure that internal routes are preferred over external routes.

Examples

The following example redistributes static routes to Level-1 of the current instance and sets the metric value to **10**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# redistribute static metric 10 level-1
```

1.69 redistribute isis level-1 into level-2

Function

Run the **redistribute isis level-1 into level-2** command to redistribute the Level-1 reachable routing information of the specified IS-IS instance to Level-2 of the current instance.

Run the **no** form of this command to remove this configuration.

All Level-1 routes will be automatically redistributed to Level-2 by default.

Syntax

redistribute isis [*tag*] **level-1 into level-2** [**distribute-list** *acl-name* | **route-map** *route-map-name*]

no redistribute isis [*tag*] **level-1 into level-2** [**distribute-list** *acl-name* | **route-map** *route-map-name*]

Parameter Description

tag: Name of the IS-IS instance whose routing information will be redistributed. **distribute-list** *acl-name*: Filters redistributed routes by using **distribute-list**. *acl-name* indicates the associated prefix list, which can be a standard, an extended, or a name prefix list. The format is as follows:

{ *<1-99>* | *<100-199>* | *<1300-1999>* | *<2000-2699>* | *acl-name* }

In IS-IS IPv6 address family configuration mode, only the name prefix list can be used, in the format of *acl-name*.

route-map *route-map-name*: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of *route-map-name* cannot exceed 32 characters. No route map is configured by default.

Command Modes

IS-IS routing process configuration mode

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

You can use the **route-map** or **distribute-list** parameter to filter the specified instance's Level-1 routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-2 of the current instance. The **route-map** and **distribute-list** parameters cannot be used at the same time.

The **no redistritbue isis** [*tag*] **level-2 into level-1** command is used to cancel the redistribution of the specified instance's routes. If **no redistribute** is followed by other parameters, the command will restore the default configuration, rather than cancel route redistribution.

For example, **no redistritbue isis** *tag1* **level-1 into level-2** cancels the redistribution of the routes of the IS-IS instance name *tag1*. **no redistritbue isis** *tag1* l**evel-1 into level-2 route-map** *aa* cancels the use of the route map named aa to filter redistributed routes.

Examples

The following example redistributes the Level-1 reachable routing information of the specified IS-IS instance to Level-2 of the current instance.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis aa
Hostname(config-router)# redistribute isis bb level-1 into level-2
```

1.70 redistribute isis level-2 into level-1

Function

Run the **redistribute isis level-2 into level-1** command to redistribute the Level-2 reachable routing information of the specified IS-IS instance to Level-1 of the current instance.

Run the **no** form of this command to remove this configuration.

Redistribution is disabled by default.

Syntax

redistribute isis [*tag*] **level-2 into level-1** [**distribute-list** *acl-name* | { **prefix** *ipv4-address net-mask*| **ipv6-prefix** *ipv6-address/length*} | **route-map** *route-map-name*]

no redistribute isis [*tag*] **level-2 into level-1** [**distribute-list** *acl-name* | { **prefix** *ipv4-address net-mask*| **ipv6-prefix** *ipv6-address/length*} | **route-map** *route-map-name*]

Parameter Description

tag: Name of the IS-IS instance whose routing information will be redistributed.

distribute-list *acl-name*: Filters redistributed routes by using **distribute-list**. *access-list-name* indicates the associated prefix list, which can be a standard, an extended, or a name prefix list. The format is as follows:

{ *<1-99>* | *<100-199>* | *<1300-1999>* | *<2000-2699>* | *acl-name* }

In IS-IS IPv6 address family configuration mode, only the name prefix list can be used, in the format of *acl-name.*

prefix *ipv4-address net-mask*: Configures IPv4 routes that can be redistributed. Routes are specified by address and prefix length.

ipv6-prefix *ipv6-addressIlength*: Configures IPv6 routes that can be redistributed. Routes are specified by address and prefix length.

route-map *route-map-name*: Indicates the route map used for route redistribution. It is used to filter redistributed routes or configure the attributes of redistributed routes. The value of *route-map-name* cannot exceed 32 characters. No route map is configured by default.

Command Modes

IS-IS routing process configuration mode

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

You can use the **route-map**, **distribute-list**, or **prefix** parameter to filter the specified instance's Level-2 routes to be redistributed. Only the routes that meet specific criteria can be redistributed to Level-1 of the current instance.

The **route-map**, **distribute-list**, and **prefix** parameters cannot be used at the same time. If routes are filtered based on the prefix, only the Level-2 routes of local instance can be filtered.

The **no redistritbue isis** [**tag**] **level-2 into level-1** command is used to cancel the redistribution of the specified instance's routes. If **no redistribute** is followed by other parameters, the command will restore the default configuration, rather than cancel route redistribution.

For example:

no redistritbue isis tag1 level-2 into level-1 cancels the redistribution of the routes of the IS-IS instance name tag1. **no redistritbue isis tag1 level-2 into level-1 route-map aa** cancels the use of the route map named aa to filter redistributed routes, rather than redistribution of the routes of the IS-IS instance name tag1.

Examples

The following example redistributes the Level-2 reachable routing information of the specified IS-IS instance to Level-1 of the current instance.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis aa
Hostname(config-router)# redistribute isis bb level-2 into level-1
```

1.71 router isis

Function

Run the **router isis** command to create an IS-IS instance.

Run the **no** form of this command to remove this configuration.

No IS-IS instance is configured by default.

Syntax

router isis [*tag*]

no router isis [*tag*]

Parameter Description

tag: Name of an IS-IS instance.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Use this command to initialize an IS-IS instance and enter IS-IS routing process configuration mode. An IS-IS instance will start running after a NET address is configured.

If you set the tag parameter when you start an IS-IS routing process, you need to add the tag parameter when closing the IS-IS routing process.

CPU protection is enabled by default. For packets sent to each destination group address (AllISSystems, AllL1ISSystems, and AllL2ISSystems), the number of packets sent to the CPU is limited to 400 per second. If a device has many neighbor relationships or sends Hello packets at short intervals, the IS-IS packets that the device receives may exceed the default limit, causing frequent flapping of neighbor relationships. To solve the problem, you can use the CPU protection command in global configuration mode to increase the limit.

Examples

The following example creates an IS-IS instance.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)#
```

1.72 set-overload-bit

Function

Run the **set-overload-bit** command to prevent neighbors from using the local IS-IS node as a forwarding device to forward data.

Run the **no** form of this command to remove this configuration.

A neighbor considers the local IS-IS node as a forwarding device to forward data by default.

Syntax

set-overload-bit [**on-startup** { *overload-time* | **wait-for-bgp** [*bgp-convergence-time*] }] [**suppress** { **external** | **interlevel** | **max-metric** } *] [**level-1** | **level-2**]

no set-overload-bit [**level-1** | **level-2**]

Parameter Description

on-startup: Indicates that an IS-IS node enters overload state temporarily after restart.

overload-time: Duration when an IS-IS node remains in overload state after restart, in seconds. The value range is from 5 to 86400, and the default value is **600**.

wait-for-bgp: Indicates that an IS-IS node automatically enters overload state after restart and waits for BGP convergence completion or timeout. This option is used with the keyword **on-startup**.

bgp-convergence-time: Time for waiting for BGP convergence completion, in seconds. The value range is from 5 to 86400, and the default value is **600**.

suppress: Indicates that an IS-IS node does not advertise internal routes (intra-area and inter-area routes) or external routes to neighbors when the IS-IS node is in overload state.

external: Indicates that an IS-IS node does not advertise external routes to neighbors when the IS-IS node is in overload state. This option is used with the keyword **suppress**.

interlevel: Indicates that an IS-IS node does not advertise intra-area and inter-area routes to neighbors when the IS-IS node is in overload state. This option is used with the keyword **suppress**.

max-metric: Sets the metric values of the advertised direct routes and neighbor reachable routes to the maximum values when the IS-IS node is in overload state. This option is used with the keyword **suppress**.

level-1: Sends LSPs with the overload bit only to Level-1 neighbors.

level-2: Sends LSPs with the overload bit only to Level-2 neighbors.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

This command forces an IS-IS node to configure the overload bit in non-virtual LSPs to instruct its IS-IS neighbors to avoid using the local node as a forwarding device.

If the **on-startup** keyword is included, the IS-IS node temporarily enters overload state after restart. The overload bit is automatically configured or removed by the IS-IS node based on configuration.

If the **on-startup** keyword is not included, the IS-IS node enters overload state immediately after restart. The overload bit is configured or removed manually.

Note

At the same Level, the configuration with the **on-startup** keyword and the configuration without the **on-startup** keyword are mutually exclusive.

The overload bit is used in the following three situations:

- Device overload

The local IS-IS node has overload issues, such as insufficient memory or full CPU load; as a result, its routing table has incomplete routes or does not have resource forwarding data. You can configure the overload bit in an LSP to instruct the neighbor to avoid using the local node as a forwarding device.

To configure the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or removed manually. When the local IS-IS node is restored, manually remove the command configuration; otherwise, the node is always in overload state.

- Instantaneous black hole

In the scenario described by RFC 3277, the IS-IS convergence speed is faster than the BGP speed; as a result, after an IS-IS node is restarted, a route may be instantaneously unreachable, which is called an instantaneous black hole. You can set the overload bit in an LSP to instruct the neighbor to avoid using the local node as a forwarding device until the specified time has elapsed.

To set the overload bit, run the **set-overload-bit** command with the **on-startup** keyword. The overload bit can be configured or removed automatically by the IS-IS node based on the configuration.

After the **on-startup** keyword is selected, the IS-IS node automatically enters instantaneous black hole state after restart. When a neighbor relationship is established, the IS-IS node sends an LSP with the overload bit to notify the neighbor that the local node enters instantaneous black hole (or overload) state and instruct the neighbor to avoid using the local node as a forwarding device.

After the specified time has elapsed, the IS-IS node immediately sends an LSP with the overload bit canceled to notify the neighbor that the local node has exited instantaneous black hole (or overload) state and can work as a forwarding device.

The timer is configured based on the number of routes in the network. If there are a great number of routes in the network, the timer is set to a larger value. Otherwise, the timer is set to a smaller value.

- Disabling real data forwarding on the local IS-IS node

If you only need to connect the local IS-IS node to a production network for testing or to meet other functional requirements, but does not require the node to forward real data in the network, you can set the overload bit in an LSP to instruct the neighbor to avoid using the local node as a forwarding device.

To set the overload bit, run the **set-overload-bit** command without the **on-startup** keyword. The overload bit can be configured or removed manually.

You can set the **suppress** keyword based on requirements to limit the routing information carried in an LSP in case of overload. For example, internal and external routes can be suppressed, and only the local direct route is advertised. For example, the advertised direct route and the metric value to reach a neighbor are set to the maximum values.

Examples

The following example enables an IS-IS node to automatically enter overload state after restart and not to advertise internal routes (intra-area and inter-area routes) or external routes to neighbors in the wait time 300s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# set-overload-bit on-startup 300 suppress interlevel external
```

The following example enables an IS-IS node not to advertise internal routes (intra-area and inter-area routes) or external routes to neighbors when the IS-IS node is in overload state.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# set-overload-bit suppress interlevel external
```

The following example enables an IS-IS node to automatically enter overload state after restart, wait for 300s, BGP route convergence completion or specified timer timeout, and set the metric values of the advertised direct routes and neighbor reachable routes to the maximum values.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# set-overload-bit on-startup wait-for-bgp 300 suppress
max-metric
```

1.73 show clns is-neighbors

Function

Run the **show clns is-neighbors** command to display all IS-IS neighbors and provide device adjacency relationship information.

Syntax

show clns [*tag*] **is-neighbors** [*interface-type interface-number*] [**detail**]

Parameter Description

tag: Name of a specified IS-IS instance.

interface-type interface-number: Name of a specified interface.

detail: Displays detailed information of all interfaces.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

1.76 show isis database

Function

Run the **show isis database** command to display the information of an LSP database.

Syntax

show isis [*tag*] **database** [**detail** | **verbose**] [**l1** | **l2** | **level-1** | **level-2**] [*LSPID*]

Parameter Description

tag: Name of a specified IS-IS instance.

detail: Displays detailed information.

verbose: Displays more detailed information than **detail**.

l1 | **l2** | **level-1** | **level-2**: **l1** and **level-1**: Specify the Level-1 LSP database. **l2** and **level-2**: Specify the Level-2 LSP database.

LSPID: ID of the specified LSP. Only the corresponding LSP information is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the information of an LSP database.

1.80 show isis ipv6 topology

Function

Run the **show isis ipv6 topology** command to display the IPv6 unicast topology information of an IS-IS device.

Syntax

show isis [*tag*] **ipv6 topology** [**l1** | **l2** | **level-1** | **level-2**]

Parameter Description

tag: Name of a specified IS-IS instance.

l1: Specifies Level-1 topology.

level-1: Specifies Level-1 topology.

l2: Specifies Level-2 topology.

level-2: Specifies Level-2 topology.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the IPv6 unicast topology information.

```
Hostname> enable
Hostname# show isis ipv6 topology
Area (null):
IS-IS paths to level-1 routers
System Id   Metric   Next-Hop   SNPA            Interface
r1         10      r1       00d0.f822.33ad    TenGigabitEthernet 0/1
Hostname      -N/A
IS-IS paths to level-2 routers
System Id   Metric   Next-Hop   SNPA            Interface
r1         10      r1       00d0.f822.33ad    TenGigabitEthernet 0/1
Hostname      -N/A
```

Table 1-10 Output Fields of the show isis ipv6 topology Command

1.81 show isis mesh-groups

Function

Run the **show isis mesh-groups** command to display the mesh group configuration of interfaces.

Syntax

show isis [*tag*] **mesh-groups**

Parameter Description

tag: Name of a specified IS-IS instance.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the mesh group configuration of all interfaces.

```
Hostname> enable
Hostname# show isis mesh-groups
Mesh group (blocked)
```

```
TenGigabitEthernet 0/1
Mesh group 1 :
TenGigabitEthernet 0/2
```

Table 1-11 Output Fields of the show isis mesh-groups Command

Field	Description
Mesh group (blocked) TenGigabitEthernet 0/1	Interface that blocks the mesh group
Mesh group 1 TenGigabitEthernet 0/2	Interface for mesh group 1

1.82 show isis neighbors

Function

Run the **show isis neighbors** command to display neighbor information of IS-IS.

Syntax

show isis [*tag*] **neighbors** [**detail**]

Parameter Description

tag: Name of a specified IS-IS instance.

detail: Displays detailed information.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays detailed neighbor information of IS-IS.

```
Hostname> enable
Hostname# show isis neighbors detail
Area (null):
System Id  Type  IP Address    State   Holdtime  Circuit  Interface
```

```
r1        L1    1.0.0.2      Up     9        r1.01    TenGigabitEthernet 0/1
L2    1.0.0.2      Up     9        r1.01    TenGigabitEthernet 0/1
  Adjacency ID: 1
  Uptime: 00:06:25
  Area Address(es): 49.1111
SNPA: 00d0.f8bc.de08
IPv6 Address(es): fe80::2a9:15ff:fe36:5413
Level-1 MTID: Standard
Level-2 MTID: Standard
  Level-1 Protocols Supported: IPv4, IPv6
  Level-2 Protocols Supported: IPv4, IPv6
BFD(IPv4) session state: Up
BFD(IPv6) session state: Up
```

Table 1-12 Output Fields of the show isis neighbors detail Command

Field	Description
Area	Instance tag
System Id	System ID
Type	Neighbor type
IP Address	IP address of the neighbor
State	State of the neighbor
Holdtime	Holdtime of the neighbor
Circuit	Link ID. When the network type is Broadcast, the circuit column describes the DIS considered by the neighbor r1.
Interface	Interface for neighbor establishment
Adjacency ID	Neighbor ID, arranged based on interface. The value range is from 1 to 255.
Uptime	Uptime of a neighbor connection
Area Address(es)	Area address
SNPA	SNPA address of the neighbor
Ipv6 Address(es)	IPv6 address of the neighbor
Level-1 MTID	Topology type supported by the Level-1 neighbor
Level-2 MTID	Topology type supported by the Level-2 neighbor
Level-1 Protocols Supported	IP protocol type supported by the Level-1 neighbor
Level-2 Protocols Supported	IP protocol type supported by the Level-2 neighbor

Field	Description
BFD (IPv4) session state	BFDv4 session status corresponding to the IS-IS neighbor
BFD (IPv6) session state	BFDv6 session status corresponding to the IS-IS neighbor

1.83 show isis nsr

Function

Run the **show isis nsr** command to display NSR information of IS-IS.

Syntax

show isis [*tag*] **nsr**

Parameter Description

tag: Name of a specified IS-IS instance.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the NSR information of IS-IS.

```
Hostname> enable
Hostname# show isis nsr
NSR role: master
Area (null):
NSR: enable
NSR state: realtime
Area 1:
NSR: disable
```

Table 1-13 Output Fields of the show isis nsr Command

Field	Description
NSR role	NSR role
Area	Instance tag
NSR	Whether the instance is configured with the NSR
NSR state	NSR running state of an instance. It is displayed after the instance is configured with the NSR.

1.84 show isis protocol

Function

Run the **show isis protocol** command to display protocol information of IS-IS.

Syntax

show isis [*tag*] **protocol**

Parameter Description

tag: Name of a specified IS-IS instance.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the protocol information of IS-IS.

```
Hostname> enable
Hostname# show isis protocol
IS-IS Router: (null)
  Binding VRF: vrf
  Mib-Binding: off
System ID: 0000.0000.0036   IS-type: level-2
Virtual System ID:
```

```
  1111.1111.1111, 2222.2222.2222
  Manual area address(es):
    49.0001, 49.0003
  Interfaces supported by IS-IS:
    TenGigabitEthernet 0/1, TenGigabitEthernet 0/2
  Redistributing IPv4:
isis 1, isis 2
Redistributing IPv6:
  isis 3, isis 4
  Distance: 115
  Generate narrow metrics:  Level-2
  Accept narrow metrics:    Level-2
  Generate wide metrics:    none
Accept wide metrics:     none
NSR: enable
Two-way-maintain: enable
BGP-LS: Level-2
```

Table 1-14 Output Fields of the show isis protocol Command

Field	Description
IS-IS Router	Instance tag
Binding VRF	VRF name bound to the IS-IS instance
Mib-Binding	Whether the instance is bound to SNMP operations
System ID	System ID
IS-type	Level type supported by the instance
Virtual System ID	Extended system ID
Manual area address(es)	Area ID
Interfaces supported by IS-IS	Interface associated with this instance
Redistributing IPv4	Source of the IPv4 redistributed route
Redistributing IPv6	Source of the IPv6 redistributed route
Distance	IS-IS management weight
Generate narrow metrics	Type of narrow metric generated
Accept narrow metrics	Type of narrow metric received
Generate wide metrics	Type of wide metric generated
Accept wide metrics	Type of wide metric received

Field	Description
NSR	Whether the instance is configured with the NSR. It is displayed when the instance is configured with the NSR.
Two-way-maintain	Whether the instance is configured with the two-way-maintain function
BGP-LS	Level type of the BGP-LS configured for the instance

1.87 spf-interval

Function

Run the **spf-interval** command to configure the exponential backoff algorithm of SPF calculation.

Run the **no** form of this command to restore the default configuration.

The default maximum calculation interval of two SPF calculations is **10** seconds, the delay of the first SPF calculation is **50** ms, and the maximum interval for the first and second SPF calculations is **200** ms. Exponential backoff algorithm uses level-1/Level-2. That is, it takes effect for Level-1 and Level-2 concurrently.

Syntax

spf-interval [**level-1** | **level-2**] *maximum-interval* [*initial-interval hold-interval*]

no spf-interval [**level-1** | **level-2**]

Parameter Description

level-1: Takes effect for Level-1 IS-IS.

level-2: Takes effect for Level-2 IS-IS.

maximum-interval: Maximum interval for performing two consecutive SPF calculations, in seconds. The value range is from 1 to 120.

initial-interval: Wait time for performing the SPF calculation for the first time, in milliseconds. The value range is from 0 to 60000.

hold-interval: Minimum interval for performing the SPF calculation for the first and second times, in milliseconds. The value range is 10 to 60000.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If the **level-1** or **level-2** parameter is not specified when the command is configured, the interval configuration takes effect for Level-1 and Level-2 LSPs.

Increasing the maximum interval for performing SPF calculations can avoid frequent SPF calculations and waste of CPU resources. However, a larger minimum interval also leads to slower responses to route changes.

The wait time for performing the SPF calculation for the first time is the *initial-interval*. If the network becomes unstable, the SPF calculation interval is less than the *maximum-interval*, and the interval for performing the SPF calculation for the second time becomes the *hold-interval*. A corresponding penalty is added to this interval: The next interval for the SPF calculation doubles the previous interval for the same SPF calculation, until the SPF calculation interval reaches the *maximum-interval*. Subsequent SPF calculations are performed at the *maximum-interval*. When the network becomes stable, the interval for performing the SPF calculation becomes greater than the *maximum-interval*, and the wait time for performing the SPF calculation is restored to the *initial-interval*.

Link changes have high requirements for convergence. The initial interval can be set to a small value. You can also appropriately increase the values of the preceding parameters to reduce the CPU usage.

Note

- The value of the configured *hold-interval* cannot be greater than that of *maximum-interval*. Otherwise, the value of *hold-interval* is changed to that of *maximum-interval*.
- The value of the configured *initial-interval* cannot be greater than that of *hold-interval*. Otherwise, the value of *initial-interval* is changed to that of *hold-interval*.

Examples

The following example configures an exponential backoff algorithm of SPF calculation, and sets the maximum interval of two SPF calculations to **5** seconds, the wait time of SPF calculation for the first time to **100** ms, and the interval for the first and SPF calculation to **200** ms.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# spf-interval 5 100 200
```

The following example configures an exponential backoff algorithm of SPF calculation, sets the maximum interval of two SPF calculations to **10** seconds, and uses the default values of other exponential backoff parameters.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# spf-interval 10
```

Notifications

If the configured value of *hold-interval* is greater than *maximum-interval* (for example, the configured value of *hold-interval* is **1500** ms, and the *maximum-interval* is **1** second), the following notification will be displayed:

```
% ISIS: hold_interval (1500ms) should be no more than maximum_interval (1s), set to
(1000ms).
```

If the configured value of *initial-interval* is greater than *hold-interval* (for example, the configured value of *initial-interval* is **20** ms, and the *hold-interval* is **10** ms), the following notification will be displayed:

```
% ISIS: initial_interval (20ms) should be no more than hold_interval (10ms), set to
(10ms).
```

1.88 summary-address

Function

Run the **summary-address** command to configure IPv4 summarized routes.

Run the **no** form of this command to remove this configuration.

The route summarization function is disabled by default.

Syntax

summary-address *ipv4-address net-mask* [**level-1** | **level-1-2** | **level-2**] [**metric** *metric-value*]

no summary-address *ipv4-address net-mask*

Parameter Description

ipv4-address: IPv4 address of the summarized route.

net-mask: Network mask of the summarized route.

level-1: Takes effect for Level-1 summarized routes.

level-1-2: Takes effect for Level-1 and Level-2 summarized routes.

level-2: Takes effect for Level-2 summarized routes.

metric-value: Metric of the summarized route. The value range is from 1 to 4294967295, and the default value is **0**.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

If the configured summarized route contains routing information about a reachable address or network segment, the summarized route, instead of detailed routes, is advertised externally.

Examples

The following example sets the IPv4 summarized route to 10.10.0.0/24 on Level-2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# summary-address 10.10.0.0 255.255.255.0 level-2
```

1.89 summary-prefix

Function

Run the **summary-prefix** command to configure IPv6 summarized routes.

Run the **no** form of this command to remove this configuration.

The route summarization function is disabled by default.

Syntax

summary-prefix *ipv6-prefix/prefix-length* [**level-1** | **level-1-2** | **level-2**]

no summary-prefix *ipv6-prefix/prefix-length*

Parameter Description

ipv6-prefix/prefix-length: Network address of the summarized route and its IPv6 prefix length. It follows the X:X:X:X::X/<0-128> format.

level-1: Takes effect for Level-1 summarized routes.

level-1-2: Takes effect for Level-1 and Level-2 summarized routes.

level-2: Takes effect for Level-2 summarized routes. By default, the setting takes effect for Level-2.

Command Modes

IS-IS IPv6 address family configuration mode

Default Level

14

Usage Guidelines

If the configured summarized route contains routing information about a reachable address or network segment, the summarized route, instead of detailed routes, is advertised externally.

Examples

The following example sets the IPv6 summarized route to 1000::/96 on Level-2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# address-family ipv6
Hostname(config-router-af)# summary-prefix 1000::/96 level-2
```

1.90 two-way-maintain

Function

Run the **two-way-maintain** command to enable the two-way maintenance function of IS-IS.

Run the **no** form of this command to disable this function.

The two-way maintenance function is enabled by default.

Syntax

two-way-maintain

no two-way-maintain

Parameter Description

N/A

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

In a large network, a lot of packets may be sent or received, occupying a great proportion of CPU and memory. As a result, some packets are delayed or discarded. If the time required for processing hello packets exceeds the neighbor holdtime, the corresponding adjacency times out and is removed. If the two-way maintenance function is enabled, in addition to the hello packets, the LSP, CSNP, and PSNP packets from a neighbor can also be used to maintain the bidirectional communication between neighbors when a large number of packets exist in the network. This prevents termination of the adjacency caused by delayed or discarded hello packets.

Examples

The following example enables the two-way maintenance function of IS-IS.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis 1
Hostname(config-router)# no two-way-maintain
```

1.91 virtual-system

Function

Run the **virtual-system** command to configure an additional system ID for fragment extension.

Run the **no** form of this command to disable this function.

The fragment extension function is disabled by default.

Syntax

virtual-system *system-id*

no virtual-system *system-id*

Parameter Description

system-id: ID of an additional system, six bytes.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Use this command to configure the additional system ID of an IS-IS routing process, which is used by the extended LSP that is generated after the 256 fragments of the original LSP are used up. To enable fragment extension, run this command to configure an additional system ID and run the **lsp-fragments-extend** command to configure fragment extension.

Examples

The following example sets the Additional system ID to 0000.0000.0034 for fragment extension.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router isis
Hostname(config-router)# virtual-system 0000.0000.0034
```

1.92 vrf

Function

Run the **vrf** command to bind an IS-IS instance to a VRF table.

Run the **no** form of this command to remove this configuration.

VRF binding of an IS-IS instance is disabled by default.

Syntax

vrf *vrf-name*

no vrf *vrf-name*

Parameter Description

vrf-name: Name of a configured VRF.

Command Modes

IS-IS routing process configuration mode

Default Level

14

Usage Guidelines

Before you bind an IS-IS instance to a VRF table, ensure that the VRF table has been configured. If you need to establish an IS-IS IPv6 neighbor relationship, enable IPv6 and ensure that the table to be bound is a multiprotocol VRF table.

Note the following constraints or conventions for the binding operation:

- The IS-IS instances bound with the same non-default VRF table must be configured with different system IDs.
- The IS-IS instances bound with different VRF tables can be configured with the same system ID.
- One IS-IS instance can be bound with only one VRF table, but one VRF table can be bound to multiple IS-IS instances.
- When the VRF table bound to an IS-IS instance is changed, all IS-IS interfaces associated with the instance will be deleted. That is, the **ip** (or **ipv6**) **router isis [tag]** interface configuration and the redistribution configuration in routing process configuration mode will be deleted.

Examples

The following example binds an IS-IS instance to vrf_1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrf definition vrf_1
Hostname(config-vrf)# address-family ipv4
Hostname(config-vrf-af)# exit-address-family
Hostname(config)# router isis
Hostname(config-router)# vrf vrf_1
```

Notifications

If the VRF bound does not exist, the following notification will be displayed:

```
% The VRF does not exist
```

1 BGP Commands

Command	Function
address port	Configure the address and port number of a BGP Monitoring Protocol (BMP) server.
address-family ipv4	Enter the IPv4 address family mode of Border Gateway Protocol (BGP).
address-family ipv4 vrf	Enter the IPv4 VRF address family mode of BGP and enable the exchange function of VRF routing information.
address-family ipv6	Enter the IPv6 address family mode of BGP and enable the exchange function of IPv6 routing information of BGP.
address-family ipv6 vrf	Enter the IPv6 VRF address family mode and enable the exchange function of IPv6 routing information of a VRF instance.
adj-rib-in post-policy	Configure BMP to monitor the routing information received from a peer after the routing policy is applied.
adj-rib-in pre-policy	Configure BMP to monitor the unchanged routing information received from a peer.
adj-rib-out post-policy	Configure BMP to monitor the routes sent to a peer after the routing policy is applied.
aggregate-address	Configure a route aggregation entry of BGP.
bgp additional-paths select	Enable the selection function of alternative additional paths (ADD-PATH) routes.
bgp advertise lowest-priority on-startup	Adjust the priority of routes advertised during device restart to the lowest level.
bgp advertise non-transitive extcommunity	Add the non-transmissive extended community attribute when BGP advertises routes to an External BGP (EBGP) neighbor.
bgp advertise-map	Match a global routing policy with sent routes.
bgp always-compare-med	Enable the Multi Exit Discriminator (MED) comparison function of BGP.

bgp asnotation dot	Display 4-byte AS numbers in dot mode and match regular expressions. Two decimals are separated by dot, for example 65535.65535.
bgp bestpath aigp ignore	Disable AIGP metric value comparison when the optimal path is selected.
bgp bestpath as-path ignore	Not compare AS path length when the optimal path is selected.
bgp bestpath as-path multipath-relax	Enable AS-PATH loose comparison of multiple paths in load balancing mode for BGP.
bgp bestpath compare-confed-aspath	Compare AS path length when the optimal path is selected.
bgp bestpath compare-routerid	Compare path router IDs when the optimal path is selected.
bgp bestpath igp-metric ignore	Not compare the next-hop IGP metric values when the optimal path is selected.
bgp bestpath med confed	Compare path MED values from the same AS alliance when the optimal path is selected.
bgp bestpath med missing-as-worst	Set the priority of a path without the MED attribute to the lowest level when the optimal path is selected.
bgp bestpath multipath-compare-routerid	Enable the function of comparing router IDs of multiple paths in load balancing mode.
bgp bmp-active	Enable all BMP servers to monitor all BGP neighbors.
bgp client-to-client reflection	Enable the route reflection function between device clients.
bgp cluster-id	Configure the cluster ID for a route reflector.
bgp confederation identifier	Configure an ID for an AS alliance.
bgp confederation peers	Configure a member AS for an AS alliance.
bgp dampening	Enable the route dampening function and configure dampening parameters.
bgp default ipv4-unicast	Configure the default address family as the IPv4 unicast address family.
bgp default local-preference	Configure the default LOCAL_PREF attribute.
bgp default route-target filter	Enable the Route-Target filtering function.

bgp deterministic-med	Preferentially compare path MED values for peers from the same AS.
bgp dmzlink-bw	Advertise bandwidth of a specified interface as an extended attribute.
bgp enforce-first-as	Configure a device to check the first AS number of the AS_PATH field in update packets.
bgp fast-external-fallover	Enable the fast link detection function of EBGP neighbors.
bgp fast-reroute	Enable the fast rerouting (FRR) function of BGP.
bgp fast-withdraw	Enable the fast withdrawal function of a specified BGP route.
bgp graceful-restart	Enable the function of global BGP graceful restart (GR).
bgp graceful-restart disable	Disable the GR function of a specified BGP address family.
bgp graceful-restart restart-time	Configure the GR time of BGP.
bgp graceful-restart stalepath-time	Configure the hold time of a stale route by a GR Helper during BGP GR.
bgp initial-advertise-delay	Enable the function of BGP delayed advertisement upon system restart.
bgp install standby-path	Enable the function of standby path installation of BGP.
bgp link-state-group up-delay	Configure the delay time to unbind the downlink port in the link state tracking group associated with the BGP neighbors.
bgp log-neighbor-changes	Configure a device to record BGP state changes without enabling the debugging function.
bgp maxas-limit	Limit the quantity of AS numbers in the AS_PATH attribute for BGP routes.
bgp maximum-neighbor	Configure the maximum number of BGP neighbors.
bgp maximum-prefix	Configure the maximum number of route entries in global configuration mode or for specified VRF instances.
bgp mp-error-handle session-retain	Configure BGP to retain BGP sessions when it detects a multiprotocol route error.

bgp nexthop trigger delay	Configure a delay of updating the routing table after the next hop of a BGP route changes.
bgp nexthop trigger enable	Enable the function of next hop trigger update.
bgp notify unsupport-capability	Enable the detection function of neighbor address family capability.
bgp nsr	Enable the global non-stop routing (NSR) function of BGP.
bgp recursion host	Enable BGP routes to recurse to only host routes.
bgp redistribute-internal	Configure BGP to allow the routes received from IBGP neighbors to be redistributed to Interior Gateway Protocol (IGP).
bgp route-reflector attribute-change	Allow the route reflector to modify route attributes.
bgp router-id	Configure a router ID when the BGP is running.
bgp scan-rib disable	Update the routing table in event triggering mode.
bgp scan-time	Configure the interval of regular scanning of BGP.
bgp shutdown	Actively shut down all connections.
bgp sourced-paths	Import routes with multiple paths or multiple next hops from other protocol modules.
bgp tcp-source-check disable	Disable the function of TCP source address checking of BGP.
bgp timer accuracy-control	Enable the strict execution function of internal timers of BGP.
bgp upgrade-cli	Configure the CLI display mode of BGP as address family configuration mode or scope configuration mode.
bmp server	Configure a BMP server instance and enter the BMP configuration mode.
buffer-size	Configure the maximum number of packets or bytes in the buffer of a BMP instance.
clear bgp advertise lowest-priority on-startup	Restore the priority of advertised routes to BGP neighbors to the level before the configuration of the **bgp advertise lowest-priority on-startup** command.
clear bgp all	Clear all the address families of BGP.

clear bgp all peer-group	Clear a specified peer group of BGP.
clear bgp all update-group	Clear the sessions of all members in an update group.
clear bgp ipv4 unicast	Clear the specified sessions of an IPv4 unicast address family.
clear bgp ipv4 unicast dampening	Clear the route flapping information of an IPv4 unicast address family and remove route dampening.
clear bgp ipv4 unicast external	Clear the EBGP connections of all IPv4 unicast address families.
clear bgp ipv4 unicast flap-statistics	Clear the statistics about route flapping of an IPv4 unicast address family.
clear bgp ipv4 unicast peer-group	Clear the sessions of all members of a peer group in an IPv4 unicast address family.
clear bgp ipv4 unicast table-map	Clear and update the Table-map configuration of an IPv4 unicast address family of BGP.
clear bgp ipv4 unicast update-group	Clear the sessions of all members of an update group in an IPv4 unicast address family.
clear bgp ipv6 unicast	Clear the specified sessions of an IPv6 unicast address family of BGP.
clear bgp ipv6 unicast dampening	Clear the route flapping information and route dampening of an IPv6 unicast address family.
clear bgp ipv6 unicast external	Clear all the EBGP connections of an IPv6 unicast address family.
clear bgp ipv6 unicast flap-statistics	Clear the statistics about route flapping of an IPv6 unicast address family.
clear bgp ipv6 unicast peer-group	Clear the sessions of all members of a peer group in an IPv6 unicast address family.
clear bgp ipv6 unicast table-map	Clear and update the Table-map configuration of an IPv6 unicast address family.
clear bgp ipv6 unicast update-group	Clear all the member sessions of an update group in an IPv6 unicast address family.
clear bmp	Reset BMP.
clear ip bgp	Clear the specified sessions of an IPv4 unicast address family of BGP.

clear ip bgp dampening	Clear the route flapping information and route dampening of an IPv4 unicast address family.
clear ip bgp external	Clear EBGP connections of all IPv4 unicast address families.
clear ip bgp flap-statistics	Clear statistics about route flapping of an IPv4 unicast address family.
clear ip bgp peer-group	Clear sessions of all members in a peer group in an IPv4 unicast address family.
clear ip bgp table-map	Clear old information and update the Table-map's routing information in an IPv4 unicast address family.
clear ip bgp update-group	Clear sessions of all members in a peer group in an IPv4 unicast address family.
default-information originate	Configure BGP to advertise redistributed default routes.
default-metric	Use the manually configured metric value for a redistributed route of BGP.
description	Configure description information of a BMP instance.
distance bgp	Configure the administrative distance of a BGP route.
exit-address-family	Exit the address family configuration mode of BGP.
failure-retry-delay	Configure the time to reestablish a connection with a BMP server.
import path selection	Configure a route import policy.
maximum-paths	Configure EBGP/IBGP multipath load balancing and specify the number of equivalent paths.
maximum-prefix	Configure the maximum number of route prefixes in a routing information base under an address family.
neighbor activate	Activate neighbors or peer groups in current address mode.
neighbor additional-paths	Enable the ADD-PATH function of the specified peer.
neighbor advertise additional-paths	Advertise the specific type of alternative ADD-PATH routes to peers.
neighbor advertisement-interval	Configure the route update interval of BGP.
neighbor aigp	Enable the AIGP function of BGP neighbors.

neighbor allowas-in	Allow the local device to receive update packets that carry the AS number of the local device.
neighbor as-loop-check out	Enable the loop detection function in the outbound direction of a BGP neighbor.
neighbor as-origination-interval	Configure the interval of advertising the local initial BGP route to a specified peer.
neighbor as-override	Configure a PE device to overwrite the AS number of a site.
neighbor bmp-active	Configure a specified BMP server to monitor neighbors.
neighbor default-fast-withdraw	Allow a BGP speaker to quickly withdraw the default route from a peer (group).
neighbor default-originate	Allow a BGP speaker to advertise the default route to a peer (group).
neighbor description	Configure the description statement of a specified peer (group).
neighbor distribute-list	Implement an ACL-based routing policy when routing information is sent to and received from a specified BGP peer.
neighbor dmzlink-bw	Carry the link bandwidth attribute in the specified neighbor's routes sent to IBGP neighbors.
neighbor domain	Configure a domain group for a specified BGP peer.
neighbor domain-unsuppress	Disable the domain group of a specified BGP peer from suppressing detailed routes.
neighbor ebgp-multihop	Establish BGP connections with non-directly-connected EBGP peers.
neighbor fall-over bfd	Correlate BGP with Bidirectional Forwarding Detection (BFD).
neighbor filter-list	Apply the AS path filtering rule to the routing information received from and sent to a specified BGP peer (group).
neighbor global-nexthop-replace-local	Use the local address of a BGP IPv6 link as the global next hop address when IPv6 routing information is sent to the local peer (group) of the BGP IPv6 link.

neighbor ha-mode nsr	Enable the nonstop routing (NSR) function for a specified BGP peer (group).
neighbor link state group	Associate a BGP peer (group) with a link state tracking group.
neighbor local-as	Configure the local AS number for a specified BGP peer (group).
neighbor maximum-prefix	Configure the maximum number of prefixes received from a specified BGP peer.
neighbor next-hop-self	Configure the next hop of a route advertised to a specified BGP peer as the local device.
neighbor next-hop-unchanged	Retain the next hop of a route advertised to a specified peer (group).
neighbor password	Enable TCP MD5 authentication and configure a password when a BGP connection is established with a specified BGP peer.
neighbor peer-group (assigning members)	Configure a specified BGP peer as a member of a BGP peer group.
neighbor peer-group (creating)	Create a BGP peer group.
neighbor pic-disable	Disable the private PIC processing on routes distributed to and received from specified BGP peers.
neighbor prefix-list	Implement the prefix list-based routing policy for routing information sent to and received from the specified BGP peers.
neighbor remote-as	Configure a BGP peer (group).
neighbor remove-private-as	Remove the private AS number from the AS_PATH attribute of the routes sent to a specified EBGP peer.
neighbor route-map	Match a received or an advertised route with a route map.
neighbor route-reflector-client	Configure the local device as a route reflector and specify a client for it.
neighbor send-community	Advertise community attributes to a specified BGP neighbor.
neighbor shutdown	Shut down the connection of a specified peer.

neighbor soft-reconfiguration inbound	Save original routing information sent by a specified BGP peer.
neighbor soo	Configure the Site-of-Origin (SoO) attribute of a neighbor.
neighbor timers	Configure the duration of Keepalive, Hold-Time, and Connect-Retry timers that are used to establish a BGP connection with a specified BGP peer.
neighbor transport connection-mode	Configure the connection establishment mode of BGP neighbors.
neighbor ttl-security hops	Configure GTSM security check for BGP neighbors.
neighbor unsuppress-map	Selectively advertise the routing information that is suppressed by route aggregation.
neighbor update-delay	Delay the advertisement of BGP peers.
neighbor update-source	Configure a network interface used to establish a BGP connection with a specified IBGP peer.
neighbor version	Configure the BGP version number for a specified BGP peer.
neighbor weight	Configure a weight value for a specified BGP peer.
network	Add static routing entries to a BGP routing table and advertise them to peers.
network synchronization	Synchronize a device with the local route to advertise the routing information configured by the network command.
overflow memory-lack	Configure BGP to enter the overflow state when the memory is insufficient.
redistribute	Redistribute the routing information of another routing protocol to a BGP instance.
redistribute isis	Redistribute the routing information of the IS-IS routing protocol to a BGP instance.
redistribute ospf	Redistribute the routing information of the Open Shortest Path First (OSPF) routing protocol to a BGP instance.
route mirroring	Enable the function of BGP packet mirroring.
router bgp	Enable the BGP protocol, configure a local AS number, and enter the BGP configuration mode.

scope	Enter the scope configuration mode and associate a VRF instance with BGP.
show bgp all	Display all the routing information of BGP.
show bgp bmp	Display BMP server information.
show bgp develop	Display the development information of BGP.
show bgp grst	Display GR information.
show bgp hash-peer	Display the hash table information of all neighbors.
show bgp ipv4 unicast	Display the IPv4 unicast routing information in BGP routing information.
show bgp ipv4 unicast dampening	Display the BGP IPv4 unicast route flapping information.
show bgp ipv4 unicast neighbors	Display the IPv4 unicast neighbor information of BGP.
show bgp ipv4 unicast paths	Display the IPv4 unicast path information in a routing information base.
show bgp ipv4 unicast summary	Display the BGP IPv4 unicast summary information.
show bgp ipv4 unicast update-group	Display the BGP IPv4 unicast update group information.
show bgp ipv6 unicast	Display the IPv6 unicast routing information in BGP routing information.
show bgp ipv6 unicast dampening	Display the IPv6 unicast route flapping parameters configured by BGP.
show bgp ipv6 unicast neighbors	Display the IPv6 unicast neighbor information of BGP.
show bgp ipv6 unicast paths	Display the IPv6 unicast path information in a routing information base.
show bgp ipv6 unicast summary	Display the BGP IPv6 unicast summary information.
show bgp ipv6 unicast update-group	Display the BGP IPv6 unicast update group information.
show bgp log-info	Display BGP log information.
show bgp log-warn	Display BGP alarm information.
show bgp memory	Display BGP memory information.
show bgp nsr	Display NSR information.

show bgp route-block	Display black hole route statistics.
show bgp rpi	Display RPI policy information.
show bgp statistics	Display BGP statistics.
show ip bgp	Display the routing information of an IPv4 unicast address family of BGP.
stats-reporting-period	Configure the interval of regularly sending state statistics by BGP.
synchronization	Enable the function of routing information synchronization between BGP and IGP.
table-map	Control the routing information sent to the core routing table by BGP.
timers bgp	Configure the duration of BGP timers.
update-source	Configure a network interface used to establish a TCP connection with a specified BMP server.

1.1 address port

Function

Run the **address port** command to configure the address and port number of a BGP Monitoring Protocol (BMP) server.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No BMP server is configured with address or port number by default.

Syntax

address { *bmp-server-ipv4-address* | *bmp-server-ipv6-address* } **port** *port-number*

no address { *bmp-server-ipv4-address* | *bmp-server-ipv6-address* } **port** *port-number*

default address { *bmp-server-ipv4-address* | *bmp-server-ipv6-address* } **port** *port-number*

Parameter Description

bmp-server-ipv4-address: IPv4 address of a specified BMP server.

bmp-server-ipv6-address: IPv6 address of a specified BMP server.

port-number: Listening port number of a specified BMP server.

Command Modes

BMP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the address of the specified BMP server to 10.0.0.1 and the port number to 12345.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
Hostname(config-bmpsrvr)# address 10.0.0.1 port 12345
```

Notifications

N/A

Common Errors

The address of the BMP server is a local address.

```
% Cannot configure the local system as bmp server
```

Platform Description

N/A

Related Commands

- **bmp server**

1.2 address-family ipv4

Function

Run the **address-family ipv4** command to enter the IPv4 address family mode of Border Gateway Protocol (BGP).

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

BGP is configured with the IPv4 unicast address family mode by default.

Syntax

address-family ipv4 [**unicast**]

no address-family ipv4 [**unicast**]

default address-family ipv4 [**unicast**]

Parameter Description

unicast: Enters the IPv4 unicast address family mode. If this parameter is not specified, BGP enters the IPv4 unicast address family mode.

Command Modes

BGP configuration mode

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can enter the configuration mode of the IPv4 address family of BGP to configure routes and neighbors of the IPv4 address family. Or, you can configure IPv4 neighbors in the BGP configuration mode, and activate them in the configuration mode of the IPv4 address family.

The **exit-address-family** command is configured to exit the configuration mode of the IPv4 address family.

Examples

The following example enters the IPv4 unicast address family mode of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family ipv4 unicast
Hostname(config-router-af)#
```

Notifications

If configuration is completed in the scope Virtual Routing Forwarding (VRF) mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Invalid address family ipv4 unicast vrf vrf-name.
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **exit-address-family**

1.3 address-family ipv4 vrf

Function

Run the **address-family ipv4 vrf** command to enter the IPv4 VRF address family mode of BGP and enable the exchange function of VRF routing information.

Run the **no** form of this command to remove this configuration and disable this function.

Run the **default** form of this command to restore the default configuration.

No IPv4 VRF address family of BGP is configured by default.

Syntax

address-family ipv4 vrf *vrf-name*

no address-family ipv4 vrf *vrf-name*

default address-family ipv4 vrf *vrf-name*

Parameter Description

vrf-name: VRF name.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

In the IPv4 VRF address family mode of BGP, you can configure Provider Edge (PE) or Multi-VPN-Instance Customer Edge (MEC) devices to exchange BGP routing information with Customer Edge (CE) devices.

The **exit-address-family** command is configured to exit the configuration mode of the IPv4 VRF address family.

Note

If the **scope** command is not configured to associate a VRF instance with BGP, the **neighbor** command configured in the **address-family ipv4 vrf** command is displayed in the **address-family ipv6 vrf** command.

Examples

The following example enables the exchange function of routing information for VRF VPN 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family ipv4 vrf vpn1
```

Notifications

If no VRF instance is configured, the following notification will be displayed:

```
% VRF vrf-name does not exist!
```

If the VRF instance is not configured with an RD, the following notification will be displayed:

```
% VRF vrf-name does not have an RD configured.
```

If the VRF instance does not activate the IPv4 address family, the following notification will be displayed:

```
% Invalid address family ipv4 unicast vrf %s.
```

If the BGP instance does not automatically obtain a router ID, the following notification will be displayed:

```
%Warning: The router identifier is 0.0.0.0, use 'bgp router-id' to configure a valid identifier.
```

If the command configuration fails due to other reasons, the following notification will be displayed:

```
% Can not bind vrf!
```

Common Errors

1.4 address-family ipv6

Function

Run the **address-family ipv6** command to enter the IPv6 address family mode of BGP and enable the exchange function of IPv6 routing information of BGP.

Run the **no** form this command to remove this configuration and disable this function.

Run the **default** form of this command to restore the default configuration.

No IPv6 address family of BGP is configured by default.

Syntax

address-family ipv6 [**unicast**]

no address-family ipv6 [**unicast**]

default address-family ipv6 [**unicast**]

Parameter Description

unicast: Enters the configuration mode of the IPv6 unicast address family. This parameter is optional. If this parameter is not specified, BGP enters the IPv6 unicast address family mode.

Command Modes

BGP configuration mode

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can enter the configuration mode of the IPv6 address family of BGP to configure routes and neighbors of the IPv6 address family. Or, you can configure IPv6 neighbors in the BGP configuration mode, and activate them in the configuration mode of the IPv6 address family.

The **exit-address-family** command is configured to exit the configuration mode of the IPv6 address family.

Examples

The following example enters the IPv6 address family mode of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family ipv6
```

Notifications

If the global IPv6 unicast routing capability is not activated, the following notification will be displayed:

```
% IPv6 routing not enabled, BGP process can't configure
```

If configuration is completed in the scope VRF mode and the IPv6 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Invalid address family ipv6 unicast vrf vrf-name.
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **exit-address-family**

1.5 address-family ipv6 vrf

Function

Run the **address-family ipv6 vrf** command to enter the IPv6 VRF address family mode and enable the exchange function of IPv6 routing information of a VRF instance.

Run the **no** form of this command to remove this configuration and disable this function.

Run the **default** form of this command to restore the default configuration.

No IPv6 VRF address family is configured by default.

Syntax

address-family ipv6 vrf *vrf-name*

no address-family ipv6 vrf *vrf-name*

default address-family ipv6 vrf *vrf-name*

Parameter Description

vrf-name: VRF name.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

In the IPv6 VRF address family mode of BGP, you can configure PE or MEC devices to exchange BGP routing information with CE devices.

The **exit-address-family** command is configured to exit the configuration mode of the IPv6 VRF address family.

Note

If the **scope** command is not configured to associate a VRF instance with BGP, the **neighbor** configured in the **address-family ipv6 vrf** command in global configuration mode is displayed in the **address-family ipv4 vrf** command. Commands configured for single address families are displayed in the address family mode only configured by the commands.

Examples

The following example enables the IPv6 routing exchange capability for VRF VPN 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family ipv6 vrf vpn1
```

Notifications

If no VRF instance is configured, the following notification will be displayed:

```
% VRF vrf-name does not exist!
```

If the VRF instance is not configured with a Route Distinguisher (RD), the following notification will be displayed:

```
% VRF vrf-name does not have an RD configured.
```

If the VRF instance does not activate the IPv6 address family, the following notification will be displayed:

```
% Invalid address family ipv6 unicast vrf %s.
```

If the global IPv6 unicast routing capability is not activated, the following notification will be displayed:

```
% IPv6 routing not enabled,BGP IPv6 can't configure
```

If the BGP instance does not automatically obtain a router ID, the following notification will be displayed:

```
% Warning: The router identifier is 0.0.0.0, use 'bgp router-id' to configure a valid identifier.
```

If the command configuration fails due to other reasons, the following notification will be displayed:

```
% Can not bind vrf!
```

1.9 aggregate-address

Function

Run the **aggregate-address** command to configure a route aggregation entry of BGP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No route aggregation entry of BGP is configured by default.

Syntax

aggregate-address { *ipv4-address mask* | *prefix* } [**advertise-map** route-map-name | **as-set** | **attribute-map** *route-map-name* | **summary-only** | **suppress-map** route-map-name] *

no aggregate-address { *ipv4-address mask* | *prefix* }

default aggregate-address { *ipv4-address mask* | *prefix* }

Parameter Description

ipv4-address: Aggregated IPv4 address.

mask: Mask of an aggregated IPv4 address.

prefix: Prefix of an aggregated IPv4 address.

advertise-map *route-map-name*: Configures a policy to generate route aggregation. *route-map-name* is the name of a route map and does not exceed 32 characters in length.

as-set: Reserves the AS path information within the aggregate address range. If this parameter is not specified, the AS path information within the aggregate address range is not reserved.

attribute-map *route-map-name*: Configures a route policy to control route aggregation attributes. *route-map-name* is the name of a route map and does not exceed 32 characters in length.

summary-only: Advertises only aggregate paths. If this parameter is not specified, all paths are advertised.

suppress-map *route-map-name*: Suppresses the route map of a specified route. *route-map-name* is the name of a route map and does not exceed 32 characters.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 address family of BGP

Configuration mode of the IPv6 unicast address family of BGP

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

All path information before and after aggregation is advertised by default. If only path information after aggregation needs to be advertised, specify the **summary-only** parameter during configuration.

Examples

The following example configures IPv4 route aggregation entries and reserves the AS path information within the aggregate path range.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# aggregate-address 10.0.0.0 255.0.0.0 as-set
```

Notifications

If the entered network address is invalid, the following notification will be displayed:

```
% Invalid network address
```

When the configured route aggregation entry is already configured, the following notification will be displayed:

```
% The same object already exists
```

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

If the deleted route aggregation entry is not configured, the following notification will be displayed:

```
% Unknown object, configure first
```

1.10 bgp additional-paths select

Function

Run the **bgp additional-paths select** command to enable the selection function of alternative additional paths (ADD-PATH) routes.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The selection function of alternative ADD-PATH routes is disabled by default.

Syntax

bgp additional-paths select { **all** | **best** *best-number* | **ecmp** }

no bgp additional-paths select

default bgp additional-paths select

Parameter Description

all: Selects all valid routes as alternative ADD-PATH routes of the "all" type.

best *best-number*: Selects the next-best routes as alternative ADD-PATH routes of the "best number" type. The value of *best-number* is **2** or **3**.

ecmp: Selects the Equal-Cost Multipath Routing (ECMP) routes as alternative ADD-PATH routes of the "ECMP" type. You also need to select ECMP routes.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast address family of BGP

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 unicast address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Default Level

14

Usage Guidelines

To advertise alternative ADD-PATH routes, you need to run the **neighbor advertise additional-paths** and **neighbor additional-paths** commands.

Examples

The following example selects the next-best routes as alternative ADD-PATH routes of the "best number" type.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp additional-paths select best 2
```

The following example selects the alternative ADD-PATH routes of the "ECMP" type.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000

1.11 bgp advertise lowest-priority on-startup

Function

Run the **bgp advertise lowest-priority on-startup** command to adjust the priority of routes advertised during device restart to the lowest level.

Run the **no** form of this command to remove this configuration.

Run the **default** form of command to restore the default configuration.

BGP does not modify the priority of advertised routes by default.

Syntax

bgp advertise lowest-priority on-startup [*recover-time*]

no bgp advertise lowest-priority on-startup

default bgp advertise lowest-priority on-startup

Parameter Description

recover-time: Timer time in seconds at which the priority of advertised routes is restored. The value range is from 1 to 65535, and the default value is **600**.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

You can run this command to restore the priority of advertised routes to the original level before adjustment.

Examples

The following example configures BGP to adjust the priority of advertised routes to the lowest level upon device restart.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp advertise lowest-priority on-startup
```

1.12 bgp advertise non-transitive extcommunity

Function

Run the **bgp advertise non-transitive extcommunity** command to add the non-transmissive extended community attribute when BGP advertises routes to an External BGP (EBGP) neighbor.

Run the **no** form of this command to remove this configuration.

Run the **default** form of command to restore the default configuration.

BGP does not carry the non-transmissive extended community attribute when it advertises routes to an EBGP neighbor.

Syntax

bgp advertise non-transitive extcommunity

no bgp advertise non-transitive extcommunity

default bgp advertise non-transitive extcommunity

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

A device does not advertise the non-transmissive extended community attribute to a neighbor when it advertises routes to an EBGP peer. This command is configured to forcibly advertise the non-transmissive extended community attribute.

Routing information advertised to EBGP neighbors and Internal BGP (IBGP) neighbors of an alliance carries the non-transmissive extended community attribute.

Examples

The following example configures BGP to carry the non-transmissive extended community attribute when it advertises routes to an EBGP peer.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp advertise non-transitive extcommunity
```

1.13 bgp advertise-map

Function

Run the **bgp advertise-map** command to match a global routing policy with sent routes.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No global routing policy matches routes sent to neighbors by default.

Syntax

bgp advertise-map *route-map-name*

no bgp advertise-map

default bgp advertise-map

Parameter Description

route-map-name: Name of a matched route map.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast address family of BGP

Configuration mode of the IPv4 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

When the **bgp advertise-map** and **neighbor route-map out** commands are configured, the two policies take effect. However, the policy configured in the **bgp advertise-map** command has a higher priority than the other one.

Examples

The following example matches sent routes with a route map named MAP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp advertise-map MAP
```

1.14 bgp always-compare-med

Function

Run the **bgp always-compare-med** command to enable the Multi Exit Discriminator (MED) comparison function of BGP.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The MED comparison function is disabled by default.

Syntax

bgp always-compare-med

no bgp always-compare-med

default bgp always-compare-med

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

Only MED values of paths of peers from the same AS are compared by default. You can run this command to force devices to compare MED values of different AS paths. If there are multiple valid paths to the same destination address, the path with a smaller MED value has a higher priority.

This command is not recommended unless different ASs in the network use the same IGP and route selection methods.

Examples

The following example compares MED attributes during BGP route calculation.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp always-compare-med
```

1.15 bgp asnotation dot

Function

Run the **bgp asnotation dot** command to display 4-byte AS numbers in dot mode and match regular expressions. Two decimals are separated by dot, for example 65535.65535.

Run the **no** form of this command to configure BGP to display 4-byte AS numbers in decimal notation mode.

Run the **default** form of this command to restore the default configuration.

AS numbers are expressed in decimal notation mode by default.

Syntax

bgp asnotation dot

no bgp asnotation dot

default bgp asnotation dot

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

4-byte AS numbers support two expression modes: decimal notation mode and dot mode. The decimal notation mode is the same as the original expression mode, that is, the 4 bytes of an AS number are expressed in decimal notation. The conversion between the dot mode and decimal notation mode is as follows: 4-byte decimal AS number = x * 65536 + Y. For example:

- For an AS number 65534 in decimal mode, it is 65,534 in dot mode. An AS number smaller than 65536 is the same in decimal mode and dot mode.
- For an AS number 65536 in decimal mode, it is 1.0 in dot mode.
- For an AS number 65538 in decimal mode, it is 1.2 in dot mode.

The display mode of 4-byte AS numbers does not affect the expression mode of the 4-byte AS numbers in BGP commands. The decimal notation and dot modes are supported in BGP commands. The display mode of 4-byte AS numbers in a regular expression must be consistent with the current display mode. Otherwise, the regular expression cannot be matched.

After this command is configured, you must run the **clear ip bgp *** command to reset peers and match regular expressions again according to filtering conditions.

Examples

The following example displays 4-byte AS numbers in dot mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp asnotation dot
```

1.18 bgp bestpath as-path multipath-relax

Function

Run the **bgp bestpath as-path multipath-relax** command to enable AS-PATH loose comparison of multiple paths in load balancing mode for BGP.

Run the **no** form of this command to enable AS-PATH precise comparison of multiple paths in load balancing mode for BGP.

Run the **default** form of this command to restore the default configuration.

AS-PATH loose comparison of multiple paths in load balancing mode is not configured for BGP by default.

Syntax

bgp bestpath as-path multipath-relax

no bgp bestpath as-path multipath-relax

default bgp bestpath as-path multipath-relax

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

BGP must accurately compare AS-PATH attributes by default while selecting equal-cost multipath. Equal-cost multipath can be selected only when the AS-PATH attribute is identical. As a result, load balancing cannot be implemented for the paths. After AS-PATH loose comparison is enabled, load balancing can be implemented for multiple paths if the AS-PATH length is compared.

Examples

The following example enables AS-PATH loose comparison for multiple paths in load balancing mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp bestpath as-path multipath-relax
```

1.19 bgp bestpath compare-confed-aspath

Function

Run the **bgp bestpath compare-confed-aspath** command to compare AS path length when the optimal path is selected.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The AS-PATH attributes of internal EBGP routes from an alliance are not compared by default when the optimal path is selected. Routes are selected based on other conditions.

Syntax

bgp bestpath compare-confed-aspath

no bgp bestpath compare-confed-aspath

default bgp bestpath compare-confed-aspath

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

When the same routes learned from EBGP neighbors in an alliance are selected, the AS path length is not compared by default. After this command is run, a device compares AS path length during route selection. The route with a shorter AS path has a higher priority.

If a route is not configured with the AS-PATH attribute, the device cannot compare the AS path length of this route.

Examples

The following example compares AS path length when the optimal path is selected.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp bestpath compare-confed-aspath
```

1.26 bgp client-to-client reflection

Function

Run the **bgp client-to-client reflection** command to enable the route reflection function between device clients.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The route reflection function between clients is enabled by default.

Syntax

bgp client-to-client reflection

no bgp client-to-client reflection

default bgp client-to-client reflection

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

Generally, you do not need to create connections between the clients of a route reflector because the route reflector can reflect the routes between the clients. If a full mesh of connections is established among all clients, you can cancel the function of client route reflection of the route reflector.

Examples

The following example disables the route reflection function between clients of a device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# no bgp client-to-client reflection
```

1.27 bgp cluster-id

Function

Run the **bgp cluster-id** command to configure the cluster ID for a route reflector.

Run the **no** form of this command to configure BGP to use a local router ID as the cluster ID.

Run the **default** form of this command to restore the default configuration.

The cluster ID of a route reflector is used as the route ID of the route reflector by default.

Syntax

bgp cluster-id [*cluster-id* | *ipv4-address*]

no bgp cluster-id

default bgp cluster-id

Parameter Description

cluster-id: Cluster ID of a route reflector. The value range is from 1 to 4294967295.

ipv4-address: Cluster ID of a route reflector.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

Generally, only one route reflector is configured in a cluster. In this case, you can use the router ID of the route reflector to identify this cluster. To increase reliability, you can configure multiple route reflectors in a cluster. In this case, you must configure the cluster ID to ensure that the route reflector can identify route update messages from other route reflectors in the cluster.

Examples

The following example configures the cluster ID of a route reflector as 10.0.0.1.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp cluster-id 10.0.0.1
```

Notifications

If the entered cluster ID is invalid, the following notification will be displayed:

```

1.28 bgp confederation identifier

Function

Run the **bgp confederation identifier** command to configure an ID for an AS alliance.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No ID is configured for an AS alliance of BGP by default.

Syntax

bgp confederation identifier *as-number*

no bgp confederation identifier

default bgp confederation identifier

Parameter Description

as-number: ID of an AS alliance. The value range is from 1 to 65535. A device can be configured with a 4-byte AS number. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

An alliance is method of reducing the IBGP peer connections within an AS.

An AS is divided into multiple sub ASs and configured with a unified alliance ID (namely, AS number) for these sub ASs to form an alliance. Outside the alliance, the entire alliance is still considered as an AS and only the AS number of the alliance is visible. Inside the alliance, a full mesh of IBGP peers is established for BGP speakers

within a sub AS, and EBGP peer connections are established for BGP speakers in different sub ASs. Though EBGP connections are established between BGP speakers in different sub ASs, the next hop, MED, local priority and other information keep unchanged when information is exchanged.

Examples

The following example sets the ID of an AS alliance to **65000**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp confederation identifier 65000
```

No member AS is configured for an AS alliance by default.

Syntax

bgp confederation peers *as-number*&<1-n>

no bgp confederation peers *as-number*&<1-n>

default bgp confederation peers *as-number*&<1-n>

Parameter Description

as-number&<1-n>: Member AS within an alliance. A 4-byte AS number can be configured. That is, the AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode. & <1-n> specifies that 1 to *n* members ASs can be configured for an alliance.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

An alliance is method of reducing the IBGP peer connections within an AS.

An AS is divided into multiple sub ASs and configured with a unified alliance ID (namely, AS number) for these sub ASs to form an alliance. Outside the alliance, the entire alliance is still considered as an AS and only the AS number of the alliance is visible. Inside the alliance, a full mesh of IBGP peers is established for BGP speakers within a sub AS, and EBGP peer connections are established for BGP speakers in different sub ASs. Though EBGP connections are established between BGP speakers in different sub ASs, the next hop, MED, local priority and other information keep unchanged when information is exchanged.

Examples

The following example configures members ASs 65000 and 65100 for an alliance.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp confederation peers 65000 65100
```

1.30 bgp dampening

Function

Run the **bgp dampening** command to enable the route dampening function and configure dampening parameters.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The route dampening function is disabled by default.

Syntax

bgp dampening [*half-life* [*reusing suppressing maximun-supress-time*] [**withdrawal-ignore**] | **route-map** *route-map-name*]

no bgp dampening

default bgp dampening

Parameter Description

half-life: Half life time. When the life time in minutes reaches this value, the penalty is halved. The value range is from 1 to 45, and the default value is **15**.

reusing: Reuse Limit. When the penalty is reduced to this value, the route is activated again. The value range is from 1 to 10000, and the default value is **750**.

suppressing: Suppress limit. When the penalty is greater than this value, the route is suppressed. The value range is from 1 to 20000, and the default value is **2000**.

maximun-supress-time: Maximum time of route suppression. When the time in minutes exceeds this value, the route is activated. The value range is from 1 to 255, and the default value is **60**.

withdrawal-ignore: Specifies that the penalty does not increase when the route is activated again.

route-map *route-map-name*: Calls a route map to apply the route dampening function to a specific route. Route dampening is applied to all routes by default.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast address family of BGP

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 unicast address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used to suppress unstable EBGP routes and does not apply to IBGP routes.

Penalty is used to describe route stability. A greater penalty indicates a more unstable route. The penalty increases by 1000 each time route flapping occurs once (a withdraw packet is received). The penalty does not increase after it reaches a value. This value is called the upper limit of penalty. The value is subject to the configured *maximun-supress-time*. The formula is as follows: Upper limit of penalty = 2 ^ (*maximun-supress-time*/*half-life*) * *reusing.* Because the upper limit of penalty cannot exceed 20000, the values of *maximun-supress-time*, *half-life*, and *reusing* must be adjusted based on the network status.

1. Relationship between *Half-time and maximun-supress-time*: *half-time* ≤ *maximum-supress-time*

2. Relationship between *reusing*, *suppressing*, and upper limit of penalty: *reusing* ≤ *suppressing* ≤ upper limit of penalty

Users can specify only the *half-life* value. In this case, the value of *maximun-supress-time* is (*half-life* × 4), and the values of *reusing* and *suppressing* are 750 and 2000 respectively.

If the penalty of an EBGP route exceeds the value of *suppressing*, the route is suppressed. A suppressed route is neither used during BGP route selection nor advertised to other BGP peers. If the suppressed routes go on flapping, the penalty rises to the upper limit of penalty.

If the *half-life* of a suppressed route passes, the penalty is halved. If the penalty decreases to the value of *reusing*, the route of update packets is selected by BGP again at the last update. If the penalty decreases to the value 0, the route of withdraw packets is removed from the BGP routing table at the last update.

By default, the penalty value increases by 1000 when a route is reactivated and increases by 500 when a route is updated.

Route suppression information is recalculated during active/standby switchover in the Virtual Switching Unit (VSU) environment.

Examples

The following example sets the **Half-life-time** to **30** minutes, **Reuse Limit** to **1200**, **Suppress Limit** to **10000**, and **Max-suppress-time** to **120** minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp dampening 30 1200 10000 120
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

If configuration is completed in the scope VRF mode and the IPv6 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv6 unicast of vrf vrf-name enabled.
```

If the configured **maximun-supress-time** value is smaller than the **Half-life-time** value, the following notification will be displayed:

```
% Maximum suppress time cannot be less than half life time.
```

If the configured **Suppress Limit** value is smaller than the **Reuse Limit** value, the following notification will be displayed:

```
% Suppress value cannot be less than reuse value.
```

If the upper limit of the penalty obtained based on the configured parameters is greater than 10000, the following notification will be displayed:

```
% Either maximun-supress-time time or reusing value is too large.
```

If the upper limit of the penalty obtained based on the configured parameters is smaller than the **Suppress Limit** value, the following notification will be displayed:

```
% Either maximun-supress-time time or reusing value is too small.
```

1.32 bgp default local-preference

Function

Run the **bgp default local-preference** command to configure the default LOCAL_PREF attribute.

Run the **no** form of this command to restore the default LOCAL_PREF attribute.

Run the **default** form of this command to restore the default configuration.

The default LOCAL_PREF value is **100**.

Syntax

bgp default local-preference *local-preference-value*

no bgp default local-preference

default bgp default local-preference

Parameter Description

local-preference-value: Attribute value of a local priority. The value range is from 0 to 4294967295, and the default value is **100**.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

BGP uses the LOCAL_PREF attribute as a basis for comparing priorities of paths learned from IBGP peers. A path with a larger LOCAL_PREF value has a higher priority.

When sending external routes to IBGP peers, a BGP speaker adds the LOCAL_PREF attribute.

Examples

The following example sets the default LOCAL_PREF value to **200**.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp default local-preference 200
```

1.33 bgp default route-target filter

Function

Run the **bgp default route-target filter** command to enable the Route-Target filtering function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The Route-Target filtering function is enabled by default.

Syntax

bgp default route-target filter

no bgp default route-target filter

default bgp default route-target filter

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

After the **no bgp default route-target filter** command is run, BGP receives all VPN routes whether the Route-Target of the local VRF instance is filtered or not.

When a PE route reflector client is configured for BGP, the device receives all VPN routes, regardless of the configuration of this command.

Examples

The following example disables the Route-Target filtering function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# no bgp default route-target filter
```

Function

Run the **bgp dmzlink-bw** command to advertise bandwidth of a specified interface as an extended attribute.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No bandwidth of a specified interface is advertised as an extended attribute.

Syntax

bgp dmzlink-bw

no bgp dmzlink-bw

default bgp dmzlink-bw

Parameter Description

N/A

Command Modes

BGP configuration mode

IPv4 unicast address family mode of BGP

IPv6 unicast address family mode of BGP

IPv4 VRF address family mode of BGP

IPv6 VRF address family mode of BGP

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used to configure links for directly connected EBGP peers. After the **neighbor send-community** command is configured, the extended community attribute of link bandwidth is transmitted to IBGP peers. This command is used with the **maximum-paths { ebgp | ibgp }** *maximum-paths-number* command to configure load balancing for multiple paths on links with unequal bandwidth. This command takes effect only when each directly connected EBGP peer carries the extended community attribute of link bandwidth.

Examples

The following example advertises the bandwidth of a specified interface as an extended attribute in the IPv4 address family.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# address-family ipv4
Hostname(config-router-af)# bgp dmzlink-bw
```

1.36 bgp enforce-first-as

Function

Run the **bgp enforce-first-as** command to configure a device to check the first AS number of the AS_PATH field in update packets.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

A device checks the first AS number of the AS_PATH field in update packets by default.

Syntax

bgp enforce-first-as

no bgp enforce-first-as

default bgp enforce-first-as

Parameter Description

N/A

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

A device obtains routing information by receiving update packets. When the device attempts to advertise the routing information learned from the update packets to other devices:

- If the routing information is advertised to EBGP peers, the device adds the local AS number to the AS_PATH field as the first AS number. The EBGP peers can know the ASs that the packets need to pass before they reach the destination address based on the AS_PATH attribute in this routing information.
- If the routing information is advertised to IBGP peers, the AS_PATH attribute remains unchanged.

After this command is configured, the device determines the first AS number of the AS_PATH attribute in update packets when it receives the update packets from EBGP peers. If the first AS number is not the AS number of the EBGP peers, the packets are directly discarded.

Examples

The following example configures a device to check the first AS number of the AS_PATH field in update packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# bgp enforce-first-as
```

Function

Run the **bgp fast-reroute** command to enable the fast rerouting (FRR) function of BGP.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The FRR function is disabled by default.

Syntax

bgp fast-reroute

no bgp fast-reroute

default bgp fast-reroute

Parameter Description

N/A

Command Modes

BGP configuration mode

IPv4 unicast address family mode of BGP

IPv6 unicast address family mode of BGP

IPv4 VRF address family of BGP

IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

The FRR function of BGP is restricted by the following:

- Only one backup route is generated and the next hop of the backup route cannot be the same as that of the preferred route.
- A backup next hop cannot be generated for an Equal-Cost Multi-Path Routing (ECMP) route.
- The FRR function of BGP has a lower priority than that of VPN. That is, if VPN FRR is enabled in the VRF mode, the FRR function of BGP can take effect only when VPN FRR fails to calculate a backup route.
- This command and the **bgp install standby-path** command cannot be configured concurrently.

Examples

The following example enables the FRR function of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65530
Hostanme(config-router)# bgp fast-reroute
```

1.39 bgp fast-withdraw

Function

Run the **bgp fast-withdraw** command to enable the fast withdrawal function of a specified BGP route.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The fast withdrawal function for a specified BGP route is disabled by default.

Syntax

bgp fast-withdraw { **access-list** { *access-list-number* | *access-list-name* } | **prefix-list** *prefix-list-name* | **route-map** *route-map-name* }

no bgp fast-withdraw { **access-list** | **prefix-list** | **route-map** }

default bgp fast-withdraw { **access-list** | **prefix-list** | **route-map** }

Parameter Description

access-list-number: Number of an Access Control List (ACL). The value range is from 1 to 199 or from 1300 to 2699.

access-list-name: Name of an ACL.

prefix-list-name: Name of a prefix list.

route-map-name: Name of a matched route map rule.

Command Modes

BGP configuration mode

IPv4 unicast address family mode of BGP

IPv6 unicast address family mode of BGP

IPv4 VRF address family of BGP

IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

The fast withdrawal function of a specified BGP route is restricted by the following:

- Either the **prefix-list** or **access-list** keyword takes effect.

Examples

The following example enables the fast withdrawal function of a specified BGP route.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostanme(config-router)# bgp fast-withdraw route-map bgp-filter
```

1.40 bgp graceful-restart

Function

Run the **bgp graceful-restart** command to enable the function of global BGP graceful restart (GR).

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function of global BGP GR is enabled by default.

Syntax

bgp graceful-restart

no bgp graceful-restart

default bgp graceful-restart

Parameter Description

N/A

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

BGP GR enables a device to keep the BGP routing table valid and continue to forward data during restart. After this command is configured, the device can execute GR or help neighbors execute GR.

The BGP GR capability is advertised through the capability field in an open message and negotiated in the initial establishment of connections between a device and its peer. Both the device and its peer must support the GR capability. If neither of them support GR, the route device does not correctly implement GR.

After this command is configured, it does not take effect to all established BGP connections. Therefore, to negotiate immediately about the GR capability on these BGP connections, forcibly restart the BGP connections to renegotiate about GR capability between the local device and its peer. You can run the **clear ip bgp** command to restart the BGP connections between peers.

BGP detects neighbor GR based on TCP failure messages. If a TCP failure occurs in non-GR scenario, for example, the **shutdown** command is run in interface configuration mode, BGP enters the GR Helper state and retains neighbor routes, and converges the routes after GR times out or a connection with the neighbor is reestablished.

Examples

The following example enables the global BGP GR function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 500
Hostanme(config-router)# bgp graceful-restart
```

1.41 bgp graceful-restart disable

Function

Run the **bgp graceful-restart disable** command to disable the GR function of a specified BGP address family.

Run the **no** form of this command to enable the GR function of a specified BGP address family.

Run the **default** form of this command to restore the default configuration.

When the global BGP GR function is enabled, the GR function of each BGP address family is enabled by default.

Syntax

bgp graceful-restart disable

no bgp graceful-restart disable

default bgp graceful-restart disable

Parameter Description

N/A

Command Modes

BGP configuration mode

IPv4 unicast address family mode of BGP

IPv4 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

When the BGP GR function is enabled, this activates the GP capability of address families by default, except those that do not support GR. You can run this command in address family configuration mode to disable the GR capability of the specified address family. If this command is configured in BGP mode, it acts on IPv4 unicast address families.

When the BGP GR function is disabled, the GR capability of all address families is disabled.

Examples

The following example disables the GR capability of the IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostanme(config-router)# bgp graceful-restart
Hostanme(config-router)# address-family ipv4
Hostanme(config-router-af)# bgp graceful-restart disable
```

Notifications

If the GR capability is not supported in the current address family, the following notification will be displayed:

```
% The address family does not support graceful restart
```

Common Errors

1.42 bgp graceful-restart restart-time

Function

Run the **bgp graceful-restart restart-time** command to configure the GR time of BGP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The GR time is **120** seconds by default.

Syntax

bgp graceful-restart restart-time *restart-time*

no bgp graceful-restart restart-time

default bgp graceful-restart restart-time

Parameter Description

restart-time: Expected maximum wait time before the establishment of a connection between the GR Helper and the GR Restarter, in seconds. The value range is from 1 to 3600.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

The restart time is advertised by the GR Restarter to the GR Helper, which indicates the expected maximum wait time before the establishment of a connection between the GR Helper and the GR Restarter. If no BGP connection is established between the GR Helper and GR Restarter after this timer expires, the BGP connection request fails. A normal BGP restart process is performed. During this process, all routes of this neighbor are deleted and data forwarding is affected.

This value is advertised in the GR capability field of the Open message of BGP. You are advised to configure the same GR restart time for the devices at both ends of a session.

This command does not take immediately effect to all established BGP connections. Therefore, you must forcibly disconnect and reestablish the BGP connections to renegotiate the GR capability and advertise the latest restart time to the GR Helper. You can run the **clear ip bgp** command to forcibly disconnect and reestablish a BGP connection. The configured restart time should not be greater than the Hold Time of the BGP peer; otherwise, the Hold Time is used as the restart time and advertised to the BGP peer during GR capability advertisement.

Examples

The following example sets the GR time of BGP to **150** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 500
Hostanme(config-router)# bgp graceful-restart
Hostanme(config-router)# bgp graceful-restart restart-time 150
```

1.43 bgp graceful-restart stalepath-time

Function

Run the **bgp graceful-restart stalepath-time** command to configure the hold time of a stale route by a GR Helper during BGP GR.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default hold time of a stale route by a GR Helper during BGP GR is **360** seconds.

Syntax

bgp graceful-restart stalepath-time *stalepath-time*

no bgp graceful-restart stalepath-time

default bgp graceful-restart stalepath-time

Parameter Description

stalepath-time: Maximum hold time in seconds of a stale route after a connection with a GR device is recovered. The value range is from 1 to 3600.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

This command applies to GR Helpers.

StalePath-time specifies the maximum wait time of the EOR flag from the GR Restarter after a connection is recovered between the GR Helper and the GR Restarter. Upon detecting the disconnection from the GR Restarter, the GR Helper marks the original routes to the GR Restarter as Stale, but uses these routes to calculate and forward routes. The GR Helper updates route information based on the route update message received from the GR Restarter and removes the Stale mark from the routes. In the stalepath-time, the stale routes are deleted if they are not updated. This mechanism is used to ensure route convergence if the GR Helper does not receive the EOR flag for a long time.

Examples

The following example sets the hold time of a stale route by a GR Helper during BGP GR to **240** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 500
Hostanme(config-router)# bgp graceful-restart
Hostanme(config-router)# bgp graceful-restart stalepath-time 240
```

1.44 bgp initial-advertise-delay

Function

Run the **bgp initial-advertise-delay** command to enable the function of BGP delayed advertisement upon system restart.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function of BGP delayed advertisement upon system restart is disabled by default.

Syntax

bgp initial-advertise-delay { *delay-time* [*startup-time*] [**wait-for-controller**] | **prefix-list** *prefix-list-name* }

no bgp initial-advertise-delay [**prefix-list**]

default bgp initial-advertise-delay [**prefix-list**]

Parameter Description

delay-time: Interval in seconds of route advertisement after the BGP neighborship is established upon system restart. The value range is from 1 to 1800, and the default value is **1**.

startup-time: Time range in seconds for system restart. In this range, neighbors use the delayed advertisement mechanism of routes. The value range is from 5 to 58400, and the default value is **600**.

wait-for-controller: Waits for the controller to deliver messages and triggers route advertisement.

prefix-list: Immediately sends routes that match the prefix list upon system restart.

prefix-list-name: Name of a prefix list. The name does not exceed 255 characters.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

Users can adjust the BGP route advertisement upon system restart according to the hardware conditions, neighbor number, route number, and deployment requirements of devices.

Generally, after a connection is established between the local device and its neighbor, a first route is advertised immediately, and later routes are advertised at the default interval (for details, see the **bgp additional-paths select**

- **neighbor additional-paths**

neighbor advertisement-interval command). This command can modify BGP peers to advertise routes to neighbors upon system restart. After this command is configured, BGP advertises routes to neighbors at an interval *delay-time* within the *startup-time* of the device after system restart.

If the **wait-for-controller** keyword is configured, the device waits for the controller to deliver route advertisement messages and trigger route advertisement upon receiving EOR messages from neighbors. In the *startup-time*, if no message is received, routes are sent forcibly.

After this command is configured, routes that are advertised at a normal interval are affected. You can specify the **prefix-list** parameter to prevent routes that match the prefix list from being affected by the delayed advertisement mechanism and send the routes at the default interval. For the range of address families applicable to the prefix list, see the **neighbor pic-disable** command.

Examples

The following example configures BGP to send routes at an interval of 60 seconds within 500 seconds upon system restart, and to send routes that match the prefix list aa at a normal interval.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 500
Hostanme(config-router)# bgp initial-advertise-delay 60 500
Hostanme(config-router)# bgp initial-advertise-delay prefix-list aa

1.48 bgp maxas-limit

Function

Run the **bgp maxas-limit** command to limit the quantity of AS numbers in the AS_PATH attribute for BGP routes.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The quantity of AS numbers in the AS_PATH attribute for routes is not limited by default.

Syntax

bgp maxas-limit *maxas-limit-number*

no bgp maxas-limit

default bgp maxas-limit

Parameter Description

maxas-limit-number: Maximum quantity of AS numbers carried in the AS_PATH attribute. The value range is from 1 to 512.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

After this command is configured, this routing information is discarded if the quantity of AS numbers in the AS_PATH attribute in the routing information received from a peer exceeds the specified upper threshold.

After you change the configuration, you must manually run the **clear ip bgp** command to reset neighbors so as to validate the command.

Examples

The following example sets the maximum allowable quantity of AS numbers in the AS_PATH attribute for a BGP route to **100**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp maxas-limit 100
```

1.49 bgp maximum-neighbor

Function

Run the **bgp maximum-neighbor** command to configure the maximum number of BGP neighbors.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of neighbors is not configured by default.

Syntax

bgp maximum-neighbor *maximum-neighbor-numbers* **warning-only**

no bgp maximum-neighbor

default bgp maximum-neighbor

Parameter Description

maximum-neighbor-numbers: Maximum number of neighbors. The value range is from 1 to 15000.

warning-only: Gives an alarm only.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Usage Guidelines

When the number of BGP neighbors exceeds the specified maximum value, the device gives an alarm.

Examples

The following example sets the maximum number of BGP neighbors to **1000** in global configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# bgp maximum-neighbor 1000 warning-only
```

1.50 bgp maximum-prefix

Function

Run the **bgp maximum-prefix** command to configure the maximum number of route entries in global configuration mode or for specified VRF instances.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The function of route entry limit is disabled in global configuration mode or for specified VRF instances by default.

Syntax

bgp maximum-prefix *maximum-prefix-numbers* [**vrf** *vrf-name*]

no bgp maximum-prefix [**vrf** *vrf-name*]

default bgp maximum-prefix [**vrf** *vrf-name*]

Parameter Description

maximum-neighbor-numbers: Maximum number of route entries. The value range is from 1 to 4294967295.

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, the route entry limit function is enabled in global configuration mode.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Usage Guidelines

The prefix information of BGP routes may be imported by configuring the **redistribute** command, learned from neighbors, or imported from other VRF instances. In any scenario, if the imported prefix information of BGP routes in an address family enables the routes in global configuration mode or for specified VRF instances to reach the upper limit, the route prefix information of this address family is not added. In this case, the table of this address family and all neighbors in this address family enters the overflow state. In this case, the device prompts that BGP enters the overflow state in global configuration mode or for specified VRF instances.

You can run the **show bgp** { *address-family* | **all** } **summary** command to display the state of the routing information base.

To clear this state, you need to reconfigure BGP or run the **clear bgp** *address-family* ***** command to reset the address family. If the address family enters the overflow state because the prefix information of BGP routes reaches the maximum number of entries, you can configure the *maximum-prefix-numbers* parameter to change the setting.

For IPv4 unicast routes, even if the address family reaches the overflow state, route prefixes may be received in the following scenarios:

- The routing information with same prefixes is configured in the routing information base.
- A route overwriting the prefix (except for the default route) is configured in the routing information base and the next hop of this route is different from that of the newly received route.

Examples

The following example sets the maximum number of prefixes of BGP routes to **100** in global configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# bgp maximum-prefix 100
```

1.51 bgp mp-error-handle session-retain

Function

Run the **bgp mp-error-handle session-retain** command to configure BGP to retain BGP sessions when it detects a multiprotocol route error.

Run the **no** form of this command to configure BGP to terminate BGP sessions when it detects a multiprotocol route error.

Run the **default** form of this command to restore the default configuration.

BGP terminates BGP sessions by default when it detects a multiprotocol route error.

Syntax

bgp mp-error-handle session-retain [**refresh-timer** *refresh-timer*]

no bgp mp-error-handle session-retain

default bgp mp-error-handle session-retain

Parameter Description

refresh-timer *refresh-timer*: Configures the wait time in seconds for automatic route recovery. The value range is from 10 to 65535, and the default value is **120**.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

Upon receiving Update packets from a neighbor, the device terminates the BGP session if it detects a multiprotocol route error. This will cause flapping of the routes in all address families of this neighbor. That is, the routing error in an address family affects the route stability in other address families. After this command is configured, only the routing information related to this address family is deleted, and BGP sessions and other address families are not affected if an error occurs in the routing attribute of an address family. This enhances the stability of BGP.

You can specify the **refresh-timer** keyword to configure the wait time for automatic route recovery. But a neighbor must support the route-refresh capability. After the *refresh-timer* times out, BGP sends the route update messages of the address family to the neighbor and re-advertises all routing information of the address family to this neighbor. If the **refresh-timer** keyword is not specified during the command configuration, the default value is **120** seconds.

Examples

The following example configures BGP to retain BGP sessions when it detects a multiprotocol route error.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# router bgp 100
Hostname(config-router)# bgp mp-error-handle session-retain
```

1.52 bgp nexthop trigger delay

Function

Run the **bgp nexthop trigger delay** command to configure a delay of updating the routing table after the next hop of a BGP route changes.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default delay of updating the routing table is **5** seconds after the next hop of a BGP route changes.

Syntax

bgp nexthop trigger delay *delay-time*

no bgp nexthop trigger delay

default bgp nexthop trigger delay

Parameter Description

delay-time: Delay in seconds of updating the routing table after the next hop of a BGP route changes. The value range is from 0 to 100.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command can take effect only when the **bgp nexthop trigger enable** command is configured.

Examples

The following example sets the delay of updating the routing table to **30** seconds after the next hop of a BGP route changes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# bgp nexthop trigger delay 30
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

If the function of next hop trigger update is disabled, the following notification will be displayed:

```
% Can't disable scan-rib, please enable nexthop trigger first
```

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function of next hop trigger update is enabled by default.

Syntax

bgp nexthop trigger enable

no bgp nexthop trigger enable

default bgp nexthop trigger enable

Parameter Description

N/A

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

Next hop update of BGP is triggered by events. After this function is enabled, the device notifies BGP of this change when a device updates the next hop in the routing information base (RIB). This shortens the response time of BGP to the next hop change in the RIB routes and improves the overall convergence performance of BGP.

Examples

The following example enables the function of next hop trigger update.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# bgp nexthop trigger enable
```

Notifications

If this function is disabled in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If this function is disabled in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

1.54 bgp notify unsupport-capability

Function

Run the **bgp notify unsupport-capability** command to enable the detection function of neighbor address family capability.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The detection function of neighbor address family capability is disabled by default.

Syntax

bgp notify unsupport-capability

no bgp notify unsupport-capability

default bgp notify unsupport-capability

Parameter Description

N/A

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

If the neighbor address family capability of BGP on the local device is not consistent with that on the neighbor, neighbor connections can still be established by default. After this command is configured, a notification packet carrying the unsupported address family is sent to the neighbor if the address family capability is supported only on the local device.

Examples

The following example enables the detection function of neighbor address family capability of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp notify unsupport-capability
```

1.57 bgp redistribute-internal

Function

Run the **bgp redistribute-internal** command to configure BGP to allow the routes received from IBGP neighbors to be redistributed to Interior Gateway Protocol (IGP).

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

BGP allows the routes received from IBGP neighbors to be redistributed to IGP.

Syntax

bgp redistribute-internal

no bgp redistribute-internal

default bgp redistribute-internal

Parameter Description

N/A

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used to determine whether to allow IBGP routes to be redistributed to IGP, including Routing Information Protocol (RIP), Open Shortest Path First (OSPF), and Intermediate System-to-Intermediate System (IS-IS).

Examples

The following example allows routes received from IBGP neighbors to be redistributed to IGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp redistribute-internal
```

1.58 bgp route-reflector attribute-change

Function

Run the **bgp route-reflector attribute-change** command to allow the route reflector to modify route attributes.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

No route reflector is allowed to modify route attributes by default.

Syntax

bgp route-reflector attribute-change

no bgp route-reflector attribute-change

default bgp route-reflector attribute-change

Parameter Description

N/A

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

Generally, the route reflector cannot modify route attributes through routing policies, because this may cause a routing loop. After this command is configured, the route reflector can forcibly modify route attributes through routing policies. This command is used to replan network traffic.

Examples

The following example allows the route reflector to modify route attributes.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp route-reflector attribute-change
```

1.59 bgp router-id

Function

Run the **bgp router-id** command to configure a router ID when the BGP is running.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The loopback interface of a device is preferred as the router ID by default. If no loopback interface is available, the router ID of the local device is used.

Syntax

bgp router-id *ipv4-address*

no bgp router-id

default bgp router-id

Parameter Description

ipv4-address: Specified router ID in the format of an IPv4 address.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

The ID of each device in an AS must be unique.

Examples

The following example sets the router ID to 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp router-id 10.0.0.1
```

1.60 bgp scan-rib disable

Function

Run the **bgp scan-rib disable** command to update the routing table in event triggering mode.

Run the **no** form of this command to update the routing table in regular scanning mode.

Run the **default** form of this command to restore the default configuration.

BGP updates the routing table in regular scanning mode by default.

Syntax

bgp scan-rib disable

no bgp scan-rib disable

default bgp scan-rib disable

Parameter Description

N/A

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

BGP provides two route update mechanisms: regular-scanning update and event-triggering update.

- Regular-scanning update specifies that BGP updates the routing table based on an internal timer.
- Event-triggering update specifies that BGP updates the routing table when the BGP configuration commands are changed due to user configuration or when the next hop of a BGP route changes.

Examples

The following example configures the routing table update mode as event triggering.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp scan-rib disable
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

If regular scanning is disabled while BGP route synchronization is enabled, the following notification will be displayed:

```
% Can't disable scan-rib, please disable synchronization first
```

If regular scanning is disabled while next hop trigger update is disabled, the following notification will be displayed information:

```
% Can't disable scan-rib, please enable nexthop trigger first
```

1.61 bgp scan-time

Function

Run the **bgp scan-time** command to configure the interval of regular scanning of BGP.

Run the **no** form of this command to configure the interval of regular scanning of BGP to a default value.

Run the **default** form of this command to restore the default configuration.

The default interval of regular scanning is **60** seconds.

Syntax

bgp scan-time *scan-time*

no bgp scan-time

default bgp scan-time

Parameter Description

scan-time: Interval in seconds of regular scanning. The value range is from 5 to 60.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used to configure the interval of regular scanning. The configuration takes effect when the route update mechanism of BGP is configured as regular scanning.

Examples

The following example sets the interval of regular scanning to **30** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp scan-time 30
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```

1.62 bgp shutdown

Function

Run the **bgp shutdown** command to actively shut down all connections.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

All connections of BGP are not shut down actively by default.

Syntax

bgp shutdown [**graceful** [**community** *community-value*] [**delay** *delay-time*]]

no bgp shutdown

default bgp shutdown

Parameter Description

graceful: Shuts down BGP connections in smooth manner.

community *community-value*: Specifies the community attribute value in a route sent to neighbors, in the format of AA:NN (AS number: 2-byte number) or a numeric. The value range is from 0 to 4294967295. If this parameter is not specified, the community attribute value is not carried.

delay *delay-time*: Specifies the delay time in seconds for shutting down BGP connections. The value range is from 1 to 65535. If this parameter is not specified, BGP connections are shut down on time.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used to shut down valid BGP connections and delete all related routing information. If this command is configured in BGP configuration mode or scope configuration mode of BGP, all BGP connections are disabled in global configuration mode. If this command is configured in the configuration mode of the IPv4 VRF address family or the IPv6 VRF address family of BGP, all BGP connections in the corresponding VRF instances are shut down.

If BGP connections are shut down in smooth manner, the device sends a route carrying the LOCAL_PREF or MED attribute to its neighbors. Upon receiving the route update information, the neighbors adjust the service traffic route to bypass this device. After a period (this period is automatically calculated based on the number of advertised routes or it is specified), the device actively shuts down BGP connections with neighbors.

Examples

The following example shuts down all the BGP connections in global configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp shutdown
```

The following example shuts down all the BGP connections in global configuration mode in smooth manner.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp shutdown graceful
```

Function

Run the **bgp sourced-paths** command to import routes with multiple paths or multiple next hops from other protocol modules.

Run the **no** form of this command to import routes with single path or single next hop from other protocol modules.

Run the **default** form of this command to restore the default configuration.

BGP imports routes with single path or single next hop by default from other protocol modules.

Syntax

bgp sourced-paths *protocol-type* **all**

no bgp sourced-paths *protocol-type* **all**

default bgp sourced-paths *protocol-type* **all**

Parameter Description

protocol-type: Source protocol type of a redistributed route.

- **arp-host**: Specifies a host route converted from ARP.
- **isis**: Specifies an IS-IS route.

- **ospf**: Specifies an OSPF route.
- **rip**: Specifies an RIP route.
- **static**: Specifies a static route.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command needs to be used with the **redistribute** command to import routes with multiple next hops from other protocols to BGP.

Examples

The following example imports static routes with multiple paths or multiple next hops.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp sourced-paths static all
```

1.65 bgp timer accuracy-control

Function

Run the **bgp timer accuracy-control** command to enable the strict execution function of internal timers of BGP.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The strict execution function of internal timers of BGP is disabled by default.

Syntax

bgp timer accuracy-control

no bgp timer accuracy-control

default bgp timer accuracy-control

Parameter Description

N/A

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

Internal timers of BGP can generate a random offset at a specified time by default. Therefore, you try not to allow excessive timers to time out concurrently. You can configure this command to allow BGP timers to strictly execute their functions according to the specified time. Unless in a special requirement, you are advised not to enable this function.

Examples

The following example enables the strict execution function of internal timers of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# bgp timer accuracy-control
```

Function

Run the **bgp upgrade-cli** command to configure the CLI display mode of BGP as address family configuration mode or scope configuration mode.

Run the **no** form of this command to configure the CLI display mode of BGP as automatic identification based on user configuration.

Run the **default** form of this command to restore the default configuration.

The CLI display mode of BGP is configured as address family configuration mode by default.

Syntax

bgp upgrade-cli vrf { **af-mode** | **scope-mode** }

no bgp upgrade-cli vrf { **af-mode** | **scope-mode** }

default bgp upgrade-cli vrf { **af-mode** | **scope-mode** }

Parameter Description

af-mode: Configures the CLI display mode of BGP as address family configuration mode.

scope-mode: Configures the CLI display mode of BGP as scope configuration mode.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

You can run this command to switch the CLI display mode of BGP. The CLI display modes of BGP include address family configuration mode and scope configuration mode.

- If the CLI display mode is configured as address family configuration mode, all CLI commands are displayed in address family configuration mode.
- If the CLI display mode is configured as scope configuration mode, all CLI commands are displayed in scope configuration mode or address family configuration mode of the scope.

Examples

The following example configures the CLI display mode of BGP as scope configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 500
Hostname(config-router)# bgp upgrade-cli scope-mode
```

1.67 bmp server

Function

Run the **bmp server** command to configure a BMP server instance and enter the BMP configuration mode.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No BMP server instance is configured by default.

Syntax

bmp server *bmp-server-number*

no bmp server *bmp-server-number*

default bmp server *bmp-server-number*

Parameter Description

bmp-server-number: Number of a configured BMP server instance. The value range is from 1 to 8.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures BMP server instance 1 and enters the BMP configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
```

1.68 buffer-size

Function

Run the **buffer-size** command to configure the maximum number of packets or bytes in the buffer of a BMP instance.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The number of packets or bytes in the buffer of a BMP instance is not limited by default.

Syntax

buffer-size *buffer-size-maximum*

no buffer-size

default buffer-size

Parameter Description

buffer-size-maximum: Maximum number of packets or bytes in the buffer of a BMP instance, in bytes. The value range is from 40960 to 4294967295.

Command Modes

BMP configuration mode

Default Level

14

Usage Guidelines

When a server cannot receive BMP packets due to insufficient memory or other reasons, the monitor packets on the server cannot be sent out and occupy the memory space. Therefore, you must limit the maximum number of packets or bytes in the buffer. When the number of packets or bytes in the buffer reaches the limit, the session with the BMP server is reset to release the cached packets.

Examples

The following example sets the maximum number of packets or bytes in the buffer of BMP instance 1 to **409600000**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
Hostname(config-bmpsrvr)# buffer-size 409600000
```

1.69 clear bgp advertise lowest-priority on-startup

Function

Run the **clear bgp advertise lowest-priority on-startup** command to restore the priority of advertised routes to BGP neighbors to the level before the configuration of the **bgp advertise lowest-priority on-startup** command**.**

Syntax

clear bgp advertise lowest-priority on-startup

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **bgp advertise lowest-priority on-startup** command is configured for a device, the device adjusts the priority of advertised routes to the lowest level after restart. You can run the **clear bgp advertise lowest-priority on-startup** command to restore the priority of advertised routes to the level before such adjustment.

Examples

The following example restores the route priority to the level before adjustment.

```
Hostname> enable
Hostname# clear bgp advertise lowest-priority on-startup
```

1.70 clear bgp all

Function

Run the **clear bgp all** command to clear all the address families of BGP.

Syntax

clear bgp all [*as-number*] [**soft**] [**in** | **out**]

Parameter Description

as-number: Specified AS in which the sessions of all peers are reset. A 4-byte AS number can be configured. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to reset the sessions of all supported address families, including sessions in the VRF instances of each address family. If the **soft** and **in** or **out** keywords are not specified, this command directly resets BGP sessions.

Examples

The following example clears all the address families of BGP.

```
Hostname> enable
Hostname# clear bgp all
```

1.71 clear bgp all peer-group

Function

Run the **clear bgp all peer-group** command to clear a specified peer group of BGP.

Syntax

clear bgp all peer-group *peer-group-name* [**soft**] [**in** | **out**]

Parameter Description

peer-group-name: Specified peer group to be reset.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to reset the sessions of all supported address families, including session connections in the VRF instances of each address family. If no optional parameter is specified, this command directly resets BGP sessions.

Examples

The following example clears all the connections of all BGP peers in the peer group **test**.

```
Hostname> enable
Hostname# clear bgp all peer-group test
```

1.72 clear bgp all update-group

Function

Run the **clear bgp all update-group** command to clear the sessions of all members in an update group.

Syntax

clear bgp all update-group [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**] [**in** | **out**]

Parameter Description

neighbor-ipv4-address: IPv4 address of the specified neighbor to be reset.

neighbor-ipv6-address: IPv6 address of the specified neighbor to be reset.

update-group-index: Index of a specified update group to be reset.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to reset the BGP sessions of all members in the update group. If the **soft** and **in** or **out** keywords are not specified, this command directly resets BGP sessions.

Examples

The following example clears the routing information received by all peers of all update groups that the neighbor 1.1.1.1 belongs to.

```
Hostname> enable
Hostname# clear bgp all update-group 1.1.1.1 in
```

1.73 clear bgp ipv4 unicast

Function

Run the **clear bgp ipv4 unicast** command to clear the specified sessions of an IPv4 unicast address family.

Syntax

clear bgp ipv4 unicast [**vrf** vrf-name] { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**soft**] [**in** | **out**]

Parameter Description

vrf-name: Specified VRF name. If this parameter is not specified, global VRF instances are specified.

*****: Resets all the peer sessions in the address family.

as-number: Specified AS in which all member sessions are reset. A 4-byte AS number can be configured. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

neighbor-ipv4-address: IPv4 address of the specified peer whose BGP sessions are reset.

neighbor-ipv6-address: IPv6 address of the specified peer whose BGP sessions are reset.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft** and **in** or **out** keywords are not specified, this command directly resets BGP sessions.

Examples

The following example clears all sessions of an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# clear bgp ipv4 unicast *
```

1.74 clear bgp ipv4 unicast dampening

Function

Run the **clear bgp ipv4 unicast dampening** command to clear the route flapping information of an IPv4 unicast address family and remove route dampening.

Syntax

clear bgp ipv4 unicast [**vrf** *vrf-name*] **dampening** [*ipv4-address* [*mask*]]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all route flapping information is cleared.

ipv4-address: IPv4 route address. If this parameter is not specified, the route flapping information and route dampening of all IPv4 addresses is cleared.

mask: Mask. If this parameter is not specified, the route flapping information and route dampening of a specified IPv4 address is cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to clear the route flapping information of BGP to remove route dampening.

Examples

The following example clears the route flapping of the IPv4 unicast address family 192.168.0.0/16 and removes route dampening.

```
Hostname> enable
Hostname# clear bgp ipv4 unicast dampening 192.168.0.0 255.255.0.0

1.75 clear bgp ipv4 unicast external

Function

Run the **clear bgp ipv4 unicast external** command to clear the EBGP connections of all IPv4 unicast address families.

Syntax

clear bgp ipv4 unicast [**vrf** *vrf-name*] **external** [**soft**] [**in** | **out**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, global VRF instances are specified.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft** and **in** or **out** keywords are not specified, BGP sessions are directly reset.

Examples

The following example resets routes received by all EBGP neighbors of an IPv4 unicast address family.

```
Hostname> enable
Hostname# clear bgp ipv4 unicast external in

1.76 clear bgp ipv4 unicast flap-statistics

Function

Run the **clear bgp ipv4 unicast flap-statistics** command to clear the statistics about route flapping of an IPv4 unicast address family.

Syntax

clear bgp ipv4 unicast [**vrf** *vrf-name*] **flap-statistics** [ipv4-*address* [*mask*]]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, global VRF instances are specified.

ipv4-address: IPv4 route address. If this parameter is not specified, the statistics about route flapping of all IPv4 addresses is cleared.

mask: Mask. If this parameter is not specified, the statistics about route flapping of a specified IPv4 address is cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to only clear the statistics about routes that are not dampened, but is not used to release dampened routes. To clear the statistics about all routes and release dampened routes, you can run the **clear ip bgp dampening** command.

Examples

The following example clears the statistics about route flapping of all IPv4 unicast address families.

```
Hostname> enable
Hostname# clear bgp ipv4 unicast flap-statistics
```

Function

Run the **clear bgp ipv4 unicast peer-group** command to clear the sessions of all members of a peer group in an IPv4 unicast address family.

Syntax

clear bgp ipv4 unicast [**vrf** *vrf-name*] **peer-group** *peer-group-name* [**soft**] [**in** | **out**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, global VRF instances are specified.

peer-group-name: Name of a peer group.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft** and **in** or **out** keywords are not specified, BGP sessions are directly reset.

Examples

The following example resets routing information received by all peers of the peer group my-group in an IPv4 unicast address family.

```
Hostname> enable
Hostname# clear bgp ipv4 unicast peer-group my-group in

1.78 clear bgp ipv4 unicast table-map

Function

Run the **clear bgp ipv4 unicast table-map** command to clear and update the Table-map configuration of an IPv4 unicast address family of BGP.

Syntax

clear bgp ipv4 unicast [**vrf** *vrf-name*] **table-map**

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, global VRF instances are specified.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

The Table-map configuration is reapplied to update the delivered core routing table.

Examples

The following example clears and updates the Table-map configuration of an IPv4 unicast address family.

```
Hostname> enable
Hostname# clear bgp ipv4 unicast table-map
```

Syntax

clear bgp ipv4 unicast [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**] [**in** | **out**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, global VRF instances are specified.

neighbor-ipv4-address: IPv4 address of a specified neighbor to be reset in the update group.

neighbor-ipv6-address: IPv6 address of a specified neighbor to be reset in the update group.

update-group-index: Index of a specified update group to be reset.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft** and **in** or **out** keywords are not specified, BGP sessions are directly reset.

Examples

The following example resets the routing information received by all peers in the update group that the local device configured in the IPv4 unicast address family 1.1.1.1 belongs to.

```
Hostname> enable
Hostname# clear bgp ipv4 unicast update-group 1.1.1.1 in

1.80 clear bgp ipv6 unicast

Function

Run the **clear bgp ipv6 unicast** command to clear the specified sessions of an IPv6 unicast address family of BGP.

Syntax

clear bgp ipv6 unicast [**vrf** *vrf-name*] { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**soft**] [**in** | **out**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, global VRF instances are specified.

*****: Resets all the peer sessions in the address family.

as-number: Specified AS in which the sessions of all members are reset. A 4-byte AS number can be configured. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

neighbor-ipv4-address: IPv4 address of the specified peer whose BGP sessions are reset.

neighbor-ipv6-address: IPv6 address of the specified peer whose BGP sessions are reset.

soft: Performs a soft reset on routing information.

in: Resets received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft** and **in** or **out** keywords are not specified, BGP sessions are directly reset.

Examples

1.88 clear ip bgp

Function

Run the **clear ip bgp** command to clear the specified sessions of an IPv4 unicast address family of BGP.

Syntax

clear ip bgp [**vrf** *vrf-name*] { ***** | *as-number* | *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**soft**] [**in** | **out**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

*****: Resets all peer sessions in the address family.

as-number: Specified AS in which the BGP sessions of all members are reset. A 4-byte AS number can be configured. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

neighbor-ipv4-address: IPv4 address of a specified peer whose BGP sessions are reset.

neighbor-ipv6-address: IPv6 address of a specified peer whose BGP sessions are reset.

soft: Performs a soft reset on routing information.

in: Reset received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft**, **in** or **out** parameter is not specified, BGP sessions are directly reset.

When a routing policy or BGP configuration changes, you can terminate and reestablish a BGP connection to execute the new routing policy or configuration. By configuring soft reset of BGP, you can execute a new routing policy without terminating a BGP session connection.

This command requires all connected BGP neighbors to support the routing update function. You can run the **show ip bgp neighbors** command to determine whether BGP peers support this function. If the BGP peers do not support this function, you can run the **neighbor soft-reconfiguration inbound** command to save original routing information for each specified BGP peer on the local BGP speaker. Saving routing information consumes device resources.

Examples

The following example resets sessions of all peers in an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# clear ip bgp *
```

Run the **clear ip bgp dampening** command to clear the route flapping information and route dampening of an IPv4 unicast address family.

Syntax

clear ip bgp [**vrf** *vrf-name*] **dampening** [*ipv4-address* [*mask*]]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all route flapping information is cleared.

If the optional parameter is not carried, all route flapping information is cleared.

ipv4-address: IPv4 address. If this parameter is not specified, the route flapping information and route dampening of all IPv4 addresses is cleared.

mask: Mask. If this parameter is not specified, the route flapping information and route dampening of a specified IPv4 address is cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to clear the route flapping information of BGP to remove route dampening.

Examples

The following example clears the flapping and dampening state of routes of the IPv4 unicast address family 192.168.0.0/16.

```

1.91 clear ip bgp flap-statistics

Function

Run the **clear ip bgp flap-statistics** command to clear statistics about route flapping of an IPv4 unicast address family.

Syntax

clear ip bgp [**vrf** *vrf-name*] **flap-statistics** [*ipv4-address* [*mask*]]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

address: IPv4 address. If this parameter is not specified, the statistics about route flapping of all IPv4 addresses is cleared.

mask: Mask. If this parameter is not specified, the statistics about route flapping of a specified IPv4 address is cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to only clear statistics about routes that are not dampened but is not used to release dampened routes. To clear statistics about all routes and release dampened routes, you can run the **clear ip bgp dampening** command.

Examples

The following example clears statistics about route flapping of all IPv4 unicast address families.

```
Hostname> enable
Hostname# clear ip bgp flap-statistics
```

1.92 clear ip bgp peer-group

Function

Run the **clear ip bgp peer-group** command to clear sessions of all members in a peer group in an IPv4 unicast address family.

Syntax

clear ip bgp [**vrf** *vrf-name*] **peer-group** *peer-group-name* [**soft**] [**in** | **out**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

peer-group-name: Name of a peer group.

soft: Performs a soft reset on routing information.

in: Reset received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft**, **in** or **out** parameter is not specified, BGP sessions are directly reset.

Examples

The following example resets routing information received by all peers of the peer group my-group in an IPv4 unicast address family.

```
Hostname> enable
Hostname# clear ip bgp peer-group my-group in
```

1.93 clear ip bgp table-map

Function

Run the **clear ip bgp table-map** command to clear old information and update the Table-map's routing information in an IPv4 unicast address family.

Syntax

clear ip bgp [**vrf** *vrf-name*] **table-map**

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example updates the Table-map's routing information in an IPv4 unicast address family.

```
Hostname> enable
Hostname# clear ip bgp table-map
```

1.94 clear ip bgp update-group

Function

Run the **clear ip bgp update-group** command to clear sessions of all members in a peer group in an IPv4 unicast address family.

Syntax

clear ip bgp [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**soft**]] [**in** | **out**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

neighbor-ipv4-address: IPv4 address of a specified neighbor to be reset in the update group.

neighbor-ipv6-address: IPv6 address of a specified neighbor to be reset in the update group.

update-group-index: Index of a specified update group to be reset.

soft: Performs a soft reset on routing information.

in: Reset received routing information.

out: Resets distributed routing information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the **soft**, **in** or **out** parameter is not specified, BGP sessions are directly reset.

Examples

The following example resets the routing information received by all peers in the update group that the local device configured in the IPv4 unicast address family 1.1.1.1 belongs to.

```
Hostname> enable
Hostname# clear ip bgp update-group 1.1.1.1 in
```

1.95 default-information originate

Function

Run the **default-information originate** command to configure BGP to advertise redistributed default routes.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

BGP does not advertise redistributed default routes by default.

Syntax

default-information originate

no default-information originate

default default-information originate

Parameter Description

N/A

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast address family of BGP

Configuration mode of the IPv6 unicast address family of BGP

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command and the **redistribute** command must be configured at the same time. This command takes effect only when the redistributed routes contain default routes.

This command is similar to the **network** command. When you configure the **default-information originate** command, you must run the **redistribute** command to redistribute default routes so as to validate such default routes. To configure the **network** command, you need to only configure default routes for Interior Gateway Protocol (IGP).

Examples

The following example configures BGP to advertise redistributed default routes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# default-information originate
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

1.96 default-metric

Function

Run the **default-metric** command to use the manually configured metric value for a redistributed route of BGP.

Run the **no** form of this command to use the default metric value for a redistributed route of BGP.

Run the **default** form of this command to restore the default configuration.

The default metric value is used for a redistributed route of BGP.

Syntax

default-metric *metric-value*

no default-metric

default default-metric

Parameter Description

metric-value: Manually configured metric value. The value range is from 1 to 4294967295.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used to configure the metric value for a redistributed route of BGP to ensure the complete metric value of the redistributed route.

The metric value configured by this command cannot overwrite the metric value configured by the **redistribute metric** command.

If this command is run for redistributed connected routes, the metric value is **0**.

Examples

The following example sets the default metric value of a BGP redistributed route to **45**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# default-metric 45
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

1.97 description

Function

Run the **description** command to configure description information of a BMP instance.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No description information is configured for a BMP instance by default.

Syntax

description *description-text*

no description

default description

Parameter Description

description-text: Text describing this BMP instance. A maximum of 80 characters are entered.

Command Modes

BMP configuration mode

Default Level

14

Usage Guidelines

You can run this command to add description characters to a BMP instance so that users can mark the characteristics of this BMP instance.

Examples

The following example configures description information of a BMP instance.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
Hostname(config-bmpsrvr)# description test
```

Notifications

If over 80 characters are entered, the following notification will be displayed:

```
The description length exceed 80, please reconfig
```

1.98 distance bgp

Function

Run the **distance bgp** command to configure the administrative distance of a BGP route.

Run the **no** form of this command to restore the administrative distance of a BGP route to a default value.

Run the **default** form of this command to restore the default configuration.

The default administrative distance of a route learned by BGP from an EBGP peer is **20** and that of a route learned by BGP from an IBGP peer is **200**.

Syntax

distance bgp *external-distance internal-distance local-distance*

no distance bgp

default distance bgp

Parameter Description

external-distance: Administrative distance of routes learned from EBGP peers. The value range is from 1 to 255.

internal-distance: Administrative distance of routes learned from IBGP peers. The value range is from 1 to 255.

local-distance: Administrative distance of routes learned from peers, including better routes that can be learned from IGP. Generally, these routes are indicated by the **network backdoor** command. The value range is from 1 to 255, and the default value is **200**.

Command Modes

BGP configuration mode

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You are not advised to change the administrative distance of BGP routes. If it needs change, follow the rules below when configuring this command:

- The *external-distance* must be smaller than that of other IGP routing protocols such as OSPF and RIP.
- The *internal-distance* and *local-distance* must be greater than that of other IGP routing protocols.

Examples

The following example configures the administrative distance of a BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# distance bgp 20 20 200
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

1.99 exit-address-family

Function

Run the **exit-address-family** command to exit the address family configuration mode of BGP.

Each address family is configured with an exit mode by default.

Syntax

exit-address-family

Parameter Description

N/A

Command Modes

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can run this command to exit from different address family configuration modes to the BGP configuration mode.

Examples

The following example exits the current address family configuration mode of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# address-family ipv4 unicast
Hostname(config-router-af)# exit-address-family
Hostname(config-router)#
```

1.100 failure-retry-delay

Function

Run the **failure-retry-delay** command to configure the time to reestablish a connection with a BMP server.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The time to reestablish a connection with a BMP server is not configured by default.

Syntax

failure-retry-delay *retry-delay-interval*

no failure-retry-delay

default failure-retry-delay

Parameter Description

retry-delay-interval: Interval in seconds to reestablish a connection with a BMP server. The value range is from 30 to 720.

Command Modes

BMP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the time to reestablish a connection with a BMP server to **60** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
Hostname(config-bmpsrvr)# failure-retry-delay 60
```

1.101 import path selection

Function

Run the **import path selection** command to configure a route import policy.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Only preferred routes are imported by default.

Syntax

import path selection { **all** | **bestpath** | **multipath** }

no import path selection

default import path selection

Parameter Description

all: Imports all routes with next hops.

bestpath: Imports preferred routes with next hops.

multipath: Imports preferred and equivalent routes with next hops.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can use this command to import routing entries between different VRF instances.

Examples

The following example imports all routes with next hops to a global IPv4 routing table.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65530
Hostname(config-router)# import path selection all
```

1.102 maximum-paths

Function

Run the **maximum-paths** command to configure EBGP/IBGP multipath load balancing and specify the number of equivalent paths.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

EBGP/IBGP multipath load balancing is not configured by default.

Syntax

maximum-paths { **ebgp** | **ibgp** } *maximum-paths-number*

no maximum-paths { **ebgp** | **ibgp** }

default maximum-paths { **ebgp** | **ibgp** }

Parameter Description

ebgp: Configures the number of equivalent paths of the EBGP multipath load balancing function.

ibgp: Configures the number of equivalent paths of the IBGP multipath load balancing function.

maximum-paths-number: Maximum number of equivalent paths. The value range is from 1 to 32. If the value is **1**, the function of EBGP multipath load balancing is disabled.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast address family of BGP

Configuration mode of the IPv6 unicast address family of BGP

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

If you specify the **ebgp** keyword when configuring this command, you can configure the function of multipath load balancing for routes of alliance EBGP and local VRF instances and specify the number of equivalent routes.

Note

This command does not allow IBGP and EBGP routes to form equivalent routes.

Examples

The following example configures EBGP load balancing and sets the maximum number of equivalent paths to **2**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65530
Hostname(config-router)# maximum-paths ebgp 2
```

1.103 maximum-prefix

Function

Run the **maximum-prefix** command to configure the maximum number of route prefixes in a routing information base under an address family.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The number of route prefixes in a BGP routing information base under an address family is not limited by default.

Syntax

maximum-prefix *maximum-prefix-number*

no maximum-prefix

default maximum-prefix

Parameter Description

maximum-prefix-number: Maximum number of route prefixes in a BGP routing information base under an address family. The value range is from 1 to 4294967295.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

The route prefixes of a BGP address family may be configured by the **redistribute** command, learned from neighbors, or imported from other VRF instances. When the number of route prefixes of this BGP address family reaches the threshold, the route prefixes of this address family do not increase. In this case, the table of this address family and all neighbors in this address family enter the overflow state. To clear this state, you must reconfigure BGP or run the **clear bgp** *addressfamily* ***** command to reset the address family.

You can run the **show bgp** { *addressfamily* | **all** } **summary** command to display the state of the routing information base.

Note

If an address family enters the overflow state because the number of BGP route prefixes reaches the threshold, you can configure the **maximum-prefix** parameter to change the state of the address family.

For IPv4 unicast routes, even if the address family reaches the overflow state, it can still receive route prefixes in the following scenarios:

- The routing information with same route prefixes is configured in the routing information base.
- The prefix of a route (except for the default route) is configured in the routing information base and the next hop of this route differs from that of the newly received route.

Examples

The following example sets the maximum number of prefixes in a BGP routing information base under an IPv4 unicast address family to **65535**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family ipv4
Hostname(config-router-af)# maximum-prefix 65535
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

1.104 neighbor activate

Function

Run the **neighbor activate** command to activate neighbors or peer groups in current address mode.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No neighbor or peer group is activated by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **activate**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **activate**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **activate**

Parameter Description

neighbor-ipv6-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

After the **neighbor remote-as** command is configured in an IPv4 Unicast address family of BGP or BGP configuration mode for the specified peer, the system automatically configures the **neighbor activate** command for this peer. In other address family configuration modes, the **neighbor activate** command must be manually configured.

Examples

The following example activates the route interaction capability of the neighbor 10.0.0.1 in the configuration mode of the IPv4 address family.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router)# address-family ipv4
Hostname(config-router-af)# neighbor 10.0.0.1 activate
```

Notifications

If configuration is completed in the scope VRF mode and the IPv4 address family is not activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name inactive.
```

If configuration is completed in the scope VRF mode and the IPv4 VRF mode is first activated by a VRF instance, the following notification will be displayed:

```
% Address family ipv4 unicast of vrf vrf-name enabled.
```

If the IPv6 unicast routing capability is not activated in global configuration mode and the neighbor address family capability of the IPv6 address is not configured or the neighbor is not activated, the following notification will be displayed:

```
% Can't activate ipv6 neighbor, please use ipv6 unicast routing first!
```

If the IPv6 routing capability for a neighbor is activated in an address family that does not support IPv6 addresses, the following notification will be displayed:

```
% IPv6 neighbor not supported in the address-family
```

1.105 neighbor additional-paths

Function

Run the **neighbor additional-paths** command to enable the ADD-PATH function of the specified peer.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The ADD-PATH function is disabled by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **additional-paths** { **send** [**receive**] | **receive** }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **additional-paths** { **send** [**receive**] | **receive** }

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **additional-paths** { **send** [**receive**] | **receive** }

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

send: Enables the ADD-PATH route sending capability on a device. Only when the ADD-PATH receiving capability is enabled on peers can the device advertise ADD-PATH routes.

receive: Enables the ADD-PATH route receiving capability on a device. Only when the ADD-PATH sending capability is enabled on peers can the local device receive ADD-PATH routes.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Default Level

14

Usage Guidelines

The local device can advertise ADD-PATH routes only when the ADD-PATH sending capability is enabled on the local device and the ADD-PATH receiving capability is enabled on peers.

This command is effective to IBGP neighbors only. After this command is configured, BGP neighbor relationship is reestablished.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example enables the ADD-PATH function for the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.0.0.1 additional-paths send
```

1.106 neighbor advertise additional-paths

Function

Run the **neighbor advertise additional-paths** command to advertise the specific type of alternative ADD-PATH routes to peers.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

A device does not advertise alternative ADD-PATH routes to peers by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertise additional-paths** { **all** | **best** *best-number* | **ecmp** }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertise additional-paths**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertise additional-paths**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

all: Advertises "all" types of alternative ADD-PATH routes.

best *best-number*: Advertises the "best number" type of alternative ADD-PATH routes. The value of the best number is **2** or **3**.

ecmp: Advertises the "ecmp" type of alternative ADD-PATH routes.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Default Level

14

Usage Guidelines

You can select a specific type of ADD-PATH routes by configuring the **bgp additional-paths select** command. When the type of the selected alternative ADD-PATH routes is different from that of the ones to be advertised, the device does not advertise the alternative ADD-PATH routes, but only the optimal route.

The local device can advertise ADD-PATH routes only when the ADD-PATH sending capability is enabled on the local device and the ADD-PATH receiving capability is enabled on peers.

This command is effective to IBGP neighbors only.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example configures neighbor 10.0.0.1 to advertise the "best number" type of routes as alternative ADD-PATH routes if permitted.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.0.0.1 advertise additional-paths best 2
```

1.107 neighbor advertisement-interval

Function

Run the **neighbor advertisement-interval** command to configure the route update interval of BGP.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default route update interval of BGP is **0** seconds for IBGP connections and **30** seconds for EBGP connections.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertisement-interval** *advertisement-interval*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertisement-interval**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **advertisement-interval**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

advertisement-interval: Route update interval, in seconds. The value range is from 0 to 600.

Command Modes

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example sets the interval of sending BGP route updates to the peer 10.0.0.1 to **10** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router)# neighbor 10.0.0.1 advertisement-interval 10
```

The AIGP function of BGP neighbors is disabled by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **aigp** [**send med**]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **aigp**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **aigp**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

send med: Converts AIGP Metric values to MED values when routes are advertised to a specified neighbor.

Command Modes

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Default Level

14

Usage Guidelines

If this command is not configured for a specified neighbor, the device neither receives AIGP attributes of this neighbor nor sends routes carrying the AIGP attributes to this neighbor.

If the neighbor device does not support the AIGP function, you can specify the **send med** keyword to convert the AIGP value to the MED value.

If the 64-bit AIGP Metric value is greater than 4294967295, the 32-bit MED value is 4294967295 after conversion.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example creates a neighbor and enables the AIGP function for this neighbor in the configuration mode of the BGP IPv4 VRF address family.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# address-family ipv4 vrf vpn1
Hostname(config-router-af)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router-af)# neighbor 10.0.0.1 aigp
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

1.109 neighbor allowas-in

Function

Run the **neighbor allowas-in** command to allow the local device to receive update packets that carry the AS number of the local device.

Run the **no** form of this command not to receive update packets that carry the AS number of the local device.

Run the **default** form of this command to restore the default configuration.

No update packets that carry the AS number of the local device are allowed to be received by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **allowas-in** [*occurrence-number*]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **allowas-in**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **allowas-in**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

occurrence-number: Occurrence times of an AS number. The value range is from 1 to 10, and the default value is **3**.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

After this command is configured on a PE device in the Hub-Spoke network, the PE device can receive update packets that carry the AS number of the local device. The PE device is configured with two VRF instances. Here, one VRF instance is used to receive routing information of all PE devices and advertise the information to a CE device. The other VRF instance is used to receive routing information of the CE device and advertise the information to all PE devices.

When this command is configured, a specified peer can be an IBGP or EBGP peer.

Examples

The following example creates a neighbor 10.0.0.1 in IPv4 VRF configuration mode of BGP and allows the local device to receive update packets that carry the AS number of the local device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# address-family ipv4 vrf vpn1
Hostname(config-router-af)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router-af)# neighbor 10.0.0.1 allowas-in
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

Common Errors

1.110 neighbor as-loop-check out

Function

Run the **neighbor as-loop-check out** command to enable the loop detection function in the outbound direction of a BGP neighbor.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The loop detection function in the outbound direction of a BGP neighbor is disabled by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-loop-check out**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as**-**loop**-**check out**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as**-**loop**-**check out**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

When the loop detection function in the outbound direction of a BGP neighbor is enabled, a device filters routes that carry the AS number of this neighbor in the AS_PATH attribute when it advertises routes to this neighbor.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example creates a neighbor in IPv4 VRF configuration mode of BGP and enables the loop detection function in the outbound direction of this neighbor.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# address-family ipv4 vrf vpn1
Hostname(config-router-af)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router-af)# neighbor 10.0.0.1 as-loop-check out
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

Common Errors

1.111 neighbor as-origination-interval

Function

Run the **neighbor as-origination-interval** command to configure the interval of advertising the local initial BGP route to a specified peer.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default interval of advertising the local initial BGP route to a specified peer is **1** second.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-origination-interval** *seconds*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-origination-interval**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-origination-interval**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

as-origination-interval: Interval in seconds of advertising the local initial BGP route. The value range is from 1 to 65535.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example creates a neighbor in IPv4 VRF configuration mode of BGP and sets the interval of advertising the local initial BGP route to the neighbor to **10** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# address-family ipv4 vrf vpn1
Hostname(config-router-af)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router-af)# neighbor 10.0.0.1 as-origination-interval 10
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

1.112 neighbor as-override

Function

Run the **neighbor as-override** command to configure a PE device to overwrite the AS number of a site.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No PE is configured to overwrite the AS number of a site by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as-override**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as**-**override**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **as**-**override**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

Normally, BGP does not receive any routing information that has the same AS number as the local AS number. You can run this command to overwrite the AS number so that BGP can receive any routing information that is sent from the same AS number.

In a VPN, if two CE devices share the same AS number, they cannot receive peer information each other. After this command is configured on a PE device, the PE device overwrites the AS number of the CE devices so that they can receive routing information each other.

This command applies to only the specified EBGP peers.

Examples

The following example creates a neighbor in the configuration mode of the IPv4 VRF address family of BGP and overwrites the AS number of this neighbor site.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# address-family ipv4 vrf vpn1
Hostname(config-router-af)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router-af)# neighbor 10.0.0.1 as-override
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

1.113 neighbor bmp-active

Function

Run the **neighbor bmp-active** command to configure a specified BMP server to monitor neighbors.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No neighbor is monitored by any BMP server by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **bmp-active** { **all** | **server** *server-number*&<1-8> }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **bmp**-**active** { **all** | **server** *server-number*&<1-8> }

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **bmp**-**active** { **all** | **server** *server-number*&<1-8> }

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

all: Specifies all BMP servers.

server-number&<1-8>: Instance number of a specified BMP server. The value range is from 1 to 8. &<1-8> specifies that the instance numbers of 1 to 8 specified BMP servers can be entered.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

If you do not configure this command, no neighbor is monitored by any BMP server.

Examples

This command creates a neighbor in BGP configuration mode and specifies this neighbor to be monitored by all BMP servers.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router)# neighbor 10.0.0.1 bmp-active all
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

1.114 neighbor default-fast-withdraw

Function

Run the **neighbor default-fast-withdraw** command to allow a BGP speaker to quickly withdraw the default route from a peer (group).

Run the **no** form of this command to disable a BGP speaker from quickly withdrawing the default route from a peer (group).

Run the **default** form of this command to restore the default configuration.

No BGP speaker quickly withdraws the default route from a peer (group) by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-fast-withdraw**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-fast-withdraw**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-fast-withdraw**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

After this command is configured, a device advertises a default route withdrawal message to this neighbor and then reselects a route if the original preferred route or equivalent route is not configured or is invalid.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example allows a BGP speaker to send a default route withdraw message to the peer 10.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.1.1.1 remote-as 80
Hostname(config-router)# neighbor 10.1.1.1 default-fast-withdraw
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

1.115 neighbor default-originate

Function

Run the **neighbor default-originate** command to allow a BGP speaker to advertise the default route to a peer (group).

Run the **no** form of this command to disable a BGP speaker from advertising the default route to a peer (group).

Run the **default** form of this command to restore the default configuration.

No BGP speaker is allowed to advertise the default route to a peer (group) by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*]

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **default-originate** [**route-map** *map-tag*]

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

route-map *map-tag*: Name of a route-map. The route-map-name does not exceed 32 characters.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command allows the routing table of the local device to have a default route. After this command is configured, the device sends a default route with the next hop being the local device to its neighbors.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example configures a BGP speaker to advertise the default route to the peer 10.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.1.1.1 remote-as 80
Hostname(config-router)# neighbor 10.1.1.1 default-originate
```

Notifications

1.117 neighbor distribute-list

Function

Run the **neighbor distribute-list** command to implement an ACL-based routing policy when routing information is sent to and received from a specified BGP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No ACL-based routing policy is implemented by default when routing information is sent to and received from a specified BGP peer.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **distribute-list** { *access-list-name* | *access-list-number* } { **in** | **out** }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **distribute-list** { *access-list-name* | *access-list-number* } { **in** | **out** }

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **distribute-list** { *access-list-name* | *access-list-number* } { **in** | **out** }

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

access-list-name: ACL name.

access-list-number: Number of an ACL. The value range is from 1 to 199 or from 1300 to 2699.

in: Applies the ACL to received routing information.

out: Applies the ACL to distributed routing information.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is configured based on address families. You can configure different filtering policies in different address families to control routing.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example filters the routes received from the peer 10.1.1.1 according to an ACL named **in**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.1.1.1 remote-as 80
Hostname(config-router)# neighbor 10.1.1.1 distribute-list bgp-filter in
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If an outbound policy is configured for the members in the peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

If a prefix filtering list is configured for this peer (group), the following notification will be displayed:

```
% Prefix/distribute list can not co-exist, update the prefix/distribute list config
```

1.118 neighbor dmzlink-bw

Function

Run the **neighbor dmzlink-bw** command to carry the link bandwidth attribute in the specified neighbor's routes sent to IBGP neighbors.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No link bandwidth attribute is carried in the specified neighbor's routes sent to IBGP neighbors by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **dmzlink-bw**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **dmzlink-bw**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **dmzlink-bw**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command applies to only EBGP neighbors with a specified single hop.

To send the extended community attribute of link bandwidth to IBGP neighbors, you must run the **neighbor send-community** command to enable the function of sending the extended community attribute.

Examples

The following example advertises to IBGP neighbors the extended community attribute of link bandwidth in IPv4 routes sent from an EBGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 remote-as 65100
Hostname(config-router)# neighbor 10.0.0.1 dmzlink-bw

1.121 neighbor ebgp-multihop

Function

Run the **neighbor ebgp-multihop** command to establish BGP connections with non-directly-connected EBGP peers.

Run the **no** form of this command not to establish BGP connections with non-directly-connected EBGP peers.

Run the **default** form of this command to restore the default configuration.

No BGP connections are established with non-directly-connected EBGP peers.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ebgp-multihop** [*ttl*]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ebgp**-**multihop**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ebgp**-**multihop**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

ttl: Maximum number of hops. The value range is from 1 to 255. If this parameter is not specified, the maximum number of hops is **255**.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

To avoid route loop and flapping, you must configure a route (except the default route) between the EBGP peers that are connected through multiple hops.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example establishes a BGP connection with the non-directly-connected EBGP peer 10.0.0.1 and sets the maximum number of hops to **255**.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 remote-as 65100
Hostname(config-router)# neighbor 10.0.0.1 ebgp-multihop 255
```

1.122 neighbor fall-over bfd

Function

Run the **neighbor fall-over bfd** command to correlate BGP with Bidirectional Forwarding Detection (BFD).

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

BGP is not correlated with BFD by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **fall-over bfd**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **fall-over bfd**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **fall-over bfd**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can run this command to detect changes of a specific neighbor and accelerate BGP convergence.

Before configuration, you must configure the BFD session parameters for the interface of the IP address of the neighbor.

Examples

The following example enables BGP correlation with BFD and uses Bidirectional Forwarding Detection (BFD) to detect the forwarding route to the neighbor 172.16.0.2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 45000
Hostname(config-router)# neighbor 172.16.0.2 remote-as 45001
Hostname(config-router)# neighbor 172.16.0.2 fall-over bfd
```

1.123 neighbor filter-list

Function

Run the **neighbor filter-list** command to apply the AS path filtering rule to the routing information received from and sent to a specified BGP peer (group).

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No AS path filtering rule is applied to the routing information received from and sent to a specified AS peer (group) by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **filter-list** *as-path-access-list-number* { **in** | **out** }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **filter-list** *as-path-access-list-number* { **in** | **out** }

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **filter-list** *as-path-access-list-number* { **in** | **out** }

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

neighbor filter-list: Number of the AS path filtering list. The value range is from 1 to 500.

in: Applies the AS path filtering list to received routing information.

out: Applies the AS path filtering list to distributed routing information.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is configured based on address families. You can configure different filtering policies in different address families to control routing.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example applies the AS path filtering list 1 to the routing information sent to the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip as-path access-list 1 deny _123_
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 remote-as 65100
Hostname(config-router)# neighbor 10.0.0.1 filter-list 1 out
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If an outbound policy is configured for the members in the peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

Common Errors

1.124 neighbor global-nexthop-replace-local

Function

Run the **neighbor global-nexthop-replace-local** command to use the local address of a BGP IPv6 link as the global next hop address when IPv6 routing information is sent to the local peer (group) of the BGP IPv6 link.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The local address of a BGP IPv6 link is not used as the global next hop address by default when IPv6 routing information is sent to the local peer (group) of the BGP IPv6 link.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **global-nexthop-replace-local**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **global-nexthop-replace-local**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **global-nexthop-replace-local**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

By default, two next hop addresses, namely, the global address and local address, are carried in the IPv6 routing information that is sent to the local peer (group) of the BGP IPv6 link. If this command is configured for the peer (group), the global next hop address advertised to this peer (group) is replaced with the local address of the next hop link.

This command is not effective to the non-link local peer (group).

Examples

The following example uses the local address of a link as the global next hop address when a route is advertised to the peer FE80::1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family ipv6
Hostname(config-router-af)# neighbor FE80::1%vlan101 remote-as 1
Hostname(config-router-af)# neighbor FE80::1%vlan101 global-nexthop-replace-local
```

1.125 neighbor ha-mode nsr

Function

Run the **neighbor ha-mode nsr** command to enable the nonstop routing (NSR) function for a specified BGP peer (group).

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The NSR function for a BGP peer (group) is disabled by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ha-mode nsr**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ha-mode nsr**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ha-mode nsr**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

ha-mode: Specifies the high availability (HA) mode.

nsr: Enables the NSR mode.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

The NSR function synchronizes state and data information between the active BGP and standby BGP of VSU. When the active BGP fails, the standby BGP can take over the BGP services to keep route availability.

A neighbor can enable multiple address families. The BGP NSR function is supported in only the IPv4/IPv6 Unicast address families. If a neighbor activates other address families, the NSR function cannot be enabled.

Examples

The following example enables the NSR function for the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 remote-as 65100
Hostname(config-router)# neighbor 10.0.0.1 ha-mode nsr
```

1.127 neighbor local-as

Function

Run the **neighbor local-as** command to configure the local AS number for a specified BGP peer (group).

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No local AS number is configured for a BGP peer (group) by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **local-as** *as-number* [**no-prepend** [**replace-as** [**dual-as**]]]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **local-as**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **local-as**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

as-number: Configured local AS number. The value range is from 1 to 65535. A 4-byte AS number can be configured. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

no-prepend: Does not add the local AS number to the AS-PATH attribute in the routing information received from a peer. If this parameter is not specified, the local AS number is added to the AS-PATH attribute in the routing information received from a peer.

replace-as: Replaces the BGP AS number with the local AS number in the AS-PATH attribute of the routing information sent to a peer. If this parameter is not specified, the BGP AS number is not replaced with the local AS number in the AS-PATH attribute of the routing information sent to a peer.

dual-as: Enables a peer to use the BGP AS number or local AS number to establish a BGP connection with a device. If this parameter is not specified, the peer can use only the local AS number to establish a BGP connection with the local device.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command applies to only the specified EBGP peers. If the attributes of the peers change, for example, the EBGP peers change to IBGP peers or alliance EBGP peers, the local AS number and options configured for

these peers are deleted. The configured local AS number must be different from the BGP AS number and the remote AS number of the peers. If an alliance is configured, the local AS number must differ from the alliance ID. If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. Users are not allowed to separately configure a local AS number for a member in the peer group.

After this command is configured, a peer device can use this local AS number as a remote AS number to establish a BGP connection with the local device. If you do not specify any optional item for this command, the peer device can use only the local AS number to establish a BGP connection with the local device. The peer device also adds the local AS number to the AS-PATH attribute of the received routing information before routing information is sent to the peer.

Examples

The following example sets the local AS number of the peer 10.0.0.1 to **23**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 remote-as 65100
Hostname(config-router)# neighbor 10.0.0.1 local-as 23
```

1.128 neighbor maximum-prefix

Function

Run the **neighbor maximum-prefix** command to configure the maximum number of prefixes received from a specified BGP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The number of prefixes received from a specified BGP peer is not limited by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **maximum-prefix** *maximum-prefix-value* [*maximum-prefixthreshold*] [**restart-time** *restart-time* | **warning-only** [**suppress**]]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **maximum**-**prefix**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **maximum**-**prefix**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

maximum-prefix-value: Maximum number of prefixes that can be received. The value range is from 1 to 4294967295.

maximum-prefix-threshold: Percentage of the prefix number that triggers an alarm to the maximum number of prefixes. The value range is from 1 to 100, and the default value is **75**.

restart-time: Specifies the time of restoring the state machine of the neighbor after the local device enters the idle state because the number of route prefixes exceeds the upper limit.

restart-time: Time of restoring the state machine of a specified neighbor. The value range is from 1 to 65535.

warning-only: Generates a log without terminating a BGP connection when the number of route entries reaches the upper limit.

suppress: Stops learning entries when the number of route entries reaches the upper limit.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

When the received routing information exceeds the configured upper limit, the device terminates the BGP connection by default. If the **warning-only** keyword is specified when this command is configured, the device can retain the BGP connection when the received routing information exceeds the configured upper limit.

If the **suppress** keyword is specified when this command is configured, the device can stop learning route entries when the received routing information exceeds the configured upper limit. In this case, real route entries exceed the configured upper limit of the device. Because the route learning sequence may change before and after the reestablishment of neighbor relationships, the learned entries may be inconsistent.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example sets the maximum number of IPv4 unicast routes that are received by the peer 10.0.0.1 to **1000**.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 maximum-prefix 1000
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

1.129 neighbor next-hop-self

Function

Run the **neighbor next-hop-self** command to configure the next hop of a route advertised to a specified BGP peer as the local device.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The next hop of a route advertised to an EBGP peer is configured as the local BGP speaker, and the next hop of a route advertised to an IBGP peer is not changed by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **next-hop-self**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **next**-**hop**-**self**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **next**-**hop**-**self**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used in non-full-mesh networks such as Frame Relay and X.25. In this type of networks, the BGP speakers in the same subnet may not access each other directly.

If you specify a BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example configures the next hop of an IPv4 unicast route advertised to the peer 10.0.0.1 as the local BGP speaker.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 next-hop-self
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

If a peer (group) is configured with an unchanged next hop, the following notification will be displayed:

```
% Cannot co-exist with next-hop-unchanged, Deconfigure first
```

1.130 neighbor next-hop-unchanged

Function

Run the **neighbor next-hop-unchanged** command to retain the next hop of a route advertised to a specified peer (group).

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The next hop of a route advertised to an EBGP peer is changed to the local BGP speaker, and the next hop of a route advertised to an IBGP peer is not changed.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **next-hop-unchanged**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **next-hop-unchanged**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **next-hop-unchanged**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

next-hop-unchanged: Retains the next hop of a route sent to a BGP peer (group).

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast address family of BGP

Configuration mode of the IPv6 unicast address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is not configured on a route reflector. If you configure this command on the client of a route reflector, you cannot run the **neighbor next-hop-self** command on the client to modify the next hop of the route.

Examples

The following example advertises an IPv4 route to the peer 10.1.1.1 without changing the next hop of the route.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# address-family ipv4
Hostname(config-router-af)# neighbor 10.1.1.1 next-hop-unchanged
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

If a peer (group) is configured with a next hop being itself, the following notification will be displayed:

```
% Cannot co-exist with next-hop-self, Deconfigure first
```

If a peer (group) is not a multi-hop EBGP neighbor, the following notification will be displayed:

```
% Can propagate the nexthop only to multi-hop EBGP neighbor
```

1.131 neighbor password

Function

Run the **neighbor password** command to enable TCP MD5 authentication and configure a password when a BGP connection is established with a specified BGP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

TCP MD5 authentication is not enabled by default when a BGP connection is established with a specified BGP peer.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **password** [**0** | **7**] *password-string*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **password**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **password**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

0: Displays an unencrypted password.

7: Displays an encrypted password.

password-string: Password used for TCP MD5 authentication. A maximum of 80 characters are entered.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command calls TCP MD5 authentication. Therefore, you must configure the same password for the peers that have established a BGP connection with the local device. Otherwise, the neighbor relationship cannot be established. After this command is configured, the local device reestablishes a BGP connection with the BGP peers.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

You can configure one password only for each neighbor. In any address family configuration mode or BGP configuration mode, the configured password for a specified neighbor overwrites the original one.

Examples

The following example sets the password for TCP MD5 authentication of the peer 10.0.0.1 to **test**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 password test
```

Notifications

If the configured plaintext password exceeds 80 characters, the following notification will be displayed:

```
% Password length too large, must be less or equal than 80
```

If the configured cyphertext password exceeds 162 characters, the following notification will be displayed:

```
% Password length too large, must be less or equal than 162
```

1.132 neighbor peer-group (assigning members)

Function

Run the **neighbor peer-group** command to configure a specified BGP peer as a member of a BGP peer group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No specified BGP peer is configured as a member of a BGP peer group.

Syntax

neighbor { neighbor-ipv4-address | neighbor-ipv6-address } **peer-group** *peer-group-name*

no neighbor { neighbor-ipv4-address | neighbor-ipv6-address } **peer-group** *peer-group-name*

default neighbor { neighbor-ipv4-address | neighbor-ipv6-address } **peer-group** *peer-group-name*

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

A member of a peer group can inherit all configurations of a peer.

You can separately configure commands for each member in the peer group to overwrite unified configuration of the peer group. The configured commands do not include those configurations that influence route update. Each member in the peer group inherits the following configurations of the peer group:
remote-as, **update-source**, **local-as**, **reconnect-interval**, **times**, **advertisemet-interval**, **default-originate**, **next-hop-self**, **remove-private-as**, **send-community**, **distribute-list out**, **filter-list out**, **prefix-list out**, **route-map-name out**, **unsuppress-map**, **route-reflector-client**, and **as-origination-interval**.

Note

You may not put neighbors in different address families into the same peer group, nor add IBGP peers and EBGP peers to the same peer group.

Examples

The following example adds the peer 10.0.0.1 to the peer group **test**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor test peer-group
Hostname(config-router)# neighbor 10.0.0.1 peer-group test
```

Notifications

If the configured neighbor has the same address as the local interface, the following notification will be displayed:

```
% Cannot configure the local system as neighbor
```

When the IPv6 unicast routing capability is not activated in global configuration mode, if an IPv6 neighbor is configured, the following notification will be displayed:

```
% Cannot configure IPv6 neighbor, please use ipv6 unicast-routing first!
```

If the peer group is not configured, the following notification will be displayed:

```
% Configure the peer-group first
```

If no Remote AS is configured for the peer group and members are created in the peer group, the following notification will be displayed:

```
% Specify remote-as or peer-group remote AS first
```

If a configured peer belongs to another peer group, the following notification will be displayed:

```
% Cannot change the peer-group. Deconfigure first
```

If a member in the peer group and a configured peer belong to different types, the following notification will be displayed:

```
% Peer with AS as-number cannot be in this peer-group, members must be all internal
or all external
```

1.133 neighbor peer-group (creating)

Function

Run the **neighbor peer-group** command to create a BGP peer group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The function of a BSP peer group is disabled by default.

Syntax

neighbor *peer-group-name* **peer-group**

no neighbor *peer-group-name* **peer**-**group**

default neighbor *peer-group-name* **peer**-**group**

Parameter Description

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

If BGP peers share the same distribution list, update source or route filtering policy, you can assign these peers to the same peer group to simplify configuration and improve calculation update efficiency.

Examples

The following example creates a peer group **test**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor test peer-group
```

1.134 neighbor pic-disable

Function

Run the **neighbor pic-disable** command to disable the private PIC processing on routes distributed to and received from specified BGP peers.

Run the **no** form of this command to enable the private PIC process for routes advertised to and received from BGP peers.

Run the **default** form of this command to restore the default configuration.

A device performs the private PIC processing on routes sent to and received from BGP peers by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **pic-disable**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **pic-disable**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **pic-disable**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

The CF type and E1 subtype of extended community attributes are used as the extended community attributes of the private PIC processing. This command is configured to disable the private PIC processing to ensure the compatibility of the extended community attributes for device connection with products of other vendors.

Examples

The following example disables the private PIC processing for the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 pic-disable
```

1.135 neighbor prefix-list

Function

Run the **neighbor prefix-list** command to implement the prefix list-based routing policy for routing information sent to and received from the specified BGP peers.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No prefix list-based routing policy is implemented for routing information sent to and received from the specified BGP peers by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **prefix-list** *prefix-list-name* { **in** | **out** }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **prefix-list** *prefix-list-name* { **in** | **out** }

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **prefix-list** *prefix-list-name* { **in** | **out** }

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

prefix-list-name: Name of a prefix list. It contains not more than 32 characters.

in: Applies the prefix list to received routing information.

out: Applies the prefix list to distributed routing information.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is configured based on address families. You can configure different filtering policies in different address families to control routing.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example configures a prefix list bgp-filter to filter routes received from the BGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip prefix-list bgp-filter deny 10.0.0.1/16
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 prefix-list bgp-filter in
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If an outbound policy is configured for the members in the peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

Common Errors

1.136 neighbor remote-as

Function

Run the **neighbor remote-as** command to configure a BGP peer (group).

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No BGP peer (group) is configured by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as** *as-number*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remote-as**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

as-number: AS number of a BGP peer (group). A 4-byte AS number can be configured. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example creates an EBGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 remote-as 80
```

Notifications

If the address of a BGP neighbor is a local IPv6 link address, the following notification will be displayed:

```
% Using IPv6 link-local address as peer address must specify update-source interface
```

Common Errors

The address of a BGP neighbor is a local address.

```
% Cannot configure the local system as neighbor
```

IGBP neighbors are configured in BGP IPv4 VRF or BGP IPv6 VRF configuration mode.

```
% PE - CE peering must be EBGP.
```

1.137 neighbor remove-private-as

Function

Run the **neighbor remove-private-as** command to remove the private AS number from the AS_PATH attribute of the routes sent to a specified EBGP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The private AS number is not removed from the AS_PATH attribute of the routes sent to a specified EBGP peer by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remove-private-as** [**force** [**ignore-remote-as**]] [**replace-as**]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remove**-**private**-**as**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **remove**-**private**-**as**

Parameter Description

neighbor-ipv4-address: IPv4 address of the specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

force: Forcibly removes the private AS number.

ignore-remote-as: Ignores the private AS number.

replace-as: Replaces the private AS number with the local AS number.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is effective to EBGP peers only.

The AS number range is from 1 to 4294967295. The range of private AS numbers is from 64512 to 65534 or from 4200000000 to 4294967294, and they are used for specific private applications. Normally, you can configure this command to prevent the private AS number from being leaked to a public network.

If the following conditions are met, the software does not remove the private AS number from the AS_PATH attribute of routes:

- The AS_PATH attribute contains both the private AS number and public AS number.
- The private AS number contained in the AS_PATH attribute will be sent to an EBGP peer to prevent route loop.

If the preceding two conditions are met, you can specify the **force** parameter to forcibly remove a private AS number.

When the private AS number is removed forcibly, you can specify the **force ignore-remote-as** parameter to ignore the neighbor AS number.

You can specify the **replace-as** parameter to replace the private AS number with the local AS number to prevent the AS path from being shortened and thus avoid selecting a wrong route.

Examples

The following example removes the private AS from the AS-PATH attribute of routes advertised to the EBGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
```

```
Hostname(config-router)# neighbor 10.0.0.1 remove-private-as
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

If configuration is completed for an IBGP peer, the following notification will be displayed:

```
% Private AS cannot be removed for IBGP peers
```

Common Errors

1.138 neighbor route-map

Function

Run the **neighbor route-map** command to match a received or an advertised route with a route map.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no route map is configured to match a received or an advertised route.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route-map** *map-tag* { **in** | **out** }

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

map-tag: Name of a route map.

in: Applies a route map to received routes.

out: Applies a route map to advertised routes.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command can apply different rules to filter routes received from or sent to different neighbors to purify and control routing.

This command is configured based on address families. You can configure different filtering policies in different address families.

Examples

The following example filters routes received from the peer 10.0.0.1 by using the route map map-tag.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 route-map map-tag in
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If an outbound policy is configured for the members in the peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

1.139 neighbor route-reflector-client

Function

Run the **neighbor route-reflector-client** command to configure the local device as a route reflector and specify a client for it.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The local device is not configured as a route reflector by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route-reflector-client**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route**-**reflector**-**client**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **route**-**reflector**-**client**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of the specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

All IGBP speakers in an AS must establish a full mesh of neighbor relationships by default. To avoid route loop, a BGP speaker does not forward a learned IBGP route to other IGBP peers.

After this command is configured, all IGBP speakers in the AS do not need to establish a full mesh of neighbor relationships, and the route reflector forwards the learned IBGP route to the client of the route reflector.

Examples

The following example configures the peer 10.0.0.1 as the client of a route reflector.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 route-reflector-client
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

If configuration is completed for an EBGP peer (group), the following notification will be displayed:

```
% Invalid command. Not an internal neighbor
```

If this capability is configured for a peer group and disabled for the members in the peer group, the following notification will be displayed:

```
% This peer is a peer-group member.  Please change peer-group configuration
```

1.140 neighbor send-community

Function

Run the **neighbor send-community** command to advertise community attributes to a specified BGP neighbor.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No community attribute is advertised to a specified BGP neighbor by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **send-community** [**both** | **standard** | **extended**]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **send-community** [**both** | **standard** | **extended**]

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **send-community** [**both** | **standard** | **extended**]

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

both: Transmits standard and extended community attributes.

both: Transmits only standard community attributes.

both: Transmits only extended community attributes.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can configure this command to transmit specified community attributes to a specified neighbor or a group of neighbors.

Examples

The following example carries the community attributes in the routes advertised to the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 send-community both
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

If configuration is completed for an EBGP peer (group), the following notification will be displayed:

```
% Invalid command. Not an internal neighbor
```

If this capability is configured for a peer group and disabled for the members in the peer group, the following notification will be displayed:

1.141 neighbor shutdown

Function

Run the **neighbor shutdown** command to shut down the connection of a specified peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The function of a specified BGP peer is enabled by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **shutdown** [**graceful** [**community** *community-value*] [**delay** *delay-time*]]

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **shutdown**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **shutdown**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

graceful: Shuts down BGP connections in smooth manner.

community *community-value*: Specifies the community attribute value carried in a route sent to a neighbor. It follows the format of AA:NN (AS number: 2-byte number) or the value is a numeric. The value range is from 0 to 4294967295.

delay *delay-time*: Specifies the delay time for shutting down BGP connections. The value range is from 1 to 65535.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is used to shut down the valid connection established with a specified peer (group) and delete all related routing information. The software retains any configuration of this specified peer (group).

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

If a BGP connection is shut down in smooth manner, the device sends a route carrying the Community, LOCAL_PREF, or MED attribute to a specified neighbor. After the neighbor receives the route update information.

After a period (this period is automatically calculated based on the number of advertised routes or it is specified), the device actively shuts down BGP connections with neighbors.

Examples

The following example actively shuts down the connection with the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.0.0.1 shutdown
```

The following example shuts down the connection with the peer 10.0.0.1 in a smooth manner.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 60
Hostname(config-router)# neighbor 10.0.0.1 shutdown graceful
```

Notifications

If this function is enabled on a peer group and configuration of group members is deleted, the following notification will be displayed:

```
% Peer-group has been shutdown. Activate the peer-group first
```

Common Errors

N/A

Platform Description

1.142 neighbor soft-reconfiguration inbound

Function

Run the **neighbor soft-reconfiguration inbound** command to save original routing information sent by a specified BGP peer.

Run the **no** form of this command not to save original routing information of a specified BGP peer.

Run the **default** form of this command to restore the default configuration.

No original routing information of a specified BGP peer is saved by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soft-reconfiguration inbound**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soft-reconfiguration inbound**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soft-reconfiguration inbound**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command causes a BGP session to restart and retains the unchanged routing information sent by a BGP peer (group).

Configuring this command consumes more memory. If the local device and BGP peer support the route update function, you do not need to configure this command. You can run the **show ip bgp neighbors** command to judge whether a BGP peer supports the route update function.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example retains the original routing information of the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 soft-reconfiguration inbound
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

If this capability is configured for a peer group and disabled for the members in the peer group, the following notification will be displayed:

```
% This peer is a peer-group member.  Please change peer-group configuration
```

Common Errors

1.143 neighbor soo

Function

Run the **neighbor soo** command to configure the Site-of-Origin (SoO) attribute of a neighbor.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No neighbor is configured with the SoO attribute by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soo** *soo-value*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soo**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **soo**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

soo-value: Value of the SoO attribute. *soo-value* can be set as follows:

- *soo-value=as-number*: *nn*

  as-number is a public 2-byte AS number. *nn* is user-defined in the range from 0 to 4294967295.

- *soo-value=ip-address*: *nn*

  ip-address must be a global IP address. *nn* is user-defined in the range from 0 to 65535.

- *soo-value=as4-number*: *nn*

  as4-number is a public 4-byte AS number. *nn* is user-defined in the range from 0 to 65535.

Command Modes

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

When multiple CE devices of a VPN site use a BGP protocol to be connected with different PE devices, VPN routes sent from the CE devices to the PE devices may go back to this site. This situation causes a route loop in the site.

After this command is configured, if a PE device receives a route from a CE device, the PE device adds the SoO attribute to the route before forwarding the route to other PE devices. The other PE devices check the SoO attribute before they advertise the route to the CE device. If this attribute is consistent with that configured locally, the PE devices do not advertise the route to the CE device.

Examples

The following example configures the SoO attribute for the peer 10.0.0.1 in a VRF instance.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family ipv4 vrf vpn1
Hostname(config-router-af)# neighbor 10.0.0.1 remote-as 100
Hostname(config-router-af)# neighbor 10.0.0.1 soo 100:100
```

1.144 neighbor timers

Function

Run the **neighbor timers** command to configure the duration of Keepalive, Hold-Time, and Connect-Retry timers that are used to establish a BGP connection with a specified BGP peer.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The Keepalive timer duration is **60** seconds, Hold-Time timer duration is **180** seconds, and Connect-Retry timer duration is **15** seconds by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **timers** { *keepalive-interval holdtime* [*minimum-holdtime*] | **connect** *connect-retry* }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **timers** [**connect**]

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **timers** [**connect**]

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

keepalive-interval: Interval in seconds to send Keepalive messages to a specified BGP peer. The value range is from 0 to 65535, and the default value is **60**.

holdtime: Valid interval in seconds of a BGP peer. The value range is from 0 to 65535, and the default value is **180**.

minimum-holdtime: Minimum hold time in seconds of an advertisement from a neighbor. The value range is from 0 to 65535, and the value **0** specifies no limit.

connect: Specifies the reconnection time.

connect-retry: Interval in seconds to initiate a reconnection to a specified BGP peer. The value range is from 1 to 65535, and the default value is **15**.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

The *keepalive-interval* value cannot be greater than 1/3 of the *holdtime*.

If time is configured for a single peer or peer group, this peer or peer group is connected with peers based on the configured time other than the globally configured time.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

If you remove this command or restore the default configuration and specify the **connect** parameter, the command takes effect to the reconnection time. If you do not specify the **connect** parameter, the command takes effect to the sending interval and hold time of Keepalive messages.

Examples

The following example configures the sending interval and hold time of Keepalive messages of the BGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 timers 80 240
```

The following example configures the reconnection time of the BGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
```

```
Hostname(config-router)# neighbor 10.0.0.1 timers connect 100
```

Notifications

If configuration is completed for the members in a peer group, the following notification will be displayed:

```
% Invalid command for a peer-group member
```

If the configured hold time is smaller than 3 but not equal to 0, the following notification will be displayed:

```
% Hold time must be 0 or greater than 2 seconds
```

Common Errors

1.145 neighbor transport connection-mode

Function

Run the **neighbor transport connection-mode** command to configure the connection establishment mode of BGP neighbors.

Run the **no** form of this command to restore the connection establishment mode of BGP neighbors to a default value.

Run the **default** form of this command to restore the default configuration.

A BGP neighbor can actively or passively establish connections by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **transport connection-mode** { **active-only** | **both** | **passive-only** }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **transport connection-mode**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **transport connection-mode**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

active-only: Specifies a neighbor to only actively establish connections.

Both: Specifies a neighbor to actively or passively establish connections.

passive-only: Specifies a neighbor to only passively establish connections.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You cannot concurrently configure the **active-only** or **passive-only** parameter for two devices that work as peers mutually.

Neighbors in a network segment can passively establish connections only, and their connection modes are not controlled by this command.

Examples

The following example configures only active connections for the BGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 45000
Hostname(config-router)# neighbor 10.0.0.1 remote-as 45001
Hostname(config-router)# neighbor 10.0.0.1 transport connection-mode active-only
```

1.146 neighbor ttl-security hops

Function

Run the **neighbor ttl-security hops** command to configure GTSM security check for BGP neighbors.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function of GTSM security check is not configured by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ttl-security hops** *hop-count*
no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ttl-security hops**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **ttl-security hops**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

hop-count: Maximum number of hops from a specified local device to a specified peer. The value range is from 1 to 255.

Command Modes

BGP configuration mode

IPv4 VRF configuration mode of BGP

IPv6 VRF configuration mode of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

After this command is configured, the packets from a specified peer can be passed if their TTL values are within the specified range. Otherwise, the packets are discarded.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example enables the function of GTSM security check for BGP packets of the peer 10.0.0.1 and sets the maximum number of hops from a specified peer to a local device to **1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 ttl-security hops 1
```

1.147 neighbor unsuppress-map

Function

Run the **neighbor unsuppress-map** command to selectively advertise the routing information that is suppressed by route aggregation.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Routing information suppressed by route aggregation is not selectively advertised by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **unsuppress-map** *map-tag*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **unsuppress**-**map** *map-tag*

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **unsuppress**-**map** *map-tag*

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

map-tag: Name of a route map. It contains not more than 32 characters.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command can advertise the specified suppressed routes.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If this command is configured for a member in the peer group, this command overwrites the peer group-based configuration.

Examples

The following example uses the route map unspress-route to filter routes advertised to the peer 10.0.0.1 and advertises the matched routing information suppressed by route aggregation.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 unsuppress-map unspress-route
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

1.148 neighbor update-delay

Function

Run the **neighbor update-delay** command to delay the advertisement of BGP peers.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The advertisement of BGP peers is not delayed by default.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **update-delay** *update-delay-time*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **update**-**delay**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **update**-**delay**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

update-delay-time: Delay time in seconds of first route advertisement of a specified BGP peer. The value range is from 0 to 3600, and the value **0** specifies no limit.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can configure this command to specify the delay time of route advertisement during the first establishment of a connection with the BGP peer 10.0.0.1.

After BGP is enabled, neighbors will negotiate to reach the established state and send update packets to each other. If you configure this command, the local device sends routes received from a specified neighbor to other neighbors after a specified delay time. If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command.

Examples

The following example sets the delay time of first route advertisement to **60** seconds during the first establishment of a connection with the BGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 update-delay 60
```

1.149 neighbor update-source

Function

Run the **neighbor update-source** command to configure a network interface used to establish a BGP connection with a specified IBGP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The optimal local interface is used as the output interface by default.

Syntax

neighbor { *neighbor-ipv4-address* | *peer-group-name* } **update-source** { *interface-type interface-number* | *source-ipv4-address* }

neighbor { *neighbor-ipv6-address* | *peer-group-name* } **update-source** { *interface-type interface-number* | *source-ipv6-address* }

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **update-source**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **update-source**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

interface-type interface-number: Interface type and interface number.

source-ipv4-address: IPv4 address of the network interface used to establish a BGP connection.

source-ipv6-address: IPv6 address of the network interface used to establish a BGP connection.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

Note

You are advised to use this command to specify a source address if you establish multiple peer relationships between two devices through multiple links.

You can run this command to establish a BGP connection with BGP peers through the loopback interface.

If you directly specify a network interface to establish a BGP connection, the address of the network interface must be a local valid one. Otherwise, the BGP connection cannot be established.

If this command is configured for a specified BGP peer group, all members in the peer group inherit the configuration of this command. If a network interface is specified, a member in a peer group can inherit the configuration of this command only when the peer address of the member has the same type as the network interface address.

If you want to use a local IPv6 link address to establish BGP neighborship, you must use the local link address for the local device and peer. The BGP neighborship can be established only when the outbound interface address of the peer device is consistent with the local specified neighbor address. You can configure the same local link address for different interfaces. Therefore, you can but specify the interface name.

The local IPv6 link address can be used to establish only single-hop BGP neighborship.

Examples

The following example uses loopback 1 as a TCP source address during the establishment of a BGP connection with the peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.0.0.1 update-source loopback 1
```

Notifications

If the configured source address is invalid, the following notification will be displayed:

```
% Invalid host address: ipv4-address
```

If the source address of a peer group is configured as an IPv4 address, the following notification will be displayed:

```
% Source address %s is valid for IPv4 address members only
```

If the source address of a peer group is configured as an IPv6 address, the following notification will be displayed:

```
% Source address %s is valid for IPv6 address members only
```

If the neighbor relationship of a local link address is established and the local interface address is configured as the source address of a local link, the following notification will be displayed:

```
% % IPv6 link-local peer does not support IPv6 address as the update-source
```

If the source address is configured as a local IPv6 link address, the following notification will be displayed:

```
% Specify IPv6 link-local address as the update-source can't identify the only link
```

1.150 neighbor version

Function

Run the **neighbor version** command to configure the BGP version number for a specified BGP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No BGP version number is configured for a specified BGP peer.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **version 4**

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **version**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **version**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

4: Specifies the BGP version number as **4**.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 VRF address family of BGP

Configuration mode of the IPv6 VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

After this command is configured, the version negotiation function of BGP becomes invalid.

Examples

The following example sets the BGP version number of peers to **4**.

```
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.1.1.1 version 4
```

1.151 neighbor weight

Function

Run the **neighbor weight** command to configure a weight value for a specified BGP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No weight value is configured for a specified BGP peer by default. The initial weight value of routes learned from neighbors is **0**, and the initial weight value of routes generated locally is **32768**.

Syntax

neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **weight** *weight-value*

no neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **weight**

default neighbor { *neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-group-name* } **weight**

Parameter Description

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-group-name: Name of a specified peer group.

weight-value: Weight value of a neighbor. The value range is from 0 to 65535.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

After this command is configured, routes received from a specified neighbor use the specified value as the initial weight value. A greater weight value indicates a higher priority of a route.

Running the **set weight** command in the route map of a neighbor overwrites the configured weight value of this command.

Examples

The following example sets the weight value of routes received from the peer 10.1.1.1 to **73**.

```
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 10.1.1.1 weight 73
```

Notifications

If this neighbor is not activated in this address family, the following notification will be displayed:

```
% Activate the neighbor for the address family first
```

1.152 network

Function

Run the **network** command to add static routing entries to a BGP routing table and advertise them to peers.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static routing entry is added to a BGP routing table and advertised to peers by default.

Syntax

network *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**]

no network *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**]

default network *network-number* [**mask** *mask*] [**route-map** *map-tag*] [**backdoor**]

Parameter Description

network-number: Network number.

mask: Subnet mask.

route-map *map-tag*: Specifies the name of a route map. The value cannot exceed 32 characters.

backdoor: Specifies the route as a backdoor route.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command allows IGP routes to be added to a BGP routing table. The advertised route information includes directly connected routes, static routes, and dynamic routes.

When this command is run, you can specify a route map. The route map allows you to modify the advertised route information.

Examples

The following example configures a BGP speaker to advertise the route 10.0.0.0/16.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# network 10.0.0.1 mask 255.255.0.0
```

1.153 network synchronization

Function

Run the **network synchronization** command to synchronize a device with the local route to advertise the routing information configured by the **network** command.

Run the **no** form of this command to configure a device to directly advertise the routing information configured by the **network** command, whether the local route is synchronized or not.

Run the **default** form of this command to restore the default configuration.

By default, a device synchronizes with the local route to advertise the routing information configured by the **network** command.

Syntax

network synchronization

no network synchronization

default network synchronization

Parameter Description

N/A

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

You can run this command to modify the device action on the routing information configured by the **network** command in advertisement. You are not advised to configure a device to directly advertise routing information configured by the **network** command, because this may cause a route black hole.

Examples

The following example configures a BGP speaker to synchronize with the local route to advertise routing information configured by the **network** command.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# network synchronization
```

1.154 overflow memory-lack

Function

Run the **overflow memory-lack** command to configure BGP to enter the overflow state when the memory is insufficient.

Run the **no** form of this command to disable BGP from entering the overflow state when the memory is insufficient.

Run the **default** form of this command to restore the default configuration.

BGP enters the overflow state by default when the memory is insufficient.

Syntax

overflow memory-lack

no overflow memory-lack

default overflow memory-lack

Parameter Description

N/A

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

After entering the overflow state, BGP discards learned routes. This ensures that the memory does not increase.

After this command is run, a route loop may occur on the entire network if the BGP address family enters the overflow state and discards learned routes. To reduce the occurrence of this problem, BGP generates a default route toward the null interface. This route always exists in the overflow state.

You can run the **clear bgp** { *addressfamily* | **all** } command to reset the BGP session and clear the overflow state of the BGP address family.

You can run the **no** form of this command to disable BGP from entering the overflow state when the memory is insufficient. This may consume memory resources. When the memory usage exceeds the threshold of the software, all BGP neighbors are disconnected and all learned routes are removed.

Examples

The following example disables BGP from entering the overflow state when the memory is insufficient.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# no overflow memory-lack
```

1.155 redistribute

Function

Run the **redistribute** command to redistribute the routing information of another routing protocol to a BGP instance.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No routing information of another routing protocol is redistributed to a BGP instance by default.

Syntax

redistribute *protocol-type* [**metric** *metric-value* | **route-map** *map-tag*] *

no redistribute *protocol-type* [**metric** | **route-map**] *

default redistribute *protocol-type* [**metric** | **route-map**] *

Parameter Description

protocol-type: Source protocol type of a redistributed route. The parameter can be set to one of the following values:

- **arp-host**: Specifies a host route converted from ARP.
- **connected**: Specifies a directly connected route.
- **rip**: Specifies an RIP route.
- **static**: Specifies a static route.

route-map *map-tag*: Specifies the name of an associated route map. No route map is associated by default.

metric *metric-value*: Specifies the default metric value for a redistributed route. The value range is from 0 to 4294967295.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

If you specify an optional parameter during the configuration of the **no** form of this command, you remove only the configuration of the parameter, but do not remove the redistribution of routing information.

The metric values of routes are processed in the following order:

(1) If you work out a route map during the configuration of this command, the software applies the route map to process the metric value of a redistributed route. If you configure metric processing for the route map, you use the processed metric value.

(2) If you do not configure metric processing for the route or you only specify the **metric** parameter and *metric-value* during the configuration of this command, you use the *metric-value*.

(3) If no metric processing method is configured and no parameter is specified, the software directly uses the value of the redistributed route.

Examples

The following example configures BGP to redistribute static routes and filters the redistributed routes according to the route map static-rmap.

```
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# redistribute static route-map-name static-rmap
```

1.156 redistribute isis

Function

Run the **redistribute isis** command to redistribute the routing information of the IS-IS routing protocol to a BGP instance.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No routing information of the IS-IS routing protocol is redistributed to a BGP instance by default.

Syntax

redistribute isis [*isis-tag*] [{ **level-1** | **level-1-2** | **level-2** } | **metric** *metric-value* | **route-map** *map-tag*] *
no redistribute isis [*isis-tag*] [{ **level-1** | **level-1-2** | **level-2** } | **metric** | **route-map**] *

default redistribute isis [*isis-tag*] [{ **level-1** | **level-1-2** | **level-2** } | **metric** | **route-map**] *

Parameter Description

isis-tag: Process name of a redistributed IS-IS route.

level-1: Redistributes only level 1 routing information of IS-IS.

level-1-2: Redistributes both level 1 and level 2 routing information of IS-IS.

level-2: Redistributes only level 2 routing information of IS-IS. This is the default configuration of IS-IS route redistribution.

metric: Configures the default metric value of a redistributed route.

metric-value: Default metric value of a redistributed route. The value range is from 0 to 4294967295.

route-map: Configures an associated route map. If this parameter is not specified, no route map is associated.

map-tag: Name of a route map.

14

Usage Guidelines

If you specify an optional parameter during the configuration of the **no** form of this command, you remove only the configuration of the parameter, but do not remove the redistribution of routing information. After all subtypes of routes are deleted, the default type of routes are redistributed.

The IS-IS routes are filtered in the following order:

(1) First, IS-IS route types are filtered based on the configured **level** parameter.

(2) Then, they are filtered based on the rule of a route map.

The metric values of routes are processed in the following order:

(3) If you work out a route map during the configuration of this command, the software applies the route map to process the metric value of a redistributed route. If you configure metric processing for the route map, you use the processed metric value.

(4) If you do not configure metric processing for the route map or you only specify the **metric** parameter and *metric-value* during the configuration of this command, you use the *metric-value*.

(5) If no metric processing method is configured and no parameter is specified, the software directly uses the value of the redistributed route.

Examples

The following example configures BGP to redistribute IS-IS routes and filters the redistributed routes based on the route map static-rmap.

```
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# redistribute isis route-map-name static-rmap
```

1.157 redistribute ospf

Function

Run the **redistribute ospf** command to redistribute the routing information of the Open Shortest Path First (OSPF) routing protocol to a BGP instance.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No routing information of the OSPF routing protocol is redistributed to a BGP instance by default.

Syntax

redistribute ospf *process-id* [**match** { { **external** | { **external 1** | **external 2** }* } | **internal** | { **nssa-external** | { **nssa-external 1** | **nssa-external 2** } * } } * | **metric** *metric-value* | **route-map** *map-tag*] *

no redistribute ospf *process-id* [**match** { { **external** | { **external 1** | **external 2** }* } | **internal** | { **nssa-external** | { **nssa-external 1** | **nssa-external 2** } * } } * | **metric** | **route-map**] *

default redistribute ospf *process-id* [**match** { { **external** | { **external 1** | **external 2** }* } | **internal** | { **nssa-external** | { **nssa-external 1** | **nssa-external 2** } * } } * | **metric** | **route-map**] *

Parameter Description

process-id: Process ID of a redistributed OSPF route.

match: Specifies the subtype of a matched OSPF route.

external: Specifies the external types of OSPF routes, including type 1 and type 2.

external 1: Specifies the external type 1 of OSPF routes.

external 2: Specifies the external type 2 of OSPF routes.

internal: Specifies the internal subtype of OSPF routes, which is the default value of the **match** keyword for redistributed OSPF routes.

nssa-external: Specifies the NSSA external types of OSPF routes, including type 1 and type 2.

nssa-external 1: Specifies the NSSA external type 1 of OSPF routes.

nssa-external 2: Specifies the NSSA external type 2 of OSPF routes.

metric: Configures the default metric value of a redistributed route.

metric-value: Default metric value of a redistributed route. The value range is from 0 to 4294967295.

route-map: Configures an associated route map. If this parameter is not specified, no route map is associated.

map-tag: Name of a route map.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

If you specify an optional parameter during the configuration of the **no** form of this command, you remove only the configuration of the parameter, but do not remove the redistribution of routing information. After all subtypes of routes are deleted, the default type of routes are redistributed.

The OSPF routes are filtered in the following order:

(1) First, OSPF route types are filtered based on the configured **match** parameter.

(2) Then, they are filtered based on the rule of a route map.

The metric values of routes are processed in the following order:

(3) If you work out a route map during the configuration of this command, the software applies the route map to process the metric value of a redistributed route. If you configure metric processing for the route map, you use the processed metric value.

(4) If you do not configure metric processing for the route map or you only specify the **metric** parameter and *metric-value* during the configuration of this command, you use the *metric-value*.

(5) If no metric processing method is configured and no parameter is specified, the software directly uses the value of the redistributed route.

Examples

The following example configures BGP to redistribute routes of the OSPF process 2 and filters the redistributed routes based on the route map static-rmap.

```
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# redistribute ospf 2 route-map-name static-rmap
```

1.158 route mirroring

Function

Run the **route mirroring** command to enable the function of BGP packet mirroring.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function of BGP packet mirroring is disabled by default.

Syntax

route mirroring

no route mirroring

default route mirroring

Parameter Description

N/A

Command Modes

BMP configuration mode

Default Level

14

Usage Guidelines

Mirrored packets are sent to a BMP server. Mirroring BGP packets affects BGP performance.

Examples

The following example enables the function of BGP packet mirroring of BMP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
Hostname(config-bmpsrvr)# route mirroring
```

1.159 router bgp

Function

Run the **router bgp** command to enable the BGP protocol, configure a local AS number, and enter the BGP configuration mode.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

BGP is disabled by default.

Syntax

router bgp *as-number*

no router bgp *as-number*

default router bgp *as-number*

Parameter Description

as-number: AS number. A 4-byte AS number can be configured. That is, the new AS number range is from 1 to 4294967295, or from 1 to 65535.65535 in dot mode.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can configure this command to enable the BGP protocol.

RFC 4893 defines a newly reserved AS number 23456, and the number cannot be used as a private AS number. The value range of the original private AS numbers from 64512 to 65534 remains valid, and 65535 is reserved for special purposes.

RFC 5398 defines two groups of AS numbers, their value ranges are from 64496 to 64511 and from 65536 to 65551.

Examples

The following example enables the BGP protocol and sets the local AS number to **65000**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
```

1.160 scope

Function

Run the **scope** command to enter the scope configuration mode and associate a VRF instance with BGP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No scope address family is configured by default.

Syntax

scope vrf *vrf-name*

no scope vrf *vrf-name*

default scope vrf *vrf-name*

Parameter Description

vrf *vrf-name*: VRF name.

Command Modes

BGP configuration mode

Default Level

14

Usage Guidelines

You can run the **exit** command to exit the scope configuration mode.

Note

In the scope configuration mode, commands configured in the BGP configuration mode are converted to scope command mode. To restore the scope command mode to the original command mode, you can configure the **no router bgp** command and reconfigure the commands.

Examples

The following example enters the scope VRF configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# scope vrf VRF
Hostname(config-router-scope)#
```

1.161 show bgp all

Function

Run the **show bgp all** command to display all the routing information of BGP.

Syntax

show bgp all [**aggregate** | **community** [*community-number* [**exact-match**]] | **community-list** *community-name*&<1-n> [**extact-match**] | **extcommunity-list** *extcommunity-name* [**exact-match**] | **filter-list** *path-list-number* | **inconsistent-as** | **quote-regexp** *regexp* | **regexp** *regexp*]

show bgp all dampening { **dampened**-**paths** | **flap**-**statistics** | **parameters** }

show bgp all neighbors [{ *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**advertised**-**routes** [**check**] | **ha-mode** [**adj-in** [**detail**] | **adj-out**] | **hide-info** | **policy** [**detail**] | **received**-**routes** | **routes**]]

show bgp all paths

show bgp all summary

show bgp all update-**group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**ha-mod adj-out** | **summary**]

Parameter Description

aggregate: Displays the routing aggregation information.

community: Displays the routing information that contains the specified community number.

community-number: Specified community number. This parameter can be entered for multiple times. This parameter follows the format of AA:NN (AS number: 2-byte number) or is set to one of the following community names:

- **gshut**
- **internet**
- **local-as**
- **no-advertise**
- **no-export**

exact-match: Specifies the routing information that exactly matches community values or a community list.

community-list *community-name*: Displays the BGP routing information that matches a specified community list. *community-name* specifies the name of a community list.

extcommunity-list *extcommunity-name*: Displays the BGP routing information that contains the name of a specified extended community list or the number of a community list. *extcommunity-name* specifies the name of an extended community list or the number of a community list.

filter-list *path-list-number*: Displays the routing information that matches the filtering list. *path-list-number* is the number of a filtering list. The value range is from 1 to 500.

inconsistent-as: Displays the inconsistent routing information of the source AS.

quote-regexp *regexp*: Displays the BGP routing information that matches a regular expression within the specified double quotation marks in the AS-PATH attribute.

regexp *regexp*: Displays the BGP routing information that matches a specified regular expression in the AS-PATH attribute.

dampening: Displays route suppression information.

dampened-paths: Displays suppressed routing information.

flap-statistics: Displays route flapping statistics.

parameters: Displays route flapping parameters.

neighbors: Displays BGP neighbor information.

neighbor-ipv4-address: IPv4 address of a specified neighbor.

neighbor-ipv6-address: IPv6 address of a specified neighbor.

advertised-routes: Displays all the routing information sent to a specified peer.

check: Displays route filtering debugging information.

hide-info: Displays BGP NSR information.

adj-in: Displays the routing information received by the BGP neighbor NSR.

detail: Displays detailed information.

adj-out: Displays the routing information sent by the BGP neighbor NSR.

hide-info: Displays internal information.

policy: Displays the routing policy information about the BGP neighbor.

received-routes: Displays all the routing information received from a specified peer, including received routes and rejected routes.

routes: Displays all the routing information received from peers.

paths: Displays the routing information in a routing information base.

summary: Displays BGP neighbor information.

update-group: Displays update group information.

update-group-index: Index of a specified update group.

ha-mod adj-out: Displays the routing information sent by the BGP neighbor NSR.

summary: Displays summary information.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to display all the family address information in the BGP routing information.

Examples

The following example displays all neighbor information.

```
Hostname> enable
Hostname# show bgp all
For address family: IPv4 Unicast
BGP table version is 1, local router ID is 1.2.3.4
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
            S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network          Next Hop            Metric     LocPrf     Weight Path
*> 1.0.0.0          0.0.0.0                  0                32768    ?
Total number of prefixes 1
For address family: IPv6 Unicast
BGP table version is 1, local router ID is 1.2.3.4
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
            S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
   Network          Next Hop            Metric     LocPrf     Weight Path
*> 5750:1::/120     ::                       0                32768    ?
Total number of prefixes 1
```

Table 1-1 Output Fields of the show bgp all Command

Field	Description
For address family	BGP address family information
BGP table version	BGP table version
local router ID	Local router ID, which is a loopback address generally
Status codes	Status code of a BGP route
s	Suppressed route
d	Route flapping shielding
h	Historic route, unavailable route
*	Valid route
>	Optimal route

Field	Description
i	IBGP route
r	RIB failed to install a routing table
S	Stale route
Origin Codes	Original code of a BGP route
i	IGP originating route in a BGP routing table
e	EGP originating route in a BGP routing table
?	Unable to determine the source of a route in a BGP routing table
Network	Network routing information in the format of aa:bb. aa specifies a site ID and bb specifies a label block offset.
Next hop	IP address of a next hop
Metric	Metric value of a route
LocPrf	Local priority
Weight	Weight. The weight of a locally generated route is 32768.
Path	AS path that reaches the destination network

1.162 show bgp bmp

Function

Run the **show bgp bmp** command to display BMP server information.

Syntax

show bgp bmp { **neighbor** | **server** [*server-number*] [**detail**] | **summary** }

Parameter Description

neighbor: Displays the neighbors monitored by a BMP server.

server: Displays BMP server instance information.

server-number: ID of a specified BMP server instance.

detail: Displays the detailed information of a BMP server instance.

summary: Display the summary information about connection establishment of a BMP server.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

Examples

The following example displays the BMP server instance information.

```
Hostname> enable
Hostname# show bgp bmp server 1
BMP server 1
  BMP state = Idle
  up time       Never
  BGP monitor neighbors: 4
  route mirroring
```

The following example displays the neighbors monitored by a BMP server.

```
Hostname> enable
Hostname# show bgp bmp neighbor
Neighbor       CfgSvr#          ActSvr#
3.3.3.1        1               1
3.3.3.2        1               1
```

Table 1-2 Output Fields of the show bgp bmp neighbor Command

Field	Description
Neighbor	Address of a monitored neighbor
CfgSvr#	Instance ID of the configured BMP server that monitors this neighbor
ActSvr#	Instance ID of the BMP server that is activated to monitor this neighbor

The following example displays the summary information about connection establishment of a BMP server.

```
Hostname> enable
Hostname# show bgp bmp summary
ID   Host               Port     State       Time       NBRs
1    123.123.123.123     12345    Active      Never      4
```

Table 1-3 Output Fields of the show bgp bmp summary Command

Field	Description
ID	Address of a monitored neighbor

Field	Description
Host	Instance ID of the configured BMP server that monitors this neighbor
Port	Listening port of a BMP server
State	Connection state of a BMP server
Time	Connection or disconnection time of a BMP server
NBRs	Number of neighbors monitored by a BMP server

1.163 show bgp develop

Function

Run the **show bgp develop** command to display the development information of BGP.

Syntax

show bgp develop { **bgp-instance** | **cap** | **connected** | **evi-rd-hash** | **ifx-link-group** | **interface nd** [*ifx-number*] | **io-process** [**log-info** | **log-warn** | **master** | **memory** | **peer** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *peer-id*]] | **link-state-group** | **mom** | **peer-as** | **pic-info** | **route-shake** | **thread** | **vr** | **vrf-rd-hash** }

Parameter Description

bgp-instance: Displays specific information of a BGP instance.

cap: Displays state information of a BGP capability.

connected: Displays BGP neighbor connection information.

evi-rd-hash: Displays RD information of all EVI instances.

ifx-link-group: Displays link group information.

interface nd: Displays IPv6 neighbor information.

ifx-number: Interface IFX number. The value range is from 1 to 16777215.

io-process: Displays all IO processes or a single IO process.

log-info: Displays the log information of all IO processes or a single IO process.

log- warn: Displays the alarm information of all IO processes or a single IO process.

master: Displays the main information of all IO processes or a single IO process.

memory: Displays the memory information of all IO processes or a single IO process.

peer: Displays the IO statistics about a peer.

neighbor-ipv4-address: IPv4 address of a specified peer.

neighbor-ipv6-address: IPv6 address of a specified peer.

peer-id: ID of a specified peer.

link-state-group: Displays the BGP link state group information.

mom: Displays the MOM connection state.

peer-as: Displays the number of neighbors.

pic-info: Displays the PIC information of BGP.

route-shake: Displays the route flapping information.

thread: Displays all BGP thread information.

vr: Displays global VR details.

vrf-rd-hash: Displays the VRF RD information of BGP.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to locate faults.

Examples

The following example displays the RD information of all VRF instances.

```
Hostname> enable
Hostname# show bgp develop vrf-rd-hash
VRF RD Hash:
  rd: 2:2, owner: VRF(v2)
  rd: 1:1, owner: VRF(v1)
```

1.166 show bgp ipv4 unicast

Function

Run the **show bgp ipv4 unicast** command to display the IPv4 unicast routing information in BGP routing information.

Syntax

show bgp ipv4 unicast [*prefix-ipv4-address* [*network-mask* [**longer-prefixes**]] | **aggregate** | **cidr-only** | **community** [*community-number*&<1-n> [**exact-match**]] | **community-list** *community-name* [**exact-match**] | **extcommunity-list** *extcommunity-name* [**exact-match**] | **filter-list** *path-list-number* | **global-vrf detail** | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **quote-regexp** *regexp* | **regexp** *regexp* | **route-map** *map-tag*]

show bgp ipv4 unicast vrf *vrf-name* [*prefix-ipv4-address* [*network-mask* [**longer-prefixes**]] | **aggregate** | **cidr-only** | **community** [*community-number*&<1-n> [**exact-match**]] | **community-list** *community-name* [**exact-match**] | **extcommunity-list** *extcommunity-name* [**exact-match**] | **filter-list** *path-list-number* | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **quote-regexp** *regexp* | **regexp** *regexp* | **route-map** *map-tag*]]

Parameter Description

prefix-ipv4-address: IPv4 address of a specified prefix.

network-mask: Mask of a specified network prefix.

longer-prefixes: Displays the specific routing information included in a specified prefix.

aggregate: Displays the detailed information of an aggregate route.

cidr-only: Displays the classless routing information.

community: Displays the routing information that contains the specified community number.

community-number&<1-n>: Specified community number. &<1-n> specifies that this parameter can be entered *n* times. This parameter follows the format of AA:NN (AS number: 2-byte number) or is set to one of the following community names:

- **gshut**
- **internet**
- **local-as**
- **no-advertise**
- **no-export**

exact-match: Specifies the routing information that exactly matches community values or a community list.

community-list *community-name*: Displays the BGP routing information that matches a specified community list. *community-name* specifies the name of a community list.

extcommunity-list *extcommunity-name*: Displays the BGP routing information that contains the name of a specified extended community list or the number of a community list. *extcommunity-name* specifies the name of an extended community list or the number of a community list.

filter-list *path-list-number*: Displays the routing information that matches the filtering list. *path-list-number* is the number of the filtering list. The value range is from 1 to 500.

global-vrf detail: Displays global VRF information.

inconsistent-as: Displays the inconsistent routing information of the source AS.

prefix-list *ip-prefix-list-name*: Displays the routing information that matches a specified prefix filtering list.

quote-regexp *regexp*: Displays the routing information that matches a regular expression within the specified double quotation marks in the AS-PATH attribute.

regexp *regexp*: Displays the routing information that matches a specified regular expression in the AS-PATH attribute.

route-map *map-tag*: Displays the routing information that matches the filtering condition of a specified route map. *map-tag*: Name of a route map.

vrf *vrf-name*: Specifies a VRF name.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can use this command to display the BGP IPv4 unicast routing information. By specifying parameters, you can filter routing information that matches the specified conditions.

Examples

The following example displays the routing information of an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv4 unicast
BGP table version is 2, local router ID is 192.168.183.1
Status codes: s suppressed, d damped, h history, * valid, > best, i - internal,
              S Stale
Origin codes: i - IGP, e - EGP, ? - incomplete
```

```
   Network         Next Hop             Metric     LocPrf  Path
*>i44.0.0.0         192.168.195.183         0        100     i
*>i64.12.0.0/16     192.168.195.183         0        100     i
*>i172.16.0.0/24    192.168.195.183         0        100     i
*>i202.201.0.0      192.168.195.183         0        100     i
*>i202.201.1.0      192.168.195.183         0        100     i

```

```
Total number of prefixes 2
```

Table 1-4 Output Fields of the show bgp ipv4 unicast Command

Field	Description
BGP table version	BGP table version
local router ID	Local router ID, which is a loopback address generally
Status codes	Status code of a BGP route
s	Suppressed route
d	Route flapping shielding
h	Historic route, unavailable route
*	Valid route
>	Optimal route
i	IBGP route
S	Stale route
Origin Codes	Original code of a BGP route
i	IGP originating route in a BGP routing table
e	EGP originating route in a BGP routing table
?	Unable to determine the source of a route in a BGP routing table
Network	Network routing information in the format of aa:bb. aa specifies a site ID and bb specifies a label block offset.
Next hop	IP address of a next hop
Metric	Metric value of a route
LocPrf	Local priority
Path	AS path that reaches the destination network

1.167 show bgp ipv4 unicast dampening

Function

Run the **show bgp ipv4 unicast dampening** command to display the BGP IPv4 unicast route flapping information.

Syntax

show bgp ipv4 unicast [**vrf** *vrf-name*] **dampening** { **dampened-paths** | **flap-statistics** | **parameters** }

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

dampened-paths: Displays the suppressed routes in the IPv4 routing information of BGP.

flap-statistics: Displays the route flapping statistics in the IPv4 routing information of BGP.

parameters: Displays the parameters of the IPv4 unicast route flapping information configured by BGP.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the parameters of an IPv4 unicast route flapping information of BGP.

Examples

The following example displays the route flapping and damping parameters of an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv4 unicast dampening parameters
dampening 10 750 2000 40
Dampening Control Block(s):
Reachability Half-Life time    : 10 min
Reuse penalty                : 750
Suppress penalty             : 2000
Max suppress time            : 40 min
Max penalty (ceil)           : 12000
```

Table 1-5 Output Fields of the show bgp ipv4 unicast dampening parameters Command

Field	Description
dampening	Route flapping parameter
Reachability Half-Life time	Half-life time
Reuse penalty	A route is damped when the penalty is reduced to this value.

Field	Description
Suppress penalty	A route is damped when the penalty reaches this value.
Max suppress time	Maximum route suppression time
Max penalty (ceil)	Maximum penalty

1.168 show bgp ipv4 unicast neighbors

Function

Run the **show bgp ipv4 unicast neighbors** command to display the IPv4 unicast neighbor information of BGP.

Syntax

show bgp ipv4 unicast [**vrf** *vrf-name*] **neighbors** [{ *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**advertised-routes** [**check**] | **ha-mode** [**adj-in** [**detail**] | **adj-out**] | **hide-info** | **policy** [**detail**] | **received-routes** | **routes**]]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

neighbor-ipv4-address: IPv4 address of a specified neighbor.

neighbor-ipv6-address: IPv6 address of a specified neighbor.

advertised-routes: Displays all the routing information sent to a specified peer.

check: Displays route filtering debugging information.

ha-mode: Displays BGP NSR information.

adj-in: Displays the routing information received by the BGP neighbor NSR.

detail: Displays detailed information.

adj-out: Displays the routing information sent by the BGP neighbor NSR.

hide-info: Displays internal information.

policy: Displays the routing policy information about the BGP neighbor.

received-routes: Displays all the routing information received from a specified peer, including received routes and rejected routes.

routes: Displays all the routing information received from peers.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the IPv4 unicast neighbor connection information of BGP.

Examples

The following example displays the neighbor information of an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv4 unicast neighbors
BGP neighbor is 192.168.195.183, remote AS 23, local AS 23, internal link
  BGP version 4, remote router ID 44.0.0.1
  BGP state = Established, up for 00:06:37
  Last read 00:06:37, hold time is 180, keepalive interval is 60 seconds
  Neighbor capabilities:
    Route refresh: advertised and received (old and new)
Address family IPv4 Unicast: advertised and received
Graceful restart: advertised and received
Remote Restart timer is 120 seconds
  Received 14 messages, 0 notifications, 0 in queue
    open message:1 update message:4 keepalive message:9
    refresh message:0 dynamic cap:0 notifications:0
  Sent 12 messages, 0 notifications, 0 in queue
    open message:1 update message:3 keepalive message:8
    refresh message:0 dynamic cap:0 notifications:0
  Route refresh request: received 0, sent 0
  Minimum time between advertisement runs is 0 seconds
 For address family: IPv4 Unicast
  BGP table version 2, neighbor version 1
  Index 2, Offset 0, Mask 0x4
  Inbound soft reconfiguration allowed
  8 accepted prefixes
  0 announced prefixes
 Connections established 2; dropped 1
Local host: 192.168.195.239, Local port: 1074
Foreign host: 192.168.195.183, Foreign port: 179
Nexthop: 192.168.195.239
Nexthop global: ::
Nexthop local: ::
BGP connection: non shared network
Last Reset: 00:06:43, due to BGP Notification sent
Notification Error Message: (Cease/Unspecified Error Subcode)
Using BFD to detect fast fallover
```

Table 1-6 Output Fields of the show bgp ipv4 unicast neighbors Command

Field	Description
BGP neighbor	Address of a BGP peer
remote AS	Remote AS number
local AS	Local AS number
internal link	IBGP peer
BGP version	BGP version number after negotiation
remote router ID	Router ID of remote BGP
BGP state	State machine state of a peer
Neighbor capabilities	Capability negotiation state of a peer
For address family: IPv4 Unicast	Statistics about IPv4 unicast address family of a peer

1.169 show bgp ipv4 unicast paths

Function

Run the **show bgp ipv4 unicast paths** command to display the IPv4 unicast path information in a routing information base.

Syntax

show bgp ipv4 unicast [**vrf** *vrf-name*] **paths**

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the path information in a routing database.

Examples

The following example displays the path information of an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv4 unicast paths
Address       Refcnt Path
[0x1d7806a0:0] (67)
[0x1d7389a0:13] (20) 10
```

1.170 show bgp ipv4 unicast summary

Function

Run the **show bgp ipv4 unicast summary** command to display the BGP IPv4 unicast summary information.

Syntax

show bgp ipv4 unicast [**vrf** *vrf-name*] **summary**

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the BGP IPv4 unicast neighbor information.

Examples

The following example displays the neighbor summary information of an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv4 unicast summary
BGP router identifier 192.168.183.1, local AS number 23
BGP table version is 2
2 BGP AS-PATH entries
1 BGP community entries
Neighbor        V    AS   MsgRcvd  MsgSent  TblVer  InQ  OutQ  Up/Down  State/PfxRcd
192.168.195.79   4    24     0       0       0     0    0    never      Active
192.168.195.183  4    23     17      15      1     0    0    00:09:04    8

1.171 show bgp ipv4 unicast update-group

Function

Run the **show bgp ipv4 unicast update-group** command to display the BGP IPv4 unicast update group information.

Syntax

show bgp ipv4 unicast [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**ha-mod adj-out** | **summary**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

neighbor-ipv4-address: IPv4 address of a specified neighbor.

neighbor-ipv6-address: IPv6 address of a specified neighbor.

update-group-index: Specific update group information.

ha-mod adj-out: Displays the routing information sent by the BGP neighbor NSR.

summary: Displays neighbor summary information.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the BGP IPv4 unicast update group information.

Examples

The following example displays the update group information of an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv4 update-group
BGP version 4 update-group 1(ref 2), internal, Address Family: IPv4 Unicast
  Update message formated 2, replicated 2
  Minimum route advertisement interval is 0 seconds
  Minimum AS origination interval is 1 seconds
  Format state: Current working
              Refresh blocked
  Has 1 members:
   192.168.195.183
```

Table 1-9 Output Fields of the show bgp ipv4 unicast update-group Command

Field	Description
BGP version	BGP version number
update-group	BGP route update group
internal	IBGP route
Address Family	Address family information
Update message formated	Format of an update message

Field	Description
replicated	Replicate message
Minimum route advertisement interval	Minimum route advertisement interval
Minimum AS origination interval	Minimum sending interval of an update message in which the AS route of the BGP speaker resides changes
Format state	Format state
members	Neighbor information

The following example displays the neighbor summary information of update group 1 in an IPv4 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv4 unicast update-group 1 summary
BGP router identifier 192.168.183.1, local AS number 23
BGP table version is 2
2 BGP AS-PATH entries
1 BGP community entries

1.172 show bgp ipv6 unicast

Function

Run the **show bgp ipv6 unicast** command to display the IPv6 unicast routing information in BGP routing information.

Syntax

show bgp ipv6 unicast [*prefix-ipv6-address/prefix-length* [**longer-prefixes**] | **aggregate** | **community** [*community-number*&<1-n> [**exact-match**]] | **community-list** *community-name* [**exact-match**] | **extcommunity-list** *extcommunity-name* [**exact-match**] | **filter-list** *path-list-number* | **global-vrf detail** | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **quote-regexp** *regexp* | **regexp** *regexp* | **route-map** *map-tag*]]

show bgp ipv6 unicast vrf *vrf-name* [*prefix-ipv6-address/prefix-length* [**longer-prefixes**] | **aggregate** | **community** [*community-number*&<1-n> [**exact-match**]] | **community-list** *community-name* [**exact-match**] | **extcommunity-list** *extcommunity-name* [**exact-match**] | **filter-list** *path-list-number* | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **quote-regexp** *regexp* | **regexp** *regexp* | **route-map** *map-tag*]

Parameter Description

prefix-ipv6-address/prefix-length: Specific IPv6 route prefix in a routing table.

longer-prefixes: Displays the specific routing information included in a specified prefix.

aggregate: Displays the detailed information of an aggregate route.

community: Displays the routing information that contains the specified community number.

community-number&<1-n>: Specified community number. &<1-n> specifies that this parameter can be entered *n* times. This parameter follows the format of AA:NN (AS number: 2-byte number) or is set to one of the following community names:

- **gshut**
- **internet**
- **local-as**
- **no-advertise**
- **no-export**

exact-match: Specifies the routing information that exactly matches community values or a community list.

community-list *community-name*: Displays the BGP routing information that matches a specified community list. *community-name* specifies the name of a community list.

extcommunity-list *extcommunity-name*: Displays the BGP routing information that contains the name of a specified extended community list or the number of a community list. *extcommunity-name* specifies the name of an extended community list or the number of a community list.

filter-list *path-list-number*: Displays the routing information that matches the filtering list. *path-list-number* is the number of a filtering list. The value range is from 1 to 500.

global-vrf detail: Displays the global VRF information.

inconsistent-as: Displays the inconsistent routing information of the source AS.

prefix-list *ip-prefix-list-name*: Displays the routing information that matches a specified prefix filtering list.

quote-regexp *regexp*: Displays the routing information that matches a regular expression within the specified double quotation marks in the AS-PATH attribute.

regexp *regexp*: Displays the routing information that matches a specified regular expression in the AS-PATH attribute.

route-map *map-tag*: Displays the routing information that matches the filtering condition of a specified route map. *map-tag*: Name of a route map.

vrf *vrf-name*: Specifies a VRF name.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to display the IPv6 unicast routing information of BGP. By specifying parameters, you can filter the routing information that matches the specified conditions.

1.173 show bgp ipv6 unicast dampening

Function

Run the **show bgp ipv6 unicast dampening** command to display the IPv6 unicast route flapping parameters configured by BGP.

Syntax

show bgp ipv6 unicast [**vrf** *vrf-name*] **dampening** { **dampened-paths** | **flap-statistics** | **parameters** }

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

dampened-paths: Displays the suppressed routes in the BGP IPv6 routing information.

flap-statistics: Displays the route flapping statistics in the BGP IPv6 routing information.

parameters: Displays the IPv6 unicast route flapping parameters configured by BGP.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the parameters of the BGP IPv6 unicast route flapping information.

Function

Run the **show bgp ipv6 unicast neighbors** command to display the IPv6 unicast neighbor information of BGP.

Syntax

show bgp ipv6 unicast [**vrf** *vrf-name*] **neighbors** [{ *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**advertised-routes** [**check**] | **ha-mode** [**adj-in** [**detail**] | **adj-out**] | **hide-info** | **policy** [**detail**] | **received-routes** | **routes**]]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

neighbor-ipv4-address: IPv4 address of a specified neighbor.

neighbor-ipv6-address: IPv6 address of a specified neighbor.

advertised-routes: Displays all the routing information sent to a specified peer.

check: Displays route filtering debugging information.

ha-mode: Displays BGP NSR information.

adj-in: Displays the routing information received by the BGP neighbor NSR.

detail: Displays detailed information.

adj-out: Displays the routing information sent by the BGP neighbor NSR.

hide-info: Displays internal information.

policy: Displays the routing policy information about the BGP neighbor.

received-routes: Displays all the routing information received from a specified peer, including received routes and rejected routes.

routes: Displays all the routing information received from peers.

Command Modes

1.177 show bgp ipv6 unicast update-group

Function

Run the **show bgp ipv6 unicast update-group** command to display the BGP IPv6 unicast update group information.

Syntax

show bgp ipv6 unicast [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**ha-mod adj-out** | **summary**]

Parameter Description

vrf *vrf-name*: Specifies a VRF name. If this parameter is not specified, all VRF instances are specified.

neighbor-ipv4-address: IPv4 address of a specified neighbor.

neighbor-ipv6-address: IPv6 address of a specified neighbor.

update-group-index: Specific update group information.

ha-mod adj-out: Displays the routing information sent by the BGP neighbor NSR.

summary: Displays neighbor summary information.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the IPv6 unicast update group information of BGP.

Examples

The following example displays the update group information of an IPv6 unicast address family of BGP.

```
Hostname> enable
Hostname# show bgp ipv6 update-group
BGP version 4 update-group 1(ref 2), internal, Address Family: IPv6 Unicast
  Update message formated 2, replicated 2
  Minimum route advertisement interval is 0 seconds
  Minimum AS origination interval is 1 seconds
  Format state: Current working
              Refresh blocked
  Has 1 members:
   192:168:195::183
```

Table 1-12 Output Fields of the show bgp ipv6 update-group Command

Field	Description
BGP version	BGP version number

1.181 show bgp nsr

Function

Run the **show bgp nsr** command to display NSR information.

Syntax

show bgp nsr { **info** | **sock-cb** [*sock-cb-id*] | **sock-list** | **status** }

Parameter Description

info: Displays NSR basic information.

sock-cb: Displays the socket CB information of BGP.

sock-cb-id: Specified socket CB information of BGP. The value range is from 0 to 4294967295.

sock-list: Displays saved socket handle information.

status: Displays NSR state information.

1.183 show bgp rpi

Function

Run the **show bgp rpi** command to display RPI policy information.

Syntax

show bgp rpi { **acl** [**detail**] | **as-path-access-list** | **community-list** | **extcommunity-list** | **ip-prefix-list** | **ipv6-prefix-list** | **route-map** }

Parameter Description

acl: Displays the ACL information of an RPI policy.

detail: Displays the ACL details of an RPI policy.

as-path-access-list: Displays the AS path information of an RPI policy.

community-list: Displays the attribute configuration information of an RPI policy.

extcommunity-list: Displays the extended attribute configuration information of an RPI policy.

ip-prefix-list: Displays the IPv4 route filtering information of an RPI policy.

ipv6-prefix-list: Displays the IPv6 route filtering information of an RPI policy.

route-map: Displays the route map information of an RPI policy.

1.184 show bgp statistics

Function

Run the **show bgp statistics** command to display BGP statistics.

Syntax

show bgp statistics [**vrf** *vrf-name*]

Parameter Description

vrf *vrf-name*: Displays the BGP statistics of a VRF instance. If this parameter is not specified, global BGP statistics information is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays BGP statistics.

```
Hostname> enable
Hostname# show bgp statistics
Local as 100, Router id 1.1.1.1
  Total neighbor 10, Established neighbor 9, Admin-Down neighbor 1
  IBGP neighbor 8, Established IBGP neighbor 8, Admin-Down IBGP neighbor 0
  EBGP neighbor 2, Established EBGP neighbor 1, Admin-Down EBGP neighbor 1
  AS-PATH entries 1, Community entries 1, Extended-Community entries 0
  For address family: IPv4 Unicast
Activated neighbor 9, Unactivated neighbor 0
Activated IBGP neighbor 8, Unactivated IBGP neighbor 0
Activated EBGP neighbor 1, Unactivated EBGP neighbor 0
  For address family: IPv6 Unicast
Activated neighbor 0, Unactivated neighbor 9
Activated IBGP neighbor 0, Unactivated IBGP neighbor 0
Activated EBGP neighbor 0, Unactivated EBGP neighbor 0
```

Table 1-14 Output Fields of the show bgp statistics Command

Field	Description
Router id	BGP router ID
Total neighbor	Total number of neighbors
Established neighbor	Number of established neighbors
Admin-Down neighbor	Number of admin-down neighbors
IBGP neighbor	Number of IBGP neighbors
Established IBGP neighbor	Number of established IBGP neighbors
Admin-Down IBGP neighbor	Number of admin-down IBGP neighbors
EBGP neighbor	Number of EBGP neighbors
AS-PATH entries	Number of AS-PATH entries
Community entries	Number of community entries

Field	Description
Extended-Community	Number of extended community entries
Established EBGP neighbor	Number of established EBGP neighbors
Admin-Down EBGP neighbor	Number of admin-down EBGP neighbors
Activated neighbor	Number of activated neighbors
Unactivated neighbor	Number of unactivated neighbors, excluding unestablished neighbors
Activated IBGP neighbor	Number of activated IBGP neighbors
Unactivated IBGP neighbor	Number of unactivated IBGP neighbors, excluding unestablished neighbors
Activated EBGP neighbor	Number of activated EBGP neighbors
Unactivated EBGP neighbor	Number of unactivated EBGP neighbors, excluding unestablished neighbors

1.185 show ip bgp

Function

Run the **show ip bgp** command to display the routing information of an IPv4 unicast address family of BGP.

Syntax

show ip bgp [*prefix-ipv4-address* [*network-mask* [**longer-prefixes**]] | **aggregate** | **cidr-only** | **community** [*community-number*&<1-n> [**exact-match**]] | **community-list** *community-name* [**exact-match**] | **extcommunity-list** *extcommunity-name* [**exact-match**] | **filter-list** *path-list-number* | **global-vrf detail** | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **quote-regexp** *regexp* | **regexp** *regexp* | **route-map** *map-tag*]

show ip bgp vrf *vrf-name* [*prefix-ipv4-address* [*network-mask* [**longer-prefixes**]] | **aggregate** | **cidr-only** | **community** [*community-number*&<1-n> [**exact-match**]] | **community-list** *community-name* [**exact-match**] | **extcommunity-list** *extcommunity-name* [**exact-match**] | **filter-list** *path-list-number* | **inconsistent-as** | **prefix-list** *ip-prefix-list-name* | **quote-regexp** *regexp* | **regexp** *regexp* | **route-map** *map-tag*]]

show ip bgp [**vrf** *vrf-name*] **dampening** { **dampened-paths** | **flap-statistics** | **parameters** }

show ip bgp [**vrf** *vrf-name*] **neighbors** [{ *neighbor-ipv4-address* | *neighbor-ipv6-address* } [**advertised-routes** [**check**] | **ha-mode** [**adj-in** [**detail**] | **adj-out**] | **hide-info** | **policy** [**detail**] | **received-routes** | **routes**]]

show ip bgp [**vrf** *vrf-name*] **paths**

show ip bgp [**vrf** *vrf-name*] **summary**

show ip bgp [**vrf** *vrf-name*] **update-group** [*neighbor-ipv4-address* | *neighbor-ipv6-address* | *update-group-index*] [**ha-mod adj-out** | **summary**]

Parameter Description

prefix-ipv4-address: IPv4 address of a specified prefix.

network-mask: Mask of a specified network prefix.

longer-prefixes: Displays the specific routing information included in a specified prefix.

aggregate: Displays the detailed information of an aggregate route.

cidr-only: Displays the classless routing information.

community: Displays the routing information that contains the specified community number.

community-number&<1-n>: Specified community attribute number. &<1-n> specifies that this parameter can be entered *n* times. This parameter follows the format of AA:NN (AS number: 2-byte number) or is set to one of the following community names:

- **gshut**
- **internet**
- **local-as**
- **no-advertise**
- **no-export**

exact-match: Specifies the routing information that exactly matches community values or a community list.

community-list *community-name*: Displays the BGP routing information that matches a specified community list. *community-name* specifies the name of a community list.

extcommunity-list *extcommunity-name*: Displays the BGP routing information that contains the name of a specified extended community list or the number of a community list. *extcommunity-name* specifies the name of an extended community list or the number of a community list.

filter-list *path-list-number*: Displays the routing information that matches the filtering list. *path-list-number* is the number of a filtering list. The value range is from 1 to 500.

global-vrf detail: Displays the global VRF information.

inconsistent-as: Displays the inconsistent routing information of the source AS.

prefix-list *ip-prefix-list-name*: Displays the routing information that matches a specified prefix filtering list.

quote-regexp *regexp*: Displays the routing information that matches a regular expression within the specified double quotation marks in the AS-PATH attribute.

regexp *regexp*: Displays the routing information that matches a specified regular expression in the AS-PATH attribute.

route-map *map-tag*: Displays the routing information that matches the filtering condition of a specified route map. *map-tag*: Name of a route map.

vrf *vrf-name*: Specifies a VRF name.

dampening: Displays the IPv4 unicast route flapping information configured by BGP.

dampened-paths: Displays the suppressed routes in the BGP IPv4 routing information.

flap-statistics: Displays the route flapping statistics in the BGP IPv4 routing information.

parameters: Displays the parameters of the IPv4 unicast route flapping information configured by BGP.

neighbors: Displays the BGP IPv4 unicast neighbor information.

neighbor-ipv4-address: IPv4 address of a specified neighbor.

neighbor-ipv6-address: IPv6 address of a specified neighbor.

advertised-routes: Displays all the routing information sent to a specified peer.

check: Displays route filtering debugging information.

ha-mode: Displays BGP NSR information.

adj-in: Displays the routing information received by the BGP neighbor NSR.

adj-out: Displays the routing information sent by the BGP neighbor NSR.

hide-info: Displays internal information.

policy: Displays the routing policy information about the BGP neighbor.

received-routes: Displays all the routing information received from a specified peer, including received routes and rejected routes.

routes: Displays all the routing information received from peers.

paths: Displays IPv4 unicast routing information in a routing information base.

summary: Displays BGP IPv4 unicast summary information.

update-group: Displays BGP IPv4 unicast update group information.

update-group-index: Specific update group information.

ha-mod adj-out: Displays the routing information sent by the BGP neighbor NSR.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

The **show ip bgp** command has the same function as the **show bgp ipv4 unicast** command. All the parameters in the latter command can be used in the former command.

1.186 stats-reporting-period

Function

Run the **stats-reporting-period** command to configure the interval of regularly sending state statistics by BGP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

BMP does not regularly send state statistics by default.

Syntax

stats-reporting-period *report-time*

no stats-reporting-period

default stats-reporting-period

Parameter Description

report-time: Automatic scanning interval, in seconds. The value range is from 30 to 65535.

Command Modes

BMP configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the interval of regularly sending state statistics by BGP. If the statistics count result is 0, no information is sent. If this command is not configured, each change in the statistics count causes the software to send state statistics. Frequent change in the count causes the software to send much state statistics, which wastes device resources.

Examples

The following example sets the interval of regularly sending state statistics by BMP to **30** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
Hostname(config-bmpsrvr)# stats-reporting-period 30
```

1.187 synchronization

Function

Run the **synchronization** command to enable the function of routing information synchronization between BGP and IGP.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function of routing information synchronization between BGP and IGP is disabled by default.

Syntax

synchronization

no synchronization
default synchronization

Parameter Description

N/A

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

BGP and IGP synchronization aims to prevent any possible route black hole.

In the following situations, users can disable synchronization to fast converge routing information:

- No routing information passes through this local AS. Generally, this AS is a stub AS.
- All devices within the AS run BGP. A full mesh of connections is established among all BGP speakers (a neighbor relationship is established between each two BGP speakers).

Examples

The following example enables the function of routing information synchronization between BGP and IGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# synchronization
```

1.188 table-map

Function

Run the **table-map** command to control the routing information sent to the core routing table by BGP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

BGP does not modify the attribute of routing information sent to the core routing table by default.

Syntax

table-map *route-map-name*

no table-map

default table-map

Parameter Description

route-map-name: Name of an applied route map.

Command Modes

BGP configuration mode

Configuration mode of the IPv4 unicast/VRF address family of BGP

Configuration mode of the IPv6 unicast/VRF address family of BGP

Scope configuration mode of BGP

Default Level

14

Usage Guidelines

This command is effective to only IPv4 address families.

You can run this command to control the routing information sent to the core routing table by BGP. You can run this command to modify the attribute of routing information sent to the core routing table. If the route is matched, BGP modifies the attribute of the routing information and sends the route. If the route is not matched or route matching is denied, BGP does not modify the attribute of the routing information, but still sends the route.

Changes in the configuration of this command are not reflected in the core routing table immediately, but reflected a moment later. To update the routing table immediately, you can run the **clear ip bgp** [**vrf** *vrf-name*] **table-map** command. You run the **clear ip bgp** [**vrf** *vrf-name*] **table-map** command to not change the routes sent to the core routing table. If you run the **table-map** command, you do not result in forwarding flapping.

Examples

The following example configures BGP to filter and update routes to the core routing table based on the route map bgp_tm.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# table-map bgp_tm
```

1.189 timers bgp

Function

Run the **timers bgp** command to configure the duration of BGP timers.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default sending interval and hold time of Keepalive messages are **60** seconds and **180** seconds respectively. The minimum hold time is not limited.

Syntax

timers bgp *keepalive-time holetime* [*minimum-holdtime*]

no timers bgp

default timers bgp

Parameter Description

keepalive-time: Interval in seconds of sending Keepalive messages to a specified BGP peer. The value range is from 0 to 65535, and the default value is **60**.

holdtime: Valid interval in seconds of a BGP peer. The value range is from 0 to 65535, and the default value is **180**.

minimum-holdtime: Minimum hold time in seconds of a neighbor advertisement. The value range is from 0 to 65535, and the value **0** specifies no limit.

Command Modes

BGP configuration mode

Scope VRF configuration mode of BGP

Default Level

14

Usage Guidelines

The *keepalive-interval* value cannot be greater than 1/3 of the *holdtime*.

If time is configured for a single peer or peer group, this peer or peer group is connected with peers based on the configured time other than the globally configured time.

Examples

The following example sets the sending interval and hold time of Keepalive messages to **80** seconds and **240** seconds respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# timers bgp 80 240
```

1.190 update-source

Function

Run the **update-source** command to configure a network interface used to establish a TCP connection with a specified BMP server.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The optimal local interface is used as the output interface by default.

Syntax

update-source *interface-type interface-number*

no update-source

default update-source

Parameter Description

interface-type interface-number: Interface type and interface number.

Command Modes

BMP configuration mode

Default Level

14

Usage Guidelines

You can run this command to establish a TCP connection with BMP servers through the loopback interface.

If you directly specify a network interface to establish a TCP connection, the address of the network interface must be a local valid one. Otherwise, the TCP connection cannot be established.

Examples

The following example uses loopback 1 interface as a TCP source address to establish a connection with the BGP peer 10.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bmp server 1
Hostname(config-bmpsrvr)# update-source loopback 1
```

1 VRF Commands

Command	Function
address-family	Enable the IPv4 or IPv6 protocol in a multiprotocol VPN Routing and Forwarding Table (VRF) and enter the corresponding address family configuration mode.
alloc-label	Configure the label allocation mode.
description	Configure the description of the VRF.
exit-address-family	Exit the address family configuration mode of the multiprotocol VRF.
export map	Configure a policy for exporting the extended community attributes of VPN routes from the local VRF to the remote device.
import map	Configure a policy for importing VPN routes from a remote device to the local VRF.
ip vrf	Configure a single-protocol VRF.
ip vrf forwarding	Add an interface to a single-protocol VRF.
ip vrf receive	Import the direct route and host route of an interface to a specified VRF.
maximum routes	Configure the maximum number of routes in a VRF.
rd	Configure the RD value of a VRF.
route-target	Configure the RT value of a VRF.
vrf definition	Configure a multiprotocol VRF.
vrf forwarding	Add an interface to a multiprotocol VRF.
vrf global-vrf	Enter the global VRF configuration mode.
vrf receive	Import the IPv4 or IPv6 local host routes and direct routes of an interface to a specified VRF.
show global-vrf	Display the global VRF information.
show ip vrf	Display the VRF information.
show vrf	Display the VRF information.

1.1 address-family

Function

Run the **address-family** command to enable the IPv4 or IPv6 protocol in a multiprotocol VPN Routing and Forwarding Table (VRF) and enter the corresponding address family configuration mode.

Run the **no** form of this command to disable the IPv4 or IPv6 protocol for the multiprotocol VRF.

Run the **default** form of this command to restore the default configuration.

No IPv4 or IPv6 protocol is enabled for the multiprotocol VRF by default.

Syntax

address-family { **ipv4** | **ipv6** }

no address-family { **ipv4** | **ipv6** }

default address-family { **ipv4** | **ipv6** }

Parameter Description

ipv4: Enables the IPv4 protocol and enters the IPv4 address family configuration mode.

ipv6: Enables the IPv6 protocol and enters the IPv6 address family configuration mode.

Command Modes

Multiprotocol VRF configuration mode

Global VRF configuration mode

Default Level

14

Usage Guidelines

This command applies to only multiprotocol VRFs.

Examples

The following example configures a multiprotocol VRF named **vrf1**, enables the IPv4 protocol, and enters the IPv4 address family configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrf definition vrf1
Hostname(config-vrf)# address-family ipv4
Hostname(config-vrf-af)#
```

1.2 alloc-label

Function

Run the **alloc-label** command to configure the label allocation mode.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No label allocation mode is configured by default.

Syntax

alloc-label { **per-route** | **per-vrf** }

no alloc-label

default alloc-label

Parameter Description

per-route: Configures the label allocation mode based on each VPN route.

per- vrf: Configures the label allocation mode based on each VRF.

Command Modes

Single-protocol VRF configuration mode

Configuration mode of multiprotocol VRF IPv4 address family

Configuration mode of multiprotocol VRF IPv6 address family

Configuration mode of global VRF IPv4 address family

Configuration mode of global VRF IPv6 address family

Default Level

14

Usage Guidelines

RFC4364 describes two label allocation modes in L3VPN applications:

- Route-based label allocation mode:

  One route corresponds to one label. The advantage is that the system can look up the ILM table based on the label value and quickly forward packets to the next hop. The disadvantage is that the capacity of the ILM table must be large.

- VRF-based label allocation mode:

One VRF corresponds to one label. The advantage is that all routes in the VRF share this label, which reduces the capacity of the ILM table. The disadvantage is that packet forwarding is slower than that in route-based label allocation mode. This is because the system needs to look up the table twice in the forwarding process. It first looks up the ILM table to find the VRF where the packet is located, and then forwards the packet based on the destination IP address in the routing table of the VRF.

Examples

The following example configures the route-based label allocation mode for the single-protocol VRF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip vrf VPNA
Hostname(config-vrf)# alloc-label per-route
```

The following example configures the route-based label allocation mode for the IPv4 address family of the multiprotocol VRF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrf definition VPNA
Hostname(config-vrf)# address-family ipv4
Hostname(config-vrf-af)# alloc-label per-route
```

1.3 description

Function

Run the **description** command to configure the description of the VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No VRF description is configured by default.

Syntax

description *description*

Parameter Description

description: Description of a configured VRF. It is a case-sensitive string of 1 to 244 characters.

Command Modes

Single-protocol VRF configuration mode

Multiprotocol VRF configuration mode

Global VRF configuration mode

Default Level

14

Usage Guidelines

This command is applicable to both the single-protocol and multiprotocol VRFs.

Examples

The following command configures a single-protocol VRF named **vrf1** and sets its description to **vpn-a**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip vrf vrf1
Hostname(config-vrf)# description vpn-a
```

The following command configures a multiprotocol VRF named **vrf2** and sets its description to **vpn- b** .

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrf definition vrf2
Hostname(config-vrf)# description vpn-b
```

1.5 export map

Function

Run the **export map** command to configure a policy for exporting the extended community attributes of VPN routes from the local VRF to the remote device.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No policy for exporting the extended community attributes associated with the VRF is configured by default.

Syntax

export map *route-map-name*

no export map

default export map

Parameter Description

map *route-map-name*: Configures the name of the associated route map.

Command Modes

Single-protocol VRF configuration mode

Configuration mode of multiprotocol VRF IPv4 address family

Configuration mode of multiprotocol VRF IPv6 address family

Configuration mode of global VRF IPv4 address family

Configuration mode of global VRF IPv6 address family

Default Level

14

Usage Guidelines

To more precisely control the extended community attributes of exported routes, you can define a precise rule as needed in the associated route map. You can run this command to add or modify the extended community attributes defined by the **route-target export** command. You can only run the **match ip address** and **set extcommunity** commands to configure rules for a route map associated by this command.

Examples

The following example configures an associated export policy for the VRF **VPNA**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip vrf VPNA
Hostname(config-vrf)# export map rma
```

Notifications

1. When unsupported commands, such as **set ip tos**, are configured in the route map associated by this command, the following notification will be displayed:

```
% bgp export map not support set ip tos
```

2. When the associated route map such as **imp_map** does not exist, the following notification will be displayed:

```
% route-map imp_map not exist
```

Common Errors

1.6 import map

Function

Run the **import map** command to configure a policy for importing VPN routes from a remote device to the local VRF.

Run the **no** form of this command to remove the import policy associated with the VRF.

Run the **default** form of this command to restore the default configuration.

No import policy associated with the VRF is configured by default.

Syntax

import map *route-map-name*

no import map

default import map

Parameter Description

map *route-map-name*: Configures the name of the associated route map.

Command Modes

Single-protocol VRF configuration mode

Configuration mode of multiprotocol VRF IPv4 address family

Configuration mode of multiprotocol VRF IPv6 address family

Configuration mode of global VRF IPv4 address family

Configuration mode of global VRF IPv6 address family

Default Level

14

Usage Guidelines

To more precisely filter routes imported to the local VRF, you can define a precise rule as needed in the associated route map. The rule defined by the **import map** command takes effect after the **Import** extended community attributes defined in the VRF. That is, only after these routes match the extended community attributes defined by the **route-target import** command in the VRF, the VPN routes received from the remote device can be filtered again by rules defined the **import map** command. You can only run the **match ip address** and **match extcommunity** commands to configure rules for a route map associated by the **import map** command.

Examples

The following example configures an import policy associated with the VRF **VPNA**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip vrf VPNA
Hostname(config-vrf)# import map rma
```

Notifications

1. When unsupported commands, such as **set ip tos**, are configured in the route map associated by this command, the following notification will be displayed:

```
% bgp export map not support set ip tos
```

2. When the associated route map such as **exp_map** does not exist, the following notification will be displayed:

```
% route-map exp_map not exist
```

1.8 ip vrf forwarding

Function

Run the **ip vrf forwarding** command to add an interface to a single-protocol VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No interface is added to any single-protocol VRF by default.

Syntax

ip vrf forwarding *vrf-name*

no ip vrf forwarding *vrf-name*

default ip vrf forwarding *vrf-name*

Parameter Description

vrf-name: Name of a configured VRF. This VRF must be a single-protocol VRF.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

On a VRF-enabled device, if you add an interface to a single-protocol VRF and enable IPv6 on the interface, the device does not forward the IPv6 packets received on this interface. Therefore, to add an interface to a VRF and enable IPv6 on the interface, run the **vrf forwarding** command.

Examples

The following example adds the interface GigabitEthernet 0/1 to a single-protocol VRF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip vrf forwarding redvrf
```

1.9 ip vrf receive

Function

Run the **ip vrf receive** command to import the direct route and host route of an interface to a specified VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No direct route and host route of an interface are imported to any specified VRF by default.

Syntax

ip vrf receive *vrf-name*

no ip vrf receive *vrf-name*

default ip vrf receive *vrf-name*

Parameter Description

vrf-name: Name of a configured VRF. This VRF must be a single-protocol VRF.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The **ip vrf receive** command is used to select a VRF based on policy-based routing (PBR). This command imports the host route and direct route of the primary and secondary addresses of an interface to a specified VRF. To import the host route and direct route of an interface to multiple VRFs, run this command multiple times. Unlike the **ip vrf forwarding** command, this command does not add the interface to a VRF, and the interface is still global.

The **ip vrf forwarding** and **ip vrf receive** commands are mutually exclusive on a specified interface. If you configure the two commands one after another, an error prompt is displayed.

If you configure **ip vrf forwarding** and then **ip vrf receive**, the following notification will be displayed:

```
% Cannot configure 'ip vrf receive' if interface is under a VRF
```

If you configure **ip vrf receive** and then **ip vrf forwarding**, the following notification will be displayed:

```
% Cannot configure 'ip vrf forwarding VRF_1' on this interface, please unconfigure ’ip vrf receive’ and ’vrf receive’ first
```

Examples

The following example imports the host route and direct route in the network segment for the interface GigabitEthernet 0/1 to **VRF_1** and **VRF_2**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 192.168.1.2 255.255.255.0
```

```
Hostname(config-if-GigabitEthernet 0/1)# ip vrf receive VRF_1
Hostname(config-if-GigabitEthernet 0/1)# ip vrf receive VRF_2
Hostname(config-if-GigabitEthernet 0/1)# end
```

1.10 maximum routes

Function

Run the **maximum routes** command to configure the maximum number of routes in a VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of routes is not configured by default.

Syntax

maximum routes *limit* { *warning-threshold* | **warning-only** }

no maximum routes

default maximum routes

Parameter Description

limit: Maximum number of routes in a VRF. Beyond this limit, no more routes are written into the core routing table. The value range is from 1 to 4294967295.

warning-threshold: Warning log threshold, in percentage. Once this threshold is reached, the warning log is displayed. The value range is from 1 to 100.

warning-only: Specifies that when the maximum number of routes is reached, warnings are displayed, but routes can still be added to the core routing table.

Command Modes

Single-protocol VRF configuration mode
Configuration mode of multiprotocol VRF IPv4 address family
Configuration mode of multiprotocol VRF IPv6 address family
Configuration mode of global VRF IPv4 address family
Configuration mode of global VRF IPv6 address family

Default Level

14

Usage Guidelines

This command is used to limit the number of routes in a VRF. To receive warnings only, specify *warning-only*.

Examples

The following example sets the maximum number of routes in the single-protocol VRF **vrf1** to 1,000, and displays warnings when the number of such routes exceeds 1,000.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip vrf vrf1
Hostname(config-vrf)# maximum routes 1000 warning-only
```

The following example sets the maximum number of routes in the single-protocol VRF **vrf2** to 10,000, and displays warnings when the number of such routes exceeds 10,000.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrf definition vrf1
Hostname(config-vrf)# address-family ipv4
Hostname(config-vrf-af)# maximum routes 10000 warning-only
```

1.11 rd

Function

Run the **rd** command to configure the RD value of a VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No RD value is configured for a VRF by default.

Syntax

rd *rd-value*

no rd

default rd

Parameter Description

rd-value: RD value of the VRF. The following RD formats are supported:

as-num: *nn*, where *as-num* is the 2-byte public AS number, and *nn* is defined by the user, and ranges from 0 to 4294967295.

Ip-addr: *nn*, where *ip-addr* must be a global IP address, and *nn* is defined by the user, and ranges from 0 to 65535.

as4-num: *nn*, where *as4-num* is a 4-byte public AS number and ranges from 1 to 4294967295 (1.0 to 65535.65535 in dot mode), and *nn* is defined by the user, and ranges from 1 to 65535.

Command Modes

Single-protocol VRF configuration mode

Multiprotocol VRF configuration mode

Global VRF configuration mode

Default Level

14

Usage Guidelines

The existing RD value of a VRF cannot be modified. To modify an existing RD value, you must first delete the VRF, reconfigure the VRF, and then configure the RD value. A VRF has only one RD value.

The RD value of the 4-byte AS is in the format of AS4:NN. AS4 can be expressed in decimal or dot mode. AS4 range is from 1 to 4294967295, which is from 1.0 to 65535.65535 in dot mode. NN ranges from 1 to 65535.

The AS number in the range of 1 to 65535 is displayed in both decimal mode and dot mode. Therefore, save the AS number in the range from 1 to 65535 as a 2-byte AS number.

Examples

The following example sets the RD value of **vrf1** to **100:1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip vrf vrf1
Hostname(config-vrf)# rd 100:1
```

Notifications

1. If the configuration modifies an existing RD, the following error prompt will be displayed:

```
% Configuration can't be changed
```

2. If the configuration deletes an existing RD, the following error prompt will be displayed:

```
% Can not delete an exist rd value!
```

3. If the configured RD value is used by another VRF, for example, the RD of **vrf2** is set to **100:1**, the following error prompt will be displayed:

```
% "rd" 100:1 already in use by VRF vrf1
```

1.12 route-target

Function

Run the **route-target** command to configure the RT value of a VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No RT value is configured for a VRF by default.

Syntax

route-target { **both** | **export** | **import** } *route-value*

no route-target { **both** | **export** | **import** } *route-value*

default route-target { **both** | **export** | **import** } *route-value*

Parameter Description

both: Configures both the **Import** and **Export** RT attributes.

export: Configures the **Export** RT attribute.

import: Configures the **Import** RT attribute.

route-value: Value of the RT. The following RD formats are supported:

as-num: *nn*, where *as-num* is the 2-byte public AS number, and *nn* is defined by the user, and ranges from 0 to 4294967295.

Ip-addr: *nn*, where *ip-addr* must be a global IP address, and *nn* is defined by the user, and ranges from 0 to 65535.

as4-num: *nn*, where *as4-num* is a 4-byte public AS number and ranges from 1 to 4294967295 (1.0 to 65535.65535 in dot mode), and *nn* is defined by the user, and ranges from 1 to 65535.

Command Modes

Single-protocol VRF configuration mode

Multiprotocol VRF configuration mode

Configuration mode of multiprotocol VRF IPv4 address family

Configuration mode of multiprotocol VRF IPv6 address family

Global VRF configuration mode

Configuration mode of global VRF IPv4 address family

Configuration mode of global VRF IPv6 address family

Default Level

14

Usage Guidelines

You can configure multiple **Import** or **Export** RT values for a VRF.

Examples

The following example configures the RT for **vrf1**. Set the **Import** RT values to **100:1** and **100:4**, and the **Export** RT values to **100:2** and **100:4**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip vrf vrf1
Hostname(config-vrf)# route-target import 100:1
Hostname(config-vrf)# route-target export 100:2
Hostname(config-vrf)# route-target both 100:4
```

1.14 vrf forwarding

Function

Run the **vrf forwarding** command to add an interface to a multiprotocol VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No interface is added to any multiprotocol VRF by default.

Syntax

vrf forwarding *vrf-name*

no vrf forwarding *vrf-name*

default vrf forwarding *vrf-name*

Parameter Description

vrf-name: Name of a configured VRF. This VRF must be a multiprotocol VRF.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You are not allowed to run the **ip vrf forwarding** command to add an interface to a multiprotocol VRF, or run the **vrf forwarding** command to add an interface to a single-protocol VRF.

You are not allowed to add an interface to a multiprotocol VRF not configured with any address family.

When you add an interface to a multiprotocol VRF, existing IPv4/IPv6 or VRRP IPv4/IPv6 addresses on the interface are deleted, and the IPv6 protocol is disabled on the interface.

When you add an interface to a multiprotocol VRF not configured with any IPv4 address family, you are not allowed to configure the IPv4 and VRRP IPv4 addresses on this interface. You must configure the IPv4 address family for the multiprotocol VRF before configuring the IPv4 and VRRP IPv4 addresses on this interface.

When you add an interface to a multiprotocol VRF without any IPv6 address family, you are not allowed to configure the IPv6 and VRRP IPv6 addresses on this interface. You must configure the IPv6 address family for the multiprotocol VRF before configuring the IPv6 or VRRP IPv6 addresses on this interface.

If the IPv4 address family is deleted from the multiprotocol VRF, the IPv4 and VRRP IPv4 addresses of all interfaces added to this VRF are deleted, and the IPv4 static routes in the VRF or the IPv4 static routes with this VRF as their next-hop VRF are also deleted. If the IPv6 address family is deleted from the multiprotocol VRF, the IPv6 and VRRP IPv6 addresses of all interfaces added to the VRF are deleted. When the IPv6 protocol is disabled on the interface, the IPv6 static routes in the VRF or the IPv6 static routes with this VRF as their next-hop VRF are also deleted.

Examples

The following example adds the interface GigabitEthernet 0/1 to the multiprotocol VRF **vrf1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrf definition vrf1
Hostname(config-vrf)# address-family ipv4
Hostname(config-vrf-af)# exit-address-family
Hostname(config-vrf)# address-family ipv6
Hostname(config-vrf-af)# exit-address-family
Hostname(config-vrf)# interface gigabitethernet 0/1
```

```
Hostname(config-if-GigabitEthernet 0/1)# vrf forwarding vrf1
Hostname(config-if-GigabitEthernet 0/1)# ip address 1.1.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 1000::1/64
```

1.16 vrf receive

Function

Run the **vrf receive** command to import the IPv4 or IPv6 local host routes and direct routes of an interface to a specified VRF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no IPv4 or IPv6 local host route and direct route of an interface are imported to a specified VRF.

Syntax

vrf receive *vrf-name*

no vrf receive *vrf-name*

default vrf receive *vrf-name*

Parameter Description

vrf-name: Name of a configured VRF. This VRF must be a multiprotocol VRF.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command does not add the interface to the specified VRF, and the interface is still a global interface.

If you need to use PBR to select a VRF, run the **vrf receive** command on the interface to which PBR is applied to import the direct route and host route on the interface to each VRF available for choice.

When you configure the IPv4 address family for a multiprotocol VRF, the IPv4 local host route and direct route of the interface are added to the IPv4 routing table of the specified VRF, and the IPv4 local host route in the VRRP group on this interface in Master state is also added to the IPv4 routing table of the specified VRF, When you configure the IPv6 address family for a multiprotocol VRF, the IPv6 local host route and direct route of the

interface are added to the IPv6 routing table of the specified VRF, and the IPv6 local host route in Master state in the VRRP group on this interface is also added to the IPv6 routing table of the specified VRF,

On a specified interface, **ip vrf forwarding** and **vrf receive** are mutually exclusive, so are **vrf forwarding** and **vrf receive**. If you configure any of the above pairs of commands for an interface one after another, an error prompt is displayed.

If you configure **ip vrf forwarding** or **vrf forwarding** and then **vrf receive**, the following notification will be displayed:

```
% Cannot configure 'vrf receive' if interface is under a VRF
```

If you run **vrf receive**, and then **ip vrf forwarding** or **vrf forwarding**, the following notification will be displayed:

```
% Cannot configure 'vrf forwarding vrf2' on this interface, please delete'ip vrf receive' and 'vrf receive' first.
```

Examples

The following example enables the interface GigabitEthernet 0/1 to select a VRF based on IPv6 PBR.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrf definition vrf1
Hostname(config-vrf)# address-family ipv6
Hostname(config-vrf-af)# exit-address-family
Hostname(config-vrf)# vrf definition vrf2
Hostname(config-vrf)# address-family ipv6
Hostname(config-vrf-af)# exit-address-family
Hostname(config-route-map)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 policy route-map pbr-vrf-selection
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 1000::1/64
Hostname(config-if-GigabitEthernet 0/1)# vrf receive vrf1
Hostname(config-if-GigabitEthernet 0/1)# vrf receive vrf2
```

1.18 show ip vrf

Function

Run the **show ip vrf** command to display the VRF information.

Syntax

show ip vrf [**brief** | **count** | **detail** | **interfaces**] [*vrf-name*]

Parameter Description

brief: Displays the brief information of the VRF and its interfaces.

count: Displays the VRF capacity and the current number of configured VRFs.

detail: Displays the detailed information of the VRF.

interfaces: Displays the detailed information of the interfaces to which the VRF applies.

vrf-name: Name of a configured VRF.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

N/A

Examples

The following example displays the information of a single-protocol VRF.

```
Hostname> enable
Hostname# show ip vrf
Name                                Interfaces
aaa                                 GigabitEthernet 0/0
                                    GigabitEthernet 0/1
```

Table 1-2 Output Fields of the show ip vrf Command

Field	Description
Name	Name of the VRF.
Interfaces	Interface list of the VRF.

The following example displays the brief information of a single-protocol VRF.

```
Hostname> enable
Hostname# show ip vrf brief
Name                          Default RD              Interfaces
refvrf                        <not set>
vrf1                          <not set>
```

Table 1-3 Output Fields of the show ip vrf brief Command

Field	Description
Name	Name of the VRF
Default RD	Default RD of the VRF
Interfaces	Interface list of the VRF

The following example displays the VRF capacity and the current number of configured VRFs.

```
Hostname> enable
Hostname# show ip vrf count
  VRF Limit:                512
  Count of in use instances:   3
  Count of remaining instances: 509
```

Table 1-4 Output Fields of the show ip vrf count Command

Field	Description
VRF Limit	VRF capacity limit.
Count of in use instances	Number of configured VRFs.
Count of remaining instances	Number of VRFs that can be configured.

The following example displays the detailed information of a single-protocol VRF.

```
Hostname> enable
Hostname# show ip vrf detail
VRF refvrf (VRF ID = 1); default RD <not set>
  No interfaces
VRF Table ID = 1
```

```
  No Export VPN route-target communities
  No Import VPN route-target communities
  No import route-map
  No export route-map
  Alloc-label per-vrf: -/aggregate(refvrf)
Route warning limit 1000, current count 4
```

Table 1-5 Output Fields of the show ip vrf detail Command

Field	Description
VRF	Name of the VRF
VRF ID	VRF ID associated with the VRF name
default RD	Default RD of the VRF
VRF Table ID	ID of the VRF table.
Export VPN route-target communities	VPN RT community attributes to be exported
Import VPN route-target communities	VPN RT community attributes to be imported.
import route-map	Route map information to be imported
export route-map	Route map information to be exported
Alloc-label per-vrf	Label value allocated to each VRF

The following example displays the interface information of a VRF.

```
Hostname> enable
Hostname# show ip vrf interfaces
Interface           IP-Address      VRF          Protocol
```

1.19 show vrf

Function

Run the **show vrf** command to display the VRF information.

Syntax

show vrf [**brief** | **count** | **detail** | **ipv4** | **ipv6**] [*vrf-name*]

Parameter Description

brief: Displays the brief information of VRFs.

count: Displays the VRF capacity and the current number of configured VRFs.

detail: Displays the detailed information of VRFs.

ipv4: Displays the information of VRFs configured with an IPv4 address family.

ipv6: Displays the information of VRFs configured with an IPv6 address family.

vrf-name: Specifies the name of the VRF to be displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to display single-protocol and multiprotocol VRFs.

Examples

The following example displays all VRFs.

```
Hostname> enable
Hostname# show vrf
  Name       Default RD        Protocols   Interfaces
  aaa        <not set>         ipv4
  aab        <not set>
  bbb        <not set>         ipv6
  ccc        <not set>         ipv4,ipv6   Vl1
```

Table 1-7 Output Fields of the show vrf Command

Field	Description
Name	Name of the VRF
Default RD	Default RD of the VRF

Protocol	Address family enabled for the VRF. ● **IPv4** indicates that the IPv4 address family is enabled. ● **IPv6** Indicates that the IPv6 address family is enabled.
Interfaces	Interface list under the VRF, that is, the list of interfaces configured with the **vrf forwarding** or **ip vrf forwarding** command.

The following example displays the information of VRFs for which the IPv4 address family is configured.

```
Hostname> enable
Hostname# show vrf ipv4
Name               Default RD          Protocol(s)         Interface
refvrf             <not set>           ipv4               <none>

1 Routing Policy Commands

Command	Function
ip as-path access-list	Configure an autonomous system (AS) path filtering rule based on a regular expression.
ip community-list	Configure a community list.
ip extcommunity-list	Configure an extcommunity list to be used by a route map. This route map is used to filter virtual private network (VPN) routes in the BGP application. **standard** defines a standard community list and controls access to this list. **expanded** defines an expanded community list and controls access to this list. After an extcommunity list is created, the system enters the **ip extcommunity-list** configuration mode.
ip prefix-list	Create a prefix list or add a prefix list entry.
ip prefix-list description	Add a text description for a prefix list.
ip prefix-list sequence-number	Enable the function of displaying sequence numbers in a prefix list.
ipv6 prefix-list	Create an IPv6 prefix list or add a prefix list entry.
ipv6 prefix-list description	Add a text description for an IPv6 prefix list.
ipv6 prefix-list sequence-number	Enable the function of displaying sequence numbers in an IPv6 prefix list.
match as-path	Configure the AS path attribute permitted in the ACL to match routes.
match community	Configure the community attribute permitted in the ACL to match routes.
match extcommunity	Configure an extcommunity list to match routes.
match interface	Configure a specified interface as the next-hop outbound interface.
match ip address	Configure the target network routes that are permitted in an ACL or prefix list.
match ip next-hop	Configure the target network routes whose next-hop IP addresses match rules in the ACL or prefix list.

match ip policy	Configure the target network routes that are permitted in the ACL and match a specified L3 authentication traffic diversion domain type.
match ip route-source	Configure the target network routes whose source IP addresses match rules in the ACL or prefix list.
match ipv6 address	Configure the target IPv6 network routes that are permitted in the ACL or prefix list.
match ipv6 next-hop	Configure the target network routes whose next-hop IPv6 addresses match rules in the ACL or prefix list.
match ipv6 route-source	Configure the target network routes whose source IPv6 addresses match rules in the ACL or prefix list.
match metric	Configure the metric values of routes.
match origin	Configure the source type of BGP routes.
match route-type	Configure the route type.
match tag	Configure the tags of routes.
memory-lack exit-policy	Specify the exit policy for the upper-layer routing protocols when the free memory space reaches the lower level.
route-map	Configure a route map and enter the route map configuration mode.
set aggregator as	Specify the AS value of the aggregator for routes that match the rules.
set aigp-metric	Specify the Accumulated IGP Metric Attribute (AIGP) metric for routes that match the rules.
set as-path replace	Replace the AS_PATH values for routes that match the rules with specified values.
set as-path prepend	Add the specified AS_PATH values for routes that match the rules.
set atomic-aggregate	Configure the atomic-aggregate attribute for routes.
set comm-list delete	Delete all community values from routes that match the rules according to the community list.
set community	Specify the community values for routes that match the rules.
set dampening	Configure the flapping parameters for routes that match the rules.

set distance	Configure the management distance for routes that match the rules.
set extcomm-list delete	Delete all extended community values from the routes that match the rules according to the extcommunity list.
set extcommunity	Specify the extended community values for routes that match the rules.
set fast-reroute	Specify the backup outbound interface and backup next hop of FRR for routes that match the rules.
set ip default next-hop	Specify the default next-hop IPv4 address for packets that match the rules.
set ip dscp	Configure the differentiated service code point (DSCP) value for packets matching the rules.
set ip next-hop	Specify the next-hop IPv4 address for packets that match the rules.
set ip next-hop recursive	Specify the recursive next-hop IP address for packets that match the rules.
set ip next-hop self	Set the next hop to the device itself for packets that match the rules.
set ip next-hop unchanged	Set the next hops of routes that match the rules to keep unchanged.
set ip next-hop verify-availability	Verify availability of the next-hop IPv4 address.
set ip precedence	Configure the priority of the IPv4 header for packets that match the rules.
set ip tos	Configure the ToS of the IPv4 header for a packet that matches the rules.
set ipv6 default next-hop	Specify the default next-hop IPv6 address for IPv6 packets that match the rules.
set ipv6 next-hop	Specify the next-hop IPv6 address for IPv6 packets that match the rules.
set ipv6 next-hop recursive	Specify the recursive next-hop IPv6 address for packets that match the rules.
set ipv6 next-hop self	Set the next hop to the device itself for IPv6 routes that match the rules.

set ipv6 next-hop unchanged	Set the next hop to keep unchanged for IPv6 routes that match the rules.
set ipv6 next-hop verify-availability	Verify availability of the next-hop IPv6 address.
set ipv6 precedence	Configure the priority of the IPv6 header for packets that match the rules.
set l3vpn nexthop local-vrf	Set the L3 VPN next hop to the local VRF instance for packets matching the match rules.
set level	Specify the type of the destination area to which routes that match the rules will be advertised.
set local-preference	Configure the LOCAL_PREFERENCE value for routes that match the rules.
set metric	Configure the metric value for routes that match the rules.
set metric-type	Configure the metric type for routes that match the rules.
set next-hop	Specify the next-hop IP address for routes that match the rules.
set next-hop self	Set the next hop to the device itself for routes that match the rules.
set next-hop unchanged	Set the next hop to keep unchanged for routes that match the rules.
set origin	Specify the source for routes that match the rules.
set originator-id	Specify the originator address for routes that match the rules.
set qos-id	Specify the QoS ID for routes that match the rules.
set tag	Configure the tag for routes that match the rules.
set weight	Configure the weight for BGP routes that match the rules.
show ip as-path-access-list	Display the AS-path list information.
show ip community-list	Display the community list information.
show ip extcommunity-list	Display the extcommunity list information.
show ip prefix-list	Display the information about a prefix list or prefix list entries.

show ip protocols	Display the status information of the IPv4 routing protocols that are currently running.
show ipv6 prefix-list	Display the information about an IPv6 prefix list or prefix list entries.
show route-map	Display the route map configurations.

1.1 ip as-path access-list

Function

Run the **ip as-path access-list** command to configure an autonomous system (AS) path filtering rule based on a regular expression.

Run the **no** form of this command to remove this configuration.

By default, no AS path filtering rule is configured.

Syntax

ip as-path access-list *path-list-num* { **permit** | **deny** } *regular-expression*

no ip as-path access-list *path-list-num* [{ **permit** | **deny** } *regular-expression*]

Parameter Description

path-list-num: Identifier of an AS path list. The value range is from 1 to 500.

permit: Permits access.

deny: Denies access.

regular-expression: Regular expression. It is a string of 1 to 255 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures an AS path filtering rule to match only the path information containing the AS number of 123.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip as-path access-list 105 deny ^123$
```

Notifications

When you delete an AS path filtering rule, if the entered rule name or the filtering rule does not exist, the following notification will be displayed:

```
% This object doesn't exist
```

If you enter an invalid filtering rule, the following notification will be displayed:

```
% Can't compile regexp
```

When you configure a duplicate AS path filtering rule, the following notification will be displayed:

```
% Insertion failed with duplicate policy
```

Common Errors

N/A

Platform Description

N/A

Related Commands

show ip bgp filter-list (BGP)

1.2 ip community-list

Function

Run the **ip community-list** command to configure a community list.

Run the **no** form of this command to remove this configuration.

By default, no community list is configured.

Syntax

ip community-list { *community-list-number* | **standard** *community-list-name* } { **permit** | **deny** } [{ *community-list-number* | **internet** | **local-AS** | **no-advertise** | **no-export** | **gshut** }]

ip community-list { *community-list-number* | **expanded** *community-list-name* } { **permit** | **deny** } [*regular-expression*]

no ip community-list { { **standard** | **expanded** } *community-list-name* | *community-list-number* }

Parameter Description

standard: Specifies a standard community list.

expanded: Specifies an expanded community list.

community-list-name: Name of a community list. It is a string of less than 80 characters.

community-list-number: Number of a community list. For a standard community list, the range is from 1 to 99. For an expanded community list, the range is from 100 to 199.

permit: Permits access.

deny: Denies access.

community-number: Value of the community attribute. The format is AA:NN (AS number: 2-byte number) or the value is a number. The value range is from 0 to 4294967295.

Internet: Specifies the Internet community. All paths belong to this community.

local-AS: Specifies that the path matching a route in the community list is not advertised to other ASs. When an AS alliance is configured, the path is not advertised to other ASs or sub ASs.

no-advertise: Specifies that the path is not advertised to any Border Gateway Protocol (BGP) peer.

no-export: Specifies that the path is not advertised to External Border Gateway Protocol (EBGP) peers.

gshut: Specifies that the route matching the community list is advertised by a graceful shutdown neighbor.

regular-expression: Regular expression. It is a string of 1 to 255 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to define a community list used for BGP. **standard** defines a standard community list and controls access to this list. **expanded** defines an expanded community list and controls access to this list.

A community list supports up to 32 community values, including **internet**, **local-AS**, **no-advertise**, and **no-export**.

Examples

The following example configures the standard community list **test** to reject routes that contain the community attributes of **100:20** and **200:20**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip community-list standard test deny 100:20 200:20
```

The following example configures the standard community list **test2** to allow routes that contain the community attribute of **Internet**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip community-list standard test2 permit internet
```

Notifications

If the name of a specified community list is all numbers, the following notification will be displayed:

```
% Community-list name cannot have all digits
```

If the name of a specified community list contains more than 80 characters, the following notification will be displayed:

```
% Community-list name lengths should be less than 80 chars
```

When you delete a community list but the entered list or filtering rule does not exist, the following notification will be displayed:

```
% This object doesn't exist
```

When you configure a duplicate community filtering rule, the following notification will be displayed:

```
% Insertion failed with duplicate policy
```

When you configure a community filtering rule with a duplicate sequence number, the following notification will be displayed:

```
% Community-list entry with this sequence already exist
```

When you configure both a standard community list and an expanded community list by using the same name, the following notification will be displayed:

```
% Community-list name conflict with previous defined
```

Common Errors

N/A

Platform Description

N/A

Related Commands

1.3 ip extcommunity-list

Function

Run the **ip extcommunity-list** command to configure an extcommunity list to be used by a route map. This route map is used to filter virtual private network (VPN) routes in the BGP application. **standard** defines a standard community list and controls access to this list. **expanded** defines an expanded community list and controls access to this list. After an extcommunity list is created, the system enters the **ip extcommunity-list** configuration mode.

Run the **no** form of this command to remove this configuration.

By default, no extcommunity list is configured.

Syntax

ip extcommunity-list { *standard-list* | **standard** *list-name* } { **permit** | **deny** } [**rt** *rt-value* | **soo** *soo-value*]

ip extcommunity-list { *expanded-list* | **expanded** *list-name* } { **permit** | **deny** } [*regular-expression*]

ip extcommunity-list { *expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name* }

no ip extcommunity-list { *expanded-list* | **expanded** *list-name* | *standard-list* | **standard** *list-name* }

Parameter Description

expand-list: ID of an expanded extcommunity list. The value range is from 100 to 199. One extcommunity list may contain multiple rules.

standard-list: ID of a standard extcommunity list. The value range is from 1 to 99. One extcommunity list may contain multiple rules.

expanded *list-name*: Specifies the name of an expanded extcommunity list. When this parameter is used, the system enters the expanded extcommunity list configuration mode. The name contains up to 32 characters.

standard *list-name*: Specifies the name of a standard extcommunity list. When this parameter is used, the system enters the standard extcommunity list configuration mode. The name contains up to 32 characters.

permit: Defines a permit extcommunity rule.

deny: Defines a deny extcommunity rule.

regular-expression: Regular expression used to define a template for matching an extcommunity. It is a string of 1 to 255 characters.

rt *rt-value* | **soo** *soo-value*: Configures the extcommunity attributes to be matched. You can enter the route target (RT) and site of origin (SOO) attributes for multiple times.

rt *rt-value*: Configures the RT attribute. This parameter can be used only for the standard extcommunity configuration, but not for the expanded extcommunity configuration.

soo *soo-value*: Configures the SOO attribute. This parameter can be used only for the standard extcommunity configuration, but not for the expanded extcommunity configuration.

rt-value and *soo-value*: Value of an extended community (extend_community_value).

extend_community_value has three options:

extend_community _value = as_num:nn

as_num is a 2-byte public AS number. nn is configurable. The value range is from 0 to 4294967295.

extend_community_value = ip_addr:nn

ip_addr must be a global IP address. nn is configurable. The value range is from 0 to 65535.

extend_community_value = as4_num:nn

an4_num is a 4-byte public AS number. nn is configurable. The value range is from 1 to 65535. The AS number range is from 1 to 4294967295, or 1 to 65535.65535 in dot mode.

Command Modes

Global configuration mode and ip extcommunity-list configuration mode

Default Level

14

Usage Guidelines

This command is used to create an extcommunity list that has multiple extcommunity values. This list is used in the **match extcommunity** rule in a route map to match the extcommunity attribute of BGP routes, so as to achieve the purpose of route filtering.

In the definition of an expanded extcommunity rule, *regular-expression* is described as follows:

- Character: No special meaning.
- Period (.): Matches any single character.
- Asterisk (*): Matches zero or any sequence in a string.
- Plus sign (+): Matches one or any sequence in a string.
- Question mark (?): Matches zero or one symbol in a string.
- Caret (^): Matches the start of a string.
- Dollar sign ($): Matches the end of a string.
- Underline (_): Matches commas, brackets, start and end of a string, and spaces.
- Square brackets ([]): Matches a single character within a range.

In expanded ip extcommunity-list configuration mode, the following commands are available:

- [*sequence-number*] **deny** *regular-expression*: Defines a deny extcommunity rule.
- [*sequence-number*] **permit** *regular-expression*: Defines a permit extcommunity rule.
- **exit:** Exits the current mode.
- **no** [*sequence-number*] **deny** *regular-expression*: Deletes a deny extcommunity rule.
- **no** [*sequence-number*] **permit** *regular-expression*: Deletes a permit extcommunity rule.

In standard ip extcommunity-list configuration modes, the following commands are available:

- [*sequence-number*] **deny** { [**rt** *value*] [**soo** *value*] }: Defines a deny extcommunity rule.
- [*sequence-number*] **permit** { [**rt** *value*] [**soo** *value*] }: Defines a permit extcommunity rule.
- **exit**: Exits the current mode.
- **no** [*sequence-number*] **deny** { [**rt** *value*] [**soo** *value*] }: Deletes a deny extcommunity rule.
- **no** [*sequence-number*] **permit** { [**rt** *value*] [**soo** *value*] }: Deletes a permit extcommunity rule.

Examples

The following example configures the extcommunity list **1** to allow traffic with the RT attribute of 100:1.

The following example configures the standard extcommunity list **aaa** to allow traffic with the RT attribute of 100:2.

The following example configures the expanded extcommunity list **ext1** to allow traffic with the extcommunity attribute of 200:[0~9][0~9].

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip extcommunity-list 1 permit rt 100:1
Hostname(config)# ip extcommunity-list standard aaa permit rt
100:2
Hostname(config)# ip extcommunity-list expanded ext1 permit 200:[0~9][0~9]
```

The following example configures the route map **rt_in_filter** to match routes with the extcommunity lists **1** and **ext1**, and applies the route map to the VPN address family in AS 65000 of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map rt_in_filter
Hostname(config-route-map)# match extcommunity 1
Hostname(config-route-map)# match extcommunity ext1
Hostname(config)# router bgp 65000
Hostname(config-router)# address-family vpn
Hostname(config-router-af)# neighbor 3.3.3.3 send-community extended
Hostname(config-router-af)# neighbor 3.3.3.3 route-map rt_in_filter in
```

Notifications

When you delete a community list but the entered list or filtering rule does not exist, the following notification will be displayed:

```
% This object doesn't exist
```

When you configure a duplicate extcommunity filtering rule, the following notification will be displayed:

```
% Insertion failed with duplicate policy
```

When you configure an extcommunity filtering rule with a duplicate sequence number, the following notification will be displayed:

```
% Extcommunity-List entry with this sequence already exist
```

When you configure both a standard and expanded extcommunity lists with the same name, the following notification will be displayed:

```
% Extcommunity-list name conflict with previous defined
```

1.4 ip prefix-list

Function

Run the **ip prefix-list** command to create a prefix list or add a prefix list entry.

Run the **no** form of this command to remove this configuration.

By default, no prefix list is configured.

Syntax

ip prefix-list *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv4-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

no ip prefix-list *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv4-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

Parameter Description

prefix-list-name: Name of a prefix list.

seq-number: Sequence number assigned to a prefix list entry. The value range is from 1 to 2147483647. If no sequence number is specified in this command, the system will assign a default sequence number to the prefix list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each unassigned entry is the first multiple of 5 and greater than the previous sequence number.

deny: Denies access when rules are matched.

permit: Permits access when rules are matched.

ipv4-prefix: Network address and mask. The mask length ranges from 0 to 32.

minimum-prefix-length: Minimum range (namely, the start length of a range).

maximum-prefix-length: Maximum range (namely, the end length of a range).

Note

- The keyword **ge** indicates the greater than or equal to operation.
- The keyword **le** indicates the smaller than or equal to operation.
- If both **ge** and **le** are not configured, rules are matched only when the mask length is exactly the same as the configured mask length.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The **ip prefix-list** command is used to configure an IP prefix list. The keyword **permit** or **deny** in a prefix list determines the permit or deny action when the prefix list is matched.

The prefix list defines the exact match or range match for a prefix. The keyword **ge** or **le** defines the prefix range used for matching, and provides more flexible matching configuration than *ipv4-prefix*. If the keyword **ge** or **le** is not configured in the command, *ipv4-prefix* provides an accurate prefix range for matching. If only **ge** is configured, the matching range is from *minimum-prefix-length* to 32. If only **le** is configured, the matching range is from *ipv4-prefix* to *maximum-prefix-length*. If both are configured, the matching range is from *minimum-prefix-length* to *maximum-prefix-length*. That is, the relationship between *ipv4-prefix* mask length, *minimum-prefix-length*, and *maximum-prefix-length* is as follows: *ipv4-prefix* mask length < *minimum-prefix-length* < *maximum-prefix-length* <= 32.

Examples

The following example configures the prefix list **pre1** to match the traffic with the address segment 201.1.1.0/24, and filters the routing information output when RIP routes are redistributed to OSPF based on **pre1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip prefix-list pre1 permit 201.1.1.0/24
Hostname(config)# router ospf
Hostname(config-router)# distribute-list prefix pre1 out rip
Hostname(config-router)# end
```

Notifications

When you configure a prefix list entry with duplicate rules, the following notification will be displayed:

```
% Insertion failed with duplicate policy
```

1.7 ipv6 prefix-list

Function

Run the **ipv6 prefix-list** command to create an IPv6 prefix list or add a prefix list entry.

Run the **no** form of this command to remove this configuration.

By default, no prefix list is configured.

Syntax

ipv6 prefix-list *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix-length*] [**le** *maximum-prefix-length*]

no ipv6 prefix-list *prefix-list-name* [**seq** *seq-number*] { **deny** | **permit** } *ipv6-prefix* [**ge** *minimum-prefix- length*] [**le** *maximum-prefix-length*]

Parameter Description

prefix-list-name: Name of a prefix list.

seq-number: Sequence number assigned to a prefix list entry. The value range is from 1 to 2147483647. If no sequence number is specified in this command, the system will assign a default sequence number to the prefix list entry. The default sequence number of the first entry is 5. Subsequently, the default sequence number of each entry not assigned a value is the first multiple of 5 greater than the previous sequence number.

deny: Denies access when rules are matched.

permit: Permits access when rules are matched.

ipv6-prefix: Network address and mask. The mask value range is from 0 to 128.

minimum-prefix-length: Minimum range (namely, the start length of a range).

maximum-prefix-length: Maximum range (namely, the end length of a range).

Note

- The keyword **ge** indicates the greater than or equal to operation.
- The keyword **le** indicates the smaller than or equal to operation.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The **ipv6 prefix-list** command is used to configure an IPv6 prefix list. The keyword **permit** or **deny** in a prefix list determines the permit or deny action when the prefix list is matched.

The prefix list defines the exact match or range match for a prefix. The keyword **ge** or **le** defines the prefix range used for matching, and provides more flexible matching configuration than *ipv6-prefix*. If the keyword **ge** or **le** is not configured in the command, *ipv6-prefix* provides an accurate prefix range for matching. If only **ge** is configured, the matching range is from *minimum-prefix-length* to 128. If only **le** is configured, the matching range is from *ipv6-prefix* to *maximum-prefix-length*. If both are configured, the matching range is from *minimum-prefix-length* to *maximum-prefix-length*. That is, the relationship between *ipv6-prefix* mask length, *minimum-prefix-length*, and *maximum-prefix-length* is as follows: *ipv6-prefix* mask length < *minimum-prefix-length* < *maximum-prefix-length* <= 128.

Examples

The following example configures the IPv6 prefix list **pre** to allow traffic in the address segment 2222::/64, and filters the routing information output when the OSPF process **1** is redistributed to RIP based the IPv6 prefix list **pre**.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# ipv6 prefix-list pre permit 2222::/64
Hostname(config)# ipv6 router rip
Hostname(config-router)# redistribute ospf 1
Hostname(config-router)# distribute-list prefix pre out
Hostname(config-router)# end
```

Notifications

1.10 match as-path

Function

Run the **match as-path** command to configure the AS path attribute permitted in the ACL to match routes.

Run the **no** form of this command to remove this configuration.

By default, no AS-path list is configured for packet matching.

Syntax

match as-path *as-path-acl-list-number*&<1-10>

no match as-path *as-path-acl-list-number*&<1-10>

Parameter Description

as-path-acl-list-number&<1-10>: Number of an ACL. The value range is from 1 to 500. &<1-10> indicates that you can enter the parameters up to 10 times in this command.

By default, if you do not specify the ACL number when removing the ACL configurations, all ACLs are removed.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

When using this command in BGP, you can configure multiple ACL numbers in this command.

In a route map policy, one or more **match** or **set** commands can be configured. If no **match** command is configured, all traffic is matched. If no **set** command is configured, no operation is performed.

Examples

The following example configures the route map **ROUTEMAP2IBGP**, and matches routes with the AS-path lists **20** and **30**.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# route-map ROUTEMAP2IBGP
Hostname(config-route-map)# match as-path 20 30
```

Notifications

If more than 10 AS-path lists are configured, the following notification will be displayed:

```
% Match as-path command only support 10 aspath-access-list
```

Common Errors

1.11 match community

Function

Run the **match community** command to configure the community attribute permitted in the ACL to match routes.

Run the **no** form of this command to remove this configuration.

By default, no community list is configured.

Syntax

match community { *community-list-number* | *community-list-name* } [**exact-match** | *community-list-number* | *community-list-name*]&<1-6>

no match community { *community-list-number* | *community-list-name* } [**exact-match** | *community-list-number* | *community-list-name*]&<1-6>

Parameter Description

[**exact-match** | *community-list-number* | *community-list-name*]&<1-6>: &<1-6> indicates that you can enter the parameters up to six times in this command.

community-list-number: Number of a community list. For a standard community list, the range is from 1 to 99. For an extcommunity list, the range is from 100 to 199.

community-list-name: Name of a community list. It is a string of less than 80 characters.

exact-match: Specifies the exact match list.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

When using this command in BGP, you can configure up to six community list numbers or names in total in this command. Every **exact-match** keyword applies only to the previous list, instead of all lists.

In a route map rule, one or more **match** or **set** commands can be configured. If no **match** command is configured, all rules are matched. If no **set** command is configured, no operation is performed.

Examples

The following example configures the community list **1** to allow traffic with the community values of 100:2 and 100:30, and configures the route map **set_lopref** to set the local preference to 20 for routes that exactly match the community list **1** in the route map.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip community-list 1 permit 100:2 100:30
Hostname(config)# route-map set_lopref
Hostname(config-route-map)# match community 1 exact-match
Hostname(config-route-map)# set local-preference 20
```

Notifications

If the name of a specified community list of the name type is all numbers, the following notification will be displayed:

```
% Community-list name cannot have all digits
```

If the name of a specified community list contains 80 characters or more, the following notification will be displayed:

```
% Community-list name lengths should be less than 80 chars
```

If more than six community lists are configured in a single command, the following notification will be displayed:

```
% Match community command only support six community-list
```

If more than six community lists are configured in total, the following notification will be displayed:

```
% Match community can't exceed 6!
```

Common Errors

1.12 match extcommunity

Function

Run the **match extcommunity** command to configure an extcommunity list to match routes.

Run the **no** form of this command to remove this configuration.

By default, no extcommunity list is configured.

Syntax

match extcommunity { *standard-list-number* | *standard-list-name* | *expanded-list-num* | *expanded-list-name* }&<1-6>

no match extcommunity [*standard-list-number* | *standard-list-name* | *expanded-list-num* | *expanded-list-name*]&<1-6>

Parameter Description

{ *standard-list-number* | *standard-list-name* | *expanded-list-num* | *expanded-list-name* }&<1-6>: &<1-6> indicates that you can enter the parameters up to six times in this command.

standard-list-number: Number of a standard extcommunity list. The value range is from 1 to 99.

standard-list-name: Name of a standard extcommunity list.

expanded-list-num: Number of an expanded extcommunity list. The value range is from 100 to 199.

expanded-list-name: Name of an expanded extcommunity list.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

When using this command in BGP, you can configure multiple extcommunity list numbers or names in this command but ensure that the total count does not exceed six. An extcommunity list may contain multiple extcommunity attribute values.

A route map that uses the extcommunity attributes for matching is applicable to the following scenarios:

- In the route map associated with the **import map** command, the RT attribute is used to filter routes imported to the virtual routing and forwarding (VRF) instance.
- In the route map associated with the **neighbor route-map in** and **neighbor route-map out** commands, if the **match extcommunity** command is configured in VPNv4 address family configuration mode of BGP, the RT attribute is used to filter VPNv4 routes that are received from or will be sent to a BGP peer.

Examples

The following example configures the extcommunity list **1** to allow traffic with the RT values of 100:1 and 100:2.

```
Hostname(config)# ip extcommunity-list 1 permit rt 100:1
Hostname(config)# ip extcommunity-list 1 permit rt 100:2
```

The following example defines a match rule in route map configuration mode.

```
Hostname(config)# route-map rt
Hostname(config-route-map)# match extcommunity 1
```

The following example applies the route map to the VPNV4 address family in BGP 100.

```
Hostname(config)# router bgp 100
Hostname(config-router)# address-family vpnv4
```

```
Hostname(config-router-af)# neighbor 3.3.3.3 route-map rt in
```

Notifications

If the name of a specified extcommunity list of the name type is all numbers, the following notification will be displayed:

```
% Extcommunity-list name cannot have all digits
```

If the name of a specified extcommunity list name contains 80 characters or more, the following notification will be displayed:

```
% Extcommunity-list name lengths should be less than 80 chars
```

If more than six extcommunity lists are configured in a single command, the following notification will be displayed:

```
% Match extcommunity command only support six extcommunity-list
```

If more than six extcommunity lists are configured in total, the following notification will be displayed:

```
% Match extcommunity can't exceed 6!
```

1.13 match interface

Function

Run the **match interface** command to configure a specified interface as the next-hop outbound interface.

Run the **no** form of this command to remove this configuration.

By default, no next-hop outbound interface is configured.

Syntax

match interface { *interface-type interface-number* }&<1-4>

no match interface [*interface-type interface-number*]&<1-4>

Parameter Description

interface-type: Interface type.

interface-number: Interface number.

{ *interface-type interface-number* }&<1-4>: &<1-4> indicates that you can enter the parameters up to four times in this command.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

You can configure multiple interfaces in this command.

Note

By default, if you do not specify the interface type or number when removing the configurations, the configurations of all interfaces are removed.

Examples

The following example configures the route map **redrip** to match traffic with the GigabitEthernet 0/1 interface that is used as the outbound interface, and filters RIP routes redistributed to OSPF based on the rule in the route map **redrip**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match interface GigabitEthernet 0/1
```

Notifications

If more than four interface are specified, the following notification will be displayed:

```
% Match interface can't exceed 4!
```

If the specified interface is an L2 interface (for example, L2 interface GigabitEthernet 0/0), the following notification will be displayed:

```
% Invalid parameter: GigabitEthernet 0/0, only support layer 3 interface.
```

1.14 match ip address

Function

Run the **match ip address** command to configure the target network routes that are permitted in an ACL or prefix list.

Run the **no** form of this command to remove this configuration.

By default, no ACL or prefix list used for packet matching is configured.

Syntax

match ip address { { *acl-number* | *acl-name* } &<1-6> | **prefix-list** *prefix-list-name*&<1-6> }

no match ip address [[*acl-number* | *acl-name*]&<1-6> | **prefix-list** *prefix-list-name*&<1-6>]

Parameter Description

acl-number: Number of an ACL. The following value ranges are supported. For a standard IP ACL, the range is from 1 to 99 or from 1300 to 1999. For an extended IP ACL, the range is from 100 to 199 or from 2000 to 2699.

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list *prefix-list-name*&<1-6>: Specifies the name of the prefix list to be matched. &<1-6> indicates that you can enter the parameters up to six times in this command.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

You can configure multiple ACL numbers or names in this command.

Note

By default, if you do not specify the ACL number when removing the ACL configurations, configurations of all ACLs are removed.

Examples

The following example configures a route map to redistribute only RIP routes that match the ACL 10 to OSPF, and sets the route type to the external route type-1 and the initial metric to 40.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# access-list 10 permit 200.168.23.0 0.0.0.255
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match ip address 10
Hostname(config-route-map)# set metric 40
Hostname(config-route-map)# set metric-type type-1
```

Notifications

If the specified ACL name is invalid, for example, **match ip address 12345**, the following notification will be displayed:

```
% ACL name 12345 is invalid
```

If you configure this command to configure an ACL after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set access-list match with prefix-list exits!
```

If you configure this command to configure a prefix list after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set prefix-list match with access-list exists!
```

If more than six ACLs are specified in a single command, the following notification will be displayed:

1.15 match ip next-hop

Function

Run the **match ip next-hop** command to configure the target network routes whose next-hop IP addresses match rules in the ACL or prefix list.

Run the **no** form of this command to remove this configuration.

By default, no ACL or prefix list used for next-hop IP address matching is configured.

Syntax

match ip next-hop { { *acl-number* | *acl-name* } &<1-6> | **prefix-list** *prefix-list-name*&<1-6> }

no match ip next-hop [[*acl-number* | *acl-name*]&<1-6> | **prefix-list** *prefix-list-name*&<1-6>]

Parameter Description

acl-number: Number of an ACL. The following value ranges are supported. For a standard IP ACL, the range is from 1 to 99 or from 1300 to 1999. For an extended IP ACL, the range is from 100 to 199 or from 2000 to 2699.

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list *prefix-list-name*&<1-6>: Specifies the name of the prefix list to be matched. &<1-6> indicates that you can enter the parameters up to six times in this command.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

You can configure multiple ACL numbers or names in this command.

Note

By default, if you do not specify the ACL number when removing the ACL configurations, configurations of all ACLs are removed.

Examples

The following example configures the route map **redrip** to match traffic with the next-hop IP addresses matching ACL 10 or 20, and redistributes RIP routes to OSPF based on the rule in the route map **redrip**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# access-list 10 permit host 192.168.10.1
Hostname(config)# access-list 20 permit host 172.16.20.1
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match ip next-hop 10 20
```

Notifications

If the specified ACL name is invalid, for example, **match ip next-hop 12345**, the following notification will be displayed:

```
% ACL name 12345 is invalid
```

If you use this command to configure an ACL after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set access-list match with prefix-list exits!
```

If you use this command to configure a prefix list after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set prefix-list match with access-list exists!
```

If more than six ACLs are specified in a single command, the following notification will be displayed:

```
% Match ip next-hop command only support six IP access-list
```

If more than six ACLs are configured in total, the following notification will be displayed:

```
% ACL can't exceed 6!
```

If more than six prefix lists are specified in a single command, the following notification will be displayed:

```
% Match ip next-hop command only support six IP prefix-list

1.16 match ip policy

Function

Run the **match ip policy** command to configure the target network routes that are permitted in the ACL and match a specified L3 authentication traffic diversion domain type.

Run the **no** form of this command to remove this configuration.

Syntax

match ip policy { *acl-number* | *acl-name* }&<1-6> **class** *class-id*

no match ip policy [*acl-number* | *acl-name*]&<1-6>

Parameter Description

acl-number: Number of an ACL. The following value ranges are supported. For a standard IP ACL, the range is from 1 to 99 or from 1300 to 1999. For an extended IP ACL, the range is from 100 to 199 or from 2000 to 2699.

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

class-id: ID of the L3 authentication traffic diversion domain type. The value range is from 1 to 60. The L3 authentication traffic diversion domain type is specified by the Web authentication module.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for policy-based routing (PBR) configuration.

You can configure only one ACL number or name in this command. *class-id* indicates the L3 authentication traffic diversion domain type to be matched. They together describe the packets that match the specific user type.

Examples

The following example configures the route map **pbr1** to match traffic with the L3 authentication traffic diversion domain of **acl1** and set class ID of the domain type to **10**, and applies the route map **pbr1** to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip policy route-map pbr1
Hostname(config-if-GigabitEthernet 0/1)# exit
Hostname(config)# route-map pbr1 permit 10
Hostname(config-route-map)# match ip policy acl1 class 10
```

Notifications

If the specified ACL name is invalid, for example, **match ip address 12345**, the following notification will be displayed:

```
% ACL name 12345 is invalid
```

If more than one **match ip policy** is configured, the following notification will be displayed:

```
% Match ip policy command only support one rule
```

1.17 match ip route-source

Function

Run the **match ip route-source** command to configure the target network routes whose source IP addresses match rules in the ACL or prefix list.

Run the **no** form of this command to remove this configuration.

By default, no ACL or prefix list is configured to match the source IP addresses of routes.

Syntax

match ip route-source { { *acl-number* | *acl-name* } &<1-6> | **prefix-list** *prefix-list-name*&<1-6> }

no match ip route-source [[*acl-number* | *acl-name*]&<1-6> | **prefix-list** *prefix-list-name*&<1-6>]

Parameter Description

acl-number: Number of an ACL. The following value ranges are supported. For a standard IP ACL, the range is from 1 to 99 or from 1300 to 1999. For an extended IP ACL, the range is from 100 to 199 or from 2000 to 2699.

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list *prefix-list-name*&<1-6>: Specifies the name of the prefix list to be matched. &<1-6> indicates that you can enter the parameters up to six times in this command.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

You can configure multiple ACL numbers in this command.

Note

By default, if you do not specify the ACL number when removing the ACL configurations, configurations of all ACLs are removed.

Examples

The following example configures the route map **redrip** to match traffic with the source IP addresses matching ACL 5, and redistribute RIP routes that match the rule in the route map **redrip** to OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets
Hostname(config-router)# route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# access-list 5 permit host 192.168.100.1
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match ip route-source 5
```

Notifications

If the specified ACL name is invalid, for example, **match ip route-source 12345**, the following notification will be displayed:

```
% ACL name 12345 is invalid
```

If you configure this command to configure an ACL after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set access-list match with prefix-list exits!
```

If you configure this command to configure a prefix list after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set prefix-list match with access-list exists!
```

If more than six ACLs are specified in a single command, the following notification will be displayed:

```
% Match ip route-source command only support six IP access-list
```

If more than six ACLs are configured in total, the following notification will be displayed:

```
% ACL can't exceed 6!
```

If more than six prefix lists are specified in a single command, the following notification will be displayed:

```
% Match ip route-source command only support six IP prefix-list
```

If more than six prefix lists are configured in total, the following notification will be displayed:

```
% Prefix-list can't exceed 6!
```

1.18 match ipv6 address

Function

Run the **match ipv6 address** command to configure the target IPv6 network routes that are permitted in the ACL or prefix list.

Run the **no** form of this command to remove this configuration.

By default, no IPv6 ACL or IPv6 prefix list is configured for packet matching.

Syntax

match ipv6 address { *acl-name* | **prefix-list** *prefix-list-name* }

no match ipv6 address

Parameter Description

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list *prefix-list-name*: Specifies the name of an IPv6 prefix list used for matching.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

- The sequence number of a route map can be followed by only one IPv6 ACL.
- The default sequence number of a route map is 10.
- The IPv6 PBR function cannot be used together with the parameter **prefix-list**. If they are used together, this parameter does not take effect.

Examples

The following example configures the route map **redip** to match traffic with the IPv6 ACL **v6acl** and set the metric to **30**, and applies the route map **redip** when RIP routes are redistributed to OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# exit
Hostname(config)# ipv6 access-list v6acl
Hostname(config-ipv6-acl)# permit ipv6 2620::/64 any
Hostname(config-ipv6-acl)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match ipv6 address v6acl
Hostname(config-route-map)# set metric 30
```

Notifications

If the specified ACL name is invalid, for example, **match ipv6 address 123456**, the following notification will be displayed:

```
% ACL name 123456 is invalid
```

If you configure this command to configure an ACL after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set access-list match with prefix-list exits!
```

If you configure this command to configure a prefix list after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set prefix-list match with access-list exists!
```

1.19 match ipv6 next-hop

Function

Run the **match ipv6 next-hop** command to configure the target network routes whose next-hop IPv6 addresses match rules in the ACL or prefix list.

Run the **no** form of this command to remove this configuration.

By default, no IPv6 ACL or IPv6 prefix list is configured for next-hop IP address matching.

Syntax

match ipv6 next-hop { *acl-name* | **prefix-list** *prefix-list-name* }

no match ipv6 next-hop

Parameter Description

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list *prefix-list-name*: Specifies the name of an IPv6 prefix list to be matched.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the route map **redip** to match routes with the next hop matching the IPv6 ACL **v6acl** and set the metric to **40**, and applies the route map **redip** when RIP routes are redistributed to OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# exit
Hostname(config)# ipv6 access-list v6acl
Hostname(config-ipv6-acl)# 10 permit ipv6 2720::/64 any
Hostname(config-ipv6-acl)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match ipv6 next-hop v6acl
Hostname(config-route-map)# set metric 40
```

Notifications

If the specified ACL name is invalid, for example, **match ipv6 next-hop 123456**, the following notification will be displayed:

```
% ACL name 123456 is invalid
```

If you configure this command to configure an ACL after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set access-list match with prefix-list exits!
```

If you configure this command to configure a prefix list after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set prefix-list match with access-list exists!

1.20 match ipv6 route-source

Function

Run the **match ipv6 route-source** command to configure the target network routes whose source IPv6 addresses match rules in the ACL or prefix list.

Run the **no** form of this command to remove this configuration.

By default, no IPv6 ACL or IPv6 prefix list is configured to match the source IP addresses of routes.

Syntax

match ipv6 route-source { *acl-name* | **prefix-list** *prefix-list-name* }

no match ipv6 route-source

Parameter Description

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

prefix-list *prefix-list-name*: Specifies the name of an IPv6 prefix list to be matched.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the route map **redip** to match traffic with the source IP addresses matching the IPv6 ACL **v6acl** and set the metric to **50**, and applies the route map **redip** when RIP routes are redistributed to OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# exit
Hostname(config)# ipv6 access-list v6acl
Hostname(config-ipv6-acl)# 10 permit ipv6 5200::/64 any
Hostname(config-ipv6-acl)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match ipv6 route-source v6acl
Hostname(config-route-map)# set metric 50
```

Notifications

If the specified ACL name is invalid, for example, **match ipv6 route-source 123456**, the following notification will be displayed:

```
% ACL name 123456 is invalid
```

If you configure this command to configure an ACL after you have configured a prefix list by using this command, the following notification will be displayed:

```
% Can't set access-list match with prefix-list exits!
```

If you configure this command to configure a prefix list after you have configured a prefix list by using this command, the following notification will be displayed:

1.21 match metric

Function

Run the **match metric** command to configure the metric values of routes.

Run the **no** form of this command to remove this configuration.

By default, no metric values of routes are configured.

Syntax

match metric *metric*

no match metric

Parameter Description

metric: Value of the metric. The value range is from 0 to 4294967295.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the route map **redist-rip** to match traffic with the metric value of **10**, and configures OSPF to redistribute RIP routes based on the route map **redist-rip**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redist-rip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# route-map redist-rip permit 10
Hostname(config-route-map)# match metric 10
```

1.22 match origin

Function

Run the **match origin** command to configure the source type of BGP routes.

Run the **no** form of this command to remove this configuration.

By default, no source type of BGP routes is configured.

Syntax

match origin { **egp** | **igp** | **incomplete** }

no match origin [**egp** | **igp** | **incomplete**]

Parameter Description

egp: Specifies that the source is the remote Exterior Gateway Protocol (EGP).

igp: Specifies that the source is the local Interior Gateway Protocol (IGP).

incomplete: Specifies that the source is incomplete.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

Only routes with a single type of source can be matched. Routes with different source types cannot be matched simultaneously.

This command is used to set the route source for matching.

Examples

The following example configures the route map **MY_MAP** to match routes with the source **egp** and sets the community to **109**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map MY_MAP 10 permit
Hostname(config-route-map)# match origin egp
Hostname(config-route-map)# set community 109
Hostname(config-route-map)# exit
```

The following example configures the route map **MAP20** to match routes with the source **incomplete** and sets the community to **no-export**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map MAP20 20 permit
Hostname(config-route-map)# match origin incomplete
Hostname(config-route-map)# set community no-export
```

1.23 match route-type

Function

Run the **match route-type** command to configure the route type.

Run the **no** form of this command to remove this configuration.

By default, no rule is configured to match any route type.

Syntax

match route-type { **static** | **connect** | **rip** | **local** | **internal** | **external** [**type-1** | **type-2**] | **nssa-external** [**type-1** | **type-2**] | **level-1** | **level-2** | **evpn-type-1** | **evpn-type-2** | **evpn-type-3** | **evpn-type-4** | **evpn-type-5** }&<1-6>

no match route-type [**static** | **connect** | **rip** | **local** | **internal** | **external** [**type-1** | **type-2**] | **nssa-external** [**type-1** | **type-2**] | **level-1** | **level-2** | **evpn-type-1** | **evpn-type-2** | **evpn-type-3** | **evpn-type-4** | **evpn-type-5**]&<1-n>

Parameter Description

[**static** | **connect** | **rip** | **local** | **internal** | **external** [**type-1** | **type-2**] | **nssa-external** [**type-1** | **type-2**] | **level-1** | **level-2** | **evpn-type-1** | **evpn-type-2** | **evpn-type-3** | **evpn-type-4** | **evpn-type-5**]&<1-16>: &<1-16> indicates that you can enter the parameters up to 16 times in this command, with only once for each route type.

static: Specifies a static route.

connect: Specifies a direct route.

rip: Specifies an RIP route.

local: Specifies a local route.

internal: Specifies an OSPF internal route.

external: Specifies an external route (BGP or OSPF external route).

nssa-external: Specifies an OSPF NSSA external route.

type-1 | **type-2**: Specifies a type-1 or type-2 external route of OSPF.

level-1 | **level-2**: Specifies a level-1 or level-2 route of ISIS.

evpn-type-1 | **evpn-type-2** | **evpn-type-3** | **evpn-type-4** | **evpn-type-5**: Specifies the five route types of BGP EVPN.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the route map **redrip** to match traffic with the route type **internal**, and applies the route map **redip** when OSPF routes are redistributed to RIP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router rip
Hostname(config-router)# redistribute ospf route-map redrip
Hostname(config-router)# network 192.168.12.0
Hostname(config-router)# exit

1.24 match tag

Function

Run the **match tag** command to configure the tags of routes.

Run the **no** form of this command to remove this configuration.

By default, no routes with tags are matched.

Syntax

match tag *tag*&<1-4>

no match tag [*tag*&<1-4>]

Parameter Description

tag: Tag value of a route. The value range is from 0 to 4294967295. & <1-4> indicates that up to four tags can be configured.

By default, if you do not specify the optional parameter when removing the configurations, all route tag configurations are removed.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the route map **redrip** to match routes with tags 50 and 80, and applies the route map **redip** when OSPF routes are redistributed to RIP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router rip
Hostname(config-router)# redistribute ospf 100 route-map redrip
Hostname(config-router)# network 192.168.12.0
Hostname(config-router)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match tag 50 80
```

1.25 memory-lack exit-policy

Function

Run the **memory-lack exit-policy** command to specify the exit policy for the upper-layer routing protocols when the free memory space reaches the lower level.

Run the **no** form of this command to restore the default configuration.

By default, the routing protocol with the highest memory usage exits.

Syntax

memory-lack exit-policy { **bgp** | **ospf** | **pim-sm** | **rip** }

no memory-lack exit-policy

Parameter Description

bgp: Specifies that BGP exits first when the memory is insufficient.

ospf: Specifies that OSPF exits first when the memory is insufficient.

pim-sm: Specifies that PIM-SM exits first when the memory is insufficient.

rip: Specifies that RIP exits first when the memory is insufficient.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the free memory space reaches the lower level, this command can disable one routing protocol to release the memory resources and protect the operation of other protocols in the system.

You should know routing protocols that support the main network services, and in the case of insufficient memory, disable one of the least important protocols to protect main services in this extreme situation. If you set a disabled routing protocol to exit first when the memory is sufficient, the system still cannot obtain sufficient memory resources.

Specifying a routing protocol to exit first can, to some extent, protect main network services when the system memory is insufficient. If the memory is further consumed, all routing protocols need to exit and stop running.

Examples

The following example configures a policy that enables BGP to exit first.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# memory-lack exit-policy bgp
```

1.26 route-map

Function

Run the **route-map** command to configure a route map and enter the route map configuration mode.

Run the **no** form of this command to remove this configuration.

By default, no route map is configured.

Syntax

route-map *route-map-name* [**permit** | **deny**] [*sequence-number*]

no route-map *route-map-name* [{ **permit** | **deny** } *sequence-number*]

Parameter Description

route-map-name: Name of a route map. You can define a name that is easy to remember. With this name, you can use the route map in the redistribution configuration commands in the routing process. Multiple policies can be defined in a route map, and one policy corresponds to one sequence number.

permit: If the **permit** keyword is defined, and the rule defined in **match** is matched, the **set** command controls route redistribution. For PBR, the **set** command controls packet forwarding and exit of the route map.

If the **permit** keyword is defined, but the rule defined in **match** is not matched, the system switches to the next route map policy until the **set** command is executed.

deny: If the **deny** keyword is defined, and the rule defined in **match** is matched, no operation is performed. This route map policy does not allow route redistribution or PBR, and the system exits the route map.

If the **deny** keyword is defined, but the rule defined in **match** is not matched, the system switches to the next route map policy until the **set** command is executed.

sequence-number: Sequence number of a route map policy. A policy with a smaller sequence number is used first. The value range is from 0 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The route map is currently used for:

- Route redistribution control

  Route redistribution control redistributes routes from one routing process to another. For example, the routes in the OSPF routing domain can be redistributed and then advertised to the RIP routing domain, or vice versa. Mutual redistribution of routes can be carried out among all IP routing protocols.

  In route redistribution, mutual distribution of routes between two routing domains is often controlled conditionally through the application of a route map. In a route map policy, one or more **match** and **set** commands can be configured. If no **match** command is configured, all traffic is matched. If no **set** command is configured, no operation is performed.

- PBR

  The PBR provides a data packet routing and forwarding mechanism that is more flexible than target network-based routing. After PBR is applied on a device, the device determines how to process packets that need to be routed according to a route map. The route map determines the next hop forwarding device of a packet.

  To apply PBR, you must specify a route map for PBR, and create this map. A route map consists of multiple policies, and one or more match rules and relevant actions are defined for each policy. After PBR is applied

to an interface, all packets received by the interface are checked. Packets that do not match any policy in the route map are routed and forwarded as usual. Packets that match a policy in the route map are processed based on the action defined in the policy.

When configuring a route map, use the sequence number of the route map as follows:

- If you do not specify *sequence-number* when creating the first route map policy, the default sequence number is 10.
- If only one route map policy exists and you do not specify *sequence-number*, a new route map policy is not created. Instead, the existing route map policy is configured.
- If multiple route map policies exist, you must specify *sequence-number*; otherwise, an error prompt is displayed.

Examples

The following example configures the route map **redrip** to match traffic with the metric value of 4, set the initial metric value to **40**, the route type to the external route **type-1**, and the route tag to **40**, and applies the route map **redip** when RIP routes are redistributed in OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match metric 4
Hostname(config-route-map)# set metric 40
Hostname(config-route-map)# set metric-type type-1
Hostname(config-route-map)# set tag 40
```

Notifications

If the specified route map name contains more than 32 characters, the following notification will be displayed:

```
% Route-map name string length can not exceed 32.
```

1.27 set aggregator as

Function

Run the **set aggregator as** command to specify the AS value of the aggregator for routes that match the rules.

Run the **no** of this command to remove this configuration.

By default, no aggregator AS value is specified.

Syntax

set aggregator as *as-number ipv4-address*

no set aggregator as [*as-number ipv4-address*]

Parameter Description

as-number: AS number of the aggregator. The AS number range is from 1 to 4294967295, or 1.0 to 65535.65535 in dot mode.

ipv4-address: Address of the aggregator.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used for PBR configuration in BGP to set the aggregator attributes of routes.

This command has only one set of parameters: *as-number* and *ipv4-address*, and does not support multiple sets of parameters.

Examples

The following example configures the route map **set-as-path** to set the AS number of the route aggregator to **3** and IP address to **2.2.2.2**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map set-as-path
Hostname(config-route-map)# match as-path 1
Hostname(config-route-map)# set aggregator as 3 2.2.2.2

1.28 set aigp-metric

Function

Run the **set aigp-metric** command to specify the Accumulated IGP Metric Attribute (AIGP) metric for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no AIGP metric attribute is configured for routes.

Syntax

set aigp-metric { *metric-number* | **igp-metric** }

no set aigp-metric

Parameter Description

metric-number: AIGP metric value. The value range is from 0 to 4294967295.

igp-metric: Configures the AIGP metric to the IGP metric type.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used for PBR configuration in EGP to configure the AIGP metric of routes.

This command has only one set of parameters, and does not support multiple sets of parameters.

Examples

The following example configures the route map **test** to set the AIGP metric of routes to **100**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map test
Hostname(config-route-map)# set aigp-metric 100
```

1.29 set as-path replace

Function

Run the **set as-path replace** command to replace the AS_PATH values for routes that match the rules with specified values.

Run the **no** form of this command to remove this configuration.

By default, the AS_PATH values of matched routes will not be replaced.

Syntax

set as-path replace *as-number*&<1-10>

no set as-path replace

Parameter Description

as-number&<1-10>: AS number of the AS_PATH value to be replaced. &<1-10> indicates that you can enter the parameter up to 10 times in this command.

Note

The AS number range is from 1 to 4294967295, or 1.0 to 65535.65535 in dot mode.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration to replace the AS_PATH values of matched routes. Up to 10 AS_PATH values can be replaced at a time.

Examples

The following example configures the route map **set-as-path** to replace the AS_PATH values with "100 101 102" for routes that match the AS-path list 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map set-as-path
Hostname(config-route-map)# match as-path 1
Hostname(config-route-map)# set as-path replace 100 101 102
```

Notifications

If more than 10 AS_PATH values are configured in total, the following notification will be displayed:

```
% Cannot have more than 10 as-paths replaced
```

1.30 set as-path prepend

Function

Run the **set as-path prepend** command to add the specified AS_PATH values for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no rule is configured to add AS_PATH values for routes.

Syntax

set as-path prepend *as-number*&<1-10>

no set as-path prepend

Parameter Description

as-number&<1-10>: AS number of the AS_PATH to be added. &<1-10> indicates that you can enter the parameter up to 10 times in this command. The AS number range is from 1 to 4294967295, or 1.0 to 65535.65535 in dot mode.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration to add the AS_PATH values to the matched routes. Up to 10 AS_PATH values can be added at a time.

Examples

The following example configures the route map **set-as-path** to add the AS_PATH values "100 101 102" for routes that match the AS-path list 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map set-as-path
Hostname(config-route-map)# match as-path 1
Hostname(config-route-map)# set as-path prepend 100 101 102
```

Notifications

If more than 10 AS_PATH values are configured in total, the following notification will be displayed:

```
% Cannot have more than 10 as-paths prepended
```

1.31 set atomic-aggregate

Function

Run the **set atomic-aggregate** command to configure the atomic-aggregate attribute for routes.

Run the **no** form of this command to remove this configuration.

By default, no atomic-aggregate attribute is configured for routes.

Syntax

set atomic-aggregate

no set atomic-aggregate

Parameter Description

N/A

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used in BGP to configure the atomic-aggregate attribute for routes.

Examples

The following example configures the route map **test** to configure the atomic-aggregate attribute for routes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map test
Hostname(config-route-map)# set atomic-aggregate
```

1.32 set comm-list delete

Function

Run the **set comm-list delete** command to delete all community values from routes that match the rules according to the community list.

Run the **no** form of this command to remove this configuration.

By default, no community value is deleted from matched routes according to the community list.

Syntax

set comm-list { *community-list-number* | *community-list-name* } **delete**

no set comm-list { *community-list-number* | *community-list-name* } **delete**

Parameter Description

community-list-number: Number of the community list. For a standard community list, the range is from 1 to 99. For an expanded community list, the range is from 100 to 199.

community-list-name: Name of a community list, comprising less than 80 characters.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used for PBR configuration to delete the community values from matched routes.

Examples

The following example configures the route map **ROUTEMAPIN** to delete the community values (100:10 and 100:2) from matched routes according to Community-List 500, configures the route map **ROUTEMAPOUT** to delete the community values (not 100:50 or 100:.*) from matched routes according to Community-List 120,

applies the route map **ROUTEMAPIN** to the inbound direction of the neighbor 172.16.233.33 in AS 100 of BGP,

and applies the route map **ROUTEMAPOUT** to the outbound direction of the neighbor 172.16.233.33 in AS 100 of BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 100
Hostname(config-router)# neighbor 172.16.233.33 remote-as 120
Hostname(config-router)# neighbor 172.16.233.33 route-map ROUTEMAPIN in
```

```
Hostname(config-router)# neighbor 172.16.233.33 route-map ROUTEMAPOUT out
Hostname(config-router)# exit
Hostname(config)# ip community-list 500 permit 100:10
Hostname(config)# ip community-list 500 permit 100:20
Hostname(config)# ip community-list 120 deny 100:50
Hostname(config)# ip community-list 120 permit 100:.*
Hostname(config)# route-map ROUTEMAPIN permit 10
Hostname(config-route-map)# set comm-list 500 delete
Hostname(config-route-map)# exit
Hostname(config)# route-map ROUTEMAPOUT permit 10
Hostname(config-route-map)# set comm-list 120 delete
```

Notifications

If the name of a specified community list of the name type is all numbers, the following notification will be displayed:

```
% Community-list name cannot have all digits
```

If the name of a specified community list contains 80 characters or more, the following notification will be displayed:

```
% Community-list name lengths should be less than 80 chars
```

1.33 set community

Function

Run the **set community** command to specify the community values for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no community value is specified for a route.

Syntax

set community { **none** | { *community-number* | **internet** | **local-AS** | **no-advertise** | **no-export** }&<1-32> [**additive**] }

no set community

Parameter Description

{ *community-number* | **internet** | **local-AS** | **no-advertise** | **no-export** }&<1-32>: &<1-32> indicates that you can enter the parameter up to 32 times in this command.

community-number: Value of the community attribute.

The format is AA:NN (AS number: 2-byte number) or the value is a number. The value range is from 0 to 4294967295.

Internet: Specifies the Internet community. All paths belong to this community.

local-as: Specifies that a path is not advertised to other ASs. When an AS alliance is configured, the path is not advertised to other ASs or sub ASs.

no-advertise: Specifies that the path is not advertised to any BGP peer.

no-export: Specifies that the path is not advertised to EBGP peers.

additive: Adds a community value based on the original community attribute.

none: Keeps the community attribute empty.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the community attribute for matched routes.

Examples

The following example configures the route map **SET_COMMUNITY**, sets the community attribute to **109:10** for routes that match as-path 1 in a policy with the sequence number of 10, and sets the community attribute to **no-export** for routes that match as-path 2 in a policy with the sequence number of 20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map SET_COMMUNITY 10 permit
Hostname(config-route-map)# match as-path 1
Hostname(config-route-map)# set community 109:10
Hostname(config-route-map)# exit
Hostname(config)# route-map SET_COMMUNITY 20 permit
Hostname(config-route-map)# match as-path 2
Hostname(config-route-map)# set community no-export
```

Notifications

If more than 32 community values are configured, the following notification will be displayed:

```
% Cannot have more than 32 community attributes
```

1.34 set dampening

Function

Run the **set dampening** command to configure the flapping parameters for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, when the half-life period is 15 minutes, and the penalty value of a route is lower than 750, route suppression is canceled. When the penalty value of a route exceeds 2000, the route is suppressed. A route can be suppressed for a maximum of 60 minutes.

Syntax

set dampening *half-life reuse suppress max-suppress-time*

no set dampening

Parameter Description

half-life: Half-life period when a route is accessible or not accessible, in minutes. The value range is from 1 to 45.

reuse: When the penalty value of a route is smaller than this value, route suppression is canceled. The value range is from 1 to 20000.

suppress: When the penalty value of a route is greater than this value, the route is suppressed. The value range is from 1 to 20000.

max-suppress-time: Longest time that a route can be suppressed, in minutes. The value range is from 1 to 255.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the flapping parameters for matched routes.

Examples

The following example configures a route map to set the route flapping parameters (*half-life*: **30** min, *reuse*: **1500**, *suppress*: **10000**, and *max-suppress-time*: **120** min), and applies the route map to BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map tag
Hostname(config-route-map)# match as path 10
Hostname(config-route-map)# set dampening 30 1500 10000 120
Hostname(config-route-map)# exit
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 172.16.233.52 route-map tag in
```

Notifications

If the configured *suppress* is smaller than *reuse* or the configured *max-suppress-time* is smaller than *half-life*, the following notification will be displayed:

```
% Invalid value
```

1.35 set distance

Function

Run the **set distance** command to configure the management distance for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no management distance is modified for matched routes.

Syntax

set distance *distance-number*

no set distance

Parameter Description

distance-number: Route management distance. The value range is from 1 to 255.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

The route management distance affects route selection. Therefore, configure it carefully based on the actual network topology.

Examples

The following example configures the route map **test** to set the management distance of routes that match the rules to **112**, and applies the route map to the OSPF process.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map test
Hostname(config-route-map)# set distance 112
```

```
Hostname(config)#exit
Hostname(config)# router ospf 1
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# distance 111 route-map test
Hostname(config-router)# exit
```

1.36 set extcomm-list delete

Function

Run the **set extcomm-list delete** command to delete all extended community values from the routes that match the rules according to the extcommunity list.

Run the **no** form of this command to remove this configuration.

By default, the extended community values of matched routes are not deleted.

Syntax

set extcomm-list { *extcommunity-list-number* | *extcommunity-list-name* } **delete**

no set extcomm-list { *extcommunity-list-number* | *extcommunity-list-name* } **delete**

Parameter Description

extcommunity-list-number: Number of an extcommunity list. For a standard extcommunity list, the range is from 1 to 99. For an expanded extcommunity list, the range is from 100 to 199.

extcommunity-list-name: Name of an extcommunity list. It is a string of less than 80 characters.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used for PBR configuration to delete the extended community values from matched routes.

Examples

The following example configures the route map **ROUTEMAPIN** to delete all extended community values from routes that match the rules according to the extcommunity list 10.

The following example configures the route map **ROUTEMAPOUT** to delete all extended community values from routes that match the rules according to the extcommunity list 120.

The following example applies the route maps **ROUTEMAPIN** and **ROUTEMAPOUT** to AS 65000 in BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 65000
Hostname(config-router)# neighbor 172.16.233.33 remote-as 65531
Hostname(config-router)# address-family vpnv4 unicast
Hostname(config-router-af)# neighbor 172.16.233.33 activate
Hostname(config-router-af)# neighbor 172.16.233.33 route-map ROUTEMAPIN in
Hostname(config-router-af)# neighbor 172.16.233.33 route-map ROUTEMAPOUT out
Hostname(config-router)# exit
Hostname(config)# ip extcommunity-list 10 permit rt 100:10
Hostname(config)# ip extcommunity-list 10 permit rt 100:20
Hostname(config)# ip extcommunity-list 120 deny 100:50
Hostname(config)# ip extcommunity-list 120 permit 100:.*
Hostname(config)# route-map ROUTEMAPIN permit 10
Hostname(config-route-map)# set extcomm-list 10 delete
Hostname(config-route-map)# exit
Hostname(config)# route-map ROUTEMAPOUT permit 10
Hostname(config-route-map)# set extcomm-list 120 delete
```

Notifications

If the name of a specified extcommunity list of the name type is all numbers, the following notification will be displayed:

1.37 set extcommunity

Function

Run the **set extcommunity** command to specify the extended community values for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no extended community values are specified for matched routes.

Syntax

set extcommunity { **rt** *extend-community-value* | **soo** *extend-community-value* }

no set extcommunity { **rt** | **soo** }

Parameter Description

rt: Configures the RT value of a route.

soo: Configures the SOO value of a route.

extend-community-value: Value of an extended community.

extend_community_value has three options:

extend_community _value = as_num:nn

as_num is a 2-byte public AS number. nn is configurable. The value range is from 0 to 4294967295.

extend_community_value = ip_addr:nn

ip_addr must be a global IP address. nn is configurable. The value range is from 0 to 65535.

extend_community_value = as4_num:nn

an4_num is a 4-byte public AS number. nn is configurable. The value range is from 0 to 65535.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used for PBR configuration to configure the extended community values for matched routes.

Note

- You can configure the AS4 extended community, that is, the extended community with the 4-byte AS number. The format of the AS4 extended community is AS4:NN. AS4 can be expressed in decimal or dot mode. AS4 ranges from 1 to 4294967295, which is 1 to 65535.65535 in dot mode. The NN range is from 0 to 65535.
- The AS number in the range of 1 to 65535 is displayed the same in both decimal mode and dot mode. Therefore, save the AS number in the range of 1 to 65535 as a 2-byte AS number.

Examples

The following example configures the route map **MAP_NAME**, matches routes with ACL 2, and sets the extended community attribute RT to 100:2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 2 permit 192.168.78.0 255.255.255.0
Hostname(config)# route-map MAP_NAME permit 10
Hostname(config-route-map)# match ip address 2
Hostname(config-route-map)# set extcommunity rt 100:2
```

1.38 set fast-reroute

Function

Run the **set fast-reroute** command to specify the backup outbound interface and backup next hop of FRR for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no backup outbound interface and backup next hop of FRR are specified for matched routes.

Syntax

set fast-reroute backup-interface *interface-type interface-number* **backup-nexthop** *ipv4-address*

no set fast-reroute

Parameter Description

interface-type interface-number: Backup outbound interface.

ipv4-address: Backup next hop, which is mandatory for non-P2P interfaces.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used in FRR configuration to configure the backup outbound interface and backup next hop of IP FRR. If the current software version supports only one backup route, only one set of <interface, next hop> parameters can be configured in this command.

Note

FRR backup entries should not be the direct or local host routes.

Examples

The following example configures the route map **frr** to set the backup outbound interface to **GigabitEthernet 0/1** and the backup next hop to **192.168.1.2** for routes matching ACL 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 2 permit 192.168.78.0 255.255.255.0
Hostname(config)# route-map frr permit 10
Hostname(config-route-map)# match ipv4-address 2
Hostname(config-route-map)# set fast-reroute backup-interface GigabitEthernet 0/1
backup-nexthop 192.168.1.2
```

Notifications

If the specified interface is an L2 interface (for example, L2 interface GigabitEthernet 0/0), the following notification will be displayed:

```
% Invalid parameter: GigabitEthernet 0/0, only support layer 3 interface.
```

1.39 set ip default next-hop

Function

Run the **set ip default next-hop** command to specify the default next-hop IPv4 address for packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no default next-hop IPv4 address is specified for matched routes.

Syntax

set ip default next-hop { *ipv4-address* [*weight*] }&<1-32>

no set ip default next-hop [*ipv4-address* [*weight*]&<1-32>

Parameter Description

{ *ipv4-address* [*weight*] }&<1-32>: &<1-32> indicates that you can enter the parameter up to 32 times in this command.

ipv4-address: IP address of the next hop.

weight: Weight of the next hop.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command supports two operation modes: weighted cost multipath (WCMP) load balancing mode and non-WCMP load balancing mode. In WCMP load balancing mode, the system performs WCMP load balancing on traffic based on the configured *weight*.

You can configure up to 32 IP addresses in this command.

If you add the *weight* value after *ipv4 address*, you can configure up to four **next-hop** addresses.

If **vrf** *vrf-name* is specified, packets are forwarded across VRF instances. If **global** is specified, packets are forwarded from the VRF instance to the public network. If [**vrf** *vrf-name* | **global**] is not specified, the VRF instance is inherited, that is, the next hop belongs to the VRF instance that receives the packets.

Note

If you configure *weight* after any **next-hop**, the operation mode of this **set** command automatically switches to WCMP load balancing mode. In WCMP load balancing mode, the default value of *weight* is **1** if *weight* is not specified for the **next-hop** address.

The difference between the **set ip next-hop** and **set ip default next-hop** commands is as follows: If the **set ip next-hop** command is configured, the system uses PBR first to forward packets. If the **set ip default next-hop** command is configured, the system uses the route forwarding table first to forward packets.

You can run this command to configure a customized default route for specific users. If the software cannot find a route to forward packets, these packets are forwarded to the next hop configured in this command.

Examples

The following example configures the route map **equal-access** to forward packets that are received by GigabitEthernet 0/1 from 1.1.1.1 to 6.6.6.6 if the software cannot find a forwarding route for them, to forward packets that are received from 2.2.2.2 to 7.7.7.7 if the software cannot find a forwarding route for them, and to drop other packets if the software cannot find a forwarding route for them.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#access-list 1 permit 1.1.1.1 0.0.0.0
Hostname(config)#access-list 2 permit 2.2.2.2 0.0.0.0
```

```
Hostname(config)#interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)#ip policy route-map equal-access
Hostname(config)#route-map equal-access permit 10
Hostname(config- route-map)#match ip address 1
Hostname(config-route-map)#set ip default next-hop 6.6.6.6
Hostname(config)#route-map equal-access permit 20
Hostname(config-route-map)#match ip address 2
Hostname(config-route-map)#set ip default next-hop 7.7.7.7
Hostname(config)#route-map equal-access permit 30
Hostname(config- route-map)#set default interface null 0
```

1.40 set ip dscp

Function

Run the **set ip dscp** command to configure the differentiated service code point (DSCP) value for packets matching the rules.

Run the **no** form of this command to remove this configuration.

By default, no DSCP is configured in an IPv4 packet for matched routes.

Syntax

set ip dscp *dscp_value*

no set ip dscp

Parameter Description

dscp_value: DSCP value in the IP header of an IP packet.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the route map **smallpak** to set the DSCP value to **20** for packets that are received by GigabitEthernet 0/1 and smaller than 500 bytes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip policy route-map smallpak
Hostname(config)# route-map smallpak permit 10
Hostname(config-route-map)# match length 0 500
Hostname(config-route-map)# set ip dscp 20
```

Notifications

If you configure this command after the **set ip tos** or **set ip precedence** command has been configured, the following notification will be displayed:

1.41 set ip next-hop

Function

Run the **set ip next-hop** command to specify the next-hop IPv4 address for packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no next-hop IPv4 address is specified for matched packets.

Syntax

set ip next-hop { *ipv4-address* [*weight*] }&<1-32>

no set ip next-hop [*ipv4-address* [*weight*]&<1-32>

Parameter Description

{ *ipv4-address* [*weight*] }&<1-32>: &<1-32> indicates that you can enter the parameter up to 32 times in this command.

ipv4-address: IP address of the next hop.

weight: Weight of the next hop. The value range is from 1 to 8.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration.

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In WCMP load balancing mode, the system performs WCMP load balancing on traffic based on the configured weight.

You can configure up to 32 IP addresses in this command.

If you add the *weight* value after *ipv4 address*, you can configure up to four **next-hop** addresses.

If **vrf** *vrf-name* is specified, packets are forwarded across VRF instances. If **global** is specified, packets are forwarded from the VRF instance to the public network. If [**vrf** *vrf-name* | **global**] is not specified, the VRF instance is inherited, that is, the next hop belongs to the VRF instance that receives the packets.

Note

If you configure *weight* after any **next-hop**, the operation mode of this **set** command automatically switches to WCMP load balancing mode. In WCMP load balancing mode, the default value of *weight* is **1** if *weight* is not specified for the **next-hop** address.

Examples

The following example configures the route map **load-balance** to forward packets received by GigabitEthernet 0/1 from the network segment 10.0.0.0/8, to 192.168.100.1, forward packets received from the network segment 172.16.0.0/16 to 172.16.100.1, and drop other packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip policy route-map load-balance
Hostname(config)# access-list 10 permit 10.0.0.0 0.255.255.255
Hostname(config)# access-list 20 permit 172.16.0.0 0.0.255.255
Hostname(config)#route-map load-balance permit 10

1.42 set ip next-hop recursive

Function

Run the **set ip next-hop recursive** command to specify the recursive next-hop IP address for packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no recursive next-hop IPv4 address is specified for matched packets.

Syntax

set ip next-hop recursive *ipv4-address*

no set ip next-hop recursive

Parameter Description

ipv4-address: Recursive next-hop IP address.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration. You can configure only one such **set** command in a route map policy.

The recursive next-hop IP addresses can be recursively sought in static or dynamic routes that have an outbound interface and a next-hop IP address. Recursion can be performed up to 32 times. If the recursive next-hop IP address is sought in a static route, recursion can be performed only once.

Examples

The following example configures the route map **load-balance** to forward packets received by GigabitEthernet 0/1 from the network segment 10.0.0.0/8 to the recursive next hop 192.168.100.1, forward packets received from the network segment 172.16.0.0/16 to the recursive next hop 172.16.100.1, and forward other packets based on the common routes by default.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)#interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)#ip policy route-map load-balance
Hostname(config)#access-list 10 permit 10.0.0.0 0.255.255.255
Hostname(config)#access-list 20 permit 172.16.0.0 0.0.255.255
Hostname(config)#route-map load-balance permit 10
Hostname(config-route-map)#match ip address 10
Hostname(config-route-map)#set ip next-hop recursive 192.168.100.1
Hostname(config)#route-map load-balance permit 20
Hostname(config-route-map)#match ip address 20
Hostname(config-route-map)#set ip next-hop recursive 172.16.100.1
```

1.43 set ip next-hop self

Function

Run the **set ip next-hop self** command to set the next hop to the device itself for packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, the next hop is not set to the device itself for matched packets.

Syntax

set ip next-hop self

no set ip next-hop self

Parameter Description

N/A

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure a route map to associate with BGP, and set the next hops of routes to be sent to the device itself.

Examples

The following example configures the route map **abc** to set the next hop to the device itself, and applies this route map to routes advertised to the neighbor 1.1.1.1 in AS 65000 in BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#route-map abc
Hostname(config-route-map)#set ip next-hop self
Hostname(config)#router bgp 65000
Hostname(config-router)#neighbor 1.1.1.1 route-map abc out
```

1.44 set ip next-hop unchanged

Function

Run the **set ip next-hop unchanged** command to set the next hops of routes that match the rules to keep unchanged.

Run the **no** form of this command to remove this configuration.

By default, the next hop is not set to keep unchanged for a matched packet. This command is used for route map management in BGP.

Syntax

set ip next-hop unchanged

no set ip next-hop unchanged

Parameter Description

N/A

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure a route map to associate with BGP, and set the next hops of routes to be sent to keep unchanged.

Examples

The following example configures the route map **abc** to set the next hop to keep unchanged, and applies this route map to the routes sent to the neighbor 1.1.1.1 in AS 65000 in BGP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#route-map abc
Hostname(config-route-map)#set ip next-hop unchanged
Hostname(config)#router bgp 65000
Hostname(config-router)#neighbor 1.1.1.1 route-map abc out

1.45 set ip next-hop verify-availability

Function

Run the **set ip next-hop verify-availability** command to verify availability of the next-hop IPv4 address.

Run the **no** form of this command to remove this configuration.

By default, availability of the next-hop IPv4 address is not verified for matched packets.

Syntax

set ip next-hop verify-availability *ipv4-address* [*weight*] { **track** *track-obj-number* | **bfd** *interface-type interface-number gateway* }

no set ip next-hop verify-availability *ipv4-address* [*weight*] { **track** *track-obj-number* | **bfd** *interface-type interface-number gateway* }

Parameter Description

ipv4-address: IP address of the next hop.

weight: Weight in the load balancing mode. The value range is from 1 to 8.

track: Checks whether the next hop is effective by means of tracking.

track-obj-number: Number of the tracked object. The value range is from 1 to 700.

bfd: Specifies that Bidirectional Forwarding Detection (BFD) is used for neighbor detection.

interface-type: Interface type.

interface-number: Interface number.

gateway: IP address of the gateway, which is the neighbor IP address of BFD. If the next hop is set to the neighbor, BFD is used to detect availability of the forwarding path.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration to verify availability of the next-hop IPv4 address.

Examples

The following example configures the route map **rmap** to verify availability of the next hop 192.168.1.2 by using a tracked object with the number of 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map rmap permit 10
Hostname(config-route-map)# set ip next-hop verify-availability 192.168.1.2 track 1
```

1.46 set ip precedence

Function

Run the **set ip precedence** command to configure the priority of the IPv4 header for packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no IPv4 header priority is configured for matched packets.

Syntax

set ip precedence { *precedence* | **critical** | **flash** | **flash-override** | **immediate** | **internet** | **network** | **priority** | **routine** }

no set ip precedence

Parameter Description

precedence: Priority of an IPv4 header indicated by a number. The value range is from 0 to 7.

7: critical

6: flash

5: flash-override

4: immediate

3: internet

2: network

1: priority

0: routine

critical | **flash** | **flash-override** | **immediate** | **internet** | **network** | **priority** | **routine**: Specifies the priority of an IP header.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

The priority of the IP packet header is configured so that IP packets are routed based on different priorities during PBR.

You can configure multiple **set ip precedence** commands in a route map policy, but only the last command takes effect, and a priority is specified for the header of a matched IP packet during PBR.

Examples

The following example configures the route map **name** to set the precedence of packets matching ACL 1 (source address: 192.168.217.68) to 4, and applies the route map to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit 192.168.217.68 0.0.0.0
Hostname(config)# route-map name
Hostname(config-route-map)# match ip address 1
Hostname(config-route-map)# set ip precedence 4
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip policy route-map name
```

Notifications

If you configure this command after the **set ip dscp** command has been configured, the following notification will be displayed:

```
% Route-map: can not set ip precedence.
% Remove set ip dscp clause before set ip precedence.
```

1.47 set ip tos

Function

Run the **set ip tos** command to configure the ToS of the IPv4 header for a packet that matches the rules.

Run the **no** form of this command to remove this configuration.

By default, no ToS is configured for the IP header of a matched packet.

Syntax

set ip tos { *tos-number* | **max-reliability** | **max-throughput** | **min-delay** | **min-monetary-cost** | **normal** }

no set ip tos

Parameter Description

tos-number: ToS of an IPv4 header indicated by a number. The value range is from 0 to 15.

max-reliability | **max-throughput** | **min-delay** | **min-monetary-cost** | **normal**: ToS of an IPv4 header. The ToS values correspond to numbers as follows:

max-reliability: 2

max-throughput: 4

min-delay: 8

min-monetary-cost: 1

normal: 0

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

The ToS of the IP packet header is configured to deliver different quality of service (QoS) for IP packets that are routed using PBR. A ToS value is specified for the header of a matched IP packet during PBR.

Examples

The following example configures the route map **name** to set the ToS of packets matching ACL 1 (source address: 192.168.217.68) to 4, and applies the route map to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit 192.168.217.68 0.0.0.0
Hostname(config)# route-map name
Hostname(config-route-map)# match ip address 1
Hostname(config-route-map)# set ip tos 4
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip policy route-map name
```

Notifications

If you configure this command after the **set ip dscp** command has been configured, the following notification will be displayed:

```
% Route-map: can not set ip tos.
% Remove set ip dscp clause before set ip tos.
```

1.48 set ipv6 default next-hop

Function

Run the **set ipv6 default next-hop** command to specify the default next-hop IPv6 address for IPv6 packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no default next-hop IPv6 address is specified for matched routes.

Syntax

set ipv6 default next-hop { *ipv6-address* [*weight*] }&<1-32>

no set ipv6 default next-hop [*ipv6-address* [*weight*]]&<1-32>

Parameter Description

{ *ipv6-address* [*weight*] }&<1-32>: &<1-32> indicates that you can enter the parameter up to 32 times in this command.

ipv6-address: Next-hop IPv6 address for packet forwarding. The next hop must be an adjacent device.

weight: Weight in load balancing mode. The value range is from 1 to 8.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration. After PBR is applied to an interface, if the routing table does not contain the common route (that is, non-default route) to the destination address of an IPv6 packet that matches the related rules, the packet is forwarded to the next hop specified by the **set ipv6 default nexthop** command; otherwise, the packet is forwarded based on the common route. Note that the rules here are IPv6-related rules.

This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In WCMP load balancing mode, the system performs WCMP load balancing on traffic based on the configured *weight*.

Restrictions and guidelines:

- You can configure up to 32 IP addresses in this command.
- If the weight of the next hop is specified, you can configure up to four next-hop addresses.
- If **vrf** *vrf-name* is specified, packets are forwarded across VRF instances.
- If **global** is specified, packets are forwarded from the VRF instance to the public network.
- If [**vrf** *vrf-name* | **global**] is not specified, the VRF instance is inherited when the IPv6 packet is forwarded, that is, the next hop belongs to the VRF instance that receives the IPv6 packet.

When an egress of packets is selected based on policy-based routing and the routing table, the priorities are as follows:

set ipv6 next-hop > Common route (non-default route) > **set ipv6 default next-hop** > Default route.

Note

- This function does not take effect on network segments with the mask length exceeding 64.
- When you configure this command together with **set ipv6 next-hop verify-availability**, the next hop configured in **set ipv6 next-hop verify-availability** takes effect first.
- If you configure *weight* after any next-hop address, the operation mode of this **set** command is automatically changed to WCMP. In WCMP load balancing mode, the default value of *weight* is **1** if *weight* is not specified for the **next-hop** address.

Examples

The following example configures the route map **rm_if_0_0** to set the default next hop of traffic that matches IPv6 ACL **acl_for_pbr** (destination address: 2001:0db8:2001:1760::/64) to **2002:0db8:2003:1::95**, and applies the route map to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl_for_pbr
Hostname(config -ipv6-acl)# permit ipv6 any 2001:0db8:2001:1760::/64
Hostname(config)# route-map rm_if_0_0
Hostname(config-route-map)# match ipv6 address acl_for_pbr
Hostname(config-route-map)# set ipv6 default next-hop
2002:0db8:2003:1::95
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 policy route-map rm_if_0_0
```

1.49 set ipv6 next-hop

Function

Run the **set ipv6 next-hop** command to specify the next-hop IPv6 address for IPv6 packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no next-hop IPv6 address is specified for a matched route.

Syntax

set ipv6 next-hop { *ipv6-address* [*weight*] }&<1-32>

no set ipv6 next-hop [*ipv6-address* [*weight*]]&<1-32>

Parameter Description

{ *ipv6-address* [*weight*] }&<1-32>: &<1-32> indicates that you can enter the parameter up to 32 times in this command.

ipv6-address: Next-hop IPv6 address for packet forwarding. The next hop must be an adjacent device.

weight: Weight in load balancing mode. The value range is from 1 to 8.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration. This command supports two operation modes: WCMP load balancing mode and non-WCMP load balancing mode. In WCMP load balancing mode, the system performs WCMP load balancing on traffic based on the configured *weight*.

Restrictions and guidelines:

- You can configure up to 32 IP addresses in this command.
- If the weight of the next hop is specified, you can configure up to four next-hop addresses.
- If **vrf** *vrf-name* is specified, packets are forwarded across VRF instances.
- If **global** is specified, packets are forwarded from the VRF instance to the public network.
- If [**vrf** *vrf-name* | **global**] is not specified, the VRF instance is inherited when the IPv6 packet is forwarded, that is, the next hop belongs to the VRF instance that receives the IPv6 packet.

Note

If you configure *weight* after any next-hop address, the operation mode of this **set** command is automatically changed to WCMP. In WCMP load balancing mode, the default value of *weight* is **1** if *weight* is not specified for the **next-hop** address.

When an egress of packets is selected based on policy-based routing and the routing table, the priorities are as follows:

set ipv6 next-hop > **set ipv6 next-hop recursive >** Common route (non-default route) > **set ipv6 default next-hop** > Default route

Examples

The following example configures the route map **rm_if_0_0** to set the next-hop address of traffic that matches IPv6 ACL **acl_for_pbr** (destination address: 2001:0db8:2001:1760::/64) to **2002:0db8:2003:1::95**, and applies the route map to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl_for_pbr
Hostname(config -ipv6-acl)# permit ipv6 any 2001:0db8:2001:1760::/64
Hostname(config)# route-map rm_if_0_0
Hostname(config-route-map)# match ip address acl_for_pbr
Hostname(config-route-map)# set ipv6 next-hop 2002:0db8:2003:1::95
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 policy route-map rm_if_0_0
```

1.50 set ipv6 next-hop recursive

Function

Run the **set ipv6 next-hop recursive** command to specify the recursive next-hop IPv6 address for packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no recursive next-hop IPv6 address is specified for matched packets.

Syntax

set ipv6 next-hop recursive *ipv6-address*

no set ipv6 next-hop recursive

Parameter Description

ipv6-address: Recursive next-hop IPv6 address.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration. You can configure only one such **set** command in a route map policy.

The recursive next-hop IPv6 addresses can be recursively sought in static or dynamic routes that have an outbound interface and a next-hop IPv6 address. Recursion can be performed up to 32 times. If the recursive next-hop IPv6 address is sought in a static route, recursion can be performed only once.

Examples

The following example configures the route map **rm_if_0_0** to set the recursive next-hop address of traffic that matches IPv6 ACL **acl_for_pbr** (destination address: 2001:0db8:2001:1760::/64) to **2002:0db8:2003:1::95**, and applies the route map to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl_for_pbr
Hostname(config -ipv6-acl)# permit ipv6 any 2001:0db8:2001:1760::/64
Hostname(config)# route-map rm_if_0_0
Hostname(config-route-map)# match ip address acl_for_pbr
Hostname(config-route-map)# set ipv6 next-hop recursive 2002:0db8:2003:1::95
Hostname(config)# interface GigabitEthernet 0/1

1.53 set ipv6 next-hop verify-availability

Function

Run the **set ipv6 next-hop verify-availability** command to verify availability of the next-hop IPv6 address.

Run the **no** form of this command to remove this configuration.

By default, availability of the next-hop IPv6 address is not verified for matched packets.

Syntax

set ipv6 next-hop verify-availability *ipv6-address* [*weight*] **bfd** *interface-type interface-number gateway*

no set ip next-hop verify-availability *ipv6-address* [*weight*] **bfd** *interface-type interface-number gateway*

Parameter Description

ipv6-address: IPv6 address of the next hop.

weight: Weight in load balancing mode. The value range is from 1 to 8.

bfd: Specifies that BFD is used for neighbor detection.

interface-type: Interface type.

interface-number: Interface number.

gateway: IPv6 address of the gateway, that is, the IPv6 address of the BFD neighbor. If the next hop is set to the neighbor, BFD is used to detect availability of the forwarding path.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration to verify availability of the next-hop IPv6 address.

Examples

The following example configures a route map to associate with BFD, and uses BFD to verify availability of 2001:1::2, which is the next hop of the forwarding path.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map rmap permit 10
Hostname(config-route-map)# set ipv6 next-hop verify-availability 2001:1::2 bfd
GigabitEthernet 0/1 2001:1::2
```

1.54 set ipv6 precedence

Function

Run the **set ipv6 precedence** command to configure the priority of the IPv6 header for packets that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no IPv6 header priority is configured for matched packets.

Syntax

set ipv6 precedence { *precedence-number* | **critical** | **flash** | **flash-override** | **immediate** | **internet** | **network** | **priority** | **routine** }

no set ipv6 precedence

Parameter Description

precedence-number: Priority of an IP header indicated by a number. The value range is from 0 to 7.

7: critical

6: flash

5: flash-override

4: immediate

3: internet

2: network

1: priority

0: routine

critical | **flash** | **flash-override** | **immediate** | **internet** | **network** | **priority** | **routine**: Specifies the priority of an IP header.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

The priority of the IPv6 packet header is often configured so that IP packets are routed based on different priorities during PBR.

You can configure multiple **set ipv6 precedence** commands in a route map policy, but only the last command takes effect, and a priority is specified for the header of a matched IP packet during PBR.

Examples

The following example configures a route map to change the priority of IPv6 packet headers to **3**.

```
Hostname(config)#route-map pbr-aaa permit 10
Hostname(config-route-map)# set ipv6 precedence 3
```

The following example configures a route map to change the priority of IPv6 packet headers to **immediate**.

```
Hostname(config-route-map)# set ipv6 precedence immediate
```

1.56 set level

Function

Run the **set level** command to specify the type of the destination area to which routes that match the rules will be advertised.

Run the **no** form of this command to remove this configuration.

By default, the type of the destination area is not specified for matched routes.

Syntax

set level { **level-1** | **level-1-2** | **level-2** | **stub-area** | **backbone** }

no set level

Parameter Description

level-1: Advertises redistributed routes to an IS-IS level-1 area.

level-2: Advertises redistributed routes to an IS-IS level-2 area.

level-1-2: Advertises redistributed routes to IS-IS level-1 and level-2 areas.

stub-area: Advertises redistributed routes to an OSPF stub area.

backbone: Advertises redistributed routes to the OSPF backbone area.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

When routes are redistributed to the OSPF network or IS-IS hierarchical network, this command is used to configure the type of the area to which the redistributed routes are to be advertised.

Examples

The following example configures the route map **redrip** to set the type of the destination area, to which the redistributed routes are to be advertised, to the backbone area, and redistribute RIP routes to the OSPF backbone area.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# set level backbone

1.57 set local-preference

Function

Run the **set local-preference** command to configure the LOCAL_PREFERENCE value for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no LOCAL_PREFERENCE value is configured for matched routes.

Syntax

set local-preference *precedence-number*

no set local-preference

Parameter Description

precedence-number: LOCAL_PREFERENCE value indicated by a number. The value range is from 0 to 4294967295.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the local priority for matched routes. You can configure only one LOCAL_PREFERENCE value.

Examples

The following example configures a route map to set LOCAL_PREFERENCE of routes that match ACL 1 to a high priority **6800** in the policy with the sequence number of 10, and set LOCAL_PREFERENCE of routes that match ACL 2 to a low priority **50** in the policy with the sequence number of 20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map SET_PREF permit 10
Hostname(config-route-map)# match as-path 1
Hostname(config-route-map)# set local-preference 6800
Hostname(config-route-map)# exit
```

```
Hostname(config)# route-map SET_PREF permit 20
Hostname(config-route-map)# match as-path 2
Hostname(config-route-map)# set local-preference 50
```

1.58 set metric

Function

Run the **set metric** command to configure the metric value for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, the metric of a matched route is not modified.

Syntax

set metric { **+** *metric-value* | **-** *metric-value* | *metric-value* }

no set metric

Parameter Description

+: Increases the metric (on the basis of the metric value of the original route).

-: Decreases the metric (on the basis of the metric value of the original route).

metric-value: Metric value of a redistributed route. The value range is from 0 to 4294967295.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

The route metric affects route selection. Therefore, configure it carefully based on the actual network topology. Pay attention to the upper and lower limits of the metric in each routing protocol when configuring, increasing, or decreasing the metric. For example, when routes of other protocols are redistributed to RIP, the metric falls within the range of 1 to 16 after metric increase/decrease.

Examples

The following example configures the route map **redrip** to set the initial route metric to 40 and change the metric based on the route map **redrip** when RIP routes are redistributed to OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# set metric 40
```

1.59 set metric-type

Function

Run the **set metric-type** command to configure the metric type for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, the metric type of a matched route is not modified.

Syntax

set metric-type { **external** | **internal** | **type-1** | **type-2** }

no set metric-type

Parameter Description

external: Specifies the external route type of OSPF.

internal: Specifies the internal route type of OSPF.

type-1: Specifies external OE1 route type of OSPF.

type-2: Specifies the external OE2 route type of OSPF.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to modify the OSPF route type. You can use it for route redistribution or PBR.

Examples

The following example configures the route map **redrip** to set the route type to **type-1**, and change the route type based on the route map **redrip** when RIP routes are redistributed to OSPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# set metric-type type-1
```

1.60 set next-hop

Function

Run the **set next-hop** command to specify the next-hop IP address for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no next-hop IP address is specified for matched routes.

Syntax

set next-hop *ipv4-address*

no set next-hop

Parameter Description

ipv4-address: IPv4 address of the next hop.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used only for PBR configuration. You can use it to flexibly adjust the next hop of a route based on the matching conditions.

Examples

The following example configures the route map **redrip** to set the next hop of routes that match ACL 1 to 192.168.1.2

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# match ip address 1
Hostname(config-route-map)# set next-hop 192.168.1.2
```

Notifications

If the configured IP address is an invalid host address (valid host addresses include class A addresses except those starting with 0 or 127, class B addresses, and class C addresses), the following notification will be displayed:

```
% Can't set invalid nexthop address!

1.61 set next-hop self

Function

Run the **set next-hop self** command to set the next hop to the device itself for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, the next hop is not set to the device itself for matched routes.

Syntax

set next-hop self

no set next-hop self

Parameter Description

N/A

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure a route map to associate with BGP, and set the next hops of routes to be sent to the device itself.

Examples

The following example configures the route map **abc** to set the next hop of a BGP route to the device itself, and applies the route map **abc** when BGP 65000 advertises routes to the neighbor 1.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#route-map abc
Hostname(config-route-map)#set next-hop self
Hostname(config)#router bgp 65000
Hostname(config-router)#neighbor 1.1.1.1 route-map abc out
```

1.62 set next-hop unchanged

Function

Run the **set next-hop unchanged** command to set the next hop to keep unchanged for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no next hop is set to keep unchanged for matched routes. This command is used for route map management in BGP.

Syntax

set next-hop unchanged

no set next-hop unchanged

Parameter Description

N/A

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure a route map to associate with BGP, and set the next hops of routes to be sent to keep unchanged.

Examples

The following example configures the route map abc to set the next hop of a BGP route to keep unchanged, and applies the route map when BGP 1 advertises routes to the neighbor 1.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#route-map abc
Hostname(config-route-map)#set next-hop unchanged
Hostname(config)#router bgp 1
Hostname(config-router)#neighbor 1.1.1.1 route-map abc out
```

1.63 set origin

Function

Run the **set origin** command to specify the source for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no route source is specified for matched routes.

Syntax

set origin { **egp** | **igp** | **incomplete** }

no set origin

Parameter Description

egp: Specifies that the source is the remote EGP.

igp: Specifies that the source is the local IGP.

incomplete: Specifies that the route source is unknown.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the source for a matched route. You can configure only one route source.

Examples

The following example configures the route map **SET_ORIGIN** to set the route source to **igp** for routes that match ACL 1 in the policy with the sequence number of 10, and set the route source to **egp** for routes that match ACL 2 in the policy with the sequence number of 20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map SET_ORIGIN 10 permit
Hostname(config-route-map)# match as-path 1
Hostname(config-route-map)# set origin igp
Hostname(config-route-map)# exit
Hostname(config)# route-map SET_ORIGIN 20 permit
Hostname(config-route-map)# match as-path 2
Hostname(config-route-map)# set origin egp
```

1.64 set originator-id

Function

Run the **set originator-id** command to specify the originator address for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no route originator address is configured for matched routes.

Syntax

set originator-id *ipv4-address*

no set originator-id [*ipv4-address*]

Parameter Description

ipv4-address: Address of the originator.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the originator address for a matched route.

Examples

The following example configures the route map **SET_ORIGIN** to set the originator address to **5.5.5.5** for routes that match ACL 1 in the policy with the sequence number of 10 and set the originator address to **5.5.5.6** for routes that match ACL 2 in the policy with the sequence number of 20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map SET_ORIGIN 10 permit
Hostname(config-route-map)# match as-path 1
Hostname(config-route-map)# set originator-id 5.5.5.5
Hostname(config-route-map)# exit
Hostname(config)# route-map SET_ORIGIN 20 permit
Hostname(config-route-map)# match as-path 2
Hostname(config-route-map)# set originator-id 5.5.5.6
```

1.65 set qos-id

Function

Run the **set qos-id** command to specify the QoS ID for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no QoS ID is specified for matched routes.

Syntax

set qos-id *qos-id*

no set qos-id

Parameter Description

qos-id: QoS ID of a route. The value range is from 1 to 255.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used for PBR configuration in BGP to set the QoS ID for routes.

This command supports only one parameter (QoS ID), and does not support the configuration of multiple QoS IDs.

Examples

The following example sets the QoS ID of routes that match the rules to **1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# route-map test
Hostname(config-route-map)# set qos-id 1
```

1.66 set tag

Function

Run the **set tag** command to configure the tag for routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no route tag is configured for matched routes.

Syntax

set tag *tag*

no set tag

Parameter Description

tag: Tag of a redistributed route. The value range is from 0 to 4294967295.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is applicable only to route redistribution. If this command is not configured, the original route tag is retained.

Examples

The following example configures the route map **redip** to set the tag to **100** for routes that match the rules, configure OSPF to redistribute RIP routes based on the route map **redip**, and set the tag of redistributed routes to **100**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router ospf
Hostname(config-router)# redistribute rip subnets route-map redrip
Hostname(config-router)# network 192.168.12.0 0.0.0.255 area 0
Hostname(config-router)# exit
Hostname(config)# route-map redrip permit 10
Hostname(config-route-map)# set tag 100
```

1.67 set weight

Function

Run the **set weight** command to configure the weight for BGP routes that match the rules.

Run the **no** form of this command to remove this configuration.

By default, no weight is configured for matched routes.

Syntax

set weight *weight-number*

no set weight

Parameter Description

weight-number: Weight of a route. The value range is from 0 to 65535.

Command Modes

Route map configuration mode

Default Level

14

Usage Guidelines

This command is only used to modify the weight of a BGP route.

By default, the weight of a route received from a neighbor is obtained based on the configuration of **neighbor weight**, and the weight of a local route is always 32768.

You can run this command to modify the default weight allocated by BGP.

Examples

The following example configures the route map **nei-rmap-in** to set the weight to **100** for BGP routes that match the rules, and applies this route map when routes sent from the BGP neighbor 1.1.1.1 are received.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# router bgp 1
Hostname(config-router)# neighbor 1.1.1.1 route-map nei-rmap-in in
Hostname(config-router)# exit
Hostname(config)# route-map nei-rmap-in permit 10
Hostname(config-route-map)# set weight 100
```

1.68 show ip as-path-access-list

Function

Run the **show ip as-path-access-list** command to display the AS-path list information.

Syntax

show ip as-path-access-list [*as-path-access-list-num*]

Parameter Description

as-path-access-list-num: Number of an AS-path list. The value range is from 1 to 500.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the AS-path list information.

Examples

The following example displays the information about all AS path lists.

```
Hostname> enable
Hostname# show ip as-path-access-list
AS path access list 30

1.69 show ip community-list

Function

Run the **show ip community-list** command to display the community list information.

Syntax

show ip community-list [*community-list-number* | *community-list-name*]

Parameter Description

community-list-number: Number of a community list to be displayed. For a standard community list, the range is from 1 to 99. For an expanded community list, the range is from 100 to 199.

community-list-name: Name of a community list to be displayed.

It is a string of less than 80 characters.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the community list information.

Examples

The following example displays the information about all community lists.

```
Hostname> enable
Hostname# show ip community-list
Community-list standard local
permit local-AS
Community-list standard Red-Giant
permit 0:10
deny 0:20
```

Table 1-2 Output Fields of the show ip community-list Command

1.71 show ip prefix-list

Function

Run the **show ip prefix-list** command to display the information about a prefix list or prefix list entries.

Syntax

show ip prefix-list [*prefix-name*]

Parameter Description

prefix-name: Name of a prefix list.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no prefix list name is specified, the configurations of all prefix lists are displayed. Otherwise, only configurations of the specified prefix list are displayed.

Examples

The following example displays the information of all IPv4 prefix lists.

```
Hostname> enable
Hostname# show ip prefix-list
ip prefix-list pre: 2 entries
seq 5 permit 192.168.64.0/24
seq 10 permit 192.2.2.0/24
```

Table 1-4 Output Fields of the show ip prefix-list Command

Field	Description
ip prefix-list pre	Name of an IPv4 prefix list
2 entries	Number of rules in the prefix list
seq 5	Sequence number of a filtering rule
permit	Mode of a filtering rule
192.168.64.0/24	IPv4 route prefix

1.72 show ip protocols

Function

Run the **show ip protocols** command to display the status information of the IPv4 routing protocols that are currently running.

Syntax

show ip protocols [**vrf** *vrf-name*] [**bgp** | **isis** | **ospf** | **rip**]

Parameter Description

vrf *vrf-name*: Specifies the name of a VRF instance. If this parameter is not specified, the status information of running routing protocols in the global VRF instance is displayed.

bgp: Displays status information of the BGP protocol.

isis: Displays status information of the ISIS protocol.

ospf: Displays status information of the OSPF protocol.

rip: Displays status information of the RIP protocol.

If no keyword is configured after **protocols**, the status information of all running routing protocols is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

Only the status information of running routing protocols is displayed, and that of disabled routing protocols is not displayed.

Examples

The following example displays the status information of running routing protocols in the global VRF instance.

```
Hostname> enable
Hostname# show ip protocols
Routing Protocol is "ospf 1"
  Outgoing update filter list for all interfaces is not set
  Incoming update filter list for all interfaces is not set
  Router ID 57.57.57.57
  Memory Overflow is enabled
  Router is not in overflow state now
  It is an autonomous system boundary router
  Redistributing External Routes from,
    connected, includes subnets in redistribution
    bgp, includes subnets in redistribution
  Number of areas in this router is 2: 2 normal 0 stub 0 nssa
  Routing for Networks:
    57.57.57.57 0.0.0.0 area 0
    163.18.4.0 0.0.0.255 area 0

```

Table 1-5 Output Fields of the show ip protocols Command

Field	Description
Routing Protocol is "ospf 1"	Name of a routing protocol
Redistributing External Routes from	Route redistribution status of the routing protocol
Distance:	Distance of the routing protocol
Router ID	Unique ID of the device
Memory Overflow	Whether the memory overflow alarm function is enabled
Number of areas in this router	Number of areas where the routing protocol is applied
Routing for Networks	Area distribution of interfaces where the current routing protocol is applied
Reference bandwidth unit	Reference bandwidth unit of the interface cost
IGP synchronization	IGP synchronization function
Default-information originate	Allows the BGP speaker to advertise the default route to the peer group.
Default local-preference applied to incoming route	Default local-preference value
Redistributing	Route redistribution type
Neighbor(s)	BGP neighbor list
Address	Address of a BGP neighbor
AddressFamily	Address family of a BGP neighbor
FiltIn	AS filtering in the inbound direction
FiltOut	AS filtering in the outbound direction
DistIn	ACL filtering in the inbound direction
DistOut	ACL filtering in the outbound direction
RouteMapIn	Routing policy in the inbound direction
RouteMapOut	Routing policy in the outbound direction

1.73 show ipv6 prefix-list

Function

Run the **show ipv6 prefix-list** command to display the information about an IPv6 prefix list or prefix list entries.

Syntax

show ipv6 prefix-list [*prefix-name*]

Parameter Description

prefix-name: Name of an IPv6 prefix list.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no prefix list name is specified, the configurations of all prefix lists are displayed. Otherwise, only configurations of the specified prefix list are displayed.

Examples

The following example displays the information about all IPv6 prefix lists.

```
Hostname> enable
Hostname# show ipv6 prefix-list
ipv6 prefix-list p6: 2 entries
     seq 5 permit 13::/20
     seq 10 permit 14::/20
```

Table 1-6 Output Fields of the show ipv6 prefix-list Command

Field	Description
ipv6 prefix-list p6	Name of an IPv6 prefix list

1.74 show route-map

Function

Run the **show route-map** command to display the route map configurations.

Syntax

show route-map [*route-map-name*]

Parameter Description

route-map-name: Name of a route map to be displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no route map name is specified, the configurations of all route maps are displayed. Otherwise, only configurations of the specified route map are displayed.

Examples

The following example displays the route map information.

```
Hostname> enable
Hostname# show route-map
route-map AAA, permit, sequence 10
Match clauses:
ip address 2
Set clauses:
metric 10
```

Table 1-7 Output Fields of the show route-map Command

Field	Description
route-map	Name of a route map
permit	Permit keyword contained in a route map policy
sequence 10	Sequence number of a route map policy
match clauses	Match rule. Whether the **set** operation is performed depends on the **permit** or **deny** keyword in the route map policy.
set clauses	Processing action to be performed after the match rule is matched.

clear ip pbr statistics	Clear the statistics about packets forwarded by the IPv4 Policy-Based Routing (PBR).
clear ipv6 pbr statistics	Clear the statistics about packets forwarded by the IPv6 PBR.
ip local policy route-map	Apply PBR to packets sent by the local device.
ip policy	Configure redundant backup or load balancing among multiple next hops for PBR.
ip policy route-map	Apply PBR to an interface.
ip policy-source in-interface	Apply source-address-based PBR to IPv4 packets received by a specified interface.
ipv6 local policy route-map	Apply PBR to IPv6 packets sent by the local device.
ipv6 policy	Configure redundant backup or load balancing among multiple next hops for PBR.
ipv6 policy route-map	Apply the IPv6 PBR to an interface.
ipv6 policy-source in-interface	Apply source-address-based PBR to IPv6 packets received by a specified interface.
show ip pbr bfd	Display the correlation between the IPv4 PBR and BFD.
show ip pbr route	Display the IPv4 PBR applied to an interface.
show ip pbr route-map	Display the route map information of IPv4 PBR.
show ip pbr source-route	Display the routing information of the source-address-based IPv4 PBR.
show ip pbr statistics	Display the statistics about packets forwarded by the IPv4 PBR.
show ip policy	Display interfaces for which the PBR is configured and the name of the route map applied to each interface.
show ipv6 pbr bfd	Display the correlation between the IPv6 PBR and BFD.

show ipv6 pbr route	Display the IPv6 PBR applied to an interface.
show ipv6 pbr route-map	Display the route map information of IPv6 PBR.
show ipv6 pbr source-route	Display the routing information of the source-address-based IPv6 PBR.
show ipv6 pbr statistics	Display the statistics about packets forwarded by the IPv6 PBR.
show ipv6 policy	Display interfaces for which the IPv6 PBR is configured and the name of the route map applied to each interface.

1.1 clear ip pbr statistics

Function

Run the **clear ip pbr statistics** command to clear the statistics about packets forwarded by the IPv4 Policy-Based Routing (PBR).

Syntax

clear ip pbr statistics [**interface** *interface-type interface-number* | **local**]

Parameter Description

interface *interface-type interface-number*: Clears the statistics about packets forwarded by the IPv4 PBR on the specified interface. If optional parameters are not specified, the statistics about packets forwarded by all interfaces to which the IPv4 PBR applies is cleared.

local: Clears the statistics about packets forwarded by the IPv4 PBR on a local interface.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

You can run this command to clear the statistics about packets forwarded by the IPv4 PBR.

Examples

The following example clears the statistics about packets forwarded by the IPv4 PBR.

```
Hostname# enable
Hostname# clear ip pbr statistics
```

1.2 clear ipv6 pbr statistics

Function

Run the **clear ipv6 pbr statistics** command to clear the statistics about packets forwarded by the IPv6 PBR.

Syntax

clear ipv6 pbr statistics [**interface** *interface-type interface-number* | **local**]

Parameter Description

interface *interface-type interface-number*: Clears the statistics about packets forwarded by the IPv6 PBR on the specified interface. If optional parameters are not specified, the statistics about packets forwarded by all interfaces to which the IPv6 PBR applies is cleared.

local: Clears the statistics about packets forwarded by the IPv6 PBR on a local interface.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

You can run this command to clear the statistics about packets forwarded by the IPv6 PBR.

Examples

The following example clears the statistics about packets forwarded by the IPv6 PBR.

```
Hostname> enable
Hostname# clear ipv6 pbr statistics
```

1.3 ip local policy route-map

Function

Run the **ip local policy route-map** command to apply PBR to packets sent by the local device.

Run the **no** form of this command to remove this configuration.

By default, no PBR is applied to the local device.

Syntax

ip local policy route-map *route-map-name*

no ip local policy route-map

Parameter Description

route-map-name: Name of the route map.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command enables PBR for only IP packets that are sent by the local device and match the policy. It is not applicable to IP packets received by the local device.

To apply PBR, you must specify a route map for PBR, and create this map. A route map consists of multiple policies, and one or more match rules and relevant actions are defined for each policy. After PBR is applied to an interface, all packets received by the interface are checked. Packets that do not match any policy in the route map are routed and forwarded as usual. Packets that match a policy in the route map are processed based on the action defined in the policy.

Examples

The following example routes all packets from the source address 192.168.217.10 through the GigabitEthernet 0/1 interface.

(1) Step 1: Configure ACL 1 to match packets with the source IP address 192.168.217.10.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit host 192.168.217.10
```

(2) Step 2: Configure the route map **lab1**, and send packets that matches ACL 1 from the GigabitEthernet 0/1 interface.

```
Hostname(config)# route-map lab1 permit 10
Hostname(config-route-map)# match ip address 1
Hostname(config-route-map)# set interface GigabitEthernet 0/1
Hostname(config-route-map)# exit
```

(3) Step 3: Apply PBR to packets sent by the local device.

```
Hostname(config)# ip local policy route-map lab1
```

1.4 ip policy

Function

Run the **ip policy** command to configure redundant backup or load balancing among multiple next hops for PBR.

Run the **no** form of this command to restore the forwarding mode of PBR.

By default, multiple next hops of the PBR adopt the redundant backup mode.

Syntax

ip policy { load-balance | redundance }

no ip policy

Parameter Description

load-balance: Adopts load balancing.

redundance: Adopts redundant backup.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run the **set ip next-hop** command to configure multiple next hops. The next-hop selection policy configured by this command is redundant backup or load balancing. When redundant backup is configured, only the first parsed next hop of PBR takes effect. When load balancing is configured, multiple parsed next hops of PBR take effect. You can configure up to 8 next hops in the case of Weighted Cost Multiple Path (WCMP), or 32 next hops in the case of Equal Cost Multiple Path (ECMP).

Caution

The next hop refers to the next hop of which the MAC address is learned.

Examples

The following example configures multiple next hops in the route map and sets the redundant backup mode in global configuration mode so that only the first next hop takes effect after PBR is applied to GigabitEthernet 0/1.

(1) Step 1: Configure ACL 1 to match the traffic from the IP address 10.0.0.1, and ACL 2 to match the traffic from the IP address 20.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit host 10.0.0.1
Hostname(config)# access-list 2 permit host 20.0.0.1
```

(2) Step 2: Configure the sequence number 10 for the route map **lab1**, and set multiple next hops for traffic that matches ACL 1. Configure the sequence number 20 for the route map **lab1**, and set multiple next hops for traffic that matches ACL 2.

```
Hostname(config)# route-map lab1 permit 10
Hostname(config-route-map)# match ip address 1
Hostname(config-route-map)# set ip next-hop 196.168.4.6
Hostname(config-route-map)# set ip next-hop 196.168.4.7
Hostname(config-route-map)# set ip next-hop 196.168.4.8
Hostname(config-route-map)# exit
Hostname(config)# route-map lab1 permit 20
Hostname(config-route-map)# match ip address 2
Hostname(config-route-map)# set ip next-hop 196.168.5.6
Hostname(config-route-map)# set ip next-hop 196.168.5.7
Hostname(config-route-map)# set ip next-hop 196.168.5.8
Hostname(config-route-map)# exit
```

(3) Step 3: Apply PBR to the interface, and configure the redundant backup mode.

```
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if)# ip policy route-map lab1
Hostname(config-if)# exit
Hostname(config)# ip policy redundance
```

1.5 ip policy route-map

Function

Run the **ip policy route-map** command to apply PBR to an interface.

Run the **no** form of this command to remove this configuration.

By default, no PBR is configured on an interface.

Syntax

ip policy route-map *route-map*

no ip policy route-map

Parameter Description

route-map: Name of the route map.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

PBR must be applied to a specified interface and to only packets received by this interface. You can configure only one route map for an interface on a device. If you configure multiple route maps for the same interface, the latest route map overwrites the previous route maps.

To apply PBR, you must specify a route map for PBR, and create this map. A route map consists of multiple policies, and one or more match rules and relevant actions are defined for each policy. After PBR is applied to an interface, all packets received by the interface are checked. Packets that do not match any policy in the route map are routed and forwarded as usual. Packets that match a policy in the route map are processed based on the action defined in the policy.

Examples

The following example configures PBR for packets received by GigabitEthernet 0/0, sets the next hop of packets with the source address 10.0.0.1 to **196.168.4.6** and the next hop of packets with the source address 20.0.0.1 to **196.168.5.6**; otherwise, packets are normally forwarded.

(1) Step 1: Configure ACL 1 to match the traffic from the IP address 10.0.0.1, and ACL 2 to match the traffic from the IP address 20.0.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit host 10.0.0.1
Hostname(config)# access-list 2 permit host 20.0.0.1
```

(2) Step 2: Configure the sequence number 10 for the route map **lab1**, and set the next hop of traffic that matches ACL 1 to **196.168.4.6**. Configure the sequence number 20 for route map **lab1**, and set the next hop of traffic that matches ACL 2 to **196.168.5.6**.

```
Hostname(config)# route-map lab1 permit 10
Hostname (config-route-map)# match ip address 1
Hostname(config-route-map)# set ip next-hop 196.168.4.6
Hostname(config-route-map)# exit
Hostname(config)# route-map lab1 permit 20
Hostname(config-route-map)# match ip address 2
Hostname(config-route-map)# set ip next-hop 196.168.5.6
Hostname(config-route-map)# exit
```

(3) Step 3: Apply PBR to the interface.

```
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if)# ip policy route-map lab1
Hostname(config-if)# exit
```

1.6 ip policy-source in-interface

Function

Run the **ip policy-source in-interface** command to apply source-address-based PBR to IPv4 packets received by a specified interface.

Run the **no** form of this command to remove this configuration.

By default, no source-address-based PBR takes effect on an interface.

Syntax

ip policy-source in-interface *interface-type interface-number sequence* { *source-address mask* | *source-address/mask* } { [**default**] **next-hop** [*ipv4-address* [*weight*]]&<1-4> | [**default**] **interface** { *out-interface-type out-interface-number* }&<1-4> }

no ip policy-source in-interface *interface-type sequence* [{ *source-address mask* | *source-address/mask* } [[**default**] **next-hop** [*ipv4-address* [*weight*]]&<1-4> | [**default**] **interface** { *out-interface-type out-interface-number* } &<1-4>]]

Parameter Description

interface-type interface-number: Type and number of the interface to which source-address-based PBR is applied.

sequence: Sequence number of a policy. A smaller sequence number indicates a higher priority.

source-address: IPv4 address.

mask: Mask of the IPv4 address.

default: If this parameter is configured, the system preferentially uses the route forwarding table to forward packets; otherwise, the system preferentially use PBR to forward packets.

next-hop [*ipv4-address* [*weight*]]&<1-4>: You can enter up to four next-hop IPv4 addresses and weight values.

ipv4-address: IPv4 address of the next hop.

weight: Weight of the next hop. The value range is from 1 to 8, and the default value is **1**.

interface *out-interface-type out-interface-number*: Output interface type and number of the next hop.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can specify multiple **ip policy-source in-interface** commands for the same interface. The sequence numbers of different source addresses must be different. A smaller sequence number indicates a higher priority of the source-address-based PBR.

If the sequence numbers are the same, the priorities of next hop types are as follows: **vrf** *vrf-name* > **next-hop** *ipv4-address* > **interface** *out-interface-type*> **default next-hop** *ipv4-address* > **default interface** *out-interface-type*.

The source-address-based PBR has a lower priority than the interface-based PBR. If the source-address-based PBR and the interface-based PBR are applied to the same interface, only the interface-based PBR takes effect.

Examples

The following example configures PBR for packets received by GigabitEthernet 0/0, sets the next hop of packets with the source address 10.0.0.2 to **196.168.1.2** and the next hop of packets with the source address 20.0.0.2 to **196.168.2.2**; otherwise, packets are normally forwarded.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip policy-source in-interface gigabitEthernet 0/0 1 10.0.0.2
255.255.255.255 next-hop 196.168.1.2
Hostname(config)# ip policy-source in-interface gigabitEthernet 0/0 2 20.0.0.2
255.255.255.255 next-hop 196.168.2.2
```

1.7 ipv6 local policy route-map

Function

Run the **ipv6 local policy route-map** command to apply PBR to IPv6 packets sent by the local device.

Run the **no** form of this command to disable this feature.

By default, no IPv6 PBR is applied to the local device.

Syntax

ipv6 local policy route-map *route-map-name*

no ipv6 local policy route-map

Parameter Description

route-map-name: Name of the route map applied to the local PBR. It is configured by the **route-map** command.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command enables PBR for only IPv6 packets (such as **ping** packets) that are sent by the local device and match the policy. It is not applicable to IPv6 packets received by the local device.

To apply PBR, you must specify a route map for PBR, and create this map. A route map consists of multiple policies, and one or more match rules and relevant actions are defined for each policy. After PBR is applied to an interface, all packets received by the interface are checked. Packets that do not match any policy in the route map are routed and forwarded as usual. Packets that match a policy in the route map are processed based on the action defined in the policy.

Examples

The following example applies PBR to a local device. Packets that are routed from 2003:1000::10/80 to 2001:100::/64 and match the ACL **aaa** are sent to the device 2003:1001::2.

(1) Configure the ACL **aaa** to match packets that are routed from 2003:1000::10/80 to 2001:100::/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list aaa
Hostname(config-ipv6-acl)# permit ipv6 2003:1000::10/80 2001:100::/64
Hostname(config-ipv6-acl )# exit
```

(2) Configure the route map **pbr-aaa**, and set the next hop of packets that match the ACL **aaa** to **2003:1001::2**.

```
Hostname(config)# route-map pbr-aaa permit 10
Hostname(config-route-map)# match ipv6 address aaa
Hostname(config-route-map)# set ipv6 next-hop 2003:1001::2
Hostname(config-route-map)# exit
```

(3) Apply PBR to the device.

```
Hostname(config)# ipv6 local policy route-map pbr-aaa
```

1.8 ipv6 policy

Function

Run the **ipv6 policy** command to configure redundant backup or load balancing among multiple next hops for PBR.

Run the **no** form of this command to restore the default configuration.

By default, multiple next hops of the IPv6 PBR adopt the redundant backup mode.

Syntax

ipv6 policy { load-balance | redundance }

no ipv6 policy

Parameter Description

load-balance: Adopts load balancing.

redundance: Adopts redundant backup.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run the **set ipv6 next-hop** command to configure multiple next hops. The next-hop selection policy configured by this command is redundant backup or load balancing. When redundant backup is configured, only the first parsed next hop of PBR takes effect. When load balancing is configured, multiple parsed next hops of PBR take effect. You can configure up to 8 next hops in the case of Weighted Cost Multiple Path (WCMP), or 32 next hops in the case of Equal Cost Multiple Path (ECMP).

Caution

The next hop refers to the next hop of which the MAC address is learned.

Examples

The following example configures the load balancing mode among multiple next hops.

(1) Configure ACL 1 to match the traffic from the IP address 1000::1, and ACL 2 to match the traffic from the IP address 2000::1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list 1
```

```
Hostname(config-ipv6-acl )# permit ipv6 1000::1 any
Hostname(config-ipv6-acl )# exit
Hostname(config)# ipv6 access-list 2
Hostname(config-ipv6-acl )# permit ipv6 2000::1 any
Hostname(config-ipv6-acl )# exit
```

(2) Configure the sequence number 10 for the route map **lab1**, and set multiple next hops for traffic that matches ACL 1. Configure the sequence number 20 for the route map **lab1**, and set multiple next hops for traffic that matches ACL 1.

```
Hostname(config)# route-map lab1 permit 10
Hostname(config-route-map)# match ipv6 address 1
Hostname(config-route-map)# set ipv6 next-hop 2002::1
Hostname(config-route-map)# set ipv6 next-hop 2002::2
Hostname(config-route-map)# set ipv6 next-hop 2002::3
Hostname(config-route-map)# exit
Hostname(config)# route-map lab1 permit 20
Hostname(config-route-map)# match ipv6 address 2
Hostname(config-route-map)# set ipv6 next-hop 2002::5
Hostname(config-route-map)# set ipv6 next-hop 2002::6
Hostname(config-route-map)# set ipv6 next-hop 2002::7
Hostname(config-route-map)# exit
```

(3) Apply PBR to the interface.

```
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if)# ipv6 policy route-map lab1
Hostname(config-if)# exit
Hostname(config)# ipv6 policy load-balance
```

1.9 ipv6 policy route-map

Function

Run the **ipv6 policy route-map** command to apply the IPv6 PBR to an interface.

Run the **no** form of this command to remove this configuration.

By default, no IPv6 PBR is configured on an interface.

Syntax

ipv6 policy route-map *route-map-name*

no ipv6 policy route-map

Parameter Description

route-map-name: Name of the route map, which is configured by the **route-map** command.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The IPv6 PBR applied to an interface takes effect on only IPv6 packets received by this interface. You can configure only one IPv6 route map for an interface on a device. If you configure multiple route maps for the same interface, the latest route map overwrites the previous route maps.

To apply PBR, you must specify a route map for PBR, and create this map. A route map consists of multiple policies, and one or more match rules and relevant actions are defined for each policy. After PBR is applied to an interface, all packets received by the interface are checked. Packets that do not match any policy in the route map are routed and forwarded as usual. Packets that match a policy in the route map are processed based on the action defined in the policy.

Rules in the route map used for the IPv6 PBR must be supported by IPv6; otherwise, these rules do not take effect.

Examples

The following example configures PBR for IPv6 packets received by GigabitEthernet 0/0, sets the next hop of packets with the source address 10::/64 to **2000:1** and the next hop of packets with the source address 20::/64 to **2000::2**; otherwise, packets are normally forwarded.

(1) Configure the ACL **acl_for pbr1** to match the traffic from the source address 10::/64, and the ACL **acl_for_pbr2** to match the traffic from the source address 20::/64.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# ipv6 access-list acl_for_pbr1
Hostname (config-ipv6-acl)# permit ipv6 10::/64  any
Hostname (config-ipv6-acl)# exit
Hostname(config)# ipv6 access-list acl_for_pbr2
Hostname (config-ipv6-acl)# permit ipv6 20::/64  any
Hostname (config-ipv6-acl)# exit
```

(2) Configure the sequence number 10 for the route map **rm_pbr**, and set the next hop of traffic that matches the ACL **acl_for_pbr1** to **2000::1**. Configure the sequence number 20 for the route map **rm_pbr** , and set the next hop of traffic that matches the ACL **acl_for_pbr2** to **2000::2**.

```
Hostname(config)# route-map rm_pbr  permit 10
Hostname (config-route-map)# match ipv6 address acl_for_pbr1
Hostname(config-route-map)# set ipv6 next-hop 2000::1
Hostname(config-route-map)# exit
Hostname(config)# route-map rm_pbr  permit 20
Hostname(config-route-map)# match ipv6 address acl_for_pbr2
Hostname(config-route-map)# set ipv6 next-hop 2000::2
Hostname(config-route-map)# exit
```

(3) Apply the route map to the interface.

```
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if)# no switchport
Hostname(config-if)# ipv6 policy route-map rm_pbr
```

1.10 ipv6 policy-source in-interface

Function

Run the **ipv6 policy-source in-interface** command to apply source-address-based PBR to IPv6 packets received by a specified interface.

Run the **no** form of this command to remove this configuration.

By default, no source-address-based IPv6 PBR takes effect on an interface.

Syntax

ipv6 policy-source in-interface *interface-type interface-number sequence source-address/prefix-length* { [**default**] **next-hop** [*ipv6-address* [*weight*]]&<1-4> | [**default**] **interface** *out-interface-type*&<1-4> }

no ipv6 policy-source in-interface *interface-type sequence* [*source-address/prefix-length* [[**default**] **next-hop** [*ipv6-address* [*weight*]]&<1-4> | [**default**] **interface** *out-interface-type*&<1-4>]]

Parameter Description

interface-type interface-number: Type and number of the interface to which source-address-based PBR is applied.

sequence: Sequence number of a policy. A smaller sequence number indicates a higher priority.

source-address: IPv6 address.

prefix-length: Prefix length of the IPv6 address.

default: If this parameter is configured, the system preferentially uses the route forwarding table to forward packets; otherwise, the system preferentially uses PBR to forward packets.

next-hop [*ipv6-address* [*weight*]]&<1-4>: You can enter up to four next-hop IPv6 addresses and weight values.

ipv6-address: IPv6 address of the next hop.

weight: Weight of the next hop. The value range is from 1 to 8, and the default value is **1**.

interface *out-interface-type*: Output interface type of the next hop.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can specify multiple **ipv6 policy-source in-interface** commands for the same interface. The sequence numbers of different source addresses must be different. A smaller sequence number indicates a higher priority of the source-address-based PBR.

If the sequence numbers are the same, the priorities of next hop types are as follows: **vrf** *vrf-name* > **next-hop** *ipv6-address* > **interface** *out-interface-type*> **default next-hop** *ipv6-address* > **default interface** *out-interface-type*.

The source-address-based PBR has a lower priority than the interface-based PBR. If the source-address-based PBR and the interface-based PBR are applied to the same interface, only the interface-based PBR takes effect.

Examples

The following example configures PBR for IPv6 packets received by GigabitEthernet 0/0, sets the next hop of packets with the source address 10::/64 to **2000:1** and the next hop of packets with the source address 20::/64 to **2000::2**; otherwise, packets are normally forwarded.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 policy-source in-interface gigabitEthernet 0/0 2 10::/64 next-hop
2000::1
Hostname(config)# ipv6 policy-source in-interface gigabitEthernet 0/0 2 20::/64 next-hop
2000::2
```

Table 1-2 Output Fields of the show ip pbr route Command

Field	Description
PBR IPv4 Route Summary	Number of IPv4 PBR entries.
Interface	Interface applying the PBR.
Sequence	Sequence number corresponding to the PBR.

Field	Description
ACL	ID of the ACL used in the matching rule.
ACL_CLS	Type of the ACL used in the matching rule, for example, the IP standard ACL.
Min Length	Minimum packet length set in the matching length
Max Length	Maximum packet length set in the matching length.
VRF ID	ID of the VRF correlated with the interface.
Route Flags	PBR flag.
Route Type	PBR type. The value **PBR** indicates a PBR route, and **Normal** indicates a common route.
Direct	PBR matching mode, which is **permit** or **deny**.
Priority	PBR priority, which is **High** or **Low**.
Tos_Dscp	Indicates whether to configure the ToS or DSCP rule.
Precedence	Indicates whether to configure the set ip precedence rule.
Mode	Configures the redundant backup or load balancing mode for the next hop.
Nexthop Count	Configures the number of next hops. Up to 32 next hops are configured for ECMP.
Nexthop	Configures the IPv4 address of the next hop.
Weight	Configures the weight value of the next hop.
Ifindex	Configures the index of the output interface corresponding to the next hop.

1.13 show ip pbr route-map

Function

Run the **show ip pbr route-map** command to display the route map information of IPv4 PBR.

Syntax

show ip pbr route-map *route-map-name*

Parameter Description

route-map-name: Name of the route map, which is configured by the **route-map** command.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the route map information of IPv4 PBR.

Examples

The following example displays the route map information of IPv4 PBR.

```
Hostname> enable
Hostname# show ip pbr route-map rm
Pbr VRF: GLOBAL, ID: 0
 Forward Mode: redundance
 Forwarding: On

route-map rm
  route-map index: sequence 10, permit
    Match rule:
      ACL ID :     0, ACL CLS: 0, Name: acl1
    Set rule:
      IPv4 Nexthop: 192.168.8.100, (VRF Name: , ID: 0), Weight: 0
      PBR state info ifx: GigabitEthernet 0/1, Connected: True, Track State: Up
```

Table 1-3 Output Fields of the show ip pbr route-map rm Command

Field	Description
Pbr VRF	Name and ID of the VRF.
Forward Mode	Configures the load balancing or redundant backup mode for the next hop.
Forwarding	Indicates whether to enable IP route forwarding.
Route-map index	Sequence number and type of the route submap.

Field	Description
Match rule	Matching rule.
Set rule	Set rule.
PBR state info	PBR private data, for example, the output interface and connection status of the next hop.

1.14 show ip pbr source-route

Function

Run the **show ip pbr source-route** command to display the routing information of the source-address-based IPv4 PBR.

Syntax

show ip pbr source-route [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Displays the IPv4 PBR applied to the specified interface. If optional parameters are not specified, all interfaces to which the IPv4 PBR is applied are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the configured source-address-based PBR.

Examples

The following example displays the routing information of the source-address-based IPv4 PBR.

```
Hostname> enable
Hostname# show ip pbr source-route
```

```
PBR IPv4 Source Route
Interface       : GigabitEthernet 0/1
  Sequence      : 10
  Source address : 10.1.1.1/24
  VRF ID        : 0
  Route Flags    :
   Route Type    : PBR
   Direct       : Permit
   Priority     : High
   Match_ipaddr  : Exist
  Mode          : redundance
  Nexthop Count  : 1
   Nexthop[0]   : 192.168.8.100
   Weight[0]    : 1
   Ifindex[0]   : 2
```

Table 1-4 Output Fields of the show ip pbr source-route Command

Field	Description
Interface	Interface applying the PBR.
Sequence	Sequence number corresponding to the PBR.
VRF ID	ID of the VRF correlated with the interface.
Route Flags	PBR flag.
Route Type	PBR type. The value **PBR** indicates a PBR route, and **Normal** indicates a common route.
Direct	PBR matching mode, which is **permit** or **deny**.
Priority	PBR priority, which is **High** or **Low**.
Mode	Configures the redundant backup or load balancing mode for the next hop.
Nexthop Count	Configures the number of next hops. Up to 32 next hops are configured for ECMP.
Nexthop	Configures the IPv4 address of the next hop.
Weight	Configures the weight value of the next hop.
Ifindex	Configures the index of the output interface corresponding to the next hop.

1.15 show ip pbr statistics

Function

Run the **show ip pbr statistics** command to display the statistics about packets forwarded by the IPv4 PBR.

Syntax

show ip pbr statistics [**interface** *interface-type interface-number* | **local**]

Parameter Description

interface *interface-type interface-number*: Displays the IPv4 PBR applied to the specified interface. If optional parameters are not specified, all interfaces to which the IPv4 PBR is applied are displayed.

local: Displays the IPv4 PBR applied to a local interface.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the statistics about packets forwarded by the IPv4 PBR.

Examples

The following example displays the statistics about packets forwarded by the IPv4 PBR.

```
Hostname> enable
Hostname# show ip pbr statistics
IPv4 Policy-based route statistic
 gigabitEthernet 0/1
   statistics : 10
```

1.16 show ip policy

Function

Run the **show ip policy** command to display interfaces for which the PBR is configured and the name of the route map applied to each interface.

Syntax

show ip policy [*route-map-name*]

Parameter Description

route-map-name: The interfaces applying the route map specified by this parameter. If optional parameters are not specified, all interfaces configured with the PBR are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the PBR configured in the current system.

Examples

The following example displays all the interfaces for which the PBR is configured and the name of the route map applied to each interface.

```
Hostname> enable
```

```
Hostname# show ip policy
Banlance Mode: redundance
Interface            Route map
local               test
GigabitEthernet 0/0    test
```

1.17 show ipv6 pbr bfd

Function

Run the **show IPv6 pbr bfd** command to display the correlation between the IPv6 PBR and BFD.

Syntax

show ipv6 pbr bfd

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the correlation between the IPv6 PBR and BFD.

Examples

The following example displays the correlation between the IPv6 PBR and BFD.

```
Hostname> enable
Hostname# show ipv6 pbr bfd
VRF ID  Ifindex  Host                                  State  Refcnt
    0       13  2000::2                                Up       1
```

Table 1-7 Output Fields of the show ipv6 pbr bfd Command

Field	Description
VRF ID	VRF of the interface carrying the BFD neighbor correlated with PBR
Ifindex	Index of the interface carrying the BFD neighbor correlated with PBR
Host	IPv6 address of the peer
State	Up or down state of the BFD neighbor correlated with PBR
Refcnt	Neighbor reference count

1.18 show ipv6 pbr route

Function

Run the **show IPv6 pbr route** command to display the IPv6 PBR applied to an interface.

Syntax

show ipv6 pbr route [**interface** *interface-type interface-number* | **local**]

Parameter Description

interface *interface-type interface-number*: Displays the IPv6 PBR applied to the specified interface. If optional parameters are not specified, all interfaces to which the IPv6 PBR is applied are displayed.

local: Displays the IPv6 PBR applied to a local interface.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the PBR configured for an interface.

Examples

The following example displays the IPv6 PBR applied to an interface.

```
Hostname> enable
Hostname# show ipv6 pbr route
PBR IPv6 Route Summary : 1
Interface       : GigabitEthernet 0/2
  Sequence      : 10
  ACL[0]       : 2901
ACL_CLS[0]    : 0
  Min Length    : None
  Max Length    : None
  VRF ID        : 0
  Route Flags    :
   Route Type    : PBR
   Direct       : Permit
   Priority     : High
   Tos_Dscp     : None
   Precedence    : None
  Tos_Dscp      : 0

  Nexthop Count  : 1
   Nexthop[0]   : 10::1
   Weight[0]    : 1
   Ifindex[0]   : 3
```

Table 1-8 Output Fields of the show ipv6 pbr route Command

Field	Description
PBR IPv4 Route Summary	Number of IPv4 PBR entries.

Field	Description
Interface	Interface applying the PBR.
Sequence	Sequence number corresponding to the PBR.
ACL	ID of the ACL used in the matching rule.
ACL_CLS	Type of the ACL used in the matching rule, for example, the IP standard ACL.
Min Length	Minimum packet length set in the matching length.
Max Length	Maximum packet length set in the matching length.
VRF ID	ID of the VRF correlated with the interface.
Route Flags	PBR flag.
Route Type	PBR type. The value **PBR** indicates a PBR route, and **Normal** indicates a common route.
Direct	PBR matching mode, which is **permit** or **deny**.
Priority	PBR priority, which is **High** or **Low**.
Tos_Dscp	Indicates whether to configure the ToS or DSCP rule.
Precedence	Indicates whether to configure the set ip precedence rule.
Mode	Configures the redundant backup or load balancing mode for the next hop.
Nexthop Count	Configures the number of next hops. Up to 32 next hops are configured for ECMP.
Nexthop	Configures the IPv4 address of the next hop.
Weight	Configures the weight value of the next hop.
Ifindex	Configures the index of the output interface corresponding to the next hop.

1.19 show ipv6 pbr route-map

Function

Run the **show IPv6 pbr route-map** command to display the route map information of IPv6 PBR.

Syntax

show ipv6 pbr route-map *route-map-name*

Parameter Description

route-map-name: Name of the route map, which is configured by the **route-map** command.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the route map information of IPv6 PBR.

Examples

The following example displays the route map information of IPv6 PBR.

```
Hostname> enable
Hostname# show ipv6 pbr route-map rm6
Pbr VRF: GLOBAL, ID: 0
 Forward Mode: redundance
 Forwarding: On

route-map rm6
  route-map index: sequence 10, permit
Match rule:
  ACL ID :     0, ACL CLS: 0, Name: acl6
    Set rule:
      IPv6 Nexthop: 10::1, (VRF Name: , ID: 0), Weight: 0
      PBR state info ifx: GigabitEthernet 0/0, Connected: True, Track State: Up
```

Table 1-9 show ipv6 pbr route-map rm6:

Field	Description
Pbr VRF	Name and ID of the VRF.

Field	Description
Forward Mode	Configures the load balancing or redundant backup mode for the next hop.
Forwarding	Indicates whether to enable IP route forwarding.
Route-map index	Sequence number and type of the route submap.
Match rule	Matching rule.
Set rule	Set rule.
PBR state info	PBR private data, for example, the output interface and connection status of the next hop.

1.20 show ipv6 pbr source-route

Function

Run the **show ipv6 pbr source-route** command to display the routing information of the source-address-based IPv6 PBR.

Syntax

show ipv6 pbr source-route [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Displays the IPv6 PBR applied to the specified interface. If optional parameters are not specified, all interfaces to which the IPv6 PBR is applied are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the configured source-address-based PBR.

Examples

The following example displays the routing information of the source-address-based IPv6 PBR.

```
Hostname> enable
Hostname# show ipv6 pbr source-route
PBR IPv6 Source Route
Interface       : GigabitEthernet 0/1
  Sequence      : 10
  Source address : 1000::1/64
  VRF ID        : 0
  Route Flags    :
   Route Type    : PBR
   Direct       : Permit
   Priority     : High
   Match_ipaddr  : Exist
  Mode          : redundance
  Nexthop Count  : 1
   Nexthop[0]   : 1001::2
   Weight[0]    : 1
   Ifindex[0]   : 3
```

Table 1-10 Output Fields of the show ipv6 pbr source-route Command

Field	Description
Interface	Interface applying the PBR.
Sequence	Sequence number corresponding to the PBR.
VRF ID	ID of the VRF correlated with the interface.
Route Flags	PBR flag.
Route Type	PBR type. The value **PBR** indicates a PBR route, and **Normal** indicates a common route.
Direct	PBR matching mode, which is **permit** or **deny**.
Priority	PBR priority, which is **High** or **Low**.
Mode	Configures the redundant backup or load balancing mode for the next hop.
Nexthop Count	Configures the number of next hops. Up to 32 next hops are configured for ECMP.
Nexthop	Configures the IPv4 address of the next hop.
Weight	Configures the weight value of the next hop.

Field	Description
Ifindex	Configures the index of the output interface corresponding to the next hop.

1.21 show ipv6 pbr statistics

Function

Run the **show ipv6 pbr statistics** command to display the statistics about packets forwarded by the IPv6 PBR.

Syntax

show ipv6 pbr statistics [**interface** *interface-type interface-number* | **local**]

Parameter Description

interface *interface-type interface-number*: Displays the IPv4 PBR applied to the specified interface. If optional parameters are not specified, all interfaces to which the IPv4 PBR is applied are displayed.

local: Displays the IPv4 PBR applied to a local interface.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to verify the statistics about packets forwarded by the IPv6 PBR.

Examples

The following example displays the statistics about packets forwarded by the IPv6 PBR.

```
Hostname> enable
Hostname# show ipv6 pbr statistics
IPv6 Policy-based route statistic
 gigabitEthernet 0/1
   statistics : 20
```

1.22 show ipv6 policy

Function

Run the **show IPv6 policy** command to display interfaces for which the IPv6 PBR is configured and the name of the route map applied to each interface.

Syntax

show ipv6 policy [*route-map-name*]

Parameter Description

route-map-name: Name of the route map used for PBR.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can run this command to check the layer-3 interfaces that apply the IPv6 PBR in the current system.

Examples

The following example displays all the interfaces for which the IPv6 PBR is configured and the name of the route map applied to each interface.

```
Hostname> enable
Hostname# show ipv6 policy
```

```
Banlance Mode: redundance
Interface            Route map
VLAN 1               RM_for_Vlan_1
VLAN 2               RM_for_Vlan_2
```

Table 1-12 Output Fields of the show ipv6 policy Command

1 Key Commands

Command	Function
accept-lifetime	Configure the accept-lifetime.
key	Configure a key in the key chain.
key chain	Configure a key chain, and enter the key chain configuration mode.
key-string	Configure a key string in the key configuration mode of the key chain.
send-lifetime	Configure the send-lifetime.
show key chain	Display the key chain configurations.

1.1 accept-lifetime

Function

Run the **accept-lifetime** command to configure the accept-lifetime.

Run the **no** form of this command to remove this configuration.

By default, the accept-lifetime of a key chain is disabled.

Syntax

accept-lifetime *start-time* { **infinite** | *end-time* | **duration** *duration-time* }

no accept-lifetime

Parameter Description

start-time: Start time of the lifetime.

infinite: Specifies that the key is always effective from the start time.

end-time: End time of the lifetime, which must be later than *start-time*.

duration *duration-time*: Specifies the duration of the lifetime starting from *start-time* in seconds. The range is from 1 to 2147483646.

Command Modes

Key configuration mode of the key chain

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the key chain **kc**, and enters the key chain configuration mode. The example also configures the key **1**, enters the key **1** configuration mode, and defines the accept-lifetime of the key chain.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# key chain kc
Hostname(config-keychain)# key 1
Hostname(config-keychain-key)# key-string Hello
Hostname(config-keychain-key)# accept-lifetime 16:30:00 Oct 1 2010 duration 43200
```

Related Commands

- key
- key chain

1.2 key

Function

Run the **key** command to configure a key in the key chain.

Run the **no** form of this command to remove this configuration.

By default, no key is configured.

Syntax

key *key-id*

no key *key-id*

Parameter Description

key-id: ID of the authentication key in the key chain. The value range is from 0 to 2147483647.

Command Modes

Key chain configuration mode.

Default Level

14

Usage Guidelines

After the key is configured, it must meet two conditions before it takes effect: (1) the key-string is configured; (2) the key is in the lifetime (send-lifetime and accept-lifetime). If the lifetime is not configured, the key is considered effective permanently once the key-string is configured. Two effective states are defined: effective on the sending end and effective on the receiving end. The two states correspond to send-lifetime and accept-lifetime respectively.

If there is no special demand, you can configure a key by incrementing the key-id to avoid the authentication state oscillation caused by the possible changes of effective keys. If multiple effective keys exist, each routing protocol uses the key with the smallest key-id.

In the TCP enhanced authentication scenario, the key-id ranges from 0 to 63.

Examples

The following example configures the key chain **ripkeys**, enters the key chain configuration mode, and configures the key **1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# key chain ripkeys
Hostname(config-keychain)# key 1
```

Notifications

Related Commands

- **key chain**
- **key-string**

1.3 key chain

Function

Run the **key chain** command to configure a key chain, and enter the key chain configuration mode.

Run the **no** form of this chain command to remove this configuration.

By default, no key chain is configured.

Syntax

key chain *key-chain-name*

no key chain *key-chain-name*

Parameter Description

key-chain-name: Name of the key chain.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To make a key chain take effect, you must configure at least one key.

Examples

The following example configures the key chain **ripkeys**, and enters the key chain configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# key chain ripkeys
```

Notifications

N/A

Common Errors

Related Commands

- **key**
- **key-string**

1.4 key-string

Function

Run the **key-string** command to configure a key string in the key configuration mode of the key chain.

Run the **no** form of this command to remove this configuration.

By default, no key string is configured.

Syntax

key-string [**0** | **7**] *string-text*

no key-string

Parameter Description

0: Specifies that the key is displayed in plaintext.

7: Specifies that the key is displayed in ciphertext.

string-text: key string. The plaintext key contains less than 80 characters; the ciphertext key contains less than 162 characters. The configured ciphertext parameter should be an even number of hexadecimal numbers (0-f). When the **service password-encryption** command is configured to enable the encryption service, the plaintext key is converted into a ciphertext key once the following condition is met: the ciphertext corresponding to the plaintext password is an even number of hexadecimal numbers and does not carry non-printable characters.

Command Modes

Key configuration mode of the key chain

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the key chain **ripkeys**, enters the key chain configuration mode, configures the key **1**, enters the key **1** configuration mode, and sets the key string to **abc**.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# key chain ripkeys
Hostname(config-keychain)# key 1
Hostname(config-keychain-key)# key-string abc
```

Notifications

When the configured plaintext key contains more than 80 characters or the ciphertext key contains more than 162 characters, the following error prompt will be displayed:

```
%Error: key string too long
```

When the configured ciphertext key such as **key-string 7 123** does not meet the encryption rule, the following error prompt will be displayed:

```
% Invalid encrypted password: 123
```

Common Errors

- **key chain**

1.5 send-lifetime

Function

Run the **send-lifetime** command to configure the send-lifetime.

Run the **no** form of this command to remove this configuration.

By default, the send-lifetime of a key chain is disabled.

Syntax

send-lifetime *start-time* { **infinite** | *end-time* | **duration** *duration-time* }

no send-lifetime

Parameter Description

start-time: Start time of the lifetime.

infinite: Specifies that the key is always effective from the start time.

end-time: End time of the lifetime, which must be later than *start-time*.

duration *duration-time*: Specifies the duration of the lifetime starting from *start-time* in seconds. The value range is from 1 to 2147483646.

Command Modes

Key configuration mode of the key chain

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the key chain **kc**, enters the key chain configuration mode, configures the key **1**, enters the key **1** configuration mode, and sets the send-lifetime of the key chain to 43,200 seconds starting from 16:30:00 Oct 1 2010.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# key chain kc
Hostname(config-keychain)# key 1
Hostname(config-keychain-key)# key-string World
Hostname(config-keychain-key)# send-lifetime 16:30:00 Oct 1 2010 duration 43200
```

Common Errors

1.6 show key chain

Function

Run the **show key chain** command to display the key chain configurations.

Syntax

show key chain [*keychain-name*]

Parameter Description

keychain-name: Configurations of the specified key chain.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no key chain name is specified, the configurations of all key chains are displayed. Otherwise, only configurations of the specified key chain are displayed.

Examples

The following example displays the information of all key chains.

```
Hostname(config)#show key chain
key chain kc
   key 1 -- text "Hostname"
      accept-lifetime (12:11:00 May  2 2001) - (infinite)
      send-lifetime (always valid) - (always valid) [valid now]
```

Table 1-1 Output Fields of the show key chain Command

Field	Description
key chain	Name of the key chain
key	ID and string of the key
accept-lifetime	Lifetime of a key in the receiving direction
send-lifetime	Lifetime of a key in the sending direction

1 IPv4 Multicast Route Management Commands

Command	Function
clear ip mroute	Clear IP multicast routing information.
clear ip mroute statistics	Clear statistics about the IP multicast routing information.
ip mroute	Configure a multicast static route.
ip multicast-routing	Enable the multicast routing function.
ip multicast boundary	Configure a multicast border for a specified group.
ip multicast route-limit	Configure the maximum number of entries for an IPv4 multicast routing table.
ip multicast rpf longest-match	Enable RPF route selection based on the longest match rule.
ip multicast static	Enable L2 direction control for multicast streams.
ip multicast ttl-threshold	Configure a time to live (TTL) threshold for an interface.
mc ref synchronize all	Restore a multicasting failure.
multicast ip-mac-mapping verification	Filter out multicast streams whose IP addresses do not match MAC addresses.
msf force-forwarding	Enable forced forwarding of multicast packets by software.
msf ipmc-overflow override	Enable the overwriting mechanism upon overflow of multicast hardware forwarding entries.
msf nsf	Configure multicast non-stop forwarding parameters.
show ip mrf mfc	Display forwarding entries of IPv4 multicast routes.
show ip mroute	Display information of a multicast forwarding entry.
show ip mroute count	Display count information of a multicast routing table.
show ip mroute dense	Display information of a multicast forwarding entry.
show ip mroute sparse	Display information of a multicast forwarding table.
show ip mroute static	Display IPv4 multicast static routes.
show ip mroute summary	Display information of a multicast forwarding entry.

show ip mvif	Display basic information of a multicast interface.
show ip rpf	Display the RPF information of a specified source address.
show msf msc	Display an IPv4 multi-layer multicast forwarding table.
show msf nsf	Display configuration of multicast non-stop forwarding.

1.1 clear ip mroute

Function

Run the **clear ip mroute** command to clear IP multicast routing information.

Syntax

clear ip mroute { * | *group-address* [*source-address*] }

Parameter Description

*: Clears all forwarding information in the multicast routing table.

group-address: Group address of a multicast route.

source-address: Source address of a multicast route.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to clear IP multicast routing information.

Examples

The following example clears IP multicast routing information of the group with address 230.0.0.1.

```
Hostname> enable
Hostname# clear ip mroute 230.0.0.1
```

1.2 clear ip mroute statistics

Function

Run the **clear ip mroute statistics** command to clear statistics about the IP multicast routing information.

Syntax

clear ip mroute statistics { ***** | *group-address* [*source-address*] }

Parameter Description

*: Clears statistics about all the forwarding entries in the multicast routing table.

group-address: Group address of a multicast route.

source-address: Source address of a multicast route.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example clears statistics about the multicast routing information of the group with address 230.0.0.1.

```
Hostname> enable
Hostname# clear ip mroute statistics 230.0.0.1
```

Notifications

1.3 ip mroute

Function

Run the **ip mroute** command to configure a multicast static route.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No multicast static route is configured by default.

Syntax

ip mroute *source-address mask* [**bgp** | **isis** | **ospf** | **rip** | **static**] { *rpf-addrress* | *interface-type interface-number* } [*distance*]

no ip mroute *source-address mask* [**bgp** | **isis** | **ospf** | **rip**]

default ip mroute *source-address mask* [**bgp** | **isis** | **ospf** | **rip**]

Parameter Description

source-address: Multicast source address.

mask: Mask of the multicast source address.

bgp: Uses the BGP protocol.

isis: Uses the IS-IS protocol.

ospf: Uses the OSPF protocol.

rip: Uses the RIP protocol.

static: Uses a static route.

rpf-address: Address of the reverse path forwarding (RPF) neighbor (next hop to the multicast source).

interface-type interface-number: RPF interface (outbound interface to the multicast source).

distance: Route administrative distance. The value range is from 0 to 255, and the default value is **0**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Multicast static routes are applicable only to RPF checking.

If an IP address of the outbound interface, other than that of the next hop, must be specified for a multicast static route, the outbound interface must be of the point-to-point type.

Examples

The following example configures a multicast static route and sets the address range of a source specific multicast (SSM) group to 232/8.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip mroute 172.16.0.0 255.255.0.0 172.30.10.13
```

Notifications

If the number of multicast static routes on a device reaches the upper limit, the following notification will be displayed:

```
Exceeding maximum static multicast route limit.
```

Common Errors

1.4 ip multicast-routing

Function

Run the **ip multicast-routing** command to enable the multicast routing function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The multicast routing function is disabled by default.

Syntax

ip multicast-routing

no ip multicast-routing

default ip multicast-routing

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The IPv4 multicast routing function must be enabled before an IPv4 multicast protocol is enabled.

Examples

The following example enables the multicast routing function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip multicast-routing
```

1.5 ip multicast boundary

Function

Run the **ip multicast boundary** command to configure a multicast border for a specified group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No multicast border is configured by default.

Syntax

ip multicast boundary *access-list* [**in** | **out**]

no ip multicast boundary *access-list* [**in** | **out**]

default ip multicast boundary *access-list* [**in** | **out**]

Parameter Description

access-list: Group address range defined by an ACL.

in: Indicates that a multicast border applies to the inbound direction of a multicast stream.

out: Indicates that a multicast border applies to the outbound direction of a multicast stream.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is executed, Internet Group Management Protocol (IGMP) and Protocol Independent Multicast Sparse Mode (PIM-SM) packets in the group range are filtered on this interface and multicast streams do not pass through this interface.

This command is associated with a standard access control list (ACL). If an extended ACL is used, an error occurs in filtering.

Examples

The following example configures SVI 1 as a border of all multicast groups.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list standard mul-boun
Hostname(config-std-nacl)# permit 233.3.3.0 0.0.0.255
Hostname(config-std-nacl)# exit
Hostname(config)# interface vlan 1
Hostname(config-if)# ip multicast boundary mul-boun
```

1.6 ip multicast route-limit

Function

Run the **ip multicast route-limit** command to configure the maximum number of entries for an IPv4 multicast routing table.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

A maximum of 1000 entries can be added to an IPv4 multicast routing table by default.

Syntax

ip multicast route-limit *route-limit* [*max-threshold*]

no ip multicast route-limit

default ip multicast route-limit

Parameter Description

route-limit: Maximum number of multicast routes. The value range is from 1 to 64000.

max-threshold: Threshold number of multicast routes that triggers an alarm. The value range is from 1 to 64000, and the default value is **64000**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Due to limitations on hardware resources, routing entries that exceed the range permitted by hardware can be forwarded only by software, deteriorating the performance.

The configured value of *max-threshold* must be smaller than or equal to the value of *route-limit*.

Examples

The following example sets the maximum number of entries that can be added to an IPv4 multicast routing table to **500**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip multicast route-limit 500
```

- **show ip mroute count**

1.7 ip multicast rpf longest-match

Function

Run the **ip multicast rpf longest-match** command to enable RPF route selection based on the longest match rule.

Run the **no** form match this command to disable this function.

Run the **default** form of this command to restore the default configuration.

A route with the highest priority is selected as the RPF route by default. If the priorities are consistent, a route is selected in the sequence of multicast static route, Multiprotocol Extensions for BGP (MBGP) route, and unicast route.

Syntax

ip multicast rpf longest-match

no ip multicast rpf longest-match

default ip multicast rpf longest-match

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The RPF route selection rules are as follows:

(1) Select an optimal route respectively from the multicast static routing table, MBGP routing table, and unicast routing table for RPF checking. Select one route out of the three optimal routes as the RPF route.

(2) If the command of RPF route selection based on the longest match rule is configured, the route with the longest match is selected out of the three optimal routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the priorities are consistent, a route is selected in the sequence of multicast static route, MBGP route, and unicast route.

(3) If the command of RPF route selection based on the longest match rule is not configured, the route with the highest priority is selected out of the three optimal routes. If the priorities are consistent, a route is selected in the sequence of multicast static route, MBGP route, and unicast route.

Examples

The following example enables RPF route selection based on the longest match rule.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip multicast rpf longest-match
```

1.8 ip multicast static

Function

Run the **ip multicast static** command to enable L2 direction control for multicast streams.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

No L2 direction control is enabled for a multicast stream by default.

Syntax

ip multicast static *source-address group-address interface-type interface-number*

no ip multicast static *source-address group-address interface-type interface-number*

default ip multicast static *source-address group-address interface-type interface-number*

Parameter Description

source-address: Address of a multicast source.

group-address: Address of a multicast group.

interface-type interface-number: L2 interface that is allowed to forward this multicast stream.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can configure this command multiple times for a multicast stream. That is, configure multiple interfaces to forward the stream. After direction control is enabled for a multicast stream, this multicast stream can be forwarded only by these configured interfaces. Other interfaces are not allowed to forward the stream.

This command controls only the forwarding of multicast streams on interfaces, but does not directly affect the processing of protocol packets by the multicast protocols. However, some features of the multicast protocols (PIM-DM or PIM-SM) depend on the multicast streams. Behaviors of the multicast routing protocols may be affected.

Examples

The following example allows the multicast streams (192.168.43.4 and 225.1.1.5) to be forwarded from GigabitEthernet 0/1 and GigabitEthernet 0/2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip multicast static 192.168.43.4 225.1.1.5 gigabitEthernet 0/1
Hostname(config)# ip multicast static 192.168.43.4 225.1.1.5 gigabitEthernet 0/2
```

1.9 ip multicast ttl-threshold

Function

Run the **ip multicast ttl-threshold** command to configure a time to live (TTL) threshold for an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default TTL threshold for an interface is **0**.

Syntax

ip multicast ttl-threshold *ttl-threshold-value*

no ip multicast ttl-threshold

default ip multicast ttl-threshold

Parameter Description

ttl-threshold-value: TTL threshold for an interface. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

A device with multicast enabled can maintain a TTL threshold for each interface. Multicast packets whose TTL values are greater than the TTL threshold of the interface are forwarded and those whose TTL values are smaller are discarded. A TTL threshold takes effect only for multicast frames and must be configured on L3 interfaces.

Examples

The following example sets the TTL threshold for an interface to **5**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip multicast ttl-threshold 5
```

1.10 mc ref synchronize all

Function

Run the **mc ref synchronize all** command to restore a multicasting failure.

Syntax

mc ref synchronize all

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the quantity of software entries is greater than the entry capacity supported by the hardware, and when the used entries drop below the hardware entry capacity, the entries that failed to be added cannot be automatically added again. You must manually run corresponding command to trigger entry adding. When an error occurs during multicasting, you can use this command to refresh the configuration.

Examples

The following example restores multicasting failure.

```
Hostname> enable
Hostname# mc ref synchronize all
```

1.15 show ip mrf mfc

Function

Run the **show ip mrf mfc** command to display forwarding entries of IPv4 multicast routes.

Syntax

show ip mrf mfc [*soure-address group-address*]

Parameter Description

source-address: Source address in the forwarding entry of a multicast route.

group-address: Group address in the forwarding entry of a multicast route.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

The two parameters are optional, and the source address and group address must be specified simultaneously.

When no source address or group address is specified, all multicast forwarding cache (MFC) entries are displayed.

Examples

The following example displays all IPv4 multicast route forwarding entries whose source address is 20.0.1.30 and group address is 233.3.3.3.

```
Hostname> enable
Hostname# show ip mrf mfc 20.0.1.30 233.3.3.3
Multicast Routing and Forwarding Cache Table
(20.0.1.30, 233.3.3.3)
  FAST_SW, SWTCHED, MIN_MTU: 1500, MIN_MTU_IFINDEX: 4099, WRONG IF: 0
  Incoming interface: VLAN 1[4097]
  Outgoing interface list:
VLAN 3 (1)
```

Table 1-1 Output Fields of the show ip mrf mfc Command

Field	Description
FAST_SW	A flag indicating whether an entry allows quick forwarding. If non-Ethernet interface frame relay exists, no quick entry is generated.
SWTCHED	Specifies whether an entry is added to next-layer forwarding table.
MIN_MTU MTU	Minimum maximum transmission unit (MTU) value of an entry
MIN_MTU_IFINDEX	Index of an interface with the minimum MTU value
WRONG IF	Counts of multicast packets that come from an incorrect interface
Incoming interface	RPF inbound interface of an entry
VLAN 3 (1)	Specifies that the L3 outbound interface of an entry belongs to VLAN 3. The value 1 indicates the TTL threshold of this L3 interface.

1.23 show ip rpf

Function

Run the **show ip rpf** command to display the RPF information of a specified source address.

Syntax

show ip rpf *source-address*

Parameter Description

source-address: Source address.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays RPF information destined to 192.168.1.54.

```
Hostname# show ip rpf 192.168.1.54
RPF information for 192.168.1.54
RPF interface: VLAN 1
RPF neighbor: 0.0.0.0
RPF route: 192.168.1.0/24
RPF type: unicast (connected)
RPF recursion count: 0
Doing distance-preferred lookups across tables
Distance: 0
Metric: 0
```

Table 1-9 Output Fields of the show ip rpf Command

Field	Description
RPF interface	RPF interface
RPF neighbor	RPF neighbor
RPF route	RPF route
RPF type	RPF type
RPF recursion count	RPF recursion count
Distance	Administrative distance
Metric	Measurement

1.24 show msf msc

Function

Run the **show msf msc** command to display an IPv4 multi-layer multicast forwarding table.

Syntax

show msf msc [*soure-address*] [*group-address*] [*vlan-id*]

Parameter Description

soure-address: Source address in the multi-layer forwarding entry.

group-address: Group address in the multi-layer forwarding entry.

vlan-id: VLAN ID which an inbound interface belongs to in the multi-layer forwarding entry.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

When only the source address is specified as S1, all MSC entries with the source address being S1 are displayed.

When the source address is specified as S1 and the group address is specified as G1, all MSC entries with the source address being S1 and the group address being G1 are displayed.

When the source address is specified as S1, the group address is specified as G1, and the VLAN ID is specified as V1, all MSC entries with the source address being S1, group address being G1, and the inbound interface belonging to V1 are displayed.

Examples

The following example displays the IPv4 multi-layer multicast forwarding entries with the source address being 192.168.195.25.

```
Hostname> enable
Hostname# show msf msc 192.168.195.25
Multicast Switching Cache Table
(192.168.195.23, 233.3.3.3, 1), SYNC, MTU:0, 1 OIFs
  VLAN 1(0): 1 OPORTs, REQ: DONE
OPORT 6, IGMP-SNP, REQ: DONE
```

Table 1-10 Output Fields of the show msf msc Command

Field	Description
192.168.195.23	Source address in an entry
233.3.3.3	Group address in an entry
1	VLAN ID that an inbound interface of an entry belongs to
SYNC	Specifies that an entry has been synchronized to the bottom layer hardware.
MTU	MTU value of an entry
OIFs	Number of L3 outbound interfaces in an entry

Field	Description
VLAN1(0)	VLAN ID which L3 outbound interface OIFs belong to
1 OPORTs	Number of L2 interfaces belonging to the L3 outbound interface OIF
REQ: DONE	Specifies that this OIF has been set to the bottom layer hardware.
OPORT 6	L2 interfaces belonging to this OIF. The interfaces are indexed as 6.
IGMP-SNP	Specifies that this interface is created based on the IGMP Snooping protocol. **PIM-SNP**: This interface is created based on the PIM Snooping protocol. **ROUTER**: This interface is created based on the L3 protocol.
REQ: DONE	Specifies that this interface has been set to the bottom layer hardware.

1 IGMP Commands

Command	Function
clear ip igmp group	Clear dynamic group member records in the IGMP cache.
clear ip igmp interface	Clear all IGMP statistics and group member records on an interface.
ip igmp access-group	Specify groups that the hosts are allowed to join on the interface.
ip igmp immediate-leave group-list	Enable the fast leave function on an interface.
ip igmp join-group	Add an interface to a group.
ip igmp last-member-query-count	Configure the times for sending specific group query packets on an interface.
ip igmp last-member-query-interval	Configure the interval for sending specific group query packets on an interface.
ip igmp limit	Configure the maximum number of IGMP group member records.
ip igmp mroute-proxy	Enable the MRoute proxy function on an interface.
ip igmp proxy-service	Enable the proxy service function on an interface.
ip igmp query-interval	Configure an interval for querying common group members.
ip igmp query-max-response-time	Configure the maximum response time for Query packets on an interface.
ip igmp query-timeout	Configure the survival period of other querier on an interface.
ip igmp robustness-variable	Configure the querier robustness variable on an interface.
ip igmp ssm-map enable	Enable the IGMP SSM mapping function.
ip igmp ssm-map static	Configure static mapping entries.
ip igmp static-group	Add a static interface to a group.
ip igmp version	Configure the IGMP version on an interface.

ip igmp enforce-router-alert	Enable the function of checking the Router Alert option in an IGMP packet and discarding an IGMP packet that does not carry the Router Alert option.
ip igmp enforce-source-subnet	Enable the source address checking function for IGMP Report packets.
ip igmp send-router-alert	Enable the function of containing the Router Alert option in an IGMP packet to be sent.
show ip igmp groups	Display groups directly connected to a device and group information learned from IGMP.
show ip igmp interface	Display configurations of an interface.
show ip igmp ssm-mapping	Display IGMP SSM mapping information.

1.1 clear ip igmp group

Function

Run the **clear ip igmp group** command to clear dynamic group member records in the IGMP cache.

Syntax

clear ip igmp group [*group-address* [*interface-type interface-number*]]

Parameter Description

group-address: Address of a group.

interface-type interface-number: Interface type and interface number.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

The IGMP cache contains a list, which includes multicast groups to which hosts directly connected to a subnet are added. If a device is added to a multicast group, this group is included in this list as well.

If no parameter is specified in the command, all dynamic group member records are cleared from the IGMP cache.

Examples

The following example clears dynamic group member records in the IGMP cache.

```
Hostname> enable
Hostname# clear ip igmp group
```

Notifications

Platform Description

N/A

1.2 clear ip igmp interface

Function

Run the **clear ip igmp interface** command to clear all IGMP statistics and group member records on an interface.

Syntax

clear ip igmp interface *interface-type interface-number*

Parameter Description

interface-type interface-number: Interface type and interface number.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to clear all IGMP learned group information and packet statistics on an interface. The packet statistics include received Report packets, Leave packets, and group member records on the current interface.

Examples

The following example clears all IGMP statistics and group member records on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear ip igmp interface GigabitEthernet 0/1
```

Notifications

N/A

Platform Description

1.3 ip igmp access-group

Function

Run the **ip igmp access-group** command to specify groups that the hosts are allowed to join on the interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Hosts can join any group by default.

Syntax

ip igmp access-group { *acl-name* | *acl-number* }

no ip igmp access-group

default ip igmp access-group

Parameter Description

acl-name: Name of a standard IP ACL that hosts can join. The value is a case-sensitive string of 1 to 99 characters.

acl- number: No. of a standard IP ACL that hosts can join. The value range is from 1 to 199 or from 1300 to 2699.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can run this command on an interface to specify groups that you want hosts directly connected to a network segment to join. ACLs are used to limit the group address range. Report packets from groups denied by the ACLs are discarded.

When IGMPv3 is enabled, this command supports extended ACLs. When a received IGMP Report packet is (S1, S2, S3 … Sn, G), this command uses corresponding ACL to match (*,G). Therefore, to normally use this command, you must explicitly configure a (*,G) in the extended ACLs to filter (S1, S2, S3 … Sn, G).

Examples

The following example allows hosts on GigabitEthernet 0/1 to join only the group with the address 225.2.2.2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit 225.2.2.2 0.0.0.0
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp access-group 1
```

The following example associates a group list with extended ACLs on GigabitEthernet 0/1 to allow the interface to process IGMP packets with the source address 1.1.1.1 and group address 233.3.3.3.

```
Hostname# configure terminal
Hostname(config)# ip access-list extended ext_acl
Hostname(config-ext-nacl)# permit ip host 1.1.1.1 host 233.3.3.3
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp access-group ext_acl
```

1.4 ip igmp immediate-leave group-list

Function

Run the **ip igmp immediate-leave group-list** command to enable the fast leave function on an interface.

Run the **no** form of this command to disable this function on the interface.

Run the **default** form of this command to restore the default configuration.

The fast leave function on an interface is disabled by default.

Syntax

ip igmp immediate-leave group-list { *acl-name* | *acl-number* }

no ip igmp immediate-leave

default ip igmp immediate-leave

Parameter Description

acl-name: Name of a standard IP ACL. The value is a case-sensitive string of 1 to 99 characters.

acl- number: No. of a standard IP ACL. The value range is from 1 to 99 or from 1300 to 1999.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command applies to an interface that runs IGMPv2 or IGMPv3 and that is connected to only one host.

After the fast leave function is enabled, if a device receives an IGMP Leave packet of a specified group, the device directly deletes this interface from the group member records to shorten the leave latency.

Examples

The following example enables the fast leave function on an interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit 225.192.20.0 0.0.0.255
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp immediate-leave group-list 1
```

Notifications

If no access list exists, the following notification will be displayed:

```
% access-list 1 not exist
```

Common Errors

1.5 ip igmp join-group

Function

Run the **ip igmp join-group** command to add an interface to a group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No interface is added to a group by default.

Syntax

ip igmp join-group *group-address*

no ip igmp join-group *group-address*

default ip igmp join-group *group-address*

Parameter Description

group-address: Address of a group.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is run, the interface will simulate host behaviors and send a Join packet to the upstream device to join the specified group.

This command is used in lab test.

Examples

The following example adds GigabitEthernet 0/1 to the group with the address 233.3.3.3.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp join-group 233.3.3.3
```

Notifications

If the group address is invalid, the following notification will be displayed:

```
Illegal multicast group address
```

If the interfaces in a group are full, the following notification will be displayed:

```
IGMP join-group limit reached
```

1.6 ip igmp last-member-query-count

Function

Run the **ip igmp last-member-query-count** command to configure the times for sending specific group query packets on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Specific group query packets are sent twice by default.

Syntax

ip igmp last-member-query-count *last-member-query-count-number*

no ip igmp last-member-query-count

default ip igmp last-member-query-count

Parameter Description

last-member-query-count-number: Times for sending specific group query packets. The value range is from 2 to 7.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command applies to IGMPv2 or IGMPv3 only.

After receiving a Leave packet through an interface, a multicast device continuously sends specific group query packets and waits for responses from the host. After timeout, the device considers that no group member exists in the directly-connected network segment and deletes this interface from the IGMP group member records. The timeout time is a product of the interval for sending specific group query packets and the times for sending the specific group query packets.

Examples

The following example sets the times for sending specific group query packets to 3 on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp last-member-query-count 3
```

Run the **ip igmp last-member-query-interval** command to configure the interval for sending specific group query packets on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The interval for sending specific group query packets is **1** second by default.

Syntax

ip igmp last-member-query-interval *last-member-query-interval*

no ip igmp last-member-query-interval

default ip igmp last-member-query-interval

Parameter Description

last-member-query-interval: Interval for sending specific group query packets, in 0.1 seconds. The value range is from 1 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command applies to IGMPv2 and IGMPv3 only.

After receiving a Leave packet through an interface, a multicast device continuously sends specific group query packets and waits for responses from the host. After timeout, the device considers that no group member exists in the directly-connected network segment and deletes this interface from the IGMP group member records. Timeout period = Interval for sending specific group query packets * Times for sending the specific group query packets

Examples

The following example sets the interval for sending specific group query packets to 20 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp last-member-query-interval 200
```

1.8 ip igmp limit

Function

Run the **ip igmp limit** command to configure the maximum number of IGMP group member records.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of IGMP group member records on an interface is **4000** by default. This number is **64000** in global configuration mode by default.

Syntax

ip igmp limit *limit-number* [**except** *acl-name* | **except** *acl-number*]

no ip igmp limit

default ip igmp limit

Parameter Description

limit *limit-number*: Specifies the maximum number of IGMP group member records. The value range is from 1 to 64000.

except *acl-name*: Specifies the name of a standard IP ACL. The groups in the ACL are not counted. The value is a case-sensitive string of 1 to 99 characters.

except *acl-number*: Specifies the No. of a standard IP ACL. The groups in the ACL are not counted. The value range is from 1 to 99 or from 1300 to 1999.

Command Modes

Global configuration mode

Interface configuration mode

Default Level

14

Usage Guidelines

In global configuration mode, this command limits the number of IGMP group member records on a multicast device.

In interface configuration mode, this command limits the number of IGMP group member records on an interface.

If the number of group member records exceeds the interface limit or global limit, subsequent received Report packets are ignored.

If an except list is configured, Report packets in a specified range can be normally processed, but they are not counted.

Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, the global limit prevails.

Examples

The following example sets the maximum number of group members on GigabitEthernet 0/1 to 300, excluding the groups in the ACL1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp limit 300 except acl1
```

Notifications

If no access list exists, the following notification will be displayed:

```
% access-list acl1 not exist
```

Common Errors

1.9 ip igmp mroute-proxy

Function

Run the **ip igmp mroute-proxy** command to enable the MRoute proxy function on an interface.

Run the **no** form of this command to disable this function on an interface.

Run the **default** form of this command to restore the default configuration.

The MRoute proxy function on an interface is disabled by default.

Syntax

ip igmp mroute-proxy *interface-type interface-number*

no ip igmp mroute-proxy

default ip igmp mroute-proxy

Parameter Description

interface-type interface-number: Type and number of a specified upstream interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can run the **ip igmp proxy-service** command to configure the upstream interface in the root direction of the multicast distribution tree as a proxy service interface.

You can run the **ip igmp mroute-proxy** command to configure the downstream interface in the leaf direction of the multicast distribution tree as an MRoute proxy interface.

The proxy service interface forwards an IGMP Query packet to the MRoute proxy interface. The MRoute proxy interface forwards an IGMP Report packet to the proxy service interface.

Examples

The following example enables the proxy service function on GigabitEthernet 0/1 and the MRoute proxy function on GigabitEthernet 0/2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp proxy-service
Hostname(config-if-GigabitEthernet 0/1)# exit
Hostname(config)# interface GigabitEthernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# ip igmp mroute-proxy GigabitEthernet 0/1
```

Notifications

If the multicast proxy function on an interface is disabled, the following notification will be displayed:

```
Mroute proxy had configured
```

Common Errors

Function

Run the **ip igmp proxy-service** command to enable the proxy service function on an interface.

Run the **no** form of this command to disable this function on an interface.

Run the **default** form of this command to restore the default configuration.

The proxy service function on an interface is disabled by default.

Syntax

ip igmp proxy-service

no ip igmp proxy-service

default ip igmp proxy-service

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can run the **ip igmp proxy-service** command to configure the upstream interface in the root direction of the multicast distribution tree as a proxy service interface.

You can run the **ip igmp mroute-proxy** command to configure the downstream interface in the leaf direction of the multicast distribution tree as an MRoute proxy interface.

The proxy service interface forwards an IGMP Query packet to the MRoute proxy interface. The MRoute proxy interface forwards an IGMP Report packet to the proxy service interface.

A maximum of 32 proxy service interfaces can be configured on a device. After receiving an IGMP Query packet, the proxy service interface makes a response based on the IGMP group member records.

If the **switchport** command is executed on the proxy service interface, the **ip igmp mroute-proxy** command configured on the MRoute proxy interface is automatically deleted.

Examples

The following example enables the proxy service function on GigabitEthernet 0/1 and the MRoute proxy function on GigabitEthernet 0/2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp proxy-service
```

```
Hostname(config-if-GigabitEthernet 0/1)# exit

Run the **default** form of this command to restore the default configuration.

The maximum response time for query packets on an interface is **10** seconds by default.

Syntax

ip igmp query-max-response-time *query-max-response-time*

no ip igmp query-max-response-time

default ip igmp query-max-response-time

Parameter Description

query-max-response-time: Maximum response time, in seconds. The value range is from 1 to 25.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After sending Query packets, the interface waits for responses. After timeout, the interface considers that no group member exists in the directly-connected network segment and deletes the group information.

Examples

The following example sets the maximum response interval to 20 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp query-max-response-time 20
```

Run the **default** form of this command to restore the default configuration.

The survival period of other querier is **255** seconds by default.

Syntax

ip igmp query-timeout *query-timeout*

no ip igmp query-timeout

default ip igmp query-timeout

Parameter Description

query-timeout: Survival period of other querier, in seconds. The value range is from 60 to 300.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After sending a Query packet, an interface waits for Query packets from other devices. After timeout, the device considers that it is the only querier on the directly-connected network segment.

Examples

The following example sets the survival period of other querier to 200 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp query-timeout 200

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default querier robustness variable is **2**.

Syntax

ip igmp robustness-variable *robustness-variable-number*

no ip igmp robustness-variable

default ip igmp robustness-variable

Parameter Description

robustness-variable-number: Querier robustness variable. The value range is from 2 to 7.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The querier robustness variable is used to calculate the aging time of a forwarding entry after a device receives an IGMP Report packet. Aging time = Query interval × Robustness variable + 10

Examples

The following example sets the querier robustness variable to 3 on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp robustness-variable 3

Run the **default** form of this command to restore the default configuration.

The IGMP SSM mapping function is disabled by default.

Syntax

ip igmp ssm-map enable

no ip igmp ssm-map enable

default ip igmp ssm-map enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run the **ip igmp ssm-map static** command to configure static mapping entries.

After this function is enabled, when an interface running IGMPv3 receives an IGMPv1 or IGMPv2 Report packet, the interface adds a static mapping source address.

Examples

The following example enables the IGMP SSM mapping function and sets the group mapping source address of ACL 11 to 192.168.2.2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp ssm-map enable

1.16 ip igmp ssm-map static

Function

Run the **ip igmp ssm-map static** command to configure static mapping entries.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static mapping entry is configured by default.

Syntax

ip igmp ssm-map static { *acl-name* | *acl-number* } *source-address*

no ip igmp ssm-map static { *acl-name* | *acl-number* } *source-address*

default ip igmp ssm-map static { *acl-name* | *acl-number* } *source-address*

Parameter Description

acl-name: Name of a standard IP ACL. The value is a case-sensitive string of 1 to 99 characters.

acl- number: No. of a standard IP ACL. The value range is from 1 to 99 or from 1301 to 1999.

source-address: Source address.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run the **ip igmp ssm-map enable** command to enable the IGMP SSM mapping function.

You can run this command to configure a static mapping entry.

After a static mapping entry is configured, when an interface running IGMPv3 receives an IGMPv1 or IGMPv2 Report packet, the interface adds a static mapping source address.

Examples

The following example enables the IGMP SSM mapping function and sets the group mapping source address of ACL 11 to 192.168.2.2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp ssm-map enable
Hostname(config)# ip igmp ssm-map static 11 192.168.2.2
```

Notifications

If *source-address* is not a unicast address, the following notification will be displayed:

```
% Invalid input, not a unicast IP address 224.1.1.1!
```

If an inexistent ACL is applied, the following notification will be displayed:

```
% access-list 1 not exist
```

1.17 ip igmp static-group

Function

Run the **ip igmp static-group** command to add a static interface to a group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static interface is added to a group by default.

Syntax

ip igmp static-group *group-address*

no ip igmp static-group *group-address*

default ip igmp static-group *group-address*

Parameter Description

group-address: Address of a group.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command adds an interface to a group without IGMP packet exchange. Even if no host exists in the group that resides on the same network segment as the interface, this interface is added to the group member records.

The record generated by adding a static interface to a group can be removed by using the **no ip igmp static-group** command, other than the **clear ip igmp group** command.

Examples

The following example adds GigabitEthernet 0/1 to the group with the address 236.6.6.6.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp static-group 236.6.6.6
```

Notifications

If the group address is not an address of a multicast group, the following notification will be displayed:

```
Not a IP multicast group address
```

If the multicast group is full, the following notification will be displayed:

```
IGMP static-group limit reached
```

1.18 ip igmp version

Function

Run the **ip igmp version** command to configure the IGMP version on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

IGMPv2 runs on an interface by default.

Syntax

ip igmp version { **1** | **2** | **3** }

no ip igmp version

default ip igmp version

Parameter Description

1: Indicates IGMPv1.

2: Indicates IGMPv2.

3: Indicates IGMPv3.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is executed, the IGMP function automatically restarts.

Examples

The following example configures IGMPv3 on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip igmp version 3
```

1.20 ip igmp enforce-source-subnet

Function

Run the **ip igmp enforce-source-subnet** command to enable the source address checking function for IGMP Report packets.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The source address checking function for IGMP Report packets is disabled by default.

Syntax

ip igmp enforce-source-subnet

no ip igmp enforce-source-subnet

default ip igmp enforce-source-subnet

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run the **ip igmp enforce-source-subnet** command to enable the source address checking function for IGMP Report packets. Only IGMP Report packets whose source addresses are on the same network segment as the packet receiving interface are received.

You can run the **no** form of this command to disable the source address checking function for IGMP Report packets.

If the source address in an IGMP Report packet is on the same network segment as the packet receiving interface, the packet can be received and the packet sending host can join the local group. If the source address in an IGMP Report packet is not on the same network segment as the packet receiving interface, the packet is rejected and the packet sending host cannot join the local group.

Examples

The following example enables source address checking for IGMP Report packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp enforce-source-subnet
```

1.22 show ip igmp groups

Function

Run the **show ip igmp groups** command to display groups directly connected to a device and group information learned from IGMP.

Syntax

show ip igmp groups [*interface-type interface-number*] [*group-address*] [**detail**]

Parameter Description

group-address: Address of a group.

interface-type interface-number: Interface type and interface number.

detail: Displays detailed information.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is specified in the command, the group addresses, interface types, and all multicast groups directly connected to the interfaces are displayed.

Examples

The following example displays all group information.

```
Hostname> enable
Hostname# show ip igmp groups
IGMP Connected Group Membership
Group Address Interface Uptime Expires  Last Reporter
224.0.1.1       eth2  00:00:09  00:04:17  10.10.0.82
224.0.1.24      eth2  00:00:06  00:04:14  10.10.0.84
224.0.1.40      eth2  00:00:09  00:04:15  10.10.0.91
```

```
224.0.1.60      eth2  00:00:05  00:04:15  10.10.0.7
239.255.255.250 eth2  00:00:12  00:04:15  10.10.0.228
239.255.255.254 eth2  00:00:08  00:04:13  10.10.0.84
```

The following example displays detailed information of a group with the address 224.1.1.1.

```
Hostname> enable
Hostname# show ip igmp groups 224.1.1.1 detail
Interface: eth1
Group: 224.1.1.1
Uptime: 00:00:42
Group mode: Include
Last reporter: 192.168.50.111
TIB-A Count: 2
TIB-B Count: 0
Group source list: (R - Remote, M - SSM Mapping)
Source Address Uptime v3 Exp Fwd Flags
192.168.55.55 00:00:42 00:03:38 Yes R
192.168.55.66 00:00:42 00:03:38 Yes R
```

Table 1-1 Output Fields of the show ip igmp groups Command

Field	Description
Group Address	Group address
Interface	Interface
Uptime	Update time
Expires	Remaining time
Last Reporter	Address of the last host that sends a Report packet
TIB-A Count	Number of source nodes in INCLUDE mode
TIB-B Count	Number of source nodes in EXCLUDE mode
Group source list	Linked list of source addresses
Source Address	Source address
Uptime	Source update time
v3 Exp	Source timeout time
Fwd Flags	Method of recording source addresses

1.23 show ip igmp interface

Function

Run the **show ip igmp interface** command to display configurations of an interface.

Syntax

show ip igmp interface [*interface-type interface-number*]

Parameter Description

interface-type interface-number: Interface type and interface number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is specified in the command, configurations of all interfaces are displayed.

Examples

The following example displays configurations of all interfaces.

```
Hostname> enable
Hostname# show ip igmp interface
Interface vlan 1(Index 4294967295)
IGMP Active, Non-Querier, Version 3 (default)
IGMP querying router is 0.0.0.0
IGMP query interval is 125 seconds
IGMP querier timeout is 255 seconds
IGMP max query response time is 10 seconds
Last member query response interval is 1000 milliseconds
Group Membership interval is 260 seconds
```

Table 1-2 Output Fields of the show ip igmp interface Command

Field	Description
Interface	Interface description
IGMP Active	IGMP status of an interface
IGMP querying router is x	Address of an IGMP querier router
IGMP query interval is x seconds	IGMP query interval

Field	Description
IGMP querier timeout is x seconds	IGMP query timeout time
IGMP max query response time is x seconds	Maximum response time for IGMP query packets
Last member query response interval is x milliseconds	Interval for querying the last member
Group Membership interval is x seconds	Interval for sending group member relationship

Function

Run the **show ip igmp ssm-mapping** command to display IGMP SSM mapping information.

Syntax

show ip igmp ssm-mapping [*group-address*]

Parameter Description

group-address: Address of a group.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is specified in the command, all IGMP SSM mapping information is displayed.

Examples

The following example displays the IGMP SSM mapping information of a group with the address 233.3.3.3.

```
Hostname> enable
Hostname# show ip igmp ssm-mapping 233.3.3.3
Group address: 233.3.3.3
Database    : Static
Source list  : 192.3.3.3
           : 3.3.3.3
```

1 PIM-SM Commands

Command	Function
clear ip pim sparse-mode bsr rp-set	Clear dynamic rendezvous point (RP) information.
clear ip pim sparse-mode track	Reset the statistics start time and clear the counter of the PIM packets.
ip pim accept-bsr list	Limit the BSR address range.
ip pim accept-crp-with-null-group	Enable the BSR to receive C-RP-ADV packets with Prefix-Count being 0.
ip pim accept-crp list	Limit the C-RP address range and the address range of the groups served by the C-RPs.
ip pim accept-register	Limit the (S, G) address range in the register messages.
ip pim bsr-border	Configure a BSR border.
ip pim bsr-candidate	Configure C-BSRs.
ip pim bfd	Configure PIM-BFD correlation.
ip pim dr-priority	Configure the DR priority.
ip pim ignore-rp-set-priority	Ignore RP priority for RP election.
ip pim jp-timer	Configure the join/prune packet sending interval.
ip pim neighbor-filter	Enable the neighbor filtering function.
ip pim neighbor-tracking	Enable the neighbor tracking function.
ip pim override-interval	Configure the prune override interval of an interface.
ip pim probe-interval	Configure the register-probe time.
ip pim propagation-delay	Configure the propagation delay of an interface.
ip pim query-interval	Configure the hello message sending interval.
ip pim register-checksum-wholepkt	Calculate the checksum of entire packets.
ip pim register-decapsulate-forward	Enable the function for the RP to decapsulate register messages and forward multicast packets in the messages.
ip pim register-rate-limit	Limit the sending rate of register messages.

ip pim register-rp-reachability	Enable the RP reachability checking function before a register message is sent.
ip pim register-source	Specify a source IP address in register messages.
ip pim register-suppression	Configure the register suppression time.
ip pim rp-address	Configure static RPs.
ip pim rp-candidate	Configure C-RPs.
ip pim rp-register-kat	Configure the (S, G) entry timeout period on the RP.
ip pim sparse-mode	Enable the PIM-SM function on an interface.
ip pim sparse-mode passive	Enable the PIM-SM passive mode on an interface.
ip pim sparse-mode subvlan	Enable the PIM-SM function for sub VLANs of a super VLAN interface.
ip pim spt-threshold	Enable the shortest path tree (SPT) switchover function.
ip pim ssm	Enable the SSM function and configure an SSM group address range.
ip pim triggered-hello-delay	Configure the hello message sending delay on an interface.
show ip pim sparse-mode bsr-router	Display BSR information.
show ip pim sparse-mode interface	Display PIM-SM information of an interface.
show ip pim sparse-mode local-members	Display local IGMP information of a PIM-SM interface.
show ip pim sparse-mode mroute	Display PIM-SM routing information.
show ip pim sparse-mode neighbor	Display neighbor information.
show ip pim sparse-mode nexthop	Display next hop information, including interface number, address, and metric value of a next hop.
show ip pim sparse-mode rp-hash	Display RP information corresponding to a multicast group address.
show ip pim sparse-mode rp mapping	Display all RPs and the groups served by the RPs on the local device.
show ip pim sparse-mode track	Display the number of PIM packets sent and received since the statistic start time.

1.1 clear ip pim sparse-mode bsr rp-set

Function

Run the **clear ip pim sparse-mode bsr rp-set** command to clear dynamic rendezvous point (RP) information.

Syntax

clear ip pim sparse-mode bsr rp-set *

Parameter Description

*: Clears all dynamic RP information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to refresh the RP-Set.

This command cannot clear static RPs.

Examples

The following example clears dynamic RP-Set information.

```
Hostname> enable
Hostname# clear ip pim sparse-mode bsr rp-set *
```

Notifications

After the RP-Set information is cleared, the following notification will be displayed:

```
RP is changed for group range 224.0.0.0/4.  Perform RP change handler
```

Platform Description

N/A

1.2 clear ip pim sparse-mode track

Function

Run the **clear ip pim sparse-mode track** command to reset the statistics start time and clear the counter of the PIM packets.

Syntax

clear ip pim sparse-mode track

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example resets the statistic start time and clears the counter of the PIM packets.

```
Hostname> enable
Hostname# clear ip pim sparse-mode track
```

1.3 ip pim accept-bsr list

Function

Run the **ip pim accept-bsr list** command to limit the BSR address range.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The BSR address range is not limited by default.

Syntax

ip pim accept-bsr list { *acl-name* | *acl-number* }

no ip pim accept-bsr

default ip pim accept-bsr

Parameter Description

list *acl-name*: Uses a standard IP ACL name to limit the BSR address range. The value is a case-sensitive string of 1 to 99 characters.

list *acl-number*: Uses a standard IP ACL number to limit the BSR address range. The value range is from 1 to 99 or from 1300 to 1999.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is run, the PIM-SM device receives only BSMs sent by legitimate BSRs.

Examples

The following example receives BSMs sent by the legitimate BSRs determined by the access list 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit 192.168.1.0 0.0.0.255
Hostname(config)# ip pim accept-bsr list 1
```

Notifications

If no ACL is configured to limit the BSR address range, the following notification will be displayed:

```
% access-list 1 not exist
```

1.4 ip pim accept-crp-with-null-group

Function

Run the **ip pim accept-crp-with-null-group** command to enable the BSR to receive C-RP-ADV packets with Prefix-Count being 0.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.
The function for the BSR to receive C-RP-ADV packets with Prefix-Count being 0 is disabled by default.

Syntax

ip pim accept-crp-with-null-group

no ip pim accept-crp-with-null-group

default ip pim accept-crp-with-null-group

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is run on a C-BSR and this C-BSR is elected as the BSR, the BSR can receive C-RP-ADV packets with Prefix-Count being 0. This C-RP can support all groups.

Examples

The following example enables the BSR to receive C-RP-ADV packets with Prefix-Count being 0.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip pim accept-crp-with-null-group
```

1.5 ip pim accept-crp list

Function

Run the **ip pim accept-crp list** command to limit the C-RP address range and the address range of the groups served by the C-RPs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The C-BSRs receive all external C-RP advertisement packets by default.

Syntax

ip pim accept-crp list { *acl-name* | *acl-number* }

no ip pim accept-crp

default ip pim accept-crp

Parameter Description

list *acl-name*: Uses an extended IP ACL name to limit the C-RP address range and the address range of the groups served by the C-RPs. The value is a case-sensitive string of 1 to 99 characters.

list *acl-number*: Uses an extended IP ACL number to limit the C-RP address range and the address range of the groups served by the C-RPs. The value range is from 100 to 199 or from 2000 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is run on a C-BSR and this C-BSR is elected as the BSR, the BSR can limit the C-RP address range and the address range of the groups served by the C-RPs.

Examples

The following example sets the C-RP address range and the address range of the groups served by the C-RPs to extended ACL 100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list extended 100
Hostname(config-ext-nacl)# permit ip 192.168.195.0 0.0.0.255 225.1.1.1 0.0.0.255
Hostname(config-ext-nacl)# exit
Hostname(config)# ip pim accept-crp list 100
```

Notifications

If no ACL is configured, the following notification will be displayed:

```
% access-list 1 not exist
```

Common Errors

N/A

Platform Description

1.6 ip pim accept-register

Function

Run the **ip pim accept-register** command to limit the (S, G) address range in the register messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The (S, G) address range of register messages is not limited by default. The RP receives register messages with any (S, G) address.

Syntax

ip pim accept-register { **list** { *acl-name* | *acl-number* } | **route-map** *route-map-name* } *
no ip pim accept-register
default ip pim accept-register

Parameter Description

list *acl-name*: Uses an extended IP ACL name to limit the (S, G) address range. The value is a case-sensitive string of 1 to 99 characters.

list *acl-number*: Uses an extended IP ACL number to limit the (S, G) address range. The value range is from 100 to 199 or from 2000 to 2699.

route-map *route-map-name*: Uses a route map to limit the (S, G) address range.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be run on a static RP or C-RP to limit the (S, G) address range in register messages.

Examples

The following example sets the (S, G) address range in register messages to access list 100, the source address to 192.168.195.0 with reverse mask 0.0.0.255, and the multicast group address to 255.1.1.1 with reverse mask 0.0.0.255.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 100 permit ip 192.168.195.0 0.0.0.255 225.1.1.1
0.0.0.255
Hostname(config)# ip pim accept-register list 100
```

1.7 ip pim bsr-border

Function

Run the **ip pim bsr-border** command to configure a BSR border.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.
No BSR border is configured by default.

Syntax

ip pim bsr-border
no ip pim bsr-border
default ip pim bsr-border

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To limit BSM flooding, you can configure a BSR border on the interface. Then, this interface discards received BSMs without forwarding them.

Examples

The following example configures a BSR border of PIM on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim bsr-border
```

1.8 ip pim bsr-candidate

Function

Run the **ip pim bsr-candidate** command to configure C-BSRs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.
No C-BSR is configured by default.

Syntax

ip pim bsr-candidate *interface-type interface-number* [*hash-mask-length* [*priority-value*]]

no ip pim bsr-candidate

default ip pim bsr-candidate

Parameter Description

interface-type interface-number: Specified interface.

hash-mask-length: Length of a hash mask configured for the RP election mechanism. The value range is from 0 to 32, and the default value is **10**.

priority-value: C-BSR priority. The value range is from 0 to 255, and the default value is **64**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In a PIM-SM domain, a unique BSR must be available. The BSR collects and releases RP information. Multiple C-BSRs elect an acknowledged BSR based on BSMs. Before a BSR is elected, each C-BSR considers itself a BSR and periodically sends a BSM with the multicast address 224.0.0.13 in the PIM-SM domain. This message includes the address and priority of the BSR.

This command can be used to send a BSM to all PIM neighbors through the interface assigned to the BSR. Each neighbor compares the original BSR address with the address in the received BSM. If the received BSM indicates that the C-BSR of the received BSM boasts a higher priority or a larger IP address, the neighbor saves the address in the BSM as the BSR address and forwards the BSM. Otherwise, the neighbor discards the BSM.

A C-BSR considers itself the BSR until the C-BSR receives a BSM indicating a higher priority from another C-BSR.

Examples

The following example configures a C-BSR to send a BSM through GigabitEthernet 0/1, and sets the hash mask length for the RP election mechanism to **30** and the priority to **192**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip pim bsr-candidate GigabitEthernet 0/1 30 192
```

Notifications

If the current interface is not set to the SM mode, the following notification will be displayed:

```
Warning: PIMSM not configured on %s, BSR messages not originated.
```

1.9 ip pim bfd

Function

Run the **ip pim bfd** command to configure PIM-BFD correlation.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Syntax

ip pim bfd

no ip pim bfd

default ip pim bfd

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Bidirectional forwarding detection (BFD) is used to quickly detect or monitor links or IP route forwarding connectivity in a network.

Based on the PIM-SM protocol, a designated router (DR) is defined. This DR is the unique role that forwards multicast data in a shared network.

Devices in the shared network exchange hello messages and elect a DR based on the hello messages. When the DR is faulty, a new round of DR election can be started only after the PIM neighbor ages. If this command is run, when the DR is faulty, this faulty DR can be detected and a new round of election can be started in milliseconds.

Examples

The following example configures PIM-BFD correlation on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname (config-if-GigabitEthernet 0/1)# ip pim bfd
```

1.10 ip pim dr-priority

Function

Run the **ip pim dr-priority** command to configure the DR priority.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default DR priority is **1**.

Syntax

ip pim dr-priority *priority-value*

no ip pim dr-priority

default ip pim dr-priority

Parameter Description

priority-value: DR priority. A larger value indicates a higher priority. The value range is from 0 to 4294967294.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If multiple devices in a LAN join DR election, the election result is subject to the priorities in hello messages. The device with the highest priority is elected as the DR. If the priorities in the hello messages are the same or the priority parameter is not set in the hello messages, the device with the largest IP address is elected as the DR.

Examples

The following example sets the DR priority to **10000** on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim dr-priority 10000
```

1.13 ip pim neighbor-filter

Function

Run the **ip pim neighbor-filter** command to enable the neighbor filtering function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The neighbor filtering function is disabled by default.

Syntax

ip pim neighbor-filter { *acl-name* | *acl-number* }

no ip pim neighbor-filter { *acl-name* | *acl-number* }

default ip pim neighbor-filter { *acl-name* | *acl-number* }

Parameter Description

acl-name: Standard IP ACL name that is used to limit the address range of neighbors. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Standard IP ACL number that is used to limit the address range of neighbors. The value range is from 1 to 99.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The neighbor filtering function can strengthen PIM network security and limit the valid address range of neighbors. If a neighbor is filtered out based on an access filtering list, PIM-SM does not create peer relationship with the neighbor or stops the peer relationship with this neighbor.

Examples

The following example uses ACL 14 to filter out a neighbor with the IP address 192.168.1.5 and the mask 0.0.0.255 on GigabitEthernet 0/1. PIM-SM does not create peer relationship with the neighbor (192.168.1.5).

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# access-list 14 deny 192.168.1.5 0.0.0.255
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim neighbor-filter 14
Hostname(config-if-GigabitEthernet 0/1)# exit
```

Notifications

If no ACL is configured, the following notification will be displayed:

```
% access-list 14 not exist
```

Common Errors

1.14 ip pim neighbor-tracking

Function

Run the **ip pim neighbor-tracking** command to enable the neighbor tracking function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The neighbor tracking function is disabled by default.

Syntax

ip pim neighbor-tracking

no ip pim neighbor-tracking

default ip pim neighbor-tracking

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After the suppression capability of an interface is enabled, when a multicast device plans to send a join packet to an uplink multicast device but it receives a join packet sent from the neighbor to the uplink multicast device, this local multicast device suppresses its own join packet. If the suppression capability of the interface is disabled, the join packet can be sent. When the suppression capability of downlink hosts is disabled, an uplink device can

determine the number of the downlink hosts based on the quantity of received join packets. This is neighbor tracking.

Examples

The following example disables the suppression function on GigabitEthernet 0/1 to implement neighbor tracking.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim neighbor-tracking
```

1.15 ip pim override-interval

Function

Run the **ip pim override-interval** command to configure the prune override interval of an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.
The default prune override interval is **2500** ms.

Syntax

ip pim override-interval *override-interval*

no ip pim override-interval

default ip pim override-interval

Parameter Description

override-interval: Prune override interval, in milliseconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Modifying the propagation delay or override delay affects the prune override interval.

The network administrator needs to ensure that the prune override interval is smaller than the prune packet hold time. Otherwise, a short interrupt may occur.

Examples

The following example sets the prune override interval to 3000 ms on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim override-interval 3000
```

1.16 ip pim probe-interval

Function

Run the **ip pim probe-interval** command to configure the register-probe time.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default register-probe time is **5** seconds.

Syntax

ip pim probe-interval *interval*

no ip pim probe-interval

default ip pim probe-interval

Parameter Description

interval: Register-probe interval, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The register-probe time refers to the time when the source DR is allowed to send null register messages to the RP before the register suppression timer times out.

The register-probe time cannot be greater than a half of the register suppression time. Otherwise, the configuration fails and an alarm is generated.

The sum of the three times register suppression time and the register-probe time does not exceed 65535. Otherwise, the configuration fails and an alarm is generated.

Examples

The following example sets the register-probe time to 6 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip pim probe-interval 6
```

1.17 ip pim propagation-delay

Function

Run the **ip pim propagation-delay** command to configure the propagation delay of an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default propagation delay of an interface is **500** ms.

Syntax

ip pim propagation-delay *propagation-delay*

no ip pim propagation-delay

default ip pim propagation-delay

Parameter Description

propagation-delay: Propagation delay, in milliseconds. The value range is from 1 to 32767.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Modifying the propagation delay or override delay affects the prune override interval.

The network administrator must ensure that the override interval is smaller than the prune packet hold time. Otherwise, a short interrupt may occur.

Examples

The following example sets the override delay to 600 ms on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim propagation-delay 600
```

1.18 ip pim query-interval

Function

Run the **ip pim query-interval** command to configure the hello message sending interval.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The hello message is sent at an interval of **30** seconds by default.

Syntax

ip pim query-interval *interval*

no ip pim query-interval

default ip pim query-interval

Parameter Description

interval: Hello message sending interval, in seconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When the hello message sending interval is updated, the hello message hold time is updated accordingly. The hello message hold time is 3.5 times the hello message sending interval. If the product of the hello message sending interval and 3.5 is greater than 65535, the hello message sending interval is forcibly reset to 18725.

Examples

The following example sets the hello message sending interval to 123 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim query-interval 123
```

1.19 ip pim register-checksum-wholepkt

Function

Run the **ip pim register-checksum-wholepkt** command to calculate the checksum of entire packets.

Run the **no** form of this command to remove this configuration and calculate the checksum of headers of PIM packets and register messages, rather than the entire packets.

Run the **default** form of this command to restore the default configuration.

By default, only the headers of PIM packets and register messages, rather than the entire packets, are specified for calculating the checksum.

Syntax

ip pim register-checksum-wholepkt [**group-list** { *acl-name* | *acl-number* }]

no ip pim register-checksum-wholepkt [**group-list** { *acl-name* | *acl-number* }]

default ip pim register-checksum-wholepkt [**group-list** { *acl-name* | *acl-number* }]

Parameter Description

group-list *acl-name*: Uses a standard IP ACL name to limit the addresses of multicast groups that support this configuration. The value is a case-sensitive string of 1 to 99 characters.

group-list *acl-number*: Uses a standard IP ACL number to limit the addresses of multicast groups that support this configuration. The value range is from 1 to 99 or from 1300 to 1999.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The checksum of the entire PIM protocol packets (including encapsulated multicast packets), rather than the PIM headers of separate register messages, is calculated.

If the **group-list** parameter is not specified, the entire packet checksum calculation method applies to register messages with any group address.

If you run the **no** or **default** form of this command to specify the **group-list** parameter and specify to use the configured ACL, the limits of the ACL associated with the **group-list** parameter are removed. In this case, the entire packet checksum calculation method applies to register messages with any group address.

Examples

The following example calculates the checksum of the entire packets whose multicast group addresses comply with ACL 99, where the multicast group address is 225.1.1.1 and the reverse mask is 0.0.0.255.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 99 permit 225.1.1.1 0.0.0.255
Hostname(config)# ip pim register-checksum-wholepkt group-list 99
```

Notifications

If no ACL is configured, the following notification will be displayed:

```
% access-list 99 not exist
```

1.20 ip pim register-decapsulate-forward

Function

Run the **ip pim register-decapsulate-forward** command to enable the function for the RP to decapsulate register messages and forward multicast packets in the messages.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function for the RP to decapsulate register messages and forward multicast packets in the messages is disabled by default.

Syntax

ip pim register-decapsulate-forward

no ip pim register-decapsulate-forward

default ip pim register-decapsulate-forward

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is run on a static RP or C-RP to decapsulate the received register messages and forward the multicast packets in the received register messages.

The register message decapsulation and multicast packet forwarding function is implemented by this command. If there are too many register messages to be decapsulated and forwarded, the CPU is overloaded. Therefore, you are not advised to enable this function.

Examples

The following example decapsulates the received register messages and forwards the multicast packets in the received register messages on the RP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip pim register-decapsulate-forward
```

Function

Run the **ip pim register-rate-limit** command to limit the sending rate of register messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The sending rate of register messages is not limited by default.

Syntax

ip pim register-rate-limit *rate*

no ip pim register-rate-limit

default ip pim register-rate-limit

Parameter Description

rate: Maximum number of register messages that can be sent per second. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the sending rate of register messages in (S, G) status, rather than that of the entire system. Running this command can reduce the load of the source DR and RP. Register messages sent at a rate exceeding the limit are discarded.

Examples

The following example sets the sending rate of register messages to 3000 per second.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip pim register-rate-limit 3000
```

1.23 ip pim register-source

Function

Run the **ip pim register-source** command to specify a source IP address in register messages.

Run the **no** form of this command to specify the address of the DR interface connected to the source as the source IP address of register messages.

Run the **default** form of this command to restore the default configuration.

The source IP address in the register messages is the address of the DR interface connected to the source by default.

Syntax

ip pim register-source { *local-address* | *interface-type interface-number* }
no ip pim register-source
default ip pim register-source

Parameter Description

local-address: Source IP address in register messages.

interface-type interface-number: IP address of local interface, which is specified as source IP address of register messages.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The configured source address in register messages must be reachable so that the source can react properly when the RP sends a correct register-stop message.

It is recommended that the loopback address be used as the source IP address in register messages. Other physical addresses can be used as the source IP addresses in register messages as well.

The status of the PIM function does not affect this configuration.

Examples

The following example specifies the IP address 192.168.195.80 of GigabitEthernet 0/1 as the source IP address in register messages.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# ip pim register-source 192.168.195.80
Hostname(config)# ip pim register-source GigabitEthernet 0/1
```

Function

Run the **ip pim register-suppression** command to configure the register suppression time.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.
The default register suppression time is **60** seconds.

Syntax

ip pim register-suppression *suppression-time*

no ip pim register-suppression

default ip pim register-suppression

Parameter Description

suppression-time: Register suppression time, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be run on the DR to configure the register suppression time.

If the **ip pim rp-register-kat** command is not run on the DR, configuring the register suppression time on the RP changes the RP keep-alive time.

Examples

The following example sets the register suppression time to 100 seconds.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# ip pim register-suppression 100
```

Notifications

If two times the register-probe time is greater than the register suppression time, the following notification will be displayed:

```
WARNING: Register suppression interval MUST be larger than twice the register
probe interval. Please set a larger one.
```

If the sum of three times register suppression time and the register-probe time is greater than 65535, the following notification will be displayed:

```
WARNING: Register suppression interval is too large. It may cause (3*RST+probe-
interval) > 65535.
```

1.25 ip pim rp-address

Function

Run the **ip pim rp-address** command to configure static RPs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static RP is configured by default.

Syntax

ip pim rp-address *rp-address* [{ *acl-name* | *acl-number* }]

no ip pim rp-address *rp-address* [{ *acl-name* | *acl-number* }]

default ip pim rp-address *rp-address* [{ *acl-name* | *acl-number* }]

Parameter Description

rp-address: IP address of an RP.

acl-name: Standard IP ACL name that is used to limit the address range of groups served by this RP. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Standard IP ACL number that is used to limit the address range of groups served by this RP. The value range is from 1 to 99 or from 1300 to 1999.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If static and dynamic RPs are available at the same time, dynamic RPs are preferred.

If multiple static RPs serve the same multicast group, the static RP with a larger address is preferred.

If the *acl-name* or *acl-number* parameter is not specified, the static RPs serve all groups.

Examples

The following example sets the IP address of a static RP to 210.34.0.55, the address of the group served by this RP to 255.1.1.1 (defined based on access list 4), and the reverse mask to 0.0.0.255.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 4 permit 225.1.1.1 0.0.0.255
Hostname(config)# ip pim rp-address 210.34.0.55 4
```

Notifications

If the RP address is not a valid address, the following notification will be displayed:

```
Illegal RP address, ignored
```

If the number of RP addresses reaches the upper limit, the following notification will be displayed:

```
Reach PIM-SM static RP configuration limit 65536
```

If no ACL is configured, the following notification will be displayed:

```
% access-list 4 not exist
```

1.26 ip pim rp-candidate

Function

Run the **ip pim rp-candidate** command to configure C-RPs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No C-RP is configured by default.

Syntax

ip pim rp-candidate *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval*] [**group-list** { *acl-name* | *acl-number* }]

no ip pim rp-candidate [*interface-type interface-number*]

default ip pim rp-candidate [*interface-type interface-number*]

Parameter Description

interface-type interface-number: Name of an interface whose IP address is used as the C-RP address.

priority-value: RP priority. The value range is from 0 to 255, and the default value is **192**.

interval: Interval of sending C-RP messages to the BSR. The value range is from 1 to 16383, and the default value is **60** seconds.

group-list *acl-name*: Uses a standard IP ACL name to limit the address range of groups served by this C-RP. The value is a case-sensitive string of 1 to 99 characters. By default, a C-RP serves all groups.

group-list *acl-number*: Uses a standard IP ACL number to limit the address range of groups served by this C-RP. The value range is from 1 to 99. By default, the C-RP serves all groups.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In PIM-SM, a rendezvous point tree (RPT) created based on multicast routing data takes the RP as a root and group members as leaves. An RP is elected from C-RPs. After a BSR is elected, all C-RPs periodically send unicast messages to the BSR and then the BSR forwards the messages throughout the PIM domain.

When an ACL is used to specify the address range of groups served by the C-RP, only the permit access control entry (ACE) is calculated, and the deny ACE is not calculated.

Examples

The following example sets the address of GigabitEthernet 0/1 to the C-RP address, the RP priority to 200, and the interval of sending C-RP messages to the BSR to 70 seconds, and uses the ACL to limit the address range of groups served by the C-RP to 225.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 3 permit 225.1.1.1 0.0.0.255
Hostname(config)# ip pim rp-candidate GigabitEthernet 0/1 priority 200 group-list
3 interval 70
```

Notifications

If the multicast function is not enabled on an interface, the following notification will be displayed:

```
Warning: PIMSM not configured on %s, Candidate-RP not advertised
```

1.28 ip pim sparse-mode

Function

Run the **ip pim sparse-mode** command to enable the PIM-SM function on an interface.

Run the **no** form of this command to disable this function on an interface.

Run the **default** form of this command to restore the default configuration.
The PIM-SM function is disabled on an interface by default.

Syntax

ip pim sparse-mode

no ip pim sparse-mode

default ip pim sparse-mode

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Before PIM-SM is enabled, you must enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if PIM-SM is enabled.

It is not recommended that different IPv4 multicast routing protocols be configured on interfaces of a device.

When PIM-SM is enabled, IGMP is automatically enabled on different interfaces.

The multicast function can be enabled on a tunnel interface that does not support multicast. In this case, no notification will be displayed and multicast packets will not be sent or received.

A multicast tunnel cannot be nested and does not support multicast data QoS/ACL.

Examples

The following example enables the PIM-SM function on GigabitEthernet 0/1.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim sparse-mode
```

Notifications

If the specified interface does not exist, the following notification will be displayed:

```
ip pim sparse-mode (vif == NULL)
```

If the multicast function is not enabled, the following notification will be displayed:

```
WARNING:  \"ip multicast-routing\"  is not configured, PIM Sparse-mode
```

If the interfaces exceed the upper limit, the following notification will be displayed:

```
PIM-SM Configure failed! VIF limit exceeded in NSM!!!
```

1.29 ip pim sparse-mode passive

Function

Run the **ip pim sparse-mode passive** command to enable the PIM-SM passive mode on an interface.

Run the **no** form of this command to disable this mode.

Run the **default** form of this command to restore the default configuration.

The PIM-SM passive mode is disabled on an interface by default.

Syntax

ip pim sparse-mode passive

no ip pim sparse-mode passive

default ip pim sparse-mode passive

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Before the PIM-SM passive mode is enabled, you must enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if the PIM-SM passive mode is enabled.

When the PIM-SM passive mode is enabled, IGMP is automatically enabled on different interfaces.

After the PIM-SM passive mode is enabled on an interface, the interface does not receive or send PIM packets, but it can forward multicast packets. It is recommended that the PIM-SM passive mode be enabled on an interface of a stub network device connected to hosts. This avoids L2 flooding of the PIM hello messages.

Examples

The following example enables the PIM-SM passive mode on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim sparse-mode passive
```

Notifications

N/A

Common Errors

The PIM-SM passive mode is enabled on an interface connected to a source. The source interface does not send or receive PIM packets; therefore, it loses the DR election capability. It is not recommended that the PIM-SM passive mode be enabled on an interface connected to a source.

After the PIM-SM passive mode is enabled on an interface, if two devices in the same network segment forward multicast data, assertion election cannot proceed. As a result, two identical multicast packets are sent to this network segment.

If the PIM-SM passive mode is enabled on an interface of an intermediate device deployed on an L3 multicast network, the networking fails because the interface does not receive or send PIM packets.

Platform Description

N/A

1.30 ip pim sparse-mode subvlan

Function

Run the **ip pim sparse-mode subvlan** command to enable the PIM-SM function for sub VLANs of a super VLAN interface.

Run the **no** form of this command to disable this function for sub VLANs of a super VLAN interface.

Run the **default** form of this command to restore the default configuration.

The PIM-SM function is disabled on a super VLAN interface by default.

Syntax

ip pim sparse-mode subvlan { **all** | *vlan-id* }

no ip pim sparse-mode subvlan

default ip pim sparse-mode subvlan

Parameter Description

all: Sends PIM-SM protocol packets to all sub VLANs.

vlan-id: ID of a sub VLAN to which PIM-SM protocol packets are sent.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Generally, a super VLAN contains many sub VLANs. If PIM-SM is enabled on a super VLAN interface, the super VLAN interface duplicates the protocol packets and sends them to all sub VLANs. If the number of sub VLANs is too many, exceeding the processing capability of the device, packets are discarded, resulting in protocol flapping.

In most scenarios, the PIM-SM protocol is disabled by default and not needed on a super VLAN interface. This interface does not send or receive PIM packets. If the PIM-SM protocol is needed on a super VLAN interface in some scenarios, you can run this command to enable the protocol.

Examples

The following example enables PIM-SM packets to be sent to sub VLAN 200 on super VLAN 100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 100
Hostname(config-vlan)# supervlan
Hostname(config-vlan)# interface vlan 100
Hostname(config-if-vlan 100)# ip pim sparse-mode subvlan 200
```

Notifications

If this command is run on a non-super VLAN interface, the following notification will be displayed:

```
%% this command can apply to supervlan switch virtual interface only.
```

If the specified sub VLAN ID is consistent with the VLAN ID of an SVI, the following notification will be displayed:

```
%% subvlan vid(%d) is equal to SVI vlan id, not support
```

Common Errors

- This command is run on a non-super VLAN interface.
- The sub VLAN specified on a super VLAN interface cannot communicate with neighbors.

Platform Description

1.31 ip pim spt-threshold

Function

Run the **ip pim spt-threshold** command to enable the shortest path tree (SPT) switchover function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The SPT switchover function is disabled by default.

Syntax

ip pim spt-threshold [**group-list** { *acl-name* | *acl-number* }]

no ip pim spt-threshold [**group-list** { *acl-name* | *acl-number* }]

default ip pim spt-threshold [**group-list** { *acl-name* | *acl-number* }]

Parameter Description

group-list *acl-name*: Uses a standard IP ACL name to limit the address range of groups that support SPT switchover. The value is a case-sensitive string of 1 to 99 characters.

group-list *acl-number*: Uses a standard IP ACL number to limit the address range of groups that support SPT switchover. The value range is from 1 to 99 or from 1300 to 1999.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the **group-list** parameter is not specified, all groups support SPT switchover.

If you run the **no** or **default** form of this command to specify the **group-list** parameter and specify to use the configured ACL, the limits on the ACL associated with the **group-list** parameter are removed. In this case, all groups are allowed to switch over from an RPT to an SPT.

Examples

The following example uses ACL 12 to specify the multicast group with the address 225.1.1.1 and reverse mask 0.0.0.255 to support SPT switchover.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 12 permit 225.1.1.1 0.0.0.255
```

```
Hostname(config)# ip pim spt-threshold group-list 12
```

1.32 ip pim ssm

Function

Run the **ip pim ssm** command to enable the SSM function and configure an SSM group address range.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The SSM function is disabled by default.

Syntax

ip pim ssm { **default** | **range** { *acl-name* | *acl-number* } }

no ip pim ssm

default ip pim ssm

Parameter Description

default: Specifies the default SSM group address range. The value range is from 232.0.0.0 to 232.0.0.8.

range *acl-name*: Uses a standard IP ACL name to limit the SSM group address range. The value is a case-sensitive string of 1 to 99 characters.

range *acl-number*: Uses a standard IP ACL number to limit the SSM group address range. The value range is from 1 to 99.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If SSM applications must be implemented in the PIM-SM network, this command must be run.

Examples

The following example enables the SSM function and sets the SSM group address range to 232/8.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip pim ssm default
```

The following example enables the SSM function and sets the SSM group address range to 226/8.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 10 permit 226.0.0.1 0.0.0.255
Hostname(config)# ip pim ssm range 10
```

1.33 ip pim triggered-hello-delay

Function

Run the **ip pim triggered-hello-delay** command to configure the hello message sending delay on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.
The default hello message sending delay is **5** seconds.

Syntax

ip pim triggered-hello-delay *delay*
no ip pim triggered-hello-delay
default ip pim triggered-hello-delay

Parameter Description

delay: Hello message sending delay, in seconds. The value range is from 1 to 5.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When a PIM interface is enabled or detects a new neighbor, a random time is generated. Within the time, the interface sends hello messages.

Examples

The following example sets the hello message sending delay to 3 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim triggered-hello-delay 3
```

1 PIM-DM Commands

Command	Function
clear ip pim dense-mode track	Clear statistical information about PIM-DM packets.
ip pim bfd	Enable the PIM-BFD function on an interface.
ip pim dense-mode	Enable the PIM-DM function on an interface.
ip pim dense-mode passive	Enable the PIM-DM passive mode on an interface.
ip pim dense-mode subvlan	Enable the PIM-DM function on a super VLAN interface.
ip pim neighbor-filter	Enable the neighbor filtering function on an interface.
ip pim override-interval	Configure the prune override interval of hello messages.
ip pim propagation-delay	Configure the propagation delay of hello messages.
ip pim query-interval	Configure the hello message sending interval.
ip pim state-refresh disable	Disable the PIM-DM state refresh function on an interface.
ip pim state-refresh origination-interval	Configure the PIM-DM SRM sending interval on an interface.
ip pim mib dense-mode	Switch over the management object of the MIB function from PIM-SM to PIM-DM.
show ip pim dense-mode interface	Display information of a PIM-DM interface.
show ip pim dense-mode mroute	Display PIM-DM routing entry information.
show ip pim dense-mode neighbor	Display PIM-DM neighbor information.
show ip pim dense-mode nexthop	Display PIM-DM next hop information.
show ip pim dense-mode track	Display statistical information about PIM-DM packets.

1.1 clear ip pim dense-mode track

Function

Run the **clear ip pim dense-mode track** command to clear statistical information about PIM-DM packets.

Syntax

clear ip pim dense-mode track

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command resets the statistic start time and clears the counter of PIM-DM packets.

Examples

The following example clears statistical information about the PIM-DM packets.

```
Hostname> enable
Hostname# clear ip pim dense-mode track
```

1.2 ip pim bfd

Function

Run the **ip pim bfd** command to enable the PIM-BFD function on an interface.

Run the **no** form of this command to disable this function.

The PIM-BFD function is disabled on an interface by default.

Syntax

ip pim bfd

no ip pim bfd

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Bidirectional forwarding detection (BFD) is a detection mechanism applying to an entire network and it is used to quickly detect or monitor links or IP route forwarding connectivity in a network.

PIM-DM uses the assertion election mechanism. The assertion winning device functions as a unique forwarder of multicast data in a shared network. If multiple devices in a shared network receive multicast data concurrently, they forward the data to the same devices. These devices mutually transmit assert packets and elect a winning device based on the assert packets. The winning device forwards traffic. When the neighbor interface changes, the change can be quickly detected by BFD correlation and a new round of election can be initiated.

Examples

The following example enables the PIM-BFD function on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim bfd
```

1.3 ip pim dense-mode

Function

Run the **ip pim dense-mode** command to enable the PIM-DM function on an interface.

Run the **no** form of this command to disable this function on an interface.

Run the **default** form of this command to restore the default configuration.

The PIM-DM function is disabled on an interface by default.

Syntax

ip pim dense-mode

no ip pim dense-mode

default ip pim dense-mode

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The PIM-DM function must be enabled on an interface to process PIM packets of PIM neighbors so that a PIM-DM network can be constructed. PIM-DM can effectively solve multicast data transmission of small networks with densely located hosts. You are advised to enable PIM-DM on all L3 interfaces of the PIM-DM network and configure the same IPv4 multicast routing protocol on interfaces of a device.

Before PIM-DM is enabled, you must enable the multicast routing and forwarding function in global configuration mode. Otherwise, the PIM-DM function does not take effect. When PIM-DM is enabled, IGMP is automatically started on different interfaces.

For tunnel interfaces, only 4Over4, 4Over4 GRE, 4Over6, and 4Over6 GRE support the IPv4 multicast function. The multicast function can be enabled on a tunnel interface that does not support multicast. In this case, no notification is displayed and multicast packets are not sent or received through this interface. A multicast tunnel must be created on an Ethernet interface, and it cannot be nested and does not support multicast data QoS/ACL.

Examples

The following example enables the PIM-DM function on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim dense-mode
```

Notifications

If the multicast routing function is not enabled on a device, the following notification will be displayed:

```
WARNING:  "ip multicast-routing"  is not configured, PIM Dense-mode will not
start-up.
```

If the number of multicast interfaces on a device reaches the upper limit, the following notification will be displayed:

```
Operation failed: PIM-DM VIF limit exceeded
```

If the interface is not added to the global VRF, the following notification will be displayed:

```
PIM-DM allow to configure on vrf 0 only
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **ip multicast-routing** (IPv4 multicast routing management)

1.4 ip pim dense-mode passive

Function

Run the **ip pim dense-mode passive** command to enable the PIM-DM passive mode on an interface.

Run the **no** form of this command to disable this mode on an interface.

Run the **default** form of this passive command to restore the default configuration.

The PIM-DM passive mode is disabled on an interface by default.

Syntax

ip pim dense-mode passive

no ip pim dense-mode passive

default ip pim dense-mode passive

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Before the PIM-DM passive mode is enabled, enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if PIM-DM passive mode is enabled.

When the PIM-DM passive mode is enabled, IGMP is automatically enabled on different interfaces.

After the PIM-DM passive mode is enabled on an interface, the interface does not receive or send PIM packets, but it can forward multicast packets. You are advised to enable the PIM-DM passive mode on an interface of a stub network device connected to hosts. This avoids L2 flooding of the PIM hello messages.

Examples

The following example enables the PIM-DM passive mode on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
```

```
Hostname(config-if-GigabitEthernet 0/1)# ip pim dense-mode passive
```

Notifications

If the multicast routing function is not enabled on a device, the following notification will be displayed:

```
WARNING: "ip multicast-routing" is not configured, PIM Dense-mode passive will
not start-up.
```

If the number of multicast interfaces on a device reaches the upper limit, the following notification will be displayed:

```
Operation failed: PIM-DM VIF limit exceeded
```

If the interface is not added to the global VRF, the following notification will be displayed:

```
PIM-DM allow to configure on vrf 0 only
```

Common Errors

If two devices in a network segment forward multicast packets, assertion election cannot proceed. If the **pim dense-mode passive** mode is enabled on the interface, the assertion election mechanism fails. As a result, two identical multicast packets are sent to this network segment.

If the **pim dense-mode passive** mode is enabled on an interface of an intermediate device deployed on an L3 multicast network, the networking fails because the interface does not receive or send PIM packets.

Platform Description

N/A

Related Commands

- **ip multicast-routing** (IPv4 multicast routing management)

1.5 ip pim dense-mode subvlan

Function

Run the **ip pim dense-mode subvlan** command to enable the PIM-DM function on a super VLAN interface.

Run the **no** form of this command to disable this function on a super VLAN interface.

Run the **default** form of this command to restore the default configuration.

The PIM-DM function is disabled on a super VLAN interface by default.

Syntax

ip pim dense-mode subvlan [**all** | *subvlan-id*]

no ip pim dense-mode subvlan

default ip pim dense-mode subvlan

Parameter Description

all: Specifies that PIM-DM packets are sent to all sub VLANs.

subvlan-id: ID of a sub VLAN to which PIM-DM packets are sent. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Generally, a super VLAN contains many sub VLANs. If PIM-DM is enabled on a super VLAN interface, the super VLAN interface duplicates the protocol packets and sends them to all sub VLANs. If the number of sub VLANs is too many, exceeding the processing capability of the device, packets are discarded, resulting in protocol flapping.

In most scenarios, the PIM-DM protocol is disabled by default and not needed on a super VLAN interface. This interface does not send or receive PIM packets. If the PIM-DM protocol is needed on a super VLAN interface in some scenarios, you can run this command to enable the protocol. Note that if all sub VLANs are specified to receive packets, the transmission performance may be reduced, causing neighbor flapping.

Examples

The following example enables the PIM-DM function on the super VLAN interface with VLAN 100 and specifies PIM packets to be sent to sub VLAN 200.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface vlan 100
Hostname(config-if-vlan 100)# ip pim dense-mode subvlan 200
```

Notifications

If this command is run on a non-super VLAN interface, the following notification will be displayed:

```
%% this command can apply to supervlan switch virtual interface only.
```

If the specified sub VLAN ID is consistent with the VLAN ID of an SVI, the following notification will be displayed:

```
%% subvlan vid(%d) is equal to SVI vlan id, not support
```

Common Errors

- This command is run on a non-super VLAN interface.
- The sub VLAN specified on a super VLAN interface cannot communicate with neighbors.

1.6 ip pim neighbor-filter

Function

Run the **ip pim neighbor-filter** command to enable the neighbor filtering function on an interface.

Run the **no** form of this command to disable this function on the interface.

Run the **default** form of this command to restore the default configuration.

The neighbor filtering function is disabled on an interface by default.

Syntax

ip pim neighbor-filter { *acl-name* | *acl-number* }

no ip pim neighbor-filter { *acl-name* | *acl-number* }

default ip pim neighbor-filter { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of a standard IP ACL. The value is a case-sensitive string of 1 to 99 characters.

acl- number: No. of a standard IP ACL. The value range is from 1 to 99.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If a neighbor is filtered out based on an access filtering list, PIM-DM does not create peer relationship with the neighbor or stops the peer relationship with this neighbor.

Only addresses that meet ACL filtering conditions can be used as PIM neighbors of the current interface. Otherwise, the addresses filtered out cannot be neighbors. Peering refers to exchange of protocol packets between PIM neighbors. If peering with a PIM device is suspended, the neighbor relationship with it cannot be formed so that PIM protocol packets will not be received from the device.

Examples

The following example enables the neighbor filtering function on GigabitEthernet 0/1 and uses ACL 14 as the filtering rule.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim neighbor-filter 14
```

1.9 ip pim query-interval

Function

Run the **ip pim query-interval** command to configure the hello message sending interval.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Hello messages are sent at an interval of **30** seconds by default.

Syntax

ip pim query-interval *query-interval*

no ip pim query-interval

default ip pim query-interval

Parameter Description

query-interval: Hello message sending interval, in seconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the hello message sending interval is configured, the hello message hold time is updated as a product of 3.5 and the hello message sending interval.

Examples

The following example sets the hello message sending interval to 123 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip pim query-interval 123
```

1.10 ip pim state-refresh disable

Function

Run the **ip pim state-refresh disable** command to disable the PIM-DM state refresh function on an interface.

Run the **no** form of this command to restore the PIM-DM state refresh function on an interface.

Run the **default** form of this command to restore the default configuration.

The PIM-DM SRMs are processed and forwarded by default.

Syntax

ip pim state-refresh disable

no ip pim state-refresh disable

default ip pim state-refresh disable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the PIM state refresh function is disabled, SRMs are not processed or forwarded. The SR Cap option is not included in a hello message, and is not processed when the hello message is received.

Disabling the PIM-DM state refresh function may cause the converged PIM-DM MDT to re-converge, which leads to unnecessary bandwidth waste and multicast routing table flapping. Therefore, you are not advised to disable this function in general conditions.

Examples

The following example disables the PIM-DM state refresh function on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config-if-GigabitEthernet 0/1)# ip pim state-refresh disable
```

1 IGMP Snooping Commands

Command	Function
clear ip igmp snooping gda-table	Clear dynamic forwarding entries.
clear ip igmp snooping statistics	Clear IGMP snooping statistics.
deny	Deny a range of multicast groups specified by a profile.
ip igmp profile	Create a profile and enter the profile configuration mode.
ip igmp snooping dyn-mr-aging-time	Configure the aging time of dynamic multicast router ports.
ip igmp snooping fast-leave enable	Enable the port fast leave function.
ip igmp snooping filter	Apply a profile to a port to restrict the multicast groups that user hosts connecting to the port can join.
ip igmp snooping vlan filter	Apply a profile to a VLAN to restrict the multicast groups that user hosts in the VLAN can join.
ip igmp snooping host-aging-time	Configure the aging time for IGMP snooping dynamic member ports.
ip igmp snooping ivgl	Enable IGMP snooping globally and run the Independent VLAN Group Learning (IVGL) mode.
ip igmp snooping ivgl-svgl	Enable IGMP snooping globally and run the IVGL-SVGL mode.
ip igmp snooping l2-entry-limit	Configure the maximum number of multicast groups allowed for concurrent request globally.
ip igmp snooping limit-ipmc vlan address server	Specify a multicast group address and multicast source address for a VLAN.
ip igmp snooping max-groups	Configure the maximum number of multicast groups that can be dynamically learned by a port.
ip igmp snooping mrouter learn pim-dvmrp	Enable the function of dynamic multicast router port learning.
ip igmp snooping preview	Enable the multicast preview function.
ip igmp snooping preview interval	Configure the multicast preview duration.

ip igmp snooping querier	Enable the IGMP snooping querier function.
ip igmp snooping querier address	Configure the source IP address of the IGMP snooping querier.
ip igmp snooping querier max-response-time	Configure the maximum response time of IGMP snooping queriers.
ip igmp snooping querier query-interval	Configure the interval for an IGMP snooping querier to send Query packets.
ip igmp snooping querier timer expiry	Configure the aging time of IGMP snooping queriers.
ip igmp snooping querier version	Specify the version of an IGMP snooping querier
ip igmp snooping query-max-response-time	Configure the maximum response time for Query packets.
ip igmp snooping source-check default-server	Enable the source IP address check function and specify the source IP address.
ip igmp snooping source-check port	Enable the source port check function.
ip igmp snooping suppression enable	Enable the Report packet suppression function.
ip igmp snooping svgl	Enable IGMP snooping globally and run the Shared VLAN Group Learning (SVGL) mode.
ip igmp snooping svgl profile	Specify the range of multicast groups applied in the SVGL mode.
ip igmp snooping svgl subvlan	Specify the sub VLANs applied in the SVGL mode.
ip igmp snooping svgl vlan	Specify the shared VLAN applied in the SVGL mode.
ip igmp snooping tunnel	Enable the function of transparent IGMP packet transmission on the QinQ port.
ip igmp snooping vlan	Enable the IGMP snooping function in IVGL mode on a VLAN.
ip igmp snooping vlan mrouter interface	Configure a static multicast router port.
ip igmp snooping vlan static interface	Configure a static member port.
permit	Permit a range of multicast groups defined by a profile.
range	Define a range of multicast groups for a profile.
show ip igmp profile	Display configurations of a profile.

show ip igmp snooping	Display IGMP snooping information.
show ip igmp snooping gda-table	Display the IGMP snooping forwarding table.
show ip igmp snooping interfaces	Display multicast filter configurations on a port.
show ip igmp snooping mrouter	Display IGMP snooping multicast router ports.
show ip igmp snooping querier	Display IGMP snooping querier information.
show ip igmp snooping statistics	Display IGMP snooping statistics.

1.1 clear ip igmp snooping gda-table

Function

Run the **clear ip igmp snooping gda-table** command to clear dynamic forwarding entries.

Syntax

clear ip igmp snooping gda-table

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

An Internet Group Management Protocol (IGMP) snooping forwarding entry includes the virtual local area network (VLAN) ID, multicast group address, multicast router ports, and member ports.

A VLAN ID (VID) and multicast group address uniquely identify a forwarding entry.

A forwarding entry may contain multiple multicast router ports, which may be dynamically learned or statically configured. Static multicast router ports never age.

A forwarding entry may contain multiple member ports, which may be dynamically learned or statically configured. Static member ports never age. This command cannot be used to delete static member ports.

Examples

The following example clears IGMP snooping dynamic forwarding entries.

```
Hostname> enable
Hostname# clear ip igmp snooping gda-table
```

1.2 clear ip igmp snooping statistics

Function

Run the **clear ip igmp snooping statistics** command to clear IGMP snooping statistics.

Syntax

clear ip igmp snooping statistics

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command can be used to clear statistics displayed by running the **show ip igmp snooping querier**

Function

Run the **show ip igmp snooping querier** command to display IGMP snooping querier information.

Syntax

show **ip igmp snooping querier** [**detail** | **vlan** *vlan-id*]

Parameter Description

vlan *vlan-id*: Specifies a VLAN. If this parameter is not specified, configurations of all VLANs are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays IGMP snooping querier information.

```
Hostname# enable
Hostname# show ip igmp snooping querier
Vlan     IP Address          IGMP Version          Port
-----------------------------------------------------------
3        1.1.1.1               1                switch
```

Table 1-1 Output Fields of the show ip igmp snooping querier Command

1.3 deny

Function

Run the **deny** command to deny a range of multicast groups specified by a profile.

The **deny** action is performed for a profile by default.

Syntax

deny

Parameter Description

N/A

Command Modes

Profile configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ip igmp profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups.

Examples

The following example creates profile 1, defines the group range of 224.2.2.2 to 224.2.2.244, and denies profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp profile 1
Hostname(config-profile)# range 224.2.2.2 224.2.2.244
Hostname(config-profile)# deny
```

1.4 ip igmp profile

Function

Run the **ip igmp profile** command to create a profile and enter the profile configuration mode.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No profile is created by default.

Syntax

ip igmp profile *profile-number*

no ip igmp profile *profile-number*

default ip igmp profile *profile-number*

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ip igmp profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups.

(4) If the Deny action is configured and no multicast group range is configured, no group is denied. The effect is same as that of permitting all groups.

(5) If the Permit action is configured and no multicast group range is configured, no group is permitted. The effect is same as that of denying all groups.

Examples

The following example creates profile 1, defines the group range of 224.2.2.2 to 224.2.2.244, and permits profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp profile 1
Hostname(config-profile)# range 224.2.2.2 224.2.2.244
Hostname(config-profile)# permit
```

1.5 ip igmp snooping dyn-mr-aging-time

Function

Run the **ip igmp snooping dyn-mr-aging-time** command to configure the aging time of dynamic multicast router ports.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default aging time of dynamic multicast router ports is 300s.

Syntax

ip igmp snooping dyn-mr-aging-time *dynamic-mroute-aging-time*

no ip igmp snooping dyn-mr-aging-time

default ip igmp snooping dyn-mr-aging-time

Parameter Description

dynamic-mroute-aging-time: Aging time of dynamic router ports, in seconds. The value range is from 1 to 3600.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If a dynamic multicast router port does not receive a general IGMP Query packet or a Protocol Independent Multicast (PIM) Hello packet before the aging time expires, the device deletes the port from the multicast router port list.

When the dynamic multicast router port learning function is enabled, you can run this command to adjust the aging time of dynamic multicast router ports. A too short aging time may cause multicast router ports to be added and deleted frequently.

Examples

The following example sets the aging time of dynamic multicast router ports to 100s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping dyn-mr-aging-time 100
```

1.6 ip igmp snooping fast-leave enable

Function

Run the **ip igmp snooping fast-leave enable** command to enable the port fast leave function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The port fast leave function is disabled by default.

Syntax

ip igmp snooping fast-leave enable

no ip igmp snooping fast-leave enable

default ip igmp snooping fast-leave enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the port fast leave function is enabled and a port receives a Leave packet, the port is directly deleted from the member port list of the corresponding multicast forwarding entry. When receiving group-specific Query packets, the device does not forward the packets to this port. Leave packets include IGMPv2 Leave packets and IGMPv3 Report packets of the INCLUDE type without carrying any source address.

The port fast leave function is applicable when only one host is connected to each port. This function helps save bandwidth and resources.

Examples

The following example enables the port fast leave function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping fast-leave enable
```

1.7 ip igmp snooping filter

Function

Run the **ip igmp snooping filter** command to apply a profile to a port to restrict the multicast groups that user hosts connecting to the port can join.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No profile is applied to a port by default.

Syntax

ip igmp snooping filter *profile-number*

no ip igmp snooping filter

default ip igmp snooping filter

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To specify a profile in the **ip igmp snooping filter** command, you must first create the profile.

After this command is configured on a port and the port receives a Report packet from a user host, the device checks whether the multicast address that the user host wants to join is within the multicast group range allowed by the profile. If yes, the user host can join the group. If no, the user host is not allowed to join the group.

Examples

The following example applies profile 1 to port GigabitEthernet 0/1 to restrict the multicast groups that user hosts connecting to the port can join.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if)# ip igmp snooping filter 1
```

Notifications

When the configured profile does not exist, the following notification will be displayed:

```
% Error: Configure vlan filter fail
```

Common Errors

1.8 ip igmp snooping vlan filter

Function

Run the **ip igmp snooping vlan filter** command to apply a profile to a VLAN to restrict the multicast groups that user hosts in the VLAN can join.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No profile is applied to a VLAN by default.

Syntax

ip igmp snooping vlan *vlan-id* **filter** *profile-number*

no ip igmp snooping vlan *vlan-id* **filter**

default ip igmp snooping vlan *vlan-id* **filter**

Parameter Description

vlan-id: VLAN ID. The value range is from 1 to 4094.

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To specify a profile in the **ip igmp snooping vlan filter** command, you must first create the profile.

After this command is configured on a VLAN and the VLAN receives a Report packet from a user host, the device checks whether the multicast address that the user host wants to join is within the multicast group range allowed by the profile. If yes, the user host can join the group. If no, the user host is not allowed to join the group.

Examples

The following example applies profile 1 to VLAN 1 to restrict the multicast groups that the user hosts in the VLAN can join.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping vlan 1 filter 1
```

Notifications

When the configured profile does not exist, the following notification will be displayed:

```
% Error: Configure vlan filter fail
```

Common Errors

1.9 ip igmp snooping host-aging-time

Function

Run the **ip igmp snooping host-aging-time** command to configure the aging time for IGMP snooping dynamic member ports.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default aging time of IGMP dynamic member ports is 260s.

Syntax

ip igmp snooping host-aging-time *host-aging-time*

no ip igmp snooping host-aging-time

default ip igmp snooping host-aging-time

Parameter Description

host-aging-time: Aging time, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the device running IGMP snooping receives an IGMP Join packet from a host to join an IP multicast group, the device adds the port receiving the packet to the member port list and sets an aging time for the port.

If the port is already in the member port list, the device resets the aging timer of the port. The timer time is *host-aging-time*. After the timer times out, it is deemed that no user host receives multicast packets through this port, and the multicast device deletes the port from the IGMP snooping member port list. After this command is configured, the aging timer value of dynamic member ports is *host-aging-time* for subsequent IGMP Join packets. The configured aging time takes effect after the next Join packet is received, and the started member port aging timers are not updated.

Examples

The following example sets the aging time of IGMP dynamic member ports to 30s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping host-aging-time 30
```

1.10 ip igmp snooping ivgl

Function

Run the **ip igmp snooping ivgl** command to enable IGMP snooping globally and run the Independent VLAN Group Learning (IVGL) mode.

Run the **no** form of this command to disable IGMP snooping.

Run the **default** form of this command to restore the default configuration.

IGMP snooping is disabled by default.

Syntax

ip igmp snooping ivgl

no ip igmp snooping

default ip igmp snooping

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In IVGL mode, multicast streams in different VLANs are independent of each other. A host can request only a multicast router port in the same VLAN to receive multicast data. Upon receiving multicast data in any VLAN, the device running IGMP snooping forwards the data only to member ports in the same VLAN.

Examples

The following example enables IGMP snooping and runs the IVGL mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping ivgl
```

Notifications

When the device does not support the IVGL mode, the following notification will be displayed:

```
% Error: It’s invalid to configure IVGL mode in this product.
```

When L2 static multicast flow control is configured on the device, the following notification will be displayed, asking you to disable L2 static multicast flow control first:

```
% Error: IGMP Snooping conflicts with ip multicast static rule, please disable ip multicast static rule and try again.
```

1.11 ip igmp snooping ivgl-svgl

Function

Run the **ip igmp snooping ivgl-svgl** command to enable IGMP snooping globally and run the IVGL-SVGL mode.

Run the **no** form of this command to disable IGMP snooping.

Run the **default** form of this command to restore the default configuration.

IGMP snooping is disabled by default.

Syntax

ip igmp snooping ivgl-svgl

no ip igmp snooping

default ip igmp snooping

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In IVGL-SVGL mode, the IVGL and SVGL modes coexist. A profile must be used to define a range of multicast groups applied in SVGL mode. Multicast data in this range applies to the SVGL mode, and other multicast data applies to the IVGL mode.

Note

The IVGL-SVGL mode is exclusive from the IP multicast function. If you want to enable IP multicast, please select the IVGL mode.

Examples

The following example enables IGMP snooping and runs the IVGL mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping ivgl
```

The following example enables IGMP snooping and runs the IVGL-SVGL mode, sets the shared VLAN to VLAN 1, and sets the range of multicast groups applied in SVGL mode to Profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp profile 1
Hostname(config-profile)# permit
Hostname(config-profile)# range 224.1.1.1 238.1.1.1
Hostname(config-profile)# exit
Hostname(config)# ip igmp snooping ivgl-svgl
Hostname(config)# ip igmp snooping svgl profile 1
```

Notifications

When L2 static multicast flow control is configured on the device, the following notification will be displayed, asking you to disable L2 static multicast flow control first:

```
% Error: IGMP Snooping conflicts with ip multicast static rule, please disable ip multicast static rule and try again.
```

When the device does not support the SVGL mode, the following notification will be displayed:

```
% Error: It's invalid to configure SVGL mode in this product.
```

When the device enables the L3 IPv4 multicast routing function and does not support the configuration of SVGL mode, the following notification will be displayed:

```
% Error: You must disable ip multicast-routing first.
```

If no SVGL profile is configured when the SVGL mode is enabled, the following notification will be displayed:

```
% Warning: Please remember to configure SVGL profile
```

1.12 ip igmp snooping l2-entry-limit

Function

Run the **ip igmp snooping l2-entry-limit** command to configure the maximum number of multicast groups allowed for concurrent request globally.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of multicast groups allowed for concurrent request globally is **64000** by default.

Syntax

ip igmp snooping l2-entry-limit *l2-entry-limit*

no ip igmp snooping l2-entry-limit

default ip igmp snooping l2-entry-limit

Parameter Description

l2-entry-limit: Maximum number of multicast groups. The value range is from 0 to 65536.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The global maximum number of multicast groups allowed for concurrent request indicates groups on all ports in all VLANs and includes dynamically learned and statically configured multicast groups. When the number of multicast groups reaches the limit, learning new group records or configuring new static multicast group member ports are not allowed.

Examples

The following example sets the maximum number of multicast groups allowed for concurrent request globally to **2000**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping l2-entry-limit 2000
```

1.13 ip igmp snooping limit-ipmc vlan address server

Function

Run the **ip igmp snooping limit-ipmc vlan address server** command to specify a multicast group address and multicast source address for a VLAN.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Only the multicast source address is specified by default.

Syntax

ip igmp snooping limit-ipmc vlan *vlan-id* **address** *group-address* **server** *source-address*

no ip igmp snooping limit-ipmc vlan *vlan-id* **address** *group-address*

default ip igmp snooping limit-ipmc vlan *vlan-id* **address** *group-address*

Parameter Description

vlan-id: VLAN ID. The value range is from 1 to 4094.

group-address: Multicast group address.

source-address: Multicast source address.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The source IP address check function and IP multicast routing function are mutually exclusive.

The source IP address check function is used to restrict the source IP address of multicast traffic. After the source IP address check function is enabled, multicast traffic with invalid multicast source address will be discarded.

To configure the source IP address check function, perform the following steps:

(1) Enable the source IP address check function and specify the multicast source address.

(2) (Optional) Specify a multicast group address and multicast source address for a specific VLAN.

Examples

The following example enables the source IP address check function to allows hosts in VLAN 203 and VLAN 204 to receive multicast traffic only from the source IP address of 192.168.1.10 and multicast group address of 229.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan range 203-204
Hostname(config-vlan-range)# exit
Hostname(config)# ip igmp snooping source-check default-server 192.168.1.11
Hostname(config)# ip igmp snooping limit-ipmc vlan 203 address 229.1.1.1 server
192.168.1.10
Hostname(config)# ip igmp snooping limit-ipmc vlan 204 address 229.1.1.1 server
192.168.1.10
```

Notifications

When the set source IP address is the same as the address of default source IP address check, the following notification will be displayed:

```
% Error: Please reset the limit ipmc ip address,because it's equal to the default source
ip
```

If the default source IP address check function is not enabled, the following notification will be displayed:

```
% Warning: Remember to configure source-ip check ability!
```

Common Errors

- The source IP address check function is not enabled.
- The source IP address specified in **ip igmp snooping limit-ipmc** is the same as the source IP address specified in **ip igmp snooping source-check default-server**.

Platform Description

1.14 ip igmp snooping max-groups

Function

Run the **ip igmp snooping max-groups** command to configure the maximum number of multicast groups that can be dynamically learned by a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of multicast groups that can be dynamically learned by a port is 64,000 by default.

Syntax

ip igmp snooping max-groups *max-groups*

no ip igmp snooping max-groups

default ip igmp snooping max-groups

Parameter Description

max-groups: Maximum number of multicast groups. The value range is from 0 to 64000.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is configured and the number of multicast groups dynamically learned by a port exceeds the limit, the device no longer learns IGMP Report packets over this port to create new forwarding entries.

The number of multicast groups that can be dynamically learned by a port is counted based on the VLANs to which the port belongs. For example, if a port belongs to three VLANs and the port receives requests of multicast group 224.1.1.1 from each VLAN, the number of multicast groups dynamically learned by the port is 3 instead of 1.

Examples

The following example sets the maximum number of multicast groups that can be dynamically learned by GigabitEthernet 0/1 to **100**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if)# ip igmp snooping max-group 100
```

1.15 ip igmp snooping mrouter learn pim-dvmrp

Function

Run the **ip igmp snooping mrouter learn pim-dvmrp** command to enable the function of dynamic multicast router port learning.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

Dynamic multicast router port learning is enabled by default.

Syntax

ip igmp snooping [**vlan** *vlan-id*] **mrouter learn pim-dvmrp**

no ip igmp snooping [**vlan** *vlan-id*] **mrouter learn pim-dvmrp**

default ip igmp snooping [**vlan** *vlan-id*] **mrouter learn pim-dvmrp**

Parameter Description

vlan *vlan-id*: Specifies a VLAN. The value range is from 1 to 4094. If this parameter is not specified, the dynamic multicast router port learning function is enabled or disabled for all VLANs.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A multicast router port directly connects an IGMP snooping-enabled multicast device to a neighbor multicast device in which a multicast routing protocol is enabled. By default, when the dynamic multicast router port learning function is enabled, the device automatically listens to IGMP Query/DVMRP/PIM Hello packets and dynamically identifies multicast router ports.

To dynamically learn multicast router ports, enable the dynamic multicast router port learning function.

To configure static multicast router ports, run the **ip igmp snooping vlan mrouter interface** command.

To disable the dynamic multicast router port learning function for all VLANs, run the **no ip igmp snooping mrouter learn pim-dvmrp** command.

To disable the dynamic multicast router port learning function for a specific VLAN, run the **no ip igmp snooping vlan** *vlan-id* **mrouter learn pim-dvmrp** command.

When the source port check function is enabled, only multicast traffic from the multicast router ports is valid and the multicast device forwards the traffic to registered ports. Multicast data from non-multicast router ports is invalid and will be discarded.

Examples

The following example enables dynamic multicast router port learning only on VLAN 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ip igmp snooping mrouter learn pim-dvmrp
Hostname(config)# ip igmp snooping vlan 1 mrouter learn pim-dvmrp
```

1.16 ip igmp snooping preview

Function

Run the **ip igmp snooping preview** command to enable the multicast preview function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The multicast preview function is disabled by default.

Syntax

ip igmp snooping preview *profile-number*

no ip igmp snooping preview

default ip igmp snooping preview

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the multicast preview function is enabled, a user who doesn't have access permission to certain multicast traffic (namely the user filtered out by IGMP snooping filter) can preview partial content of the multicast traffic. A profile is used to define the range of multicast groups allowed for preview.

The multicast preview function must be used in conjunction with IGMP snooping filter or multicast control.

Examples

The following example enables the multicast preview function (with profile 1 applied) to be used together with IGMP snooping filter (with profile 2 applied) configured on GigabitEthernet.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping preview 1
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if)# ip igmp snooping filter 2
```

Notifications

When the configured profile does not exist, the following notification will be displayed:

```
% Error: The profile doesn't exist, Please configure it first of all
```

Common Errors

IGMP snooping filter or multicast control is not used to control permissions of multicast groups.

1.17 ip igmp snooping preview interval

Function

Run the **ip igmp snooping preview interval** command to configure the multicast preview duration.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default multicast preview duration is 60s.

Syntax

ip igmp snooping preview interval *preview-interval*

no ip igmp snooping preview interval

default ip igmp snooping preview interval

Parameter Description

preview-interval: Multicast preview duration, in seconds. The value range is from 1 to 300.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example enables the multicast preview function and sets the preview duration to 100s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping preview 1
Hostname(config)# ip igmp snooping preview interval 100
```

1.18 ip igmp snooping querier

Function

Run the **ip igmp snooping querier** command to enable the IGMP snooping querier function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The IGMP snooping querier function is disabled by default.

Syntax

ip igmp snooping [**vlan** *vlan-id*] **querier**

no ip igmp snooping [**vlan** *vlan-id*] **querier**

default ip igmp snooping [**vlan** *vlan-id*] **querier**

Parameter Description

vlan *vlan-id*: Specifies a VLAN. If this parameter is not specified, the IGMP snooping querier function is enabled or disabled for all VLANs.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To activate the IGMP querier function on a VLAN, you must enable the function globally and then enable it on the VLAN.

If the IGMP snooping querier function is disabled globally, the function is disabled on all VLANs.

Examples

The following example enables the IGMP querier function on VLAN 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping querier
Hostname(config)# ip igmp snooping vlan 2 querier
```

Notifications

When the IGMP querier function is enabled on a VLAN before it is enabled globally, the following notification will be displayed:

```
% Command did not take effect due to reason: IGMP switch querier is globally disabled
```

Common Errors

The IGMP querier function is enabled on a VLAN before it is enabled globally. As a result, the IGMP querier function on the VLAN does not take effect.

1.19 ip igmp snooping querier address

Function

Run the **ip igmp snooping querier address** command to configure the source IP address of the IGMP snooping querier.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The source IP address configuration applies to all VLANs by default.

Syntax

ip igmp snooping [**vlan** *vlan-id*] **querier address** *source-address*

no ip igmp snooping [**vlan** *vlan-id*] **querier address**

default ip igmp snooping [**vlan** *vlan-id*] **querier address**

Parameter Description

vlan *vlan-id*: Specifies a VLAN. The querier source IP address configured on a specific VLAN, if any, prevails.

source-address: Source IP address of the querier.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the querier function is enabled, you must specify a source IP address for the querier so that the querier function can take effect.

The querier source IP address configured on a specific VLAN, if any, prevails.

Examples

The following example sets the source IP address of the IGMP snooping querier to **1.1.1.1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping querier address 1.1.1.1
```

The following example sets the source IP address of the IGMP snooping querier on VLAN 3 to **1.1.1.1**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 3
Hostname(config-vlan)# exit
Hostname(config)# ip igmp snooping vlan 3 querier address 1.1.1.1
```

Function

Run the **ip igmp snooping querier max-response-time** command to configure the maximum response time of IGMP snooping queriers.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum response time of IGMP snooping queriers is 10s by default.

Syntax

ip igmp snooping [**vlan** *vlan-id*] **querier max-response-time** *max-response-time*

no ip igmp snooping [**vlan** *vlan-id*] **querier max-response-time**

default ip igmp snooping [**vlan** *vlan-id*] **querier max-response-time**

Parameter Description

vlan *vlan-id*: Specifies a VLAN. The maximum response time configured on a specific VLAN, if any, prevails.

max-response-time: Maximum response time of queriers, in seconds. The value range is from 1 to 25.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The maximum response time configured on a specific VLAN, if any, prevails.

Examples

The following example sets the maximum response time of queriers to 15s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping querier max-response-time 15
```

The following example sets the maximum response time of queriers on VLAN 3 to 15s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 3
Hostname(config-vlan)# exit
Hostname(config)# ip igmp snooping vlan 3 querier max-response-time 15
```

1.21 ip igmp snooping querier query-interval

Function

Run the **ip igmp snooping querier query-interval** command to configure the interval for an IGMP snooping querier to send Query packets.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default interval for an IGMP snooping querier to send Query packets is 60s.

Syntax

ip igmp snooping [**vlan** *vlan-id*] **querier query-interval** *query-interval*

no ip igmp snooping [**vlan** *vlan-id*] **querier query-interval**

default ip igmp snooping [**vlan** *vlan-id*] **querier query-interval**

Parameter Description

vlan *vlan-id*: Specifies a VLAN. The query interval configured on a specific VLAN, if any, prevails.

query-interval: Interval for a querier to send Query packets, in seconds. The value range is from 1 to 18000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The query interval configured on a specific VLAN, if any, prevails.

Examples

The following example sets the query interval to 100s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping querier query-interval 100
```

The following example sets the query interval on VLAN 3 to 100s.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# vlan 3
Hostname(config-vlan)# exit
Hostname(config)# ip igmp snooping vlan 3 querier query-interval 100
```

1.22 ip igmp snooping querier timer expiry

Function

Run the **ip igmp snooping querier timer expiry** command to configure the aging time of IGMP snooping queriers.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default aging time of IGMP snooping queriers is 125s.

Syntax

ip igmp snooping [**vlan** *vlan-id*] **querier timer expiry** *timeout*

no ip igmp snooping [**vlan** *vlan-id*] **querier timer expiry**

default ip igmp snooping [**vlan** *vlan-id*] **querier timer expiry**

Parameter Description

vlan *vlan-id*: Specifies a VLAN. The querier aging time configured on a specific VLAN, if any, prevails.

timeout: Aging time of a querier, in seconds. The value range is from 60 to 300.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the IGMP querier function is enabled and multiple queriers are configured in the network, querier election will be performed. The device elected as the querier will send Query packets periodically. Other candidate queriers receive Query packets from the elected querier. If a candidate querier does not receive Query packets

from the elected querier within a specific period of time, the candidate querier regards that it is the only querier in the directly-connected network segment and initiates a new round querier election.

The querier aging time configured on a specific VLAN, if any, prevails.

Examples

The following example sets the querier aging time to 60s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping querier timer expiry 60
```

The following example sets the querier aging time on VLAN 3 to 60s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 3
Hostname(config-vlan)# exit
Hostname(config)# ip igmp snooping vlan 3 querier timer expiry 60
```

1.23 ip igmp snooping querier version

Function

Run the **ip igmp snooping querier version** command to specify the version of an IGMP snooping querier

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default version of an IGMP snooping querier is **version 2**.

Syntax

ip igmp snooping [**vlan** *vlan-id*] **querier version** { **1** | **2** }

no ip igmp snooping [**vlan** *vlan-id*] **querier version**

default ip igmp snooping [**vlan** *vlan-id*] **querier version**

Parameter Description

vlan *vlan-id*: Specifies a VLAN. The IGMP snooping querier version configured on a specific VLAN, if any, prevails.

1: Specifies IGMPv1.

2: Specifies IGMPv2.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

An IGMP snooping querier supports IGMPv1, IGMPv2, and IGMPv3.

The IGMP snooping querier version configured on a specific VLAN, if any, prevails.

Examples

The following example sets the IGMP snooping querier version to IGMPv1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping querier version 1
```

The following example sets the IGMP snooping querier version on VLAN 3 to IGMPv1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 3
Hostname(config-vlan)# exit
Hostname(config)# ip igmp snooping vlan 3 querier version 1
```

1.24 ip igmp snooping query-max-response-time

Function

Run the **ip igmp snooping query-max-response-time** command to configure the maximum response time for Query packets.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum response time for Query packets is 10s by default.

Syntax

ip igmp snooping query-max-response-time *query-max-response-time*

no ip igmp snooping query-max-response-time

default ip igmp snooping query-max-response-time

Parameter Description

query-max-response-time: Maximum response time for Query packets, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When receiving group-specific Query packets, the multicast device will reset the aging timers of all dynamic member ports of this multicast group. The timer time is *query-max-aging-time*. After the timer times out, it is deemed that no user host receives multicast packets through this port, and the multicast device deletes the port from the IGMP snooping member port list.

The configured aging time takes effect after the next Query packet is received, and the started aging timers are not updated. For IGMPv3 group-specific Query packets, the multicast device does not update the timers.

Examples

The following example sets the maximum response time for Query packets to 100s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping query-max-response-time 100
```

1.25 ip igmp snooping source-check default-server

Function

Run the **ip igmp snooping source-check default-server** command to enable the source IP address check function and specify the source IP address.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

Source IP address check is disabled by default.

Syntax

ip igmp snooping source-check default-server *source-address*

no ip igmp snooping souce-check

default ip igmp snooping souce-check

Parameter Description

source-address: Multicast source IP address.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The source IP address check function and IP multicast routing function are mutually exclusive.

The source IP address check function is used to restrict the source IP address of multicast traffic. After the source IP address check function is enabled, multicast traffic with invalid multicast source address will be discarded.

To configure the source IP address check function, perform the following steps:

(1) Enable the source IP address check function and specify the multicast source address.

(2) (Optional) Specify a multicast group address and multicast source address for a specific VLAN.

Examples

The following example enables the source IP address check function to allow hosts in VLAN 203 and VLAN 204 to receive multicast traffic only from the source IP address 192.168.1.10 and multicast group address 229.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan range 203-204
Hostname(config-vlan-range)# exit
Hostname(config)# ip igmp snooping source-check default-server 192.168.1.10
Hostname(config)# ip igmp snooping limit-ipmc vlan 203 address 229.1.1.1 server
192.168.1.10
```

```
Hostname(config)# ip igmp snooping limit-ipmc vlan 204 address 229.1.1.1 server
192.168.1.10
```

Notifications

When the set default source IP address is the same as that specified in the **ip igmp snooping limit-ipmc** command, the following notification will be displayed:

```
% Error: The default-server address is conflict!
```

When the L3 multicast routing function is enabled, the following notification will be displayed:

```
% Error: You must disable multicast-routing first
```

If the device does not support the source IP address check function, the following notification will be displayed:

```
% Error: Switch does not support source-ip check!
```

Common Errors

The source IP address specified in **ip igmp snooping source-check default-server** is the same as the source IP address specified in **ip igmp snooping limit-ipmc**.

Platform Description

1.26 ip igmp snooping source-check port

Function

Run the **ip igmp snooping source-check port** command to enable the source port check function.

Run the **no** form of this command to disable this function.

Run the **default** form of this port command to restore the default configuration.

Source port check is disabled by default.

Syntax

ip igmp snooping source-check port

no ip igmp snooping source-check port

default ip igmp snooping source-check port

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The source port check function is used to restrict multicast traffic to be forwarded only through multicast router ports. After this function is enabled, only multicast traffic received on multicast router ports is valid. Multicast traffic received on other ports is invalid and will be discarded. If no multicast router port exists in a VLAN, multicast traffic in the VLAN will be discarded.

When the source port check function is disabled, multicast traffic received on any port is valid and will be forwarded to the corresponding member ports.

Examples

The following example enables the source port check function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping source-check port
```

Notifications

If the device does not support the source port check function, the following notification will be displayed:

```
% Error: Source-port check is invalid in this product
```

Common Errors

1.27 ip igmp snooping suppression enable

Function

Run the **ip igmp snooping suppression enable** command to enable the Report packet suppression function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

Report packet suppression is disabled by default.

Syntax

ip igmp snooping suppression enable

no ip igmp snooping suppression enable

default ip igmp snooping suppression enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When Report packet suppression is enabled, the IGMP multicast device forwards only the first Report packet from a specific VLAN for a multicast group to the multicast router port and suppresses subsequent Report packets for the same multicast group during one query interval. This function helps reduce the number of packets in the network.

Only IGMPv1 and IGMPv2 Report packets can be suppressed, and IGMPv3 Report packets cannot be suppressed.

Examples

The following example enables the Report packet suppression function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping suppression enable
```

1.28 ip igmp snooping svgl

Function

Run the **ip igmp snooping svgl** command to enable IGMP snooping globally and run the Shared VLAN Group Learning (SVGL) mode.

Run the **no** form of this command to disable IGMP snooping.

Run the **default** form of this command to restore the default configuration.

IGMP snooping is disabled by default.

Syntax

ip igmp snooping svgl

no ip igmp snooping

default ip igmp snooping

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In SVGL mode, hosts in different VLANs share multicast data. Hosts can request multicast data across VLANs. A shared VLAN (VLAN 1 by default) needs to be designated. Only multicast data in the shared VLAN can be forwarded to all member ports of the group address. These member ports can be in other VLANs. A profile must be used to define a range of multicast groups applied in SVGL mode. Only multicast data from this range can be forwarded across VLANs, and other multicast data will be discarded.

Note

The SVGL mode is exclusive from the IP multicast function. If you want to enable IP multicast, please select the IVGL mode.

Examples

The following example enables IGMP snooping and runs the SVGL mode, sets the shared VLAN to VLAN 1, and sets the range of multicast groups applied in SVGL mode to Profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp profile 1
Hostname(config-profile)# permit
Hostname(config-profile)# range 224.1.1.1 238.1.1.1
Hostname(config-profile)# exit
Hostname(config)# ip igmp snooping svgl
Hostname(config)# ip igmp snooping svgl profile 1
```

Notifications

When L2 static multicast flow control is configured on the device, the following notification will be displayed, asking you to disable L2 static multicast flow control first:

```
% Error: IGMP Snooping conflicts with ip multicast static rule, please disable ip multicast static rule and try again.
```

When the device does not support the SVGL mode, the following notification will be displayed:

```
% Error: It's invalid to configure SVGL mode in this product.
```

When the device enables the L3 IPv4 multicast routing function and does not support the configuration of SVGL mode, the following notification will be displayed:

```
% Error: You must disable ip multicast-routing first.
```

If no SVGL profile is configured when the SVGL mode is enabled, the following notification will be displayed:

```
% Warning: Please remember to configure SVGL profile
```

Run the **ip igmp snooping svgl profile** command to specify the range of multicast groups applied in the SVGL mode.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No multicast group is associated with the SVGL mode by default.

Syntax

ip igmp snooping svgl profile *profile-number*

no ip igmp snooping svgl profile

default ip igmp snooping svgl profile

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the device running IGMP snooping operates in SVGL or IVGL-SVGL mode, the multicast groups associated with the SVGL mode must be configured.

First, define the multicast groups applied in the SVGL mode in a profile. Then, apply this profile in this command.

Examples

The following example applies profile 2 to the SVGL mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#ip igmp profile 2
Hostname(config-profile)#permit
Hostname(config-profile)#range 225.1.1.1 225.1.255.255
Hostname(config-profile)#exit

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

All VLANs except the shared VLAN are sub VLANs in SVGL mode by default.

Syntax

ip igmp snooping svgl subvlan [*vlan-range*]

no ip igmp snooping svgl subvlan [*vlan-range*]

default ip igmp snooping svgl subvlan [*vlan-range*]

Parameter Description

vlan-range: VLAN ID or VLAN ID range. *vlan-range* can be set to a single VLAN or a range of VLANs. When a range of VLANs is configured, use commas (,) to separate VIDs. Consecutive VIDs can also be connected using hyphens (-). There is no sequence requirement for the VIDs.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the device running IGMP snooping operates in SVGL or IVGL-SVGL mode, you can run this command to configure the multicast groups associated with the SVGL mode.

Examples

The following example sets the shared VLAN to VLAN 3 and sub VLANs to VLANs 2, 5, 6, and 7 for the SVGL mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan range 2-3,5-7
Hostname(config-vlan-range)# exit
Hostname(config)# ip igmp snooping svgl vlan 3
Hostname(config)# ip igmp snooping svgl subvlan 2,5-7
```

Notifications

When the number of configured sub VLANs exceeds the limit 127, the following notification will be displayed:

```
% Error: Reach max subvlan entries than what allowed
```

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function of transparent IGMP packet transmission on the QinQ port is disabled by default.

Syntax

ip igmp snooping tunnel

no ip igmp snooping tunnel

default ip igmp snooping tunnel

Parameter Description

N/A

Default Level

14

Command Modes

Global configuration mode

Usage Guidelines

On a device with IGMP snooping enabled and a dot1q-tunnel (QinQ) port configured, IGMP snooping will process the IGMP packets received on the QinQ port using the following two modes:

- Mode 1: Transmit IGMP packets in transparent mode on the QinQ port. Create multicast entries on the VLAN where the IGMP packets are located and forward IGMP packets on the VLAN. For example, IGMP snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an IGMP Report packet is sent from VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 10 and forwards the IGMP Report packet to the multicast router port of VLAN 10.
- Mode 2: Create multicast entries on the default VLAN of the QinQ port. Encapsulate the IGMP packets with the VLAN tag of the default VLAN where the QinQ port is located and forward the packets within the default VLAN. For example, IGMP snooping is enabled for a device, Port A on the device is designated as the QinQ port, the default VLAN of this port is VLAN 1, and Port A allows the passage of VLAN 1 and VLAN 10 packets. When an IGMP Report packet is sent from VLAN 10 to Port A, IGMP snooping establishes a multicast entry for VLAN 1, encapsulates the IGMP Report packet with the tag of VLAN 1, and forwards the packet to the multicast router port of VLAN 1.

IGMP snooping works in mode 2 by default.

Examples

The following example enables the function of transparent IGMP packet transmission on the QinQ port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping tunnel
```

1.33 ip igmp snooping vlan

Function

Run the **ip igmp snooping vlan** command to enable the IGMP snooping function in IVGL mode on a VLAN.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

If the IGMP snooping function in IVGL mode is enabled globally, the function is enabled on all VLANs.

If the IGMP snooping function in IVGL mode is disabled globally, the function is disabled on all VLANs.

Syntax

ip igmp snooping vlan *vlan-id*

no ip igmp snooping vlan *vlan-id*

default ip igmp snooping vlan *vlan-id*

Parameter Description

vlan-id: VLAN ID. The value range is from 1 to 4094.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the IGMP snooping function in IVGL mode is enabled globally, you can run the **no ip igmp snooping vlan** *vlan-id* command to enable the IGMP snooping function in IVGL mode on VLANs except the specified VLAN.

Examples

The following example enables the IGMP snooping function in IVGL mode globally and disables the function on VLAN 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping ivgl
Hostname(config)# no ip igmp snooping vlan 2
```

1.34 ip igmp snooping vlan mrouter interface

Function

Run the **ip igmp snooping vlan mrouter interface** command to configure a static multicast router port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static multicast router port is configured by default.

Syntax

ip igmp snooping vlan *vlan-id* **mrouter interface** *interface-type interface-number*

no ip igmp snooping vlan *vlan-id* **mrouter interface** *interface-type interface-number*

default ip igmp snooping vlan *vlan-id* **mrouter interface** *interface-type interface-number*

Parameter Description

vlan-id: VLAN ID. The value range is from 1 to 4094.

interface-type interface-number: Interface name.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To dynamically learn multicast router ports, enable the dynamic multicast router port learning function, which is enabled by default.

To configure static multicast router ports, run the **ip igmp snooping vlan mrouter interface** command. Static multicast router ports never age.

If a port is configured as a static multicast router port, the device can forward all received multicast traffic over this port.

When the source port check function is enabled, only multicast traffic from the multicast router ports is valid and the multicast device forwards the traffic to registered ports. Multicast data from non-multicast router ports is invalid and will be discarded.

Examples

The following example configures GigabitEthernet 0/1 in VLAN 1 as a static multicast router port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping vlan 1 mrouter interface gigabitethernet 0/1
```

Notifications

When a static multicast router port fails to be configured, the following notification will be displayed:

```
% Error: Configure this interface static multicast route failure
```

Common Errors

1.35 ip igmp snooping vlan static interface

Function

Run the **ip igmp snooping vlan static interface** command to configure a static member port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static member port is configured by default.

Syntax

ip igmp snooping vlan *vlan-id* **static** *group-address* **interface** *interface-type interface-number*

no ip igmp snooping vlan *vlan-id* **static** *group-address* **interface** *interface-type interface-number*

default ip igmp snooping vlan *vlan-id* **static** *group-address* **interface** *interface-type interface-number*

Parameter Description

vlan-id: VLAN ID. The value range is from 1 to 4094.

group-address: Multicast group address.

interface-type interface-number: Interface name.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

An IGMP snooping forwarding entry includes the VLAN ID, multicast group address, multicast router ports, and member ports.

A VID and multicast group address uniquely identify a forwarding entry.

A forwarding entry may contain multiple multicast router ports, which may be dynamically learned or statically configured. Static multicast router ports never age.

A forwarding entry may contain multiple member ports, which may be dynamically learned or statically configured. Static member ports never age. The **clear ip igmp snooping gda-table** command cannot be used to delete static member ports.

Examples

The following example establishes a forwarding entry and sets the VLAN ID to 1, multicast group address to 224.1.1.1, and static member port to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp snooping vlan 1 static 224.1.1.1 interface gigabitethernet
0/1
```

Notifications

When a static member port fails to be configured, the following notification will be displayed:

```
% Error: Configure static multicast group in this port fail
```

Common Errors

1.36 permit

Function

Run the **permit** command to permit a range of multicast groups defined by a profile.

The **deny** action is performed for a profile by default.

Syntax

permit

Parameter Description

N/A

Command Modes

Profile configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ip igmp profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups. The default action is **deny**.

Examples

The following example permits multicast groups in the range of 224.2.2.2 to 224.2.2.244 defined by profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp profile 1
Hostname(config-profile)# range 224.2.2.2 224.2.2.244
Hostname(config-profile)# permit

1.37 range

Function

Run the **range** command to define a range of multicast groups for a profile.

Run the **no** form of this command to remove this configuration.

No multicast group range is defined for a profile by default.

Syntax

range *low-ip-address* [*high-ip-address*]

no range *low-ip-address* [*high-ip-address*]

Parameter Description

low-ip-address: Start IP address of a multicast group range.

high-ip-address: End IP address of a multicast group range.

Command Modes

Profile configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ip igmp profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups. The default action is **deny**.

Examples

The following example permits multicast groups in the range of 224.2.2.2 to 224.2.2.244 defined by profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip igmp profile 1
Hostname(config-profile)# range 224.2.2.2 224.2.2.244

1.39 show ip igmp snooping

Function

Run the **show ip igmp snooping** command to display IGMP snooping information.

Syntax

show ip igmp snooping [**vlan** *vlan-id*]

Parameter Description

vlan *vlan-id*: Specifies a VLAN. If this parameter is not specified, configurations of all VLANs are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the IGMP snooping status and parameters globally or on a specific VLAN.

Examples

The following example displays IGMP snooping information globally.

```
Hostname> enable
Hostname# show ip igmp snooping
IGMP Snooping running mode: IVGL
IGMP Snooping L2-entry-limit: 64000
Source port check: Disable
Source ip check: Disable
IGMP Fast-Leave: Disable

1 MSDP Commands

Command	Function
clear ip msdp peer	Reset the TCP connection with an MSDP peer and clear statistics about the MSDP peer.
clear ip msdp sa-cache	Clear the SA cache entries.
clear ip msdp statistics	Clear statistics about an MSDP peer.
ip msdp default-peer	Configure a default MSDP peer.
ip msdp description	Add description information for an MSDP peer.
ip msdp filter-sa-request	Filter SA request messages from an MSDP peer.
ip msdp mesh-group	Add an MSDP peer to a mesh group.
ip msdp originator-id	Configure the primary address of a specified interface as the initiator address in SA messages.
ip msdp password peer	Enable the MD5 authentication function on the TCP connection with an MSDP peer.
ip msdp peer connect-source	Add an MSDP peer.
ip msdp redistribute	Control the (S, G) information released on an MSDP device.
ip msdp sa-filter in	Configure an incoming filter of SA messages.
ip msdp sa-filter out	Configure an outgoing filter of SA messages.
ip msdp sa-limit	Define the maximum number of SA cache entries from an MSDP peer.
ip msdp shutdown	Disable the connection with an MSDP peer.
ip msdp timer	Configure a TCP reconnection interval.
ip msdp ttl-threshold	Define the time to live (TTL) value of the multicast packets in SA messages.
ip msdp peer-limit	Define the number of MSDP peers supported on a device.
ip msdp global-sa-limit	Define the SA cache capacity supported on a device.

show ip msdp count	Display the number of sources and number of groups in SA messages and the number of SA cache entries from MSDP peers.
show ip msdp mesh-group	Display the information of a mesh group.
show ip msdp peer	Display detailed information about an MSDP peer.
show ip msdp rpf-peer	Display the MSDP RPF peer information corresponding to the address of a specified initiator.
show ip msdp sa-cache	Display the learned (S, G) information.
show ip msdp sa-originated	Display the (S, G) information that meets the redistribution filtering rule and is initiated by the local device.
show ip msdp summary	Display summary information of all MSDP peers.

1.1 clear ip msdp peer

Function

Run the **clear ip msdp peer** command to reset the TCP connection with an MSDP peer and clear statistics about the MSDP peer.

Syntax

clear ip msdp peer *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

"Reset" means canceling and then re-establishing the TCP connection with the MSDP peer.

Examples

The following example resets the TCP connection with the MSDP peer 218.14.5.23 and clears statistics about this MSDP peer.

```
Hostname> enable
Hostname# clear ip msdp peer 218.14.5.23
```

Notifications

N/A

Platform Description

N/A

1.2 clear ip msdp sa-cache

Function

Run the **clear ip msdp sa-cache** command to clear the SA cache entries.

Syntax

clear ip msdp sa-cache [*ipv4-group-address*]

Parameter Description

ipv4-group-address: Address of an IPv4 multicast group.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to clear the SA cache entries learned from MSDP peers. If no multicast group address is specified, all SA cache entries are cleared.

After the SA cache entries are cleared, the MSDP device needs to re-learn SA messages.

Examples

The following example clears SA cache entries learned from the multicast group 224.1.1.1.

```
Hostname> enable
Hostname# clear ip msdp sa-cache 224.1.1.1
```

Notifications

N/A

Platform Description

N/A

1.3 clear ip msdp statistics

Function

Run the **clear ip msdp statistics** command to clear statistics about an MSDP peer.

Syntax

clear ip msdp statistics [*ipv4-peer-address*]

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to refresh the statistics about an MSDP peer without resetting the TCP connection with the MSDP peer, including MSDP peer information, resetting information, and I/O information.

Examples

The following example clears the statistics about the MSDP peer 61.83.1.52.

```
Hostname> enable
Hostname# clear ip msdp statistics 61.83.1.52
```

Notifications

N/A

Platform Description

N/A

1.4 ip msdp default-peer

Function

Run the **ip msdp default-peer** command to configure a default MSDP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No default MSDP peer is configured by default.

Syntax

ip msdp default-peer *ipv4-peer-address* [**prefix-list** *prefix-list-name*]

no ip msdp default-peer *ipv4-peer-address*

default ip msdp default-peer *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

prefix-list *prefix-list-name*: Specifies a prefix list.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

SA messages from MSDP peers may fail the peer RPF check and then be discarded. If an MSDP peer is configured as a default MSDP peer, SA messages from this MSDP peer pass the peer RPF check.

If the **prefix-list** keyword parameter is not specified, all SA messages are accepted.

If an inexistent **prefix-list** is specified, all SA messages are accepted.

If an existent **prefix-list** is specified, only the SA messages of RPs specified in this prefix list are accepted.

Examples

The following example configures the MSDP peer 172.16.33.1 as a default peer.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 172.16.33.1 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp peer 172.16.34.2 connect-source gigabitethernet 0/2
Hostname(config)# ip msdp default-peer 172.16.33.1
```

Notifications

Related Commands

- **ip prefix-list** (IP routing/routing policy)
- **ip msdp peer connect-source**

1.5 ip msdp description

Function

Run the **ip msdp description** command to add description information for an MSDP peer.

Run the **no** form of command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No description information is added for an MSDP peer by default.

Syntax

ip msdp description *ipv4-peer-address description*

no ip msdp description *ipv4-peer-address*

default ip msdp description *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

description: Description information. It is a string of 1 to 256 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The administrator can add description information for MSDP peers so that the MSDP peers can be distinguished with ease.

If description information A is specified for an MSDP peer, the description information of the MSDP peer is displayed as "A".

If no description information is specified for an MSDP peer, the description information of the MSDP peer is displayed as "No description".

Examples

The following example adds customer-a as the description information of the peer 172.17.1.2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 172.171.1.2 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp description 172.171.1.2 customer-a
```

1.6 ip msdp filter-sa-request

Function

Run the **ip msdp filter-sa-request** command to filter SA request messages from an MSDP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

All SA request messages from MSDP peers are received and replied by default.

Syntax

ip msdp filter-sa-request *ipv4-peer-address* [{ **list** *acl-name* | **list** *acl-number* }]

no ip msdp filter-sa-request *ipv4-peer-address*

default ip msdp filter-sa-request *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

list *acl-name*: Uses an IP standard ACL name to define the address range of multicast groups. The value is a case-sensitive string of 1 to 99 characters.

list *acl-number*: Uses an IP standard ACL number to define the address range of multicast groups. The value range is from 1 to 99 or from 1300 to 1999.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the **list** keyword parameter is not specified, all the SA request messages are ignored.

If the **list** keyword parameter is specified but this ACL is not configured, all SA request messages are ignored.

If the **list** keyword parameter is specified and this ACL is configured, only the SA request messages allowed by the ACL are accepted, and other SA request messages are ignored.

Examples

The following example uses ACL 1 that defines the valid address range of multicast groups as 224.0.1.0/24 to filter SA request messages from the peer 172.16.223.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 172.16.223.1 connect-source gigabitethernet 0/1
Hostname(config)# access-list 1 permit 224.0.1.1 0.0.0.255
Hostname(config)# ip msdp filter-sa-request 172.16.223.1 list 1
```

1.7 ip msdp mesh-group

Function

Run the **ip msdp mesh-group** command to add an MSDP peer to a mesh group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No mesh group is configured and no MSDP peer is added to any mesh group by default.

Syntax

ip msdp mesh-group *mesh-name ipv4-peer-address*

no ip msdp mesh-group *mesh-name ipv4-peer-address*

default ip msdp mesh-group *mesh-name ipv4-peer-address*

Parameter Description

mesh-name: Name of a mesh group. The value is a case-sensitive string of 1 to 256 characters.

ipv4-peer-address: IPv4 address of an MSDP peer.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

An MSDP peer relationship must be established between every two MSDP peers in the same mesh group.

SA messages from members of a mesh group can pass the peer RPF check.

SA messages from a mesh group member are not forwarded to the other members in the same mesh group.

Examples

The following example adds the MSDP peer 192.168.1.3 to a mesh group MSDP-Mesh.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 192.168.1.3 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp mesh-group msdp-mesh 192.168.1.3
```

1.8 ip msdp originator-id

Function

Run the **ip msdp originator-id** command to configure the primary address of a specified interface as the initiator address in SA messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no primary address of an interface is specified as the initiator address of SA messages.

Syntax

ip msdp originator-id *interface-type interface-number*

no ip msdp originator-id

default ip msdp originator-id

Parameter Description

interface-type interface-number: Interface type and interface number.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command configures the primary address of an interface as the initiator address in SA messages. If no IP address is configured for this interface or this interface is down, the RP address configured with PIM, other than the primary IP address of this interface, is used as the initiator address in SA messages.

In anycast RP deployment mode, this command must be used to modify the initiator address in SA messages.

Examples

The following example configures the IP address of Loopback0 as the initiator address in SA messages.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface loopback 0
Hostname(config-if-Loopback 0)# exit
Hostname(config)# ip msdp originator-id loopback 0
```

1.9 ip msdp password peer

Function

Run the **ip msdp password peer** command to enable the MD5 authentication function on the TCP connection with an MSDP peer.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The MD5 authentication function is disabled by default.

Syntax

ip msdp password peer *ipv4-peer-address* [*encryption-type*] *password-string*

no ip msdp password peer *ipv4-peer-address*

default ip msdp password peer *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

encryption-type: Encryption level. The value is 0 or 7, and the default value is **0**. A larger value means a higher encryption level.

password-string: Cypher used for TCP MD5 authentication. If the encryption level is 0, a cypher can consist of 80 characters at most. If the encryption level is 7, a cypher can consist of 160 characters at most.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To authenticate the ID of an MSDP peer, enable MD5 authentication on the TCP connection established with this MSDP peer. The MSDP peers must have the consistent configuration, and the cipher must be the same; otherwise, the connection fails.

If the configuration or cipher changes, the local device does not stop the current session, and attempts to use a new cipher to retain the current session until timeout.

Note

- If the encryption level is 0, the key set for TCP connection is the original key entered from the console. That is, Ruijie devices with encryption level 0 can match devices of any other vendor with encryption level 0. When MSDP devices of Ruijie Networks interact with MSDP devices of another vendor and authentication is needed, encryption level 0 is used.
- If the encryption level is 7, the key set for TCP connection is not the original key entered from the console. The original key string is calculated using the key algorithms of Ruijie Networks to obtain a new key string. And then, the new key string is set for TCP connection. Therefore, encryption level 7 boasts higher security. Encryption level 7 of Ruijie Networks is supported on any Ruijie device. However, devices of Ruijie Networks may not interact with devices of any other vendor in this case. This is because the key algorithms of each vendor are private and not publicized.
- If the encryption level is specified as 7, the length of the entered ciphertext string must be an even number equal to or greater than four.

Examples

The following example configures the MD5 cypher of TCP connection with the peer 10.32.43.144 as test.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 10.32.43.144 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp password peer 10.32.43.144 0 test
```

Notifications

If MD5 authentication is enabled on the local device but not enabled on the MSDP peer, the following notification will be displayed:

```
%TCP-BADAUTH: MD5 digest NOT expected but found (200.200.200.6,
39996)->(200.200.200.16, 639)
```

If the MD5 cypher configured on the local device is inconsistent with that configured on the MSDP peer, the following notification will be displayed:

```
%TCP-BADAUTH: MD5 digest failed for (200.200.200.6, 12302)->(200.200.200.16, 639)
```

Common Errors

1.10 ip msdp peer connect-source

Function

Run the **ip msdp peer connect-source** command to add an MSDP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No MSDP peer is added by default.

Syntax

ip msdp peer *ipv4-peer-address* **connect-source** *interface-type interface-number*

no ip msdp peer *ipv4-peer-address*

default ip msdp peer *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer. The MSDP peer uses this IPv4 address to establish a TCP connection with the local device.

interface-type interface-number: Type and number of a local interface. A loopback interface is recommended. The local device uses the primary IPv4 address of this interface to establish a TCP connection with the MSDP peer. If no IPv4 address is configured for this interface or the interface is down, the MSDP peer relationship cannot be established.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A TCP connection is established between the local device and the MSDP peer.

This command configures the connection only on the local device. The same settings must be configured on the MSDP peer.

Examples

The following example uses the IP address of loopback 0 to establish an MSDP peer relationship with 192.168.5.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface loopback 0
Hostname(config-if-Loopback 0)# exit
Hostname(config)# ip msdp peer 192.168.5.1 connect-source loopback 0
```

1.11 ip msdp redistribute

Function

Run the **ip msdp redistribute** command to control the (S, G) information released on an MSDP device.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

All (S, G) information registered on the local RP is released on the MSDP device by default.

Syntax

ip msdp redistribute [{ **list** *acl-name* | **list** *acl-number* } | **route-map** *route-map-name*] *

no ip msdp redistribute

default ip msdp redistribute

Parameter Description

list *acl-name*: Uses an IP extended ACL name to define the valid address range of (S, G) information. The value is a case-sensitive string of 1 to 99 characters.

list *acl-number*: Uses an IP extended ACL number to define the valid address range of (S, G) information. The value range is from 100 to 199 or from 2000 to 2699.

route-map *route-map-name*: Uses a route map to define the valid address range of (S, G) information.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The **ip msdp redistribute** command is also referred to as redistribution filter. After this command is configured, only allowed (S, G) information of the local or other domains can pass filtering on the MSDP device.

- If the **list** keyword parameter is specified, only the (S, G) information matching this ACL is released.
- If the **route-map** keyword parameter is specified, only the (S, G) information matching this route map is released.
- If both the parameters are specified, only the (S, G) information matching the ACL and route map is released.
- If no parameter is specified, no (S, G) information is released.

The methods of associating the redistribution filter with the route map are as follows:

- If the applied *route-map* does not exist, all multicast source information is filtered out.
- If BGP is not enabled on the local device, all multicast source information is filtered out.

Based on the optimal route, the AS path of a specified address is calculated. For the address of an external AS, the AS path is obtained based on the optimal route. For the address of a local AS, an AS path that includes the local AS is constructed. The AS path result is filtered based on the route map applied to the AS path.

The local device is RP on which BGP is enabled and the AS number is set to 100. The route map associated with redistribution is named re-route-map. To enable multicast source information to be redistributed in the local AS, include the AS path matching rule of the local AS in the route map. Some configuration of the route map and AS path ACL is as follows:

```
route-map re-route-map permit 10
match as-path 1
ip as-path access-list 1 permit 100
```

Examples

The following example uses ACL 100 to define the (S, G) information that can pass filtering by an MSDP device and sets the address range of the multicast source to 200.200.200.0/24 and the address range of the multicast group to 225.1.1.0/24.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# ip access-list extended 100
Hostname(config-ext-nacl)# permit ip 200.200.200.0 0.0.0.255 225.1.1.0 0.0.0.255
Hostname(config)# ip msdp redistribute list 100
```

1.12 ip msdp sa-filter in

Function

Run the **ip msdp sa-filter in** command to configure an incoming filter of SA messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

All SA messages from MSDP peers are received by default.

Syntax

ip msdp sa-filter in *ipv4-peer-address* [{ **list** *acl-name* | **list** *acl-number* } | **route–map** *route-map-name* | { **rp-list** *acl-name* | **rp-list** *acl-number* } | **rp-route-map** *rp-route-map-name*] *

no ip msdp sa-filter in *ipv4-peer-address*

default ip msdp sa-filter in *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

list *acl-name*: Uses an IP extended ACL name to define the (S, G) information that can pass filtering. The value is a case-sensitive string of 1 to 99 characters.

list *acl- number*: Uses an IP extended ACL number to define the (S, G) information that can pass filtering. The value range is from 100 to 199 or from 2000 to 2699.

route-map *route-map-name*: Specifies the route map name of (S, G) information. The (S, G) information can pass filtering only when the AS path of the source route matches the AS path of this route map.

rp-list *acl-name*: Uses an IP standard ACL name to define the RP range in the (S, G) information that can pass filtering. The value is a case-sensitive string of 1 to 99 characters.

rp-list *acl-number*: Uses an IP standard ACL number to define the RP range in the (S, G) information that can pass filtering. The value range is from 1 to 99.

rp-route-map *rp-route-map-name*: Specifies the route map name of an RP. The (S, G) information can pass filtering only when the AS path of the RP route matches the AS path of this route map.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If this command is configured, but no ACL or route map is specified, all incoming SA messages are filtered out.

If only one keyword (**list** or **route-map**) is specified and the (S, G) information in an SA message meets the rule specified by the keyword, the (S, G) is received.

If only one keyword (**rp-list** or **rp-route-map**) is specified and the RP address in an SA message meets the rule specified by this keyword, this SA message is received.

If two or more of the keywords (including **list**, **route-map, rp-list**, and **rp-route-map**) are specified and the (S, G) information in an SA message meets the rules specified by all the keywords, this SA message is received.

The methods of associating the incoming SA message filter with the route map are as follows:

(1) If the applied *route-map* does not exist, all multicast source information is filtered out.

(2) If BGP is not enabled on the local device, all multicast source information is filtered out.

(3) Based on the optimal route, the AS path of a specified address is calculated. For the address of an external AS, the AS path is obtained based on the optimal route. For the address of a local AS, an AS path that includes the local AS is constructed. The AS path result is filtered based on the route map applied to the AS path.

Examples

The following example filters all SA messages from the peer 10.234.1.43.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 10.234.1.43 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp sa-filter in 10.234.1.43
```

1.13 ip msdp sa-filter out

Function

Run the **ip msdp sa-filter out** command to configure an outgoing filter of SA messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, all SA messages are forwarded to MSDP peers.

Syntax

ip msdp sa-filter out *ipv4-peer-address* [**list** { *acl-name* | *acl-number* } | **route–map** *route-map-name* | **rp-list** { *acl-name* | *acl-number* } | **rp-route-map** *rp-route-map*] *

no ip msdp sa-filter out *ipv4-peer-address*

default ip msdp sa-filter out *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

list *acl-name*: Uses an IP extended ACL name to define the (S, G) information that can pass filtering. The value is a case-sensitive string of 1 to 99 characters.

list *acl- number*: Uses an IP extended ACL number to define the (S, G) information that can pass filtering. The value range is from 100 to 199 or from 2000 to 2699.

route-map *route-map-name*: Specifies the route map name of (S, G) information. The (S, G) information can pass filtering only when the AS path of the source route matches the AS path of this route map.

rp-list *acl-name*: Uses an IP standard ACL name to define the RP range in the (S, G) information that can pass filtering. The value is a case-sensitive string of 1 to 99 characters.

rp-list *acl-number*: Uses an IP standard ACL number to define the RP range in the (S, G) information that can pass filtering. The value range is from 1 to 99.

rp-route-map *rp-route-map-name*: Specifies the route map name of an RP. The (S, G) information can pass filtering only when the AS path of the RP route matches the AS path of this route map.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If this command is configured, but no ACL or route map is specified, no SA message is sent to this MSDP peer.

If only one of the keywords (including **list**, **route-map**, **rp-list**, and **rp-route-map**) is specified and the (S, G) information in an SA message meets the rule specified by this keyword, this SA message is forwarded to this MSDP peer.

If two or more of the keywords (including **list**, **route-map**, **rp-list**, and **rp-route-map**) are specified and the (S, G) information in an SA message meets the rules specified by these keywords, this SA message is forwarded to this MSDP peer.

The methods of associating the outgoing SA message filter with the route map are as follows:

(1) If the applied *route-map* does not exist, all multicast source information is filtered out.

(2) If BGP is not enabled on the local device, all multicast source information is filtered out.

(3) Based on the optimal route, the AS path of a specified address is calculated. For the address of an external AS, the AS path is obtained based on the optimal route. For the address of a local AS, an AS path that includes the local AS is constructed. The AS path result is filtered based on the route map applied to the AS path.

Examples

The following example uses ACL 100 to define the multicast source information sent to the peer 10.234.1.43, and sets the address range of the multicast source to 10.211.0.0/16 and the address range of the multicast group to 224.12.0.0/16.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 100 permit ip 10.211.0.0 0.0.255.255 224.12.0.0
0.0.255.255
Hostname(config)# ip msdp peer 10.234.1.43 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp sa-filter out 10.234.1.43 list 100
```

1.14 ip msdp sa-limit

Function

Run the **ip msdp sa-limit** command to define the maximum number of SA cache entries from an MSDP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of SA cache entries from an MSDP peer is not specified by default.

Syntax

ip msdp sa-limit *ipv4-peer-address sa-limit*

no ip msdp sa-limit *ipv4-peer-address*

default ip msdp sa-limit *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

sa-limit: Maximum number of SA cache entries. The value range is from 1 to 4096.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is configured to prevent SA message flooding from an MSDP peer.

After the local device learns A SA entries from an MSDP peer and the maximum number of SA cache entries set for this MSDP peer is B, if the value of A is greater than that of B, the SA entries learned from this MSDP peer are not cleared immediately. Rather, the number of SA entries automatically drops to B based on the SA entry aging mechanism (no more than 135 seconds). This command does not take effect immediately, and it is used to retain valid multicast source information as much as possible and improve the network efficiency. To immediately clear the SA entries from this MSDP peer, you can use this command together with the **clear ip msdp sa-cache** command.

Examples

The following example sets the limit of SA entries from the MSDP peer 172.16.3.1 to 100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 172.16.3.1 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp sa-limit 172.16.3.1 100
```

Function

Run the **ip msdp shutdown** command to disable the connection with an MSDP peer.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The connection with an MSDP peer is enabled by default.

Syntax

ip msdp shutdown *ipv4-peer-address*

no ip msdp shutdown *ipv4-peer-address*

default ip msdp shutdown *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command disables only the TCP connection with an MSDP peer, but does not delete this MSDP peer or clear configuration of this MSDP peer.

Examples

The following example disables the connection with the MSDP peer 192.168.7.20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp shutdown 192.168.7.20
```

1.16 ip msdp timer

Function

Run the **ip msdp timer** command to configure a TCP reconnection interval.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default TCP reconnection interval is **30** seconds.

Syntax

ip msdp timer *interval*

no ip msdp timer

default ip msdp timer

Parameter Description

interval: TCP reconnection interval, in seconds. The value range is from 1 to 60.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Within the TCP reconnection interval, the MSDP peer on the proactive connection side can initiate at most one TCP connection. In some application scenarios, you can shorten the TCP reconnection interval to accelerate convergence of the MSDP peer relationship.

Examples

The following example sets the TCP reconnection interval to 20 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp timer 20
```

1.17 ip msdp ttl-threshold

Function

Run the **ip msdp ttl-threshold** command to define the time to live (TTL) value of the multicast packets in SA messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The TTL value of the multicast packets in SA messages is not defined by default.

Syntax

ip msdp ttl-threshold *ipv4-peer-address ttl-value*

no ip msdp ttl-threshold *ipv4-peer-address*

default ip msdp ttl-threshold *ipv4-peer-address*

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

ttl-value: TTL value. The value range is from 0 to 255.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command controls the sending of multicast packets encapsulated in SA messages. A multicast packet is sent to the MSDP peer only when the TTL value in the IP header of the multicast packet is equal to or greater than the preset TTL threshold. If the TTL value in the IP header of the multicast packet is smaller than the preset TTL threshold, the multicast packet is removed from the SA message and discarded before the SA message is sent to the MSDP peer.

This command affects the sending of multicast packets in SA messages, and does not affect the sending of (S, G) information in the SA messages.

Examples

The following example sets the TTL value of the peer 192.168.10.1 to 8.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer 192.168.10.1 connect-source gigabitethernet 0/1
Hostname(config)# ip msdp ttl-threshold 192.168.10.1 8
```

14

Usage Guidelines

This command is used to configure the maximum number of MSDP peers supported on a device.

When this command is configured, if the number of MSDP peers on the device exceeds the value to be configured, a prompt message is displayed indicating configuration failure. You need to delete some peers to ensure that the configuration can succeed.

Examples

The following example sets the number of MSDP peers supported on a device to 128.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp peer-limit 128
```

Notifications

If the number of MSDP peers on the device exceeds the value to be configured, the configuration fails.

When the configured number of MSDP peers on a device is 80 and there are 85 MSDP peers existing on the device, the following notification will be displayed. In this case, you need to delete at least five MSDP peers to make the configuration succeed.

```
%% Current number of msdp peers(85) exceeds configured peer limit (80).
```

1.19 ip msdp global-sa-limit

Function

Run the **ip msdp global-sa-limit** command to define the SA cache capacity supported on a device.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default SA cache capacity supported on a device is **1024**.

Syntax

ip msdp global-sa-limit *sa-limit*

no ip msdp global-sa-limit

default ip msdp global-sa-limit

Parameter Description

sa-limit: SA cache capacity supported on a device. The value range is from 1 to 4096.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to adjust the SA cache capacity of a device. You are advised to configure this command when you start the device.

During MSDP running, if the capacity is increased, the adjustment does not affect the SA cache entries that are originally learned.

If the capacity is decreased, all SA cache entries learned and initiated must be deleted and re-learned.

Examples

The following example sets the SA cache capacity supported on a device to 4096.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip msdp global-sa-limit 4096
```

1.20 show ip msdp count

Function

Run the **show ip msdp count** command to display the number of sources and number of groups in SA messages and the number of SA cache entries from MSDP peers.

Syntax

show ip msdp count [*as-number*]

Parameter Description

as-number: AS number. The value range is from 1 to 4294967295.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the number of sources and number of groups in SA messages and the number of SA cache entries from MSDP peers.

```
Hostname> enable
Hostname# show ip msdp count
SA State per Peer Counters, <Peer>: <# SA learned>
```

```
 1.1.1.2       : 0
 100.100.100.14 : 0
 100.100.100.15 : 0
 100.100.100.200: 0
 200.200.200.2  : 2
 200.200.200.3  : 0
 200.200.200.6  : 0
 200.200.200.13 : 0
 200.200.200.66 : 0
SA State per ASN Counters, <asn>: <# sources>/<# groups>
Total entries: 2
100: 1/2
```

Table 1-1 Output Fields of the show ip msdp count Command

Field	Description
<Peer>:<# SA learned>	MSDP peer and SA entries learned from this MSDP peer. For example, "200.200.200.200 : 2" indicates that two SA entries are learned from the MSDP peer 200.200.200.200.
<asn>: <# sources>/<# groups>	RP AS and the number of sources and number of groups initiated by the RP. For example, "100 : 1/2" indicates that there are one multicast source and two multicast groups in the RP of AS 100.
Total entries	Number of all SA entries learned from all MSDP peers. For example, "Total entries: 2" indicates that the number of SA entries learned from all MSDP peers is 2.

1.21 show ip msdp mesh-group

Function

Run the **show ip msdp mesh-group** command to display the information of a mesh group.

Syntax

show ip msdp mesh-group

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays information of a mesh group.

```
Hostname> enable
Hostname# show ip msdp mesh-group
MSDP peers in each Mesh-group, <Mesh-group name>:<# peers>
msdp-mesh:
  1.1.1.2
  1.1.1.3
```

Table 1-2 Output Fields of the show ip msdp mesh-group Command

Field	Description
<Mesh-group name>:<# peers>	Name of a mesh group and all MSDP peers in this mesh group. Example: msdp-mesh: 1.1.1.2 1.1.1.3 Indicates a mesh group msdp-mesh and the MSDP peers 1.1.1.2 and 1.1.1.3 in this mesh group.

1.22 show ip msdp peer

Function

Run the **show ip msdp peer** command to display detailed information about an MSDP peer.

Syntax

show ip msdp peer [*ipv4-peer-address*]

Parameter Description

ipv4-peer-address: IPv4 address of an MSDP peer.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays detailed information about the MSDP peer 20.0.0.1.

```
Hostname> enable
Hostname# show ip msdp peer 20.0.0.1
MSDP PEER 20.0.0.1 (No description), AS unknown
 Connection status:
   State: Listen, Resets: 1, Connection source: GigabitEthernet 0/1 (20.0.0.2)
   Uptime(Downtime): 00:00:25, Message sent/received: 13/19
   Input messages discarded: 0
   Connection and counters cleared 00:13:25 ago
   Local Address of connection: 20.0.0.2
   MD5 signature protection on MSDP TCP connection: enabled
 SA Filtering:
   Input (S,G) Access-list filter: None
   Input (S,G) route-map filter: None
   Input RP Access-list filter: None
   Input RP Route-map filter: None
   Output (S,G) Access-list filter: None
   Output (S,G) Route-map filter: None
   Output RP Access-list filter: None
   Output RP Route-map filter: None
 SA-Requests:
   Input filter: None
 Peer ttl threshold: 0
 SAs learned from this peer: 2, SAs limit: No-limit
 Message counters:
   SA messages discarded: 0
   SA messages in/out: 13/0
   SA Requests discarded/in: 0/0
   SA Responses out: 0
   Data Packets in/out: 6/0
```

Table 1-3 Output Fields of the show ip msdp peer Command

Field	Description
MSDP Peer	IP address of an MSDP peer.
AS	AS of MSDP peers. If an AS is unknown, it is displayed as "unknown".
State	State of an MSDP peer.
Connection source	Source interface of a TCP connection and primary IP address of this interface. If no primary IP address is available to this interface, the primary IP address of this interface is displayed as "unknown".
MD5 signature protection on MSDP TCP connection: enabled	If MD5 authentication is enabled on the TCP connection with the MSDP peer, this field is displayed. Otherwise, this field is not displayed.
Peer is member of mesh-group MSDP	If the MSDP peer is added to a mesh group, this field is displayed. Otherwise, this field is not displayed.
Uptime(Downtime)	Uptime and downtime of the MSDP peer.
Messages sent/received	Number of SA messages sent/received to/from the MSDP peer.
SA Filtering	Incoming/Outgoing SA message filtering
SAs learned from this peer	SA messages learned from the MSDP peer.
SAs limit	Maximum number of SA cache entries of the MSDP peer.
Data Packets in/out	Multicast packets in incoming/outgoing SA messages.

1.23 show ip msdp rpf-peer

Function

Run the **show ip msdp rpf-peer** command to display the MSDP RPF peer information corresponding to the address of a specified initiator.

Syntax

show ip msdp rpf-peer *ipv4-address*

Parameter Description

ipv4-address: IPv4 address of the initiator in an SA message.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the RPF peer information corresponding to the RP address 1.1.1.1.

```
Hostname> enable
Hostname# show ip msdp rpf-peer 1.1.1.1
RPF peer information for 1.1.1.1
RPF peer: 200.200.200.2
RPF rule: Peer is only active peer
RPF route/mask: Not-used
RPF type: Not-used
```

Table 1-4 Output Fields of the show ip msdp rpf-peer Command

Field	Description
RPF peer information for	RPF peer information corresponding to a specified RP address.
RPF peer	RPF peer address corresponding to a specified RP address.
RPF rule	Rule used to calculate the RPF peer corresponding to a specified RP address.
RPF route/mask	Network segment and mask corresponding to a specified RP address, used to determine the RPF peer. If the rule used to calculate the RPF peer corresponding to a specified RP address does not contain the routing information, this field is displayed as "Not-used", indicating that the network segment and mask corresponding to the RP address are not used. The rule used in the preceding example is "unique active MSDP peer". The route to the RP address is not used; therefore, this field is displayed as "Not-used".
RPF type	Routing protocol used to calculate the RPF peer corresponding to an RP address. If the rule used to calculate the RPF peer corresponding to a specified RP address does not contain the routing information, this field is displayed as "Not-used", indicating that the routing protocol is not used. The rule used in the preceding example is "unique active MSDP peer". The route to the RP address is not used; therefore, this field is displayed as "Not-used".

1.24 show ip msdp sa-cache

Function

Run the **show ip msdp sa-cache** command to display the learned (S, G) information.

Syntax

show ip msdp sa-cache [*ipv4-group-address* | *ipv4-source-address*] [*ipv4-group-address* | *ipv4-source-address*] [*as-number*]

Parameter Description

ipv4-group-address: Address of an IPv4 multicast group.

ipv4- source-address: Address of an IPv4 multicast source.

as-number: Number of an AS in which SA messages are generated. The value range is from 1 to 4294967295.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is specified, all the (S, G) information is displayed by default.

If an address is specified, the device checks whether this address is a unicast or multicast address. If the address is a unicast address, this address is treated as the multicast source (S), and all (S, G) information in which the multicast source is S is displayed. If the address is a multicast address, this address is treated as the multicast group (G), and all (S, G) information in which the multicast group is G is displayed. If this address is neither a unicast nor a multicast address, no information is displayed.

If two addresses are specified, one address is treated as the multicast source (S), and the other as the multicast group (G). If one address is the unicast address, and the other address is the multicast group address, no information is displayed.

Examples

The following example displays the learned (S, G) information.

```
Hostname> enable
Hostname# show ip msdp sa-cache
MSDP Source-Active Cache: 2 entries
  (200.200.200.200, 227.1.2.2), RP: 20.20.20.20, (M)BGP/AS 100, 04:17:09/00:02:05,
Peer 200.200.200.2
```

```
   Learned from peer 200.200.200.2, RPF peer 200.200.200.2,
   SAs received: 277, Encapsulated data received: 0
  (200.200.200.200, 227.1.2.3), RP: 20.20.20.20, (M)BGP/AS 100, 04:17:09/00:02:05,
Peer 200.200.200.2
   Learned from peer 200.200.200.2, RPF peer 200.200.200.2,
SAs received: 277, Encapsulated data received: 0
```

Table 1-5 Output Fields of the show ip msdp sa-cache Command

Field	Description
(200.200.200.200, 227.1.2.2)	Source address (first IP address) and group address (second IP address) in an SA message.
RP 20.20.20.20	RP address from which SA messages are generated.
(M)BGP/AS 100	RP AS in which SA messages are generated. The AS number is calculated based on MBGP or BGP. If the AS is unknown, it is displayed as "unknown".
04:17:09/00:02:05	Cache duration 4 hours, 17 minutes, and 9 seconds. If no local SA message is received within two minutes and five seconds, the cached SA message is deleted.
Peer 200.200.200.2	MSDP peer that this SA message comes from.
Learned from peer 200.200.200.2	MSDP peer that this SA message comes from.
RPF peer 200.200.200.2	RPF peer corresponding to the RP address from which this SA message is generated.
SAs received	Times of receiving this SA message.
Encapsulated data received	Times of encapsulating multicast data in this SA message.

1.25 show ip msdp sa-originated

Function

Run the **show ip msdp sa-originated** command to display the (S, G) information that meets the redistribution filtering rule and is initiated by the local device.

Syntax

show ip msdp sa-originated

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If multicast source (S, G) information is registered on the local RP and the local RP is configured with an MSDP peer, you can run this command to display the (S, G) information initiated by this RP.

The (S, G) information displayed by this command has met the rule specified by the redistribution filtering command **ip msdp redistribute**. You can run the **ip msdp sa-filter out** command to check whether the (S, G) information meets the outgoing SA information filtering rule and can be initiated by MSDP peers.

Examples

The following example displays (S, G) information that is initiated by the local device and meets the redistribution filtering rule.

```
Hostname> enable
Hostname# show ip msdp sa-originated
MSDP Source-Active Originated: 5 entries
(192.168.23.78, 225.0.0.1), RP: 192.168.23.249
(192.168.23.79, 225.0.0.2), RP: 192.168.23.249
(192.168.23.80, 225.0.0.3), RP: 192.168.23.249
(192.168.23.81, 225.0.0.4), RP: 192.168.23.249
(192.168.23.82, 225.0.0.5), RP: 192.168.23.249
```

Table 1-6 Output Fields of the show ip msdp sa-originated Command

Field	Description
(192.168.23.78, 225.0.0.1)	Source address (first IP address) and group address (second IP address) from which SA messages are initiated.
RP 192.168.23.249	RP address from which SA messages are initiated.

1.26 show ip msdp summary

Function

Run the **show ip msdp summary** command to display summary information of all MSDP peers.

Syntax

show ip msdp summary

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays summary information of all MSDP peers.

```
Hostname> enable
Hostname# show ip msdp summary
Msdp Peer Status Summary
Peer Address    As   State   Uptime/Downtime   Reset-Count   Sa-Count
Peer-description
200.200.200.2   100   Up     04:22:11         10           6616      No description
200.200.200.3   100   Down   19:17:13         4            0         peer-A
```

Table 1-7 Output Fields of the show ip msdp summary Command

Field	Description
Peer Address	IP address of MSDP peers.
AS	AS of MSDP peers.
State	State of MSDP peers.
Uptime/Downtime	Uptime and downtime of MSDP peers.
Reset-Count	Times of MSDP peer disconnections.
Sa-count	Number of SA messages received from this MSDP peer.
Peer-description	Description information of an MSDP peer. If no description information is specified for this MSDP peer, the description information of the MSDP peer is displayed as "No description".

1 IPv6 Multicast Route Management Commands

Command	Function
clear ipv6 mroute	Clear IPv6 multicast hardware forwarding entries.
clear ipv6 mroute statistics	Clear statistics about the IPv6 multicast hardware forwarding entries.
ipv6 mroute	Configure an IPv6 static multicast route.
ipv6 multicast boundary	Configure an IPv6 multicast border for a specified IPv6 group.
ipv6 multicast route-limit	Configure the maximum number of entries in an IPv6 multicast routing table.
ipv6 multicast-routing	Enable the IPv6 multicast routing function.
ipv6 multicast rpf longest-match	Enable the function of RPF route selection based on the longest match rule.
ipv6 multicast static	Enable the multicast stream L2 direction control function.
msf6 force-forwarding	Enable the function of forced forwarding of IPv6 multicast packets (destined for the CPU) by software.
msf6 nsf	Enable the nonstop forwarding (NSF) function.
show ipv6 mroute	Display IPv6 multicast hardware forwarding entries.
show ipv6 mroute count	Display the count of IPv6 multicast routing entries.
show ipv6 mroute sparse	Display PIM-SMv6 multicast core entries.
show ipv6 mroute static	Display the IPv6 static multicast routing information.
show ipv6 mroute summary	Display the summary information of IPv6 multicast routing entries.
show ipv6 mvif	Display IPv6 multicast interface information.
show ipv6 rpf	Display the RPF information about a specific IPv6 source address.
show ipv6 mrf6 mfc	Display IPv6 multicast routing entries.
show msf6 msc	Display IPv6 L2/L3 multicast hardware forwarding entries.

show msf6 nsf	Display IPv6 multicast NSF configuration.

1.1 clear ipv6 mroute

Function

Run the **clear ipv6 mroute** command to clear IPv6 multicast hardware forwarding entries.

Syntax

clear ipv6 mroute { ***** | *ipv6-group-address* [*ipv6-source-address*] }

Parameter Description

*****: Clears all IPv6 multicast routing entries.

ipv6-group-address: Address of an IPv6 multicast group for IPv6 multicast routing.

ipv6-source-address: Address of an IPv6 multicast source for IPv6 multicast routing.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the multicast function fails, you can run this command to clear the current IPv6 multicast routing information to facilitate problem locating and re-learn entries.

Examples

The following example clears all the IPv6 multicast routing entries.

```
Hostname> enable
Hostname# clear ipv6 mroute *
```

1.2 clear ipv6 mroute statistics

Function

Run the **clear ipv6 mroute statistics** command to clear statistics about the IPv6 multicast hardware forwarding entries.

Syntax

clear ipv6 mroute statistics { ***** | *ipv6-group-address* [*ipv6-source-address*] }

Parameter Description

*****: Specifies all IPv6 multicast routing entries.

ipv6-group-address: Address of an IPv6 multicast group for IPv6 multicast routing.

ipv6-source-address: Address of an IPv6 multicast source for IPv6 multicast routing.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the multicast function fails, you can run this command to clear the current multicast routing statistics to facilitate problem locating and re-collect information.

Examples

The following example clears statistics about all the IPv6 multicast routing entries.

```
Hostname> enable
Hostname# clear ipv6 mroute statistics *
```

1.3 ipv6 mroute

Function

Run the **ipv6 mroute** command to configure an IPv6 static multicast route.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No IPv6 static multicast route is configured by default.

Syntax

ipv6 mroute *ipv6-address/prefix-length* [*protocol*] { *ipv6-rpf-address* | *interface-type interface-number* } [*distance*]

no ipv6 mroute *ipv6-address/prefix-length* [*protocol*]

default ipv6 mroute *ipv6-address/prefix-length* [*protocol*]

Parameter Description

ipv6-address: IPv6 address of a multicast source.

prefix-length: Mask of the IPv6 address of a multicast source.

protocol: Unicast routing protocol being used.

ipv6-rpf-address: IPv6 address of an RPF neighbor (next hop to the multicast source).

interface-type interface-number: RPF interface (outbound interface to the multicast source).

distance: Route administrative distance. The value range is from 0 to 255, and the default value is **0**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A static multicast route is used for only RPF check, and specifies an RPF neighbor or interface for multicast packets from a specific source. A static multicast route is applied in mainly the following two scenarios:

- Modify an RPF route

  If a multicast device expects to receive multicast packets from a source through a specified interface but this specified interface is not the RPF interface, you can configure a static multicast route to specify this interface as an RPF interface.

- Connect an RPF route

  If two adjacent devices in a network are configured with different routing protocols, and the routes are not mutually introduced, the unicast route is interrupted. The devices cannot forward packets because no RPF route is available. In this case, you can configure a static multicast route to specify the RPF interface to complete the RPF check and implement multicast packet forwarding.

To specify an outbound interface rather than a next-hop IP address for the IPv6 static multicast route, ensure that the outbound interface is of the point-to-point type.

Examples

The following example configures an IPv6 static multicast route, and sets the network address of the IPv6 multicast to 2233::/64 and the outbound interface address of this multicast source to 3333::3333.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mroute 2233::/64 3333::3333
```

1.4 ipv6 multicast boundary

Function

Run the **ipv6 multicast boundary** command to configure an IPv6 multicast border for a specified IPv6 group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No IPv6 multicast border is configured by default.

Syntax

ipv6 multicast boundary *acl-name* [**in** | **out**]

no ipv6 multicast boundary *acl-name* [**in** | **out**]

default ipv6 multicast boundary *acl-name* [**in** | **out**]

Parameter Description

acl-name: ACL name used to define the address range of a multicast group. The value is a case-sensitive string of 1 to 99 characters.

in: Indicates that the multicast border takes effect in the inbound direction of the multicast stream.

out: Indicates that the multicast border takes effect in the outbound direction of the multicast stream.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The ACL used in this command is a standard ACL. If an extended ACL is used, the filtering result is inaccurate.

This command can be used to filter MLD and PIM-SMv6 protocol packets relevant to the IPv6 multicast group range. Multicast data streams are not sent or received by this multicast border interface.

Examples

The following example configures an IPv6 multicast border for all IPv6 multicast groups (mul-boun) on the VLAN interface SVI 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list mul-boun
Hostname(config-std-nacl)# permit ipv6 ::/0 ::/0
Hostname(config-std-nacl)# exit
Hostname(config)# interface vlan 1
Hostname(config-if)# ipv6 multicast boundary mul-boun
```

1.5 ipv6 multicast route-limit

Function

Run the **ipv6 multicast route-limit** command to configure the maximum number of entries in an IPv6 multicast routing table.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, a maximum of 4000 entries can be added to an IPv6 multicast routing table.

Syntax

ipv6 multicast route-limit *limit* [*threshold*]

no ipv6 multicast route-limit *limit* [*threshold*]

default ipv6 multicast route-limit *limit* [*threshold*]

Parameter Description

limit: Maximum number of entries in an IPv6 multicast routing table. The value range is from 1 to 64000.

threshold: A threshold that triggers an alarm if the number of IPv6 multicast routes reaches this threshold. The value range is from 1 to 64000, and the default value is **64000**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Due to limitations by hardware resources, routing entries that exceed the range permitted by hardware must be forwarded by software, which causes performance to decrease.

The configured value of *threshold* must be smaller than or equal to the configured value of *limit*.

Examples

The following example sets the maximum number of entries that can be added to an IPv6 multicast routing table to 100 and sets the threshold to 90.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 multicast route-limit 100 90
```

Notifications

When the configured value of threshold is greater than the limit, the following notification will be displayed:

```
Hostname# enable
Hostname# configure terminal
Hostname(config)# ipv6 multicast route-limit 400 4000
% Route threshold exceeds configured route limit
```

Common Errors

1.7 ipv6 multicast rpf longest-match

Function

Run the **ipv6 multicast rpf longest-match** command to enable the function of RPF route selection based on the longest match rule.

Run the **no** form of this command to select the route with the highest priority as the RPF route.

Run the **default** form of this command to restore the default configuration.

By default, the route with the highest priority is selected as the RPF route. If the routes have the same priority, the RPF route is selected in the order of IPv6 static multicast route, IPv6 MBGP route and IPv6 unicast route.

Syntax

ipv6 multicast rpf longest-match

no ipv6 multicast rpf longest-match

default ipv6 multicast rpf longest-match

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The steps for selecting an RPF route are as follows:

(1) Select one optimal route used for the RPF check from each of the IPv6 static multicast routing table, IPv6 MBGP routing table and IPv6 unicast routing table. Select one route out of the three optimal routes as the RPF route.

(2) If the command for selecting the RPF route based the longest match rule is configured, the route with the longest match is selected out of the three optimal routes as the RPF route. If the three routes share the same subnet mask, the route with the highest priority is selected. If the routes have the same priority, the RPF route is selected in the order of IPv6 static multicast route, IPv6 MBGP route, and IPv6 unicast route.

(3) If the longest match rule is not used, the route with the highest priority is selected as the RPF route. If the routes have the same priority, the RPF route is selected in the order of IPv6 static multicast route, IPv6 MBGP route, and IPv6 unicast route.

Examples

The following example enables the function of RPF route selection based on the longest match rule.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 multicast rpf longest-match
```

1.8 ipv6 multicast static

Function

Run the **ipv6 multicast static** command to enable the multicast stream L2 direction control function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

L2 direction control is disabled for multicast streams by default.

Syntax

ipv6 multicast static *ipv6-source-address ipv6-group-address interface-type interface-number*

no ipv6 multicast static *ipv6-source-address ipv6-group-address interface-type interface-number*

default ipv6 multicast static *ipv6-source-address ipv6-group-address interface-type interface-number*

Parameter Description

Ipv6-source -address: Address of a multicast source.

ipv6-group-address: Address of a multicast group.

interface-type interface-number: L2 interface that is allowed to forward the multicast stream.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Multiple commands can be configured for a specified multicast stream so that the stream can be forwarded by multiple interfaces. After direction control is enabled for a multicast stream, this stream can be forwarded only by these configured interfaces. Other interfaces are not permitted to forward the stream.

This command controls only the forwarding of multicast streams on interfaces, but does not directly affect the processing of multicast protocols on the protocol packets. Some features of multicast protocols (such as PIM-SMv6) are driven by multicast data streams, and therefore, the behavior of the multicast routing protocols may still be affected.

Examples

The following example enables the L2 direction control function for the multicast stream with the source address 2222::3333 and the group address FF66::100, and allows the stream to be forwarded through GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 multicast static 2222::3333 ff66::100 gigabitethernet 0/1
```

1.10 msf6 nsf

Function

Run the **msf6 nsf** command to enable the nonstop forwarding (NSF) function.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The NSF function is not enabled by default.

Syntax

msf6 nsf { **convergence-time** *convergence-time* | **leak** *interval* }

no msf6 nsf { **convergence-time** | **leak** }

default msf6 nsf { **convergence-time** | **leak** }

Parameter Description

convergence-time *convergence-time*: Specifies the maximum convergence time of a multicast protocol, in seconds. The value range is from 0 to 3600, and the default value is **20**.

leak *interval*: Specifies the packet leak time during multicasting, in seconds. The value range is from 0 to 3600, and the default value is **30**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the management board on a device with multiple management boards is switched over, the multicast protocol, for example, PIM-SMv6 or MLD Snooping, takes some time to complete convergence. The NSF parameters are configured to ensure nonstop forwarding of multicast data streams during re-convergence of the multicast protocol.

Examples

The following example enables the NSF function and sets the maximum convergence time of a multicast protocol to 300 seconds and the packet leak time during multicasting to 200 seconds.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname (config)# msf6 nsf convergence-time 300
Hostname (config)# msf6 nsf leak 200
```

1.18 show ipv6 mrf6 mfc

Function

Run the **show ipv6 mrf6 mfc** command to display IPv6 multicast routing entries.

Syntax

show ipv6 mrf6 mfc [*ipv6-soure-address ipv6-group-address*]

Parameter Description

ipv6-source-address: Source address in an IPv6 multicast routing entry.

ipv6-group-address: Group address in an IPv6 multicast routing entry.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

The two parameters are optional, and the source address and group address must be specified simultaneously.

When no source address or group address is specified, all multicast forwarding cache (MFC) entries are displayed.

When the source address and group address are specified, the MFC entries corresponding to the source address and group address are displayed.

Examples

The following example displays the IPv6 L3 multicast hardware forwarding entries with the source address 2001::1.

```
Hostname> enable
Hostname# show ipv6 mrf6 mfc 2001::1 ff06::1
Multicast Routing Forward Cache6 Table
(2001::1, ff06::1)
  FAST_SW, SWTCHED, MIN_MTU: 1500, MIN_MTU_IFINDEX: 4099, WRONG IF: 0
  Incoming interface: VLAN 1[4097]
  Outgoing interface list:
VLAN 3 (1)
```

Table 1-8 Output Fields of the show ipv6 mrf6 mfc Command

Field	Description
(*source-address*, *group-address*)	(Source address, group address)
FAST_SW	Flag that indicates whether the entry supports fast forward. If non-Ethernet interface, PPP interface, HDLC interface or frame relay interface exists, no fast forwarded entry is generated.
SWTCHED	Whether an entry is delivered to next-layer hardware forwarding table.
MIN_MTU MTU	Minimum MTU value of an entry.
MIN_MTU_IFINDEX	Index of an interface that has the minimum MTU value.
WRONG IF	Statistics about the multicast data packets from incorrect interfaces.
Incoming interface:*interface-type interface-number*[*lsm-ifx*]	RPF inbound interface of entries. ● *interface-type interface-number*: Interface type and interface number. ● *lsm-ifx*: Index of an LSM interface.
Outgoing interface list:	L3 outbound interface of entries.

Field	Description
interface-type interface-number (*ttl*)	• *interface-type interface-number*: Interface type and interface number. • *ttl*: TTL threshold of this L3 interface.

1.19 show msf6 msc

Function

Run the **show msf6 msc** command to display IPv6 L2/L3 multicast hardware forwarding entries.

Syntax

show msf6 msc [*ipv6-soure-address*] [*ipv6-group-address*] [*vlan-id*]

Parameter Description

ipv6-soure-address: IPv6 source address in an L2/L3 multicast hardware forwarding entry.

ipv6-group-address: IPv6 group address in an L2/L3 multicast hardware forwarding entry.

vlan-id: ID of a VLAN to which L2/L3 multicast hardware forwarding entry belongs. When this value is greater than 4096, the interface is a routed port.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

The three parameters are optional.

- When only the source address is specified as S1, all MSC entries corresponding to the source address S1 are displayed.
- When the source address is specified as S1 and the group address is specified as G1, all MSC entries corresponding to the source address S1 and group address G1 are displayed.
- When the source address is specified as S1, the group address is specified as G1, and the VLAN ID is

specified as V1, all MSC entries corresponding to the source address S1, group address G1, and VLAN ID V1 are displayed.

The parameters must be set in order, and a next parameter can be set only when the preceding parameter is set.

If no parameter is specified, all IPv6 L2/L3 multicast hardware forwarding entries are displayed.

Examples

The following example displays the IPv6 L3 multicast hardware forwarding entries with the source address 2012::16:1:0:0:2.

```
Hostname> enable
Hostname# show msf6 msc 2012::16:1:0:0:2
Multicast Switching Cache Table
(2012::16:1:0:0:2, FF1E::2:0:0:1, 4103), HIT, SYNC, MTU:9216, RP_SUP, 2 OIFs
 VLAN 4103(7): 1 OPORTs, FULL, REQ: DONE
   OPORT 7, ROUTER, REQ: DONE
 VLAN 4139(43): 1 OPORTs, FULL, REQ: DONE
   OPORT 43, ROUTER, REQ: DONE
```

Table 1-9 Output Fields of the show msf6 msc Command

Field	Description
(Ipv6-source-address, *ipv6-source-address*, *ipv6-group-address*, *vlan-id*)	(Source address, group address, VLAN ID) Example: (2012::16:1:0:0:2, FF1E::2:0:0:1, 4103)
SYNC	Indicates that the entry is synchronized to the bottom-layer hardware.
MTU	MTU value of an entry.
number OIFs	*Number* of L3 outbound interfaces in an entry
VLAN *vlan-id*(0)	ID of a VLAN to which an L3 outbound interface belongs. When this value is greater than 4096, the interface is a routed port.
oport-number OPORTs	Number of L2 ports that belong to this L3 outbound interface
REQ: DONE	Indicates that this L3 outbound interface has been set to the bottom-layer hardware.
OPORT *oport-index*	Index to the L2 ports that belong to this L3 outbound interface.
MLD-SNP	Indicates that this port is created based on the MLD Snooping protocol. If this value is ROUTER, this port is created based on an L3 protocol.
REQ: DONE	Indicates that this port has been set to the bottom-layer hardware.

1 MLD Commands

Command	Function
clear ipv6 mld group	Clear dynamic group member records in the MLD cache.
clear ipv6 mld interface	Clear all MLD statistics and group member records on an interface.
ipv6 mld access-group	Specify the address range of multicast groups that an interface can join.
ipv6 mld immediate-leave group-list	Enable the fast leave function on an interface.
ipv6 mld join-group	Add an interface to a group.
ipv6 mld last-member-query-count	Configure the group-specific query packet sending times on an interface.
ipv6 mld last-member-query-interval	Configure the group-specific query packet sending interval on an interface.
ipv6 mld limit	Configure the maximum number of MLD group members.
ipv6 mld mroute-proxy	Enable the MRoute proxy function on an interface.
ipv6 mld proxy-service	Enable the proxy service function on an interface.
ipv6 mld querier-timeout	Configure the other querier keepalive time.
ipv6 mld query-interval	Configure the general group query interval.
ipv6 mld query-max-response-time	Configure the maximum response time of query packets.
ipv6 mld robustness-variable	Configure the robustness variable of the querier.
ipv6 mld ssm-map enable	Enable the SSM mapping function.
ipv6 mld ssm-map static	Configure static mapping entries.
ipv6 mld static-group	Add an interface to a static multicast group.
ipv6 mld version	Configure an MLD version on an interface.
show ipv6 mld groups	Display groups directly connected to the device and group information learned from MLD.
show ipv6 mld interface	Display MLD information about an interface.

show ipv6 mld ssm-mapping	Display SSM mapping information.

1.1 clear ipv6 mld group

Function

Run the **clear ipv6 mld group** command to clear dynamic group member records in the MLD cache.

Syntax

clear ipv6 mld group [*ipv6-group-address*] [*interface-type interface-number*]

Parameter Description

ipv6-group-address: Address of an IPv6 multicast group.

interface-type interface-number: Interface type and interface number of a relevant interface.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

The MLD cache contains a list, which includes multicast groups that hosts in the same directly connected subnet join. If devices join a multicast group, this group is also in the list.

If no parameter is specified, all dynamic group member records are cleared from the MLD cache.

Examples

The following example clears all dynamic group member records.

```
Hostname> enable
Hostname# clear ipv6 mld group
```

The following example clears group member records about the group address FF1E::100.

```
Hostname> enable
Hostname# clear ipv6 mld group ff1e::100
```

The following example clears group member records about the group address FF1E::100 and the interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear ipv6 mld group ff1e::100 gigabitethernet 0/1
```

1.2 clear ipv6 mld interface

Function

Run the **clear ipv6 mld interface** command to clear all MLD statistics and group member records on an interface.

Syntax

clear ipv6 mld interface *interface-type interface-number*

Parameter Description

interface-type interface-number: Interface type and interface number

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to clear all group information learned from MLD and packet statistics on an interface. The packet statistics include the number of received report packets, number of done packets, and group member count on the interface.

Examples

The following example clears the MLD statistics and group member records on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear ipv6 mld interface gigabitethernet 0/1
```

1.3 ipv6 mld access-group

Function

Run the **ipv6 mld access-group** command to specify the address range of multicast groups that an interface can join.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

An interface can join any group by default.

Syntax

ipv6 mld access-group *acl-name*

no ipv6 mld access-group

default ipv6 mld access-group

Parameter Description

acl-name: ACL name referenced to specify a group address range. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command is configured on the interface to specify the address range of multicast groups that hosts in the directly-connected network segment can join. After ACLs are referenced to specify the address range of multicast groups, report packets denied by the ACLs are discarded.

When MLDv2 is enabled, this command supports extended ACLs to precisely filter source record information in MLDv2 reports. If the received MLD report packets follow the format of (S1, S2, S3 … Sn, G), the corresponding ACL is used to check the packets. Therefore, to normally use this command, you must explicitly configure (*, G) in the extended ACLs to filter (S1, S2, S3 … Sn, G).

Examples

The following example configures an ACL on GigabitEthernet 0/1 and sets the source address ranges to ::/64 and 2222::3333/64 and the destination address ranges to FF66::100/64 and FF66::100/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl

1.4 ipv6 mld immediate-leave group-list

Function

Run the **ipv6 mld immediate-leave group-list** command to enable the fast leave function on an interface.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The fast leave function is disabled on an interface by default.

Syntax

ipv6 mld immediate-leave group-list *acl-name*

no ipv6 mld immediate-leave

default ipv6 mld immediate-leave

Parameter Description

acl-name: ACL name referenced to specify a group address range. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This function applies to scenarios where only one user host is connected to an interface.

If this command is not configured, when receiving an MLD leave packet, the interface sends a group-specific query packet and waits for response from the host. If no response is received after timeout, this interface is deleted from the member record. The timeout time refers to the product of the group-specific query interval and robustness variable of MLD. The default value is **2** seconds.

After the fast leave function is enabled, when the device receives a leave packet that specifies a group in the permitted range, the device does not send a group-specific query packet and directly deletes the corresponding group. This reduces the leave latency.

Examples

The following example enables the fast leave function for the groups in the ACL, and sets the source address range in the ACL to 2222::3333/64 and the destination address range to FF66::100/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl
Hostname(config-ipv6-acl)# permit ipv6 2222::3333/64 ff66::100/64
```

```
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld immediate-leave group-list acl
```

Notifications

If no ACL is configured for reference, the following notification will be displayed:

```
% access-list acl not exist
```

1.5 ipv6 mld join-group

Function

Run the **ipv6 mld join-group** command to add an interface to a group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No interface joins any group by default.

Syntax

ipv6 mld join-group *ipv6-group-address*

no ipv6 mld join-group *ipv6-group-address*

default ipv6 mld join-group *ipv6-group-address*

Parameter Description

ipv6-group-address: Address of an IPv6 multicast group. An address starting with 0xFF*1, 0xFF*2, or 0xFF3* is not allowed.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is configured, the interface simulates a host and sends a join packet to the uplink devices to join this group.

This command is used for laboratory test.

Examples

The following example adds GigabitEthernet 0/1 to the group FF55::100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld join-group ff55::100
```

1.6 ipv6 mld last-member-query-count

Function

Run the **ipv6 mld last-member-query-count** command to configure the group-specific query packet sending times on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The group-specific query packet sending times is **2** by default.

Syntax

ipv6 mld last-member-query-count *count*

no ipv6 mld last-member-query-count

default ipv6 mld last-member-query-count

Parameter Description

count: Group-specific query packet sending times. The value range is from 2 to 7.

Default Level

14

Command Modes

Interface configuration mode

Usage Guidelines

After receiving a done packet, the interface continuously sends group-specific query packets and waits for responses from hosts. If no response is received after timeout, it is considered that no member exists in the

group in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows:

Timeout interval = last-member-query-interval × last-member-query-count + query-max-response-time/2

Examples

The following example sets the group-specific query packet sending times to 3 on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld last-member-query-count 3
```

Notifications

If the number of group-specific query packet sending times is not within the range from 2 to 7, the following notification will be displayed:

```
% Invalid Last Member Query Count value
```

Common Errors

1.7 ipv6 mld last-member-query-interval

Function

Run the **ipv6 mld last-member-query-interval** command to configure the group-specific query packet sending interval on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The group-specific query packet sending interval is **1** second by default.

Syntax

ipv6 mld last-member-query-interval *interval*

no ipv6 mld last-member-query-interval

default ipv6 mld last-member-query-interval

Parameter Description

interval: Group-specific query packet sending interval, in 0.1 seconds. The value range is from 1 to 255. The default value is 10, indicating 1 second.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After receiving a done packet, the interface continuously sends group-specific query packets and waits for responses from hosts. If no response is received after timeout, it is considered that no member exists in the group in the directly-connected network segment and the interface is deleted from the MLD group member record. The timeout interval is calculated as follows:

Timeout interval = last-member-query-interval × last-member-query-count + query-max-response-time/2

Examples

The following example sets the group-specific query packet sending interval to 2 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld last-member-query-interval 20
```

Notifications

If the value of group-specific query packet sending interval is not within the range from 1 to 255, the following notification will be displayed:

```
% Invalid Last Member Query Interval value
```

1.8 ipv6 mld limit

Function

Run the **ipv6 mld limit** command to configure the maximum number of MLD group members.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the maximum number of MLD group members on an interface is **4000**, and the maximum number of MLD group numbers on a device is **64000**.

Syntax

ipv6 mld limit *limit* [**except** *acl-name*]

no ipv6 mld limit

default ipv6 mld limit

Parameter Description

limit: Maximum number of MLD group members. The value range is from 1 to 64000.

except *access-list*: References an ACL name to specify groups that are not counted. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Interface configuration mode

Default Level

14

Usage Guidelines

In the global configuration mode, the number of members in an MLD group on a device is limited.

In the interface configuration mode, the number of members in an MLD group on an interface is limited.

If the number of group members exceeds the interface limit or global limit, subsequent report packets are ignored.

If an except list is configured, report packets in a specified range can be normally processed, and the records about these group members are not counted.

Interface and global limits can be configured separately. If the global limit is smaller than the interface limit, the global limit prevails.

Examples

The following example sets the maximum number of MLD group members on a device to **400** and sets the maximum number of MLD group members on GigabitEthernet 0/1 to **300**, excluding the groups in the IPv6 list.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list ipv6-list
Hostname(config-ipv6-acl)#permit ipv6 any ff13::/64
Hostname(config)# ipv6 mld limit 400 except ipv6-list
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld limit 300 except ipv6-list
```

Notifications

If the number of MLD group members is not within the range from 1 to 64000, the following notification will be displayed:

```
% Invalid Limit value
```

If the access list is unavailable, the following notification will be displayed:

```
% access-list acl1 not exist
```

1.9 ipv6 mld mroute-proxy

Function

Run the **ipv6 mld mroute-proxy** command to enable the MRoute proxy function on an interface.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The MRoute proxy function is disabled by default.

Syntax

ipv6 mld mroute-proxy *interface-type interface-number*

no ipv6 mld mroute-proxy

default ipv6 mld mroute-proxy

Parameter Description

interface-type interface-number: Type and number of an uplink interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The **ipv6 mld proxy-service** command is run to enable the proxy service function on an uplink interface in the root direction of the multicast distribution tree (MDT).

The **ipv6 mld mroute-proxy** command is run to enable the MRoute proxy function on a downlink interface in the leaf direction of the MDT.

The proxy service interface forwards MLD query packets to the MRoute proxy interface. The MRoute proxy interface forwards MLD report packets to the proxy service interface.

Examples

The following example enables the proxy service function on GigabitEthernet 0/1 and the MRoute proxy function on GigabitEthernet 0/2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld proxy-service
Hostname(config-if-GigabitEthernet 0/1)# exit
```

```
Hostname(config)# interface gigabitethernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# ipv6 mld mroute-proxy gigabitethernet 0/1
```

Notifications

If the multicast proxy function is already enabled on the current interface, the following notification will be displayed:

```
Mroute proxy had configured
```

Common Errors

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The proxy service function on an interface is disabled by default.

Syntax

ipv6 mld proxy-service

no ipv6 mld proxy-service

default ipv6 mld proxy-service

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The **ipv6 mld proxy-service** command is run to enable the proxy service function on an uplink interface in the root direction of the MDT.

The **ipv6 mld mroute-proxy** command is run to enable the MRoute proxy function on a downlink interface in the leaf direction of the MDT.

The proxy service interface forwards MLD query packets to the MRoute proxy interface. The MRoute proxy interface forwards MLD report packets to the proxy service interface.

A maximum of 32 proxy service interfaces can be configured on a device. After receiving MLD query packets, the proxy service interface sends report packets based on the MLD group member records.

If the **switchport** command is run on the proxy service interface of a device, the **ipv6 mld mroute-proxy** command configured on the MRoute proxy interface is automatically deleted.

Examples

The following example enables the proxy service function on GigabitEthernet 0/1 and the MRoute proxy function on GigabitEthernet 0/2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld proxy-service
Hostname(config-if-GigabitEthernet 0/1)# exit
Hostname(config)# interface gigabitethernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# ipv6 mld mroute-proxy gigabitethernet 0/1
```

1.11 ipv6 mld querier-timeout

Function

Run the **ipv6 mld querier-timeout** command to configure the other querier keepalive time.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default querier keepalive time is 255 seconds.

Syntax

ipv6 mld querier-timeout *timeout*

no ipv6 mld querier-timeout

default ipv6 mld querier-timeout

Parameter Description

timeout: Other querier keepalive time, in seconds. The value range is from 60 to 300.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When a non-querier does not receive a query packet in the same network segment within a specified period, the non-querier considers there is only one device (itself) in the directly connected network segment and initiates a new round of querier election.

Examples

The following example sets the other querier keepalive time to 200 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld querier-timeout 200
```

Notifications

If the configured other querier keepalive time is not within the range from 60 to 300, the following notification will be displayed:

```
% Invalid Querier Timeout Time value
```

Common Errors

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum response time of query packets is **10** seconds by default.

Syntax

ipv6 mld query-max-response-time *max-response-time*

no ipv6 mld query-max-response-time

default ipv6 mld query-max-response-time

Parameter Description

max-response-time: Maximum response time of query packets, in seconds. The value range is from 1 to 25.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

A query packet is sent through an interface. If no response is received after timeout, it is considered that no member exists in the group of the directly connected network segment and the group information is deleted.

Examples

The following example sets the maximum response time of query packets to 20 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld query-max-response-time 20
```

Notifications

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static mapping entry is configured by default.

Syntax

ipv6 mld ssm-map static *acl-name ipv6-source-address*

no ipv6 mld ssm-map static *acl-name ipv6-source-address*

default ipv6 mld ssm-map static *acl-name ipv6-source-address*

Parameter Description

acl-name: ACL name referenced to specify a group address range. The value is a case-sensitive string of 1 to 99 characters.

ipv6-source-address: Address of an IPv6 multicast source.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The **ipv6 mld ssm-map enable** command is run to enable the SSM mapping function.

The interface runs MLDv2. When receiving MLDv1 report packets, a multicast device adds the static mapping source address.

Examples

The following example enables the SSM mapping function, and sets the group address of static mapping entries to ACL ASD and the source address to 4444::1234.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list asd
Hostname(config-ipv6-acl)# permit ipv6 any FF34::/64
Hostname(config)# ipv6 mld ssm-map enable
Hostname(config)# ipv6 mld ssm-map static asd 4444::1234
```

Notifications

If *ipv6-source-address* is not a multicast address, the following notification will be displayed:

```
% Invalid input, not a unicast IP address 4444::1234!
```

If the name of the access list does not comply with specifications, the following notification will be displayed:

Function

Run the **ipv6 mld static-group** command to add an interface to a static multicast group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No interface is added to any static multicast group by default.

Syntax

ipv6 mld static-group *ipv6-group-address*

no ipv6 mld static-group *ipv6-group-address*

default ipv6 mld static-group *ipv6-group-address*

Parameter Description

ipv6-group-address: Address of an IPv6 multicast group.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is configured, an interface can join a group without MLD packet interaction. Even if no host in the same directly connected network segment as this interface joins this group, this interface is in the member record of this group.

The member record that is generated by adding an interface to a static group cannot be deleted by running the **clear ipv6 mld group** command, and can be deleted by running the **no ipv6 mld static-group** command.

Examples

The following example adds GigabitEthernet 0/1 to the group FF55::3.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld static-group ff55::3
```

Notifications

If an interface fails to join a static group, the following notification will be displayed:

```
Static-group create fail! addr= ff55::3
```

Function

Run the **ipv6 mld version** command to configure an MLD version on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

MLDv2 is running on an interface by default.

Syntax

ipv6 mld version { **1** | **2** }

no ipv6 mld version

default ipv6 mld version

Parameter Description

1: Uses MLDv1.

2: Uses MLDv2.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is configured, the MLD process automatically restarts.

A device is backward compatible, and can process MLD packets of the same version or earlier version. It is recommended that the MLD version of the device be later than or equal to that of a host.

Examples

The following example configures MLDv1 on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld version 1
```

Examples

The following example displays MLD information about all interfaces.

```
Hostname> enable
Hostname# show ipv6 mld interface
Interface VLAN 2 (Index 4098)
 MLD Enabled, Inactive, Version 2 (default)
 MLD interface limit is 1024
 MLD interface has 0 group-record states
 MLD interface has 1 join-group records
 MLD interface has 0 static-group records
 MLD activity: 0 joins, 0 leaves
 MLD query interval is 125 seconds
 MLD querier timeout is 255 seconds
 MLD max query response time is 10 seconds
 Last member query response interval is 10 (1/10s)
 Last member query count is 2
 Group Membership interval is 260
 Robustness Variable is 2
```

Table 1-2 Output Fields of the show ipv6 mld interface Command

Field	Description
Interface	Interface.

Field	Description
MLD interface limit is x	Maximum number of group members on an MLD interface.
MLD interface has x group-record states	Number of group record states on an interface.
MLD interface has x join-group records	Number of member join records on an interface.
MLD interface has x static-group records	Number of static group records on an interface.
MLD query interval is x seconds	MLD query interval, in seconds.
MLD querier timeout is x seconds	MLD query timeout time, in seconds.
MLD max query response time is x seconds	Maximum response time of MLD query, in seconds.
Last member query response interval is *last-member-query-response-interval* (1/10s)	Last member query interval, in 0.1 seconds.
Last member query count is *last-member-query-count*	Last member query times.
Group Membership interval is *group-membership-interval*	Membership sending interval.
Robustness Variable is *robustness*	Robustness variable.

1.21 show ipv6 mld ssm-mapping

Function

Run the **show ipv6 mld ssm-mapping** command to display SSM mapping information.

Syntax

show ipv6 mld ssm-mapping [*ipv6-group-address*]

Parameter Description

ipv6-group-address: Address of an IPv6 multicast group. If this parameter is not specified, all MLD SSM mapping information is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the SSM mapping information of the group FF66::1234.

```
Hostname> enable
Hostname# show ipv6 mld ssm-mapping ff66::1234
Group address: ff66::1234
Database    : Static
Source list  : 5555::1234
```

Table 1-3 Output Fields of the show ipv6 mld ssm-mapping Command

Field	Description
Group Address	Group address.
Database	Data state.
Source list	Linked list of source addresses.

1 PIM-SMv6 Commands

Command	Function
clear ipv6 mroute	Clear IPv6 multicast routing entries.
clear ipv6 mroute statistics	Clear statistics about IPv6 multicast routing entries.
clear ipv6 pim sparse-mode bsr rp-set	Clear all dynamic rendezvous point (RP) information.
clear ipv6 pim sparse-mode track	Set the statistics start time and clear statistics of the PIMv6 packets.
ipv6 pim accept-bsr list	Limit the address range of BSRs.
ipv6 pim accept-crp-with-null-group	Enable the BSR to receive advertisement packets with the prefix of a multicast address being 0.
ipv6 pim accept-crp list	Limit the C-RP address range and the address range of the groups served by the C-RPs.
ipv6 pim accept-register	Limit the (S, G) address range in the register messages received by an RP.
Ipv6 pim bsr-border	Configure a BSR border.
ipv6 pim bsr-candidate	Configure C-BSRs.
ipv6 pim bfd	Configure the BFD Support for PIMv6 feature on an interface, also known as PIMv6 BFD.
ipv6 pim dr-priority	Configure the DR priority.
Ipv6 pim ignore-rp-set-priority	Ignore RP priority for RP election.
ipv6 pim jp-timer	Configure the join/prune packet sending interval.
ipv6 pim neighbor-filter	Enable the neighbor filtering function.
ipv6 pim neighbor-tracking	Enable the neighbor tracking function.
ipv6 pim override-interval	Configure the prune override interval of an interface.
ipv6 pim probe-interval	Configure the register-probe time.
ipv6 pim propagation-delay	Configure the propagation delay of an interface.
ipv6 pim query-interval	Configure the hello message sending interval.
ipv6 pim register-checksum-wholepkt	Calculate the checksum of entire register messages.
ipv6 pim register-rate-limit	Limit the sending rate of register messages.

ipv6 pim register-rp-reachability	Enable the RP reachability checking function before a register message is sent.
ipv6 pim register-source	Specify a source IPv6 address in register messages.
ipv6 pim register-suppression	Configure the register suppression time.
ipv6 pim rp-address	Configure static RPs.
ipv6 pim rp-candidate	Configure C-RPs.
ipv6 pim rp-register-kat	Configure the (S, G) entry timeout period on an RP.
ipv6 pim rp embedded	Enable the RP address embedding function.
ipv6 pim sparse-mode	Enable the PIM-SMv6 function on an interface.
ipv6 pim sparse-mode passive	Enable the PIM-SMv6 passive mode on an interface.
ipv6 pim spt-threshold	Enable the shortest path tree (SPT) switchover function.
ipv6 pim ssm	Enable the SSM function and configure an SSM group address range.
ipv6 pim static-rp-preferred	Configure static DR priority to be higher than dynamic RP priority.
ipv6 pim triggered-hello-delay	Configure the hello message sending delay on an interface.
show ipv6 pim sparse-mode bsr-router	Display BSR information.
show ipv6 pim sparse-mode interface	Display PIM-SMv6 information of an interface.
show ipv6 pim sparse-mode local-members	Display local MLD information of a PIM-SMv6 interface.
show ipv6 pim sparse-mode mroute	Display PIM-SMv6 routing information.
show ipv6 pim sparse-mode neighbor	Display neighbor information.
show ipv6 pim sparse-mode nexthop	Display next hop information, including interface, address, and metric value of a next hop.
show ipv6 pim sparse-mode rp mapping	Display all RPs and the groups served by the RPs on the local device.
show ipv6 pim sparse-mode rp-hash	Display RP information corresponding to a multicast group address.
show ipv6 pim sparse-mode track	Display the number of PIM packets sent and received since the statistic start time.

1.1 clear ipv6 mroute

Function

Run the **clear ipv6 mroute** command to clear IPv6 multicast routing entries.

Syntax

clear ipv6 mroute { ***** | *ipv6-group-address* [*ipv6-source-address*] }

Parameter Description

*****: Clears all IPv6 multicast routing entries.

ipv6-group-address: Address of an IPv6 multicast group whose routing entries are to be cleared.

ipv6-source-address: Address of an IPv6 multicast source whose routing entries are to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the multicast function fails, you can run this command to clear the current multicast routing information to facilitate problem locating and re-learn entries.

Examples

The following example clears all IPv6 multicast routing entries.

```
Hostname> enable
Hostname# clear ipv6 mroute *
```

The following example clears IPv6 multicast routing entries of a specified group.

```
Hostname> enable
Hostname# clear ipv6 mroute ff66::6666
```

The following example clears multicast routing entries of a specified group and source.

```
Hostname> enable
Hostname# clear ipv6 mroute ff66::6666 3333::3333
```

1.2 clear ipv6 mroute statistics

Function

Run the **clear ipv6 mroute statistics** command to clear statistics about IPv6 multicast routing entries.

Syntax

clear ipv6 mroute statistics { ***** | *ipv6-group-address* [*ipv6-source-address*] }

Parameter Description

*****: Clears all statistics about multicast routing entries.

ipv6-group-address: Address of a specified IPv6 multicast group whose routing entry statistics are to be cleared.

ipv6-source-address: Address of a specified IPv6 multicast source whose routing entry statistics are to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If the multicast function fails, you can run this command to clear the current multicast routing statistics to facilitate problem locating and re-collect information.

Examples

The following example clears statistics about all multicast routing entries.

```
Hostname> enable
Hostname# clear ipv6 mroute statistics *
```

The following example clears statistics about multicast routing entries of a specified group.

```
Hostname> enable
Hostname# clear ipv6 mroute statistics ff66::6666
```

The following example clears statistics about multicast routing entries of a specified group and source.

```

1.3 clear ipv6 pim sparse-mode bsr rp-set

Function

Run the **clear ipv6 pim sparse-mode bsr rp-set** command to clear all dynamic rendezvous point (RP) information.

Syntax

clear ipv6 pim sparse-mode bsr rp-set *

Parameter Description

*****: Clears all dynamic RP information.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

This command is used to clear dynamic C-RP information, rather than static C-RP information.

Examples

The following example clears all dynamic RP information of PIM-SMv6.

```
Hostname> enable
Hostname# clear ipv6 pim sparse-mode bsr rp-set *
```

Notifications

After the RP-Set information is cleared, the following notification will be displayed:

```
Self RP is changed for group range %R/%u.  Perform Self RP change handler
```

Platform Description

1.5 ipv6 pim accept-bsr list

Function

Run the **ipv6 pim accept-bsr list** command to limit the address range of BSRs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

All BSMs are received by default.

Syntax

ipv6 pim accept-bsr list *acl-name*

no ipv6 pim accept-bsr

default ipv6 pim accept-bsr

Parameter Description

list *acl-name*: Uses an ACL name to limit the address range of BSRs. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example uses the ACL bsr-list to limit the address range of BSRs so that only BSMs sent from the BSRs in the bsr-list range are received.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list bsr-list
Hostname(config-ipv6-acl)# permit ipv6 9000::5/64 any
```

```
Hostname(config-ipv6-acl)# exit
Hostname(config)# ipv6 pim accept-bsr list bsr-list
```

Notifications

If no ACL is configured to limit the BSR address range, the following notification will be displayed:

```
% access-list bsr-list not exist
```

Common Errors

1.6 ipv6 pim accept-crp-with-null-group

Function

Run the **ipv6 pim accept-crp-with-null-group** command to enable the BSR to receive advertisement packets with the prefix of a multicast address being 0.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The function for the BSR to receive advertisement packets with the prefix of a multicast address being 0 is disabled by default.

Syntax

ipv6 pim accept-crp-with-null-group

no ipv6 pim accept-crp-with-null-group

default ipv6 pim accept-crp-with-null-group

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A C-RP periodically sends advertisement packets to the BSR in unicast mode. The packets include the RP priority, advertisement packet hold time (greater than the interval of sending the advertisement packet), RP address, address of the served group, and prefix of the multicast address. Upon receiving the advertisement

packets, the BSR collects the information in the packets as RP-Set in the advertisement packet hold time, encapsulates the information in a BSM, and sends the message to all PIM devices.

After this command is run on a C-BSR and this C-BSR is elected as the BSR, the BSR can receive advertisement packets with the prefix of a multicast address being 0. This C-RP can serve all groups.

Examples

The following example configures the BSR to receive advertisement packets with the prefix of the multicast address being 0 from a C-RP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim accept-crp-with-null-group
```

1.7 ipv6 pim accept-crp list

Function

Run the **ipv6 pim accept-crp list** command to limit the C-RP address range and the address range of the groups served by the C-RPs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The C-BSRs receive all external C-RP advertisement packets by default.

Syntax

ipv6 pim accept-crp list *acl-name*

no ipv6 pim accept-crp

default ipv6 pim accept-crp

Parameter Description

list *acl-name*: Uses an ACL name to limit the C-RP address range and the address range of the groups served by the C-RPs. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is run on a C-BSR and this C-BSR is elected as the BSR, the BSR can limit the C-RP address range and the address range of the groups served by the C-RPs.

Examples

The following example uses the ACL crp-list to limit the C-RP address range and the address range of the groups served by the C-RPs.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list crp-list
Hostname(config-ipv6-acl)# permit ipv6 9000::5/64 any
Hostname(config-ipv6-acl)# exit
Hostname(config)# ipv6 pim accept-crp list crp-list
```

Notifications

If no ACL is configured, the following notification will be displayed:

```
% access-list crp-list not exist
```

Common Errors

1.8 ipv6 pim accept-register

Function

Run the **ipv6 pim accept-register** command to limit the (S, G) address range in the register messages received by an RP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The (S, G) address range of register messages is not limited by default. An RP receives register messages with any (S, G) address.

Syntax

ipv6 pim accept-register { **list** *acl-name* | **route-map** *route-map-name* } *

no ipv6 pim accept-register

default ipv6 pim accept-register

Parameter Description

list *acl-name*: Uses an ACL name to limit the (S, G) group address range. The value is a case-sensitive string of 1 to 99 characters.

route-map *route-map-name*: Uses a route map to limit the (S, G) address range.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is run on a static RP or C-RP, the RP replies a register-stop message upon receiving data from an unauthorized source.

Examples

The following example uses an ACL register-access-list to deny register messages from the source FE80::2D0:F8FF:FE22:33AD.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list register-access-list
Hostname(config-ipv6-acl)# deny ipv6 fe80::2d0:f8ff:fe22:33ad/128 any
Hostname(config-ipv6-acl)# exit
Hostname(config)# ipv6 pim accept-register list register-access-list
```

1.9 Ipv6 pim bsr-border

Function

Run the **ipv6 pim bsr-border** command to configure a BSR border.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No BSR border is configured by default.

Syntax

ipv6 pim bsr-border
no ipv6 pim bsr-border
default ipv6 pim bsr-border

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To control BSM flooding, you can configure a BSR border on the interface. Then, this interface discards received BSMs without forwarding them.

Examples

The following example configures a BSR border on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim bsr-border
```

1.10 ipv6 pim bsr-candidate

Function

Run the **ipv6 pim bsr-candidate** command to configure C-BSRs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No C-BSR is configured by default.

Syntax

ipv6 pim bsr-candidate *interface-type interface-number* [*hash-mask-length* [*priority-value*]]

no ipv6 pim bsr-candidate

Parameter Description

interface-type terface-number: Interface type and interface number. You are advised to use the address of this interface as the address of a C-BSR.

hash-mask-length: Length of a hash mask configured for the RP election mechanism. The value range is from 0 to 128, and the default value is **126**.

priority-value: C-BSR priority. The value range is from 0 to 255, and the default value is **64**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In a PIM SMv6 domain, a unique BSR must be available. The BSR collects and releases RP information. Multiple C-BSRs elect an acknowledged BSR based on BSMs. Before a BSR is elected, each C-BSR considers itself a BSR and periodically sends a BSM in the PIM-SMv6 domain. This message includes the address and priority of the BSR.

This command can be used to send a BSM to all PIM neighbors through the address assigned to a BSR. Each neighbor compares the original BSR address with the address in the received BSM. If the received BSM indicates that the C-BSR of the received BSM boasts a higher priority or a larger IP address, the neighbor saves the address in the BSM as the BSR address and forwards the BSM. Otherwise, the neighbor discards the BSM.

A C-BSR considers itself the BSR until the C-BSR receives a BSM indicating a higher priority from another C-BSR.

Examples

The following example configures the address of GigabitEthernet 0/1 as the address of a C-BSR, and sets the length of the hash mask to 30 and the priority to 100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim bsr-candidate gigabitethernet 0/1 30 100
```

Notifications

If the current interface is not configured in SM mode, the following notification will be displayed:

```
Warning: PIMSMv6 not configured on %s, BSR messages not originated.
```

1.11 ipv6 pim bfd

Function

Run the **ipv6 pim bfd** command to configure the BFD Support for PIMv6 feature on an interface, also known as PIMv6 BFD.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

PIMv6 BFD is not configured on an interface by default.

Syntax

ipv6 pim bfd

no ipv6 pim bfd

default ipv6 pim bfd

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Bidirectional forwarding detection (BFD) is used to quickly detect or monitor links or IP route forwarding connectivity in a network.

Based on the PIM-SMv6 protocol, a designated router (DR) is defined. This DR is the unique role that forwards multicast data in a shared network.

Devices in the shared network exchange PIM hello messages and elect a DR based on the hello messages. When the DR is faulty, a new round of DR election can be started only after the PIM neighbor ages. If this command is run, when the DR is faulty, this faulty DR can be detected and a new round of election can be started in milliseconds.

Examples

The following example configures PIMv6 BFD on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# interface gigabitethernet 0/1
Hostname (config-if-GigabitEthernet 0/1)# ipv6 pim bfd
```

1.12 ipv6 pim dr-priority

Function

Run the **ipv6 pim dr-priority** command to configure the DR priority.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default DR priority is **1**.

Syntax

ipv6 pim dr-priority *priority-value*

no ipv6 pim dr-priority

default ipv6 pim dr-priority

Parameter Description

priority-value: DR priority. A larger value indicates a higher priority. The value range is from 0 to 4294967294.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If multiple devices in a LAN join DR election, the election result is subject to the priorities in hello messages. The device with the highest priority is elected as the DR. If the priorities in the hello messages are the same or the priority parameter is not set in the hello messages, the device with the largest IP address is elected as the DR.

Examples

The following example sets the DR priority to **11234** on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim dr-priority 11234
```

Notifications

If the priority value is smaller than 0, the following notification will be displayed:

```
% Invalid DR priority value.
```

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The join/prune packet is sent at an interval of **60** seconds by default.

Syntax

ipv6 pim jp-timer *interval*

no ipv6 pim jp-timer

default ipv6 pim jp-timer

Parameter Description

interval: Join/prune packet sending interval, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the join/prune packet sending interval to 100 seconds.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# ipv6 pim jp-timer 100
```

Notifications

If the join/prune packet sending interval is not within the range from 0 to 65535, the following notification will be displayed:

```
% Invalid Join/Prune timer value.
```

If the value of *interval* is greater than the maximum time of adding a prune packet, the following notification will be displayed:

```

1.15 ipv6 pim neighbor-filter

Function

Run the **ipv6 pim neighbor-filter** command to enable the neighbor filtering function.

Run **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The neighbor filtering function is disabled by default.

Syntax

ipv6 pim neighbor-filter *acl-name*

no ipv6 pim neighbor-filter *acl-name*

default ipv6 pim neighbor-filter *acl-name*

Parameter Description

acl-name: ACL name that is used to limit the address range of neighbors. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The neighbor filtering function can strengthen PIM network security and limit the valid address range of neighbors. If a neighbor is filtered out based on an access filtering list, PIM-SMv6 does not create peer relationship with the neighbor or stops the peer relationship with this neighbor.

Examples

The following example uses the ACL to deny requests for establishing peer relationship with the neighbor FE80::2D0:F8FF:FE22:33AD on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl
Hostname(config-ipv6-acl)# deny ipv6 fe80::2d0:f8ff:fe22:33ad/128 any
Hostname(config-ipv6-acl)# exit
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim neighbor-filter acl
```

Notifications

If no ACL is configured, the following notification will be displayed:

```
% access-list acl not exist
```

Common Errors

1.16 ipv6 pim neighbor-tracking

Function

Run the **ipv6 pim neighbor-tracking** command to enable the neighbor tracking function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The neighbor tracking function is disabled by default.

Syntax

Ipv6 pim neighbor-tracking

no ipv6 pim neighbor-tracking

default ipv6 pim neighbor-tracking

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After the suppression capability of an interface is enabled, when the local router plans to send a join packet to an uplink neighbor but it receives a join packet sent from the neighbor to the uplink router, this local router suppresses its own join packet. If the suppression capability of the interface is disabled, the join packet can be sent. When the suppression capability of downlink hosts is disabled, an uplink device can determine the number of the downlink hosts based on the quantity of received join packets. This is neighbor tracking.

Examples

The following example disables the suppression function on GigabitEthernet 0/1 and enables neighbor tracking.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim neighbor-tracking
```

1.17 ipv6 pim override-interval

Function

Run the **ipv6 pim override-interval** command to configure the prune override interval of an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default prune override interval of an interface is **2500** ms.

Syntax

ipv6 pim override-interval *override-interval*

no ipv6 pim override-interval

default ipv6 pim override-interval

Parameter Description

override-interval: Prune override interval of an interface, in milliseconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Modifying the propagation delay or prune override delay affects the prune override interval.

The network administrator needs to ensure that the prune override interval is smaller than the join/prune packet hold time. Otherwise, a short interrupt may occur.

Examples

The following example sets the prune override interval to 3000 ms on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim override-interval 3000
```

Notifications

If the configured prune override interval is not within the range from 1 to 65535, the following notification will be displayed:

```
% Invalid Hello option: override-interval value
```

1.18 ipv6 pim probe-interval

Function

Run the **ipv6 pim probe-interval** command to configure the register-probe time.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default register-probe time is **5** seconds.

Syntax

ipv6 pim probe-interval *interval*

no ipv6 pim probe-interval

default ipv6 pim probe-interval

Parameter Description

interval: Register-probe interval, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The register-probe time refers to the time when the source DR is allowed to send null register messages to the RP before the register suppression timer times out.

The register-probe time cannot be greater than a half of the register suppression time. Otherwise, the configuration fails and an alarm is generated.

The sum of the three times of register suppression time and the register-probe time does not exceed 65535. Otherwise, the configuration fails and an alarm is generated.

Examples

The following example sets the register-probe time to 6 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim probe-interval 6
```

Notifications

If the configured register-probe time is not within the range from 1 to 65535, the following notification will be displayed:

```
% Invalid probe-interval value
```

If two times of the register-probe time is greater than the register suppression time, the following notification will be displayed:

```
WARNING: Register probe interval MUST be less than half the register suppression
interval. Please set a less one.
```

If the sum of three times of register suppression time and the register-probe time is greater than 65535, the following notification will be displayed:

```
WARNING: Register probe interval is too large. It may cause (3*RST+probe-
interval) > 65535.
```

1.19 ipv6 pim propagation-delay

Function

Run the **ipv6 pim propagation-delay** command to configure the propagation delay of an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default propagation delay of an interface is **500** ms.

Syntax

ipv6 pim propagation-delay *propagation-delay*

no ipv6 pim propagation-delay

default ipv6 pim propagation-delay

Parameter Description

propagation-delay: Propagation delay of an interface, in milliseconds. The value range is from 1 to 32767.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Modifying the propagation delay or prune override delay affects the prune override interval.

The network administrator needs to ensure that the prune override interval is smaller than the join/prune packet hold time. Otherwise, a short interrupt may occur.

Examples

The following example sets the prune override delay to 600 ms on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim propagation-delay 600
```

Notifications

If the configured prune override delay is not within the range from 1 to 32767, the following notification will be displayed:

```
% Invalid Hello option: propagation-delay value
```

Common Errors

N/A

Platform Description

1.20 ipv6 pim query-interval

Function

Run the **ipv6 pim query-interval** command to configure the hello message sending interval.

Run the **no** form of command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The hello message is sent at an interval of **30** seconds by default.

Syntax

ipv6 pim query-interval *interval*

no ipv6 pim query-interval

default ipv6 pim query-interval

Parameter Description

interval: Hello message sending interval, in seconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When the hello message sending interval is updated, the hello message hold time is updated accordingly. The hello message hold time is 3.5 times of the hello message sending interval. If the product of the hello message sending interval and 3.5 is greater than 65535, the hello message sending interval is forcibly reset to 18725.

Examples

The following example sets the hello message sending interval to 60 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim query-interval 60
```

Notifications

If the configured hello message sending interval is not within the range from 1 to 32767, the following notification will be displayed:

```
% Invalid Query interval value
```

If the value of *interval* is greater than the maximum time of a request interval, the following notification will be displayed:

```
WARNING: PIMv2 Query interval too high, changed %u to %d sec.
(corresponding to maximum holdtime 0xFFFF)
```

Common Errors

1.21 ipv6 pim register-checksum-wholepkt

Function

Run the **ipv6 pim register-checksum-wholepkt** command to calculate the checksum of entire register messages.

Run the **no** form of this command to remove this configuration and calculate the checksum of headers of PIM packets and register messages, rather than the entire packets.

Run the **default** form of this command to restore the default configuration.

By default, only the headers of PIM packets and register messages, rather than the entire packets, are specified for calculating the checksum.

Syntax

ipv6 pim register-checksum-wholepkt [**group-list** *acl-name*]

no ipv6 pim register-checksum-wholepkt [**group-list** *acl-name*]

default ipv6 pim register-checksum-wholepkt [**group-list** *acl-name*]

Parameter Description

group-list *acl-name*: Uses an ACL name to limit the address range of multicast groups that support this configuration. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The checksum of the entire PIM protocol packets (including encapsulated multicast packets), rather than the PIM headers of separate register messages, is calculated.

If the **group-list** parameter is not specified, the entire packet checksum calculation method applies to register messages with any group address.

If you run the **no** or **default** form of this command to specify the **group-list** parameter and specify to use the configured ACL, the limits of the ACL associated with the **group-list** parameter are removed. In this case, the entire packet checksum calculation method applies to register messages with any group address.

Examples

The following example uses the ACL checksum-access-list to apply the entire packet checksum calculation method to the register messages with the multicast group address FF66::6666/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list checksum-access-list
Hostname(config-ipv6-acl)# permit ipv6 any ff66::6666/64
Hostname(config-ipv6-acl)# exit
Hostname(config)# ipv6 pim register-checksum-wholepkt group-list checksum-access-
list
```

Notifications

If no ACL is configured, the following notification will be displayed:

```
% access-list checksum-access-list not exist
```

Function

Run the **ipv6 pim register-rate-limit** command to limit the sending rate of register messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The sending rate of register messages is not limited by default.

Syntax

ipv6 pim register-rate-limit *rate*

no ipv6 pim register-rate-limit

default ipv6 pim register-rate-limit

Parameter Description

rate: Maximum number of register messages that can be sent per second. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the sending rate of register messages in (S, G) status, rather than that of the entire system. Running this command can reduce the load of the source DR and RP. Register messages sent at a rate exceeding the limit are discarded.

Examples

The following example limits the sending rate of register messages to 3000 per second.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim register-rate-limit 3000
```

Notifications

If the configured sending rate of register messages is not within the range from 1 to 65535, the following notification will be displayed:

```
% Invalid Limit value
```

1.24 ipv6 pim register-source

Function

Run the **ipv6 pim register-source** command to specify a source IPv6 address in register messages.

Run the **no** form of this command to remove this configuration and use the address of the DR interface connected to the source as the source IPv6 address in register messages.

Run the **default** form of this command to restore the default configuration.

The source IPv6 address in register messages is the address of the DR interface connected to the source by default.

Syntax

ipv6 pim register-source { *ipv6-local-address* | *interface-type interface-number* }

no ipv6 pim register-source

default ipv6 pim register-source

Parameter Description

ipv6-local-address: Source IPv6 address in register messages.

interface-type interface-number: Interface type and interface number. The IPv6 address of this interface is specified as the source address in register messages.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is run, the RP reachability is checked before a register message is sent. If the RP is reachable, the message is sent. Otherwise, the message is not sent.

It is recommended that loopback address be used as the source IP address in register messages. Other physical addresses can be used as the source IP addresses in register messages as well.

Examples

The following example specifies the IPv6 address 3333::3333 as the source address in register messages.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim register-source 3333::3333
```

The following example specifies the IPv6 address of GigabitEthernet 0/1 as the source IP address in register messages.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim register-source gigabitethernet 0/1
```

1.25 ipv6 pim register-suppression

Function

Run the **ipv6 pim register-suppression** command to configure the register suppression time.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default register suppression time is **60** seconds.

Syntax

ipv6 pim register-suppression *suppression-time*

no ipv6 pim register-suppression

default ipv6 pim register-suppression

Parameter Description

suppression-time: Register suppression time, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be run on the DR to configure the register message suppression time.

If the **ipv6 pim rp-register-kat** command is not run, configuring the register suppression time on the RP changes the (S, G) entry timeout period. The (S, G) entry timeout period on an RP is the sum of three times of the register suppression time and the register-probe time.

Examples

The following example sets the register suppression time to 100 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim register-suppression 100
```

Notifications

If the configured register suppression time is not within the range from 1 to 65535, the following notification will be displayed:

```
% Invalid KAT value
```

If two times of the register-probe time is greater than the register message suppression time, the following notification will be displayed:

```
WARNING: Register suppression interval MUST be larger than twice the register
probe interval. Please set a larger one.
```

If the sum of three times of register suppression time and the register-probe time is greater than 65535, the following notification will be displayed:

```
WARNING: Register suppression interval is too large. It may cause (3*RST+probe-interval) > 65535.
```

1.26 ipv6 pim rp-address

Function

Run the **ipv6 pim rp-address** command to configure static RPs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static RP is configured by default.

Syntax

ipv6 pim rp-address *ipv6-rp-address* [*acl-name*]

no ipv6 pim rp-address *ipv6-rp-address*

default ipv6 pim rp-address *ipv6-rp-address*

Parameter Description

ipv6-rp-address: IPv6 address of a static RP.

acl-name: ACL name that is used to limit address range of multicast groups served by static RPs. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If static and dynamic RPs are available at the same time, dynamic RPs are preferred.

If multiple static RPs serve the same multicast group, the static RP with a larger address is preferred.

If the *acl-name* parameter is not specified, the static RPs serve all groups.

Examples

The following example configures the static RP 3333::3333 to serve the multicast group with the address FF66::6666/64 limited by the ACL acl.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl
Hostname(config-ipv6-acl)# permit ipv6 any ff66::6666/64
Hostname(config-ipv6-acl)# exit
Hostname(config)# ipv6 pim rp-address 3333::3333 acl
```

Notifications

If the configured RP address is not a valid address, the following notification will be displayed:

```
Illegal RP address, ignored
```

If the number of the RP addresses reaches the upper limit, the following notification will be displayed:

```
Reach PIM-SMv6 static RP configuration limit 65536!
```

If no ACL is configured, the following notification will be displayed:

```
% access-list acl not exist
```

Common Errors

1.27 ipv6 pim rp-candidate

Function

Run the **ipv6 pim rp-candidate** command to configure C-RPs.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No C-RP is configured by default.

Syntax

ipv6 pim rp-candidate *interface-type interface-number* [**priority** *priority-value*] [**interval** *interval*] [**group-list** *acl-name*]

no ipv6 pim rp-candidate [*interface-type interface-number*]

default ipv6 pim rp-candidate [*interface-type interface-number*]

Parameter Description

interface-type interface-number: Interface type and interface number. The address of this interface is specified as the address of a C-RP.

priority *priority-value*: Specifies the C-RP priority. The value range is from 0 to 255, and the default value is **192**.

interval *interval*: Specifies the interval of sending C-RP messages to the BSR, in seconds. The value range is from 1 to 16383, and the default value is **60**.

group-list *acl-name*: Uses an ACL name to limit the address range of multicast groups served by a C-RP. The value is a case-sensitive string of 1 to 99 characters. If this parameter is not specified, the C-RP serves all groups.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In PIM-SMv6, an RPT created based on multicast routing takes the RP as a root. After a BSR is elected, all C-RPs periodically send unicast messages to the BSR and then the BSR forwards the messages throughout the PIM domain.

When an ACL is used to specify the address range of groups served by the C-RP, only the permit access control entry (ACE) is calculated, and the deny ACE is not calculated.

Examples

The following example configures the address of GigabitEthernet 0/1 as the C-RP address, sets the RP priority to 200 and the interval of sending C-RP messages to the BSR to 40 seconds, and uses the ACL to limit the address range of groups served by the C-RP to FF66::6666/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl
Hostname(config-ipv6-acl)# permit ipv6 any ff66::6666/64
Hostname(config-ipv6-acl)# exit
Hostname(config)# ipv6 pim rp-candidate gigabitethernet 0/1 priority 200 group-
list acl interval 40
Hostname(config)# ipv6 access-list acl
Hostname(config-ipv6-acl)# permit ipv6 any ff66::6666/64
```

Notifications

If the C-RP priority is not within the range from 0 to 255, the following notification will be displayed:

```
% Invalid C-RP Priority value
```

If the interval of sending C-RP messages to the BSR is not within the range from 1 to 16383 seconds, the following notification will be displayed:

```
% Invalid C-RP advertisement intvl value
```

If the multicast function is not enabled on an interface, the following notification will be displayed:

```
Warning: PIMSMv6 not configured on %s, Candidate-RP not advertised
```

1.28 ipv6 pim rp-register-kat

Function

Run the **ipv6 pim rp-register-kat** command to configure the (S, G) entry timeout period on an RP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The (S, G) entry timeout period on an RP is the sum of three times of the register suppression time and the register-probe time by default.

Syntax

ipv6 pim rp-register-kat *interval*

no ipv6 pim rp-register-kat

default ipv6 pim rp-register-kat

Parameter Description

Interval: (S, G) entry timeout period on an RP, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The value of the (S, G) entry timeout timer on an RP should be greater than the sum of three times of the register suppression time and the register-probe time on the source DR. Otherwise, the (S, G) on the RP may time out before the source DR sends register messages again, causing a short interrupt of multicast streams.

Examples

The following example sets the (S, G) entry timeout period in register messages to 250 seconds on an RP.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim rp-register-kat 250
```

Notifications

If the configured (S, G) entry timeout period on an RP is not within the range from 1 to 65535, the following notification will be displayed:

```
% Invalid KAT value
```

1.29 ipv6 pim rp embedded

Function

Run the **ipv6 pim rp embedded** command to enable the RP address embedding function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

For the IPv6 addresses of multicast groups that support RP address embedding, the RP address embedding function is enabled by default.

Syntax

ipv6 pim rp embedded [**group-list** *acl-name*]

no ipv6 pim rp embedded

default ipv6 pim rp embedded

Parameter Description

group-list *acl-name*: Uses an ACL name to limit the address range of multicast groups. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the **group-list** parameter is not specified, the RP address embedding function is enabled on all IPv6 addresses of multicast groups that support RP address embedding.

Examples

The following example enables the RP address embedding function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim rp embedded
```

Notifications

If the group-list is not in the embedded RP linked list, the following notification will be displayed:

```
RP embedded is configured with the same ACL again
```

1.30 ipv6 pim sparse-mode

Function

Run the **ipv6 pim sparse-mode** command to enable the PIM-SMv6 function on an interface.

Run the **no** form of this command to disable this function on an interface.

Run the **default** form of this command to restore the default configuration.

The PIM-SMv6 function on an interface is disabled by default.

Syntax

ipv6 pim sparse-mode

no ipv6 pim sparse-mode

default ipv6 pim sparse-mode

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Before PIM-SMv6 is enabled, you must enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if PIM-SMv6 is enabled.

When PIM-SMv6 is enabled, MLD is automatically enabled on different interfaces.

The multicast function can be enabled on a tunnel interface that does not support multicast. In this case, no notification will be displayed and multicast packets will not be sent or received.

A multicast tunnel cannot be nested and does not support multicast data QoS/ACL.

IPv6 multicast forwarding is not supported on a super VLAN.

Examples

The following example enables the PIM-SMv6 function on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode
```

Notifications

If the specified interface does not exist, the following notification will be displayed:

```
ipv6 pim sparse-mode (vif == NULL)
```

If the multicast function is not enabled, the following notification will be displayed:

```
WARNING:  \"ip multicast-routing\"  is not configured
```

If the number of configured multicast interfaces exceeds the upper limit, the following notification will be displayed:

```
PIM-SMv6 Configure failed! VIF limit exceeded in NSM!!!
```

Common Errors

Platform Description

N/A

Related Commands

- **ipv6 multicast-routing** (IPv6 multicast routing management)

1.31 ipv6 pim sparse-mode passive

Function

Run the **ipv6 pim sparse-mode passive** command to enable the PIM-SMv6 passive mode on an interface.

Run the **no** form of this command to disable this mode.

Run the **default** form of this command to restore the default configuration.

The PIM-SMv6 mode is disabled on an interface by default.

Syntax

ipv6 pim sparse-mode passive

no ipv6 pim sparse-mode passive

default ipv6 pim sparse-mode passive

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Before the PIM-SMv6 passive mode is enabled, you must enable the multicast routing and forwarding function in global configuration mode. Otherwise, multicast packets cannot be sent even if the PIM-SMv6 passive mode is enabled.

When the PIM-SMv6 mode is enabled, MLD is automatically enabled on different interfaces.

After the PIM-SMv6 passive mode is enabled on an interface, the interface does not receive or send PIM packets, but it can forward multicast packets. It is recommended that the PIM-SMv6 passive mode be enabled on an interface of a stub routing device connected to hosts. This avoids L2 flooding of the PIM hello messages.

Examples

The following example enables the PIM-SMv6 passive mode on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim sparse-mode passive
```

Notifications

N/A

Common Errors

If the PIM-SMv6 passive mode is enabled on an interface connected to a source, the source interface does not send or receive PIM packets. Consequently, the source loses the DR election capability. It is not recommended that the PIM-SMv6 passive mode be enabled on an interface connected to a source.

After the PIM-SMv6 passive mode is enabled on an interface, if two devices in the same network segment forward multicast data, assertion election cannot proceed. As a result, two identical multicast packets are sent to this network segment.

If the PIM-SMv6 passive mode is enabled on an interface of an intermediate device deployed on an L3 multicast network, the networking fails because the interface does not receive or send PIM packets.

Platform Description

N/A

Related Commands

1.32 ipv6 pim spt-threshold

Function

Run the **ipv6 pim spt-threshold** command to enable the shortest path tree (SPT) switchover function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The SPT switchover function is disabled by default.

Syntax

ipv6 pim spt-threshold [**group-list** *acl-name*]

no ipv6 pim spt-threshold [**group-list** *acl-name*]

default ipv6 pim spt-threshold [**group-list** *acl-name*]

Parameter Description

group-list *acl-name*: Uses an ACL name to limit the address range of groups that support SPT switchover. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the **group-list** *acl-name* parameter is not specified, all multicast groups support SPT switchover.

If you run the **no** or **default** form of this command to specify the **group-list** parameter and specify to use the configured ACL, the limits on the ACL associated with the **group-list** parameter are removed. In this case, all groups are allowed to switch over from an RPT to an SPT.

Examples

The following example uses the ACL acl to set the address range of the multicast source that supports SPT switchover to FE80::2D0:F8FF:FE22:33AD and the address range of the multicast group to FF66::6666/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl
Hostname(config-ipv6-acl)# permit ipv6 fe80::2d0:f8ff:fe22:33ad/128 ff66::6666/64
Hostname(config-ipv6-acl)# exit
Hostname(config)# ipv6 pim spt-threshold group-list acl
```

Function

Run the **ipv6 pim ssm** command to enable the SSM function and configure an SSM group address range.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The SSM function is disabled by default.

Syntax

ipv6 pim ssm { **default** | **range** *acl-name* }

no ipv6 pim ssm

default ipv6 pim ssm

Parameter Description

default: Specifies the default SSM group address range to FF3X::/32.

range *acl-name*: Uses an ACL name to limit the SSM group address range. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If SSM needs to be applied in a PIM-SMv6 network, this command must be run.

Examples

The following example enables the SSM function and sets the multicast source address range to FE80::2D0:F8FF:FE22:33AD/128 and the multicast group address range to FF32::3333/64.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list acl
Hostname(config-ipv6-acl)# permit ipv6 fe80::2d0:f8ff:fe22:33ad/128 ff32::3333/64

- **ipv6 mld ssm-map static** (MLD)
- **show ipv6 mld ssm-mapping** (MLD)

1.34 ipv6 pim static-rp-preferred

Function

Run the **ipv6 pim static-rp-preferred** command to configure static DR priority to be higher than dynamic RP priority.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Dynamic RP priority is higher than static DR priority by default.

Syntax

ipv6 pim static-rp-preferred

no ipv6 pim static-rp-preferred

default ipv6 pim static-rp-preferred

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is run, the static RP priority is higher than the dynamic DR priority.

Examples

The following example configures static DR priority to be higher than dynamic RP priority.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 pim static-rp-preferred
```

Notifications

After static DR priority is configured to be higher than dynamic RP priority and RP switchover is performed, the following notification will be displayed.

```
RP is changed for group range %R/%u.  Perform RP change handler
```

Common Errors

N/A

Platform Description

N/A

Related Commands

1.35 ipv6 pim triggered-hello-delay

Function

Run the **ipv6 pim triggered-hello-delay** command to configure the hello message sending delay on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default hello message sending delay is **5** seconds.

Syntax

ipv6 pim triggered-hello-delay *delay*

no ipv6 pim triggered-hello-delay

default ipv6 pim triggered-hello-delay

Parameter Description

delay: Hello message sending delay, in seconds. The value range is from 1 to 5.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When an interface is enabled or detects a new neighbor, a random time is generated. Within this time, the interface sends hello messages out.

Examples

The following example sets the hello message sending delay to 3 seconds on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 pim triggered-hello-delay 3
```

Notifications

If the hello message sending delay is not within the range from 1 to 5, the following notification will be displayed:

```
% Invalid Hello option: triggered-hello-delay value
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **show ipv6 pim sparse-mode interface**

1.36 show ipv6 pim sparse-mode bsr-router

Function

Run the **show ipv6 pim sparse-mode bsr-router** command to display BSR information.

Syntax

show ipv6 pim sparse-mode bsr-router

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays BSR information.

```
Hostname> enable
Hostname# show ipv6 pim sparse-mode bsr-router
PIMv2 Bootstrap information
This system is the Bootstrap Router (BSR)
BSR address: 3333::8888
Uptime:00:03:31, BSR Priority: 64, Hash mask length: 126
Next bootstrap message in 00:00:47
Role: Candidate BSR  Priority: 64, Hash mask length: 126
```

```
State: Elected BSR
Candidate RP: 3333::8888(GigabitEthernet 0/5)
Advertisement interval 60 seconds
Next Cand_RP_advertisement in 00:00:37
```

Table 1-1 Output Fields of the show ipv6 pim sparse-mode bsr-router Command

Field	Description
BSR address	BSR address
Uptime	Update time
BSR Priority	BSR priority
Hash mask length	Hash mask length
Next bootstrap message in *time*	Next bootstrap time
Role	BSR role
Priority	Priority
Hash mask length	Hash mask length
State	BSR status
Candidate RP	C-RP address
Advertisement interval *advertisement-interval* seconds	C-RP advertisement interval
Next Cand_RP_advertisement in *time*	Next C-RP advertisement time

1.37 show ipv6 pim sparse-mode interface

Function

Run the **show ipv6 pim sparse-mode interface** command to display PIM-SMv6 information of an interface.

Syntax

show ipv6 pim sparse-mode interface [*interface-type interface-number*] [**detail**]

Parameter Description

interface-type interface-number: Interface type and interface number. If this parameter is not specified, the PIM-SMv6 information of all interfaces is displayed.

detail: Displays the detailed PIM-SMv6 information of an interface. If this parameter is not specified, the summary information of an interface is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays PIM-SMv6 information of an interface.

```
Hostname> enable
Hostname# show ipv6 pim sparse-mode interface detail
GigabitEthernet 0/5 (vif 1):
Address fe80::2d0:f8ff:fe22:33ad, DR fe80::2d0:f8ff:fe22:34b3
Hello period 30 seconds, Next Hello in 6 seconds
Triggered Hello period 5 seconds
Secondary addresses:
   3333::8888
   4444::4444
  Neighbors:
   fe80::2d0:f8ff:fe22:34b3
```

Table 1-2 Output Fields of the show ipv6 pim sparse-mode interface detail Command

Field	Description
Address	Interface address
DR	Address of a DR in the same shared network segment as the interface
Hello period *hello-interval* seconds	Hello message sending interval: *hello-interval* seconds
Next Hello in *next-hello-time* seconds	Next hello message *next-hello-time* seconds later
Triggered Hello period *triggered-hello-time* seconds	Triggered-Hello-Delay of an interface: *triggered-hello-time* seconds
Secondary addresses	Secondary address
Neighbors	Neighbors on an interface

1.38 show ipv6 pim sparse-mode local-members

Function

Run the **show ipv6 pim sparse-mode local-members** command to display local MLD information of a PIM-SMv6 interface.

Syntax

show ipv6 pim sparse-mode local-members [*interface-type interface-number*]

Parameter Description

interface-type interface-number: Interface type and interface number. If this parameter is not specified, the local MLD information of all PIM-SMv6 interfaces is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays local MLD information of a PIM-SMv6 interface.

```
Hostname> enable
Hostname# show ipv6 pim sparse-mode local-members
PIM Local membership information
GigabitEthernet 0/5:
  (*, ff66::6666) : Include
```

Table 1-3 Output Fields of the show ipv6 pim sparse-mode local-members Command

1.39 show ipv6 pim sparse-mode mroute

Function

Run the **show ipv6 pim sparse-mode mroute** command to display PIM-SMv6 routing information.

Syntax

show ipv6 pim sparse-mode mroute [*ipv6-group-or-source-address* [*ipv6-group-or-source-address*]]

Parameter Description

ipv6-group-or-source-address: Address of an IPv6 multicast group or source (the two addresses cannot be both multicast group addresses or both source addresses).

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

Either a source address or a group address can be specified.

A source address and a group address can be specified together.

If you want to configure two addresses, they cannot be both multicast group addresses or both source addresses

If no parameter is specified, all PIM-SMv6 routing information is displayed.

Examples

The following example displays PIM-SMv6 routing information.

```
Hostname> enable
Hostname# show ipv6 pim sparse-mode mroute
IPv6 Multicast Routing Table

1.40 show ipv6 pim sparse-mode neighbor

Function

Run the **show ipv6 pim sparse-mode neighbor** command to display neighbor information.

Syntax

show ipv6 pim sparse-mode neighbor [**detail**]

Parameter Description

detail: Displays detailed neighbor information. If this parameter is not specified, the summary information of a neighbor is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays neighbor information.

```
Hostname> enable
Hostname# show ipv6 pim sparse-mode neighbor detail
Nbr fe80::2d0:f8ff:fe22:34b3 (GigabitEthernet 0/5)
 Expires in 86 seconds
  Secondary addresses:
   6666::6666
```

1.43 show ipv6 pim sparse-mode rp-hash

Function

Run the **show ipv6 pim sparse-mode rp-hash** command to display RP information corresponding to a multicast group address.

Syntax

show ipv6 pim sparse-mode rp-hash *ipv6-group-address*

Parameter Description

ipv6-group-address: Address of an IPv6 multicast group.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays RP information corresponding to a group address FF66::6666.

```
Hostname> enable
Hostname# show ipv6 pim sparse-mode rp-hash ff66::6666
 RP: 20::2
Info source: 20::2, via bootstrap

PIMv2 Hash Value 126
RP 20::2, via bootstrap, priority 200, hash value 2007554652
RP 20::1, via bootstrap, priority 200, hash value 844492565
```

Table 1-8 Output Fields of the show ipv6 pim sparse-mode rp-hash Command

Field	Description
RP: *ipv6-rp-address*	Address of the RP serving this multicast group: *ipv6-rp-address*
Info source: *ipv6-rp-address*,via bootstrap	RP address *ipv6-rp-address* is obtained from a BSM.
PIMv2 Hash Value *hash-value*	PIMv2 hash value: *hash-value*

1.44 show ipv6 pim sparse-mode track

Function

Run the **show ipv6 pim sparse-mode track** command to display the number of PIM packets sent and received since the statistic start time.

Syntax

show ipv6 pim sparse-mode track

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

When the system is started for the first time, the statistic start time is set. If you run the **clear ipv6 pim sparse-mode track** command, the statistic start time and the PIM packet counter are reset.

Examples

The following example displays the number of PIM packets sent and received since the statistic start time.

```
Hostname> enable
Hostname# show ipv6 pim sparse-mode track
PIMv6 packet counters track
Elapsed time since counters cleared: 00:04:03
                    Received   sent
Valid PIMSMv6 packets:  0         8
Hello:                 0         8

1 MLD Snooping Commands

Command	Function
clear ipv6 mld snooping gda-table	Clear Multicast Listener Discovery (MLD) snooping forwarding entries.
clear ipv6 mld snooping statistics	Clear MLD snooping statistics, including the current number of entries, entry capacity, number of different types of packets, group information, and group interface information.
deny	Deny a range of multicast groups specified by a profile.
ipv6 mld profile	Create a profile.
ipv6 mld snooping	Enable MLD snooping globally and set the working mode.
ipv6 mld snooping dyn-mr-aging-time	Configure the aging time of dynamic multicast router ports.
ipv6 mld snooping fast-leave enable	Enable the port fast leave function.
ipv6 mld snooping filter	Enable multicast group filtering on a port.
ipv6 mld snooping host-aging-time	Configure the aging time for MLD snooping dynamic member ports.
ipv6 mld snooping max-groups	Configure the maximum number of multicast groups that can be dynamically learned by a port.
ipv6 mld snooping mrouter learn	Enable the function of dynamic multicast router port learning.
ipv6 mld snooping query-max-response-time	Configure the maximum response time for Query packets.
ipv6 mld snooping source-check port	Enable the source port check function.
ipv6 mld snooping suppression enable	Enable the function of Report packet suppression.
ipv6 mld snooping svgl profile	Specify a range of multicast groups applied in the MLD snooping SVGL mode.
ipv6 mld snooping svgl vlan	Specify the shared VLAN applied in the MLD snooping SVGL mode.
ipv6 mld snooping vlan	Enable the MLD snooping function on a VLAN.

ipv6 mld snooping vlan mrouter interface	Configure a static multicast router port.
ipv6 mld snooping vlan static interface	Configure a static member port.
permit	Permit a range of multicast groups defined by a profile.
range	Define a multicast group range for a profile.
show ipv6 mld profile	Display configurations of a profile.
show ipv6 mld snooping	Display MLD snooping information.
show ipv6 mld snooping gda-table	Display MLD snooping forwarding entries.
show ipv6 mld snooping interfaces	Display multicast filtering configurations on a port.
show ipv6 mld snooping mrouter	Display MLD snooping multicast router ports.
show ipv6 mld snooping statistics	Display MLD snooping statistics.

1.1 clear ipv6 mld snooping gda-table

Function

Run the **clear ipv6 mld snooping gda-table** command to clear Multicast Listener Discovery (MLD) snooping forwarding entries.

Syntax

clear ipv6 mld snooping gda-table

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

An MLD snooping forwarding entry includes the virtual local area network (VLAN) ID, multicast group address, multicast router ports, and member ports.

A VID and multicast group address uniquely identify a forwarding entry.

A forwarding entry may contain multiple multicast router ports, which may be dynamically learned or statically configured. Static multicast router ports never age.

A forwarding entry may contain multiple member ports, which may be dynamically learned or statically configured. Static member ports never age. The **clear ipv6 mld snooping gda-table** command cannot be used to delete static member ports.

Examples

The following example clears MLD snooping multicast forwarding entries.

```
Hostname> enable
Hostname# clear ipv6 mld snooping gda-table
```

Notifications

N/A

Platform Description

N/A

1.2 clear ipv6 mld snooping statistics

Function

Run the **clear ipv6 mld snooping statistics** command to clear MLD snooping statistics, including the current number of entries, entry capacity, number of different types of packets, group information, and group interface information.

Syntax

clear ipv6 mld snooping statistics

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

After you run this command, you can run the **show ipv6 mld snooping statistics** command to display the result.

Examples

The following example clears MLD snooping statistics.

```
Hostname> enable
Hostname# clear ipv6 mld snooping statistics
```

Notifications

N/A

Platform Description

N/A

1.3 deny

Function

Run the **deny** command to deny a range of multicast groups specified by a profile.

The deny action is performed for a profile by default.

Syntax

deny

Parameter Description

N/A

Command Modes

Profile configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ipv6 mld profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups.

Examples

The following example denies multicast groups in the range of FF15::1 to FF15::100 defined by profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld profile 1
Hostname(config-profile)# range FF15::1 FF15::100
Hostname(config-profile)# deny
```

1.4 ipv6 mld profile

Function

Run the **ipv6 mld profile** command to create a profile.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No profile is configured by default.

Syntax

ipv6 mld profile *profile-number*

no ipv6 mld profile *profile-number*

default ipv6 mld profile *profile-number*

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ipv6 mld profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups.

Examples

The following example permits multicast groups in the range of FF15::1 to FF15::100 defined by profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld profile 1
Hostname(config-profile)# range FF15::1 FF15::100
Hostname(config-profile)# permit
```

Notifications

When a profile fails to be configured, the following notification will be displayed:

```
% Error: configure mld profile fail
```

1.5 ipv6 mld snooping

Function

Run the **ipv6 mld snooping** command to enable MLD snooping globally and set the working mode.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

MLD snooping is disabled by default.

Syntax

ipv6 mld snooping { **ivgl** | **svgl** | **ivgl-svgl** }

no ipv6 mld snooping [**ivgl** | **svgl** | **ivgl-svgl**]

default ipv6 mld snooping [**ivgl** | **svgl** | **ivgl-svgl**]

Parameter Description

ivgl: Sets the MLD snooping working mode to Independent VLAN Group Learning (IVGL).

svgl: Sets the MLD snooping working mode to Shared VLAN Group Learning (SVGL).

ivgl-svgl: Sets the MLD snooping working mode to IVGL-SVGL.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In IVGL mode, multicast streams in different VLANs are independent of each other. A host can request only a multicast router port in the same VLAN to receive multicast data. Upon receiving multicast data in any VLAN, the device running MLD snooping forwards the data only to member ports in the same VLAN.

In SVGL mode, hosts in different VLANs share multicast data. Hosts can request multicast data across VLANs. A shared VLAN (VLAN 1 by default) needs to be designated. Only multicast data in the shared VLAN can be forwarded to all member ports of the group address. These member ports can be in other VLANs. A profile must be used to define a range of multicast groups applied in SVGL mode. Only multicast data from this range can be forwarded across VLANs, and other multicast data will be discarded. In IVGL-SVGL mode, the IVGL and SVGL modes coexist. A profile must be used to define a range of multicast groups applied in SVGL mode. Multicast data in this range applies to the SVGL mode, and other multicast data applies to the IVGL mode.

IPv6 multicast data cannot be forwarded in super VLANs.

Examples

The following example enables MLD snooping and runs the IVGL mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping ivgl
```

The following example enables MLD snooping and runs the SVGL mode, sets the shared VLAN to VLAN 1, and sets the multicast groups associated with the SVGL mode to profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping svgl
```

```
Hostname(config)# ipv6 mld snooping svgl profile 1
```

Notifications

When the SVGL or IVGL-SVGL mode is configured before an SVGL profile is configured, the following notification will be displayed:

```
WARNING: Please remember to configure the SVGL profile!
```

Common Errors

The SVGL mode or IVGL-SVGL mode is configured before an SVGL profile is configured. When no SVGL profile is configured, all group information is filtered and no multicast data can be received.

Platform Description

N/A

1.6 ipv6 mld snooping dyn-mr-aging-time

Function

Run the **ipv6 mld snooping dyn-mr-aging-time** command to configure the aging time of dynamic multicast router ports.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default aging time of dynamic multicast router ports is 300s.

Syntax

ipv6 mld snooping dyn-mr-aging-time *dynamic-mroute-aging-time*

no ipv6 mld snooping dyn-mr-aging-time

default ipv6 mld snooping dyn-mr-aging-time

Parameter Description

dynamic-mroute-aging-time: Aging time of dynamic router ports, in seconds. The value range is from 1 to 3600.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If a dynamic multicast router port does not receive a general MLD Query packet or a Protocol Independent Multicast (PIM) Hello packet before the aging time, the device deletes the port from the multicast router port list.

When the dynamic multicast router port learning function is enabled, you can run this command to adjust the aging time of dynamic multicast router ports. A too short aging time may cause multicast router ports to be added and deleted frequently.

Dynamic multicast router port learning is enabled by default. If multicast router ports fail to be dynamically learned, run the **show running-config** command to check whether dynamic multicast router port learning is enabled.

Examples

The following example sets the aging time of dynamic multicast router ports to 100s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping dyn-mr-aging-time 100
```

1.7 ipv6 mld snooping fast-leave enable

Function

Run the **ipv6 mld snooping fast-leave enable** command to enable the port fast leave function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The port fast leave function is disabled by default.

Syntax

ipv6 mld snooping fast-leave enable

no ipv6 mld snooping fast-leave enable

default ipv6 mld snooping fast-leave enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the port fast leave function is enabled and a port receives a MLD Done packet, the port is directly deleted from the member port list of the corresponding multicast forwarding entry. When receiving group-specific Query packets, the device does not forward the packets to this port.

The port fast leave function is applicable when only one host is connected to each port. The function helps save bandwidth and resources.

Examples

The following example enables the port fast leave function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping fast-leave enable
```

1.8 ipv6 mld snooping filter

Function

Run the **ipv6 mld snooping filter** command to enable multicast group filtering on a port.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The multicast group filtering function is disabled on a port by default.

Syntax

ipv6 mld snooping filter *profile-number*

no ipv6 mld snooping filter

default ipv6 mld snooping filter

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To specify a profile in this command, you must first create the profile.

After this command is configured on a port and the port receives a Report packet from a user host, the device checks whether the multicast address that the user host wants to join is within the multicast group range allowed by the profile. If yes, the user host can join the group. If no, the user host is not allowed to join the group.

Examples

The following example enables multicast group filtering on GigabitEthernet 0/1 and allows user hosts only to join multicast group addresses defined in profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld profile 1
Hostname(config-profile)# range FF15::1 FF15::100
Hostname(config-profile)# permit
Hostname(config-profile)# exit
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld snooping filter 1
```

Notifications

N/A

Common Errors

When the configured *profile-number* does not exist, the following notification will be displayed:

```
% Error: The profile doesn't exist
```

When the multicast group filtering function fails to be configured, the following notification will be displayed:

```
% Error: Config interface filter fail, please try again later
```

Platform Description

1.9 ipv6 mld snooping host-aging-time

Function

Run the **ipv6 mld snooping host-aging-time** command to configure the aging time for MLD snooping dynamic member ports.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default aging time of dynamic member ports is 260s.

Syntax

ipv6 mld snooping host-aging-time *host-aging-time*

no ipv6 mld snooping host-aging-time

default ipv6 mld snooping host-aging-time

Parameter Description

host-aging-time: Aging time of dynamic member ports, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the device running MLD snooping receives an MLD Join packet from a host to join an IPv6 multicast group, the device adds the port receiving the packet to the member port list and sets an aging time for the port.

If the port is already in the member port list, the device resets the aging timer of the port. The timer time is *host-aging-time*. If the timer times out, it is deemed that no user host receives multicast packets through this port, and then the multicast device deletes the port from the MLD snooping member port list. After this command is configured, the aging timer value of dynamic member ports is *host-aging-time* for subsequent MLD Join packets. The aging time takes effect immediately after configuration, and the started member port aging timers are updated.

Examples

The following example sets the aging time of MLD dynamic member ports to 30s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping host-aging-time 30
```

1.10 ipv6 mld snooping max-groups

Function

Run the **ipv6 mld snooping max-groups** command to configure the maximum number of multicast groups that can be dynamically learned by a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of multicast groups that can be dynamically learned by a port is 64,000 by default.

Syntax

ipv6 mld snooping max-groups *max-groups-number*

no ipv6 mld snooping max-groups

default ipv6 mld snooping max-groups

Parameter Description

max-groups-number: Maximum number of multicast groups. The value range is from 0 to 64000.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is configured and the number of multicast groups dynamically learned by a port exceeds the limit, the device no longer learns MLD Report packets over this port to create new forwarding entries.

The number of multicast groups that can be dynamically learned by a port is counted based on the VLANs to which the port belongs. For example, if a port belongs to three VLANs and the port receives requests of multicast group FF15::100 from each VLAN, the number of multicast groups dynamically learned by the port is 3 instead of 1.

Examples

The following example sets the maximum number of multicast groups that can be dynamically learned by GigabitEthernet 0/1 to **100**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 mld snooping max-groups 100
```

Notifications

When the maximum number of multicast groups that can be dynamically learned by a port fails to be configured, the following notification will be displayed:

```
% Error: Configure interface max-groups fail, please try again later
```

When the number of existing multicast groups exceeds the configured maximum number of multicast groups that can be dynamically learned by a port, the following notification will be displayed:

```
% Warning: The current number(value) is greater than the new interface group
number(value), delete entries related to the interface
```

1.11 ipv6 mld snooping mrouter learn

Function

Run the **ipv6 mld snooping mrouter learn** command to enable the function of dynamic multicast router port learning.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

Dynamic multicast router port learning is enabled by default.

Syntax

ipv6 mld snooping [**vlan** *vlan-id*] **mrouter learn**

no ipv6 mld snooping [**vlan** *vlan-id*] **mrouter learn**

default ipv6 mld snooping [**vlan** *vlan-id*] **mrouter learn**

Parameter Description

vlan *vlan-id*: VLAN ID. The value range is from 1 to 4094.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A multicast router port is a port that directly connects an MLD snooping-enabled multicast device to a neighbor multicast device in which a multicast routing protocol is enabled. When the dynamic multicast router port learning function is enabled, the device automatically listens to the MLD Query/PIM Hello packets and dynamically identifies a multicast router port.

To dynamically learn multicast router ports, enable the dynamic multicast router port learning function.

To obtain statically configured multicast router ports, run the **ipv6 mld snooping vlan mrouter interface** command.

To disable the dynamic multicast router port learning function for all VLANs, run the **no ipv6 mld snooping mrouter learn** command.

To disable the dynamic multicast router port learning function for a specific VLAN, run the **no ipv6 mld snooping vlan** *vlan-id* **mrouter learn** command.

When the source port check function is enabled, only multicast traffic from the multicast router ports is valid and the multicast device forwards the traffic to registered ports. Multicast data from non-multicast router ports is invalid and will be discarded.

Examples

The following example enables dynamic multicast router port learning only on VLAN 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping ivgl
Hostname(config)# no ipv6 mld snooping mrouter learn
Hostname(config)# ipv6 mld snooping vlan 1 mrouter learn
```

Notifications

When dynamic multicast router port learning is enabled for a VLAN that does not exist, the following notification will be displayed:

```
% Error: Vlan does not exist
```

When dynamic multicast router port learning is enabled for a VLAN before it is enabled globally, the following notification will be displayed:

```
% Warning: Please remember to enable global mrouter learn
```

Common Errors

Function

Run the **ipv6 mld snooping query-max-response-time** command to configure the maximum response time for Query packets.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum response time for Query packets is 10s by default.

Syntax

ipv6 mld snooping query-max-response-time *query-max-response-time*

no ipv6 mld snooping query-max-response-time

default ipv6 mld snooping query-max-response-time

Parameter Description

query-max-response-time: Maximum response time for Query packets, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When receiving an MLD group-specific Query packet, the multicast device will start the aging timers of all member ports of the specific group. The timer time is the maximum response time for Query packets. After the timer expires, the device regards that no group member receives multicast traffic through a port and deletes the port from the MLD snooping forwarding table.

For MLDv2 group-specific Query packets, the multicast device does not update the timers.

The configured maximum response time for Query packets takes effect when the next Query packet is received.

Examples

The following example sets the maximum response time for Query packets to 100s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping query-max-response-time 100
```

1.13 ipv6 mld snooping source-check port

Function

Run the **ipv6 mld snooping source-check port** command to enable the source port check function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

Source port check is disabled by default.

Syntax

ipv6 mld snooping source-check port

no ipv6 mld snooping source-check port

default ipv6 mld snooping source-check port

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The source port check function is used to restrict multicast traffic to be forwarded only through multicast router ports. After this function is enabled, only multicast traffic received on multicast router ports is valid. Multicast traffic received on other ports is invalid and will be discarded. If no multicast router port exists in a VLAN, multicast traffic in the VLAN will be discarded.

When the source port check function is disabled, multicast traffic received on any port is valid and will be forwarded to the corresponding member ports.

Examples

The following example enables the source port check function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping source-check port
```

Notifications

If the device does not support the source port check function, the following notification will be displayed:

1.14 ipv6 mld snooping suppression enable

Function

Run the **ipv6 mld snooping suppression enable** command to enable the function of Report packet suppression.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

Report packet suppression is disabled by default.

Syntax

ipv6 mld snooping suppression enable

no ipv6 mld snooping suppression enable

default ipv6 mld snooping suppression enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When Report packet suppression is configured, the MLD multicast device forwards only the first Report packet from a specific VLAN for a multicast group to the multicast router port and suppresses subsequent Report packets for the same multicast group during one query interval. This function helps reduce the number of packets in the network. Only MLDv1 Report packets can be suppressed, and MLDv2 Report packets cannot be suppressed.

Examples

The following example enables the Report packet suppression function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping suppression enable
```

Notifications

When the Report packet suppression function fails to be configured, the following notification will be displayed:

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No multicast group is configured for the SVGL mode by default.

Syntax

ipv6 mld snooping svgl profile *profile-number*

no ipv6 mld snooping svgl profile

default ipv6 mld snooping svgl profile

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the device running MLD snooping operates in SVGL or IVGL-SVGL mode, the multicast groups associated with the SVGL mode must be configured.

First, define the multicast groups applied in the SVGL mode in a profile. Then, apply this profile in this command.

Examples

The following example applies profile 2 to the SVGL mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld profile 2
Hostname(config-profile)# range FF15::1 FF15::100
Hostname(config-profile)# permit
Hostname(config-profile)# exit
Hostname(config)# ipv6 mld snooping svgl profile 2
```

Notifications

Syntax

ipv6 mld snooping vlan *vlan-id* **static** *ipv6-group-address* **interface** *interface-type interface-number*

no ipv6 mld snooping vlan *vlan-id* **static** *ipv6-group-address* **interface** *interface-type interface-number*

default ipv6 mld snooping vlan *vlan-id* **static** *ipv6-group-address* **interface** *interface-type interface-number*

Parameter Description

vlan-id: VLAN ID. The value range is from 1 to 4094.

ipv6-group-address: Multicast group address.

interface-type interface-number: Interface name.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

An MLD snooping forwarding entry includes the VID, multicast group address, multicast router ports, and member ports.

A VID and multicast group address uniquely identify a forwarding entry.

A forwarding entry may contain multiple multicast router ports, which may be dynamically learned or statically configured. Static multicast router ports never age.

A forwarding entry may contain multiple member ports, which may be dynamically learned or statically configured. Static member ports never age. The **clear ipv6 mld snooping gda-table** command cannot be used to delete static member ports.

Examples

The following example sets the static member port of multicast group FF88::1 in VLAN 1 to GigabitEthernet 0/1.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# ipv6 mld snooping vlan 1 static FF88::1 interface
gigabitethernet 0/1
```

Notifications

When the multicast group address is invalid, the following notification will be displayed:

```
% Error: Invalid group address
```

When the port to be configured as a static member port is an aggregation member port, the following notification will be displayed:

```
% Error: Interface must not be member of aggregateport
```

When the port to be configured as a static member port is not in the corresponding VLAN, the following notification will be displayed:

```
% Error: Interface must be in the vlan you assigned
```

When a static member port fails to be configured, the following notification will be displayed:

```
% Error: Failed to configure static interface, please try again
```

When the number of configured static member ports exceeds the limit, the following notification will be displayed:

```
% Error: MLD snooping was trying to configure static interface than what allowed
(max_num)
```

Related Commands

- **show ipv6 mld snooping gda-table**

1.20 permit

Function

Run the **permit** command to permit a range of multicast groups defined by a profile.

The deny action is performed for a profile by default.

Syntax

permit

Parameter Description

N/A

Command Modes

Profile configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ipv6 mld profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups.

Examples

The following example permits multicast groups in the range of FF15::1 to FF15::100 defined by profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld profile 1
Hostname(config-profile)# range FF15::1 FF15::100
Hostname(config-profile)# permit
```

1.21 range

Function

Run the **range** command to define a multicast group range for a profile.

Run the **no** form of this command to remove this configuration.

No multicast group range is defined for a profile by default.

Syntax

range *low-ipv6-address* [*high-ipv6-address*]

no range *low-ipv6-address* [*high-ipv6-address*]

Parameter Description

low-ipv6-address: Start IP address of a multicast group range.

high-ipv6-address: End IP address of a multicast group range.

Command Modes

Profile configuration mode

Default Level

14

Usage Guidelines

A profile is a filter for multicast groups and referenced by other functions. To configure a profile, perform the following steps:

(1) Run the **ipv6 mld profile** command to create a profile and enter the profile configuration mode.

(2) Run the **range** command to define a multicast group range.

(3) Run the **permit** or **deny** command to permit or deny the range of multicast groups.

Examples

The following example permits multicast groups in the range of FF15::1 to FF15::100 defined by profile 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 mld profile 1
Hostname(config-profile)# range FF15::1 FF15::100
Hostname(config-profile)# permit
```

Notifications

When *low-ipv6-address* is not a multicast address, the following notification will be displayed:

```
% Error: min_ip(low-ip-address) is not multicast address
```

When *high-ipv6-address* is not a multicast address, the following notification will be displayed:

```
% Error: max_ip(high-ip-address) is not multicast address
```

When *low-ipv6-address* is greater than*high-ipv6-addres*, the following notification will be displayed:

```
% Error: range min_ip(low-ip-address) larger than max_ip(high-ip-address)
```

When the profile to which a multicast group range belongs does not exist, the following notification will be displayed:

```
% Error: The profile doesn't exist
```

When a multicast group range fails to be configured, the following notification will be displayed:

```
% Error: configure profile range fail, please try again
```

1.22 show ipv6 mld profile

Function

Run the **show ipv6 mld profile** command to display configurations of a profile.

Syntax

show ipv6 mld profile [*profile-number*]

Parameter Description

profile-number: Profile ID. The value range is from 1 to 1024. If this parameter is not configured, configurations of all profiles are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display information about configured profiles. If the *profile-number* parameter is not specified, configurations of all profiles are displayed.

Examples

The following example displays information about all configured profiles.

```
Hostname> enable
Hostname# show ipv6 mld profile
ipv6 mld profile    1
  permit
  range FF15::1 FF15::100
ipv6 mld profile    2
  deny
  range FF88::1  FF88::100
```

Table 1-1 Output Fields of the show ipv6 mld profile Command

Field	Description
profile profile-number	Profile ID
permit/deny	Filtering action of a multicast group range

Field	Description
range *low-ipv6-address high-ipv6-address*	Group range, from the start address to the end address

The following example displays configurations of profile 1.

```
Hostname# show ipv6 mld profile 1
ipv6 mld profile    1
 permit
 range FF15::1 FF15::100
```

Notifications

If you try to query the configuration of a single profile whose *profile-number* has not been configured, the following notification will be displayed:

```
No profile
```

Platform Description

N/A

1.23 show ipv6 mld snooping

Function

Run the **show ipv6 mld snooping** command to display MLD snooping information.

Syntax

show ipv6 mld snooping [**vlan** *vlan-id*]

Parameter Description

vlan *vlan-id*: Specifies a VLAN. If this parameter is not specified, configurations of all VLANs are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the MLD snooping status and parameters globally or on a specific VLAN.

Examples

The following example displays MLD snooping configurations.

- IVGL mode:

```
Hostname> enable
Hostname# show ipv6 mld snooping
MLD-snooping mode: IVGL
Source port check: Disable
```

```
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Respone Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
vlan 1
MLD Snooping state: Enabled
Multicast router learning mode: Enable
MLD Fast-Leave: Enabled
MLD VLAN Mode: STATIC
```

- SVGL mode:

```
Hostname# show ipv6 mld snooping
MLD-snooping mode: SVGL
SVGL vlan: 1
SVGL profile number: 1
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Respone Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
```

- IVGL-SVGL mode:

```
Hostname# show ipv6 mld snooping
MLD-snooping mode: IVGL-SVGL
SVGL vlan: 1
SVGL profile number: 1
Source port check: Disable
MLD Fast-Leave: Disable
MLD Report suppress: Disable
Query Max Respone Time: 10 (Seconds)
Dynamic Mroute Aging Time: 300(Seconds)
Dynamic Host Aging Time: 260(Seconds)
vlan 1
----None
MLD Snooping state: Enabled
Multicast router learning mode: Enable
MLD Fast-Leave: Enabled
MLD VLAN Mode: STATIC
```

Table 1-2 Output Fields of the show ipv6 mld snooping Command

Field	Description
MLD-snooping mode	Current MLD snooping working mode
Source port check	Whether the source port check function is enabled

Field	Description
MLD Fast-Leave	Whether the fast leave function is enabled
MLD Report suppress	Whether Report packet suppression is enabled
Query Max Response Time	Maximum response time for Query packets
Dynamic Mroute Aging Time	Aging time of dynamic multicast router ports
Dynamic Host Aging Time	Aging time of dynamic member ports
SVGL vlan	Shared VLAN in SVGL or IVGL-SVGL mode
SVGL profile number:	Multicast groups associated with the SVGL or IVGL-SVGL mode
Multicast router learning mode:	Dynamic multicast router port learning
MLD VLAN mode:	VLAN mode

1.24 show ipv6 mld snooping gda-table

Function

Run the **show ipv6 mld snooping gda-table** command to display MLD snooping forwarding entries.

Syntax

show ipv6 mld snooping gda-table

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays MLD snooping forwarding entries.

```
Hostname> enable
Hostname# show ipv6 mld snooping gda-table
Multicast Switching Cache Table
  D: DYNAMIC
  S: STATIC
  M: MROUTE
(*, FF15::100, 1):
  VLAN(1) 2 OPORTS:
    GigabitEthernet 3/1(SM)
GigabitEthernet 3/7(DSM)
```

Table 1-3 Output Fields of the show ipv6 mld snooping gda-table Command

Field	Description
VLAN	VLAN to which a port belongs
D: DYNAMIC	Dynamic member port
S: STATIC	Static member port
M: MROUTE	Multicast router port

1.25 show ipv6 mld snooping interfaces

Function

Run the **show ipv6 mld snooping interfaces** command to display multicast filtering configurations on a port.

Syntax

show ipv6 mld snooping interfaces [*interface-type interface-number*]

Parameter Description

interface-type interface-number: Interface name.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is configured, configurations of all ports are displayed.

Examples

The following example displays multicast filtering configurations on a port.

```
Hostname> enable
Hostname# show ipv6 mld snooping interfaces GigabitEthernet 0/1
      Interface            Filter profile number       max-group
GigabitEthernet 0/1          1                        102
Hostname# show ipv6 mld snooping interfaces
      Interface            Filter profile number       max-group
GigabitEthernet 3/1                                   20
```

Table 1-4 Output Fields of the show ipv6 mld snooping interfaces Command

Field	Description
Interface	Interface name.
Filter profile number	Profile referenced for multicast group filtering on a port. If no profile is configured, this parameter is not displayed.
max-group	Maximum number of multicast groups that can be dynamically learned by a port. If this parameter is not configured or is set to the default value, this parameter is not displayed.

Notifications

When configurations of a non-L2 port are queried, the following notification will be displayed:

```
% Error: Interface is not switchport port
```

When configurations of an aggregation member port are queried, the following notification will be displayed:

```
% Error: Interface must not be member of aggregateport
```

Platform Description

N/A

1.26 show ipv6 mld snooping mrouter

Function

Run the **show ipv6 mld snooping mrouter** command to display MLD snooping multicast router ports.

Syntax

show ipv6 mld snooping mrouter

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays MLD snooping multicast router ports.

```
Hostname> enable
Hostname# show ipv6 mld snooping mrouter
Multicast Switching Mroute Port
  D: DYNAMIC
  S: STATIC
(*, *, 2):
  VLAN(2)  1 MROUTES:
GigabitEthernet 3/1(DS)
```

Table 1-5 Output Fields of the show ipv6 mld snooping mrouter Command

Field	Description
VLAN	VLAN to which a port belongs
D: DYNAMIC	Dynamic multicast router port
S: STATIC	Static multicast router port

1.27 show ipv6 mld snooping statistics

Function

Run the **show ipv6 mld snooping statistics** command to display MLD snooping statistics.

Syntax

show ipv6 mld snooping statistics [**vlan** *vlan-id*]

Parameter Description

vlan *vlan-id*: Specifies a VLAN. The value range is from 1 to 4094. If this parameter is not specified, configurations of all VLANs are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays MLD snooping statistics.

```
Hostname> enable
Hostname# show ipv6 mld snooping statistics
Current number of Gda-table entries: 1
Configured Statistics database limit: 65536
Current number of MLD Listener Query packet received: 0
Current number of MLDv1 Listener Report packet received: 10
Current number of MLDv2 Listener Report packet received: 0
Current number of MLD Listener Done packet received: 0
Current number of PIM packet received: 0
GROUP     Interface   Reporter        Last join        Last leave   Report pkts
Leave pkts
FF15::1    VL1:Gi0/8   FE80::1         0d:0h:0m:5s       --       1             0
ff15::100  VL1:Gi3/1   --           --             --       0             0
```

Table 1-6 Output Fields of the show ipv6 mld snooping statistics Command

Field	Description
Current number of Gda-table entries	Number of forwarding entries
Configured Statistics database limit	Maximum number of L2 multicast entries
Current number of MLD Listener Query packet received	Number of Query packets received
Current number of MLDv1 Listener Report packet received	Number of MLDv1 Report packets received
Current number of MLDv2 Listener Report packet received	Number of MLDv2 Report packets received
Current number of MLD Listener Done packet received	Number of MLD Done packets received
Current number of PIM packet received	PIM packet data received

Field	Description
GROUP	Group information
Interface	Interface information, which VLAN an interface belongs to
Reporter	Source IP address that sends the last Report packet, which is represented by ---- during static configuration and process restart and restoration
Last join	Interval since the last Report packet is sent, which is represented by ---- during static configuration and process restart and restoration
Last leave	Interval since the last MLD Done packet is sent, which is represented by ---- during static configuration and process restart and restoration
Report pkts	Number of Report packets that are received on a port in a VLAN, which is 0 during static configuration and process restart and restoration
Leave pkts	Number of Leave packets that are received on a port in a VLAN, which is 0 during static configuration and process restart and restoration

ACL and QoS Commands

1 ACL Commands

Command	Function
access-list	Create an access control list (ACL) and add a rule.
access-list list-remark	Add a remark to an ACL.
access-list remark	Add a remark to an ACL rule.
clear access-list counters	Clear statistics on matched packets denied by an ACL.
clear counters access-list	Clear statistics on the packets matching an ACL.
deny	Add a rule of deny type to an ACL.
expert access-group	Apply an expert ACL.
expert access-list advanced	Create an expert advanced ACL.
expert access-list counter	Enable the packet matching counting function of a specified expert extended ACL.
expert access-list extended	Create an expert extended ACL.
expert access-list new-fragment-mode	Switch the fragmented packet matching mode of an expert extended ACL from the default matching mode to the new matching mode.
expert access-list resequence	Configure the start value and step of rule sequence numbers in an expert extended ACL.
global access-group	Make a global security ACL take effect on a port.
global access-group disable	Disable the global security ACL function.
global ip access-group	Make a global security ACL of IP type take effect on a port.
ip access-group	Apply an IP standard ACL or IP extended ACL.
ip access-list	Create an IP standard ACL or IP extended ACL.
ip access-list counter	Enable the packet matching counting function of an IP standard ACL or IP extended ACL.
ip access-list log-update interval	Configure the update interval of IPv4 ACL packet matching logs.

ip access-list new-fragment-mode	Configure the fragmented packet matching mode of an IP standard ACL or IP extended ACL.
ip access-list resequence	Configure the start value and step of rule sequence numbers in an IP ACL.
ipv6 access-list	Create an IPv6 ACL.
ipv6 access-list counter	Enable the packet matching counting function of an IPv6 ACL.
ipv6 access-list log-update interval	Configure the update interval of IPv6 ACL packet matching logs.
ipv6 access-list resequence	Configure the start value and step of rule sequence numbers in an IPv6 ACL.
ipv6 traffic-filter	Apply an IPv6 ACL.
list-remark	Add a remark to an ACL.
mac access-group	Apply a MAC extended ACL.
mac access-list counter	Enable the packet matching counting function of a MAC extended ACL.
mac access-list extended	Configure a MAC extended ACL.
mac access-list resequence	Configure the start value and step of rule sequence numbers in a MAC extended ACL.
permit	Add a rule of permit type to an ACL.
redirect destination interface	Configure an ACL redirection port.
remark	Add a remark to an ACL rule.
security access-group	Configure a security channel for a port.
security global access-group	Configure a global security channel.
security uplink enable	Configure an excluded port of a global security channel.
show access-group	Display the ACL configuration applied to a port.
show access-lists	Display the configuration of all ACLs or a specified ACL.
show acl res	Display information about all or a specified TCAM.
show acl res detail	Display detailed usage information of all or a specified TCAM.

show expert access-group	Display the configuration of an expert extended ACL applied to a port.
show ip access-group	Display the configuration of IP standard and IP extended ACLs applied to a port.
show ipv6 traffic-filter	Display the configuration of the IPv6 ACL applied to a port.
show mac access-group	Display the MAC extended ACL applied to a port.
show redirect	Display the redirect ACL configuration.
show svi router-acls state	Check whether an ACL applied to an SVI takes effect on L2 and L3 packets.
svi router-acls enable	Enable the function of making an ACL applied to an SVI effective only for L3 forwarded packets.

1.1 access-list

Function

Run the **access-list** command to create an access control list (ACL) and add a rule.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No ACL and its rules are configured by default.

Syntax

The commands for creating ACLs of different types are as follows:

- Create an IP standard ACL and add a rule.

  access-list *acl-number* { **deny** | **permit** } { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**log**]

- Create an IP extended ACL and add a rule.

  access-list *acl-number* { **deny** | **permit** } *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] [**log**]

Note

The commands for creating IP extended ACLs that specify some important protocols in the protocol field are as follows:

The Transmission Control Protocol (TCP) field is selected.

access-list *acl-number* { **deny** | **permit** } *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**match-all** *tcp-flag* | **established**] [**time-range** *time-range-name*] [**log**]

- Create a MAC extended ACL and add a rule.

  access-list *acl-number* { **deny** | **permit** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] [**time-range** *time-range-name*]

- Create an expert extended ACL and add a rule.

  access-list *acl-number* { **deny** | **permit** } [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*]

  The Ethernet type field or **cos** field is selected.

access-list *acl-number* { **deny** | **permit** } { *ethernet-type* | **cos** [*cos-value*] [**inner** *cos-value*] } [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**time-range** *time-range-name*]

The protocol field is selected.

access-list *acl-number* { **deny** | **permit** } *protocol* [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*]

Note

The commands for creating expert extended ACLs that specify some important protocols in the protocol field are as follows:

The Internet Control Message Protocol (ICMP) field is selected.

access-list *acl-number* { **deny** | **permit** } **icmp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*]

The Transmission Control Protocol (TCP) field is selected.

access-list *acl-number* { **deny** | **permit** } **tcp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**match-all** *tcp-flag* | **established**]

The User Datagram Protocol (UDP) field is selected.

access-list *acl-number* { **deny** | **permit** } **udp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-*ipv4-*wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*]

The commands for deleting ACLs of different types are as follows:

no access-list *acl-number*

default access-list *acl-number*

Parameter Description

acl-number: ACL number. The following value ranges are supported:

IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

deny: Configures the processing action for an ACL rule. If packets match the rule, the packets are denied.

permit: Configures the processing action for an ACL rule. If packets match the rule, the packets are permitted.

source-ipv4-address: Source IP address (host address or network address) for packet matching.

source-ipv4-wildcard: Source IP address wildcard mask, which is used to match the source IP addresses of multiple hosts. The wildcard masks can be discontinuous, for example, 0.255.0.32.

protocol: IP protocol number for matching. The value range is from 0 to 255. Some important protocol names such as *icmp*, *ip*, *ipv6*, *tcp, and udp* are listed separately.

destination-ipv4-address: Destination IP address (host address or network address) for packet matching.

destination-ipv4-wildcard: Destination IP address wildcard mask, which is used to match the destination IP addresses of multiple hosts. The wildcard masks can be discontinuous, for example, 0.255.0.32.

fragment: Matches the non-first fragment in the default fragmented packet matching mode.

precedence *precedence*: Matches the precedence value of packets. The value range is from 0 to 7. Some important precedence values such as *routine*, *priority*, *immediate*, *flash*, *flash-override*, *critical*, *internet*, and *network* are listed separately.

eq *port*: Matches packets with the L4 port ID equal to the specified value. The value range is from 0 to 65535.

gt *port*: Matches packets with the L4 port ID greater than the specified value. The value range is from 0 to 65535.

lt *port*: Matches packets with the L4 port ID less than the specified value. The value range is from 0 to 65535.

neq *port*: Matches packets with the L4 port ID not equal to the specified value. The value range is from 0 to 65535.

range: Matches the range the L4 port IDs of packets.

lower: Lower limit of the L4 port ID range for matching. The value range is from 0 to 65535.

upper: Upper limit of the L4 port ID range for matching. The value range is from 0 to 65535.

time-range *time-range-name*: Configures the name of the time range for packet filtering.

tos *tos*: Matches the type of service (ToS) value of packets. The value range is from 0 to 15. Some important service types such as *max-reliability*, *max-throughput*, *min-delay*, *min-monetary-cost*, and *normal* are listed separately.

dscp *dscp*: Matches the differentiated services code point (DSCP) value of packets. The value range is from 0 to 63. Some important differentiated services such as *default*, *ef*, *af11*, and *cs1* are listed separately.

icmp-type: Message type for matching ICMP packets. The value range is from 0 to 255.

icmp-code: Message type code for matching ICMP packets. The value range is from 0 to 255.

icmp-message: Message type name for matching ICMP packets.

source-mac-address: MAC address of the source host for matching.

source-mac-wildcard: MAC address wildcard of the source host, which is used to match the source MAC addresses of multiple hosts.

destination-mac-address: MAC address of the destination host for matching.

destination-mac-wildcard: MAC address wildcard of the destination host, which is used to match the destination MAC addresses of multiple hosts.

cos *cos-value*: Matches the priority field value in the outer tag in the L2 packets. The value range is from 0 to 7.

inner *cos-value*: Matches the priority field value in the inner tag in the L2 packets. The value range is from 0 to 7.

VID *vlan-id*: Matches the VLAN ID. The value range is from 1 to 4094.

inner *vlan-id*: Matches the inner VLAN ID. The value range is from 1 to 4094.

ethernet-type: Ethernet protocol type for matching. The value range is from 0x0000 to 0xFFFF. Some important Ethernet protocol type names such as *arp*, *aarp*, and *IPX* are listed separately.

match-all *tcp-flag*: Matches all the bits of the TCP flag.

established: Matches only the RST or ACK bit in the TCP flag, not the other bits.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To use an ACL to filter data, you must first run the **access-list** command to define a series of ACL rule statements. You can use different kinds of ACLs according to actual needs:

- An IP standard ACL (with the number from 1 to 99 and 1300 to 1999) controls packets based on the source address only.
- An IP extended ACL (with the number from 100 to 199 and 2000 to 2699) implements complex control based on the source and destination addresses.
- A MAC extended ACL (with the number from 700 to 799) performs matching based on the source and destination MAC addresses and Ethernet type.
- An expert extended ACL (with the number from 2700 to 2899) is a combination of the IP standard ACL, IP extended ACL, and MAC extended ACL. You can configure the above three kinds of ACL rules in an expert extended ACL. In addition, the expert extended ACL can also match and filter packets based on the VLAN ID.

Note

For the L3 routing protocols (including the unicast routing protocol and multicast routing protocol), the following parameters are not supported in ACL rules: **precedence** *precedence* / **tos** *tos* / **fragment** / **range** *lower upper* / **time-range** *time-range-name*.

The TCP flag contains some or all of the following bits:

- URG
- ACK
- PSH

- RST
- SYN
- FIN

The packet precedence names are as follows:

- critical
- flash
- flash-override
- immediate
- internet
- network
- priority
- routine

The service type names are as follows:

- max-reliability
- max-throughput
- min-delay
- min-monetary-cost
- normal

The message type names of ICMP packets are as follows:

- administratively-prohibited
- dod-host-prohibited
- dod-net-prohibited
- echo
- echo-reply
- fragment-time-exceeded
- general-parameter-problem
- host-isolated
- host-precedence-unreachable
- host-redirect
- host-tos-redirect
- host-tos-unreachable
- host-unknown
- host-unreachable
- information-reply
- information-request
- mask-reply
- mask-request

- mobile-redirect
- net-redirect
- net-tos-redirect
- net-tos-unreachable
- net-unreachable
- network-unknown
- no-room-for-option
- option-missing
- packet-too-big
- parameter-problem
- port-unreachable
- precedence-unreachable
- protocol-unreachable
- redirect
- router-advertisement
- router-solicitation
- source-quench
- source-route-failed
- time-exceeded
- timestamp-reply
- timestamp-request
- ttl-exceeded
- unreachable

The following are TCP port names. A port name or port ID can be used to specify a specific TCP port:

- bgp
- chargen
- cmd
- daytime
- discard
- domain
- echo
- exec
- finger
- ftp
- ftp-data
- gopher
- hostname

- ident
- irc
- klogin
- kshell
- login
- nntp
- pim-auto-rp
- pop2
- pop3
- smtp
- sunrpc
- syslog
- tacacs
- talk
- telnet
- time
- uucp
- whois
- www

The following are UDP port names. A port name or port ID can be used to specify a specific UDP port:

- biff
- bootpc
- bootps
- discard
- dnsix
- domain
- echo
- isakmp
- mobile-ip
- nameserver
- netbios-dgm
- netbios-ns
- netbios-ss
- ntp
- pim-auto-rp
- rip
- snmp

- snmptrap
- sunrpc
- syslog
- tacacs
- talk
- tftp
- time
- who
- xdmcp

The options of **Ethernet-type** are as follows:

- aarp
- arp
- appletalk
- decnet-iv
- diagnostic
- etype-6000
- etype-8042
- lat
- lavc-sca
- mop-console
- mop-dump
- mumps
- netbios
- vines-echo
- xns-idp

The available protocol layer fields of the UDF header are as follows:

- l2-head
- l3-head
- l4-head
- l5-head
- l6-head

Note

To delete ACL rules, enter the ACL configuration mode and run the **no** { *sequence-number* | **permit** | **deny** } command.

Examples

The following example creates an IP standard ACL and adds a rule: Permit the packets with a source IP address in the range of 192.168.1.64 to 192.168.1.127 to pass through.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit 192.168.1.64 0.0.0.63
```

The following example creates an IP extended ACL and adds a rule: Permit the DNS packets and ICMP packets to pass through.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 102 permit tcp any any eq domain log
Hostname(config)# access-list 102 permit udp any any eq domain log
Hostname(config)# access-list 102 permit icmp any any echo log
Hostname(config)# access-list 102 permit icmp any any echo-reply
```

The following example creates a MAC extended ACL and adds a rule: Deny Ethernet frames of the AARP protocol type sent by a source host with the MAC address 00d0.f800.0c0c.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 702 deny host 00d0f8000c0c any aarp
```

The following example creates an expert extended ACL and adds a rule: Deny all the TCP packets with the source IP address 192.168.12.3 and the source MAC address 00d0.f800.0044.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 2702 deny tcp host 192.168.12.3 host 00d0.f800.0044 any
any
Hostname(config)# access-list 2702 permit any any any any
```

Notifications

When a duplicate rule is added to the same ACL, the following notification will be displayed:

```
failed, for the entry is existed or the sequence number has been allocated!
```

1.2 access-list list-remark

Function

Run the **access-list list-remark** command to add a remark to an ACL.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No remark is added to an ACL by default.

Syntax

access-list *acl-number* **list-remark** *text*

no access-list *acl-number* **list-remark**

default access-list *acl-number* **list-remark**

Parameter Description

acl-number: ACL number. The following value ranges are supported:

IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

list-remark *text*: Configures a remark for an ACL. The value is a case-sensitive string of 1 to 100 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To view the function of an ACL conveniently in the future, run this command to add a remark to the ACL. If no ACL exists, this command creates an ACL first and then adds a remark.

Examples

The following example configures an extended ACL numbered 100 and adds the following remark to the ACL: this acl is to filter the host 192.168.4.12.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 100 list-remark this acl is to filter the host
192.168.4.12
```

- **ip access-list**

1.3 access-list remark

Function

Run the **access-list remark** command to add a remark to an ACL rule.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No remark is added to an ACL rule by default.

Syntax

access-list *acl-number* **remark** *text*

no access-list *acl-number* **remark** *text*

default access-list *acl-number* **remark** *text*

Parameter Description

acl-number: ACL number. The following value ranges are supported:

IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

remark *text*: Configures a remark for an ACL rule. The value is a case-sensitive string of 1 to 100 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To view the function of an ACL rule conveniently in the future, run this command to add a remark to the ACL rule.

Examples

The following example configures an ACL numbered 102 and its rule, and then configures the following remark for the ACL rule: deny-host-10.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 102 deny ip host 10.1.1.1 host 10.1.1.1
Hostname(config)# access-list 102 remark deny-host-10.1.1.1
```

Notifications

When no rules are configured in an ACL and an ACL rule remark is added, the following notification will be displayed:

```
The ACL has no entry.
```

1.4 clear access-list counters

Function

Run the **clear access-list counters** command to clear statistics on matched packets denied by an ACL.

Syntax

clear access-list counters [*acl-name* | *acl-number*]

Parameter Description

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: ACL number. The following value ranges are supported:

IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

To re-collect statistics on matched packets denied by a specified ACL, run this command to clear the statistics on the matched packets denied by the ACL.

Examples

The following example clears statistics on matched packets denied by an ACL numbered 1.

```
Hostname> enable
Hostname# clear access-list counters
```

1.5 clear counters access-list

Function

Run the **clear counters access-list** command to clear statistics on the packets matching an ACL.

Syntax

clear counters access-list [*acl-name* | *acl-number*]

Parameter Description

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: ACL number. The following value ranges are supported:

IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

To re-collect statistics on the packets matching a specified ACL, run this command to clear statistics on packets matching the ACL.

Examples

The following example clears statistics on the packets matching an extended ACL numbered 2700.

```
Hostname> enable
Hostname# clear counters access-list 2700
```

1.6 deny

Function

Run the **deny** command to add a rule of deny type to an ACL.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

There is a rule of deny type in an ACL by default.

Syntax

The commands for adding/deleting a rule of deny type to/from ACLs of different types are as follows:

- IP standard ACL

  Add a rule of deny type to an IP standard ACL.

  [*sequence-number*] **deny** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**log**]

  Delete a rule of deny type from an IP standard ACL.

  no { *sequence-number* | { **deny** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**log**] } }

- IP extended ACL

  Add a rule of deny type to an IP extended ACL.

  [*sequence-number*] **deny** *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] [**log**]

  Delete a rule of deny type from an IP extended ACL.

  no { *sequence-number* | { **deny** *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] [**log**] } }

Note

The commands for adding a rule of deny type to IP extended ACLs that specify some important protocols in the protocol field are as follows:

The ICMP field is selected.

[*sequence-number*] **deny icmp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] [**log**]

The TCP field is selected.

[*sequence-number*] **deny tcp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] |

[**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**match-all** *tcp-flag* | **established**] [**log**]

The UDP field is selected.

[*sequence-number*] **deny udp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**log**]

- MAC extended ACL

  Add a rule of deny type to a MAC extended ACL.

  [*sequence-number*] **deny** { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] [**time-range** *time-range-name*]

  Delete a rule of deny type from a MAC extended ACL.

  no { *sequence-number* | { **deny** { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] [**time-range** *time-range-name*] } }

- Expert extended ACL

  Add a rule of deny type to an expert extended ACL.

  [*sequence-number*] **deny** [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*]

  Delete a rule of deny type from an expert extended ACL.

  no { *sequence-number* | { **deny** [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] } }

  The Ethernet type field or **cos** field is selected.

  [*sequence-number*] **deny** { [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] } [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**time-range** *time-range-name*]

Note

The commands for adding a rule of deny type to expert extended ACLs that specify some important protocols in the protocol field are as follows:

The ICMP field is selected.

[*sequence-number*] **deny icmp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* **| host** *destination-mac-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*]

The TCP field is selected.

[*sequence-number*] **deny tcp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**match-all** *tcp-flag* | **established**]

The UDP field is selected.

[*sequence-number*] **deny udp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source*-ipv4-*wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*]

- Expert advanced ACL

  Add a rule of deny type to an expert advanced ACL.

  [sequence-number] **deny** hex hex-mask offset

  Delete a rule of deny type from an expert advanced ACL.

  no { sequence-number | **deny** hex hex-mask offset }

- IPv6 extended ACL

  Add a rule of deny type to an IPv6 extended ACL.

  [*sequence-number*] **deny** [*protocol* { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** }] [**cos** *cos-value* [**inner** *cos-value*]] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination-mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**time-range** *time-range-name*] [**log**]

  Delete a rule of deny type from an IPv6 extended ACL.

  no { *sequence-number* | { **deny** [*protocol* { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* **| host** *destination-ipv6-address* | **any** }] [**cos** *cos-value*

[**inner** *cos-value*]] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**time-range** *time-range-name*] [**log**] } }

Note

The commands for adding a rule of deny type to IPv6 extended ACLs that specify some important protocols in the protocol field are as follows:

The ICMP field is selected.

[*sequence-number*] **deny icmp** { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**time-range** *time-range-name*] [**log**]

The TCP field is selected.

[*sequence-number*] **deny tcp** { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**match-all** *tcp-flag* | **established**] [**log**]

The UDP field is selected.

[*sequence-number*] **deny udp** { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**log**]

Parameter Description

sequence-number: Sequence number of an ACL rule. The value range is from 1 to 2147483647.

deny: Configures the processing action for an ACL rule. If packets match this rule, the packets are denied.

source-ipv4-address: Source IP address (host address or network address) for packet matching.

source-ipv4-wildcard: Source IP address wildcard mask, which is used to match the source IP addresses of multiple hosts. The wildcard masks can be discontinuous, for example, 0.255.0.32.

protocol: IP protocol number for matching. The value range is from 0 to 255. Some important protocol names such as *icmp*, *ip*, *ipv6*, *tcp, and udp* are listed separately.0

destination-ipv4-address: Destination IP address (host address or network address) for packet matching.

destination-ipv4-wildcard: Destination IP address wildcard mask, which is used to match the destination IP addresses of multiple hosts. The wildcard masks can be discontinuous, for example, 0.255.0.32.

fragment: Matches the non-first fragment in the default fragmented packet matching mode.

precedence *precedence*: Matches the precedence value of packets. The value range is from 0 to 7. Some important precedence names such as *routine*, *priority*, *immediate*, *flash*, *flash-override*, *critical*, *internet*, and *network* are listed separately.

eq *port*: Matches packets with the L4 port ID equal to the specified value. The value range is from 0 to 65535.

gt *port*: Matches packets with the L4 port ID greater than the specified value. The value range is from 0 to 65535.

lt *port*: Matches packets with the L4 port ID less than the specified value. The value range is from 0 to 65535.

neq *port*: Matches packets with the L4 port ID not equal to the specified value. The value range is from 0 to 65535.

range: Matches the range of L4 port IDs of packets.

lower: Lower limit of the L4 port ID range for matching. The value range is from 0 to 65535.

upper: Upper limit of the L4 port ID range for matching. The value range is from 0 to 65535.

time-range *time-range-name*: Configures the name of the time range for packet filtering.

tos *tos*: Matches the ToS value of packets. The value range is from 0 to 15. Some important service type names such as *max-reliability*, *max-throughput*, *min-delay*, *min-monetary-cost*, and *normal* are listed separately.

dscp *dscp*: Matches the DSCP value of packets. The value range is from 0 to 63. Some important differentiated service names such as *default*, *ef*, *af11*, and *cs1* are listed separately.

icmp-type: Message type for matching ICMP packets. The value range is from 0 to 255.

icmp-code: Message type code for matching ICMP packets. The value range is from 0 to 255.

icmp-message: Message type name for matching ICMP packets.

source-mac-address: MAC address of the source host for matching.

source-mac-wildcard: MAC address wildcard of the source host, which is used to match the source MAC addresses of multiple hosts.

destination-mac-address: MAC address of the destination host for matching.

destination-mac-wildcard: MAC address wildcard of the destination host, which is used to match the destination MAC addresses of multiple hosts.

cos *cos-value*: Matches the priority field value in the outer tag in the L2 packets. The value range is from 0 to 7.

inner *cos-value*: Matches the priority field value in the inner tag in the L2 packets. The value range is from 0 to 7.

VID *vlan-id*: Matches the VLAN ID. The value range is from 1 to 4094.

inner *vlan-id*: Matches the inner VLAN ID. The value range is from 1 to 4094.

ethernet-type: Ethernet protocol type for matching. The value range is from 0x0000 to 0xFFFF. Some important Ethernet protocol type names such as *arp*, *aarp*, and *IPX* are listed separately.

match-all *tcp-flag*: Matches all the bits of the TCP flag.

established: Matches only the RST or ACK bit in the TCP flag, not the other bits.

source-ipv6-prefix: Source IPv6 network address or network type for matching.

destination-ipv6-prefix: Destination IPv6 network address or network type for matching.

prefix-length: IPv6 address mask length for matching.

source-ipv6-address: Source IPv6 address for matching.

destination-ipv6-address: Destination IPv6 address for matching.

source-ipv6-mask: Source IPv6 address mask for matching.

destination-ipv6-mask: Destination IPv6 address mask for matching.

flow-label *flow-label*: Matches the flow label value. The value range is from 0 to 1048575.

hex: Matching field in hexadecimal notation. It is used when expert advanced ACL rules are configured.

hex-mask: Matching field mask in hexadecimal notation. It is used when expert advanced ACL rules are configured.

offset: Matching start position, in bytes. It is used when expert advanced ACL rules are configured. The value range is from 0 to 79.

hex hex-mask offset: Combination of *hex*, *hex-mask*, and *offset*. Multiple such combinations can be configured.

Command Modes

ACL configuration mode

Default Level

14

Usage Guidelines

To deny some packets access to a network, you can run this command to add rules of deny type to an ACL.

Examples

The following example creates an IP standard ACL and adds a rule: Deny packets sent from the source host with the IP address 192.168.4.12.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list standard 34
Hostname(config-ext-nacl)# deny host 192.168.4.12
```

The following example creates an IP extended ACL and adds a rule: Deny services provided by the source host with the IP address 192.168.4.12 through TCP port 100.

```
Hostname# configure terminal
Hostname(config)# ip access-list extended ip-ext-acl
Hostname(config-ext-nacl)# deny tcp host 192.168.4.12 eq 100 any
```

The following example creates an expert extended ACL and adds a rule: Deny all the TCP packets with the source IP address 192.168.4.12 and the source MAC address 0013.0049.8272.

```
Hostname# configure terminal
Hostname(config)# expert access-list extended 2702
Hostname(config-exp-nacl)# deny tcp host 192.168.4.12 host 0013.0049.8272 any any
Hostname(config-exp-nacl)# permit any any any any
```

The following example creates a MAC extended ACL and adds a rule: Deny Ethernet frames of the AARP protocol type sent by the source host with the MAC address 0013.0049.8272.

```
Hostname# configure terminal
Hostname(config)# mac access-list extended mac1
Hostname(config-mac-nacl)# deny host 0013.0049.8272 any aarp
```

The following example creates an IPv6 extended ACL and adds a rule numbered 11: Deny packets sent from the source host with the IP address 2000::1.

```
Hostname# configure terminal
Hostname(config)# ipv6 access-list v6-acl
Hostname(config-ipv6-acl)# 11 deny ipv6 host 2000::1 any
```

1.7 expert access-group

Function

Run the **expert access-group** command to apply an expert ACL.

Run the **no** form of this command to cancel the application.

Run the **default** form of this command to restore the default configuration.

No expert ACL is applied by default.

Syntax

expert access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

no expert access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

default expert access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

Parameter Description

acl-name: Name of an expert ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an expert ACL. The value range is from 2700 to 2899.

in: Filters the incoming packets of a port.

out: Filters the outgoing packets of a port.

counter-only: Configures a special ACL for packet counting on a port.

control-plane: Configures a control plane ACL.

forward-control-plane: Configures a control and forwarding plane ACL.

forward-plane: Configures a forwarding plane ACL.

Command Modes

Global configuration mode

Interface configuration mode

SVI interface configuration mode

Default Level

14

Usage Guidelines

To make an expert ACL take effect, run this command to apply the ACL in global configuration mode, interface configuration mode, or switch virtual interface (SVI) interface configuration mode. The **counter-only** option is not supported in global configuration mode. The **expert access-group** { *acl-name* | *acl-number* } { **in** | **out** } **counter-only** command configured on a port collects statistics on packets only, without filtering them.

Examples

The following example applies the expert extended ACL named accept_00d0f8xxxxxx_only to the inbound direction of the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-Gigabitethernet 0/1)# expert access-group
accept_00d0f8xxxxxx_only in
```

The following example applies the expert extended ACL numbered 2700 to the inbound direction of the L3 Ethernet interface GigabitEthernet0/1, and collects statistics on the incoming packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# expert access-group 2700 in counter-only
```

1.8 expert access-list advanced

Function

Run the **expert access-list advanced** command to create an expert advanced ACL.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No expert advanced ACL is configured by default.

Syntax

expert access-list advanced *acl-name*

no expert access-list advanced *acl-name*

default expert access-list advanced *acl-name*

Parameter Description

acl-name: Name of an expert advanced ACL. The value is a case-sensitive string of 1 to 99 characters.

Command Modes

Global configuration mode

Default Level

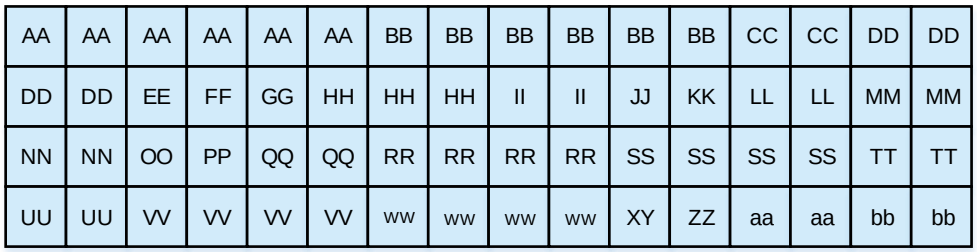
14

Usage Guidelines

To filter packets by user-defined fields, you can use an expert advanced ACL (namely, ACL 80).

Figure 1-1 shows the first 64 bytes of an L2 data frame, where each letter represents one hexadecimal number and every two letters represent one byte.

Figure 1-1 First 64 Bytes of an L2 Data Frame



AA	AA	AA	AA	AA	AA	BB	BB	BB	BB	BB	BB	CC	CC	DD	DD
DD	DD	EE	FF	GG	HH	HH	HH	II	II	JJ	KK	LL	LL	MM	MM
NN	NN	OO	PP	QQ	QQ	RR	RR	RR	RR	SS	SS	SS	SS	TT	TT
UU	UU	VV	VV	VV	VV	ww	ww	ww	ww	XY	ZZ	aa	aa	bb	bb

Table 1-1 lists the offsets of fields in an ACL 80. The offset of each field in the table is their offset in the IEEE 802.3 data frame containing the SNAP+Tag fields.

Table 1-1 Offsets of Fields in an ACL 80

Letter	Description	Offset	Letter	Description	Offset
A	Destination MAC address	0	O	TTL field	34
B	Source MAC address	6	P	Protocol number	35
C	Data frame length field	12	Q	IP checksum	36
D	VLAN tag field	14	R	Source IP address	38
E	Destination service access point (DSAP) field	18	S	Destination IP address	42
F	Source service access point (SSAP) field	19	T	TCP source port	46
G	Control field	20	U	TCP destination port	48
H	Org code field	21	V	Serial number	50
I	Encapsulated data type	24	W	Acknowledgment field	54
J	IP version No.	26	XY	IP header length and reserved bits	58
K	ToS field	27	Z	Reserved bits and flags bits	59
L	IP packet length	28	a	Windows size field	60
M	ID	30	b	Others	62
N	Flags field	32			

Examples

The following example creates an expert advanced ACL named adv-acl.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# expert access-list advanced adv-acl
Hostname(config-exp-dacl)#
```

1.9 expert access-list counter

Function

Run the **expert access-list counter** command to enable the packet matching counting function of a specified expert extended ACL.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The packet matching counting function of an expert extended ACL is disabled by default.

Syntax

expert access-list counter { *acl-name* | *acl-number* }

no expert access-list counter { *acl-name* | *acl-number* }

default expert access-list counter { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an expert extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an expert extended ACL. The value range is from 2700 to 2899.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run this command to enable the packet matching counting function to know the packet filtering situation of a specified expert extended ACL, especially to find out whether the network is attacked by a large number of illegitimate packets.

Examples

The following example enables the packet matching counting function of an expert extended ACL named exp-acl.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# expert access-list counter exp-acl
```

Notifications

When the packet matching counting function of an expert extended ACL is enabled before this ACL is configured, the following notification will be displayed:

```
Create the access-list first
```

1.10 expert access-list extended

Function

Run the **expert access-list extended** command to create an expert extended ACL.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No expert extended ACL is configured by default.

Syntax

expert access-list extended { *acl-name* | *acl-number* }

no expert access-list extended { *acl-name* | *acl-number* }

default expert access-list extended { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an expert extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an expert extended ACL. The value range is from 2700 to 2899.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To achieve the filtering effects of the IP standard ACL, IP extended ACL, and MAC extended ACL in an ACL, configure an expert extended ACL.

Examples

The following example creates an expert advanced ACL named exp-acl.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# expert access-list extended exp-acl
Hostname(config-exp-nacl)#
```

The following example creates an expert extended ACL numbered 2704.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# expert access-list extended 2704
Hostname(config-exp-nacl)#
```

Related Commands

- **expert access-group**

1.11 expert access-list new-fragment-mode

Function

Run the **expert access-list new-fragment-mode** command to switch the fragmented packet matching mode of an expert extended ACL from the default matching mode to the new matching mode.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The fragmented packet matching mode of an expert extended ACL is the default matching mode by default.

Syntax

expert access-list new-fragment-mode { *acl-name* | *acl-number* }

no expert access-list new-fragment-mode { *acl-name* | *acl-number* }

default expert access-list new-fragment-mode { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an expert extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an expert extended ACL. The value range is from 2700 to 2899.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When an ACL rule carries the fragment flag, there is no difference between the default fragmented packet matching mode and the new matching mode.

When an ACL rule does not carry the fragment flag, if the first fragment is required to match all the user-defined matching fields (including L3 and L4 information) in the ACL rule and the non-first fragments need to only match the non-L4 information in the ACL rule, you can run this command to switch the fragmented packet matching mode of the specified ACL to the new matching mode.

Examples

The following example switches the fragmented packet matching mode of an ACL numbered 2700 from the default matching mode to the new matching mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# expert access-list new-fragment-mode 2700
```

Notifications

When the fragmented packet matching mode of an expert extended ACL is configured before this ACL is configured, the following notification will be displayed:

```
Create the access-list first
```

1.12 expert access-list resequence

Function

Run the **expert access-list resequence** command to configure the start value and step of rule sequence numbers in an expert extended ACL.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default start value and step of rule sequence numbers in an expert extended ACL are both **10**.

Syntax

expert access-list resequence { *acl-name* | *acl-number* } *start-value step-value*

no expert access-list resequence { *acl-name* | *acl-number* }

default expert access-list resequence { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an expert extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an expert extended ACL. The value range is from 2700 to 2899.

start-value: Start value of rule sequence numbers. The value range is from 1 to 2147483647.

step-value: Step of rule sequence numbers. The value range is from 1 to 2147483647.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To insert a new rule into an expert extended ACL, run this command to rearrange the sequence numbers of ACL rules.

Examples

The following example configures an expert extended ACL named exp-acl, and sets the start value of rule sequence numbers to 21 and step to 43.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# expert access-list resequence exp-acl 21 43
```

1.16 ip access-group

Function

Run the **ip access-group** command to apply an IP standard ACL or IP extended ACL.

Run the **no** form of this command to cancel the application.

Run the **default** form of this command to restore the default configuration.

No IP standard ACL or IP extended ACL is applied by default.

Syntax

ip access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

no ip access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

default ip access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plane** | **counter-only** | **forward-control-plane** | **forward-plane**]

Parameter Description

acl-name: Name of an IP standard ACL or IP extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an IP standard ACL or IP extended ACL. The following value ranges are supported:

The value range of IP standard ACLs is 1 to 99 or 1300 to 1999; the value range of IP extended ACLs is 100 to 199 or 2000 to 2699.

in: Filters the incoming packets of a port.

out: Filters the outgoing packets of a port.

control-plane: Configures a control plane ACL.

counter-only: Configures a special ACL for packet counting on a port.

forward-control-plane: Configures a control and forwarding plane ACL.

forward-plane: Configures a forwarding plane ACL.

Command Modes

Global configuration mode

Interface configuration mode

SVI interface configuration mode

Default Level

14

Usage Guidelines

To make an IP standard ACL or IP extended ACL take effect, run this command to apply the ACL in global configuration mode, interface configuration mode, or SVI interface configuration mode. The ACL controls the incoming/outgoing packets of all ports, a specified SVI, or a specified port. The **counter-only** option is not supported in global configuration mode. The **ip access-group** { *acl-name* | *acl-number* } { **in** | **out** } **counter-only** command configured on a port collects statistics on packets only, without filtering them.

Examples

The following example applies the IP extended ACL numbered 120 to the inbound direction of the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip access-group 120 in
```

The following example applies the IP extended ACL numbered 120 to the inbound direction globally.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-group 120 in control-plane
```

The following example applies the IP extended ACL numbered 120 to the inbound direction of the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip access-group 120 in counter-only
```

Notifications

When an ACL is applied to the global control plane, if an ACL has been applied to the global control plane, the following notification will be displayed:

```
Another acl has attached at global control-plane, Operation fail
```

When an ACL is applied to a global network segment policy, if an ACL has been applied to the global network segment policy, the following notification will be displayed:

```
Another acl has attached at network-policy, Operation fail
```

When an ACL is applied to a global user group policy, if an ACL has been applied to the global user group policy, the following notification will be displayed:

```
Another acl has attached at user-group-policy, Operation fail
```

When a counter-only ACL is applied to a port, if the counter function of the ACL has been enabled globally, the following notification will be displayed:

```
ACL 1 has been used as a traffic matching statistics ACL.
```

When a counter-only ACL is applied to a port, if an ACL (IP standard ACL, IP extended ACL, MAC extended ACL, or expert ACL) has been applied to the same direction of the port, the following notification will be displayed:

```
Another counter-only acl has attached at GigabitEthernet 0/1, Operation fail.
```

Related Commands

- **ip access-list**

1.17 ip access-list

Function

Run the **ip access-list** command to create an IP standard ACL or IP extended ACL.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No IP standard ACL or extended ACL is configured by default.

Syntax

ip access-list { **extended** | **standard** } { *acl-name* | *acl-number* }

no ip access-list { **extended** | **standard** } { *acl-name* | *acl-number* }

default ip access-list { **extended** | **standard** } { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an IP standard ACL or IP extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an IP standard ACL or IP extended ACL. The following value ranges are supported:

The value range of IP standard ACLs is 1 to 99 or 1300 to 1999; the value range of IP extended ACLs is 100 to 199 or 2000 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To filter packets based on the source IP address only, create an IP standard ACL. To control IP packets more finely, for example, filter packets based on the destination IP address or L4 information, create an IP extended ACL. For the matching fields of the two kinds of IP ACLs, refer to the standard and extended forms of the **deny** and **permit** commands. Run the **show access-lists** command to display the ACL configuration.

Examples

The following example creates an IP standard ACL named std-acl.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list standard std-acl
Hostname(config-std-nacl)#
```

The following example creates an IP extended ACL numbered 123.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list extended 123
Hostname(config-ext-nacl)#
```

Notifications

When you create a named IP standard or IP extended ACL, if the specified name has been used by another type of ACL, the following notification will be displayed:

```
ACL type error, current ACL has been set to type mac extended.
```

When you create a named IP standard or IP extended ACL, if the number of named ACLs (all types of named ACLs) created in the device has reached 500, the following notification will be displayed:

```
Failed to create user-defined acl for the max-limit has been reached
```

When you create a named IP standard or IP extended ACL, if the length of the name entered is longer than 99 characters, the following notification will be displayed:

```
Name is too long
```

When you create a named IP standard or IP extended ACL, if the entered name begins with a number or the name is in or out, the following notification will be displayed:

```
Invalid name
```

1.18 ip access-list counter

Function

Run the **ip access-list counter** command to enable the packet matching counting function of an IP standard ACL or IP extended ACL.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The packet matching counting function of an IP standard ACL or IP extended ACL is disabled by default.

Syntax

ip access-list counter { *acl-name* | *acl-number* }

no ip access-list counter { *acl-name* | *acl-number* }

default ip access-list counter { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an IP standard ACL or IP extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an IP standard ACL or IP extended ACL. The following value ranges are supported:

The value range of IP standard ACLs is 1 to 99 or 1300 to 1999; the value range of IP extended ACLs is 100 to 199 or 2000 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run this command to enable the packet matching counting function to know the packet filtering situation of a specified IP standard ACL or IP extended ACL.

Examples

The following example enables the packet matching counting function of an IP standard ACL.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list counter std-acl
```

1.19 ip access-list log-update interval

Function

Run the **ip access-list log-update interval** command to configure the update interval of IPv4 ACL packet matching logs.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default update interval of packet matching logs is 0 minutes, that is, no ACL matching log is output.

Syntax

ip access-list log-update interval *time-value*

no ip access-list log-update interval

default ip access-list log-update interval

Parameter Description

interval *time-value*: Log update interval, in minutes. For the ACL rules with the log output option, it indicates the interval for (in minutes) outputting the ACL matching logs of a data flow. The range is from 0 to 1440. Here, **0** indicates that no ACL matching log is output.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

For the IP standard or IP extended ACL rules with the log function enabled, if packets are matched within the log output interval, a log of packet matching count is output when the log output interval expires. To change the log output interval, run this command.

Examples

The following example sets the update interval threshold of IPv4 ACL packet matching logs to 10 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list log-update interval 10
```

1.20 ip access-list new-fragment-mode

Function

Run the **ip access-list new-fragment-mode** command to configure the fragmented packet matching mode of an IP standard ACL or IP extended ACL.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The fragmented packet matching mode of an IP standard ACL or IP extended ACL is the default matching mode by default.

Syntax

ip access-list new-fragment-mode { *acl-name* | *acl-number* }

no ip access-list new-fragment-mode { *acl-name* | *acl-number* }

default ip access-list new-fragment-mode { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an IP standard ACL or IP extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an IP standard ACL or IP extended ACL. The following value ranges are supported:

The value range of IP standard ACLs is 1 to 99 or 1300 to 1999; the value range of IP extended ACLs is 100 to 199 or 2000 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When an ACL rule carries the fragment flag, there is no difference between the default fragmented packet matching mode and the new matching mode.

When the ACL rule does not carry the fragment flag, if the first fragment is required to match all the user-defined matching fields (including L3 and L4 information) in the ACL and the non-first fragments need to only match the non-L4 information in the ACL rule, you can run this command to switch the fragmented packet matching mode of the specified ACL to the new matching mode.

Examples

The following example switches the fragmented packet matching mode of an ACL numbered 100 from the default matching mode to a new matching mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list new-fragment-mode 100
```

1.21 ip access-list resequence

Function

Run the **ip access-list resequence** command to configure the start value and step of rule sequence numbers in an IP ACL.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default start value and step of rule sequence numbers in an IP ACL are both **10**.

Syntax

ip access-list resequence { *acl-name* | *acl-number* } *start-value step-value*

no ip access-list resequence { *acl-name* | *acl-number* }

default ip access-list resequence { *acl-name* | *acl-number* }

Parameter Description

acl-name: Name of an IP standard ACL or IP extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an IP standard ACL or IP extended ACL. The following value ranges are supported:

The value range of IP standard ACLs is 1 to 99 or 1300 to 1999; the value range of IP extended ACLs is 100 to 199 or 2000 to 2699.

start-value: Start value of rule sequence numbers. The value range is from 1 to 2147483647.

step-value: Step of rule sequence numbers. The value range is from 1 to 2147483647.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To insert a new rule into an IP standard ACL or IP extended ACL, run this command to rearrange the sequence numbers of ACL rules.

Examples

The following example configures an IP standard ACL numbered 1, and sets the start value of rule sequence numbers to 21 and step to 43.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list resequence 1 21 43
```

1.26 ipv6 traffic-filter

Function

Run the **ipv6 traffic-filter** command to apply an IPv6 ACL.

Run the **no** form of this command to cancel the application.

Run the **default** form of this command to restore the default configuration.

No IPv6 ACL is applied by default.

Syntax

ipv6 traffic-filter *acl-name* { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

no ipv6 traffic-filter *acl-name* { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

default ipv6 traffic-filter *acl-name* { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

Parameter Description

acl-name: Name of an IPv6 ACL. The value is a case-sensitive string of 1 to 99 characters.

in: Filters the incoming packets of a port.

out: Filters the outgoing packets of a port.

counter-only: Configures a special ACL only for packet counting on a port.

control-plane: Configures a control plane ACL.

forward-control-plane: Configures a control and forwarding plane ACL.

forward-plane: Configures a forwarding plane ACL.

Command Modes

Global configuration mode

Interface configuration mode

SVI interface configuration mode

Default Level

14

Usage Guidelines

To make an IPv6 ACL take effect, run this command to apply the ACL in global configuration mode, interface configuration mode, or SVI interface configuration mode. The ACL controls the incoming/outgoing IPv6 packets of all ports, a specified SVI, or a specified port. The **counter-only** option is not supported in global configuration mode. The **ipv6 traffic-filter** *acl-name* { **in** | **out** } **counter-only** command configured on a port collects statistics on packets only, without filtering them.

Examples

The following example applies the IPv6 ACL named v6-acl to the inbound direction of the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 traffic-filter v6-acl in
```

The following example applies the IPv6 ACL named v6-acl to the inbound direction of the L3 Ethernet interface GigabitEthernet 0/1, and collects statistics on incoming packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 traffic-filter v6-acl in counter-only
```

Function

Run the **mac access-group** command to apply a MAC extended ACL.

Run the **no** form of this command to cancel the application.

Run the **default** form of this command to restore the default configuration.

No MAC extended ACL is applied by default.

Syntax

mac access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

no mac access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

default mac access-group { *acl-name* | *acl-number* } { **in** | **out** } [**control-plan** | **counter-only** | **forward-control-plane** | **forward-plane**]

Parameter Description

acl-name: Name of a MAC extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of a MAC extended ACL. The value range is from 700 to 799.

in: Filters the incoming packets of a port.

out: Filters the outgoing packets of a port.

counter-only: Configures a special ACL for packet counting on a port.

control-plane: Configures a control plane ACL.

forward-control-plane: Configures a control and forwarding plane ACL.

forward-plane: Configures a forwarding plane ACL.

Command Modes

Global configuration mode

Interface configuration mode

SVI interface configuration mode

Default Level

14

Usage Guidelines

To make a MAC extended ACL take effect, run this command to apply the ACL in global configuration mode, interface configuration mode, or SVI interface configuration mode. The ACL controls the incoming/outgoing Ethernet packets of all ports, a specified SVI, or a specified port. The **counter-only** option is not supported in global configuration mode. The **mac access-group** { *acl-name* | *acl-number* } { **in** | **out** } **counter-only** command configured on a port collects statistics on packets only, without filtering them.

Examples

The following example applies the MAC extended ACL named accept_00d0f8xxxxxx_only to the inbound direction of the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mac access-group accept_00d0f8xxxxxx_only
in
```

The following example applies an ACL numbered 700 to the inbound direction of the L3 Ethernet interface GigabitEthernet0/1 and collects statistics on the incoming packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mac access-group 700 in counter-only
```

1.32 permit

Function

Run the **permit** command to add a rule of permit type to an ACL.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

There is no rule of permit type in an ACL by default.

Syntax

The commands for adding/deleting a rule of permit type to/from ACLs of different types are as follows:

- IP standard ACL

  Add a rule of permit type to an IP standard ACL.

  [*sequence-number*] **permit** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**log**]

  Delete a rule of permit type from an IP standard ACL.

  no { *sequence-number* | { **permit** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**time-range** *time-range-name*] [**log**] } }

- IP extended ACL

  Add a rule of permit type to an IP extended ACL.

  [*sequence-number*] **permit** *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] [**log**]

  Delete a rule of permit type from an IP extended ACL.

  no { *sequence-number* | { **permit** *protocol* { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] [**log**] } }

Note

The commands for adding a rule of permit type to IP extended ACLs that specify some important protocols in the protocol field are as follows:

The ICMP field is selected.

[*sequence-number*] **permit icmp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] [**log**]

The TCP field is selected.

[*sequence-number*] **permit tcp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**match-all** *tcp-flag* | **established**] [**log**]

The UDP field is selected.

[*sequence-number*] **permit udp** { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**log**]

- MAC extended ACL

  Add a rule of permit type to a MAC extended ACL.

  [*sequence-number*] **permit** { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] [**time-range** *time-range-name*]

  Delete a rule of permit type from a MAC extended ACL.

  no { *sequence-number* | { **permit** { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] [**time-range** *time-range-name*] } }

- Expert extended ACL

  Add a rule of permit type to an expert extended ACL.

  [*sequence-number*] **permit** [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source*-mac-*address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*]

  Delete a rule of permit type from an expert extended ACL.

  no { *sequence-number* | { **permit** [*protocol* | [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]]] [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source*-mac-*address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*] } }

  The Ethernet type or **cos** field is selected.

[*sequence-number*] **permit** { [*ethernet-type*] [**cos** [*cos-value*] [**inner** *cos-value*]] } [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [**time-range** *time-range-name*]

Note

The commands for adding a rule of permit type to expert extended ACLs that specify some important protocols in the protocol field are as follows:

The ICMP field is selected.

[*sequence-number*] **permit icmp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**time-range** *time-range-name*]

The TCP field is selected.

[*sequence-number*] **permit tcp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-ipv4-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**match-all** *tcp-flag* | **established**]

The UDP field is selected.

[*sequence-number*] **permit udp** [**VID** [*vlan-id*] [**inner** *vlan-id*]] { *source-ipv4-address source-*ipv4*-wildcard* | **host** *source-ipv4-address* | **any** } { *source-mac-address source-mac-wildcard* | **host** *source-mac-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv4-address destination-ipv4-wildcard* | **host** *destination-ipv4-address* | **any** } { *destination-mac-address destination-mac-wildcard* | **host** *destination-mac-address* | **any** } [[**precedence** *precedence*] [**tos** *tos*] | [**dscp** *dscp*]] [**fragment**] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*]

- Expert advanced ACL

  Add a rule of permit type to an expert advanced ACL.

  [*sequence-number*] **permit** *hex hex-mask offset*

  Delete a rule of permit type from an expert advanced ACL.

  no { *sequence-number* | **permit** *hex hex-mask offset* }

- IPv6 extended ACL

  Add a rule of permit type to an IPv6 extended ACL.

  [*sequence-number*] **permit** [*protocol* { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix / prefix-length* |

destination-ipv6-address destination-ipv6-mask | **host** *destination-ipv6-address* | **any** }] [**cos** *cos-value* [**inner** *cos-value*]] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination-mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**time-range** *time-range-name*] [**log**]

Delete a rule of permit type from an IPv6 extended ACL.

no { *sequence-number* | { **permit** [*protocol* { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** }] [**cos** *cos-value* [**inner** *cos-value*]] [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**time-range** *time-range-name*] [**log**] } }

Note

The commands for adding a rule of permit type to IPv6 extended ACLs that specify some important protocols in the protocol field are as follows:

The ICMP field is selected.

[*sequence-number*] **permit icmp** { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [[*icmp-type* [*icmp-code*]] | [*icmp-message*]] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**time-range** *time-range-name*] [**log**]

The TCP field is selected.

[*sequence-number*] **permit tcp** { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**match-all** *tcp-flag* | **established**] [**log**]

The UDP field is selected.

[*sequence-number*] **permit udp** { *source-ipv6-prefix / prefix-length* | *source-ipv6-address source-ipv6-mask* | **host** *source-ipv6-address* | **any** } [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] { *destination-ipv6-prefix / prefix-length* | *destination-ipv6-address destination-ipv6-mask* | **host** *destination-ipv6-address* | **any** } [{ **any** | **host** *source-mac-address* | *source-mac-address source-mac-wildcard* } { **any** | **host** *destination–mac-address* | *destination–mac-address destination-mac-wildcard* }] [**dscp** *dscp*] [**flow-label** *flow-label*] [**fragment**] [**VID** [*vlan-id*] [**inner** *vlan-id*]] [**eq** *port* | **gt** *port* | **lt** *port* | **neq** *port* | **range** *lower upper*] [**time-range** *time-range-name*] [**log**]

Parameter Description

sequence-number: Sequence number of an ACL rule. The value range is from 1 to 2147483647.

permit: Configures the processing action for an ACL rule. If packets match this rule, the packets are permitted.

source-ipv4-address: Source IP address (host address or network address) for packet matching.

source-ipv4-wildcard: Source IP address wildcard mask, which is used to match the source IP addresses of multiple hosts. The wildcard masks can be discontinuous, for example, 0.255.0.32.

protocol: IP protocol number for matching. The value range is from 0 to 255. Some important protocol names such as *icmp*, *ip*, *ipv6*, *tcp, and udp* are listed separately.

destination-ipv4-address: Destination IP address (host address or network address) for packet matching.

destination-ipv4-wildcard: Destination IP address wildcard mask, which is used to match the destination IP addresses of multiple hosts. The wildcard masks can be discontinuous, for example, 0.255.0.32.

fragment: Matches the non-first fragment in the default fragmented packet matching mode.

precedence *precedence*: Matches the precedence value of packets. The value range is from 0 to 7. Some important precedence names such as *routine*, *priority*, *immediate*, *flash*, *flash-override*, *critical*, *internet*, and *network* are listed separately.

eq *port*: Matches packets with the L4 port ID equal to the specified value. The value range is from 0 to 65535.

gt *port*: Matches packets with the L4 port ID greater than the specified value. The value range is from 0 to 65535.

lt *port*: Matches packets with the L4 port ID less than the specified value. The value range is from 0 to 65535.

neq *port*: Matches packets with the L4 port ID not equal to the specified value. The value range is from 0 to 65535.

range: Matches the range of L4 port IDs of packets.

lower: Lower limit of the L4 port ID range for matching. The value range is from 0 to 65535.

upper: Upper limit of the L4 port ID range for matching. The value range is from 0 to 65535.

time-range *time-range-name*: Configures the name of the time range for packet filtering.

tos *tos*: Matches the ToS value of packets. The value range is from 0 to 15. Some important service type names such as *max-reliability*, *max-throughput*, *min-delay*, *min-monetary-cost*, and *normal* are listed separately.

dscp *dscp*: Matches the DSCP value of packets. The value range is from 0 to 63. Some important differentiated service names such as *default*, *ef*, *af11*, and *cs1* are listed separately.

icmp-type: Message type for matching ICMP packets. The value range is from 0 to 255.

icmp-code: Message type code for matching ICMP packets. The value range is from 0 to 255.

icmp-message: Message type name for matching ICMP packets.

source-mac-address: MAC address of the source host for matching.

source-mac-wildcard: MAC address wildcard of the source host, which is used to match the source MAC addresses of multiple hosts.

destination-mac-address: MAC address of the destination host for matching.

destination-mac-wildcard: MAC address wildcard of the destination host, which is used to match the destination MAC addresses of multiple hosts.

cos *cos-value*: Matches the priority field value in the outer tag in the L2 packets. The value range is from 0 to 7.

inner *cos-value*: Matches the priority field value in the inner tag in the L2 packets. The value range is from 0 to 7.

VID *vlan-id*: Matches the VLAN ID. The value range is from 1 to 4094.

inner *vlan-id*: Matches the inner VLAN ID. The value range is from 1 to 4094.

ethernet-type: Matches the Ethernet protocol type. The value range is from 0x0000 to 0xFFFF. Some important Ethernet protocol type names such as *arp*, *aarp*, and *IPX* are listed separately.

match-all *tcp-flag*: Matches all the bits of the TCP flag.

established: Matches only the RST or ACK bit in the TCP flag, not the other bits.

source-ipv6-prefix: Source IPv6 network address or network type for matching.

destination-ipv6-prefix: Destination IPv6 network address or network type for matching.

prefix-length: IPv6 address mask length for matching.

source-ipv6-address: Source IPv6 address for matching.

destination-ipv6-address: Destination IPv6 address for matching.

source-ipv6-mask: Source IPv6 address mask for matching.

destination-ipv6-mask: Destination IPv6 address mask for matching.

flow-label *flow-label*: Matches the flow label value. The value range is from 0 to 1048575.

hex: Matching field in hexadecimal notation. It is used when expert advanced ACL rules are configured.

hex-mask: Matching field masks in hexadecimal notation. It is used when expert advanced ACL rules are configured.

offset: Matching start position, in bytes. It is used when expert advanced ACL rules are configured. The value range is from 0 to 79.

hex hex-mask offset: Combination of *hex, hex-mask*, and *offset*. Multiple such combinations can be configured.

Command Modes

ACL configuration mode

Default Level

14

Usage Guidelines

To permit some packets to enter a network, you can run this command to add rules of permit type to an ACL.

Examples

The following example creates an IP standard ACL and adds a rule: Permit packets sent from the source host with the IP address 192.168.4.12.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list standard std-acl
Hostname(config-std-nacl)# permit host 192.168.4.12
```

The following example creates an IP extended ACL and adds a rule: Permit the services provided by the source host with the IP address 192.168.4.12 through TCP port 100.

```
Hostname# configure terminal
Hostname(config)# ip access-list extended 102
Hostname(config-ext-nacl)# permit tcp host 192.168.4.12 eq 100 any
```

The following example creates an expert extended ACL and adds a rule: Permit all the TCP packets with the source IP address 192.168.4.12 and the source MAC address 0013.0049.8272.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# expert access-list extended exp-acl
Hostname(config-exp-nacl)# permit tcp host 192.168.4.12 host 0013.0049.8272 any any
Hostname(config-exp-nacl)# deny any any any any
```

The following example creates a MAC extended ACL and adds a rule: Permit the Ethernet frames of the AARP protocol type sent from the source host with the MAC address 0013.0049.8272.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mac access-list extended 702
Hostname(config-mac-nacl)# permit host 0013.0049.8272 any aarp
```

The following example creates an IPv6 extended ACL and adds a rule numbered 11: Permit packets sent from the source host with the IP address 2000::1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 access-list v6-acl
Hostname(config-ipv6-nacl)# 11 permit ipv6 host 2000::1 any
```

The following example creates an expert advanced ACL and adds a rule: Permit packets sent from the source host with the IP address 192.168.4.12.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# expert access-list advanced adv-acl
Hostname(config-exp-dacl)# permit c0a8040c ffffffff 38
```

1.33 redirect destination interface

Function

Run the **redirect destination interface** command to configure an ACL redirection port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No ACL redirection port is configured by default.

Syntax

redirect destination interface *interface-type interface-number* **acl** { *acl-name* | *acl-number* } **in**

no redirect destination interface *interface-type interface-number* **acl** { *acl-name* | *acl-number* } **in**

default redirect destination interface *interface-type interface-number* **acl** { *acl-name* | *acl-number* } **in**

Parameter Description

interface *interface-type interface-number*: Interface type and number.

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: ACL number.

in: Redirects the incoming packets of a port.

Command Modes

L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

You can configure a redirect ACL on a port to redirect the incoming packets of the port that match the ACL rules to a specified port. For example, when you need to monitor the running status of an ACL, run this command.

Examples

The following example redirects the incoming packets from the L3 Ethernet interface GigabitEthernet 0/3 that match the rule acl1 to the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/3
Hostname(config-if-GigabitEthernet 0/3)# redirect destination interface
gigabitethernet 0/1 acl acl1 in
```

1.34 remark

Function

Run the **remark** command to add a remark to an ACL rule.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No remark is added to an ACL rule by default.

Syntax

[*sequence-number*] **remark** *text*

no [*sequence-number*] **remark** *text*

default [*sequence-number*] **remark** *text*

Parameter Description

sequence-number: Sequence number of an ACL rule, to which a remark needs to be added. The value range is from 1 to 2147483647.

remark *text*: Configures a remark for an ACL rule. The value is a case-sensitive string of 1 to 100 characters.

Command Modes

ACL configuration mode

Default Level

14

Usage Guidelines

Two content remarks are forbidden in an ACL rule.

Deleting an ACL rule will delete the rule and its remark.

If the *sequence-number* parameter is specified, the remark is added to the specified ACL rule; if the *sequence-number* parameter is not specified, the remark is added to the last ACL rule.

Examples

The following example adds a remark to an ACL rule in an IP extended ACL numbered 102.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip access-list extended 102
```

```
Hostname(config-ext-nacl)# permit tcp 1.1.1.1 0.0.0.0 2.2.2.2 0.0.0.0
Hostname(config-ext-nacl)# remark first_remark
Hostname(config-ext-nacl)# permit tcp 3.3.3.3 0.0.0.0 4.4.4.4 0.0.0.0
Hostname(config-ext-nacl)# remark second_remark
```

1.35 security access-group

Function

Run the **security access-group** command to configure a security channel for a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No security channel is configured for a port by default.

Syntax

security access-group { *acl-name* | *acl-number* }

no security access-group

default security access-group

Parameter Description

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: ACL number. The following value ranges are supported:

IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

Command Modes

L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

When the authentication function is configured on a device, such as IEEE 802.1x or Web authentication, users must pass the authentication before accessing the external network. To enable users connected to a port to access the external network without undergoing authentication, run this command to configure a security channel.

Examples

The following example configures the ACL numbered 1 as a security channel on the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# security access-group 1
```

1.36 security global access-group

Function

Run the **security global access-group** command to configure a global security channel.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No global security channel is configured by default.

Syntax

security global access-group { *acl-name* | *acl-number* }

no security global access-group

default security global access-group

Parameter Description

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: ACL number. The following value ranges are supported:

IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the authentication function is configured on a device, such as IEEE 802.1x or Web authentication, users must pass the authentication before accessing the external network. To enable users connected to different ports to access the external network without undergoing authentication, run this command to configure a global security channel.

Examples

The following example configures the ACL numbered 1 as a global security channel.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# security global access-group 1
```

1.37 security uplink enable

Function

Run the **security uplink enable** command to configure an excluded port of a global security channel.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No excluded port is configured for a global security channel by default.

Syntax

security uplink enable

no security uplink enable

default security uplink enable

Parameter Description

N/A

Command Modes

L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

The global security channel takes effect on all the ports. To disable the global security channel on some ports, configure these ports as excluded ports of the global security channel.

Examples

The following example configures the L3 Ethernet interface GigabitEthernet 0/1 as an excluded port of a global security channel.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# security uplink enable
```

1.38 show access-group

Function

Run the **show access-group** command to display the ACL configuration applied to a port.

Syntax

show access-group [**interface** { *interface-type interface-number* | **vlan** *vlan-id* }]

Parameter Description

interface *interface-type interface-number*: Specifies the interface type and number.

vlan *vlan-id*: Displays the ACL configuration applied to a specified VLAN port. The value range is from 1 to 4094.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

To check whether an ACL is applied to a specified port or to find out the ports that have ACLs applied, run this command. If the parameter **interface** is not specified, ACLs applied to all ports are displayed.

Examples

The following example displays information about the ACL applied to a port of the device.

```
Hostname> enable
Hostname# show access-group
ip access-list standard ipstd3 in
Applied On interface GigabitEthernet 0/1.
ip access-list standard ipstd4 out
Applied On interface GigabitEthernet 0/1.
ip access-list extended 101 in
Applied On interface GigabitEthernet 0/3.
ip access-list extended 102 in
Applied On interface GigabitEthernet 0/8.
ipv6 traffic-filter vlan_in in
ipv6 traffic-filter vlan_out out
Applied On vlan 1
```

Table 1-2 Output Fields of the show access-group Command

Field	Description
in	Applied to the inbound direction of a port.
out	Applied to the outbound direction of a port.
Applied On interface X	Applied to interface X.

The following example displays information about the ACL applied to the port GigabitEthernet 0/3.

```
Hostname> enable
Hostname# show access-group interface gigabitethernet 0/3
ip access-list extended 101
Applied On interface GigabitEthernet 0/3 in.
```

Table 1-3 Output Fields of the show access-group interface Command

Field	Description
in	Applied to the inbound direction of a port.
out	Applied to the outbound direction of a port.
Applied On interface X	Applied to interface X.

1.39 show access-lists

Function

Run the **show access-lists** command to display the configuration of all ACLs or a specified ACL.

Syntax

show access-lists [*acl-name* | *acl-number*] [**summary**]

Parameter Description

acl-name: Name of an IP standard ACL or IP extended ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: ACL number. IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

summary: Displays the summary of an ACL.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the configuration of a specified ACL. If no ACL number or name is specified, the configuration of all ACLs is displayed.

Examples

The following example displays the configuration of the ACL named n_acl.

```
Hostname> enable
Hostname# show access-lists n_acl
ip access-list standard n_acl
```

The following example displays the configuration of the ACL numbered 102.

```
Hostname# show access-lists 102
ip access-list extended 102
```

The following example displays the configuration of all the ACLs.

```
Hostname> enable
Hostname# show access-lists
ip access-list standard n_acl
ip access-list extended 101
permit icmp host 192.168.1.1 any log (1080 matches)
  permit tcp host 1.1.1.1 any established
  deny ip any any (80021 matches)
mac access-list extended mac-acl
expert access-list extended exp-acl
ipv6 access-list extended v6-acl
petmit ipv6 ::192.168.4.12 any (100 matches)
deny any any (9 matches)
```

Table 1-4 Output Fields of the show access-lists Command

Field	Description
ip access-list standard	IP standard ACL.
ip access-list extended	IP extended ACL.
mac access-list extended	MAC extended ACL.
expert access-list extened	Expert extended ACL.
ipv6 access-list extended	IPv6 extended ACL.
permit	Rule of permit type.
deny	Rule of deny type.

1.40 show acl res

Function

Run the **show acl res** command to display information about all or a specified TCAM.

Syntax

show acl res [**dev** *dev-number* [**slot** *slot-number*]]

Parameter Description

dev *dev-number*: Displays the TCAM information of a specified device number.

slot *slot-number*: Displays the TCAM information of a specified slot number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the TCAM information of a specified device slot. If no slot number of a device is specified, the TCAM information of all the slots in the device is displayed. If no device number is specified, the TCAM information of all devices is displayed.

Examples

The following example displays the TCAM resources used, usage, and number of remaining entries on all devices.

```
Hostname> enable
Hostname# show acl res
acl usage warn limit: 100%
type          total         used          free          usage

1.41 show acl res detail

Function

Run the **show acl res detail** command to display detailed usage information of all or a specified TCAM.

Syntax

show acl res detail [**dev** *dev-number* [**slot** *slot-number*]]

Parameter Description

dev *dev-number*: Displays the detailed usage information of TCAMs in a specified device.

slot *slot-number*: Displays the detailed usage information of the TCAM in a specified slot.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the detailed usage information of the TCAM in a specified device slot. If no slot number of a device is specified, the detailed usage information of TCAMs in all the slots of the device is displayed. If no device number is specified, the detailed usage information of TCAMs in all devices is displayed.

Examples

The following example displays the detailed resource usage of TCAMs in all devices.

```
Hostname> enable
```

```
Hostname# show acl res detail
Dev: 1         Slot: 0       unit: 0              stage: IFP
group id: 2     group pri: 2   total entry: 2000      used entry: 2

1.42 show expert access-group

Function

Run the **show expert access-group** command to display the configuration of an expert extended ACL applied to a port.

Syntax

show expert access-group [**interface** { *interface-type interface-number* | **vlan** *vlan-id* }]

Parameter Description

interface *interface-type interface-number*: Specifies the interface type and number.

vlan *vlan-id*: Displays the ACL configuration applied to a specified VLAN port. The value range is from 1 to 4094.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the expert ACL applied to a port. If the parameter **interface** is not specified, the expert ACLs applied to all ports are displayed.

Examples

The following example displays information about the expert extended ACL applied to the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show expert access-group interface gigabitethernet 0/1
expert access-group ee in
Applied On interface GigabitEthernet 0/1.

1.43 show ip access-group

Function

Run the **show ip access-group** command to display the configuration of IP standard and IP extended ACLs applied to a port.

Syntax

show ip access-group [**interface** { *interface-type interface-number* | **vlan** *vlan-id* }]

Parameter Description

interface *interface-type interface-number*: Specifies the interface type and number.

vlan *vlan-id*: Displays the ACL configuration applied to a specified VLAN port. The value range is from 1 to 4094.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the IP standard and IP extended ACLs applied to a port. If the parameter **interface** is not specified, the IP standard and IP extended ACLs applied to all ports are displayed.

Examples

The following example displays information about the IP standard and IP extended ACLs applied to the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable

1.44 show ipv6 traffic-filter

Function

Run the **show ipv6 traffic-filter** command to display the configuration of the IPv6 ACL applied to a port.

Syntax

show ipv6 traffic-filter [**interface** { *interface-type interface-number* | **vlan** *vlan-id* }]

Parameter Description

interface *interface-type interface-number*: Specifies the interface type and number.

vlan *vlan-id*: Displays the ACL configuration applied to a specified VLAN port. The value range is from 1 to 4094.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the IPv6 ACL applied to a port. If the parameter **interface** is not specified, the IPv6 ACLs applied to all ports are displayed.

Examples

The following example displays information about the IPv6 ACL applied to the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show ipv6 traffic-filter interface gigabitethernet 0/1
ipv6 traffic-filter v6 in
Applied On interface GigabitEthernet 0/1.

1.46 show redirect

Function

Run the **show redirect** command to display the redirect ACL configuration.

Syntax

show redirect [**interface** { *interface-type interface-number* | **vlan** *vlan-id* }]

Parameter Description

interface *interface-type interface-number*: Specifies the interface type and number.

vlan *vlan-id*: Displays the ACL configuration applied to a specified VLAN port. The value range is from 1 to 4094.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the redirect ACL configuration. If the parameter **interface** is not specified, information about the redirect ACLs configured on all the ports is displayed.

Examples

The following example displays information about the redirect ACL configured on the L3 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show redirect interface gigabitethernet 0/1
acl redirect configuration on interface Gigabitethernet 0/1
redirect destination interface Gigabitethernet 0/1 acl 1 in
```

1.48 svi router-acls enable

Function

Run the **svi router-acls enable** command to enable the function of making an ACL applied to an SVI effective only for L3 forwarded packets.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The function of making an ACL applied to an SVI effective only for L3 forwarded packets is disabled by default. Namely, the ACL applied to an SVI is effective for both L2 and L3 forwarded packets.

Syntax

svi router-acls enable

no svi router-acls enable

default svi router-acls enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The ACL applied to an SVI is effective for both L2 and L3 forwarded packets by default. To make the ACL applied to an SVI effective only for the L3 forwarded packets, run this command. This command affects only the ACL applied to an SVI.

Examples

The following example enables the function of making the ACL applied to an SVI effective only for L3 forwarded packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# svi router-acls enable
```

1 QoS Commands

Command	Function
class	Associate a class with a policy.
class-map	Configure a class.
drop	Configure the traffic behavior of discarding packets.
drr-queue bandwidth	Configure the deficit round robin (DRR) scheduling weights for output queues.
match	Configure a matching rule for a class.
mls qos cos	Configure the IEEE 802.1p value for an interface.
mls qos enable	Enable the global QoS function.
mls qos map cos-dscp	Configure the IEEE 802.1p-to-DSCP mappings for an interface.
mls qos map dscp-cos	Configure the DSCP-to-CoS mappings.
mls qos map ip-precedence-dscp	Configure the IP PRE-to-DSCP mappings.
mls qos scheduler	Configure a scheduling policy for output queues.
mls qos trust	Configure the trust mode for an interface.
police	Configure a bandwidth limit and the traffic behavior of processing packets out of the limit.
policy-map	Configure a policy.
priority-queue	Set the scheduling policy to SP for output queues.
priority-queue cos-map	Configure the CoS-to-queue mappings.
qos queue	Configure the minimum guaranteed bandwidth or maximum limited bandwidth for a queue.
queueing wred	Enable the WRED function.
rate-limit	Configure the rate limit for an interface.
service-policy	Apply a policy.
set	Configure the traffic behavior of modifying a QoS priority.
show class-map	Display information about a class.

show mls qos interface	Display the QoS information of an interface.
show mls qos maps	Display the mappings of different priorities.
show mls qos queueing	Display the CoS-to-queue mappings and the scheduling weights of queues.
show mls qos rate-limit	Display the rate limit information of an interface.
show mls qos scheduler	Display the scheduling policy information of output queues.
show mls qos virtual-group	Display policies associated with a logical interface group.
show policy-map	Display policy information.
show qos bandwidth	Display the queue bandwidth information.
show queueing wred	Display WRED information.
show virtual-group	Display information about members contained in a logical interface group.
virtual-group	Create a logical interface group.
wfq-queue bandwidth	Configure the WFQ scheduling weights for output queues.
wrr-queue bandwidth	Configure the WRR scheduling weights for output queues.
wrr-queue cos-map	Configure the mappings from CoS values to threshold groups.
wrr-queue random-detect min-threshold	Configure the lower threshold value for WRED to discard packets.
wrr-queue random-detect probability	Configure the maximum discarding probability for WRED.

1.1 class

Function

Run the **class** command to associate a class with a policy.

Run the **no** form of this command to remove this configuration.
Run the **default** form of this command to restore the default configuration.

No class is associated with a policy by default.

Syntax

class *class-map-name*

no class *class-map-name*
default class *class-map-name*

Parameter Description

class *class-map-name*: Configures the name of a class. The value is a case-sensitive string of 1 to 31 characters.

Command Modes

Policy configuration mode

Default Level

14

Usage Guidelines

Before running this command, you must run the **class-map** command to configure a class, run the **policy-map** command to configure a policy, and enter the policy configuration mode.

When multiple classes are associated with the same policy, you are not advised to match the multiple classes with the same flow. Otherwise, the traffic behavior bound to a class takes effect on the flow randomly, and, when the device restarts, the effective traffic behavior may change.

Examples

The following example configures the policy pmap1, associates the class cmap1 with the policy, and enters the policy class configuration mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# class-map cmap1
Hostname(config-cmap)# exit
Hostname(config)# policy-map pmap1
Hostname(config-pmap)# class cmap1
Hostname(config-pmap-c)#
```

1.2 class-map

Function

Run the **class-map** command to configure a class.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No class is configured by default.

Syntax

class-map *class-map-name*

no class-map *class-map-name*

default class-map *class-map-name*

Parameter Description

class-map *class-map-name*: Configures the name of a class. The value is a case-sensitive string of 1 to 31 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure a class and enter the class configuration mode. You can run the **match** command to configure matching rules for a class.

Examples

The following example configures the class cm_acl and associates the class with an MAC extended access control list (ACL) that permits all the packets with the source MAC address 1111.2222.3333 to pass through.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mac access-list extended me
Hostname(config-ext-macl)# permit host 1111.2222.3333 any
```

```
Hostname(config-ext-macl)# exit
Hostname(config)# class-map cm_acl
Hostname(config-cmap)# match access-group me
```

The following example configures the class cm_dscp for matching packets with the differentiated services code point (DSCP) values 8, 16, and 24.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# class-map cm_dscp
Hostname(config-cmap)# match ip dscp 8 16 24
```

1.3 drop

Function

Run the **drop** command to configure the traffic behavior of discarding packets.

Run the **no** form of this command to remove this configuration.
Run the **default** form of this command to restore the default configuration.

The traffic behavior of discarding packets is not configured by default.

Syntax

drop

no drop
default drop

Parameter Description

N/A

Command Modes

Policy class configuration mode

Default Level

14

Usage Guidelines

This command can be configured only when no traffic behavior is specified for the class associated with a policy. After the traffic behavior of discarding packets is configured, you need to delete this traffic behavior before configuring other traffic behaviors.

Examples

The following example configures the policy pmap1, associates the class cm-acl with the policy, and configures the traffic behavior of discarding packets in the policy.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# policy-map pmap1
Hostname(config-pmap)# class cm-acl
Hostname(config-pmap-c)# drop
```

1.4 drr-queue bandwidth

Function

Run the **drr-queue bandwidth** command to configure the deficit round robin (DRR) scheduling weights for output queues.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default DRR scheduling weight ratio of output queues is **1:1:1:1:1:1:1:1**.

Syntax

drr-queue bandwidth *weight-value-list*

no drr-queue bandwidth

default drr-queue bandwidth

Parameter Description

weight-value-list: DRR scheduling weights for output queues. The weight value range is from 0 to 15. The value **0** indicates that the SP scheduling policy is used.

Command Modes

Global configuration mode

L2 Ethernet interface configuration mode

L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

When the DRR scheduling weights are configured for output queues in both global configuration mode and L2/L3 Ethernet interface configuration mode, the interface configuration prevails.

Examples

The following example sets the DRR scheduling weight ratio to **1:1:1:2:2:4:6:8** for global output queues.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# drr-queue bandwidth 1 1 1 2 2 4 6 8
```

The following example sets the DRR scheduling weight ratio to **1:1:2:2:2:2:4:4** for output queues on L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# drr-queue bandwidth 1 1 2 2 2 2 4 4
```

1.5 match

Function

Run the **match** command to configure a matching rule for a class.

Run the **no** form of this command to remove this configuration.
Run the **default** form of this command to restore the default configuration.

No matching rules are configured for a class by default.

Syntax

match { **access-group** { *acl-number* | *acl-name* } | **ip** { **dscp** *dscp-value-list* | **precedence** *pre-value-list* } }

no match { **access-group** { *acl-number* | *acl-name* } | **ip** { **dscp** *dscp-value-list* | **precedence** *pre-value-list* } }

Parameter Description

access-group: Matches ACL rules. Both numerically indexed ACLs and named ACLs are supported.

acl-number: Number of a numerically indexed ACL for matching. IP standard ACLs: 1 to 99 or 1300 to 1999; IP extended ACLs: 100 to 199 or 2000 to 2699; MAC extended ACLs: 700 to 799; expert extended ACLs: 2700 to 2899.

acl-name: Name of an ACL for matching. The value is a case-sensitive string of 1 to 99 characters.

ip dscp *dscp-value-list*: Matches DSCP rules. Multiple DSCP values can be matched at the same time. The value range is from 0 to 63.

ip precedence *pre-value-list*: Matches IP PRE rules. Multiple IP PRE values can be matched at the same time. The value range is from 0 to 7.

Command Modes

Class configuration mode

Default Level

14

Usage Guidelines

Before running this command, you must run the **class-map** command to configure a class and enter the class configuration mode.

Examples

The following example configures the class cmap1 for matching packets with the IP DSCP values 20, 22, 24, and 30.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# class-map cmap1
Hostname(config-cmap)# match ip dscp 20 22 24 30
```

1.6 mls qos cos

Function

Run the **mls qos cos** command to configure the IEEE 802.1p value for an interface.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default IEEE 802.1p value of an interface is **0**.

Syntax

mls qos cos *cos-value*

no mls qos cos

default mls qos cos

Parameter Description

cos *cos-value*: Configures the IEEE 802.1p value for an interface. The value range is from 0 to 7.

Command Modes

L2 Ethernet interface configuration mode

L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

When the trust mode of an interface is set to untrusted, the packets received from the interface use the IEEE 802.1p value configured for the interface.

Examples

The following example sets the IEEE 802.1p value to **7** for L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabiEthernet 0/1)# mls qos cos 7
```

1.8 mls qos map cos-dscp

Function

Run the **mls qos map cos-dscp** command to configure the IEEE 802.1p-to-DSCP mappings for an interface.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The IEEE 802.1p values 0 to 7 of an interface are mapped to DSCP values 0, 8, 16, 24, 32, 40, 48, and 56 respectively by default.

Syntax

mls qos map cos-dscp *dscp-value-list*

no mls qos map cos-dscp

default mls qos map cos-dscp

Parameter Description

dscp-value-list: DSCP values, to which IEEE 802.1p values 0 to 7 are to be mapped respectively. The value range is from 0 to 63.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the trust mode of an interface is set to trusting IEEE 802.1p, if a tagged packet of IEEE 802.1q is received from the interface, the IEEE 802.1p value carried in the packet is directly used. If the packet does not carry any tag, the IEEE 802.1p value configured for the interface is used. The mapping table configured using this command and the mapping table configured using the **mls qos map dscp-cos** command are used to jointly obtain CoS values.

Examples

The following example maps IEEE 802.1p values 0 to 7 of an interface to DSCP values 8, 10, 16, 18, 24, 26, 32, and 34 respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mls qos map cos-dscp 8 10 16 18 24 26 32 34
```

1.9 mls qos map dscp-cos

Function

Run the **mls qos map dscp-cos** command to configure the DSCP-to-CoS mappings.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

Table 1-1 lists the default mappings from DSCP values to CoS values.

Table 1-1 Default Mappings from DSCP Values to CoS Values

DSCP	CoS Value
0 to 7	0
8 to 15	1
16 to 23	2
24 to 31	3
32 to 39	4
40 to 47	5
48 to 55	6
56 to 63	7

Syntax

mls qos map dscp-cos *dscp-value*&<1-8> **to** *cos-value*

no mls qos map dscp-cos

default mls qos map dscp-cos

Parameter Description

dscp-value&<1-8>: DSCP value. &<1-8> indicates that 1 to 8 DSCP values can be configured. The value range is from 0 to 63.

cos-value: CoS values, to which DSCP values are to be mapped. The value range is from 0 to 7.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

CoS values can be obtained based on DSCP values from the mapping table configured using this command.

Examples

The following example maps DSCP values 8, 10, 16, and 18 to CoS 0.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mls qos map dscp-cos 8 10 16 18 to 0
```

1.10 mls qos map ip-precedence-dscp

Function

Run the **mls qos map ip-precedence-dscp** command to configure the IP PRE-to-DSCP mappings.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

IP PRE values 0 to 7 are mapped to DSCP values 0, 8, 16, 24, 32, 40, 48, and 56 respectively by default.

Syntax

mls qos map ip-precedence-dscp *dscp-value-list*

no mls qos map ip-precedence-dscp

default mls qos map ip-precedence-dscp

Parameter Description

dscp-value-list: DSCP values, to which IP PRE values 0 to 7 are to be mapped respectively. The value range is from 0 to 63.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the trust mode of an interface is set to trust IP PRE, if a non-IP packet is received from the interface, the packet is processed in the same way of trusting IEEE 802.1p. If an IP packet is received, the CoS value is obtained based on the IP PRE value of the packet from the mapping table configured using this command and the mapping table configured using the **mls qos map dscp-cos** command.

Examples

The following example maps IP PRE values 0 to 7 to DSCP values 8, 10, 16, 18, 24, 26, 32, and 34 respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mls qos map ip-precedence-dscp 8 10 16 18 24 26 32 34
```

1.11 mls qos scheduler

Function

Run the **mls qos scheduler** command to configure a scheduling policy for output queues.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

By default, the scheduling policy for global output queues is WRR, and no scheduling policy is configured for the output queues on an interface.

Syntax

mls qos scheduler { **drr** | **rr** | **sp** | **wfq** | **wrr** }

no mls qos scheduler

default mls qos scheduler

Parameter Description

drr: Configures DRR scheduling.

rr: Configures round robin (RR) scheduling.

sp: Configures strict priority (SP) scheduling.

wfq: Configures weighted fair queuing (WFQ) scheduling.

wrr: Configures weighted round robin (WRR) scheduling.

Command Modes

Global configuration mode

L2 Ethernet interface configuration mode
L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

If a scheduling policy is configured for an output queue in both global configuration mode and L2/L3 Ethernet interface configuration mode, the interface configuration prevails.

- In SP scheduling, packets are scheduled strictly based on the queue priorities. Only after all the packets in a queue with a higher priority are processed, can the packets in a queue with a lower priority be processed.
- RR scheduling uses the round robin method to schedule multiple queues. Only one packet in a queue is processed each time.
- WRR scheduling solves the problem that weight cannot be set for RR scheduling. WRR scheduling also adopts the round robin method to schedule multiple queues. The number of packets in a queue processed each time is proportional to the weight of the queue. RR scheduling is equivalent to WRR scheduling with the weight 1.
- DRR scheduling is similar to WRR scheduling, but implements scheduling based on the time slice, instead of the number of packets.
- WFQ scheduling fixes the problem that the queues using WRR scheduling have no fixed egress bandwidth. WFQ scheduling allocates an egress bandwidth to queues based on the queue weight, and different queues can have the opportunity of fair scheduling.

Examples

The following example sets the scheduling policy to SP scheduling for output queues.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mls qos scheduler sp
```

The following example sets the scheduling policy to DRR scheduling for output queues of L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mls qos scheduler drr
```

Function

Run the **mls qos trust** command to configure the trust mode for an interface.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default trust mode of an interface is untrusted, and the IEEE 802.1p value configured for the interface is used.

Syntax

mls qos trust { **cos** | **dscp** | **ip-precedence** }

no mls qos trust

default mls qos trust

Parameter Description

cos: Configures trusting IEEE 802.1p.

dscp: Configures trusting DSCP.

ip-precedence: Configures trusting IP PRE.

Command Modes

L2 Ethernet interface configuration mode
L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the trust mode of L2 Ethernet interface GigabitEthernet 0/1 to trust the IEEE 802.1p value configured for the interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1

1.13 police

Function

Run the **police** command to configure a bandwidth limit and the traffic behavior of processing packets out of the limit.

Run the **no** form of this command to remove this configuration.
Run the **default** form of this command to restore the configuration.

No bandwidth limit and the traffic behavior of processing packets out of the limit are configured by default.

Syntax

police *rate-value burst-value* [**exceed-action** { **cos** *cos-value* [**none-tos**] | **drop** | **dscp** *dscp-value* }]

Parameter Description

rate-value: Rate limit value, in kbps. The value range is from 64 to 33554432.

burst-value: Burst traffic limit value, in Kbytes. The value range is from 4 to 8192.

drop: Discards packets out of the bandwidth limit.

dscp *dscp-value*: Changes the DSCP value of the packets out of the bandwidth limit. The value range is from 0 to 63.

cos *cos-value*: Changes the CoS value of the packets out of the bandwidth limit. The value range is from 0 to 7.

none-tos: Keeps the DSCP value of packets unchanged when the CoS value of packets is changed.

Command Modes

Policy class configuration mode

Default Level

14

Usage Guidelines

After the traffic behavior of discarding packets is configured, you need to delete the configured traffic behavior before configuring the traffic behavior of processing packets out of the limit.

Examples

The following example configures the policy pmap1, associates the class cm-acl with the policy, sets the traffic rate limit to 102400 kbps (namely, 100 Mbps), the burst traffic limit to 4096 Kbytes, and configures the action of changing the DSCP value to 16 for traffic out of the limit.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# policy-map pmap1
Hostname(config-pmap)# class cm-acl
Hostname(config-pmap-c)# police 102400 4096 exceed-action dscp 16

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

CoS values 0 to 7 are mapped to queues 1 to 8 respectively by default.

Syntax

priority-queue cos-map *qid cos-value*&<1-8>

no priority-queue cos-map

default priority-queue cos-map

Parameter Description

qid: Queue ID, to which a CoS value is to be mapped. The value range is from 1 to 8.

cos-value&<1-8>: CoS value to be mapped to a specified queue. &<1-8> means that you can configure the mappings from 1–8 CoS values to queues. The value range is from 0 to 7.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run this command to enable packets to enter queues based on their CoS values.

Examples

The following example configures mappings from CoS values 3 and 5 to queue 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# priority-queue cos-map 1 3 5
```

Function

Run the **service-policy** command to apply a policy.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No policy is applied by default.

Syntax

service-policy { **input** | **output** } *policy-map-name*

no service-policy { **input** | **output** } *policy-map-name*

default service-policy { **input** | **output** } *policy-map-name*

Parameter Description

input: Applies a policy to the input direction of an interface.

output: Applies a policy to the output direction of an interface.

policy-map-name: Name of a policy to be applied. The value is a case-sensitive string of 1 to 31 characters.

Command Modes

Global configuration mode

L2 Ethernet interface configuration mode

L3 Ethernet interface configuration mode

Logical Interface group configuration mode

Default Level

14

Usage Guidelines

Before running this command, you must run the **policy-map** command to configure a policy.

When policies are applied in both global configuration mode and L2/L3 Ethernet interface configuration mode, the interface configuration prevails.

Examples

The following example applies the policy po to the input direction of L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# service-policy input po
```

The following example applies the policy po to the output direction of all the interfaces.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# service-policy output po
```

The following example applies the policy po to the output direction of logical interface group 3.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# virtual-group 3
Hostname(config-VirtualGroup)# service-policy output po
```

1.21 set

Function

Run the **set** command to configure the traffic behavior of modifying a QoS priority.

Run the **no** form of this command to remove this configuration.
Run the **default** form of this command to restore the default configuration.

The traffic behavior of modifying a QoS priority is not configured by default.

Syntax

set { **cos** *cos-value* | **ip dscp** *dscp-value* }

no set { **ip dscp** | **cos** }

Parameter Description

cos *cos-value*: Changes the IEEE 802.1p value of an interface. The value range is from 0 to 7.

ip dscp *dscp-value*: Changes the DSCP value. The value range is from 0 to 63.

Command Modes

Policy class configuration mode

Default Level

14

Usage Guidelines

After the traffic behavior of discarding packets is configured, you need to delete the configured traffic behavior before configuring the traffic behavior of modifying a QoS priority.

Examples

The following example configures the policy pmap1, associates the class cmap1 with the policy, and changes the IEEE 802.1p value of packets to 3.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# policy-map pmap1
Hostname(config-pmap)# class cmap1
Hostname(config-pmap-c)# set cos 3
```

1.22 show class-map

Function

Run the **show class-map** command to display information about a class.

Syntax

show class-map [*class-map-name*]

Parameter Description

class-map-name: Class name. The value is a case-sensitive string of 1 to 31 characters.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

When no class name is specified, information about all the classes is displayed.

Examples

The following example displays information about all the classes.

```
Hostname> enable
Hostname# show class-map

 Class Map cmap1
   Match ip dscp 20 40
```

```
Class Map cmap2
  Match access-group 110
```

1.23 show mls qos interface

Function

Run the **show mls qos interface** command to display the QoS information of an interface.

Syntax

show mls qos interface [*interface-type interface-number* | **policers**]

Parameter Description

interface: Displays the QoS information of all the interfaces.

interface-type interface-number: Interface type and interface number. After this parameter is specified, the QoS information of a specified interface is displayed.

policers: Displays the information about policies associated with all the interfaces.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the *interface-type interface-number* parameter is not specified, the QoS information of all the interfaces is displayed.

Examples

The following example displays the QoS information of L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show mls qos interface gigabitethernet 0/1
Interface: GigabitEthernet 0/1
Ratelimit input: 10240 256
Ratelimit output: 51200 4096
Attached input  policy-map: pmap1
Attached output policy-map:
Default trust: dscp
Default cos: 3
Scheduler type: drr
Wrr queue bandwidth: 1 1 1 1 2 2 2 2
Drr queue bandwidth: 1 1 2 2 2 2 4 4
Wfq queue bandwidth: 1 1 2 2 4 4 4 4
```

Table 1-3 Output Fields of the show mls qos interface Command

Field	Description
Interface	Name of an interface.
Ratelimit input	Rate limit in the input direction of the interface.
Ratelimit output	Rate limit in the output direction of the interface.
Attached input policy-map	Policy associated in the input direction of the interface.
Attached output policy-map	Policy associated in the output direction of the interface.
Default trust	Trust mode of the interface.
Default cos	Default IEEE 802.1p value of the interface.
Scheduler type	Scheduling policy of the interface.
Wrr queue bandwidth	WRR scheduling weights of the output queues of the interface.
Drr queue bandwidth	DRR scheduling weights of the output queues of the interface.
Wfq queue bandwidth	WFQ scheduling weights of the output queues of the interface.

The following example displays information about policies associated with all the interfaces.

```
Hostname> enable
Hostname# show mls qos interface policers
Interface: GigabitEthernet 0/1
Attached input  policy-map: pmap1
Attached output policy-map: pmap1
Interface: GigabitEthernet 0/2
Attached input  policy-map: p1
……
```

1.24 show mls qos maps

Function

Run the **show mls qos maps** command to display the mappings of different priorities.

Syntax

show mls qos maps [**cos-dscp** | **dscp-cos** | **ip-prec-dscp**]

Parameter Description

cos-dscp: Displays the IEEE 802.1p-to-DSCP mappings.

dscp-cos: Displays the DSCP-to-CoS mappings.

ip-prec-dscp: Displays the IP PRE-to-DSCP mappings.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

When no parameter is specified, the mappings of all the priorities are displayed.

Examples

The following example displays the IEEE 802.1p-to-DSCP mappings.

```
Hostname> enable
Hostname# show mls qos maps cos-dscp
cos dscp
```

```

1.25 show mls qos queueing

Function

Run the **show mls qos queueing** command to display the CoS-to-queue mappings and the scheduling weights of queues.

Syntax

show mls qos queueing [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Displays the information about the specified interface type and number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

When the **interface** *interface-type interface-number* parameter is not specified, the mappings from all the CoS values to queues and the scheduling weights of all the queues are displayed.

Examples

The following example displays the CoS-to-queue mappings and the scheduling weight of queues.

```
Hostname> enable
Hostname# show mls qos queueing
Cos-queue map:
cos qid
--- ---
0   1

1.26 show mls qos rate-limit

Function

Run the **show mls qos rate-limit** command to display the rate limit information of an interface.

Syntax

show mls qos rate-limit [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Displays the rate limit information of a specified interface type and number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the **interface** *interface-type interface-number* parameter is not specified, the rate limit information of all the interfaces is displayed.

Examples

The following example displays the rate limit information of all the interfaces.

```
Hostname> enable
Hostname# show mls qos rate-limit
Interface: GigabitEthernet 0/1
  rate limit input Kbps = 10240 burst = 256
```

Table 1-13 Output Fields of the show mls qos rate-limit Command

Field	Description
Interface	Interface name.
rate limit input Kbps = x burst = y	The bandwidth limit per second in the input direction of the interface is x kbps, and the burst traffic limit value is y Kbytes per second.
rate limit output Kbps = x burst = y	The bandwidth limit per second in the output direction of the interface is x kbps, and the burst traffic limit is y Kbytes per second.

1.27 show mls qos scheduler

Function

Run the **show mls qos scheduler** command to display the scheduling policy information of output queues.

Syntax

show mls qos scheduler [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Displays the scheduling policy information of the output queues of a specified interface type and number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the **interface** *interface-type interface-number* parameter is not specified, the scheduling policy information of the global output queues is displayed.

Examples

The following example displays the scheduling policy information of global output queues.

```
Hostname> enable
Hostname# show mls qos scheduler
Global Multi-Layer Switching scheduling
 Weighted Round Robin
Interface GigabitEthernet 0/1 Multi-Layer Switching scheduling:
 Deficit Round Robin
```

Table 1-14 Output Fields of the show mls qos scheduler Command

Field	Description
Weighted Round Robin	The queue scheduling policy is WRR, and the other types of scheduling policies are as follows: ● SP ● RR ● WFQ ● DRR
Interface	Interface name

The following example displays the scheduling policy of L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show mls qos scheduler interface gigabitethernet 0/1
Interface GigabitEthernet 0/1 Multi-Layer Switching scheduling:
 Deficit Round Robin
```

1.28 show mls qos virtual-group

Function

Run the **show mls qos virtual-group** command to display policies associated with a logical interface group.

Syntax

show mls qos virtual-group [*virtual-group-number* | **policers**]

Parameter Description

virtual-group-number: Number of a logical interface group. After this parameter is specified, policies associated with a specified logical interface group are displayed. The value range is from 1 to 128.

policers: Displays the policies associated with all the logical interface groups.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the *virtual-group-number* parameter is not specified, policies associated with all the logical interface groups are displayed.

Examples

The following example displays policies associated with all the logical interface groups.

```
Hostname> enable
Hostname# show mls qos virtual-group policers
Virtual-group: 1
Attached input policy-map: pmap1
Virtual-group: 20
Attached output policy-map: pmap2
```

Table 1-16 Output Fields of the show mls qos virtual-group policers Command

1.29 show policy-map

Function

Run the **show policy-map** command to display policy information.

Syntax

show policy-map [*policy-map-name* [**class** *class-map-name*]]

Parameter Description

policy-map-name: Name of a policy. The value is a case-sensitive string of 1 to 31 characters.

class *class-map-name*: Name of the class associated with the policy. The value is a case-sensitive string of 1 to 31 characters.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the *policy-map-name* parameter is not specified, information about all the policies is displayed.

Examples

The following example displays information about policy pmap1.

```
Hostname> enable
Hostname# show policy-map pmap1

 Policy Map pmap1
   Class cmap1
     set ip dscp 16
   Class cmap2
     police 10240 256 exceed-action dscp 8
   Class cmap3
     police 512000 4096 exceed-action drop
```

Table 1-17 Output Fields of the show policy-map Command

Field	Description
Policy Map	Name of a policy.
Class	Name of a class associated with the policy.
set	The bound traffic behavior is modifying the 802.1p and DSCP.
police	The bound traffic behavior is limiting the bandwidth and processing packets out of the limit.

The following example displays the policy pmap1, in which the traffic behavior bound to the class cmap1 is associated.

```
Hostname> enable
Hostname# show policy-map pmap1 class cmap1

   Class cmap1
     set ip dscp 16
```

1.30 show qos bandwidth

Function

Run the **show qos bandwidth** command to display the queue bandwidth information.

Syntax

show qos bandwidth [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Displays the queue bandwidth information of a specified interface type and number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the **interface** *interface-type interface-number* parameter is not specified, bandwidth information of all the queues is displayed.

Examples

The following example displays the bandwidth information of L2 Ethernet interface GigabitEthernet 0/1. The following information is displayed only for device interfaces that support separate configuration of bandwidths of unicast queues and multicast queues.

```
Hostname> enable
Hostname# show qos bandwidth interface gigabitethernet 0/1

Total mcast-queue maximum-bandwidth:          5120
```

Table 1-19 Output Fields of the show qos bandwidth interface Command

Field	Description
Interface	Name of an interface.
queue-id	Queue ID. It is displayed when the bandwidth of unicast and multicast queues is configured together.
uc-queue-id	Unicast queue ID. It is displayed when the bandwidth of unicast queues is configured separately.

Field	Description
mc-queue-id	Multicast queue ID. It is displayed when the bandwidth of multicast queues is configured separately.
minimum-bandwidth	Minimum guaranteed bandwidth, in Kbytes per second.
maximum-bandwidth	Maximum limited bandwidth, in Kbytes per second.
Total queue minimum-bandwidth	Sum of the minimum guaranteed bandwidths configured for all the queues. It is displayed when the bandwidth of unicast and multicast queues is configured together.
Total queue maximum-bandwidth	Sum of the maximum limited bandwidths configured for all the queues. It is displayed when the bandwidth of unicast and multicast queues is configured together.
Total ucast-queue minimum-bandwidth	Sum of the minimum guaranteed bandwidths configured for all the unicast queues. It is displayed when the bandwidth of unicast queues is configured separately.
Total ucast-queue maximum-bandwidth	Sum of the maximum limited bandwidths configured for all the unicast queues. It is displayed when the bandwidth of unicast queues is configured separately.

1.31 show queueing wred

Function

Run the **show queueing wred** command to display WRED information.

Syntax

show queueing wred [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Displays the WRED information of a specified interface type and number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the **interface** *interface-type interface-number* parameter is not specified, the WRED information configured for all the interfaces is displayed.

Examples

The following example displays the WRED information configured for L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show queueing wred interface gigabitethernet 0/1
---  --------- ---------- ----- ----- ------  --------- ---------- ----- ----- ------
qid  max_cell_1 min_cell 1 max_1 min_1 prob_1 max_cell_2 min_cell 2  max_2 min_2 prob_2
---  --------- ---------- ----- ----- ------  --------- ---------- ----- ----- ------
1    120000     120000    100   30    100    120000     120000     100   70    100
2    120000     120000    100   60    100    120000     120000     100   30    100
3    120000     120000    100   80    30     120000     120000     100   30    40
4    120000     120000    100   80    100    120000     120000     100   100   100
5    120000     120000    100   80    100    120000     120000     100   100   100
6    120000     120000    100   80    100    120000     120000     100   100   100
7    120000     120000    100   80    100    120000     120000     100   100   100

1.32 show virtual-group

Function

Run the **show virtual-group** command to display information about members contained in a logical interface group.

Syntax

show virtual-group [*virtual-group-number* | **summary**]

Parameter Description

virtual-group-number: Number of a logical interface group. After this parameter is specified, information about members contained in a specified logical interface group is displayed. The value range is from 1 to 128.

summary: Displays information about members contained in all the logical interface groups.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If the *virtual-group-number* parameter is not specified, information about members contained in all the logical interface groups is displayed.

Examples

The following example displays information about members contained in all the logical interface groups.

```
Hostname> enable
Hostname# show virtual-group summary
```

```
virtual-group       member
-------------       ------------------------
1                    Gi0/1 Gi0/2
2                    Gi0/0
```

Table 1-21 Output Fields of the show virtual-group summary Command

Field	Description
virtual-group	Number of a logical Interface group.
member	Member interface in the logical interface group.

1.33 virtual-group

Function

Run the **virtual-group** command to create a logical interface group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No logical interface group is created by default.

Syntax

virtual-group *virtual-group-number*

no virtual-group *virtual-group-number*

default virtual-group *virtual-group-number*

Parameter Description

virtual-group-number: Number of a logical interface group. The value range is from 1 to 128.

Command Modes

Global configuration mode

L2 Ethernet interface configuration mode

L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

In the global configuration mode, you can run this command to create a logical interface group and enter the logical interface group configuration mode.

In the L2/L3 Ethernet interface configuration mode, you can run this command to add the interface to a logical interface group. If the logical interface group is created, this command creates the logical interface group and adds the interface to the logical interface group.

Members to be added to a logical interface group must be physical interfaces or aggregation ports. The members of a logical interface group must be in the same line card or the same device.

Examples

The following example adds L2 Ethernet interface GigabitEthernet 0/1 to logical interface group 3.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# virtual-group 3
```

1.34 wfq-queue bandwidth

Function

Run the **wfq-queue bandwidth** command to configure the WFQ scheduling weights for output queues.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default WFQ scheduling weight ratio of output queues is **1:1:1:1:1:1:1:1**.

Syntax

wfq-queue bandwidth *weight-value-list*

no wfq-queue bandwidth

default wfq-queue bandwidth

Parameter Description

weight-value-list: WFQ scheduling weights for output queues. The weight value range is from 0 to 15. The value **0** indicates that the SP scheduling policy is used.

Command Modes

Global configuration mode

L2 Ethernet interface configuration mode

L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

When the WFQ scheduling weights are configured for output queues in both global configuration mode and L2/L3 Ethernet interface configuration mode, the interface configuration prevails.

Examples

The following example sets the WFQ scheduling weight ratio of global output queues to **1:1:2:4:4:4:6:8**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# wfq-queue bandwidth 1 1 2 4 4 4 6 8
```

The following example sets the WFQ scheduling weight ratio of output queues on L2 Ethernet interface GigabitEthernet 0/1 to **1:1:2:2:2:2:4:4**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# wfq-queue bandwidth 1 1 2 2 2 2 4 4
```

1.35 wrr-queue bandwidth

Function

Run the **wrr-queue bandwidth** command to configure the WRR scheduling weights for output queues.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default WRR scheduling weight ratio of output queues is **1:1:1:1:1:1:1:1**.

Syntax

wrr-queue bandwidth *weight-value-list*

no wrr-queue bandwidth

default wrr-queue bandwidth

Parameter Description

weight-value-list: WRR scheduling weights of output queues. The weight value range is from 0 to 15. The value **0** indicates that the SP scheduling policy is used.

Command Modes

Global configuration mode

L2 Ethernet interface configuration mode
L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

When the WRR scheduling weights are configured for output queues in both global configuration mode and L2/L3 Ethernet interface configuration mode, the interface configuration prevails.

Examples

The following example sets the WRR scheduling weight ratio of global output queues to **1:1:1:2:2:2:4:8**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# wrr-queue bandwidth 1 1 1 1 2 2 4 8
```

The following example sets the WRR scheduling weight ratio of output queues on L2 Ethernet interface GigabitEthernet 0/1 to **1:1:2:2:2:2:4:4**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# wrr-queue bandwidth 1 1 2 2 2 2 4 4
```

1.36 wrr-queue cos-map

Function

Run the **wrr-queue cos-map** command to configure the mappings from CoS values to threshold groups.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

All CoS values are mapped to threshold group 1 by default.

Syntax

wrr-queue cos-map *threshold-id cos*&<1-8>

no wrr-queue cos-map *threshold-id*

default wrr-queue cos-map *threshold-id*

Parameter Description

threshold-id: ID of a threshold group. Two threshold groups are supported. The value range is from 1 to 2.

cos&<1-8>: CoS value. &<1-8> indicates that you can configure the mappings from 1–8 CoS values to threshold groups. The value range is from 0 to 7.

Command Modes

L2 Ethernet interface configuration mode
L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

You can run the **mls qos map dscp-cos** and **wrr-queue cos-map** commands to configure DSCP-to-threshold mappings. When all the CoS values are mapped to the same threshold group, the enabled WRED on the interface is changed to RED.

Examples

The following example maps CoS values 1 and 6 to threshold group 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# wrr-queue cos-map 2 1 6
```

1.37 wrr-queue random-detect min-threshold

Function

Run the **wrr-queue random-detect min-threshold** command to configure the lower threshold value for WRED to discard packets.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The lower threshold value for WRED to discard packets is not configured by default.

Syntax

wrr-queue random-detect min-threshold *queue-id* [*threshold*&<1-2>]

no wrr-queue random-detect min-threshold *queue-id*

default wrr-queue random-detect min-threshold *queue-id*

Parameter Description

queue-id: ID of an interface queue. The value range is from 1 to 8.

threshold&<1-2>: Lower threshold value for WRED to discard packets, in percentage. &<1-2> indicates that you can configure 1 to 2 groups of lower threshold values. The value range is from 1 to 100.

Command Modes

L2 Ethernet interface configuration mode
L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

The maximum value of the configuration range of the lower threshold is equal to the current higher threshold. When configuring a lower threshold, pay attention to the configuration of the higher threshold.

Examples

The following example sets the two groups of lower thresholds to 60 and 70 respectively for queue 1 of L2 Ethernet interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# wrr-queue random-detect min-threshold 1 60
70
```

Run the **wrr-queue random-detect probability** command to configure the maximum discarding probability for WRED.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The maximum discarding probability for WRED is not configured by default.

Syntax

wrr-queue random-detect probability *queue-id probability*&<1-2>

no wrr-queue random-detect probability *queue-id*

default wrr-queue random-detect probability *queue-id*

Parameter Description

queue-id: ID of an interface queue. The value range is from 1 to 8.

probability&<1-2>: Maximum discarding probability of WRED, in percentage. &<1-2> indicates that you can configure 1 to 2 groups of maximum discarding probabilities. The value range is from 1 to 100.

Command Modes

L2 Ethernet interface configuration mode
L3 Ethernet interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the two groups of maximum discarding probabilities to 50 and 70 respectively for queue 1 of L2 Ethernet interface GigabitEthernet 0/1.

```

1 MMU Commands

Command	Function
mmu buffer-mode	Configure the global buffer mode.
mmu queue-guarantee	Configure a guaranteed buffer for a queue.
mmu queue-threshold	Configure a shared buffer threshold for a queue.
mmu fc-threshold	Configure a flow control threshold for a port.
mmu sample-period	Configure the monitoring data sampling period.
mmu usage-warn-limit	Configure a buffer utilization alarm threshold.
clear queue-counter	Clear the packet statistics of queues.
clear queue-buffer peaked	Clear the historical buffer utilization peak values of queues.
show queue-buffer	Display the buffer utilization information of a queue.
show queue-counter	Display the packet statistics of queues.
show mmu buffer-mode	Display the current buffer mode.

1.1 mmu buffer-mode

Function

Run the **mmu buffer-mode** command to configure the global buffer mode.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The default global buffer mode is **flowctrl-enhance**.

Syntax

mmu buffer-mode { **burst-enhance** | **flowctrl-enhance** | **normal** | **qos-enhance** }

no mmu buffer-mode

default mmu buffer-mode

Parameter Description

burst-enhance: Supports burst enhancement.

flowctrl-enhance: Supports flow control enhancement.

normal: Provides relatively fair support for flow control, burst, and QoS.

qos-enhance: Supports QoS enhancement.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the buffer mode to flow control mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mmu buffer-mode flowctrl-enhance
```

1.2 mmu queue-guarantee

Function

Run the **mmu queue-guarantee** command to configure a guaranteed buffer for a queue.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The guaranteed buffer for a queue is not configured by default.

Syntax

mmu queue-guarantee output unicast [*queue-id*&<1-8>] **set** *value*

no mmu queue-guarantee output unicast [*queue-id*&<1-8>]

default mmu queue-guarantee output unicast [*queue-id*&<1-8>]

Parameter Description

output: Performs buffer management on the egress queues.

unicast: Performs buffer management on the egress unicast queues.

queue-id&<1-8>: Queue ID. &<1-8> means that 1 to 8 queue IDs can be configured.

set *value*: Configures the guaranteed buffer of queue, in the unit of cell. The value range is from 1 to 50.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the parameter *queue-id*&<1-8> is not specified, all queues will be configured with the guaranteed buffer.

Examples

The following example sets the guaranteed buffer to 10 cells for unicast queue 1 on interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mmu queue-guarantee output unicast 1 set 10
Hostname(config-if-GigabitEthernet 0/1)# mmu queue-guarantee output multicast 1 set 10

1.3 mmu queue-threshold

Function

Run the **mmu queue-threshold** command to configure a shared buffer threshold for a queue.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The shared buffer threshold for a queue is not configured by default.

Syntax

mmu queue-threshold output unicast [*queue-id*&<1-8>] **set** *threshold*

no mmu queue-threshold output unicast [*queue-id*&<1-8>]

default mmu queue-threshold output unicast [*queue-id*&<1-8>]

Parameter Description

output: Performs buffer management on the egress queues.

unicast: Performs buffer management on the egress unicast queues.

queue-id&<1-8>: Queue ID. &<1-8> means that 1 to 8 queue IDs can be configured.

set value: Configures the shared buffer threshold for a queue, in the unit of percentage. The value range is from 1 to 100.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the parameter *queue-id*&<1-8> is not specified, all queues will be configured with the shared buffer threshold.

Examples

The following example sets the shared buffer threshold proportion to 80% for unicast queue 1 on interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mmu queue-threshold output unicast 1 set 80
```

1.4 mmu fc-threshold

Function

Run the **mmu fc-threshold** command to configure a flow control threshold for a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The flow control threshold for a port is not configured by default.

Syntax

mmu fc-threshold set *threshold*

no mmu fc-threshold

default mmu fc-threshold

Parameter Description

set *threshold*: Configures a flow control threshold for a port, in percentage. The value range is from 1 to 100.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The configuration takes effect only when flow control/priority-based flow control (PFC) is enabled on the port.

Examples

The following example sets the flow control threshold to 20% for interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mmu fc-threshold set 20

1.6 mmu usage-warn-limit

Function

Run the **mmu usage-warn-limit** command to configure a buffer utilization alarm threshold.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

The buffer utilization alarm threshold is not configured by default.

Syntax

(Global configuration mode)

mmu usage-warn-limit set *threshold*

no mmu usage-warn-limit

default mmu usage-warn-limit

(Interface configuration mode)

mmu usage-warn-limit unicast [*queue-id*&<1-8>] **set** *threshold*

no mmu usage-warn-limit unicast [*queue-id*&<1-8>]]

default mmu usage-warn-limit unicast [*queue-id*&<1-8>]]

Parameter Description

unicast: Configures the buffer utilization alarm threshold for egress unicast queues.

queue-id&<1-8>: Queue ID. &<1-8> means that 1 to 8 queue IDs can be configured.

set value: Configures the buffer utilization alarm threshold for a queue, in the unit of percentage. The value range is from 1 to 100.

Command Modes

Global configuration mode

Interface configuration mode

Default Level

14

Usage Guidelines

If the parameter *queue-id*&<1-8> is not specified, all queues will be configured with the buffer utilization alarm threshold.

The buffer utilization alarm threshold of port groups or slices takes effect for all the port groups or slices. To prevent frequent log refreshing, the alarm logs of the same port group, slice, port, or queue are printed once in 30s at most. The maximum printing interval depends on the configured sampling period.

Examples

The following example sets the buffer utilization alarm threshold to 80% for slices.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mmu usage-warn-limit set 80
```

The following example sets the buffer utilization alarm threshold to 70% for unicast queues 6 and 7 on interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mmu usage-warn-limit unicast 6 7 set 70
```

Table 1-1 Output Fields of the show queue-buffer interface Command, Displayed Based on Egress Queues

Field	Description
Dev/Slot	Device/Slot ID. ● For a box-type device, the value is displayed in the format of device ID/-.
Port-Group	Port group ID.
Total-shared	Percentage of the buffer that can be shared by the port group relative to the total buffer resource of the port group.
Guarantee-used	Percentage of the guaranteed buffer that has been used by the port group relative to the total buffer resource of the port group.
Share-used	Percentage of the shared buffer that has been used by the port group relative to the total buffer resource of the port group.
Available	Percentage of the remaining buffer that can be shared by the port group relative to the total buffer resource of the port group, or percentage of buffer currently available for a queue. Since multiple queues are preempting the shared buffer, the size of the buffer that can be requested by a queue is smaller than or equal to the **Available** value.
Warn-limit	Buffer utilization alarm threshold of the specified port group or a queue.

Field	Description
Type	Queue type: ● Unicast: Indicates a unicast queue. ● Multicast: Indicates a multicast queue.
Queue	Queue ID.
Total-used	Percentage of the buffer used in the queue, including the guaranteed buffer and shared buffer, relative to the total buffer resource of the port group.
Peak-usage	Historical buffer utilization peak value, in percentage.
Peak-time	Time corresponding to the utilization peak value.
NA	No data.

The following example displays the buffer usage information of all the ports, summarizing the queue statistics of all the ports.

```
Hostname> enable
Hostname# show queue-buffer interface
Dev/slot   Port-group   Total-shared(%)   Guarantee-used(%)   Share-used(%)
Available(%)   Warn-limit(%)
1/-       1           84.7348          0.0000            0.0000         100.0000
NA

Interface    Total-used(%)        available(%)

Hu0/8        0.0000              67.8248
Hu0/9        0.0000              67.8248
…
```

Table 1-2 Output Fields of the show queue-buffer interface Command, Displayed Based on Ports

Field	Description
Dev/Slot	Device/Slot ID. ● For the box-type device, the display format is device ID/-.

Field	Description
Port-Group	Port group ID.
Total-shared	Percentage of the buffer that can be shared by the port group relative to the total buffer resource of the port group.
Guarantee-used	Percentage of the guaranteed buffer that has been used by the port group relative to the total buffer resource of the port group.
Share-used	Percentage of the shared buffer that has been used by the port group relative to the total buffer resource of the port group.
Available	Percentage of the remaining buffer that can be shared by the port group relative to the total buffer resource of the port group.
Warn-limit	Buffer utilization alarm threshold of the specified port group.
Interface	Interface.
Total-used	Percentage of the total buffer that has been used by all queues of the port, relative to the total buffer resource of the port group.
available	Percentage of the maximum available buffer in the queues of the port, relative to the total buffer resource of the port group.

1.10 show queue-counter

Function

Run the **show queue-counter** command to display the packet statistics of queues.

Syntax

show queue-counter [**interface** [*interface-type interface-number*]]

Parameter Description

interface: Displays the packet statistics of queues on all the interfaces.

interface-type interface-number: Interface type and interface number. After this parameter is specified, the packet statistics of queues of a specified interface type and number are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

Table 1-3 Output Fields of the show queue-counter interface Command, Displayed Based on Egress Queues

Field	Description
Unicast	Unicast queue.
Multicast	Multicast queue.
Queue	Queue ID.
Transmitted Bytes	Number of bytes that have been forwarded by the specified queue.
Dropped Bytes	Number of bytes that have been dropped by the specified queue.
Transmitted Packets	Number of packets that have been forwarded by the specified queue.
Dropped Packets	Number of packets that have been dropped by the specified queue.
Transmit Rate(bps)	Average forwarding rate (bps) of the specified queue in a period of time (longer than or equal to the sampling period). The rate is calculated with the interframe gap included, and the value has a certain margin of calculation error.
Transmit Rate(pps)	Average forwarding rate (packets per second) of the specified queue in a period of time (longer than or equal to the sampling cycle). The value has a certain margin of calculation error.
Loss Rate(%)	Loss rate of bytes or packets of the specified queue. ● Byte loss rate = Number of lost bytes/(Number of lost bytes + Number of forwarded bytes). ● Packet loss rate = Number of lost packets/(Number of lost packets + Number of forwarded packets).
Loss Rate Peak(%)	Historical peak value of the loss rate.
Loss Peak Time	Time point, at which the historical peak value of the loss rate occurs.
NA	No data.

The following example displays the packet statistics of all the ports, summarizing the queue statistics of all the ports.

```
Hostname> enable

```

...

Table 1-4 Output Fields of the show queue-counter multicast Command, Displayed Based on Ports

Field	Description
Interface	Interface.
Transmitted Bytes	Total number of bytes that have been forwarded by all the queues of the port.
Dropped Bytes	Total number of bytes that have been dropped by all the queues of the port.
Transmitted Packets	Total number of packets that have been forwarded by all the queues of the port.
Dropped Packets	Total number of packets that have been dropped by all the queues of the port.
Transmit Rate(bps)	Average forwarding rate (bps) of all the queues on the port in a period of time (longer than or equal to the sampling period). The rate is calculated with the interframe gap included and the value has a certain margin of calculation error.
Transmit Rate(pps)	Average forwarding rate (packets per second) of all the queues on the port in a period of time (longer than or equal to the sampling period). The value has a certain margin of calculation error.
Loss Rate(%)	Total loss rate of bytes or packets of all the queues on the port. ● Byte loss rate = Number of lost bytes/(Number of lost bytes + Number of forwarded bytes). ● Packet loss rate = Number of lost packets/(Number of lost packets + Number of forwarded packets).

Security Commands

1 AAA Commands

Command	Function
aaa accounting commands	Configure a command accounting method list.
aaa accounting exec	Configure an EXEC accounting method list.
aaa accounting network	Configure a network accounting method list.
aaa accounting start-fail	Configure the user online/offline status after an accounting start failure.
aaa accounting update	Enable accounting update.
aaa accounting update periodic	Configure an accounting update interval.
aaa authentication dot1x	Configure an IEEE 802.1X authentication method list.
aaa authentication ftp	Configure a method list for File Transfer Protocol (FTP) authentication.
aaa authentication enable default	Configure the default method list for Enable authentication.
aaa authentication general	Configure a general authentication method list.
aaa authentication login	Configure a login authentication method list.
aaa authentication web-auth	Configure a 2nd-generation Web authentication method list.

aaa authorization config-commands	Enable command authorization in configuration modes (including global configuration mode and their submodes).
aaa authorization console	Enable command authorization for users who log in through the console.
aaa authorization exec	Configure an EXEC authorization method list.
aaa authorization network	Configure a network authorization method list.
aaa command-author cache	Enable the function of caching command authorization results.
aaa domain	Create a domain and enter the domain configuration mode.
aaa domain enable	Enable the domain-based AAA services.
aaa heartbeat enable	Enable AAA heartbeat service.
aaa local authentication attempts	Configure the maximum number of consecutive failed login attempts.
aaa local authentication lockout-time	Configure the account lockout duration after the number of consecutive failed login attempts of a user reaches the configured value.
aaa local user allow public account	Enable the function of allowing multiple clients to share a Web-authenticated local account.
aaa log enable	Enable AAA authentication logging.
aaa log rate-limit	Configure the rate of AAA user authentication success logging.

aaa new-model	Enable AAA security services.
aaa user-role default	Configure the default role for AAA authorized users.
access-limit	Configure a limit on the number of users supported in a domain.
accounting network	Configure a network accounting method list for an AAA domain.
accounting commands	Configure a command accounting method list for an AAA domain.
accounting exec	Configure an EXEC accounting method list for an AAA domain.
authentication dot1x	Configure an IEEE 802.1X authentication method list for an AAA domain.
authentication login	Configure a login authentication method list for an AAA domain.
authentication enable	Configure an Enable authentication method list for an AAA domain.
authorization network	Configure a network authorization method list for an AAA domain.
authorization commands	Configure a command authorization method list for an AAA domain.
authorization exec	Configure an EXEC authorization method list for an AAA domain.
clear aaa local user lockout	Clear the list of locked users.

show aaa accounting update	Display accounting update information.
show aaa domain	Display information about a configured domain.
show aaa lockout	Display lockout parameter configuration in the current login authentication.
show aaa group	Display all AAA server groups.
show aaa method-list	Display all AAA method lists.
show aaa user	Display information about an AAA user.
state	Configure the status of a domain.
username-format	Configure whether usernames carry domain name information during interaction between the device and the server.

Note

- Before configuring authentication, authorization and accounting (AAA) commands, run the **aaa new-model** command to enable AAA security services.
- If there are multiple methods in the authentication, authorization, or accounting method list, the methods are applied based on their sequence in the method list. The device switches to the next method only when a method fails to respond.

1.1 aaa accounting commands

Function

Run the **aaa accounting commands** command to configure a command accounting method list.

Run the **no** form of this command to remove this configuration.

No command accounting method list is configured by default.

Syntax

aaa accounting commands *level* { **default** | *list-name* } **start-stop** *method*&<1-4>

no aaa accounting commands *level* { **default** | *list-name* }

Parameter Description

level: Level of commands, for which accounting needs to be performed. Information will be recorded when a command of the configured level is executed. The value range is from 0 to 15.

default: Defines the default command accounting method list.

list-name: Name of a command accounting method list. The value is a string of 1 to 63 characters.

method&<1-4>: Command accounting method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for accounting. Only Terminal Access Controller Access-Control System Plus (TACACS+) server groups are supported. You can enter this type parameter 0–4 times in this command.

- **group tacacs+**: Uses all TACACS+ servers for accounting. You can enter this type parameter only once in this command.
- **none**: Indicates no accounting. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A configured command accounting method must be applied to a line that needs command accounting so that the method takes effect.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

If the role-based access control (RBAC) function is enabled, this command is unavailable.

Command accounting can be enabled for a user only after the user passes login authentication. If a user is not authenticated or is exempt from authentication during login, command accounting is not performed. After command accounting is enabled, the device records information about the commands of a specified level run by a user each time and sends it to the security server for accounting and user activity management.

Examples

The following example configures the default command accounting method, in which all TACACS+ servers are used to perform accounting on commands of level 15 run by users who log in to the network access server (NAS).

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa accounting commands 15 default start-stop group tacacs+
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed.
```

When the configured group type does not support the accounting type, the following notification will be displayed:

```
The accounting does not support this type of group
```

Common Errors

N/A

Platform Description

N/A

Related Commands

1.2 aaa accounting exec

Function

Run the **aaa accounting exec** command to configure an EXEC accounting method list.

Run the **no** form of this command to remove this configuration.

No EXEC accounting method list is configured by default.

Syntax

aaa accounting exec { **default** | *list-name* } **start-stop** *method*&<1-4>

no aaa accounting exec { **default** | *list-name* }

Parameter Description

default: Defines the default EXEC accounting method list.

list-name: Name of an EXEC accounting method list. The value is a string of 1 to 63 characters.

method&<1-4>: EXEC accounting method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for accounting. Only the Remote Authentication Dial-In User Service (RADIUS) and TACACS+ server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for accounting. You can enter this type parameter only once in this command.
- **group tacacs+**: Uses all TACACS+ servers for accounting. You can enter this type parameter only once in this command.
- **none**: Indicates no accounting. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After accounting is enabled, the NAS sends an accounting start message to the security server when a user logs in to the NAS CLI, and sends an accounting stop message to the security server when the user logs out. If the NAS does not send an accounting start message when a user logs in, it will not send an accounting stop message when the user logs out.

A configured EXEC accounting method must be applied to a line that needs EXEC accounting. Otherwise, the method does not take effect.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

EXEC accounting can be enabled for a user only after the user passes login authentication. If a user is not authenticated during login or the **none** authentication method is adopted, EXEC accounting will not be performed.

Examples

The following example configures the default EXEC accounting method list, in which all RADIUS server groups are used to perform accounting on access activities of users who log in to the NAS, and send accounting packets at user login and logout.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa accounting exec default start-stop group radius
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed
```

When the configured group type does not support the accounting type, the following notification will be displayed:

```
The accounting does not support this type of group
```

Common Errors

1.3 aaa accounting network

Function

Run the **aaa accounting network** command to configure a network accounting method list.

Run the **no** form of this command to remove this configuration.

No network accounting method list is configured by default.

Syntax

aaa accounting network { **default** | *list-name* } **start-stop** *method*&<1-4>

no aaa accounting network { **default** | *list-name* }

Parameter Description

default: Defines the default network accounting method list.

list-name: Name of a network accounting method list. The value is a string of 1 to 63 characters.

method&<1-4>: Network accounting method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for accounting. Only the RADIUS and TACACS+ server groups are supported. You can enter this parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for accounting. You can enter this type parameter only once in this command.
- **group tacacs+**: Uses all TACACS+ servers for accounting. You can enter this type parameter only once in this command.
- **none**: Indicates no accounting. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Accounting packets are sent when a user starts and ends the access. The accounting start packet indicates that a user is allowed to access the network regardless of whether accounting is successfully enabled.

Examples

The following example configures the default network accounting method list, in which all RADIUS servers are used to perform accounting on network service requests of users, and send accounting packets when the user access activity starts and ends.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa accounting network default start-stop group radius
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed
```

When the configured group type does not support the accounting type, the following notification will be displayed:

```
The accounting does not support this type of group
```

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Common Errors

1.4 aaa accounting start-fail

Function

Run the **aaa accounting start-fail** command to configure the user online/offline status after an accounting start failure.

Run the **no** form of this command to restore the default configuration.

The user online/offline status after an accounting start failure is not configured by default.

Syntax

aaa accounting start-fail { **offline** | **online** }

no aaa accounting start-fail

Parameter Description

offline: Sets the accounting start failure policy to offline.

online: Sets the accounting start failure policy to online.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure a policy for user accounting start failures and specify the user online/offline status after the user accounting start fails.

Examples

The following example sets the user status after an accounting start failure to offline.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa accounting start-fail offline
```

1.6 aaa accounting update periodic

Function

Run the **aaa accounting update periodic** command to configure an accounting update interval.

Run the **no** form of this command to restore the default configuration.

The default accounting update interval is **5** minutes.

Syntax

aaa accounting update periodic *interval*

no aaa accounting update periodic

Parameter Description

interval: Accounting update interval, in minutes. The value range is from 1 to 525600.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

It is recommended that the accounting update interval not be configured unless otherwise specified.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example sets the accounting update interval to **1** minute.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa new-model
Hostname(config)# aaa accounting update
Hostname(config)# aaa accounting update periodic 1
```

1.7 aaa authentication dot1x

Function

Run the **aaa authentication dot1x** command to configure an IEEE 802.1X authentication method list.

Run the **no** form of this command to remove this configuration.

No IEEE 802.1X authentication method list is configured by default.

Syntax

aaa authentication dot1x { **default** | *list-name* } *method*&<1-4>

no aaa authentication dot1x { **default** | *list-name* }

Parameter Description

default: Defines the default IEEE 802.1X authentication method list.

list-name: Name of an IEEE 802.1X authentication method list. The value is a string of 1 to 63 characters.

method&<1-4>: IEEE 802.1X authentication method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for authentication. Only RADIUS server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for authentication. You can enter this type parameter only once in this command.
- **local**: Uses the local user database for authentication. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.
- **none**: Indicates no authentication. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the IEEE 802.1X authentication service is enabled on the device, IEEE 802.1X authentication must be performed when a user accesses the device network. You can configure this command to provide a method list for IEEE 802.1X authentication. An IEEE 802.1X authentication method needs to be applied so that the method takes effect.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures an IEEE 802.1X authentication method list named **rds_d1x**, in which a RADIUS server is used for authentication first, and the local user database is used for authentication if no response is received from the RADIUS server within a period of time.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authentication dot1x rds_d1x group radius local
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed
```

When the configured group type does not support the authentication type, the following notification will be displayed:

```
The authentication does not support this type of group
```

1.8 aaa authentication ftp

Function

Run the **aaa authentication ftp** command to configure a method list for File Transfer Protocol (FTP) authentication.

Run the **no** form of this command to remove this configuration.

No FTP authentication method list is configured by default.

Syntax

aaa authentication ftp { **default** | *list-name* } *method*&<1-4>

no aaa authentication ftp { **default** | *list-name* }

Parameter Description

default: Defines the default FTP authentication method list.

list-name: Name of an FTP authentication method list. The value is a string of 1 to 63 characters.

method&<1-4>: FTP authentication method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for authentication. Only the RADIUS and TACACS+ server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for authentication. You can enter this type parameter only once in this command.
- **group tacacs+**: Uses all TACACS+ servers for authentication. You can enter this type parameter only once in this command.
- **local**: Uses the local user database for authentication. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.

- **none**: Indicates no authentication. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the AAA FTP security service is enabled on the device, FTP authentication must be performed through AAA when an FTP user accesses the device.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures an FTP authentication method list named **rds_ftp**, in which a RADIUS server is used for authentication first, and the local user database is used for authentication if no response is received from the RADIUS server within a period of time.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authentication ftp rds_ftp group radius local
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

1.9 aaa authentication enable default

Function

Run the **aaa authentication enable default** command to configure the default method list for Enable authentication.

Run the **no** form of this command to remove this configuration.

No default method list for Enable authentication is configured by default.

Syntax

aaa authentication enable default *method*&<1-4>

no aaa authentication enable default

Parameter Description

method&<1-4>: Configured Enable authentication method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **enable**: Uses the Enable server for authentication. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.
- **group** *group-name*: Uses a server group for authentication. Only the RADIUS and TACACS+ server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for authentication. You can enter this type parameter only once in this command.
- **group tacacs+**: Uses all TACACS+ servers for authentication. You can enter this type parameter only once in this command.

- **local**: Uses the local user database for authentication. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.
- **none**: Indicates no authentication. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the AAA Enable authentication service is enabled on the device, users must perform Enable authentication through AAA.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures the default method list for Enable authentication, in which a RADIUS server is used for authentication first, and the local user database is used for authentication if no response is received from the RADIUS server within a period of time.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authentication enable default group radius local

Function

Run the **aaa authentication general** command to configure a general authentication method list.

Run the **no** form of this command to remove this configuration.

No general authentication method list is configured by default.

Syntax

aaa authentication general { **default** | *list-name* } *method*&<1-4>

no aaa authentication general { **default** | *list-name* }

Parameter Description

default: Defines the default general authentication method list.

list-name: Name of a general authentication method list. The value is a string of 1 to 63 characters.

method&<1-4>: General authentication method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for authentication. Only RADIUS server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for authentication. You can enter this type parameter only once in this command.

- **local**: Uses the local user database for authentication. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.
- **none**: Indicates no authentication. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If both IEEE 802.1X authentication and Web authentication are used on the device and the configured authentication methods are the same, you can configure a general authentication method for them together. If both an IEEE 802.1X authentication method (or Web authentication method) and a general authentication method are configured, the IEEE 802.1X authentication method (or Web authentication method) is preferred.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures a general authentication method list, in which a RADIUS server is used for authentication first, and the local user database is used for authentication if no response is received from the RADIUS server within a period of time.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authentication general default group radius local
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed
```

When the configured group type does not support the authentication type, the following notification will be displayed:

```
The authentication does not support this type of group
```

1.11 aaa authentication login

Function

Run the **aaa authentication login** command to configure a login authentication method list.

Run the **no** form of this command to remove this configuration.

No login authentication method list is configured by default.

Syntax

aaa authentication login { **default** | *list-name* } *method*&<1-4>

no aaa authentication login { **default** | *list-name* }

Parameter Description

default: Defines the default login authentication method list.

list-name: Name of a login authentication method list. The value is a string of 1 to 63 characters.

method&<1-4>: Login authentication method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for authentication. Only the RADIUS and TACACS+ server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for authentication. You can enter this type parameter only once in

this command.

- **group tacacs+**: Uses all TACACS+ servers for authentication. You can enter this type parameter only once in this command.
- **local**: Uses the local user database for authentication. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.
- **none**: Indicates no authentication. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the AAA login authentication security service is enabled on the device, users must perform login authentication through AAA upon login.

A configured login authentication method must be applied to a line that needs login authentication. Otherwise, the method does not take effect.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures a login authentication method list named **list-1**, in which a RADIUS server is used for authentication first, and the local user database is used for authentication if no response is received from the RADIUS server within a period of time.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authentication login list-1 group radius local
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed
```

When the configured group type does not support the authentication type, the following notification will be displayed:

```
The authentication does not support this type of group
```

Function

Run the **aaa authentication web-auth** command to configure a 2nd-generation Web authentication method list.

Run the **no** form of this command to remove this configuration.

No 2nd-generation Web authentication method list is configured by default.

Syntax

aaa authentication web-auth { **default** | *list-name* } *method*&<1-4>

no aaa authentication web-auth { **default** | *list-name* }

Parameter Description

default: Defines the default 2nd-generation Web authentication method list.

list-name: Name of a 2nd-generation Web authentication method list. A maximum of four methods can be configured in a method list. The value is a string of 1 to 63 characters.

method&<1-4>: 2nd-generation Web authentication method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

group *group-name*: Uses a server group for authentication. Only RADIUS server groups are supported. You can enter this type parameter 0–4 times in this command.

group radius: Uses all RADIUS servers for authentication. You can enter this type parameter only once in this command.

local: Uses the local user database for authentication. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.

none: Indicates no authentication. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the 2nd-generation Web authentication service is enabled on the device, 2nd-generation Web authentication must be performed when a user accesses the device.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures a 2nd-generation Web authentication method list named **rds_web**, in which a RADIUS server is used for authentication first, and user packets are allowed to pass through and users pass authentication if no response is received from the RADIUS server within a period of time.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# aaa authentication web-auth rds_web group radius none
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed
```

When the configured group type does not support the authentication type, the following notification will be displayed:

1.13 aaa authorization config-commands

Function

Run the **aaa authorization config-commands** command to enable command authorization in configuration modes (including global configuration mode and their submodes).

Run the **no** form of this command to disable this feature.

Command authorization in configuration modes is disabled by default.

Syntax

aaa authorization config-commands

no aaa authorization config-commands

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If you need to grant authorization to commands only in non-configuration modes (such as privileged EXEC mode), use the **no** form of this command to disable command authorization in configuration modes, that is, commands in configuration modes and their submodes can be executed without authorization.

Examples

The following example enables command authorization in configuration modes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authorization config-commands
```

Notifications

1.14 aaa authorization console

Function

Run the **aaa authorization console** command to enable command authorization for users who log in through the console.

Run the **no** form of this command to disable this feature.

Command authorization is disabled for users who log in through the console by default.

Syntax

aaa authorization console

no aaa authorization console

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The device differentiates users who log in through the console from those who log in through other terminals. This command is used to enable command authorization for users who log in through the console.

If command authorization is disabled for users who log in through the console, the command authorization method list that has been applied to the console line is invalidated.

Examples

The following example enables command authorization for users who log in through the console.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# aaa authorization console
```

1.15 aaa authorization exec

Function

Run the **aaa authorization exec** command to configure an EXEC authorization method list.

Run the **no** form of this command to remove this configuration.

No EXEC authorization method list is configured by default.

Syntax

aaa authorization exec { **default** | *list-name* } *method*&<1-4>

no aaa authorization exec { **default** | *list-name* }

Parameter Description

default: Defines the default EXEC authorization method list.

list-name: Name of an EXEC authorization method list. A maximum of four methods can be configured in a method list. The value is a string of 1 to 63 characters.

method&<1-4>: EXEC authorization method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for authorization, Only the RADIUS and TACACS+ server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for authorization. You can enter this type parameter only once in this command.
- **group tacacs+**: Uses all TACACS+ servers for authorization. You can enter this type parameter only once in this command.
- **local**: Uses the local user database for authorization. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.
- **none**: Indicates no authorization. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The device allows granting CLI permissions (levels 0 to 15) to users who log in to the CLI. EXEC authorization is performed only on users who pass login authentication. If a user fails in EXEC authorization, the user cannot open the CLI.

A configured EXEC authorization method must be applied to a line that needs EXEC authorization. Otherwise, the method does not take effect.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures the default EXEC authorization method list, in which RADIUS servers are used for EXEC authorization.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authorization exec default group radius
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed

1.16 aaa authorization network

Function

Run the **aaa authorization network** command to configure a network authorization method list.

Run the **no** form of this command to remove this configuration.

No network authorization method list is configured by default.

Syntax

aaa authorization network { **default** | *list-name* } *method*&<1-4>

no aaa authorization network { **default** | *list-name* }

Parameter Description

default: Defines the default network authorization method list.

list-name: Name of a network authorization method list. A maximum of four methods can be configured in a method list. The value is a string of 1 to 63 characters.

method&<1-4>: Network authorization method. &<1-4> indicates that 1–4 methods can be configured in a list. The optional types of *method* are as follows:

- **group** *group-name*: Uses a server group for authorization. Only the RADIUS and TACACS+ server groups are supported. You can enter this type parameter 0–4 times in this command.
- **group radius**: Uses all RADIUS servers for authorization. You can enter this type parameter only once in this command.
- **group tacacs+**: Uses all TACACS+ servers for authorization. You can enter this type parameter only once in this command.
- **local**: Uses the local user database for authorization. You can enter this type parameter only once in this command. After entering this parameter, you can also enter other type parameters.
- **none**: Indicates no authorization. You can enter this type parameter only once in this command. After entering this parameter, you cannot enter other types.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The device supports authorization on all network-related services. After authorization is configured, all authenticated users or interfaces are authorized automatically.

A RADIUS or TACACS+ server completes authorization of authenticated users by returning a series of attributes. Therefore, network authorization is based on authentication. Only authenticated users can gain network authorization.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example configures the default network authorization method list, in which RADIUS servers are used to provide authorization for network service requirements.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authorization network default group radius
```

Notifications

When the specified group is not defined on the device, the following notification will be displayed:

```
%Group XXX is not existed
```

When the configured group type does not support the authorization type, the following notification will be displayed:

```
The authorization does not support this type of group
```

1.17 aaa command-author cache

Function

Run the **aaa command-author cache** command to enable the function of caching command authorization results.

Run the **no** form of this command to disable this feature.

The function of caching command authorization results is disabled by default.

Syntax

aaa command-author cache

no aaa command-author cache

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The device can locally cache command authorization results returned by an AAA server. Subsequent authorization of commands with the level same as the cached authorized commands are performed based on the locally cached results.

Cached command authorization results are valid only to the current session and commands of the current level.

Examples

The following example enables the function of caching command authorization results.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa command-author cache
```

1.18 aaa domain

Function

Run the **aaa domain** command to create a domain and enter the domain configuration mode.

Run the **no** form of this command to remove this configuration.

No domain is configured by default.

Syntax

aaa domain { **default** | *domain-name* }

no aaa domain { **default** | *domain-name* }

Parameter Description

default: Enters the configuration mode of the default domain.

domain-name: Name of a domain. After this parameter is configured, the system enters the configuration mode of the domain.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Before running this command, run the **aaa domain enable** command to enable the domain-based AAA services first.

After the domain-based AAA services are enabled, if information of a user does not carry domain information, the user belongs to the default domain **default**.

domain-name indicates the domain name. If information of a user carries the domain name, the method list associated with this domain is used. The system supports a maximum of 32 domains.

Examples

The following example enters the configuration mode of a domain named **domain.com**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa domain domain.com
Hostname(config-aaa-domain)#
```

list-name: Name of a method list.

Command Modes

Domain configuration mode

Default Level

14

Usage Guidelines

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example sets the IEEE 802.1X authentication method list to the default method list for a domain named **domain.com**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa domain domain.com
Hostname(config-aaa-domain)# authentication dot1x default
```

Notifications

If the name of a specified method list exceeds the length limit, the following notification will be displayed:

```
Method list name is too long
```

If the specified method list is not configured, the following notification will be displayed:

```
%WARNING: method list named XXX for this type is not existed
```

Common Errors

1.33 authentication login

Function

Run the **authentication login** command to configure a login authentication method list for an AAA domain.

Run the **no** form of this command to remove this configuration.

The default login authentication method list of an AAA domain is the default method list.

Syntax

authentication login { **default** | *list-name* }

no authentication login

Parameter Description

default: Uses the default method list.

list-name: Name of a method list.

Command Modes

Domain configuration mode

Default Level

14

Usage Guidelines

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example sets the login authentication method list to the default method list for a domain named **domain.com**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa domain domain.com
```

```
Hostname(config-aaa-domain)# authentication login default
```

Notifications

If the name of a specified method list exceeds the length limit, the following notification will be displayed:

```
Method list name is too long
```

If the specified method list is not configured, the following notification will be displayed:

```
%WARNING: method list named XXX for this type is not existed
```

1.34 authentication enable

Function

Run the **authentication enable** command to configure an Enable authentication method list for an AAA domain.

Run the **no** form of this command to remove this configuration.

The default Enable authentication method list of an AAA domain is the default method list.

Syntax

authentication enable default

no authentication enable

Parameter Description

default: Uses the default method list. Only the default method list is supported currently.

Command Modes

Domain configuration mode

Default Level

14

Usage Guidelines

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example sets the Enable authentication method list to the default method list for a domain named **domain.com**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa domain domain.com
Hostname(config-aaa-domain)# authentication enable default
```

Notifications

If the name of a specified method list exceeds the length limit, the following notification will be displayed:

```
Method list name is too long

1.35 authorization network

Function

Run the **authorization network** command to configure a network authorization method list for an AAA domain.

Run the **no** form of this command to remove this configuration.

The default network authorization method list of an AAA domain is the default method list.

Syntax

authorization network { **default** | *list-name* }

no authorization network

Parameter Description

default: Uses the default method list.

list-name: Name of a method list.

Command Modes

Domain configuration mode

Default Level

14

Usage Guidelines

This command is used to specify a network authorization method list for an AAA domain. The domain-based AAA services need to be enabled for the execution of this command.

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example sets the network authorization method list to the default method list for a domain named **domain.com**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa domain domain.com
Hostname(config-aaa-domain)# authorization network default
```

Notifications

If the name of a specified method list exceeds the length limit, the following notification will be displayed:

```
Method list name is too long
```

If the specified method list is not configured, the following notification will be displayed:

```
%WARNING: method list named XXX for this type is not existed
```

1.36 authorization commands

Function

Run the **authorization commands** command to configure a command authorization method list for an AAA domain.

Run the **no** form of this command to remove this configuration.

The default command authorization method list of an AAA domain is the default method list.

Syntax

authorization commands *level* { **default** | *list-name* }

no authorization commands *level*

Parameter Description

level: Level of commands that need authorization. Only authorized commands can be executed. The value range is from 0 to 15.

default: Uses the default method list.

list-name: Name of a method list.

Command Modes

Domain configuration mode

Default Level

14

Usage Guidelines

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example sets the command authorization method list to the default method list for a domain named **domain.com**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa domain domain.com
Hostname(config-aaa-domain)# authorization commands default
```

Notifications

If the name of a specified method list exceeds the length limit, the following notification will be displayed:

```
Method list name is too long
```

If the specified method list is not configured, the following notification will be displayed:

```
%WARNING: method list named XXX for this type is not existed
```

1.37 authorization exec

Function

Run the **authorization exec** command to configure an EXEC authorization method list for an AAA domain.

Run the **no** form of this command to remove this configuration.

The default EXEC authorization method list of an AAA domain is the default method list.

Syntax

authorization exec { **default** | *list-name* }

no authorization exec

Parameter Description

default: Uses the default method list.

list-name: Name of a method list.

Command Modes

Domain configuration mode

Default Level

14

Usage Guidelines

If you configure this command repeatedly, the later configuration will overwrite earlier configuration.

Examples

The following example sets the EXEC authorization method list to the default method list for a domain named **domain.com**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa domain domain.com
Hostname(config-aaa-domain)# authorization exec default
```

Notifications

If the name of a specified method list exceeds the length limit, the following notification will be displayed:

```
Method list name is too long

1.38 clear aaa local user lockout

Function

Run the **clear aaa local user lockout** command to clear the list of locked users.

Syntax

clear aaa local user lockout { **all** | **user-name** *user-name-id* }

Parameter Description

all: Indicates all locked users.

user-name *user-name-id*: Specifies the ID of a locked user.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

You can clear a specified locked user or all locked users in the list.

Examples

The following example clears all locked users.

```
Hostname> enable
Hostname# clear aaa local user lockout all
```

Notifications

When you attempt to clear a specified user and the user exists, the following notification will be displayed:

```
User XXX unlocked

1.40 show aaa domain

Function

Run the **show aaa domain** command to display information about a configured domain.

Syntax

show aaa domain [**default** | *domain-name*]

Parameter Description

default: Displays information about the default domain.

domain-name: Specified domain name. After this parameter is configured, information about the specified domain will be displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no domain name is specified, information about all domains will be displayed.

The parameter *domain-name* can be configured only after the domain-based AAA services are enabled. You can enable the domain-based AAA services by running the **aaa domain enable** command.

Examples

The following example displays information about the domain named **domain.com**.

```
Hostname> enable
Hostname# show aaa domain domain.com

=============Domain domain.com=============
State: Active
Username format: Without-domain
Access limit: No limit
802.1X Access statistic: 0

Selected method list:
 authentication dot1x default
```

Table 1-2 Output Fields of the show aaa domain Command

Field	Description
State	Status of the domain authentication function
Username format	Whether the username contains the domain name
Access limit	Whether the access is limited
802.1X Access statistic	Number of IEEE 802.1X-authenticated hosts that access the network
Selected method list	Domain authentication method list

1.44 show aaa user

Function

Run the **show aaa user** command to display information about an AAA user.

Syntax

show aaa user { **all** | **by-id** *session-id* | **by-name** *user-name* | **lockout** }

Parameter Description

all: Displays information about all AAA users.

by-id *session-id*: Displays information about an AAA user with a specified session ID. The value range is from 1 to 2147483647.

by-name *user-name*: Displays information about an AAA user with a specified username.

lockout: Displays the list of locked AAA users.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays information about all AAA users.

```
Hostname> enable
Hostname# show aaa user all
-----------------------------
       Id ----- Name
 2345687901     wwxy
```

Table 1-6 Output Fields of the show aaa user all Command

Field	Description
Id	Unique session ID of a user
Name	Name of an authenticated user

The following example displays the list of locked AAA users.

```
Hostname> enable
Hostname# show aaa user lockout

Name                          Tries     Lock      Timeout(min)
```

```
------------------------------ ---------- ---------- ------------
```

Table 1-7 Output Fields of the show aaa user lockout Command

Field	Description
Name	Name of a locked user
Tries	Number of authentication attempts
Lock	Lockout status
Timeout(min)	Remaining time before unlocking

The following example displays information about an AAA user with the session ID 2345687901.

```
Hostname> enable
Hostname# show aaa user by-id 2345687901
----------------------------
       Id ----- Name
 2345687901     wwxy
```

Table 1-8 Output Fields of the show aaa user by-id Command

Field	Description
Id	Unique session ID of a user
Name	Name of the authenticated user searched out by session ID

The following example displays information about an AAA user with the username **wwxy**.

```
Hostname> enable
Hostname# show aaa user by-name wwxy
----------------------------
```

```
      Id ----- Name
2345687901     wwxy

1 RADIUS Commands

Command	Function
aaa group server radius	Configure a Remote Authentication Dial-In User Service (RADIUS) server group.
ip radius source-interface	Configure the source IP address for RADIUS packets.
ip oob	Configure an MGMT port to be used by a RADIUS server group.
ip vrf forwarding	Specify a virtual routing and forwarding (VRF) instance for a RADIUS server group.
radius data-flow-format	Configure the units of data flows and data packets to be sent to a RADIUS server.
radius dscp	Configure the differentiated services code point (DSCP) value for RADIUS packets.
radius vendor-specific extend	Enable the function of not differentiating private vendor IDs during RADIUS packet parsing.
radius vendor-specific attribute support	Enable the function of parsing private attributes of Cisco, Huawei, and Microsoft devices carried in RADIUS packets.
radius-server accounting-on enable	Enable the function of sending accounting-on packets upon device restart.
radius-server account update retransmit	Enable the function of retransmitting accounting update packets of 2nd-generation Web-authenticated users.
radius-server attribute 31	Configure the MAC address format for the Calling-Station-ID attribute of RADIUS.
radius-server attribute nas-port-id format	Configure the encapsulation format for the NAS-Port-ID attribute of RADIUS.
radius-server attribute class	Enable the function of parsing the rate limit configuration from the class attribute of RADIUS.
radius-server dead-criteria	Configure the criteria for the device to judge that a RADIUS server is unreachable.

radius-server deadtime	Configure the duration for the device to stop sending request packets to a RADIUS server when the server is unreachable.
radius-server host	Configure a RADIUS server.
radius-server key	Configure a shared key for the communication between the device and a RADIUS server.
radius-server retransmit	Configure the number of times that the device retransmits packets to a RADIUS server before confirming that the RADIUS server is unreachable.
radius-server source-port	Configure the source port for the device to send RADIUS packets.
radius-server timeout	Configure the waiting time, after which the device retransmits a RADIUS request packet.
radius-server authentication attribute	Configure whether authentication request packets carry specified attributes.
radius-server account attribute	Configure whether RADIUS accounting request packets carry specified attributes.
radius-server authentication vendor	Configure authentication request packets to carry private attributes of other vendors.
radius-server accounting-copy	Enable the function of copying and sending RADIUS accounting packets to servers in a specified server group.
radius-server account vendor	Configure RADIUS accounting request packets to carry private attributes of other vendors.
radius set qos cos	Set the quality of service (QoS) value delivered by RADIUS to the class of service (CoS) value of an interface.
radius support cui	Enable RADIUS to support the CUI attribute.
server auth-port acct-port	Configure a server for a RADIUS server group.
show radius acct statistics	Display RADIUS accounting statistics.
show radius auth statistics	Display RADIUS authentication statistics.
show radius group	Display the configuration of a RADIUS server group.
show radius parameter	Display global parameters of a RADIUS server.
show radius server	Display the configuration of a RADIUS server.

show radius vendor-specific	Display the configurations of RADIUS private attribute types.
show radius attribute	Display RADIUS standard attributes.
show radius-server accounting-copy	Display the configuration of copying and sending accounting packets.

1.1 aaa group server radius

Function

Run the **aaa group server radius** command to configure a Remote Authentication Dial-In User Service (RADIUS) server group.

Run the **no** form of this command to remove this configuration.

No RADIUS server group is configured by default.

Syntax

aaa group server radius *group-name*

no aaa group server radius *group-name*

Parameter Description

group-name: Name of a server group.

Caution

The name of a server group cannot be the keyword **radius** or **tacacs+**. The two keywords are the default server group names of RADIUS and TACACS+ respectively.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures an AAA server group of the RADIUS type, with the name **ss**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server radius ss
Hostname(config-gs-radius)#
```

1.2 ip radius source-interface

Function

Run the **ip radius source-interface** command to configure the source IP address for RADIUS packets.

Run the **no** form of this command to restore the default configuration.

The source IP address of RADIUS packets is set by the network layer by default.

Syntax

ip radius source-interface *interface-type interface-number*

no ip radius source-interface

Parameter Description

interface-type interface-number: Interface type and interface number. The first IP address of the interface is used as the source IP address of RADIUS packets.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is configured, the device uses the first IP address of the interface specified in the command as the source address of RADIUS packets. Ensure that the communication between the configured IP address and a RADIUS server is normal. Specifying the source IP address for packets to be sent to a RADIUS server can reduce the NAS information maintenance workload on the RADIUS server.

Examples

The following example configures the first IP address of interface GigabitEthernet 0/1 as the source IP address of RADIUS packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip radius source-interface gigabitethernet 0/1
```

1.3 ip oob

Function

Run the **ip oob** command to configure an MGMT port to be used by a RADIUS server group.

Run the **no** form of this command to remove this configuration.

No MGMT port to be used by a RADIUS server group is configured by default.

Syntax

ip oob [**via Mgmt** *Mgmt_number*]

no ip

Parameter Description

via Mgmt *Mgmt_number*: MGMT port to be used by a RADIUS server group. MGMT 0 is used by default.

Command Modes

Server group configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example creates a server group named **ss** and sets the source interface to be used by the server group to send RADIUS packets to MGMT 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server radius ss
Hostname(config-gs-radius)# server 192.168.4.14
Hostname(config-gs-radius)# server 192.168.4.15
Hostname(config-gs-radius)# ip oob via mgmt 1
```

1.4 ip vrf forwarding

Function

Run the **ip vrf forwarding** command to specify a virtual routing and forwarding (VRF) instance for a RADIUS server group.

Run the **no** form of this command to remove this configuration.

No VRF instance is specified for a RADIUS server group by default.

Syntax

ip vrf forwarding *vrf-name*

no ip

Parameter Description

vrf-name: VRF instance used by a RADIUS server group.

Command Modes

Server group configuration mode

Default Level

14

Usage Guidelines

The VRF instance specified for a RADIUS server group must use a valid name configured using the **vrf definition** command in global configuration mode.

Examples

The following example sets the VRF instance used by a RADIUS server group named **ss** to **vrf-name**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server radius ss
Hostname(config-gs-radius)# server 192.168.4.12
Hostname(config-gs-radius)# server 192.168.4.13

1.5 radius data-flow-format

Function

Run the **radius data-flow-format** command to configure the units of data flows and data packets to be sent to a RADIUS server.

Run the **no** form of this command to restore the default configuration.

The default units of data flows and data packets to be sent to a RADIUS server are bytes and packets respectively.

Syntax

radius data-flow-format { { **data byte** | **data giga-byte** | **data kilo-byte** | **data mega-byte** } | { **packet giga-packet** | **packet kilo-packet** | **packet mega-packet** | **packet one-packet** } } *

no radius data-flow-format

Parameter Description

data byte: Sets the unit of data flows to bytes.

data giga-byte: Sets the unit of data flows to gigabytes.

data kilo-byte: Sets the unit of data flows to kilobytes.

data mega-byte: Sets the unit of data flows to megabytes.

packet giga-packet: Sets the unit of data packets to giga-packets.

packet kilo-packet: Sets the unit of data packets to kilo-packets.

packet mega-packet: Sets the unit of data packets to mega-packets.

packet one-packet: Sets the unit of data packets to packets.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the unit of data flows to be sent to a RADIUS server to kilobytes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius data-flow-format data kilo-byte
```

1.6 radius dscp

Function

Run the **radius dscp** command to configure the differentiated services code point (DSCP) value for RADIUS packets.

Run the **no** form of this command to restore the default configuration.

The default DSCP value of RADIUS packets is **0**.

Syntax

radius dscp *dscp-value*

no radius dscp

Parameter Description

dscp-value: DSCP value of RADIUS packets. The value range is from 0 to 63.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

DSCP is in the type of service (ToS) field of the IP header and is used to identify the packet transmission priority. A larger DSCP value indicates a higher packet priority. The default DSCP value of RADIUS packets is **0**. You can configure the DSCP value for RADIUS packets to change the transmission priority of RADIUS packets.

Examples

The following example sets the DSCP value of RADIUS packets to **2**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius dscp 2
```

1.9 radius-server accounting-on enable

Function

Run the **radius-server accounting-on enable** command to enable the function of sending accounting-on packets upon device restart.

Run the **no** form of this command to disable this feature.

The function of sending accounting-on packets upon device restart is enabled by default.

Syntax

radius-server accounting-on enable

no radius-server accounting-on enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The accounting-on function is used to notify a RADIUS server of the device restart. After the device is restarted, online users are forced offline. However, the RADIUS server does not perceive the device restart and does not log off the users. As a result, the users encounter an exception when initiating re-authentication. Therefore, it is necessary to enable the accounting-on function.

Examples

The following example enables the function of sending accounting-on packets upon device restart.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no radius-server accounting-on enable
```

1.10 radius-server account update retransmit

Function

Run the **radius-server account update retransmit** command to enable the function of retransmitting accounting update packets of 2nd-generation Web-authenticated users.

Run the **no** form of this command to disable this feature.

The function of retransmitting accounting update packets of 2nd-generation Web-authenticated users is enabled by default.

Syntax

radius-server account update retransmit

no radius-server account update retransmit

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The configuration does not affect users of other authentication types.

Examples

The following example enables the function of retransmitting accounting update packets of 2nd-generation Web-authenticated users.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server account update retransmit
```

1.11 radius-server attribute 31

Function

Run the **radius-server attribute 31** command to configure the MAC address format for the **Calling-Station-ID** attribute of RADIUS.

Run the **no** form of this command to restore the default configuration.

The MAC address format of the **Calling-Station-ID** attribute uses the unformatted pattern by default.

Syntax

radius-server attribute 31 mac format { **3hyphen** | **ietf** | **normal** | **unformatted** | { { **colon-split** | **dot-split** | **hyphen-split** } { **mode1** | **mode2** } [**lowercase** | **uppercase**] } }

no radius-server attribute 31 mac format

Parameter Description

3hyphen: Sets the MAC address format to 00d0-4096-3e4a.

ietf: Sets the MAC address format to the standard format specified in the Internet Engineering Task Force (IETF) standard (RFC3580). It uses hyphens (-) as the separator, for example, 00-D0-F8-33-22-AC.

normal: Sets the MAC address format to normal format, that is, dotted hexadecimal format using dots (.) as the separator, for example, 00d0.f833.22ac.

unformatted: Sets the MAC format type to unformatted pattern without separators, for example, 00d0f83322ac.

colon-split: Sets the MAC address format to a pattern using colons (:) as the separator. The final format is determined together with the **mode1** and **mode2** parameters.

dot-split: Sets the MAC address format to a pattern using dots (.) as the separator. The final format is determined together with the **mode1** and **mode2** parameters.

hyphen-split: Sets the MAC address format to a pattern using hyphens (-) as the separator. The final format is determined together with the **mode1** and **mode2** parameters.

mode1: Sets the MAC address format to a pattern using three groups with four characters in each group. It needs to be used together with **dot-split**, **colon-split**, and **hyphen-split**, for example, 00D0.F833.22AC, 00D0:F833:22AC, and 00D0-F833-22AC.

mode2: Sets the MAC address format to a pattern using six groups with two characters in each group. It needs to be used together with **dot-split**, **colon-split**, and **hyphen-split**, for example, 00.D0.F8.33.22.AC, 00:D0:F8:33:22:AC, and 00-D0-F8-33-22-AC.

lowercase: Sets the MAC address format to use lowercase letters.

uppercase: Sets the MAC address format to use uppercase letters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the uppercase/lowercase form is not specified for the MAC address format, the lowercase form is used by default.

Some RADIUS servers (mainly used for IEEE 802.1X authentication) can identify MAC addresses only in the IETF format. In this case, set the MAC address format of **Calling-Station-ID** to IETF.

Examples

The following example sets the MAC address format of the **Calling-Station-ID** attribute to IETF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server attribute 31 mac format ietf
```

1.12 radius-server attribute nas-port-id format

Function

Run the **radius-server attribute nas-port-id format** command to configure the encapsulation format for the **NAS-Port-ID** attribute of RADIUS.

Run the **no** form of this command to restore the default configuration.

The **NAS-Port-ID** attribute of RADIUS uses the normal encapsulation format by default.

Syntax

radius-server attribute nas-port-id format { **mode1** | **normal** | **port-vid** | **qinq** }

no radius-server attribute nas-port-id format

Parameter Description

mode1: Indicates one encapsulation format of the **NAS-Port-ID** attribute of RADIUS. The format is slot = XX; subslot = XX; port = XXX; VLAN ID = XXXX. If the range of a user interface is beyond 255, this format cannot be used. Parameters in this format are described as follows:

- **slot**: Indicates the device ID. The value range is from 0 to 15.
- **subslot**: Indicates the slot ID. The value range is from 0 to 15.
- **port**: Indicates the port ID. The value range is from 0 to 255.
- **VLAN ID**: Indicates the VLAN ID. The value range is from 1 to 4094.

normal: Indicates one encapsulation format of the **NAS-Port-ID** attribute of RADIUS. The format is %Interface_name%. **Interface_name** refers to the name of a user interface. The name is displayed based on the actual length and the maximum length is 32 bytes.

port-vid: Sets the encapsulation format to port-vid. The format is %Interface%:%vid%. Parameters in the format are described as follows:

- **Interface**: Indicates the name of a user interface. The name is displayed based on the actual length and the maximum length is 32 bytes.
- **vid**: Indicates the ID of a user VLAN.

qinq: Indicates one encapsulation format of the **NAS-Port-ID** attribute of RADIUS.

Format without an inner VID: %Interface_name%.%outer_vid4%%tag%:%outer_vid%.

Format with an inner VID: %Interface_name%.%outer_vid4%%inner_vid4%:%outer_vid%-%inner_vid%.

Parameters in the format are described as follows:

- **Interface_name**: Indicates the name of a user interface. The name is displayed based on the actual length and the maximum length is 32 bytes.
- **outer_vid4**: Indicates the outer VLAN ID (it occupies four digits and spaces are filled in when there are less than four digits).
- **inner_vid4**: Indicates the inner VLAN ID (it occupies four digits and spaces are filled in when there are less than four digits).
- **tag**: Indicates a tag and the value is **0** (it occupies four digits and spaces are filled in when there are less than four digits).
- **outer_vid**: Indicates the outer VLAN ID (the number of digits is not limited, and the actual number is printed. For example, 10 is printed for VLAN 10).
- **inner_vid**: Indicates the inner VLAN ID (the number of digits is not limited, and the actual number is printed. For example, 10 is printed for VLAN 10).

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the encapsulation format of the **NAS-Port-ID** attribute of RADIUS to QinQ format.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server attribute nas-port-id format qinq
```

1.13 radius-server attribute class

Function

Run the **radius-server attribute class** command to enable the function of parsing the rate limit configuration from the **class** attribute of RADIUS.

Run the **no** form of this command to disable this feature.

The function of parsing the rate limit configuration from the **class** attribute of RADIUS is disabled by default.

Syntax

radius-server attribute class user-flow-control { **format-16bytes** | **format-32bytes** | **unit bit/s** | **unit byte/s** }}

no radius-server attribute class user-flow-control

Parameter Description

format-16bytes: Sets the format of the rate limit value parsed from the **class** attribute to 16 bytes.

format-32bytes: Sets the format of the rate limit value parsed from the **class** attribute to 32 bytes.

unit bit/s: Sets the format of the rate limit value parsed from the **class** attribute to bps.

unit byte/s: Sets the format of the rate limit value parsed from the **class** attribute to bytes/s.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example enables the function of parsing the rate limit configuration from the **class** attribute of RADIUS and sets the format of the parsed rate limit value to 32 bytes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server attribute class user-flow-control format-32bytes
```

1.14 radius-server dead-criteria

Function

Run the **radius-server dead-criteria** command to configure the criteria for the device to judge that a RADIUS server is unreachable.

Run the **no** form of this command to restore the default configuration.

The criteria for judging that a RADIUS server is unreachable are that the timeout duration is **60** seconds and the consecutive timeout count is **10** by default.

Syntax

radius-server dead-criteria { **time** *timeout* | **tries** *tries-number* | **time** *timeout* **tries** *tries-number* }

no radius-**server dead**-**criteria** { **time** | **tries** | **time tries** }

Parameter Description

time *timeout*: Configures the timeout duration, in seconds. The value range is from 1 to 120. If the device fails to receive a correct response packet from a RADIUS server within the specified time, it is deemed that the RADIUS server meets the unreachability duration condition.

tries *tries-number*: Configures the consecutive timeout count. The value range is from 1 to 100. When the consecutive timeout count of request packets sent by the device to the same RADIUS server reaches the configured count, it is deemed that the RADIUS server meets the consecutive timeout count condition of unreachability.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If a RADIUS server meets both the duration condition and the consecutive request timeout count condition, it is deemed that the RADIUS server is unreachable. You can use this command to adjust the timeout duration and consecutive request timeout count.

Examples

The following example configures the criteria for judging that a RADIUS server is unreachable as follows: The timeout duration is **120** seconds and the consecutive timeout count to **20**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server dead-criteria time 120 tries 20
```

1.15 radius-server deadtime

Function

Run the **radius-server deadtime** command to configure the duration for the device to stop sending request packets to a RADIUS server when the server is unreachable.

Run the **no** form of this command to restore the default configuration.

Even if a RADIUS server is unreachable, the device still sends requests to the RADIUS server by default.

Syntax

radius-server deadtime *deadtime*

no radius-server deadtime

Parameter Description

deadtime: Duration for the device to stop sending requests to an unreachable RADIUS server, in minutes. The value range is from 1 to 1440.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If active detection is enabled for a RADIUS server on the device, the time parameter configured by the **radius-server deadtime** command does not take effect on the RADIUS server. Otherwise, if the duration in which the RADIUS server is unreachable exceeds the time specified by the **radius-server deadtime** command, the device automatically restores the RADIUS server to the reachable state.

Examples

The following example sets the duration for the device to stop sending request packets to an unreachable RADIUS server to **1** minute.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server deadtime 1
```

1.16 radius-server host

Function

Run the **radius-server host** command to configure a RADIUS server.

Run the **no** form of this command to remove this configuration.

No RADIUS server is configured by default.

Syntax

radius-server host [**oob** [**via Mgmt** *mgmt-number*]] { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**key** [**0** | **7**] *text-string*]

no radius-server host [**oob** [**via Mgmt** *mgmt-number*]] { *ipv4-address* | *ipv6-address* } [**auth-port** *auth-port-number* | **acct-port** *acct-port-number*] * [**test username** *username* [**ignore-acct-port**] [**ignore-auth-port**] [**idle-time** *idle-time*]] [**key** [**0** | **7**] *text-string*]

Parameter Description

oob: Configures the device to use an MGMT port to send RADIUS packets. MGMT 0 is used for sending RADIUS packets by default.

via Mgmt *mgmt-numb*: Configures an MGMT port as the source interface for sending packets to a RADIUS server.

ipv4-address: Configures an IPv4 address for the RADIUS server.

ipv6-address: Configures an IPv6 address for the RADIUS server.

auth-port *auth-port-number*: Configures the UDP port for RADIUS authentication. The value range is from 0 to 65535 and the value **0** indicates that the server does not perform authentication.

acct-port *acct-port-number*: Configures the UDP port for RADIUS accounting. The value range is from 0 to 65535 and the value **0** indicates that the server does not perform accounting.

test username *username*: Enables the active detection function for the RADIUS server and specifies the username used in active detection.

ignore-auth-port: Disables the function of detecting the authentication port of the RADIUS server. Authentication port detection is enabled by default.

ignore-acct-port: Disables the function of detecting the accounting port of the RADIUS server. Accounting port detection is enabled by default.

idle-time *idle-minutes*: Configures the interval for the device to send test packets to a reachable RADIUS server, in minutes. The value range is from 1 to 1440 and the default value is **60**.

key [**0** | **7**] *text-string*: Configures a shared key for the server. The global shared key is used by default. You can specify the encryption type for the configured key. The value **0** indicates no encryption, **7** indicates simple encryption, and **0** is used by default.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the encryption type of a shared key is **7** and the device version is downgraded to a version that does not support the Advanced Encryption Standard (AES)-128/Secure Hash Algorithm (SHA)-256 encryption algorithm, the shared key may fail to be identified. Therefore, before the device is downgraded, set the shared key to a plaintext key or type-7 ciphertext key generated on the device of an earlier version.

A RADIUS server must be defined to implement the AAA security service by using RADIUS. You can use this command to define one or more RADIUS servers.

If a RADIUS server is not added to a RADIUS server group, the device uses the global routing table when sending RADIUS packets to the RADIUS server. Otherwise, the device uses the VRF routing table of the RADIUS server group.

Examples

The following example configures a RADIUS server in an IPv4 environment.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server host 192.168.12.1
```

The following example configures a RADIUS server in an IPv4 environment, enables active detection, sets the detection interval to **60** minutes, and disables accounting UDP port detection.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server host 192.168.100.1 test username test idle-time 60
ignore-acct-port
```

The following example configures a RADIUS server in an IPv6 environment.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server host 3000::100
```

1.17 radius-server key

Function

Run the **radius-server key** command to configure a shared key for the communication between the device and a RADIUS server.

Run the **no** form of this command to remove this configuration.

No shared key for the communication between the device and a RADIUS server is configured by default.

Syntax

radius-server key [**0** | **7**] *key*

no radius-server key

Parameter Description

0 | **7**: Configures the encryption type of a key. The value **0** indicates no encryption and **7** indicates simple encryption.

key: Text of a shared key.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the encryption type of a shared key is **7** and the device version is downgraded to a version that does not support the Advanced Encryption Standard (AES)-128/Secure Hash Algorithm (SHA)-256 encryption algorithm, the shared key may fail to be identified. Therefore, before the device is downgraded, set the shared key to a plaintext key or type-7 ciphertext key generated on the device of an earlier version.

A shared key is the basis for correct communication between the device and a RADIUS server. The same shared key must be configured on the device and a RADIUS server so that they can communicate with each other successfully.

Examples

The following example sets the shared key for the communication between the NAS and a RADIUS server to **aaa**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server key aaa
```

1.18 radius-server retransmit

Function

Run the **radius-server retransmit** command to configure the number of times that the device retransmits packets to a RADIUS server before confirming that the RADIUS server is unreachable.

Run the **no** form of this command to restore the default configuration.

The device retransmits packets to a RADIUS server three times before confirming that the RADIUS server is unreachable by default.

Syntax

radius-server retransmit *retransmit-times*

no radius-server retransmit

Parameter Description

retransmit-times: Packet retransmission count before the device confirms that a RADIUS server is unreachable. The value range is from 0 to 100 and the value **0** indicates no retransmission.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The prerequisite for AAA to use the next user authentication method is that the current security server used for authentication does not respond. The criteria for the device to judge that a security server does not respond are that the security server does not respond within the duration, in which the device retransmits RADIUS packets for a specified number of times. There is a timeout interval between two consecutive retransmissions.

Examples

The following example sets the number of times that the device retransmits packets to a RADIUS server before confirming that the RADIUS server is unreachable to 4.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# radius-server retransmit 4
```

Run the **no** form of this command to remove this configuration.

No server is configured for a RADIUS server group by default.

Syntax

server { *ipv4-address* | *ipv6-address* } [**acct-port** *acct-port* | **auth-port** *auth-port*] *

no server { *ipv4-address* | *ipv6-address* } [**acct-port** *acct-port* | **auth-port** *auth-port*] *

Parameter Description

Ipv4-address: IPv4 address of a server.

Ipv6-address: IPv6 address of a server.

acct-port *acct-port*: Configures the accounting port ID for the server. The value range is from 1 to 65535, and the default value is **1813**.

auth-port *auth-port*: Configures the authentication port ID for the server. The value range is from 1 to 65535, and the default value is **1812**.

Command Modes

Server group configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example adds a server with the IP address 192.168.4.12 to a server group named **ss**, sets the authentication port ID of the server to 10000, and the accounting port ID to 10001.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server radius ss
Hostname(config-gs-radius)# server 192.168.4.12 acct-port 10000 auth-port 10001
```

The following example displays RADIUS accounting statistics.

```
Hostname> enable
Hostname# show radius acct statistics
Accounting Servers:
Server Index..................................... 1
Server Address................................... 192.168.1.1
Server Port...................................... 1813
Msg Round Trip Time.............................. 0 (msec)
First Requests................................... 1
Retry Requests................................... 1
Accounting Responses............................. 0
Malformed Msgs................................... 0
Bad Authenticator Msgs........................... 0
Pending Requests................................. 1
```

Table 1-1 Output Fields of the show radius radius acct statistics Command

Field	Description
Accounting Servers	Accounting server
Server Index	Server index
Server Address	IP address of the server
Server Port	Server port

Field	Description
Msg Round Trip Time	Duration from the time that an access request is sent to the server to the time an access response is received from the server
First Requests	Number of times that the first request is sent to the server
Retry Requests	Packet transmission count
Accounting Responses	Number of times that accounting response packets are received
Malformed Msgs	Number of RADIUS Access-Response error packets received from the server
Bad Authenticator Msgs	Number of packets with verification errors
Pending Requests	Number of RADIUS access request packets sent to the server, for which no timeout occurs and no response is received ● The value of this variable increases when an access request is sent. ● The value of this variable decreases when an access acceptance, access denial, access challenge, timeout, or retransmission message is received.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays global parameters of a RADIUS server.

```
Hostname> enable
Hostname# show radius parameter
Server Timout:   5 Seconds
Server Deadtime: 0 Minutes
Server Retries:  3
Server Dead Critera:
Time:       10 Seconds
Tries:      10
```

Table 1-4 Output Fields of the show radius parameter Command

Field	Description
Server Timout	Waiting time prior to request retransmission
Server Deadtime	Duration for the device to stop sending request packets to an unreachable RADIUS server
Server Retries	Number of times that the device sends requests consecutively before confirming that a RADIUS server is unreachable
Server Dead Criteria	Criteria for judging that a RADIUS server is unreachable
Time	If the device fails to receive a correct response packet from a RADIUS server within the time, it is judged that the RADIUS server meets the unreachability duration condition.
Tries	When the number of times that the device sends a request packet to the RADIUS server consecutively reaches the configured value, it is judged that the RADIUS server meets the consecutive timeout count condition of unreachability.

1 TACACS Commands

Command	Function
aaa group server tacacs+	Configure a Terminal Access Controller Access Control System Plus (TACACS+) server group.
ip tacacs source-interface	Configure the source address for TACACS+ packets.
ip oob	Configure an MGMT port to be used by a TACACS+ server group.
ip vrf forwarding	Specify a VRF instance for a TACACS+ server group.
server	Add a server to a TACACS+ server group.
nas-ip	Enable the function of carrying the nas-ip attribute in packets.
show tacacs	Display the interaction between the device and each TACACS+ server.
tacacs-server host	Configure a TACACS+ server.
tacacs-server key	Configure a shared key for the communication between a network access server (NAS) and a TACACS+ server.
tacacs-server timeout	Configure the global timeout duration for a TACACS+ server in the communication between the device and the TACACS+ server.
tacacs-server dead-criteria	Configure the criteria for the device to judge that a TACACS+ server is unreachable.
tacacs-server deadtime	Configure the duration for the device to stop sending request packets to an unreachable TACACS+ server.

1.1 aaa group server tacacs+

Function

Run the **aaa group server tacacs+** command to configure a Terminal Access Controller Access Control System Plus (TACACS+) server group.

Run the **no** form of this command to remove this configuration.

No TACACS+ server group is configured by default.

Syntax

aaa group server tacacs+ *group-name*

no aaa group server tacacs+ *group-name*

Parameter Description

group-name: Name of a TACACS+ server group. The value is a string of 1 to 63 characters. The name cannot be set to the default name **radius** or **tacacs+**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can group TACACS+ servers so that authentication, authorization, and accounting can be completed by different server groups.

Examples

The following example configures a TACACS+ server group named **tac1**, and adds a TACACS+ server with the IP address 1.1.1.1 to the server group.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server tacacs+ tac1
Hostname(config-gs-tacacs+)# server 1.1.1.1
```

1.2 ip tacacs source-interface

Function

Run the **ip tacacs source-interface** command to configure the source address for TACACS+ packets.

Run the **no** form of this command to remove this configuration.

No source address is configured for TACACS+ packets and the address is set by the network layer by default.

Syntax

ip tacacs source-interface *interface-type interface-number*

no ip tacacs source-interface *interface-type interface-number*

Parameter Description

interface-type interface-number: Interface type and interface number.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You can run this command to configure the source IP address for TACACS+ packets to be sent to a TACACS+ server, to reduce the network access server (NAS) information maintenance workload on the TACACS+ server. This command uses the first IP address of a specified interface as the source address of TACACS+ packets. If a specified interface belongs to a virtual routing and forwarding (VRF) instance, routes in the VRF instance are used to send packets.

Examples

The following example configures the IP address of interface GigabitEthernet 0/1 as the source address of TACACS+ packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip tacacs source-interface gigabitethernet 0/1
```

1.3 ip oob

Function

Run the **ip oob** command to configure an MGMT port to be used by a TACACS+ server group.

Run the **no** form of this command to remove this configuration.

No MGMT port to be used by a TACACS+ server group is configured by default.

Syntax

ip oob [**via Mgmt** *mgmt-number*]

no ip

Parameter Description

via Mgmt *mgmt-number*: Configures the number of an MGMT port to be used. MGMT 0 is used by default.

Command Modes

TACACS+ server group configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the MGMT port to be used by a TACACS+ server group named **ss** to MGMT 0.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server tacacs+ ss
Hostname(config-gs-tacacs+)# server 192.168.1.2
Hostname(config-gs-tacacs+)# ip oob via mgmt 0
```

1.4 ip vrf forwarding

Function

Run the **ip vrf forwarding** command to specify a VRF instance for a TACACS+ server group.

Run the **no** form of this command to remove this configuration.

No VRF instance is specified for a TACACS+ server group by default.

Syntax

ip vrf forwarding *vrf-name*

no ip

Parameter Description

vrf-name: VRF instance used by a server group.

Command Modes

TACACS+ server group configuration mode

Default Level

14

Usage Guidelines

The VRF instance specified for a TACACS+ server group must use a valid name configured using the **vrf definition** command in global configuration mode.

Examples

The following example sets the VRF instance used by a TACACS+ server group to **vrf-name**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server tacacs+ ss
Hostname(config-gs-tacacs+)# server 192.168.1.2
Hostname(config-gs-tacacs+)# ip vrf forwarding vrf-name
```

Notifications

If the name of a specified VRF instance exceeds the length limit, the following notification will be displayed:

```
Name is too long
```

If a specified VRF instance is not configured, the following notification will be displayed:

```
Invalid vrf
```

Related Commands

- **vrf definition** (IP routing/VRF)

1.5 server

Function

Run the **server** command to add a server to a TACACS+ server group.

Run the **no** form of this command to remove this configuration.

No server is added to a TACACS+ server group by default.

Syntax

server { *ipv4-address* | *ipv6-address* }

no server { *ipv4-address* | *ipv6-address* }

Parameter Description

ipv4-address: IPv4 address of a server.

Ipv6-address: IPv6 address of a server.

Command Modes

TACACS+ server group configuration mode

Default Level

14

Usage Guidelines

If multiple servers are added to one server group, when one server does not respond, the device continues to send a TACACS+ request to the next server in the server group.

Examples

The following example configures a TACACS+ server group named **tac1**, and adds a TACACS+ server with the IP address 192.168.1.2 to the server group.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa group server tacacs+ tac1
Hostname(config-gs-tacacs+)# server 192.168.1.2
```

Notifications

When a server is added to a server group but the server is not configured, the following notification will be displayed:

```
Warning: Server 1.1.1.1 is not defined.
```

Common Errors

1.6 nas-ip

Function

Run the **nas-ip** command to enable the function of carrying the **nas-ip** attribute in packets.

Run the **no** form of this command to disable this feature.

Packets do not carry the **nas-ip** attribute by default.

Syntax

nas-ip { *ipv4-address* | *ipv6-address* }

no nas-ip { *ipv4-address* | *ipv6-address* }

Parameter Description

ipv4-address: **nas-ip** attribute value of an IPv4 address.

Ipv6-address: **nas-ip** attribute value of an IPv6 address.

Command Modes

TACACS+ server group configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures a TACACS+ server group named **tac1** and enables the function of carrying the **nas-ip** attribute in packets for the server group.

```
Hostname> enable

1.8 tacacs-server host

Function

Run the **tacacs-server host** command to configure a TACACS+ server.

Run the **no** form of this command to remove this configuration.

No TACACS+ server is configured by default.

Syntax

tacacs-server host [**oob** [**via Mgmt** *mgmt-number*]] { *ipv4-address* | *ipv6-address* } [**port** *port-number*] [**test username** *username*] [**idle-time** *idle-time*] [**timeout** *timeout*] [**key** [**0** | **7**] *key*]

no tacacs-server host [**oob** [**via Mgmt** *mgmt-number*]] { *ipv4-address* | *ipv6-address* }

Parameter Description

oob: Uses an MGMT port for communication. If this parameter is not specified, a non-MGMT port is used for communication.

via Mgmt *mgmt-number*: Specifies an MGMT port. If this parameter is not specified, MGMT 0 is used.

ipv4-address: IPv4 address of a TACACS+ server.

ipv6-address: IPv6 address of a TACACS+ server.

port *port-number*: Configures a TCP port for TACACS+ communication. The value range is from 1 to 65535, and the default value is **49**.

test username *username*: Configures a username used for detection. The value is a string of 1 to 63 characters.

idle-time *idle-time*: Configures the detection interval, in minutes. The value range is from 1 to 1440 and the default value is **60**.

timeout *timeout*: Configures the communication timeout duration of a TACACS+ server, in seconds. The value range is from 1 to 1000. If this parameter is not specified, the global timeout duration is used.

key [**0** | **7**] *key*: Configures a shared key for the server. You can specify the encryption type for the configured key. The value **0** indicates no encryption and **7** indicates simple encryption. The value **0** is used by default. If this parameter is not specified, the global shared key is used.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the encryption type of a shared key is **7** and the device version is downgraded to a version that does not support the Advanced Encryption Standard (AES)-128/Secure Hash Algorithm (SHA)-256 encryption algorithm, the shared key may fail to be identified. Therefore, before the device is downgraded, set the shared key to a plaintext key or type-7 ciphertext key generated on the device of an earlier version.

Examples

The following example configures a TACACS+ server with the IPv4 address 192.168.12.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tacacs-server host 192.168.12.1
```

1.9 tacacs-server key

Function

Run the **tacacs-server key** command to configure a shared key for the communication between a network access server (NAS) and a TACACS+ server.

Run the **no** form of this command to remove this configuration.

No shared key for the communication between a NAS and a TACACS+ server is configured by default.

Syntax

tacacs-server key [**0** | **7**] *key*

no tacacs-server key

Parameter Description

0 | **7**: Configures the encryption type of a key. The value **0** indicates no encryption and **7** indicates simple encryption. If this parameter is not specified, no encryption is adopted.

key: Text of a shared key. The value is a string of 1 to 128 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If the encryption type of a shared key is **7** and the device version is downgraded to a version that does not support the AES-128/SHA-256 encryption algorithm, the shared key may fail to be identified. Therefore, before the device is downgraded, set the shared key to a plaintext key or type-7 ciphertext key generated on the device of an earlier version.

This command is used to configure a global shared key. You can use the **key** field in the **tacacs-server host** command to specify different keys for servers.

Examples

The following example sets the shared key for the communication between the NAS and a TACACS+ server to **aaa**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tacacs-server key aaa
```

1.10 tacacs-server timeout

Function

Run the **tacacs-server timeout** command to configure the global timeout duration for a TACACS+ server in the communication between the device and the TACACS+ server.

Run the **no** form of this command to restore the default configuration.

The default timeout duration of a TACACS+ server is **5** seconds in the communication between the device and the TACACS+ server.

Syntax

tacacs-server timeout *timeout*

no tacacs-server timeout

Parameter Description

timeout: Global timeout duration of a server, in seconds. The value range is from 1 to 1000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the global server response timeout duration. You can use the **timeout** field in the **tacacs-server host** command to specify different timeout duration values for servers.

Examples

The following example sets the global timeout duration to **10** seconds for a TACACS+ server in the communication between the device and the TACACS+ server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tacacs-server timeout 10
```

Related Commands

- **tacacs-server host**

1.11 tacacs-server dead-criteria

Function

Run the **tacacs-server dead-criteria** command to configure the criteria for the device to judge that a TACACS+ server is unreachable.

Run the **no** form of this command to restore the default configuration.

The criteria for the device to judge that a TACACS+ server is unreachable are that the server timeout duration is **60** seconds and the consecutive timeout count is **10** by default.

Syntax

tacacs-server dead-criteria { **time** *timeout* **tries** *tries-number* | **time** *timeout* | **tries** *tries-number* }

no tacacs-server dead-criteria { **time tries** | **time** | **tries** }

Parameter Description

time *timeout*: Configures the timeout duration to judge that a security server is unreachable, in seconds. The value range is from 1 to 120.

tries *tries-number*: Configures the consecutive timeout count to judge that a security server is unreachable. The value range is from 1 to 100.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

It is judged that a TACACS+ server is unreachable only when both conditions below are met:

- The device fails to receive a correct response packet from the TACACS+ server within the specified timeout period.
- The consecutive transmission count of a request packet sent by the device to the same TACACS+ server reaches the specified timeout count.

Examples

The following example configures the criteria for judging that a TACACS+ server is unreachable as follows: The server timeout duration is **120** seconds and the consecutive timeout count is **20**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tacacs-server dead-criteria time 120 tries 20
```

1.12 tacacs-server deadtime

Function

Run the **tacacs-server deadtime** command to configure the duration for the device to stop sending request packets to an unreachable TACACS+ server.

Run the **no** form of this command to restore the default configuration.

Even if a TACACS+ server is unreachable, the device still sends requests to the TACACS+ server by default.

Syntax

tacacs-server deadtime *deadtime*

no tacacs-server deadtime

Parameter Description

deadtime: Duration for the device to stop sending requests to an unreachable TACACS+ server, in minutes. The value range is from 1 to 1440.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If active detection is enabled for a TACACS+ server on the device, the time parameter configured by the command does not take effect on the TACACS+ server. Otherwise, if the duration in which the TACACS+ server is unreachable exceeds the time specified by the command, the device automatically restores the TACACS+ server to the reachable state.

Examples

The following example sets the duration for the device to stop sending request packets to an unreachable TACACS+ server to **1** minute.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tacacs-server deadtime 1
```

1 IEEE 802.1X Commands

Command	Function
aaa authorization ip-auth-mode	Configure the global IP authorization mode.
clear dot1x user	Delete an IEEE 802.1X-authenticated user on the device.
dot1x accounting	Configure an accounting method list.
dot1x acct-update base-on first-time server	Set the accounting update period to that delivered by the server at the first authentication.
dot1x auth-fail max-attempt	Configure the maximum number of consecutive failed authentication attempts.
dot1x auth-fail vlan	Configure the failed VLAN.
dot1x auth-mode	Configure the authentication mode.
dot1x auth-address-table	Configure a list of hosts allowed for authentication.
dot1x auth-with-order	Set the priority of MAB to be higher than that of IEEE 802.1X authentication.
dot1x authentication	Configure an authentication method list.
dot1x auto-req	Enable the active IEEE 802.1X authentication function on the device.
dot1x auto-req packet-num	Configure the maximum number of active authentication request packets that can be sent by the device.
dot1x auto-req req-interval	Configure the interval for the device to send active authentication request packets.
dot1x auto-req user-detect	Enable the function of detecting whether a user is being authenticated during active authentication.
dot1x client-probe enable	Enable online Ruijie client detection.
dot1x critical	Enable the inaccessible authentication bypass (IAB) function.
dot1x critical recovery action reinitialize	Enable the IAB recovery.
dot1x critical vlan	Configure the IAB VLAN.
dot1x dbg-filter	Configure the debugging of a specific MAC address.

dot1x default-user-limit	Configure the maximum number of users who can be authenticated on an interface.
dot1x default	Restore the default configuration of IEEE 802.1X.
dot1x dynamic-vlan enable	Enable dynamic VLAN redirection on a port.
dot1x guest-vlan	Configure the guest VLAN on a controlled port.
dot1x mab-username upper	Configure usernames used for MAB to use uppercase letters.
dot1x mac-auth-bypass	Enable single-user MAB.
dot1x mac-auth-bypass multi-user	Enable multi-user MAB.
dot1x mac-auth-bypass timeout-activity	Configure the MAB timeout duration.
dot1x mac-auth-bypass violation	Enable the MAB violation function.
dot1x mac-auth-bypass vlan	Configure the MAB VLAN.
dot1x max-req	Configure the maximum retransmission count of Request/Challenge packets.
dot1x multi-account enable	Enable multi-account authentication with one MAC address.
dot1x multi-mab quiet-period	Configure the quiet period after a multi-user MAB failure.
dot1x multi-mab quiet-user fail-times	Configure the number of authentication failures required for user entry aging.
dot1x multi-mab quiet-user authen-num	Configure the rate of initiating authentication using the MAC address in a multi-user MAB quiet user entry.
dot1x multi-mab quiet-user reject-times	Configure the server rejection count for the device to delete a quiet user entry.
dot1x mab-username format	Configure the username format for MAB.
dot1x port-control auto	Enable IEEE 802.1X authentication on a port.
dot1x port-control-mode	Configure the port control mode.
dot1x probe-timer interval	Configure the Ruijie client detection interval.
dot1x probe-timer alive	Configure the Ruijie client detection duration.
dot1x private-supplicant-only	Enable the non-Ruijie client filtering function.

dot1x pseudo source-mac	Configure a virtual MAC address as the source MAC address of IEEE 802.1X packets sent by the device.
dot1x redirect	Enable the 2nd-generation Ruijie Supplicant deployment function.
dot1x reauth-max	Configure the maximum retransmission count of the Request/Identity packets.
dot1x re-authentication	Enable re-authentication.
dot1x stationarity enable	Disable dynamic user migration.
dot1x timeout re-authperiod	Configure the re-authentication interval.
dot1x timeout quiet-period	Configure the quiet period after an authentication failure.
dot1x timeout supp-timeout	Configure the retransmission interval of Request/Challenge packets.
dot1x timeout server-timeout	Configure the server timeout duration.
dot1x timeout tx-period	Configure the retransmission interval of Request/Identity packets.
dot1x user-name compatible	Enable the compatibility with H3C IEEE 802.1X authentication clients and authentication servers.
dot1x valid-ip-acct enable	Enable the function of initiating accounting after a user's IP address is obtained.
dot1x valid-ip-acct timeout	Configure the timeout duration for an authenticated user to obtain an IP address.
dot1x system disable	Disable global IEEE 802.1X features.
show dot1x	Display IEEE 802.1X protocol parameters.
show dot1x auth-address-table	Display the list of hosts allowed for authentication.
show dot1x auto-req	Display active authentication status and parameters.
show dot1x max-req	Display the maximum retransmission count of Request/Challenge packets.
show dot1x port-control	Display information about controlled ports.
show dot1x private-supplicant-only	Display the status of the non-Ruijie client filtering function.
show dot1x probe-timer	Display the client detection parameters.
show dot1x re-authentication	Display the status of the re-authentication function.

show dot1x reauth-max	Display the maximum retransmission count of Request/Identity packets.
show dot1x summary	Display entries of users participating in authentication.
show dot1x timeout quiet-period	Display the quiet period after an authentication failure.
show dot1x timeout re-authperiod	Display the re-authentication interval.
show dot1x timeout server-timeout	Display the server timeout duration.
show dot1x timeout supp-timeout	Display the retransmission interval of Request/Challenge packets.
show dot1x timeout tx-period	Display the retransmission interval of Request/Identity packets.
show dot1x user mac	Display details about a user with a specified MAC address.
show dot1x user name	Display details about a user with a specified username.

1.1 aaa authorization ip-auth-mode

Function

Run the **aaa authorization ip-auth-mode** command to configure the global IP authorization mode.

Run the **no** form of this command to disable this feature.

Global IP authorization is disabled by default.

Syntax

aaa authorization ip-auth-mode { **dhcp-server** | **disable** | **mixed** | **radius-server** | **supplicant** }

no aaa authorization ip-auth-mode

Parameter Description

dhcp-server: Configures the Dynamic Host Configuration Protocol (DHCP) authorization mode, in which IP addresses are assigned via DHCP for binding.

disable: Disables authorization.

mixed: Configures the mixed authorization mode. In the existence of multiple global IP authorization modes, authenticated users select an IP authorization mode based on the sequence of Supplicant authorization, Remote Authentication Dial In User Service (RADIUS) authorization, and DHCP authorization.

radius-server: Configures the RADIUS authorization mode, in which IP addresses are delivered by a RADIUS server for binding.

supplicant: Configures the Supplicant authorization mode, in which Supplicant provides IP addresses for binding.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The Supplicant authorization mode supports only Ruijie Supplicant.

In RADIUS authorization mode, the server needs to deliver IP addresses through the **framed-ip** attribute.

In DHCP authorization mode, DHCP snooping or DHCP relay needs to be enabled on the device.

You are advised to use the mixed authorization mode in the case of multiple authorization modes.

Examples

The following example configures the Supplicant authorization mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# aaa authorization ip-auth-mode supplicant
```

Notifications

N/A

Common Errors

IP authorization occupies hardware resources. The considerable number of users in the network and coexistence of multiple security functions may lead to hardware resource insufficiency, which finally causes the failure of users to access the network.

1.2 clear dot1x user

Function

Run the **clear dot1x user** command to delete an IEEE 802.1X-authenticated user on the device.

Syntax

clear dot1x user { **all** | **ip** *ipv4-address* | **mac** *mac-address* | **name** *user-name* }

Parameter Description

all: Deletes all IEEE 802.1X-authenticated users.

ip *ipv4-address*: Deletes an IEEE 802.1X-authenticated user with a specific IP address.

mac *mac-address*: Deletes an IEEE 802.1X-authenticated user with a specific MAC address.

name *user-name*: Deletes an IEEE 802.1X-authenticated user with a specific username.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example deletes all IEEE 802.1X-authenticated users from the device.

```
Hostname> enable
Hostname# clear dot1x user all
```

The following example deletes an IEEE 802.1X-authenticated user with the IP address 11.1.1.1.

```
Hostname> enable
Hostname# clear dot1x user ip 11.1.1.1
```

The following example deletes an IEEE 802.1X-authenticated user with the MAC address 0012.3456.789A.

```
Hostname> enable
Hostname# clear dot1x user mac 0012.3456.789A
```

The following example deletes an IEEE 802.1X-authenticated user with the username **dot1x-user**.

```
Hostname> enable
Hostname# clear dot1x user name dot1x-user
```

1.3 dot1x accounting

Function

Run the **dot1x accounting** command to configure an accounting method list.

Run the **no** form of this command to remove this configuration.

Syntax

dot1x accounting { **default |** *list-name* }

no dot1x accounting

Parameter Description

default: Uses the default accounting method list.

list-name: Name of a specified accounting method list.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Define a method list in AAA before configuring this command.

Examples

The following example configures an accounting method list named **dot1x-acct**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x accounting dot1x-acct
```

1.4 dot1x acct-update base-on first-time server

Function

Run the **dot1x acct-update base-on first-time server** command to set the accounting update period to that delivered by the server at the first authentication.

Run the **no** form of this command to remove this configuration.

The accounting update period delivered by the server at the first authentication is not configured as the accounting update period for re-authentication by default.

Syntax

dot1x acct-update base-on first-time server

no dot1x acct-update base-on first-time server

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Some servers do not deliver the accounting update period during user re-authentication, but require that accounting update packets be sent at the accounting update period delivered at the first authentication. In this case, you can configure this command to meet this requirement.

Examples

The following example sets the accounting update period to that delivered by the server at the first authentication.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x acct-update base-on first-time server
```

1.5 dot1x auth-fail max-attempt

Function

Run the **dot1x auth-fail max-attempt** command to configure the maximum number of consecutive failed authentication attempts.

Run the **no** form of this command to restore the default configuration.

The default maximum number of consecutive failed authentication attempts is **3**.

Syntax

dot1x auth-fail max-attempt *max-attempt-number*

no dot1x auth-fail max-attempt

Parameter Description

max-attempt-number: Maximum number of consecutive failed authentication attempts. The value range is from 1 to 3.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the maximum number of times that a user is consecutively rejected by the authentication server. If the rejection count reaches this number, the port, to which the user is connected, will be added to a failed VLAN and the user is allowed to access network resources in the failed VLAN.

Examples

The following example sets the maximum number of consecutive failed authentication attempts to 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x auth-fail max-attempt 2
```

Notifications

1.6 dot1x auth-fail vlan

Function

Run the **dot1x auth-fail vlan** command to configure the failed VLAN.

Run the **no** form of this command to disable this feature.

The failed VLAN function is disabled by default.

Syntax

dot1x auth-fail vlan *vlan-id*

no dot1x auth-fail vlan

Parameter Description

vlan-id: VLAN, to which users who fail the authentication are to be added. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After the failed VLAN is configured, users who fail the authentication can access network resources only in the failed VLAN.

Examples

The following example sets the failed VLAN to VLAN 30.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x auth-fail vlan 30
```

1.7 dot1x auth-mode

Function

Run the **dot1x auth-mode** command to configure the authentication mode.

Run the **no** form of this command to restore the default configuration.

The default authentication mode is Extensible Authentication Protocol (EAP) mode.

Syntax

dot1x auth-mode { **chap** | **eap** | **pap** }

no dot1x auth-mode

Parameter Description

chap: Sets the authentication mode to Challenge-Handshake Authentication Protocol (CHAP) mode.

eap: Sets the authentication mode to EAP mode.

pap: Sets the authentication mode to Password Authentication Protocol (PAP) mode.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Select an authentication mode based on whether Ruijie Supplicant is supported and the authentication mode supported by the authentication server.

Examples

The following example sets the authentication mode to CHAP mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x auth-mode chap
```

1.8 dot1x auth-address-table

Function

Run the **dot1x auth-address-table** command to configure a list of hosts allowed for authentication.

Run the **no** form of this command to remove this configuration.

Syntax

dot1x auth-address-table address *mac-address* **interface** *interface-type interface-number*

no dot1x auth-address-table address *mac-address* **interface** *interface-type interface-number*

Parameter Description

mac-address: MAC address of an access client allowed for authentication.

interface-type interface-number: Interface type and interface number of the access client.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to allow only clients with specific MAC addresses on a specified port to perform IEEE 802.1X authentication.

Examples

The following example sets the access port of a host allowed for authentication to GigabitEthernet 0/1 and the MAC address to 00d0.f800.0cb2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x auth-address-table address 00d0.f800.0cb2 interface
gigabitEthernet 0/1

1.9 dot1x auth-with-order

Function

Run the **dot1x auth-with-order** command to set the priority of MAB to be higher than that of IEEE 802.1X authentication.

Run the **no** form of this command to restore the default configuration.

The priority of MAB is lower than that of IEEE 802.1X authentication by default.

Syntax

dot1x auth-with-order

no dot1x auth-with-order

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The priority of IEEE 802.1X authentication is higher than that of MAB by default. If IEEE 802.1X authentication is performed after MAB is completed, the IEEE 802.1X authentication result will replace the MAB result. After this function is enabled, MAB has a higher priority and the device performs MAB first. The IEEE 802.1X authentication result cannot replace the MAB result.

Examples

The following example sets the priority of MAB to be higher than that of IEEE 802.1X authentication.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x auth-with-order
```

1.11 dot1x auto-req

Function

Run the **dot1x auto-req** command to enable the active IEEE 802.1X authentication function on the device.

Run the **no** form of this command to disable this feature.

The active IEEE 802.1X authentication function is enabled by default.

Syntax

dot1x auto-req

no dot1x auto-req

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Active authentication refers that the device actively sends a Request/Identity packet, which triggers IEEE 802.1X clients to initiate IEEE 802.1X authentication.

This function must be enabled for MAB deployment.

Some clients use authentication clients embedded in the operating system (OS). They may not initiate authentication immediately after connecting to the network, and users cannot use the network promptly. The

configured active authentication can urge such clients to initiate authentication in a timely manner after they connect to the network.

Do not enable this function when a controlled port is a trunk port and is directly connected to clients. Otherwise, frequent authentication or going offline may occur.

Examples

The following example enables active 802.1X authentication on the device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x auto-req
```

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is configured, if a RADIUS server becomes reachable, it verifies the identities of users authorized by IAB in the unavailability period of RADIUS servers.

Examples

The following example enables IAB recovery.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x critical recovery action reinitialize
```

1.18 dot1x critical vlan

Function

Run the **dot1x critical vlan** command to configure the IAB VLAN.

Run the **no** form of this command to disable this feature.

The IAB VLAN function is disabled by default.

Syntax

dot1x critical vlan *vlan-id*

no dot1x critical vlan

Parameter Description

vlan-id: ID of an IAB VLAN. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the IAB VLAN to VLAN 10.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x critical vlan 10
```

1.19 dot1x dbg-filter

Function

Run the **dot1x dbg-filter** command to configure the debugging of a specific MAC address.

Run the **no** form of this command to remove this configuration.

Debugging information of all authenticated users is printed by default.

Syntax

dot1x dbg-filter *mac-address*

no dot1x dbg-filter *mac-address*

Parameter Description

mac-address: MAC address of a user whose debugging information needs to be output.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When there are a large number of users in the network and a network fault needs to be pinpointed, you can configure the debugging of users with specific MAC addresses, to avoid outputting debugging information of too many irrelevant users.

Examples

The following example debugs the MAC address 00d0.f800.0001.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x dbg-filter 00d0.f800.0001
```

1.20 dot1x default-user-limit

Function

Run the **dot1x default-user-limit** command to configure the maximum number of users who can be authenticated on an interface.

Run the **no** form of this command to restore the default configuration.

The maximum number of users who can be authenticated on an interface is unlimited.

Syntax

dot1x default-user-limit *limit-number*

no dot1x default-user-limit

Parameter Description

limit-number: Maximum number of users who can be authenticated on an interface. The value range is from 1 to 1000000.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the maximum number of users who can be authenticated on an interface to 10.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x default-user-limit 10
```

1.21 dot1x default

Function

Run the **dot1x default** command to restore the default configuration of IEEE 802.1X.

Syntax

dot1x default

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can clear existing IEEE 802.1X configurations in one-click mode. Use this command when considerable 802.1X configurations need to be cleared and reconfiguration is needed.

Examples

The following example restores the default configuration of IEEE 802.1X.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x default
```
