1.22 dot1x dynamic-vlan enable

Function

Run the **dot1x dynamic-vlan enable** command to enable dynamic VLAN redirection on a port.

Run the **no** form of this command to disable this feature.

Dynamic VLAN redirection is disabled on a port by default.

Syntax

dot1x dynamic-vlan enable

no dot1x dynamic-vlan enable

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Configure this command when authenticated users need to be added to the VLAN delivered by the server.

Examples

The following example enables dynamic VLAN redirection on a port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x dynamic-vlan enable
```

1.23 dot1x guest-vlan

Function

Run the **dot1x guest-vlan** command to configure the guest VLAN on a controlled port.

Run the **no** form of this command to disable this feature.

The guest VLAN function is disabled on a controlled port by default.

Syntax

dot1x guest-vlan *vlan-id*

no dot1x guest-vlan

Parameter Description

vlan-id: Guest VLAN, to which a port needs to be added. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The guest VLAN function is used to provide network access permissions for terminals, on which the IEEE 802.1X client is not installed.

After the guest VLAN function is configured, if no IEEE 802.1X client is detected on a controlled port, the port is added to the guest VLAN to allow terminals connected to the port to access network resources in the guest VLAN.

After guest VLAN is enabled on a port, do not configure L2 attributes, especially do not manually configure the port VLAN.

Examples

The following example sets the guest VLAN to VLAN 20 on a controlled port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x guest-vlan 20
```

1.24 dot1x mab-username upper

Function

Run the **dot1x mab-username upper** command to configure usernames used for MAB to use uppercase letters.

Run the **no** form of this command to restore the default configuration.

Usernames used for MAB use lowercase letters by default.

Syntax

dot1x mab-username upper

no dot1x mab-username upper

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to meet requirements of different servers for username uppercase/lowercase in MAB.

Examples

The following example configures usernames used for MAB to use uppercase letters.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x mab-username upper
```

1.25 dot1x mac-auth-bypass

Function

Run the **dot1x mac-auth-bypass** command to enable single-user MAB.

Run the **no** form of this command to disable this feature.

Single-user MAB is disabled by default.

Syntax

dot1x mac-auth-bypass

no dot1x mac-auth-bypass

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Single-user MAB applies to the scenario, in which a port has only one dumb terminal attached to it or a port has only one dumb terminal to be authenticated. After successful authentication, other terminals connected to the port can access the network.

Examples

The following example enables single-user MAB.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x mac-auth-bypass
```

1.26 dot1x mac-auth-bypass multi-user

Function

Run the **dot1x mac-auth-bypass multi-user** command to enable multi-user MAB.

Run the **no** form of this command to disable this feature.

Multi-user MAB is disabled by default.

Syntax

dot1x mac-auth-bypass multi-user

no dot1x mac-auth-bypass multi-user

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Multi-user MAB applies when multiple dumb terminals are connected to one port. Multi-user MAB can be used together with IEEE 802.1X authentication in mixed access scenarios such as the PC+VoIP daisy-chain topology.

Examples

The following example enables multi-user MAB.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x mac-auth-bypass multi-user
```

1.27 dot1x mac-auth-bypass timeout-activity

Function

Run the **dot1x mac-auth-bypass timeout-activity** command to configure the MAB timeout duration.

Run the **no** form of this command to remove this configuration.

MAB does not time out by default.

Syntax

dot1x mac-auth-bypass timeout-activity *timeout*

no dot1x mac-auth-bypass timeout-activity

Parameter Description

timeout: MAB timeout duration, in seconds. The value range is from 1 to 65535.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can configure this parameter to restrict the network access duration of dumb terminals.

Examples

The following example sets the MAB timeout duration to 3,600 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x mac-auth-bypass timeout-activity 3600
```

1.28 dot1x mac-auth-bypass violation

Function

Run the **dot1x mac-auth-bypass violation** command to enable the MAB violation function.

Run the **no** form of this command to disable this feature.

MAB violation is disabled by default.

Syntax

dot1x mac-auth-bypass violation

no dot1x mac-auth-bypass violation

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This function can be configured to restrict one port to have only one dumb terminal. This command applies only to single-user MAB scenarios.

Examples

The following example enables the MAB violation function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x mac-auth-bypass violation
```

1.29 dot1x mac-auth-bypass vlan

Function

Run the **dot1x mac-auth-bypass vlan** command to configure the MAB VLAN.

Run the **no** form of this command to disable this feature.

The MAB VLAN function is disabled by default.

Syntax

dot1x mac-auth-bypass vlan *vlan-id*

no dot1x mac-auth-bypass vlan *vlan-id*

Parameter Description

vlan-id: ID of a VLAN allowed for MAB. The value is a valid VLAN ID. If you configure multiple VLAN IDs, separate them with commas (,). You can also configure a VLAN ID range, for example, 3-5 indicates VLANs 3, 4, and 5.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command is configured to only allow users in a specific VLAN on an interface to perform MAB.

Examples

The following example sets MAB VLANs to VLAN 5 and VLANs 8-20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x mac-auth-bypass vlan 5, 8-20
```

1.30 dot1x max-req

Function

Run the **dot1x max-req** command to configure the maximum retransmission count of Request/Challenge packets.

Run the **no** form of this command to restore the default configuration.

The default maximum retransmission count of Request/Challenge packets is **3**.

Syntax

dot1x max-req *max-req-number*

no dot1x max-req

Parameter Description

max-req-number: Maximum retransmission count of Request/Challenge packets. The value range is from 1 to 10.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The default value is recommended.

Examples

The following example sets the maximum retransmission count of Request/Challenge packets to 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x max-req 2
```

1.32 dot1x multi-mab quiet-period

Function

Run the **dot1x multi-mab quiet-period** command to configure the quiet period after a multi-user MAB failure.

Run the **no** form of this command to restore the default configuration.

The default quiet period after a multi-user MAB failure is **30** seconds.

Syntax

dot1x multi-mab quiet-period *quiet-period*

no dot1x multi-mab quiet-period

Parameter Description

quiet-period: Quiet period after a multi-user MAB failure, in seconds. The value range is from 0 to 65535 and the value **0** indicates no quiet period.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After multi-user MAB is enabled, illegitimate users connected to an interface may attack the device. Therefore, it is necessary to prevent illegitimate users from frequently initiating authentication, in an effort to reduce the server load. Configure the quiet period after a multi-user MAB failure in global configuration mode. After configuration, if a MAC address fails the authentication, it can re-initiate authentication only after the quiet period elapses. Configure this quiet period as required.

Examples

The following example sets the quiet period after a multi-user MAB failure to 2 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x multi-mab quiet-period 2
```

Run the **no** form of this command to restore the default configuration.

The default number of authentication failures required for user entry aging is **60**.

Syntax

dot1x multi-mab quiet-user fail-times [*fail-times*]

no dot1x multi-mab quiet-user fail-times

Parameter Description

fail-times: Number of authentication failures required for user entry aging. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure aging rules for users who fail the authentication.

Examples

The following example sets the number of authentication failures required for user entry aging to 3.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x multi-mab quiet-user fail-times 3
```

Function

Run the **dot1x multi-mab quiet-user authen-num** command to configure the rate of initiating authentication using the MAC address in a multi-user MAB quiet user entry.

Run the **no** form of this command to restore the default configuration.

The default rate of initiating authentication using the MAC address in a multi-user MAB quiet user entry is **50** MAC addresses per second.

Syntax

dot1x multi-mab quiet-user authen-num [*authen-num*]

no dot1x multi-mab quiet-user authen-num

Parameter Description

authen-num: Rate of initiating authentication using the MAC address in a multi-user MAB quiet user entry, in MAC addresses per second. The value range is from 1 to 1000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the rate of initiating authentication using the MAC address in a multi-user MAB quiet user entry to 3 MAC addresses per second.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x multi-mab quiet-user authen-num 3

Run the **no** form of this command to restore the default configuration.

The default server rejection count for the device to delete a quiet user entry is **1**.

Syntax

dot1x multi-mab quiet-user reject-times [*reject-times*]

no dot1x multi-mab quiet-user reject-times

Parameter Description

reject-times: Server rejection count for the device to delete a quiet user entry.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the device to delete a quiet user entry after the server rejects the user authentication three times.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x multi-mab quiet-user reject-times 3
```

1.36 dot1x mab-username format

Function

Run the **dot1x mab-username format** command to configure the username format for MAB.

Run the **no** form of this command to remove this configuration.

No username format for MAB is configured by default.

Syntax

dot1x mab-username format [**with-colon** | **with-dot** | **with-hyphen** | **with-3hyphen**]

no dot1x mab-username format

Parameter Description

with-colon: Indicates that the username format is xx:xx:xx:xx:xx:xx.

with-dot: Indicates that the username format is xxxx.xxxx.xxxx.

with-hyphen: Indicates that the username format is xx-xx-xx-xx-xx-xx.

with-3hyphen: Indicates that the username format is xxxx-xxxx-xxxx.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the required username format for MAB is xx-xx-xx-xx-xx-xx, configure **with-hyphen** in this command.

When the required username format for MAB is xxxx.xxxx.xxxx, configure **with-dot** in this command.

When the required username format for MAB is xx:xx:xx:xx:xx:xx, configure **with-colon** in this command.

When the required username format for MAB is xxxx-xxxx-xxxx, configure **with-3hyphen** in this command.

Examples

The following example sets the username format for MAB to **with-hyphen**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x mab-username format with-hyphen
```

1.38 dot1x port-control-mode

Function

Run the **dot1x port-control-mode** command to configure the port control mode.

Run the **no** form of this command to restore the default configuration.

The default port control mode is MAC-based control.

Syntax

dot1x port-control-mode { **mac-based** | **port-based** [**single-host**] }

no dot1x port-control-mode

Parameter Description

mac-based: Sets the port control mode to MAC-based control.

port-based [**single-host**]: Sets the port control mode to port-based control. **single-host** indicates that only one client is allowed on an interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Configure the MAC-based control mode if each user on a controlled port has to pass authentication before making communication.

Configure the port-based control mode if all users on a controlled port can make communication after one of them passes the authentication.

In port-based control mode, this command can be configured only when authenticated users are dynamic users.

Examples

The following example sets the port control mode to port-based control.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dot1x port-control-mode port-based

1.39 dot1x probe-timer interval

Function

Run the **dot1x probe-timer interval** command to configure the Ruijie client detection interval.

Run the **no** form of this command to restore the default configuration.

The default client detection interval is **20** seconds.

Syntax

dot1x probe-timer interval *interval*

no dot1x probe-timer interval

Parameter Description

interval: Client detection interval, in seconds. The value range is from 1 to 32767.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The default configuration is recommended.

The interval for sending packets to detect whether Ruijie clients are online must be smaller than half of the online detection duration.

Examples

The following example sets the Ruijie client detection interval to 30 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x probe-timer interval 30
```

Function

Run the **dot1x probe-timer alive** command to configure the Ruijie client detection duration.

Run the **no** form of this command to restore the default configuration.

The default Ruijie client detection duration is **250** seconds.

Syntax

dot1x probe-timer alive *alive-time*

no dot1x probe-timer alive

Parameter Description

alive-time: Ruijie client detection duration, in seconds. The value range is from 3 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After a client is authenticated and goes online, if the device fails to receive any detection response from the client within the detection duration, the device considers the client offline.

The default configuration is recommended.

The online detection duration must be greater than twice the interval for sending packets to detect whether Ruijie clients are online.

Examples

The following example sets the Ruijie client detection duration to 120 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x probe-timer alive 120
```

no dot1x timeout server-timeout

Parameter Description

server-timeout: Server timeout time, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The server timeout duration of IEEE 802.1X must be greater than that of RADIUS.

The server timeout duration of IEEE 802.1X is smaller than that of RADIUS by default. Set the server timeout duration of RADIUS to a smaller value in actual application.

Examples

The following example sets the server timeout duration to 10 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x timeout server-timeout 10
```

1.51 dot1x timeout tx-period

Function

Run the **dot1x timeout tx-period** command to configure the retransmission interval of Request/Identity packets.

Run the **no** form of this command to restore the default configuration.

The default retransmission interval of Request/Identity packets is **3** seconds.

Syntax

dot1x timeout tx-period *interval*

no dot1x timeout tx-period

Parameter Description

interval: Retransmission interval of Request/Identity packets, in seconds. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The default value is recommended.

Examples

The following example sets the retransmission interval of Request/Identity packets to 5 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x timeout tx-period 5
```

1.52 dot1x user-name compatible

Function

Run the **dot1x user-name compatible** command to enable the compatibility with H3C IEEE 802.1X authentication clients and authentication servers.

Run the **no** form of this command to disable this feature.

The compatibility with H3C 802.1X authentication clients and authentication servers is disabled by default.

Syntax

dot1x user-name compatible

no dot1x user-name compatible

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Configure this command when H3C authentication clients and authentication servers are used for IEEE 802.1X authentication.

Configure this command when H3C authentication servers are used for MAB.

Examples

The following example enables the compatibility with H3C IEEE 802.1X authentication clients and authentication servers.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x user-name compatible
```

1.53 dot1x valid-ip-acct enable

Function

Run the **dot1x valid-ip-acct enable** command to enable the function of initiating accounting after a user's IP address is obtained.

Run the **no** form of this command to disable this feature.

The function of initiating accounting after a user's IP address is obtained is disabled by default.

Syntax

dot1x valid-ip-acct enable

no dot1x valid-ip-acct enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After this command is configured, clients do not initiate accounting immediately after passing authentication, but wait until they obtain IP addresses.

Configure this function when a server requires that accounting packets carry user IP addresses.

Examples

The following example enables the function of initiating accounting after a user's IP address is obtained.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x valid-ip-acct enable
```

1.54 dot1x valid-ip-acct timeout

Function

Run the **dot1x valid-ip-acct timeout** command to configure the timeout duration for an authenticated user to obtain an IP address.

Run the **no** form of this command to restore the default configuration.

The default timeout duration for an authenticated user to obtain an IP address is **5** minutes.

Syntax

dot1x valid-ip-acct timeout *timeout*

no dot1x valid-ip-acct timeout

Parameter Description

timeout: Allowed timeout duration for an authenticated user to obtain an IP address, in minutes. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the function of initiating accounting after a user's IP address is obtained, is enabled, a client may not initiate accounting within a long period of time due to the failure to obtain an IP address. For this, you can configure a timeout duration as required.

Examples

The following example sets the timeout duration for an authenticated user to obtain an IP address to 10 minutes.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# dot1x valid-ip-acct timeout 10
```

Related Commands

- **dot1x valid-ip-acct enable**

1.55 dot1x system disable

Function

Run the **dot1x system disable** command to disable global IEEE 802.1X features.

Run the **no** form of this command to restore the default configuration.

Global IEEE 802.1X features are enabled by default.

Syntax

dot1x system disable

no dot1x system disable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Disable global IEEE 802.1X features when servers are unavailable. After global IEEE 802.1X features are disabled, users can access the Internet without authentication and authenticated users will be brought offline.

If global IEEE 802.1X features are enabled after server recovery, users on the controlled ports need to be authenticated before accessing the Internet.

Examples

The following example disables global IEEE 802.1X features.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dot1x system disable
```

Examples

The following example displays IEEE 802.1X protocol parameters.

```
Hostname> enable
Hostname# show dot1x
802.1X basic information:
  802.1X Status ......................... enable
  Authentication Mode ................... eap
  Authorization mode .................... disable
  Total User Number ..................... 0 (exclude dynamic user)
  Authenticated User Number ............. 0 (exclude dynamic user)
  Dynamic User Number ................... 0
  Re-authentication ..................... disable
  Re-authentication Period .............. 3600 seconds
  Re-authentication max ................. 3 times
  Quiet Period .......................... 10 seconds
  Tx Period ............................. 30 seconds
  Supplicant Timeout .................... 3 seconds
  Server Timeout ........................ 5 seconds
  Maximum Request ....................... 3 times
  Client Online Probe ................... disable
```

```
Eapol Tag ............................ enable
802.1x redirect ...................... disable
Private supplicant only ............... disable
```

Table 1-1 Output Fields of the show dot1x Command

Field	Description
802.1X Status	Whether the IEEE 802.1X function is enabled
Authentication Mode	Authorization mode
Total User Number	Total number of authenticated users and users being authenticated
Authed User Number	Number of authenticated users
Dynamic User Number	Number of dynamic users in port mode
Re-authentication	Status of the re-authentication function
Re-authentication Period	Re-authentication period
Re-authentication max	Maximum number of re-authentication times
Quiet Period	Quiet period after an authentication failure
Tx Period	Retransmission interval of Request/Identity packets
Supplicant Timeout	Retransmission interval of Request/Challenge packets
Server Timeout	Server timeout duration
Maximum Request	Maximum request count
Client Online Probe	Status of online client detection
Eapol Tag	Whether EAPOL packets carry tags
802.1x redirect	Status of the 2nd-generation Ruijie Supplicant deployment function
Private supplicant only	Status of private client detection

1 Web Authentication Commands

Command	Function
accounting	Configure the accounting method list used by a template.
app-name	Configure the app name used by a template.
authentication	Configure the authentication method list used by a template.
bindmode	Configure the binding mode used by a template.
clear web-auth acl	Clear all whitelist configurations for web authentication.
clear web-auth direct-arp	Clear all Address Resolution Protocol (ARP) resources.
clear web-auth direct-host	Clear all authentication-exempted users.
clear web-auth direct-site	Clear all authentication-free network resources.
clear web-auth user	Force a user offline.
domain	Enable automatic adding of domain information after usernames.
fmt	Configure the URL format of redirection packets.
http redirect direct-arp	Configure a straight-through ARP resource range.
http redirect direct-site	Configure an authentication-free network resource range.
http redirect port	Redirect HTTP requests with specified port numbers from users.
http redirect session-limit	Configure the global maximum number of HTTP sessions allowed for an unauthenticated user.
http redirect timeout	Configure the redirection connection timeout time.
ip	Configure the IPv4 address and virtual routing and forwarding (VRF) instance of the portal server.
ip portal source-interface	Configure the portal communication source port.
port	Configure the communication port of the portal server.

redirect	Configure the encapsulation format of redirection packets.
show web-auth acl	Display whitelist configurations.
show web-auth app-config	Display app configurations.
show web-auth authmng	Display web authentication data.
show web-auth control	Display controlled authentication configurations.
show web-auth direct-arp	Display the straight-through ARP resource range.
show web-auth direct-host	Display the authentication-exempted user range.
show web-auth direct-site	Display the straight-through website range.
show web-auth ip-mapping	Display the mapping between servers and users.
show web-auth parameter	Display basic parameter configurations for web authentication.
show web-auth portal-check	Display portal-check parameters.
show web-auth rdport	Display the intercepted TCP ports.
show web-auth syslog ip	Display user online and offline records.
show web-auth template	Display the portal server configurations.
show web-auth user	Display online information of all users or a specified user, including the IP address, interface, and online time.
url	Configure the authentication page address of the portal server.
web-auth acl	Configure a whitelist.
web-auth apply-mapping	Apply the template mapping method on an interface.
web-auth dhcp-check	Enable Dynamic Host Configuration Protocol (DHCP) address check for web authentication.
web-auth dhcp-check vlan	Enable DHCP address check for web authentication on an interface.
web-auth dhcp-check disable	Disable DHCP address check on a VLAN.
web-auth direct-host	Configure the authentication-exempted user range.
web-auth enable	Enable web authentication on a port.
web-auth import-ssl	Upload the certificate and key files.

web-auth linkdown-timeout	Configure the authenticated user logout delay after a port is down.
web-auth logging enable	Configure the web authentication logging function.
web-auth mapping	Configure the webauth template mapping method.
web-auth portal direct-auth	Enable the function of adding the authentication page to Favorite.
web-auth portal extension	Enable portal specification extension.
web-auth portal key	Configure the communication key between the NAS and the portal server.
web-auth portal-check	Enable portal server detection.
web-auth portal-escape	Enable the portal escape function.
web-auth portal-import attr-26	Enable transparent transmission of RADIUS attributes.
web-auth portal-valid unique-name	Enable uniqueness check of portal authentication accounts.
web-auth radius-escape	Enable RADIUS server escape for web authentication.
web-auth ssl-policy https-redirect	Apply the HTTPS certificate and key files.
web-auth template	Create an authentication template and enter the authentication template configuration mode.
web-auth update-interval	Configure the interval for updating online user information.
web-auth vlan-control	Configure VLAN-based authentication on a port.

1.1 accounting

Function

Run the **accounting** command to configure the accounting method list used by a template.

Run the **no** form of this command to remove this configuration.

The default accounting method list is used by a template by default.

Syntax

accounting *method-list*

no accounting

Parameter Description

method-list: Name of the accounting method list used by a template.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

Before you configure an accounting method list, ensure that the accounting methods in the list have been configured on the Authentication, Authorization and Accounting (AAA) module and the method list name is the same as that configured in the AAA module.

The same authentication method needs to be used for IPv4 and IPv6 packets.

Examples

The following example configures accounting method list mlist1 for template eportalv2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template eportalv2
Hostname(config.tmplt.eportalv2)# accounting mlist1
```

1.2 app-name

Function

Run the **app-name** command to configure the app name used by a template.

Run the **no** form of this command to remove this configuration.

Syntax

app-name { **APP_AUTH** | *app-name* }

no app-name

Parameter Description

APP_AUTH: Configures the gateway authentication app.

app-name: App name used by a template.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

The name of the app interworking with the web authentication module must be correctly configured.

Examples

The following example sets the app name used by a template to **appauth**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template appauth
Hostname(config.tmplt.app)# app-name appauth
```

1.3 authentication

Function

Run the **authentication** command to configure the authentication method list used by a template.

Run the **no** form of this command to remove this configuration.

The default authentication method list is used by a template by default.

Syntax

authentication *method-list*

no authentication

Parameter Description

method-list: Name of the authentication method list used by a template.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

The authentication method list name configured by running this command must be the same as that configured in the AAA module.

The first-generation web authentication does not support the configuration of an authentication method list.

Examples

The following example configures authentication method list mlist1 for template eportalv2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template eportalv2
Hostname(config.tmplt.eportalv2)# authentication mlist1
```

1.4 bindmode

Function

Run the **bindmode** command to configure the binding mode used by a template.

Run the **no** form of this command to remove this configuration.

The default binding mode used by a template is IP address+MAC address.

Syntax

bindmode { **ip-mac-mode** | **ip-only-mode** }

no bindmode

Parameter Description

ip-mac-mode: Specifies the IP address+MAC address binding mode. In this mode, both the IP address and media access control (MAC) address are used in the forwarding entry.

ip-only-mode: Specifies the IP address binding mode. In this mode, only the IP address is used in the forwarding entry. You are advised to use this binding mode in layer 3 (L3) networks because MAC address information in L3 networks is incorrect.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the binding mode used by template eportalv2 to IP address only.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template eportalv2
Hostname(config.tmplt.eportalv2)# bindmode ip-only-mode
```

1.10 domain

Function

Run the **domain** command to enable automatic adding of domain information after usernames.

Run the **no** form of this command to remove this configuration.

No domain information is added after usernames by default.

Syntax

domain *domain-info*

no domain

Parameter Description

domain-info: Domain information to be automatically added after usernames. The value is a string of 1 to 63 bytes.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

Not all templates support automatic adding of domain information after usernames. Template eportalv1 does not support, while template eportalv2 supports.

Examples

The following example configures automatic adding of domain information "@wifi" after usernames.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template eportalv2
Hostname(config.tmplt.eportalv2)# domain @wifi
```

1.11 fmt

Function

Run the **fmt** command to configure the URL format of redirection packets.

Run the **no** form of this command to remove this configuration.

The Ruijie URL format is used for redirection packets by default.

Syntax

URL format defined for the first-generation web authentication template:

fmt { **ace** | **default** }

URL format defined for the second-generation web authentication template:

fmt { **cmcc-ext1** | **cmcc-ext2** | **cmcc-ext3** | **cmcc-mtx** | **cmcc-normal** | **ct-jc** | **cucc** | **default** }

Custom URL format:

fmt custom [**encry** { **md5** | **des** | **des_ecb** | **des_ecb3** | **none** }] [**user-ip** *user-ip-string*] [**user-mac** *user-mac-string* **mac-format** [**dot** | **line** | **none** | **5colon**]] [**user-vid** *user-vid-string*] [**user-id** *user-id-string*] [**nas-ip** *nas-ip-string*] [**nas-id** *nas-id-string*] [**nas-id2** *nas-id2-string*] [**ap-mac** *ap-mac-string* **mac-format** [**dot** | **line** | **none** | **5colon**]] [**url** *url-string*] [**ssid** *ssid-string*] [**port** *port-string*] [**ac-serialno** *ac-serialno-string*] [**ap-serialno** *ap-serinalno-string*] [**additional** *additional-string*] [**nas-name** *nas-name-string*]

no fmt

no fmt custom [**user-ip**] [**user-mac**] [**user-vid**] [**user-id**] [**nas-ip**] [**nas-id**] [**nas-id2**] [**ap-mac**] [**url**] [**ssid**] [**port**] [**ac-serialno**] [**ap-serialno**] [**additional**] [**nas-name**]

Parameter Description

cmcc-ext1: Configures the extended URL format of China Mobile Communications Corporation (CMCC).

cmcc-ext2: Configures the URL format of Liaoning Mobile.

cmcc-ext3: Configures the URL format that Ningbo/Jiaxing Mobile specifies for access controller (AC) vendors.

cmcc-mtx: Configures the URL format that CMCC specifies for AC vendors.

cmcc-normal: Configures the standard URL format of CMCC.

ct-jc: Configures the URL format of China Telecom for collection projects.

cucc: Configures the URL format of Shandong Unicom.

default: Configures the default Ruijie URL format for redirection packets.

ace: Supports access control entry (ACE) association.

custom: Specifies the custom format.

md5: Configures MD5 encryption for parameters.

des: Configures Data Encryption Standard (DES) encryption for parameters.

des_ecb: Configures des_ecb encryption for parameters.

des_ecb3: Configures des_ecb3 encryption for parameters.

none: Configures plaintext parameter transmission.

user-ip *user-ip-string*: Specifies the IP address of a user.

user-mac *user-mac-string*: Specifies the MAC address of a user.

dot: Configures the MAC address format as xxxx.xxxx.xxxx.

line: Configures the MAC address format as xx-xx-xx-xx-xx-xx.

none: Configures the MAC address format as xxxxxxxxxxxx.

5colon: Configures the MAC address format as xx:xx:xx:xx:xx:xx.

user-vid *user-vid-string*: Specifies the virtual local area network ID (VID) of a user.

user-id *user-id-string*: Specifies the user ID.

nas-ip *nas-ip-string*: Specifies the IP address of the network access server (NAS).

nas-id *nas-id-string*: Specifies the ID of the NAS.

nas-id2 *nas-id2-string*: Specifies the ID of the other NAS. (Two **nas-id** parameters can be customized.)

ap-mac *ap-mac-string*: Specifies the MAC address of the associated access point (AP).

url *url-string*: Specifies the original access URL of a user.

ssid *ssid-srting*: Specifies the Service Set Identifier (SSID) name.

port *port-string*: Specifies the user authentication port.

ac-serialno *ac-serialno-string*: Specifies the serial number (SN) of an AC.

ap-serialno *ap-serinalno-string*: Specifies the SN of an AP.

additional *additional-string*: Specifies a fixed string. Some portal servers need to be identified by special character strings.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

The URL format needs to be configured based on the interworking specifications of the portal server.

Examples

The following example sets the URL format of redirection packets to the CMCC extended format.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template eportalv2
Hostname(config.tmplt.eportalv2)# fmt cmcc-ext1
```

1.12 http redirect direct-arp

Function

Run the **http redirect direct-arp** command to configure a straight-through ARP resource range.

Run the **no** form of this command to remove this configuration.

No straight-through ARP resource range is configured by default.

Syntax

http redirect direct-arp *ipv4-address* [*mask*]

no http redirect direct- arp *ipv4-address* [*mask*]

Parameter Description

ipv4-address: IPv4 address configured as a straight-through ARP resource.

mask: Mask of the IPv4 address configured as a straight-through ARP resource.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When ARP check is enabled, users cannot learn the ARP entries of the gateway or other devices. You can run this command to permit ARP learning for a specified address or network segment.

When ARP check is enabled, you need to configure the gateway of the PCs connecting to the L2 access device as a straight-through ARP resource.

If both straight-through websites and ARP resources are configured for the same address/network segment, the commands will be combined automatically.

If no ARP option is specified in the straight-through website configuration, the option will be added automatically after combination.

When ARP check is enabled, if the outbound interface address of the PC connecting to the L2 access device is not the gateway address, you need to configure the outbound interface address as a straight-through ARP resource. If multiple outbound addresses exist, configure these addresses as straight-through ARP resources.

If ARP check is enabled, you must configure the authentication-free network resources and gateway address as straight-through ARP resources.

Examples

The following example configures the website whose IP address is 172.16.0.1 as a straight-through ARP resource.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# http redirect direct-arp 172.16.0.1
```

Notifications

When an invalid IP address/mask format is used, the following notification will be displayed:

```
%Error: Invalid IP address.
```

Common Errors

1.13 http redirect direct-site

Function

Run the **http redirect direct-site** command to configure an authentication-free network resource range.

Run the **no** form of this command to remove this configuration.

No authentication-free network resource range is configured by default.

Syntax

http redirect direct-site *ipv4-address* [*mask*] [**arp** | *port-number*&<1-8>]
no http redirect direct-site *ipv4-address* [*mask*]

Parameter Description

ipv4-address: IPv4 address configured as an authentication-free network resource.

mask: Mask of the IPv4 address configured as an authentication-free network resource.

arp: Performs ARP binding for the authentication-free network resource range when the APR check function is enabled, that is, configures the **arp** keyword. This field is required only when IPv4 network resources are configured.

port-number&<1-8>: Authentication-free L4 port. &<1-8> indicates that the parameter can be entered for a maximum of eight times. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The number of authentication-free network resources and the number of authentication-exempted users cannot exceed 1000. The actual number of available resources may be reduced because of other security modules. Therefore, it is recommended that network segments be configured if many addresses need to be configured.

Examples

The following example configures the website whose IPv4 address is 172.16.0.1 as an authentication-free network resource.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# http redirect direct-site 172.16.0.1
```

The following example configures the website whose MAC address is 0000:5e00:0101 as an authentication-free network resource.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# http redirect direct-site 0000:5e00:0101
```

Notifications

When an invalid IP address/mask format is used, the following notification will be displayed:

```
%Error: Invalid IP address.
```

Common Errors

1.14 http redirect port

Function

Run the **http redirect port** command to redirect HTTP requests with specified port numbers from users.

Run the **no** form of this command to remove this configuration.

The NAS intercepts HTTP packets with port numbers 80 and 443 from users and redirects them to the authentication page by default.

Syntax

http redirect port *port-number*

no http redirect port *port-number*

Parameter Description

port-number: Port number in HTTP requests to be intercepted. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The NAS needs to intercept HTTP packets with specified port numbers from users and redirect these HTTP packets to the authentication page to complete authentication. The port numbers can be configured.

A maximum of 10 different destination port numbers can be configured, excluding default ports 80 and 443.

The commonly used management ports on the access or convergence device, such as ports 22, 23, and 53, and ports reserved by the system are not allowed to be configured as the redirection port.

HTTP seldom uses ports with numbers smaller than 1000 except port 80. To avoid a conflict with well-known Transmission Control Protocol (TCP) ports, do not configure a port with a small number as the redirection port.

Examples

The following example redirects HTTP requests with destination port number 8080 from users.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# http redirect port 8080
```

The following example does not redirect HTTP requests with destination port number 80 from users.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no http redirect port 80
```

Notifications

When HTTP requests with the destination port set to a well-known protocol port or internal reserved port, for example, port 23, are intercepted, the following notification will be displayed:

```
%Error: Can't set local reserved port(23) as redirection port.
```

Common Errors

1.15 http redirect session-limit

Function

Run the **http redirect session-limit** command to configure the global maximum number of HTTP sessions allowed for an unauthenticated user.

Run the **no** form of this command to remove this configuration.

The global maximum number of HTTP sessions allowed for an unauthenticated user is **255** by default.

Syntax

http redirect session-limit *session-number*

no http redirect session-limit

Parameter Description

session-number: Global maximum number of HTTP sessions allowed for an unauthenticated user. The value range is from 1 to 255.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

TCP connection resources may be exhausted if unauthenticated users initiate excessive HTTP attacks. Therefore, it is necessary to restrict the maximum number of HTTP sessions allowed for unauthenticated users on the NAS. User authentication occupies one HTTP session, and other applications of a user may also need HTTP sessions. Therefore, you are not advised to set the maximum number of HTTP sessions to 1 for unauthenticated users.

If the authentication page fails to be displayed during web authentication, the maximum number of HTTP sessions may be reached. When this happens, the user can close the application programs that occupy HTTP sessions and perform web authentication again.

Examples

The following example sets the global maximum number of HTTP sessions allowed for an unauthenticated user to 4.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# http redirect session-limit 4
```

1.16 http redirect timeout

Function

Run the **http redirect timeout** command to configure the redirection connection timeout time.

Run the **no** form of this command to remove this configuration.

The default redirection connection timeout time is **3** seconds.

Syntax

http redirect timeout *timeout*

no http redirect timeout

Parameter Description

timeout: Redirection connection timeout time, in seconds. The value range is from 1 to 10.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

HTTP redirection is implemented by establishing a TCP connection between the NAS and a user host and adding the redirection page URL to the 302 packet replied by the NAS. After a TCP connection is established between the NAS and a user host, the TCP connection is closed after the NAS receives an HTTP GET/HEAD packet from the user host and responds with an HTTP redirection packet.

The redirection connection timeout time prevents a TCP connection being occupied for a long time because the user host does not send a GET/HEAD packet. After the timeout time expires, the NAS will forcibly disconnect the TCP connection.

Examples

The following example sets the redirection connection timeout time to 4 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# http redirect timeout 4
```

1.17 ip

Function

Run the **ip** command to configure the IPv4 address and virtual routing and forwarding (VRF) instance of the portal server.

Run the **no** form of this command to remove this configuration.

No portal server IPv4 address or VRF instance is configured by default.

Syntax

ip [*ipv4-address* | **oob** | **vrf** *vrf-name*]

no ip [**oob** | **vrf**]

Parameter Description

ipv4-address: IPv4 address of the portal server.

oob: Uses the MGMT port for communication.

vrf *vrf-name*: Specifies the virtual private network (VPN) instance name.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the IP address of the portal server for redirection in template eportalv1 to 172.16.0.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template eportalv1
Hostname(config.tmplt.eportalv1)# ip 172.16.0.1
```

Notifications

When the portal server IP address is changed directly, the following notification will be displayed:

1.18 ip portal source-interface

Function

Run the **ip portal source-interface** command to configure the portal communication source port.

Run the **no** form of this command to remove this configuration.

No portal communication source port is configured by default.

Syntax

ip portal source-interface *interface-type interface-num*

no ip portal source-interface

Parameter Description

interface-type interface-number: Type and number of the interface used for portal communication.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the portal communication source port is configured, the NAS uses the source port to communicate with the portal server, and the used source IP address is the IP address configured on the source port.

Only one portal communication source port can be configured.

Examples

The following example configures Aggregateport 1 as the portal communication source port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip portal source-interface aggregateport 1
```

Table 1-3 Output Fields of the show web-auth authmng statistic Command

Field	Description
Show web authentication information	Web authentication information

Field	Description
current online number	Number of online users
historical max online number	Historical maximum number of online users
aggregate online number	Accumulated number of online users
Web authentication redirect statistic	User redirection statistics
HTTP packet processing	HTTP packet processing
number of users	Number of redirected users
number of HTTP packets received	Number of received HTTP packets
redirection time consumption for successful users	Time required for redirection
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than half one second	Number of users whose redirection time is less than 0.5s
number of between half and one second	Number of users whose redirection time is from 0.5s to 1s
number of more than one second	Number of users whose redirection time is greater than 1s
Web authentication statistic	Web authentication statistics
authentication processing	Authentication
number of authentication requests received	Number of authentication requests
number of reauthentication requests received	Number of re-authentication requests
number of error password	Number of authentication failures due to incorrect passwords
number of authentication failures	Number of authentication failures due to other causes
AAA timeout	Number of AAA timeout times
authentication status timeout	Number of authentication timeout times
fail to set SCC	Number of SCC configuration failures
accounting reject	Number of rejected accounting times
accounting dev timeout	Number of accounting timeout times
user unexist	Number of times with non-existent users

Field	Description
portal timeout	Number of portal server timeout times
DHCPrelease pkt	Number of DHCP release times
sta move	Number of user migration times
clear user	Number of user clearing times
config change	Number of configuration changes
other	Number of authentication failures due to other reasons
authentication time consumption for successful users	Time required for successful authentication
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose authentication time is less than 1s
number of between one and three second	Number of users whose authentication time is from 1s to 3s
number of more than three second	Number of users whose authentication time is greater than 3s
number of less than one second(exclude server)	Number of users whose authentication time is less than 1s excluding the time for interaction between the NAS and portal server
number of between one and three second(exclude server)	Number of users whose authentication time is from 1s to 3s excluding time for interaction between the NAS and the portal server
number of more than three second(exclude server)	Number of users whose authentication time is greater than 3s excluding time for interaction between the NAS and the portal server
Web authentication offline information	Web authentication user offline information
number of offline count	Total number of offline times
number of abnormal offline(rate)	Number of abnormal offline times
number of portal timeout	Number of portal server timeout times
number of set fail	Number of entry configuration failures
number of link change	Number of link changes
no flow	Number of offline times due to no traffic
kick off	Number of times being kicked off by the server
dhcp release	Number of DHCP release times

Field	Description
STA delete	Number of STA deletion times
STA move	Number of STA migration times
active offline	Number of offline times requested by users
session timeout	Number of times with the online duration expired
cli clear	Number of users cleared in the command-line interface (CLI)
no control	Number of users who go offline because web control is disabled
interface default	Number of users who go offline because an interface is restored to the default configuration
interface destroy	Number of users who go offline because an interface is deleted
dhcp ip check	Number of users who go offline because the DHCP IP address is changed
vlan change	Number of users who go offline due to VLAN changes
intfvlan change	Number of users who go offline due to L3 VLAN configuration changes
other	Number of users who go offline due to other causes
aggregate online time	Accumulated online duration
average online time of user	Average online duration of users
Station-move	User migration
move count	Total number of migrated users
move fail	Migration failed
Other important process statistics	Other important data
Auth	Authentication
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose authentication time is less than 1s
number of more than one second	Number of users whose authentication time is greater than 1s
AAA authentication	AAA Authentication
average time consumption	Average required time
aggregate time consumption	Accumulated time

Field	Description
number of less than one second	Number of users whose authentication time is less than 1s
number of more than one second	Number of users whose authentication time is greater than 1s
Radius authentication	RADIUS authentication
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose authentication time is less than 1s
number of more than one second	Number of users whose authentication time is greater than 1s
Radius server authentication	RADIUS server authentication
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose authentication time is less than 1s
number of more than one second	Number of users whose authentication time is greater than 1s
SCC	SCC
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose authentication time is less than 1s
number of more than one second	Number of users whose authentication time is greater than 1s
Accounting	Accounting
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose accounting time is less than 1s
number of more than one second	Number of users whose accounting time is greater than 1s
AAA accounting	AAA accounting
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose accounting time is less than 1s
number of more than one second	Number of users whose accounting time is greater than 1s
Radius accounting	RADIUS accounting

Field	Description
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose accounting time is less than 1s
number of more than one second	Number of users whose accounting time is greater than 1s
Radius server accounting	RADIUS accounting
average time consumption	Average required time
aggregate time consumption	Accumulated time
number of less than one second	Number of users whose accounting time is less than 1s
number of more than one second	Number of users whose accounting time is greater than 1s

The following example displays abnormal authentication data.

```
Hostname> enable
Hostname# show web-auth authmng abnormal
record num:0, value:3000, max-num:1000, clock:1
```

Table 1-4 Output Fields of the show web-auth authmng abnormal Command

Field	Description
Record num	Number of abnormal records
value	Conditions for identifying abnormal records, that is, the timeout time. A record with 3s or longer authentication time is an abnormal record by default.
max-num	Maximum number of allowed records
clock	Time when a record is written to the flash memory. The default value is 01:00:00 [0–23].

1.24 show web-auth control

Function

Run the **show web-auth control** command to display controlled authentication configurations.

Syntax

show web-auth control

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays controlled authentication configurations.

```
Hostname> enable
Hostname# show web-auth control
 Port                  Control  Server Name         Online User Count Arp-detect
Vlan Control List
 ---------------------------- --------
 GigabitEthernet 0/1      On      eportalv2           1               On
```

Table 1-5 Output Fields of the show web-auth control Command

Field	Description
Port	Name of a controlled port
Control	Whether web authentication is enabled for a port
Server Name	Customized server name on the port. <not configured> indicates that no server name is configured.
Online User Count	Number of online users on a port
Arp-detect	Whether ARP detection for user migration is enabled
Vlan Control List	List of VLANs that can be authenticated

1.26 show web-auth direct-host

Function

Run the **show web-auth direct-host** command to display the authentication-exempted user range.

Syntax

show web-auth direct-host

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays all authentication-exempted users.

```
Hostname> enable
Hostname# show web direct-host
Direct hosts: 1
  Address        Mask          Port Binding   ARP Binding   Access Port List
  ----- ----- ---------- -----
  1.1.1.1        255.255.255.255 N/A          Off          1080
  Index     MAC-Address
  --------
```

Table 1-7 Output Fields of the show web direct-host Command

Field	Description
Address	IP address of an authentication-exempted user
Mask	Mask of the IP address of an authentication-exempted user
Port Binding	Device port bound to the IP address of an authentication-exempted user
ARP Bining	Whether ARP binding is performed
Access Port List	Bound L4 port list

1.33 show web-auth template

Function

Run the **show web-auth template** command to display the portal server configurations.

Syntax

show web-auth template

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the portal server configurations.

Examples

The following example displays portal server configurations.

```
Hostname> enable
Hostname# show web-auth template
Webauth Template Settings:
-------------------
  Name:     eportalv1
  Url:      http://17.17.1.21:8080/eportal/index.jsp
  Ip:       17.17.1.21
  BindMode:  ip-mac-mode
  Type:     v1
-------------------
  Name:     eportalv2
  Url:      http://17.17.1.21:8080/eportal/index.jsp
  Ip:       17.17.1.21
  BindMode:  ip-only-mode
  Type:     v2
  Port:     50100
  Acctmlist:
  Authmlist:
```

Table 1-14 Output Fields of the show web-auth template Command

Field	Description
Name	Template name

Field	Description
Url	Homepage address of the portal server
Ip	IP address of the server
Type	Server type (v1 for first-generation web authentication, and v2 for second-generation web authentication)
Port	Communication port for protocol packets of the portal server (This parameter is valid only for the portal server of second-generation web authentication.)
Acctmlist	Accounting method list name (This parameter is valid only for second-generation web authentication.)
Authmlist	Authentication method list name (This parameter is valid only for second-generation web authentication.)

1.34 show web-auth user

Function

Run the **show web-auth user** command to display online information of all users or a specified user, including the IP address, interface, and online time.

Syntax

show web-auth user { **all** | **ip** *ipv4-address* | **mac** *mac-address* | **name** *name* }

Parameter Description

all: Displays online information of all users.

ip *ipv4-address*: Specifies the IPv4 address of a user whose online information is displayed.

mac *mac-address*: Specifies the MAC address of a user whose online information is displayed.

name *name*: Specifies the username of a user whose online information is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays online information of all users.

```
Hostname> enable
Hostname# show web user all
Current user num: 1, Online 1
Address                          Online  Time Limit     Time Used      Status  Name
-------------- --------------- -----
172.30.33.227                     On     240d 00:00:00  0d 00:01:19    Active
linlt
```

The following example displays online information of a user whose IP address is 192.168.0.11.

```
Hostname> enable
Hostname# show web-auth user ip 192.168.0.11
Address      :   192.168.0.11
 Mac          :   00d0.f800.2233
 Port         :   Gi0/2
 Online       :   On
 Time Limit   :   0d 01:00:00
 Time Used    :   0d 00:15:10
 Time Start   :   2009-02-22 20:05:10
 Status       :   Active
```

Table 1-15 Output Fields of the show web-auth user Command

Field	Description
Address	IP address of a user
Mac	MAC address of a user
Port	Port on the user host used to connect to the NAS
Online	Whether a user is online
Time Limit	Limit of the available online time of a user (The value **0** indicates no limit.)
Time Used	User online duration
Time Start	Time when a user passes authentication and starts to get online
Status	User status, including: ● **Active**: A user gets online. ● **Create**: A user is created, and settings are not completed. ● **Destroy**: A user is deleted, and settings are not cleared.
Name	Username (This field is null for users authenticated using the first-generation web authentication solution.)

1.35 url

Function

Run the **url** command to configure the authentication page address of the portal server.

Run the **no** form of this command to remove this configuration.

No authentication page address of the portal server is configured by default.

Syntax

url *url-string*

no url

Parameter Description

url-string: Authentication page address of the portal server, which must be started with "http://" or "https://". The value is a string of up to 255 characters.

Command Modes

Template configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the authentication page address of the portal server in template eportalv1 to http://www.web-auth.net/login.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth template eportalv1
Hostname(config.tmplt.eportalv1)# url http://www.web-auth.net/login
```

Notifications

1.36 web-auth acl

Function

Run the **web-auth acl** command to configure a whitelist.

Run the **no** form of this command to remove this configuration.

No whitelist is configured by default.

Syntax

web-auth acl [**oob** | **vrf** *vrf-name*] **white-url** *white-url-name*
no web-auth acl [**oob** | **vrf** *vrf-name*] **white-url** *white-url-name*

Parameter Description

oob: Uses the MGMT port.

vrf *vrf-name*: Specifies the VPN instance name.

white-url *white-url-name*: Specifies whitelisted URLs.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

A whitelist allows users to access some network resources before authentication.

A whitelist can contain a maximum of 1000 addresses.

When whitelisted addresses are configured in domain name format, you need to configure the domain name server (DNS) function for the NAS to enable the NAS to correctly parse domain names.

Some domain names correspond to multiple IP addresses. A domain name can map to eight IP addresses at most.

Examples

The following example adds www.hostname.com to the whitelist.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth acl white-url www.hostname.com
```

1.37 web-auth apply-mapping

Function

Run the **web-auth apply-mapping** command to apply the template mapping method on an interface.

Run the **no** form of this command to remove this configuration.

No template mapping method is applied on an interface by default.

Syntax

web-auth apply-mapping *mapping-method*

no web-auth apply-mapping

Parameter Description

mapping-method: Template mapping method.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

By setting the VLAN or IP address range, you can select users for whom a template mapping method needs to be configured.

Examples

The following example applies template mapping method "test" on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)#web-auth apply-mapping test
```

1.38 web-auth dhcp-check

Function

Run the **web-auth dhcp-check** command to enable Dynamic Host Configuration Protocol (DHCP) address check for web authentication.

Run the **no** form of this command to disable this feature.

DHCP address check is disabled for web authentication by default.

Syntax

web-auth dhcp-check

no web-auth dhcp-check

Parameter Description

N/A

Command Modes

Global configuration mode

Interface configuration mode

Default Level

14

Usage Guidelines

To use this function, you must configure DHCP Snooping.

Only second-generation web authentication is supported for users with IPv4 addresses.

This function applies only to network environments with IP addresses assigned through DHCP. If users with statically configured IP addresses exist, network access of these users will be limited.

If only a few users need to use static IP addresses, configure these IP addresses as straight-through addresses. In this case, these users are exempted from authentication.

To apply this function to an interface, disable global DHCP address check first.

Examples

The following example enables DHCP address check for web authentication globally.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth dhcp-check
```

1.39 web-auth dhcp-check vlan

Function

Run the **web-auth dhcp-check vlan** command to enable DHCP address check for web authentication on an interface.

Run the **no** form of this command to disable this feature.

DHCP address check for web authentication is disabled on an interface by default.

Syntax

web-auth dhcp-check vlan *vlan-list*

no web-auth dhcp-check vlan *vlan-list*

Parameter Description

vlan *vlan-list*: Specifies the VLAN range on an interface for which DHCP address check needs to be enabled. The values are valid VIDs. Use commas (,) to separate different values. If a consecutive VLAN range exists, use a hyphen (-). For example, 3-5 indicates VLANs 3, 4, and 5.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After VLAN-based authentication is configured on a port, only the user hosts in the configured VLAN can initiate web authentication.

Examples

The following example enables DHCP address check for web authentication on GigabitEthernet 0/1 and sets the detected VLAN range to 1 and 3-5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
```

```
Hostname(config-if-GigabitEthernet 0/1)# web-auth dhcp-check vlan 1,3-5
```

1.41 web-auth direct-host

Function

Run the **web-auth direct-host** command to configure the authentication-exempted user range.

Run the **no** form of this command to remove this configuration.

No IP/MAC address range of authentication-exempted users is configured by default. All users can access network resources only after they pass web authentication.

Syntax

web-auth direct-host *ipv4-address* [*mask*] [**arp** | *port-number*&<1-8>]
web-auth direct-host *mac-address*
no web-auth direct-host { *ipv4-address* [*mask*] }
no web-auth direct-host *mac-address*

Parameter Description

ipv4-address: IPv4 address of an authentication-exempted user.

mask: Mask of the IP address of an authentication-exempted user.

arp: Performs ARP binding for network resources of authentication-exempted users when the APR check function is enabled, that is, configures the **arp** keyword. This field is required only when IPv4 network resources are configured.

port-number&<1-8>: L4 port of an authentication-exempted user. &<1-8> indicates that the parameter can be entered for a maximum of eight times. The value range is from 1 to 65535.

mac-address: MAC address of a user exempted from authentication.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The number of authentication-exempted users and the number of authentication-free network resources cannot exceed 1000. The actual number of available resources may be reduced because of other security modules. Therefore, it is recommended that network segments be configured if many addresses need to be configured.

Examples

The following example configures the user whose IPv4 address is 172.16.0.1 as an authentication-exempted user.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth direct-host 172.16.0.1
```

The following example configures the user whose IPv6 address is FF02::/64 as an authentication-exempted user.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth direct-host FF02::/64
```

The following example configures the user whose MAC address is 0000:5e00:0101 as an authentication-exempted user.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth direct-host 0000:5e00:0101
```

Notifications

When an invalid IP address/mask format is used, the following notification will be displayed:

```
%Error: Invalid IP address.
```

1.42 web-auth enable

Function

Run the **web-auth enable** command to enable web authentication on a port.

Run the **no** form of this command to disable this feature.

The web authentication function is disabled on a port by default.

Syntax

web-auth enable [*template-name* | **appauth** | **eportalv1** | **eportalv2**]

no web-auth enable

Parameter Description

template-name: Custom template whose web authentication is enabled.

eportalv1: Enables first-generation web authentication.

eportalv2: Enables second-generation web authentication.

appauth: Enables app-based authentication.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After web authentication is enabled, the first-generation web authentication template is used by default if no parameter is specified.

To apply web authentication successfully, you must configure the authentication page address.

Examples

The following example enables web authentication on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# web-auth enable
```

1.43 web-auth import-ssl

Function

Run the **web-auth import-ssl** command to upload the certificate and key files.

Syntax

web-auth import-ssl { **cert ftp:***path* | **cert tftp:***path* | **cert oob_ftp:***path* | **cert oob_tftp:***path* } { **key ftp:***path* | **key tftp:***path* | **key oob_ftp:***path* | **key oob_tftp:***path* } [**vrf** *vrf-name*]

Parameter Description

cert ftp:*path*: Configures the File Transfer Protocol (FTP) path for uploading certificate files.

cert tftp:*path*: Configures the Trivial FTP (TFTP) path for uploading certificate files.

cert oob_ftp:*path*: Configures the FTP path for uploading certificate files through the MGMT port.

cert oob_tftp:*path*: Configures the TFTP path for uploading certificate files through the MGMT port.

key ftp:*path*: Configures the FTP path for uploading key files.

Key tftp:*path*: Configures the TFTP path for uploading key files.

key oob_ftp:*path*: Configures the FTP path for uploading key files through the MGMT port.

key oob_tftp:*path*: Configures the TFTP path for uploading key files through the MGMT port.

vrf *vrf-name*: Configures the VRF instance used for uploading files.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

HTTPS is an encrypted data transmission protocol and relies on a certificate to ensure transmission security. Before enabling the HTTPS server function, you need to import an available certificate.

To configure HTTPS certificate import, first upload available HTTPS certificate and key files to the NAS and then apply the HTTPS certificate and key files.

Examples

The following example uploads the certificate and key files.

```
Hostname> enable
Hostname# configure terminal
Hostname# web-auth import-ssl cert tftp://182.168.1.1/cert.pem key
tftp://182.168.1.1/key.pem
```

1.44 web-auth linkdown-timeout

Function

Run the **web-auth linkdown-timeout** command to configure the authenticated user logout delay after a port is down.

Run the **no** form of this command to remove this configuration.

The default authenticated user logout delay after a port is down is **60** seconds.

Syntax

web-auth linkdown-timeout *linkdown-timeout*

no web-auth linkdown-timeout

Parameter Description

linkdown-timeout: Authenticated user logout delay after a port is down, in seconds. The value range is from 1 to 604800.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the authenticated user logout delay is configured on a port, the user hosts connected to the port go offline after the delay when the port is down.

You are advised to configure this function to prevent repeated user authentication in scenarios when a port goes down and then up quickly.

Examples

The following example sets the authenticated user logout delay after a port is down to 100 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth linkdown-timeout 100
```

1.45 web-auth logging enable

Function

Run the **web-auth logging enable** command to configure the web authentication logging function.

Run the **no** form of this command to disable this feature.

The web authentication logging function is disabled by default.

Syntax

web-auth logging enable *log-rate*

no web-auth logging enable

Parameter Description

log-rate: Number of logs printed every second. The value range is from 0 to 100. The value **0** indicates that the number of logs is not limited.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The logging function of the web authentication module can send log messages to the administrator to display the information and relevant events of users who get online/offline and allow users to configure a log printing rate limit.

This command applies only to logs printed in normal cases and is invalid to abnormal or critical logs.

Examples

The following example enables web authentication logging and configures no rate limit for log printing.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth logging enable 0
```

1.46 web-auth mapping

Function

Run the **web-auth mapping** command to configure the webauth template mapping method.

Run the **no** form of this command to remove this configuration.

No webauth template mapping method is configured by default.

Syntax

web-auth mapping *mapping-method* { **vlan** *vlan-list* | **ip-mapping** *ipv4-address mask* } [**template** *tmpltate-name*]

no web-auth mapping *mapping-method* { **vlan** [*vlan-list*] | **ip-mapping** *ipv4-address mask* }

Parameter Description

mapping-method: Template mapping method.

vlan *vlan-list*: Specifies the VLAN list. The values are valid VIDs. Use commas (,) to separate different values. If a consecutive VLAN range exists, use a hyphen (-). For example, 3-5 indicates VLANs 3, 4, and 5.

ipv4-address mask: IPv4 network segment and mask that uses a template.

template *tmpltate-name*: Specifies the template name.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The template mapping method is configured when multiple authentication scenarios exist on one port.

When web authentication is enabled on a port, and the method of template A is used, but some users do not apply to template A and want to use template B for authentication, you can configure a template mapping method for these users to enable these users to use the authentication method of template B.

By setting the VLAN or IP address range, you can select users for whom a template mapping method needs to be configured.

Examples

The following example configures template mapping method test1 for mapping between templates eportalv2 and VLANs 2-5 and VLAN 10.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth mapping test1 vlan 2-5,10 template eportalv2
```

The following example enables users in the network segment of 10.10.10.1 that uses template mapping method test1 to use template stu_1 for redirection.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# web-auth mapping map_test ip-mapping 10.10.10.1 255.255.255.0
template stu_1
```

1.48 web-auth portal extension

Function

Run the **web-auth portal extension** command to enable portal specification extension.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

Portal specification extension is enabled by default.

Syntax

web-auth portal extension

no web-auth portal extension

default web-auth portal extension

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Portal specification extension is enabled to support Ruijie portal servers and portal servers that comply with the CMCC WLAN Service Portal Specification.

Examples

The following example disables portal specification extension.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no web-auth portal extension
```

```
Hostname(config)# http redirect url-fmt ext1
```

1.49 web-auth portal key

Function

Run the **web-auth portal key** command to configure the communication key between the NAS and the portal server.

Run the **no** form of this command to remove this configuration.

No communication key between the NAS and the portal server is configured by default.

Syntax

web-auth portal key *key*

no web-auth portal key

Parameter Description

key: Communication key between the NAS and portal server. The value is a string of 1 to 255 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To apply web authentication successfully, you must configure the communication key between the NAS and the portal server.

The communication key can be configured in global configuration mode only. Specifying a key for each server is not supported.

Examples

The following example sets the communication key between the NAS and the portal server to web-auth.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# web-auth portal key web-auth
```

1.50 web-auth portal-check

Function

Run the **web-auth portal-check** command to enable portal server detection.

Run the **no** form of this command to remove this configuration.

The portal server detection function is disabled by default.

Syntax

web-auth portal-check [**interval** *interval*] [**timeout** *timeout*] [**retransmit** *retransmit-times*]

no web-auth porta-check

Parameter Description

interval *interval*: Specifies the detection interval, in seconds. The value range is from 1 to 1000. The default value is **10**.

timeout *timeout*: Specifies the packet timeout time, in seconds. The value range is from 1 to 1000. The default value is **5**.

retransmit *retransmit-times*: Configures the number of retransmission times upon timeout. The value range is from 1 to 100. The default value is **3**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In most networks, only one server is deployed and this function does not need to be configured.

If multiple portal servers exist, it is recommended that the detection interval and packet timeout time not be set to small values; otherwise, the NAS will send many packets within a short time, affecting performance.

Examples

The following example enables portal server detection and sets the detection interval to 20 seconds, the packet timeout time to 2 seconds, and the number of retransmission times upon timeout to 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth portal-check interval 20 timeout 2 retransmit 2
```

1.51 web-auth portal-escape

Function

Run the **web-auth portal-escape** command to enable the portal escape function.

Run the **no** form of this command to disable this feature.

Portal escape is disabled by default.

Syntax

web-auth portal-escape [**nokick**]

no web-auth portal-escape

Parameter Description

nokick: Configures not to force online users offline if the portal server is unavailable after the escape function is enabled.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You are advised to configure this command if some key services in the network need to be maintained when the portal server is faulty. The portal server detection function also needs to be configured. When all of the configured portal servers are unavailable, new users can access the Internet without authentication.

Examples

The following example enables the portal escape function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth portal-escape
```

Function

Run the **web-auth portal-import attr-26** command to enable transparent transmission of RADIUS attributes.

Run the **no** form of this command to remove this configuration.

Transparent transmission of RADIUS attributes is disabled by default.

Syntax

web-auth portal-import attr-26

no web-auth portal-import attr-26

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command applies only to the Serverless Application Model (SAM) servers and Ruijie portal servers. If the NAS interworks with a portal server provided by other vendors, enabling this function may cause the portal server to fail to respond to packets.

Examples

The following example enables transparent transmission of RADIUS attributes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)#web-auth portal-import attr-26
```

1.53 web-auth portal-valid unique-name

Function

Run the **web-auth portal-valid unique-name** command to enable uniqueness check of portal authentication accounts.

Run the **no** form of this command to disable this feature.

Uniqueness check of portal authentication accounts is disabled by default.

Syntax

web-auth portal-valid unique-name

no web-auth portal-vallid unique-name

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After uniqueness check of portal authentication accounts is enabled, the NAS returns an ACK_AUTH message carrying Errcode 2 to the portal server if account information of a new authenticated user is being used by an online user. Upon receiving such a reply message, some portal servers will send a "Terminal Preemption" prompt to user hosts. Generally, this function is enabled when the portal server needs to push the "Terminal Preemption" prompt to users.

Examples

The following example enables uniqueness check of portal authentication accounts.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth portal-valid unique-name
```

1.57 web-auth update-interval

Function

Run the **web-auth update-interval** command to configure the interval for updating online user information.

Run the **no** form of this command to remove this configuration.

The default interval for updating online user information is **180** seconds.

Syntax

web-auth update-interval *update-interval*

no web-auth update-interval

Parameter Description

update-interval: Interval for updating online user information, in seconds. The value range is from 30 to 3600.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The NAS needs to update maintained online user information, for example, the online time periodically. The interval for updating online user information can be manually configured based on different monitoring requirements for online user information in different scenarios.

The interval for updating online user information must be a multiple of 60. If the configured value is not a multiple of 60, the actual effective value is rounded up to the multiple of 60.

Examples

The following example sets the interval for updating online user information to 60 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# web-auth update-interval 60
```

1.2 direct-vlan

Function

Run the **direct-vlan** command to configure authentication-exempted VLANs.

Run the **no** form of this command to remove this configuration.

No authentication-exempted VLAN is configured by default.

Syntax

direct-vlan *vlan-list*

no direct-vlan [*vlan-list*]

Parameter Description

vlan-list: List of authentication-exempted VLANs. Use commas (,) to separate different VLANs. If a consecutive VLAN range exists, use a hyphen (-). For example, 3-5 indicates VLANs 3, 4, and 5.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To enable users in a VLAN to access the Internet without 802.1x or web authentication, you can configure the VLAN as an authentication-exempted VLAN.

Examples

The following example configures VLAN 2 as an authentication-exempted VLAN.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# direct-vlan 2
```

1.3 nac-author-user maximum

Function

Run the **nac-author-user maximum** command to configure the IPv4 user capacity on a port.

Run the **no** form of this command to remove this configuration.

The IPv4 user capacity on a port is not limited by default.

Syntax

nac-author-user maximum *max-user-number*

no nac-author-user maximum

Parameter Description

max-user-number: Maximum IPv4 user capacity. The value range is from 1 to 1024.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

IPv4 users include those generated through 802.1x authentication, web authentication, and other binding functions. IPv4 users on a port may be generated over the port or globally. For example, when a global IPv4 user is bound to a port by running the corresponding command, the user is also calculated as a user on the port.

Examples

The following example sets the IPv4 user capacity on GigabitEthernet 0/1 to 100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# nac-author-user maximum 100
```

1.4 show access-control packet statistics

Function

Run the **show access-control packet statistics** command to display the statistics about packets filtered due to access control.

Syntax

show access-control packet statistics [**interface** *interface-type interface-number* | **vlan** *vlan-id*]

Parameter Description

interface *interface-type interface-number*: Specifies the interface whose statistics about packets filtered due to access control are displayed.

vlan *vlan-id*: Specifies the VLAN whose statistics about packets filtered due to access control are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display statistics about packets filtered due to access control.

Examples

The following example displays statistics about packets filtered due to access control on all interfaces.

```
Hostname> enable
Hostname# show access-control packet statistics
Interface     Discard           Passed
----   -------   ------
Gi0/1         575              NA
Gi0/2         575              NA
Gi0/3         575              NA
Vl2000        575              NA
```

The following example displays statistics about packets filtered due to access control on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show access-control packet statistics interface GigabitEthernet 0/1
Interface : GigabitEthernet 0/1
  Discard            : 14
  Passed             : NA
```

1.7 station-move permit

Function

Run the **station-move permit** command to enable authenticated user migration.

Run the **no** form of this command to disable this feature.

Authenticated user migration is disabled by default.

Syntax

station-move permit

no station-move permit

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The authenticated user migration function allows an online authenticated user to switch to another physical location to perform authentication and go online again without getting offline.

The authenticated user migration function requires a check of users' MAC addresses, and is invalid for users who have IP addresses only.

When both 802.1x authentication and port security are enabled on a port, and port security and 802.1x authentication users get online simultaneously, 802.1x authenticated users will fail to be migrated to another port to get online because the same MAC address cannot go online through different ports.

The user online detection function can kick users offline. When the authentication user migration function is not configured and a user does not proactively get offline, the user may be kicked offline by the online detection function and can implement authentication and get online in another physical location.

When an online authenticated user moves to a new physical location, the user needs to perform 802.1x or web authentication again.

Examples

The following example enables authenticated user migration.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# station-move permit
```

1 Password Policy Commands

Command	Function
password policy life-cycle	Configure a password lifecycle.
password policy min-size	Configure the minimum password length.
password policy no-repeat-times	Prevent repeated use of passwords that are configured in the latest specified number of times.
password policy strong	Enable strong password detection.
password policy forced-password-modify	Enable forcible weak password change.
password policy printable-character-check	Enable the special character detection function.
service password-encryption	Enable encrypted password storage.
show password policy	Display configured password security policies.

1.1 password policy life-cycle

Function

Run the **password policy life-cycle** command to configure a password lifecycle.

Run the **no** form of this command to remove this configuration.

No password lifecycle is configured by default.

Syntax

password policy life-cycle *life-cycle*

no password policy life-cycle

Parameter Description

life-cycle: Password lifecycle, in days. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The password lifecycle defines the validity time of a password. If a user enters a password that has already expired during login, the system gives a prompt, indicating that the password has expired, and asks the user to reset the password.

The password lifecycle is valid only for global passwords (configured by running the **enable password** and **enable secret** commands) and local user passwords (configured by running the **username** command). It is invalid for passwords in line configuration mode.

The password lifecycle is affected when the system time is modified.

Examples

The following example sets the password lifecycle to 90 days.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# password policy life-cycle 90
```

1.2 password policy min-size

Function

Run the **password policy min-size** command to configure the minimum password length.

Run the **no** form of this command to remove this configuration.

The minimum password length is **8** by default.

Syntax

password policy min-size *min-size*

no password policy min-size

Parameter Description

min-size: Minimum password length. The value range is from 1 to 31.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The minimum password length is used to limit the length of user passwords. If the password entered by a user is shorter than the minimum password length, the system displays an error prompt, asking the user to specify another password of an appropriate length.

Examples

The following example sets the minimum password length to 8.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# password policy min-size 8
```

1.3 password policy no-repeat-times

Function

Run the **password policy no-repeat-times** command to prevent repeated use of passwords that are configured in the latest specified number of times.

Run the **no** form of this command to remove this configuration.

Repeated password use is allowed by default.

Syntax

password policy no-repeat-times *no-repeat-times*

no password policy no-repeat-times

Parameter Description

No-repeat-times: Number of times in which configured passwords cannot be repeatedly used. The value range is from 1 to 31.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The repeated password use prevention function prevents users from using historically configured passwords as new passwords. The system records passwords used by a user to a historical password list. If a newly configured password is within the list, the system gives a prompt and asks the user to specify another password. The maximum number of records in the password list can be manually configured. When the number of records in the password list reaches the limit, a new password record will overwrite the earliest password record.

The repeated password use prevention function is valid only for global passwords (configured by running the **enable password** and **enable secret** commands) and local user passwords (configured by running the **username** command). It is invalid for passwords in line configuration mode.

Examples

The following example enables repeated password use prevention function to disallow the use of historical passwords configured in the latest five times.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# password policy no-repeat-times 5
```

1.4 password policy strong

Function

Run the **password policy strong** command to enable strong password detection.

Run the **no** form of this command to disable this feature.

The strong password detection function is enabled by default.

Syntax

password policy strong

no password policy strong

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Strong password detection is used to detect the complexity of a password and prevent password crackdown due to low complexity. The strong password detection function will send an alarm in the following scenarios:

- The password is the same as the corresponding account.
- The password contains only digits.
- The password contains only uppercase letters.
- The password contains only lowercase letters.

Examples

The following example enables the strong password detection function.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# password policy strong
```

1.5 password policy forced-password-modify

Function

Run the **password policy forced-password-modify** command to enable forcible weak password change.

Run the **no** form of this command to disable this feature.

Forcible weak password change is disabled by default.

Syntax

password policy forced-password-modify

no password policy forced-password-modify

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The forcible weak password change function is used together with another password policy (such as the minimum password length or strong password detection).

After the forcible weak password change function is enabled, a warning prompt will be displayed if a user uses a weak password (containing less than 8 bytes or only digits, uppercase letters, or lowercase letters) during login or configuration. If both the forcible weak password change function and another password policy are enabled, the password will continue to be checked according to the other password policy during user login. If the password does not meet requirements of the other password policy, a prompt for changing the password will be displayed. The user is allowed to log in only after the new password meets requirements of the password policy.

The forcible weak password change function is valid only for global passwords (configured by running the **enable password** and **enable secret** commands) and local user passwords (configured by running the **username** command). It is invalid for passwords in line configuration mode.

Examples

The following example enables forcible weak password change.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# password policy forced-password-modify
```

1.6 password policy printable-character-check

Function

Run the **password policy printable-character-check** command to enable the special character detection function.

Run the **no** form of this command to disable this feature.

Special character detection is disabled by default.

Syntax

password policy printable-character-check

no password policy printable-character-check

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After strong password detection and special character detection are configured, passwords that contain only special characters are invalid and cannot be configured successfully. Special characters include space, tilde (~), backtick (`), exclamation mark (!), at sign (@), number sign (#), dollar sign ($), percent sign (%), caret (^), ampersand (&), asterisk (*), brackets (()), underscore (_), plus sign (+), minus sign (–), equal sign (=), braces ({}), vertical bar (|), square brackets ([]), backslash (\), colon (:), quotation mark ("), semicolon (;), apostrophe ('), angle brackets (<>), comma (,), period (.), and slash (/).

Examples

The following example enables special character detection.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# password policy strong
Hostname(config)# password policy printable-character-check
```

1.7 service password-encryption

Function

Run the **service password-encryption** command to enable encrypted password storage.

Run the **no** form of this command to disable this feature.

Encrypted password storage is enabled by default.

Syntax

service password-encryption

no service password-encryption

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When encrypted password storage is disabled, all passwords used in the configuration process are displayed and stored in plaintext format unless the passwords are configured in ciphertext format. For security purposes, encrypted password storage should be enabled. When encrypted password storage is enabled and the **show running-config** command is run to display configurations or the **write** command is run to save configuration files, passwords configured by users are displayed in ciphertext format. If encrypted password storage is disabled again, passwords displayed in ciphertext format will not be restored to the plaintext format.

Examples

The following example enables encrypted password storage.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# service password-encryption
```

1.8 show password policy

Function

Run the **show password policy** command to display configured password security policies.

Syntax

show password policy

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display password security policies configured on a device.

Examples

The following example displays configured password security policies.

```
Hostname> enable
Hostname# show password policy
Global password policy configurations:
 Password encryption:              Enabled
 Password strong-check:            Enabled
Password secret-dictionary-check:   Enabled
 Password min-size:                Enabled (6 characters)
 Password life-cycle:              Enabled (90 days)
 Password no-repeat-times:          Enabled (max history record: 5)
```

Table 1-1 Output Fields of the show password policy Command

Field	Description
Password encryption	Whether passwords are stored in encrypted mode
Password strong-check	Whether strong password detection is enabled
Password secret-dictionary-check	Whether password dictionary check is enabled
Password min-size	Minimum password length
Password life-cycle	Password lifecycle
Password no-repeat-times	Number of latest configured passwords that cannot be used repeatedly

Command	Function
clear ssh ip-block	Clear entries about blocked IP addresses and authentication failures.
crypto key generate	Generate the public key of the SSH server.
crypto key zeroize	Delete the public key of the SSH server.
disconnect ssh	Disconnect an established SSH client session.
disconnect ssh-session	Disconnect a suspended SSH client session.
ip scp client source-interface	Configure the source interface of the Secure copy protocol (SCP) client.
ip scp server enable	Enable the SCP server function.
ip scp server topdir	Configure the transmission path for uploading files to or downloading files from the SCP server.
ip ssh access-class	Configure an access control list (ACL) for the SSH server.
ip ssh authentication-retries	Configure the maximum number of user authentication attempts allowed on the SSH server.
ip ssh cipher-mode	Configure the encryption modes supported by the SSH server.
ip ssh compatible-ssh1x enable	Enable the SSHv1 function.
ip ssh hmac-algorithm	Configure the message authentication algorithms supported by the SSH server.
ip ssh ip-block disable	Disable the IP address blocking function of the SSH server.
ip ssh ip-block failed-times	Configure the number of authentication failures for blocking IP addresses and the time period for counting authentication failures on the SSH server.
ip ssh ip-block reactive	Configure the period for awakening blocked IP addresses.
ip ssh key-exchange	Configure the Diffie–Hellman (DH) key exchange algorithms supported by the SSH server.

ip ssh peer	Associate with the public key file and username of a client.
ip ssh port	Configure the listening port of the SSH server.
ip ssh source-interface	Configure the source interface of the SSH client.
ip ssh time-out	Configure the user authentication timeout time on the SSH server.
ip ssh version	Configure the SSH server version.
ipv6 ssh access-class	Configure an IPv6 ACL for the SSH server.
scp	Upload files to or download files from the remote SCP server.
show crypto key mypubkey	Display partial of the public key information of the SSH server.
show ip ssh	Display effective configurations of the SSH server.
show ssh	Display information about established SSH connections.
show ssh ip-block	Display information about blocked IP addresses and authentication failures.
show ssh-sessions	Display information about established SSH client sessions.
ssh	Establish an encrypted session with a remote network device.
ssh-session	Restore an established SSH client session.

1.1 clear ssh ip-block

Function

Run the **clear ssh ip-block** command to clear entries about blocked IP addresses and authentication failures.

Syntax

clear ssh ip-block { **all** | *ipv4-address* | *ipv6-address* }

Parameter Description

all: Clears all entries about blocked IP addresses and authentication failures.

ipv4-address: IPv4 source address based on which entries about blocked IP addresses and authentication failures are cleared.

ipv6-address: IPv6 source address based on which entries about blocked IP addresses and authentication failures are cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

The addresses and address description formats to be cleared can be obtained by running the **show ssh ip-block** command.

After entries about blocked IP addresses are cleared, these IP addresses are awakened immediately and can be used by Secure Shell (SSH) clients to log in to the device.

Examples

The following example clears all entries about blocked IP addresses and authentication failures.

```
Hostname> enable
Hostname# clear ssh ip-block all
```

1.2 crypto key generate

Function

Run the **crypto key generate** command to generate the public key of the SSH server.

No public key is generated on the SSH server by default.

Syntax

crypto key generate { **dsa** | **ecc** | **rsa** }

Parameter Description

dsa: Generates a Digital Signature Algorithm (DSA) key.

ecc: Generates an Elliptic Curves Cryptography (ECC) key.

rsa: Generates a Rivest-Shamir-Adleman (RSA) key.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the SSH server service is required, run this command to generate the public key of the SSH server and run the **enable service ssh-server** command to enable the SSH server function. SSHv1 uses an RSA key, and SSHv2 uses an RSA or a DSA key. If an RSA key is generated, both SSHv1 and SSHv2 can use the key. If a DSA key is generated, only SSHv2 can use the key.

An SSH client uses only one of the ECC, DSA, and RSA public key algorithms for authentication in a connection. However, different clients support different public key algorithms. To ensure that clients can successfully log in to the server, you are advised to generate the ECC, DSA, and RSA key pairs on the server.

The minimum modulus length is 512 bits for the RSA host key and 360 bits for the DSA host key. The maximum modulus length of both is 2048 bits. In SSHv2, some clients (for example, the SCP clients) require that the length of the key generated on the server must be greater than or equal to 768 bits. When configuring RSA and DSA host keys, you are advised to set the host key modulus to 768 bits or larger.

The modulus length of an ECC host key can be 256, 384, or 512 bits, and the default modulus length is 512 bits.

You can run the **show crypto key mypubkey** command to check whether the public information about the RSA key exists. If yes, the RSA key has been generated.

Examples

The following example generates the RSA public key of the SSH server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# crypto key generate rsa
```

Notifications

When the RSA key of the SSH server is generated for the first time, the following notification will be displayed:

```
Hostname(config)#crypto key generate rsa
Choose the size of the rsa key modulus in the range of 512 to 2048
and the size of the dsa key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
How many bits in the modulus [512]:
// When the generation of the RSA key is successful, the following information will
be displayed:
% Generating 512 bit RSA1 keys ...[ok]
% Generating 512 bit RSA keys ...[ok]
// When the generation of the RSA key fails, the following information will be displayed:
% Generating 512 bit RSA1 keys ...[fail]
% Generating 512 bit RSA keys ...[fail]
```

When the RSA key already exists on the server, the following notification will be displayed. If you select key replacement, you need to re-select the key bits, and information will be displayed, indicating whether the generation is successful. Otherwise, the configuration interface is closed.

```
Hostname(config)#crypto key generate rsa
% You already have RSA keys.
% Do you really want to replace them? [yes/no]:yes
Choose the size of the rsa key modulus in the range of 512 to 2048
and the size of the dsa key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
How many bits in the modulus [512]:
```

When the entered number of RSA key bits is not within the range of 512 to 2048, the following notification will be displayed:

```
Hostname(config)#crypto key generate rsa
Choose the size of the rsa key modulus in the range of 512 to 2048
and the size of the dsa key modulus in the range of 360 to 2048 for your
Signature Keys. Choosing a key modulus greater than 512 may take
a few minutes.
How many bits in the modulus [512]:360
sshd: rsa key in the range of 512 to 2048
How many bits in the modulus [512]:2590
sshd: bad data bits
How many bits in the modulus [512]:
```

Common Errors

An incorrect command is used to delete a key. The **no crypto key generate** command instead of the **crypto key zeroize** command is used to delete a key.

Platform Description

N/A

Related Commands

- **enable service** (System Configuration/Basic Management)

- crypto key zeroize

1.3 crypto key zeroize

Function

Run the **crypto key zeroize** command to delete the public key of the SSH server.

Syntax

crypto key zeroize { **dsa** | **ecc** | **rsa** }

Parameter Description

dsa: Deletes a DSA key.

ecc: Delete an ECC key.

rsa: Deletes an RSA key.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to delete the public key of the SSH server. After the public key is deleted, the SSH server state is **DISABLE**. To disable the SSH server, run the **no enable service ssh-server** command.

You can run the **show crypto key mypubkey** command to check whether the public information about the RSA key exists. If no, the RSA key has been deleted.

Examples

The following example deletes the RSA public key of the SSH server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# crypto key zeroize rsa
```

Notifications

When the RSA key already exists on the server, the following notification will be displayed:

```
Hostname(config)# crypto key zeroize rsa
% Keys to be removed
% All router certs issued using these keys will also be removed.
Do you really want to remove these keys? [yes/no]:yes
*Jan 16 06:52:57: %P17050-DEBUG: sshd: delete key file /rsa_private.bin
*Jan 16 06:52:57: %P17050-DEBUG: sshd: delete key file /rsa1_private.bin
```

When no RSA key is generated, the following notification will be displayed:

```
Hostname(config)# crypto key zeroize rsa
% The specified RSA keypair does not exist.
```

Common Errors

The **no** or **default** form of this command is used to delete a key.

Platform Description

1.4 disconnect ssh

Function

Run the **disconnect ssh** command to disconnect an established SSH client session.

Syntax

disconnect ssh { **vty** *session-id* | *session-id* }

Parameter Description

vty *session-id*: Specifies the Virtual Teletype (VTY) session ID of an SSH session to be disconnected. The value range is from 0 to 35.

session-id: Session ID of an SSH client session to be disconnected. The value range is from 0 to 35.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

Serving as an SSH server, the device may connect to multiple SSH clients. You can run this command to forcibly disconnect a client from the device. The client disconnection methods are as follows:

- Specify an SSH session ID. To display the SSH session ID of a client, run the **show ssh** command.
- Specify a VTY session ID. To display the VTY session ID of a client, run the **show users** command. This command can be used to disconnect SSH connections only.

Examples

The following example disconnects the SSH client session whose session ID is 1.

```
Hostname> enable
Hostname# disconnect ssh 1
```

The following example disconnects the SSH client session whose VTY session ID is 1.

```
Hostname> enable
Hostname# disconnect ssh vty 1
```

- **show users** (System Configuration/Line Configuration)

1.5 disconnect ssh-session

Function

Run the **disconnect ssh-session** command to disconnect a suspended SSH client session.

Syntax

disconnect ssh-session *session-id*

Parameter Description

session-id: Session ID of an SSH client session to be disconnected.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

After the device connects to the SSH server as an SSH client, you can run the corresponding command to disconnect an SSH session with the specified session ID. To display information about the SSH connections established by the device as an SSH client, run the **show ssh-session** command.

Examples

The following example disconnects the SSH client session whose ID is 1.

```
Hostname> enable
Hostname# disconnect ssh-session 1

1.6 ip scp client source-interface

Function

Run the **ip scp client source-interface** command to configure the source interface of the Secure copy protocol (SCP) client.

Run the **no** form of this command to remove this configuration.

No SCP client source interface is configured by default. SSH packets use the packet sending source address queried based on the route as the source address by default.

Syntax

ip scp client source-interface *interface-type interface-number*

no ip scp client source-interface

Parameter Description

interface-type interface-number: Type and number of the SCP client source interface whose IP address is used as the global source address of the SCP client.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used when the device serves as an SCP client. After the source interface is configured, the SCP client uses the IP address on the interface as the global source address during communication. If no source interface is configured, the source address of SCP packets will be obtained by querying the corresponding route based on the destination address. If no source interface or source IP address is independently specified for an SCP connection, the global configuration is used.

Examples

The following example configures Loopback 1 as the source interface of the SCP client and uses the IP address of Loopback 1 as the global source address of the SCP client.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip scp client source-interface loopback 1
```

1.7 ip scp server enable

Function

Run the **ip scp server enable** command to enable the SCP server function.

Run the **no** form of this command to disable this feature.

The SCP server function is disabled by default.

Syntax

ip scp server enable

no ip scp server enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the SCP server function is configured on the device, users can run the **scp** command to upload files to or download files from the device. Data exchanged during the process is encrypted for security. You can run the **show ip ssh** command to check whether the SCP server function is enabled.

Examples

The following example enables the SCP server function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip scp server enable
```

Notifications

1.8 ip scp server topdir

Function

Run the **ip scp server topdir** command to configure the transmission path for uploading files to or downloading files from the SCP server.

Run the **no** form of this command to remove this configuration.

The default transmission path for file upload and download is **flash:/**.

Syntax

ip scp server topdir { **flash:/***path* | **tmp:/***path* | **usb0:/***path* }

no ip scp server topdir

Parameter Description

flash /*path*: Selects the file transmission path from the extended flash space.

tmp /*path*: Sets the file transmission path to **tmp/vsd/**.

usb0 /*path*: Selects the file transmission path from Universal Serial Bus (USB) disk 0. This option is supported only when the device has one USB port with an extended USB flash drive inserted.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the transmission path for uploading and downloading files.

Examples

The following example sets the transmission path **tmp:/dir** for uploading files to and downloading files from the SCP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip scp server topdir tmp:/dir
```

1.9 ip ssh access-class

Function

Run the **ip ssh access-class** command to configure an access control list (ACL) for the SSH server.

Run the **no** form of this command to remove this configuration.

No ACL is configured on the SSH server by default.

Syntax

ip ssh access-class { *acl-name* | *acl-number* }

no ip ssh access-class

Parameter Description

acl-name: Name of a standard or an extended ACL used for the SSH server. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of a standard or an extended ACL used for the SSH server. The value range is from 1 to 199 or from 1300 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be used to perform ACL filtering for all connections to the SSH server. In line mode, ACL filtering is performed only for specific lines. However, ACL filtering rules of the SSH server are effective to all SSH connections.

Examples

The following example configures ACL testv4 for the SSH server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh access-class testv4
```

1.10 ip ssh authentication-retries

Function

Run the **ip ssh authentication-retries** command to configure the maximum number of user authentication attempts allowed on the SSH server.

Run the **no** form of this command to remove this configuration.

The default maximum number of authentication attempts allowed on the SSH server is **3**.

Syntax

ip ssh authentication-retries *retry-times*

no ip ssh authentication-retries

Parameter Description

retry-times: Maximum number of authentication attempts allowed. The value range is from 0 to 5.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the maximum number of authentication attempts allowed on the SSH server. If authentication still does not succeed when the maximum number of user authentication attempts is reached, user authentication fails.

Examples

The following example sets the maximum number of authentication attempts allowed on the SSH server to **2**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh authentication-retries 2
```

1.11 ip ssh cipher-mode

Function

Run the **ip ssh cipher-mode** command to configure the encryption modes supported by the SSH server.

Run the **no** form of this command to remove this configuration.

The encryption modes supported by the SSH server are **ctr** and **gcm** by default.

Syntax

ip ssh cipher-mode { **cbc** | **ctr** | **gcm** | **others** } *

no ip ssh cipher-mode

Parameter Description

cbc: Configures the SSH server to support encryption mode cipher block chaining (CBC). The corresponding encryption algorithms are DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, and Blowfish-CBC.

ctr: Configures the SSH server to support encryption mode counter (CTR). The corresponding encryption algorithms are AES128-CTR, AES192-CTR, and AES256-CTR.

gcm: Configures the SSH server to support encryption mode Galois/Counter Mode (GCM), with Galois Message Authentication Code (GMAC). The corresponding encryption algorithms are AES128-GCM and AES256-GCM.

others: Configures the SSH server to support encryption mode "others". The corresponding encryption algorithm is RC4.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

SSHv1 supports encryption algorithms DES-CBC, 3DES-CBC, and Blowfish-CBC.

SSHv2 supports encryption algorithms AES128-CTR, AES192-CTR, AES256-CTR, DES-CBC, 3DES-CBC, AES-128-CBC, AES-192-CBC, AES-256-CBC, Blowfish-CBC, AES128-GCM, AES256-GCM, and RC4.

These algorithms can be grouped into four encryption modes: CBC, CTR, GCM (with GMAC), and others.

As the cryptography continuously develops, it is approved that encryption algorithms in the CBC and others modes can be decrypted in a limited period of time. Therefore, organizations or companies that have high security requirements can set the encryption modes supported by the SSH server to CTR and GCM to enhance the security level of the SSH server.

When the CBC, CTR, or GCM mode and algorithms supported in the mode are configured, the configuration result is still the original mode. For example, if **ip ssh cipher cbc 3des-cbc** is configured, the actual configuration result is the CBC mode.

Examples

The following example sets the encryption mode supported by the SSH server to the CTR mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh cipher-mode ctr
```

1.13 ip ssh hmac-algorithm

Function

Run the **ip ssh hmac-algorithm** command to configure the message authentication algorithms supported by the SSH server.

Run the **no** form of this command to remove this configuration.

SSHv1 servers do not support any message authentication algorithms, and SSHv2 servers support the MD5, SHA1, SHA1-96, MD5-96, sha2-256, and sha2-512 message authentication algorithms by default.

Syntax

ip ssh hmac-algorithm { **md5** | **md5-96** | **sha1** | **sha1-96** | **sha2-256** | **sha2-512** }

no ip ssh hmac-algorith

Parameter Description

Md5:5: Sets the message authentication algorithm supported by the SSH server to MD5.

md5-96: Sets the message authentication algorithm supported by the SSH server to MD5-96.

sha1: Sets the message authentication algorithm supported by the SSH server to SHA1.

sha1-96: Sets the message authentication algorithm supported by the SSH server to SHA1-96.

sha2-256: Sets the message authentication algorithm supported by the SSH server to SHA2-256.

sha2-512: Sets the message authentication algorithm supported by the SSH server to SHA2-512.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

1.14 ip ssh ip-block disable

Function

Run the **ip ssh ip-block disable** command to disable the IP address blocking function of the SSH server.

Run the **no** form of this command to enable this feature.

The IP address blocking function of the SSH server is enabled by default.

Syntax

ip ssh ip-block disable

no ip ssh ip-block disable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the number of authentication failures for login through SSH reaches the configured limit in an authentication failure count period, the source IP address is blocked. That is, the SSH client that uses this

source IP address is not allowed to log in to the device to prevent the device being attacked. The SSH client can log in to the device only after the IP address is awakened.

Examples

The following example disables the IP address blocking function on the SSH server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh ip-block disable
```

Notifications

1.15 ip ssh ip-block failed-times

Function

Run the **ip ssh ip-block failed-times** command to configure the number of authentication failures for blocking IP addresses and the time period for counting authentication failures on the SSH server.

Run the **no** form of this command to remove this configuration.

The allowed maximum number of authentication failures is **6**, and the time period for counting authentication failures is **5** minutes by default.

Syntax

ip ssh ip-block failed-times *failed-times* **period** *period-time*

no ip ssh ip-block failed-times *failed-times* **period** *period-time*

Parameter Description

failed-times: Number of authentication failures for blocking IP addresses. The value range is from 1 to 10.

period-time: Time period for counting authentication failures, in minutes. The value range is from 1 to 120.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the IP address blocking function is enabled, if the number of consecutive authentication failures for device login through SSH reaches the configured limit in an authentication failure count period, the source IP address is blocked. If the number of consecutive authentication failures does not reach the configured limit in an authentication failure count period, or one authentication is successful, the authentication failures are cleared.

Examples

The following example sets the number of authentication failures for blocking IP addresses to 3 and the time period for counting authentication failures to 3 minutes on the SSH server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh ip-block failed-times 3 period 3
```

1.16 ip ssh ip-block reactive

Function

Run the **ip ssh ip-block reactive** command to configure the period for awakening blocked IP addresses.

Run the **no** form of this command to remove this configuration.

Blocked IP addresses are awakened every **5** minutes by default.

Syntax

ip ssh ip-block reactive *reactive-interval*

no ip ssh ip-block reactive

Parameter Description

reactive-interval: Period for awakening blocked IP addresses. The value range is from 1 to 1000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the time period for awakening the blocked source IP address reaches, the entry with the blocked source IP address is cleared. An SSH client can use this IP address to log in to the device.

Examples

The following example sets the time period for awakening blocked IP addresses on the SSH server to 3 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh ip-block reactive 3
```

1.17 ip ssh key-exchange

Function

Run the **ip ssh key-exchange** command to configure the Diffie–Hellman (DH) key exchange algorithms supported by the SSH server.

Run the **no** form of this command to remove this configuration.

Ruijie SSHv2 servers support diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, ecdh_sha2_nistp256, ecdh_sha2_nistp384, and ecdh_sha2_nistp521 for key exchange, and SSHv1 servers support none by default.

Syntax

ip ssh key-exchange { **dh_group_exchange_sha1** | **dh_group14_sha1** | **dh_group1_sha1** | **ecdh_sha2_nistp256** | **ecdh_sha2_nistp384** | **ecdh_sha2_nistp521** }

no ip ssh key-exchange

Parameter Description

dh_group_exchange_sha1: Sets the DH key exchange algorithm to diffie-hellman-group-exchange-sha1. The default key length is **2048** bytes, which is not configurable.

dh_group14_sha1: Sets the DH key exchange algorithm to diffie-hellman-group14-sha1. The key length is 2048 bytes.

dh_group1_sha1: Sets the DH key exchange algorithm to diffie-hellman-group1-sha1. The key length is 1024 bytes.

ecdh_sha2_nistp256: Sets the DH key exchange algorithm to ecdh_sha2_nistp256. The key length is 256 bytes.

ecdh_sha2_nistp384: Sets the DH key exchange algorithm to ecdh_sha2_nistp384. The key length is 384 bytes.

ecdh_sha2_nistp521: Sets the DH key exchange algorithm to ecdh_sha2_nistp521. The key length is 512 bytes.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The SSHv1 server does not support any DH key exchange algorithm. The SSHv2 server supports the following DH key exchange algorithms: diffie-hellman-group-exchange-sha1, diffie-hellman-group14-sha1, diffie-hellman-group1-sha1, ecdh_sha2_nistp256, ecdh_sha2_nistp384, and ecdh_sha2_nistp521. You can select DH key exchange algorithms supported by the SSH server as required.

Examples

The following example sets the DH key exchange algorithm supported by the SSH server to diffie-hellman-group14-sha1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh key-exchange dh_group14_sha1
```

1.18 ip ssh peer

Function

Run the **ip ssh peer** command to associate with the public key file and username of a client.

Run the **no** form of this command to remove this configuration.

Syntax

ip ssh peer *username* **public-key** { **dsa** | **ecc** | **rsa** } *filename-path*

no ip ssh peer *username* **public-key** { **rsa** | **dsa** | **ecc** }

Parameter Description

username: Username of a client.

dsa: Sets the public key type to DSA.

ecc: Sets the public key type to ECC.

rsa: Sets the public key type to RSA.

filename-path: Path where the public key file is stored.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example associates username **test** with the RSA public key file **flash:rsa.pub**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh peer test public-key rsa flash:rsa.pub
```

Notifications

When the number of associated public key files exceeds the maximum value 1024, the following notification will be displayed:

```
Hostname(config)# ip ssh peer test public-key rsa flash:rsa.pub
%% Too many public-keys, system support max public key 1024
```

When the name of the associated public key file is not entered, the following notification will be displayed:

```
Hostname(config)#ip ssh peer test public-key rsa flash:
% Invalid file name
```

1.19 ip ssh port

Function

Run the **ip ssh port** command to configure the listening port of the SSH server.

Run the **no** form of this command to remove this configuration.

The default listening port of the SSH server is port **22**.

Syntax

ip ssh port *ssh-monitor-port*

no ip ssh port

Parameter Description

ssh-monitor-port: Listening port of the SSH server. The value range is from 1025 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the listening port of the SSH server to **10000**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh port 10000
```

Notifications

When the configured port is the same as the current value, the following notification will be displayed:

```
Hostname(config)# ip ssh port 22
% SSH tcp-port has been 22
```

When a port in the listening state is configured as the listening port of the SSH server, the following notification will be displayed:

```
Hostname(config)# ip ssh port 10000
% SSH open tcp-port(10000) failed, please use another tcp-port,otherwise the system
will use the old tcp-port(22)!
```

When an error occurs after the configured listening port starts listening, the following notification will be displayed:

```
Hostname(config)# ip ssh port 10000
% SSH change to tcp-port(10000) fail!
```

When a listening port is successfully configured, the following notification will be displayed:

```
Hostname(config)# ip ssh port 10000
% SSH change to tcp-port(10000) success!
```

1.20 ip ssh source-interface

Function

Run the **ip ssh source-interface** command to configure the source interface of the SSH client.

Run the **no** form of this command to remove this configuration.

No SSH client source interface is configured by default.

Syntax

ip ssh source-interface *interface-type interface-number*

no ip ssh source-interface

Parameter Description

interface-type interface-number: Type and number of the SSH client source interface whose IP address is used as the global source address of the SSH client.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to specify the source interface when the device serves as an SSH client, and the IP address of which will be used as the global source address of the SSH client. When the **ssh** command is used to connect to an SSH server, this global configuration will be used if no source interface or source address is specified for this connection. When no SSH client source interface is configured, SSH packets use the packet sending source address queried based on the route as the source address.

Examples

The following example configures Loopback 1 as the source interface of an SSH client.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh source-interface loopback 1
```

1.21 ip ssh time-out

Function

Run the **ip ssh time-out** command to configure the user authentication timeout time on the SSH server.

Run the **no** form of this command to remove this configuration.

The default user authentication timeout time on the SSH server is **120** seconds.

Syntax

ip ssh time-out *timeout-time*

no ip ssh time-out

Parameter Description

timeout-time: User authentication timeout time, in seconds. The value range is from 1 to 120.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the user authentication timeout time on the SSH server. The SSH server starts the timer after receiving a user connection request. If authentication does not succeed after 120 seconds, authentication fails.

Examples

The following example sets the user authentication timeout time on the SSH server to 100 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh time-out 100
```

1.22 ip ssh version

Function

Run the **ip ssh version** command to configure the SSH server version.

Run the **no** form of this command to remove this configuration.

The SSH server is compatible with the SSHv1 and SSHv2 clients by default.

Syntax

ip ssh version *version-type*

no ip ssh version

Parameter Description

version-type: Version of the SSH server. The value is 1 or 2. The value **1** indicates that the SSH server supports only connection requests from SSHv1 clients, and the value **2** indicates that the SSH server supports only connection requests from SSHv2 clients.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the version supported by the SSH server. If the *version-type* parameter is not specified, the SSH server is compatible with SSHv1 and SSHv2 clients. That is, both SSHv1 and SSHv2 clients can connect to the SSH server. If only SSHv1 or SSHv2 is configured, only the SSH client of the configured version can be connected to the SSH server.

Examples

The following example sets the version supported by the SSH server to SSHv2 only.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip ssh version 2
```

1.24 scp

Function

Run the **scp** command to upload files to or download files from the remote SCP server.

Syntax

scp [**oob**] [**-v** { **1** | **2** } | **-c** { **3des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** | **aes128-ctr** | **aes192-ctr** | **aes256-ctr** | **aes128-gcm** | **aes256-gcm** } | **-m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha1-96** | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** } | **-p** *port-num*] * *source-file destination-file* [**/source** { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }] [**/vrf** *vrf-name*]

Parameter Description

oob: Connects to the remote SCP server through out-of-band communication (over the MGMT port typically). This option is valid only when the device has an MGMT port.

-**v** { **1 | 2** }: Configures the SSH version. The value **1** indicates SSHv1, and the value **2** indicates SSHv2. If this parameter is not specified, SSHv2 is used.

-c: Configures the data encryption algorithm. During algorithm negotiation, the SSH client sends only the user-specified encryption algorithm to the server. If the server does not support the user-specified encryption algorithm, the server closes the SSH connection. If this parameter is not specified, the SSH client sends all supported algorithms to the server during algorithm negotiation.

-**c 3des**: Sets the data encryption algorithm to 3DES.

-**c aes128-cbc**: Sets the data encryption algorithm to AES128-CBC (128-bit key).

-**c aes192-cbc**: Sets the data encryption algorithm to AES192-CBC (192-bit key).

-**c aes256-cbc**: Sets the data encryption algorithm to AES256-CBC (256-bit key).

-**c aes128-ctr**: Sets the data encryption algorithm to AES128-CTR (128-bit key).

-**c aes192-ctr**: Sets the data encryption algorithm to AES192-CTR (192-bit key).

-**c aes256-ctr**: Sets the data encryption algorithm to AES256-CTR (256-bit key).

-**c aes128-gcm**: Sets the data encryption algorithm to AES128-GCM (128-bit key).

-**c aes256-gcm**: Sets the data encryption algorithm to AES256-GCM (256-bit key).

-m: Configures the hash-based message authentication code (HMAC) algorithm. During algorithm negotiation, the SCP client sends only the user-specified HMAC algorithm to the server. If the server does not support the user-specified HMAC algorithm, the server closes the SSH connection. If this parameter is not specified, the SSH client sends all supported algorithms to the server during algorithm negotiation. Supported algorithms include hmac-md5-96, hmac-md5-128, hmac-sha1-96, hmac-sha1-160, hmac-sha2-256, and hmac-sha2-512.

-p *port-num*: Configures the destination port in packets sent from the client to the server. The value range is from 0 to 65535. If this parameter is not specified, the destination port is port 22.

source-file destination-file: File copied to the destination path, which can be from the remote server to the device or from the device to the remote server. *source-file* indicates the path where the source file is stored. *destination-file* indicates the path where a file is copied to. Files on the remote server are displayed in *username*@host:/*filename* format, and files on the device are displayed in *path*:/*filename* format. The formats are as follows:

- flash:/filename: Extended flash space.
- usb0:/filename: Extended USB disk 0. This option is supported when the device has one USB port with a USB flash drive inserted.
- tmp:/filename: Temporary tmp/vsd/ directory.

via *mgmt-name*: Specifies the MGMT port used by the SSH server when the oob option is specified.

/source: Specifies the source IP address or interface used by an SCP client.

ip *ipv4-address*: Specifies the source IPv4 address used by an SCP client.

ipv6 *ipv6-address*: Specifies the source IPv6 address used by an SCP client.

interface *interface-type interface-number*: Specifies the source interface used by an SCP client.

/vrf *vrf-name*: Specifies the virtual routing and forwarding (VRF) routing table to be displayed.

Command Modes

Privileged EXEC mode

Default Level

1

Usage Guidelines

When the device serves as an SCP client, the device can run the **scp** command to establish a connection to the SCP server to upload files to and download files from the SCP server.

SSHv1 does not support the HMAC algorithm. If both SSHv1 and the HMAC algorithm are specified, the HMAC configuration will be ignored.

Examples

The following example downloads the **config.text** file from a remote SCP server whose IP address is 192.168.23.122 to the local device using username **admin** and saves the file as **flash:/config.text**.

```
Hostname> enable
Hostname#scp admin@192.168.23.122:/config.text flash:/config.text
```

The following example uploads the **flash:/config.text** file from the local device to the remote SCP server whose IP address is 192.168.23.122 using username **admin** and saves the file as **config.text**.

```
Hostname> enable
Hostname# scp flash:/config.text admin@192.168.23.122:/config.text
```

1.25 show crypto key mypubkey

Function

Run the **show crypto key mypubkey** command to display partial of the public key information of the SSH server.

Syntax

show crypto key mypubkey { **dsa** | **ecc** | **rsa** }

Parameter Description

dsa: Displays the DSA key information.

ecc: Displays the ECC key information.

rsa: Displays the RSA key information.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display the public key information of the SSH server, including the key generation time, key name, and partial of key content.

Examples

The following example displays partial RSA key information of the SSH server.

```
Hostname> enable
Hostname# show crypto key mypubkey rsa
% Key pair was generated at: 7:1:25 UTC Jan 16 2013
 Key name: RSA1 private
 Usage: SSH Purpose Key
 Key is not exportable.
 Key Data:
       AAAAAwEA AQAAAEEA 2m6H/J+2 xOMLW5MR 8tOmpW1I XU1QItVN mLdR+G7O Q10kz+4/
       /IgYR0ge 1sZNg32u dFEifZ6D zfLySPqC MTWLfw==
% Key pair was generated at: 7:1:25 UTC Jan 16 2013
 Key name: RSA private
 Usage: SSH Purpose Key
 Key is not exportable.
```

```
Key Data:
       AAAAAwEA AQAAAEEA 0E5w2H0k v744uTIR yZBd/7AM 8pLItnW3 XH3LhEEi BbZGZvn3
       LEYYfQ9s pgYL0ZQf S0s/GY0X gJOMsc6z i8OAkQ==
```

1.26 show ip ssh

Function

Run the **show ip ssh** command to display effective configurations of the SSH server.

Syntax

show ip ssh

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display effective configurations of the SSH server, including the version, whether the SSH server function is enabled, port number, encryption mode, message authentication algorithm, authentication timeout time, and maximum number of authentication attempts allowed.

If an SSH version is configured but the corresponding server key is not generated, a message indicating that the SSH version is unavailable will be displayed.

Examples

The following example displays effective configurations of the SSH server when the SSH server and SCP server functions are disabled.

```
Hostname> enable
Hostname# show ip ssh
SSH Disable - version 1.99
please generate rsa and dsa key to enable SSH
SSH Port:             22
SSH Cipher Mode:       cbc,ctr,others
SSH HMAC Algorithm:    md5-96,md5,sha1-96,sha1
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:        disabled
SSH dh-exchange min-len: 2048
SSH ip-block:          disabled
```

The following example displays effective configurations of the SSH server when the SSH server and SCP server functions are enabled.

```
Hostname> enable
Hostname# show ip ssh
SSH Enable - version 1.99
SSH Port:             22
SSH Cipher Mode:       cbc,ctr,others
SSH HMAC Algorithm:    md5-96,md5,sha1-96,sha1
Authentication timeout: 120 secs
Authentication retries: 3
SSH SCP Server:        enabled
SSH dh-exchange min-len: 2048
SSH ip-block:          enabled
```

Table 1-2 Output Fields of the show ip ssh Command

Field	Description
SSH Enable/Disable	Whether the SSH server function is enabled
version 1|2	SSH version supported by the SSH server
please generate rsa and dsa key to enable SSH	Whether the RSA/DSA public key is generated to enable the SSH server function
SSH Port	Listening port of the SSH server
SSH Cipher Mode	Encryption mode of the SSH server
SSH HMAC Algorithm	Message authentication algorithm of the SSH server

Field	Description
Authentication timeout	User authentication timeout time
Authentication retries	Maximum number of authentication attempts allowed
SSH SCP Server enabled/disabled	Whether the SSH SCP server function is enabled
SSH dh-exchange min-len	Minimum key length negotiated by the key exchange algorithm of the SSH server
SSH ip-block enabled/disabled	Whether the IP address blocking function is enabled on the SSH server

1.27 show ssh

Function

Run the **show ssh** command to display information about established SSH connections.

Syntax

show ssh

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display information about established SSH connections, including the VTY number occupied by a connection, SSH version, encryption algorithm, message authentication algorithm, connection status, and username.

Examples

The following example displays information about established SSH connections.

```
Hostname> enable
Hostname# show ssh
Connection Version Encryption      Hmac        Compress   State          Username
       0    1.5 blowfish                    zlib      Session started test
       1    2.0 aes256-cbc      hmac-sha1    zlib      Session started test
```

Table 1-3 Output Fields of the show ssh Command

Field	Description
Connection	VTY number occupied by a connection
Version	SSH version supported by an SSH client
Encryption	Encryption algorithm
Hmac	Message authentication algorithm
Compress	Compression algorithm
State	Connection status
Username	Username

1.28 show ssh ip-block

Function

Run the **show ssh ip-block** command to display information about blocked IP addresses and authentication failures.

Syntax

show ssh ip-block { **all** | **list** }

Parameter Description

all: Displays information about all blocked IP addresses and authentication failures.

list: Displays information about blocked IP addresses.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display information about all blocked IP addresses and authentication failures. Blocked IP address information includes the source IPv4 or IPv6 addresses and remaining time for awakening blocked IP addresses. Authentication failure information includes the source IPv4 or IPv6 addresses, status, and number of authentication failures.

Examples

The following example displays information about all blocked IP addresses and authentication failures.

```
Hostname> enable
Hostname# show ssh ip-block all
------------------------
IP Address                              State      Auth-fail Count
------------------------
172.30.31.16                            AUTH FAILED    3
172.30.31.17                            BLOCKED        6
------------------------
```

Table 1-4 Output Fields of the show ssh ip-block all Command

Field	Description
IP Address	Source IPv4 or IPv6 address
State	Status ● **AUTH FAILED**: Authentication fails but the blocking conditions are not met. ● **BLOCKED**: Blocking conditions are met.
Auth-fail Count	Number of authentication failures

The following example displays information about blocked IP addresses.

```
Hostname> enable
Hostname# show ssh ip-block list
------------------------
IP Address                              UnBlock Interval (Seconds)
------------------------
172.30.31.17                            296
------------------------
```

1.29 show ssh-sessions

Function

Run the **show ssh-sessions** command to display information about established SSH client sessions.

Syntax

show ssh-sessions

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display information about established SSH client sessions, including the VTY number occupied by a connection, SSH version, and server address.

Examples

The following example displays information about established SSH client sessions.

```
Hostname> enable
Hostname# show ssh-sessions
Connect No.  SSH Version Server Address
-----  -----  ----
0          2.0        192.168.23.122
1          1.5        192.168.23.122
```

1.30 ssh

Function

Run the **ssh** command to establish an encrypted session with a remote network device.

Syntax

ssh [**oob**] [**-v** { **1** | **2** } | **-c** { **3des** | **aes128-cbc** | **aes192-cbc** | **aes256-cbc** | **aes128-ctr** | **aes192-ctr** | **aes256-ctr** | **aes128-gcm** | **aes256-gcm** } | **-l** *username* | **-m** { **hmac-md5-96** | **hmac-md5-128** | **hmac-sha1-96** | **hmac-sha1-160** | **hmac-sha2-256** | **hmac-sha2-512** } | **-p** *port-num*] * { *ip-address* | *hostname* } [**via** *mgmt-name*] [**/source** { **ip** *ipv4-address* | **ipv6** *ipv6-address* | **interface** *interface-type interface-number* }] [**/vrf** *vrf-name*]

Parameter Description

oob: Connects to the remote SSH server through out-of-band communication (over the MGMT port typically). This option is valid only when the device has an MGMT port.

-**v** { **1 | 2** }: Configures the SSH version. The value **1** indicates SSHv1, and the value **2** indicates SSHv2. If this parameter is not specified, SSHv2 is used.

-c: Configures the data encryption algorithm. During algorithm negotiation, the SSH client only sends the user-specified encryption algorithm to the server. If the server does not support the user-specified encryption algorithm, the server closes the SSH connection. If this parameter is not specified, the SSH client sends all supported algorithms to the server during algorithm negotiation.

-**c 3des**: Sets the data encryption algorithm to 3DES.

-**c aes128-cbc**: Sets the data encryption algorithm to AES128-CBC (128-bit key).

-**c aes192-cbc**: Sets the data encryption algorithm to AES192-CBC (192-bit key).

-**c aes256-cbc**: Sets the data encryption algorithm to AES256-CBC (256-bit key).

-**c aes128-ctr**: Sets the data encryption algorithm to AES128-CTR (128-bit key).

-**c aes192-ctr**: Sets the data encryption algorithm to AES192-CTR (192-bit key).

-**c aes256-ctr**: Sets the data encryption algorithm to AES256-CTR (256-bit key).

-**c aes128-gcm**: Sets the data encryption algorithm to AES128-GCM (128-bit key).

-**c aes256-gcm**: Sets the data encryption algorithm to AES256-GCM (256-bit key)

-l *username*: Specifies the username used for login.

-m: Configures the HMAC algorithm. During algorithm negotiation, the SCP client sends only the user-specified HMAC algorithm to the server. If the server does not support the user-specified HMAC algorithm, the server closes the SSH connection. If this parameter is not specified, the SSH client sends all supported algorithms to the server during algorithm negotiation. Supported algorithms include hmac-md5-96, hmac-md5-128, hmac-sha1-96, hmac-sha1-160, hmac-sha2-256, and hmac-sha2-512.

-p *port-num*: Configures the destination port in packets sent from the client to the server. The value range is from 0 to 65535. If this parameter is not specified, the destination port is port 22.

ip-address: IPv4/IPv6 address of the remote server.

hostname: IPv4/IPv6 host name of the remote server.

via *mgmt-name*: Specifies the MGMT port used by the SSH server when the oob option is configured.

/source: Specifies the source IP address or interface used by an SCP client.

ip *ipv4-address*: Specifies the source IPv4 address used by an SCP client.

ipv6 *ipv6-address*: Specifies the source IPv6 address used by an SCP client.

interface *interface-type interface-number*: Specifies the source interface used by an SCP client.

/vrf *vrf-name*: Specifies the virtual routing and forwarding (VRF) routing table to be displayed.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

When the device serves as an SSH client, the device can run the **ssh** command to establish a connection to the SSH server. This connection is similar to but more secure than a Telnet connection due to the authentication and encrypted transmission features. Different versions support different parameters. During parameter configuration, note the following:

- SSHv1 supports only the DES (56-bit key) and 3DES (168-bit key) encryption algorithms.
- SSHv2 supports the following Advanced Encryption Standards (AES): AES128-CBC, AES192-CBC, AES256-CBC, AES128-CTR, AES192-CTR, AES256-CTR, AES128-GCM, and AES256-GCM.
- SSHv1 does not support the HMAC algorithm.
- If you specify an unmatched encryption or authentication algorithm when selecting an SSH version, the unmatched algorithm will be ignored when a connection is established.

Examples

The following example uses username **admin** to log in to a device that provides the SSH server service and whose IP address is 192.168.23.122 through SSH.

```
Hostname> enable
Hostname# ssh -l admin 192.168.23.122
```

The following example uses username **admin** to log in to a device that provides the SSH server service and whose IP address is 192.168.23.122 through SSHv2. The encryption algorithm is set to **aes128-cbc**, and the authentication algorithm is set to **hmac-md5-128**.

```
Hostname> enable
Hostname# ssh -v 2 -c aes128-cbc  -m hmac-md5-128 -l admin 192.168.23.122
```

1.31 ssh-session

Function

Run the **ssh-session** command to restore an established SSH client session.

Syntax

ssh-session *session-id*

Parameter Description

session-id: ID of an established SSH client session.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

After the device establishes an SSH session with the SSH server as a client, you can press Ctrl+Shift+6+X to exit the session temporarily. After exiting the session, you can run the corresponding command to restore the session.

Examples

The following example restores the SSH client session whose session ID is 1.

```
Hostname> enable
Hostname# ssh-session 1
```

1 Global IP-MAC Address Binding Commands

Command	Function
address-bind	Configure a global IP-Media Access Control (MAC) address binding policy.
address-bind binding-filter logging	Enable address binding log filtering.
address-bind install	Enable the IP-MAC address binding function.
address-bind ipv6-mode	Configure the IPv6 address binding mode.
address-bind uplink	Configure a port as an excluded port for address binding.
show address-bind	Display the global IP-MAC address binding policy.
show address-bind uplink	Display excluded ports for address binding.

1.1 address-bind

Function

Run the **address-bind** command to configure a global IP-Media Access Control (MAC) address binding policy.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No IP-MAC address binding policy is configured by default.

Syntax

address-bind { *ipv4-address mac-address* | *ipv6-address mac-address* }

no address-bind { *ipv4-address mac-address* | *ipv6-address mac-address* }

default address-bind { *ipv4-address mac-address* | *ipv6-address mac-address* }

Parameter Description

ipv4-address mac-address: IPv4-MAC address binding.

ipv6-address mac-address: IPv6-MAC address binding.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures a global IPv4-MAC address binding policy with the IPv4 address being 192.168.5.1 and the MAC address being 00d0.f800.0001.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# address-bind 192.168.5.1 00d0.f800.0001
```

1.2 address-bind binding-filter logging

Function

Run the **address-bind binding-filter logging** command to enable address binding log filtering.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

Address binding log filtering is disabled by default.

Syntax

address-bind binding-filter logging [**rate-limit** *rate*]

no address-bind binding-filter logging

default address-bind binding-filter logging

Parameter Description

rate-limit *rate*: Specifies the rate for printing global IPv4-MAC address binding logs, in pieces per minutes. The value range is from 1 to 120. The default value is **10**. If this parameter is not specified, address binding log filtering is enabled.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the address binding log filtering function is enabled, the device prints alert logs for IP packets that do not contain bound IP address and MAC address.

When the printing rate of address binding logs exceeds the configured rate, the number of suppressed logs is displayed.

Examples

The following example enables the address binding log filtering function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# address-bind binding-filter logging
```

1.3 address-bind install

Function

Run the **address-bind install** command to enable the IP-MAC address binding function.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The IP-MAC address binding function is disabled by default.

Syntax

address-bind install

no address-bind install

default address-bind install

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After IP-MAC address binding is enabled, the device forwards packets based on the IP-MAC address binding policy.

Before enabling this function, you need to run the **address-bind** command to configure a global IP-MAC address binding policy or run the **address-bind uplink** command to configure the port on the device used to connect to the user host as an excluded port. Otherwise, the connection may be interrupted.

Examples

The following example enables the IP-MAC address binding function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# address-bind 192.168.5.1 00d0.f800.0001
Hostname(config)# address-bind install
```

1.4 address-bind ipv6-mode

Function

Run the **address-bind ipv6-mode** command to configure the IPv6 address binding mode.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default IPv6 address binding mode is the strict mode.

Syntax

address-bind ipv6-mode { **compatible** | **loose** | **strict** }

no address-bind ipv6-mode

default address-bind ipv6-mode

Parameter Description

compatible: Specifies the compatible mode.

loose: Specifies the loose mode.

strict: Specifies the strict mode.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Table 1-1 describes the forwarding rules in different IPv6 address binding modes.

Table 1-1 Forwarding Rules

Binding Mode	IPv4 Packet Forwarding Rule	IPv6 Packet Forwarding Rule
Strict	Packets matching the IPv4-MAC address binding conditions are forwarded.	Packets matching the IPv6-MAC address binding conditions are forwarded.

Binding Mode	IPv4 Packet Forwarding Rule	IPv6 Packet Forwarding Rule
Loose	Packets matching the IPv4-MAC address binding conditions are forwarded.	• If IPv6-MAC address binding is configured, packets matching the IPv6-MAC address binding conditions are forwarded. • If IPv6-MAC address binding is not configured, all IPv6 packets are forwarded.
Compatible	Packets matching the IPv4-MAC address binding conditions are forwarded.	• IPv6 packets are forwarded if they contain MAC addresses matching the MAC address in the IPv4-MAC address binding policy. • Packets matching the IPv6-MAC address binding conditions are forwarded.

Examples

The following example sets the IPv6 address binding mode to the compatible mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# address-bind ipv6-mode compatible
```

1 Port Security Commands

Command	Function
switchport port-security	Enable the port security function.
switchport port-security aging	Configure the secure address aging time and its application scope on a port.
switchport port-security binding	Configure the secure addresses bound to a port.
switchport port-security binding-filter logging	Enable address binding log filtering and configure the log printing rate.
switchport port-security interface binding	Configure security binding for a port.
switchport port-security mac-address	Configure static secure addresses.
switchport port-security interface mac-address	Configure static secure addresses.
switchport port-security maximum	Configure the maximum number of secure addresses for a port.
switchport port-security mac-address sticky	Enable sticky MAC address learning and configure sticky MAC addresses.
switchport port-security violation	Configure the method for handling packets that violate the port security requirements.
show port-security	Display port security configurations and secure addresses.

1.1 switchport port-security

Function

Run the **switchport port-security** command to enable the port security function.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The port security function is disabled by default.

Syntax

switchport port-security

no switchport port-security

default switchport port-security

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The port security function strictly controls Media Access Control (MAC) addresses and IP addresses (optional) that can access a port.

The port security function can be configured only on switching ports and layer 2 (L2) aggregation ports (APs). Ports configured with port security are called secure ports. If a secure address is configured for a secure port, the secure port allows only packets whose source address is the configured secure address to pass through. Other packets are discarded.

Examples

The following example enables port security on Gigabitethernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security

Run the **switchport port-security aging** command to configure the secure address aging time and its application scope on a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The secure address aging time is **0** (that is, not aged), and the aging time applies only to dynamically learned addresses by default.

Syntax

switchport port-security aging { **static** | **time** *aging-time* }

no switchport port-security aging { **static** | **time** }

default switchport port-security aging { **static** | **time** }

Parameter Description

static: Applies the configured aging time to manually configured and dynamically learned addresses.

time *aging-time*: Configures the aging time of all secure addresses on a port, in minutes. The value range is from 0 to 1440. When the aging time is set to **0**, secure addresses on a port will not be aged.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command together with the **switchport port-security maximum** command for configuring the maximum number of secure addresses allow the device to automatically add and delete secure addresses on a port.

When the **no switchport port-security aging time** command is run to restore the secure address aging time on a port to **0**, secure address aging is disabled on the port. The **no switchport port-security aging static** command allows the aging time to be applied only to dynamically learned secure addresses.

When port security and 802.1x authentication are both enabled but the secure address has aged, 802.1x users must re-initiate authentication requests to continue the communication.

Examples

The following example sets the aging time of secure addresses on GigabitEthernet 0/1 to 8 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if)# switchport port-security aging time 8
Hostname(config-if)# switchport port-security aging static
```

1.3 switchport port-security binding

Function

Run the **switchport port-security binding** command to configure the secure addresses bound to a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No secure address is bound to a port by default.

Syntax

switchport port-security binding [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

no switchport port-security binding [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

default switchport port-security binding [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

Parameter Description

mac-address: Source MAC address to be bound to a port, VLAN ID, and IP address.

vlan *vlan-id*: Specifies the virtual local area network (VLAN) ID to be bound to a port, source MAC address, and IP address. The value range is from 1 to 4094.

ipv4-address: IPv4 address to be bound to a port.

ipv6-address: IPv6 address to be bound to a port.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You must first enter the interface configuration mode of the port to be bound and then run this command to bind the port with the source MAC address (optional), VLAN ID (optional), and IP address. Only packets match the security binding can enter the device, and other packets will be discarded.

Packets that comply with IP-MAC address binding or IP address binding for port security can be forwarded only when their source MAC address is the secure address bound to the port.

Before dynamically learned secure addresses are added to the secure address table, packets that comply with IP-MAC address binding or IP address binding for port security cannot be forwarded.

Static secure addresses can access the Internet without authentication. If authorization exists, only static secure addresses that comply with the authorization binding can access the Internet.

Examples

The following example binds IPv4 address 192.168.1.100 to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security binding
192.168.1.100
```

The following example binds IPv4 address 192.168.1.100, MAC address 00d0.f800.5555, and VLAN 1 to GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security binding
00d0.f800.5555 vlan 1 192.168.1.100
```

1.4 switchport port-security binding-filter logging

Function

Run the **switchport port-security binding-filter logging** command to enable address binding log filtering and configure the log printing rate.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Address binding log filtering is disabled by default.

Syntax

switchport port-security binding-filter logging [**rate-limit** *rate*]

no switchport port-security binding-filter logging

default switchport port-security binding-filter logging

Parameter Description

rate-limit *rate*: Configures the rate for printing security binding logs, in pieces per second. The value range is from 1 to 120. The default value is **10**. If this parameter is not specified, address binding log filtering is enabled.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the binding log filtering function is enabled, the device prints alert logs if received IP packets do not match the bound IP and MAC addresses or the bound IP address for port security.

When the binding log printing rate exceeds the configured rate, the number of suppressed logs will be displayed.

Examples

The following example enables the binding log filtering function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# switchport port-security binding-filter logging
```

1.5 switchport port-security interface binding

Function

Run the **switchport port-security interface binding** command to configure security binding for a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No security binding is configured by default.

Syntax

switchport port-security interface *interface-type interface-number* **binding** [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

no switchport port-security interface *interface-type interface-number* **binding** [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

default switchport port-security interface *interface-type interface-number* **binding** [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* }

Parameter Description

interface *interface-type interface-number*: Specifies the interface type and number of the bound port.

mac-address: Bound source MAC address.

vlan *vlan-id*: Specifies the VLAN bound to the source MAC address.

ipv4-address: Bound IPv4 address.

ipv6-address: Bound IPv6 address.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to bind a port with a source MAC address (optional), VLAN ID (optional), and IP address as the security binding of the port. Only packets match the security binding can enter the device, and other packets will be discarded.

Unlike the **switchport port-security binding** [*mac-address* **vlan** *vlan-id*] { *ipv4-address* | *ipv6-address* } command, this command can be directly configured in global configuration mode without needing to enter the interface configuration mode of the bound port.

Packets that comply with IP-MAC address binding or IP address binding for port security can be forwarded only when their source MAC address is the secure address bound to the port.

Before dynamically learned secure addresses are added to the secure address table, packets that comply with IP-MAC address binding or IP address binding for port security cannot be forwarded.

Examples

The following example binds GigabitEthernet 0/1 to IPv4 secure address 192.168.1.100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# switchport port-security interface gigabitethernet 0/1 binding
192.168.1.100
```

The following example binds GigabitEthernet 0/1 to MAC address 00d0.f800.5555, VLAN ID 1, and IPv4 secure address 192.168.1.100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# switchport port-security interface gigabitethernet 0/1 binding
00d0.f800.5555 vlan 1 192.168.1.100
```

1.6 switchport port-security mac-address

Function

Run the **switchport port-security mac-address** command to configure static secure addresses.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No static secure address is configured by default.

Syntax

switchport port-security mac-address *mac-address* [**vlan** *vlan-id*]

no switchport port-security mac-address *mac-address* [**vlan** *vlan-id*]

default switchport port-security mac-address *mac-address* [**vlan** *vlan-id*]

Parameter Description

mac-address *mac-address*: Specifies the static secure address to be configured.

vlan *vlan-id*: Specifies the VLAN to which a MAC address belongs. The value range is from 1 to 4094. This parameter takes effect only for trunk ports.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

1.8 switchport port-security maximum

Function

Run the **switchport port-security maximum** command to configure the maximum number of secure addresses for a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default maximum number of secure addresses for a port is **128**.

Syntax

switchport port-security maximum *number*

no switchport port-security maximum

default switchport port-security maximum

Parameter Description

maximum *number*: Specifies the maximum number of secure addresses. The value range is from 1 to 128.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If you set the maximum number of secure addresses for a port to **1** and configure a secure address for this port, the workstation (whose address is the configured secure address) connected to this port will exclusively use all bandwidth of the port.

The number of secure addresses is the sum of statically configured secure addresses and dynamically learned secure addresses. The default value is **128**. If the configured maximum number of secure addresses is smaller than the current number of secure addresses, the configuration fails.

The maximum number of secure addresses takes effect only to secure addresses and is invalid to security bindings.

Caution

If 802.1x is enabled on a port but the number of authenticated users exceeds the maximum number of users configured for port security, port security cannot be enabled.

Examples

The following example sets the maximum number of secure addresses to 2 for GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security maximum 2
```

Notifications

When the configured maximum number of secure addresses is smaller than the current number of secure addresses, the following notification will be displayed:

```
Setting value is less than the current maximum.
```

Common Errors

The configured maximum number of addresses is smaller than the current number of addresses.

1.9 switchport port-security mac-address sticky

Function

Run the **switchport port-security mac-address sticky** command to enable sticky MAC address learning and configure sticky MAC addresses.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Sticky MAC address learning is disabled by default.

Syntax

switchport port-security mac-address sticky [*mac-address* [**vlan** *vlan-id*]]

no switchport port-security mac-address sticky [*mac-address* [**vlan** *vlan-id*]]

default switchport port-security mac-address sticky [*mac-address* [**vlan** *vlan-id*]]

Parameter Description

mac-address: MAC address.

vlan *vlan-id*: Specifies the VLAN to which a MAC address belongs. This parameter takes effect only for trunk ports.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Sticky MAC address learning is used to save MAC addresses dynamically learned by the device to sticky MAC addresses. Sticky MAC addresses are special MAC addresses not affected by the aging mechanism. No matter whether dynamic or static aging is configured, sticky MAC addresses will not be aged.

Examples

The following example configures sticky MAC address 00d0.f800.5555 and VLAN ID 1 for GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security mac-address sticky
00d0.f800.5555 vlan 1
```

The following example enables sticky MAC address learning for GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security mac-address sticky
```

1.10 switchport port-security violation

Function

Run the **switchport port-security violation** command to configure the method for handling packets that violate the port security requirements.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Packets that do not match the security address are discarded by default.

Syntax

switchport port-security violation { **protect** | **restrict** | **shutdown** }

no switchport port-security violation

default switchport port-security violation

Parameter Description

protect: Discards packets that do not match the security address.

restrict: Discards packets that do not match the security address and sends a trap notification.

shutdown: Discards packets that do not match the security address and disables the port.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When the number of MAC addresses learned by a port exceeds the maximum number of secure addresses, a security violation event is triggered. If the violation handling mode of the port is changed after a violation, the new violation handling mode takes effect only after the secure port is restored to the non-violation state and violates the security again.

You can configure the maximum number of secure addresses for a port. If you set the maximum number of secure addresses to **1** for a port and configure a secure address for the port, the workstation (whose address is the configured secure address) connected to this port will exclusively use all bandwidth of the port.

Examples

The following example enables port security on Gigabitethernet 0/1 and sets the port security violation handling mode to **shutdown**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security
Hostname(config-if-GigabitEthernet 0/1)# switchport port-security violation shutdown
```

1.11 show port-security

Function

Run the **show port-security** command to display port security configurations and secure addresses.

Syntax

show port-security [**all** | [**address** | **binding**] [**interface** *interface-type interface-number*]]

Parameter Description

address: Specifies the secure address to be displayed.

binding: Specifies the security binding to be displayed.

interface *interface-type interface-number*: Specifies the interface whose port security configurations are displayed.

all: Displays all effective secure addresses and security bindings.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is specified when this command is run (**show port-security**), port security configurations, violation handling, and other information of all interfaces are displayed.

Examples

The following example displays all port security configurations.

```
Hostname> enable
Hostname# show port-security
NO.  SecurePort MaxSecureAddr CurrentAddr CurrentIpBind CurrentIpMacBind
SecurityAction AgingTime
                (Count)     (Count)     (Count)        (Count)

1 IP Source Guard Commands

Command	Function
ip source binding	Add static user information to the source IP address binding database.
ip source binding sticky-mac	Enable the function of converting source IP address binding entries to static MAC address entries.
ip verify source	Enable IP Source Guard on an interface or a VLAN.
ip verify source dai-source	Enable the sole role of the source IP address binding database as the source of Dynamic ARP Inspection (DAI) binding entries.
ip verify source exclude-vlan	Specify an excluded VLAN for IP Source Guard on an interface.
ip verify source trust	Configure an IP Source Guard trusted interface.
show ip source binding	Display information of the source IP address binding database.
show ip source binding sticky-mac	Display information about source IP address binding entries converted to static MAC address entries.
show ip verify source	Display user filtering entries of IP Source Guard.

1.1 ip source binding

Function

Run the **ip source binding** command to add static user information to the source IP address binding database.

Run the **no** form of this command to remove this configuration.

No static user information is added by default.

Syntax

ip source binding *mac-address* **vlan** *vlan-id ipv4-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

no ip source binding *mac-address* **vlan** *vlan-id ipv4-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

Parameter Description

mac-address: Media access control (MAC) address of a statically added user.

vlan-id: ID of the virtual local area network (VLAN) to which a statically added user belongs. For products that support QinQ termination, it refers to the outer VLAN ID of a user.

ipv4-address: IPv4 address of a statically added user.

interface *interface-type interface-number*: Specifies the interface statically added.

ip-mac: Specifies that the IP address and MAC address binding type is used globally.

ip-only: Specifies that the IP address binding type is used globally.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Through this command, legitimate users can pass IP Source Guard detection instead of being controlled by Dynamic Host Configuration Protocol (DHCP).

This command can be configured only on L2 switching interfaces, L2 aggregation ports (link aggregation), and encapsulation subinterfaces. When this command is configured on other types of interfaces, the configuration will fail.

Users can configure global binding user records to enable legitimate users to pass IP Source Guard detection on all interfaces.

Note

- A configured binding record takes effect either on the access interface or globally.
- When duplicate user records exist, attributes of the new record will overwrite those of the old record.

Examples

The following example adds a static user record to the source IP address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IP address is 1.1.1.1, and the interface is GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip source binding 0000.0000.0001 vlan 1 1.1.1.1 interface
gigabitethernet 0/1
```

The following example adds a static user record to the source IP address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IP address is 1.1.1.1, and the filtering type is IP address and MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip source binding 0000.0000.0001 vlan 1 1.1.1.1 ip-mac
```

Notifications

When the **no** form of this command is run to delete static configuration and the entered parameters are different from those previously configured, the following notification will be displayed:

```
% Failed to execute command, because of "No such binding entry [mac 0000.0000.0001 ip
1.1.1.1 vlan 2  GLOBAL]".
```

When a user record is configured and the entered wired interface is not an L2 switching interface, L2 aggregation port, or encapsulation sub-interface, the following notification will be displayed:

```
% Failed to execute command, because of "Configure is not supported on current
interface".
```

Common Errors

1.2 ip source binding sticky-mac

Function

Run the **ip source binding sticky-mac** command to enable the function of converting source IP address binding entries to static MAC address entries.

Run the **no** form of this command to disable this feature.

The function of converting source IP address binding entries to static MAC address entries is disabled by default.

Syntax

ip source binding sticky-mac

no ip source binding sticky-mac

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The MAC address table records mapping between MAC addresses and interfaces. Unauthorized users can use MAC addresses of legitimate users to refresh MAC address table records, which will cause abnormal packet forwarding in the network. To prevent unauthorized users from refreshing the MAC address table to launch network attacks, configure this command in interface configuration mode to convert source IP address binding entries to static MAC address entries.

Examples

The following example enables the function of converting source IP address binding entries to static MAC address entries.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip source binding sticky-mac
```

Notifications

When the function of converting source IP address binding entries to static MAC address entries is enabled after the DHCP Snooping binding entry migration function is enabled globally, the following notification will be displayed:

```
% Failed to execute command, because of "Security config conflict".
```

When the function of converting source IP address binding entries to static MAC address entries is enabled on an interface after an access security control option, such as web authentication, 802.1x authentication, or port security is enabled on the interface, the following notification will be displayed:

```
%IP_SRC_GRD-STICKY_MAC: Failed to open sticky mac on interface [Interface name].
```

1.3 ip verify source

Function

Run the **ip verify source** command to enable IP Source Guard on an interface or a VLAN.

Run the **no** form of this command to disable this feature.

IP Source Guard is disabled on an interface or a VLAN by default.

Syntax

ip verify source [**port-security**]

no ip verify source

Parameter Description

port-security: Configures IP Source Guard based on IP address and MAC address.

Command Modes

Interface configuration mode

VLAN configuration mode

Default Level

14

Usage Guidelines

After IP Source Guard is enabled for an interface or a VLAN, users can detect IP packets passing through the interface or VLAN based on the IP address or IP address and MAC address.

This command can be configured only on L2 switching interfaces, L2 aggregation ports, encapsulation subinterfaces, and VLAN configuration mode. When this command is configured on other types of interfaces, the configuration will fail.

When IP Source Guard is enabled in VLAN configuration mode, it is effective to all L2 interfaces in the VLAN. Users need to configure the **ip verify source trust** command on the uplink interface to specify trusted interfaces. Otherwise, packet forwarding may fail.

Caution

Legitimate users of IP Source Guard come from DHCP Snooping and static user configuration. If IP Source Guard is enabled on an interface but no valid data source is configured, users who access the network through the interface cannot use the network normally.

Examples

The following example enables IP Source Guard on GigabitEthernet 0/1 and detects packets only based on the IP address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify source
```

The following example enables IP Source Guard on GigabitEthernet 0/1 and detects packets based on the IP address and MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify source port-security
```

The following example enables IP Source Guard on VLAN 1 and detects packets only based on the IP address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 1
Hostname(config-vlan)# ip verify source
```

The following example enables IP Source Guard on VLAN 1 and detects packets based on the IP address and MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 1
Hostname(config-vlan)# ip verify source port-security
```

Notifications

When this command is configured on a DHCP trusted interface, the following notification will be displayed:

```
% Failed to execute command, because of "Security configuration conflict in interface name".
```

Common Errors

- IP Source Guard is enabled. However, the source of legitimate user records is not configured.

Platform Description

1.4 ip verify source dai-source

Function

Run the **ip verify source dai-source** command to enable the sole role of the source IP address binding database as the source of Dynamic ARP Inspection (DAI) binding entries.

Run the **no** form of this command to remove this configuration.

The sole role of the source IP address binding database as the source of DAI binding entries is not configured by default.

Syntax

ip verify source dai-source

no ip verify source dai-source

Parameter Description

N/A

Command Modes

Interface configuration mode

VLAN configuration mode

Default Level

14

Usage Guidelines

After the sole role of the source IP address binding database as the source of DAI binding entries is configured, the bound entries are solely used for DAI and are not assigned to hardware.

This command can be configured either in interface configuration mode or VLAN configuration mode.

Examples

The following example enables the sole role of the source IP address binding database as the source of DAI binding entries on switching interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify source dai-source
```

The following example enables the sole role of the source IP address binding database as the source of DAI binding entries on VLAN 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 1
Hostname(config-vlan)# ip verify source dai-source
```

Notifications

When this command is configured on a DHCP Snooping or IP Source Guard trusted interface, the following notification will be displayed:

```
% Failed to execute command, because of "Security configuration conflict in interface name".
```

Common Errors

1.5 ip verify source exclude-vlan

Function

Run the **ip verify source exclude-vlan** command to specify an excluded VLAN for IP Source Guard on an interface.

Run the **no** form of this command to remove this configuration.

The function of specifying excluded VLANs for IP Source Guard on an interface is disabled by default.

Syntax

ip verify source exclude-vlan *vlan-id*

no ip verify source exclude-vlan *vlan-id*

Parameter Description

vlan-id: ID of the VLAN that is not controlled by IP Source Guard on an interface. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

By using this command, the specified VLANs under an interface where the IP Source Guard function is enabled can be exempted from check and filtering.

After IP Source Guard is disabled on the interface, the specified excluded VLANs will be cleared automatically.

This command can be configured on L2 switching interfaces or encapsulation subinterfaces.

Caution

An excluded VLAN can be specified for an interface only after IP Source Guard is enabled on the interface.

Examples

The following example specifies VLAN 1 as an excluded VLAN for IP Source Guard on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify source
Hostname(config-if-GigabitEthernet 0/1)# ip verify exclude-vlan 1
```

1.6 ip verify source trust

Function

Run the **ip verify source trust** command to configure an IP Source Guard trusted interface.

Run the **no** form of this command to remove this configuration.

No IP Source Guard trusted interface is configured by default.

Syntax

ip verify source trust

no ip verify source trust

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The IP Source Guard trusted interface function is mutually exclusive with the IP Source Guard interface, port security, 802.1x authorization, and Address Resolution Protocol (ARP) check services.

When an interface is configured as an IP Source Guard trusted interface, IP Source Guard is not performed for the interface and packets through this interface are released directly.

This command can be configured on L2 switching interfaces and L2 aggregation ports (link aggregation).

Caution

This command is used only to enable IPv6 Source Guard for a VLAN.

Examples

The following example configures GigabitEthernet 0/1 as an IP Source Guard trusted interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify source trust
```

Notifications

When this command is configured on an IPv6 Source Guard security interface, the following notification will be displayed:

```
% Failed to execute command, because of "Security configuration conflict ".
```

Common Errors

- An IP Source Guard security interface is configured as an IP Source Guard trusted interface.

Platform Description

N/A

1.7 show ip source binding

Function

Run the **show ip source binding** command to display information of the source IP address binding database.

Syntax

show ip source binding [*ipv4-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**dhcp-snooping** | **static**]

Parameter Description

Ipv4-address: IPv4 address whose user binding information is displayed.

mac-address: MAC address whose user binding information is displayed.

vlan-id: VLAN whose user binding information is displayed.

interface-type interface-number: Wired access interface whose user binding information is displayed.

dhcp-snooping: Displays binding information of a dynamic user.

static: Displays binding information of a static user.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays information of the source IP address binding database.

```
Hostname> enable
Hostname# show ip source binding static
NO.   MACADDRESS        IPADDRESS      LEASE(SEC)   TYPE         VLAN  INTERFACE
1     0001.0002.0001    1.2.3.2        Infinite     Static       1     Global
2     0001.0002.0002    1.2.3.3        Infinite     Static       1
GigabitEthernet 0/1
3     0001.0002.0003    1.2.3.4        Infinite     Static       1     Global
4     0001.0002.0004    1.2.3.5        Infinite     Static       1     Global
Total number of bindings: 4
```

Table 1-1 Output Fields of the show ip source binding Command

Field	Description
Total number of bindings	Number of bindings in the binding database
NO.	Record number
MACADDRESS	MAC address of a user
IPADDRESS	IP address of a user
LEASE(SEC)	Lease time of a record
TYPE	Record type
VLAN	VLAN to which a user belongs

1.9 show ip verify source

Function

Run the **show ip verify source** command to display user filtering entries of IP Source Guard.

Syntax

show ip verify source [**interface** *interface-type interface-number* | **vlan** *vlan-id*]

Parameter Description

interface-type interface-number: Interface whose user filtering entries are displayed.

vlan *vlan-id*: Specifies the VLAN whose user filtering entries are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays user filtering entries of IP Source Guard.

```
Hostname> enable
Hostname# show ip verify source
NO.   INTERFACE          FilterType  FilterStatus         IPADDRESS
MACADDRESS     VLAN TYPE
1     Global             IP+MAC     Inactive-not-apply    192.168.0.127
0001.0002.0003  1 Static
2     Global             IP-ONLY    Active              1.2.3.7
0001.0002.0007  1 Static
3     Global             IP+MAC     Active              1.2.3.6
0001.0002.0006  1 Static
4     GigabitEthernet 0/1  UNSET      Inactive-restrict-off  1.2.3.9
0001.0002.0009  1 DHCP-Snooping
5     GigabitEthernet 0/5  IP-ONLY    Active              Deny-All
```

Table 1-3 Output Fields of the show ip verify source Command

Field	Description
Total number of bindings	Number of assigned bindings

Field	Description
NO.	Record number
INTERFACE	User access interface
FilterType	Record type of a binding entry
FilterStatus	Record status of a binding entry ● **Inactive-restrict-off**: IP Source Guard is disabled for the interface to which a binding record belongs. ● **Inactive-not-apply**: A bound user record cannot be converted to a filtering entry due to system errors. ● **Active**: The filtering entry corresponding to the bound user record has taken effect.
IPADDRESS	IP address of a user
MACADDRESS	MAC address of a user
VLAN TYPE	VLAN to which a user belongs

Related Commands

- **ip verify source**

1 IPv6 Source Guard Commands

Command	Function
ipv6 source binding	Add static user information to the IPv6 source address binding database.
ipv6 source binding sticky-mac	Enable the function of converting IPv6 source address binding entries to static MAC address entries.
ipv6 verify source	Enable IPv6 Source Guard on an interface or a VLAN.
ipv6 verify source permit link-local	Enable local link address release on an interface.
ipv6 verify source trust	Configure an interface as an IPv6 Source Guard trusted interface.
show ipv6 source binding	Display information of the IPv6 source address binding database.
show ipv6 source binding sticky-mac	Display information about IPv6 source address binding entries converted to static MAC address entries.

1.1 ipv6 source binding

Function

Run the **ipv6 source binding** command to add static user information to the IPv6 source address binding database.

Run the **no** form of this command to remove this configuration.

No static user information is added by default.

Syntax

ipv6 source binding *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

no ipv6 source binding *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

Parameter Description

mac-address: Media access control (MAC) address of a statically added user.

vlan-id: ID of the virtual local area network (VLAN) to which a statically added user belongs.

ipv6-address: IPv6 address of a statically added user.

interface *interface-type interface-number*: Specifies the interface to which a statically added user belongs.

ip-mac: Specifies that the IPv6 address and MAC address binding type is used globally.

ip-only: Specifies that the IPv6 address binding type is used globally.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Through this command, legitimate users can pass IPv6 Source Guard detection instead of being controlled by Dynamic Host Configuration Protocol version 6 (DHCPv6).

This command can be configured only on L2 switching interfaces and L2 aggregation ports (link aggregation). When this command is configured on other types of interfaces, the configuration will fail.

Users can configure global binding user records to enable legitimate users to pass IPv6 Source Guard detection on all interfaces.

A configured binding record takes effect either on the access interface, VLAN, or globally.

When duplicate user records exist, attributes of the new record will overwrite those of the old record.

Examples

The following example adds a static user record to the IPv6 source address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IPv6 address is 1::1, and the interface is GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 source binding 0000.0000.0001 vlan 1 1::1 interface
gigabitethernet 0/1
```

The following example adds a static user record to the IPv6 source address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IPv6 address is 1::1, and the filtering type is IPv6 address and MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 source binding 0000.0000.0001 vlan 1 1::1 ip-mac
```

The following example adds a static user record to the IPv6 source address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IPv6 address is 1::1, and the filtering type is IPv6 address that takes effect globally.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ipv6 source binding 0000.0000.0001 vlan 1 1::1 ip-only
```

Notifications

When the **no** form of this command is run to delete static configuration and the entered parameters are different from those previously configured, the following notification will be displayed:

```
% Failed to execute command, because of "No such binding entry".
```

When a user record is configured and the entered access interface is not an L2 switching interface or L2 aggregation port, the following notification will be displayed:

```
% Failed to execute command, because of "Configure is not supported on current
interface".
```

Common Errors

1.2 ipv6 source binding sticky-mac

Function

Run the **ipv6 source binding sticky-mac** command to enable the function of converting IPv6 source address binding entries to static MAC address entries.

Run the **no** form of this command to disable this feature.

The function of converting IPv6 source address binding entries to static MAC address entries is disabled by default.

Syntax

ipv6 source binding sticky-mac

no ipv6 source binding sticky-mac

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The MAC address table records mapping between MAC addresses and interfaces. Unauthorized users can use MAC addresses of legitimate users to refresh MAC address table records, which will cause abnormal packet forwarding in the network. To prevent unauthorized users from refreshing the MAC address table to launch network attacks, configure this command in interface configuration mode to convert IPv6 source address binding entries to static MAC address entries.

Examples

The following example enables the function of converting IPv6 source address binding entries to static MAC address entries.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 source binding sticky-mac
```

Notifications

When the function of converting IPv6 source address binding entries to static MAC address entries is enabled on an interface after an access security control option, such as web authentication, 802.1x authentication, or port security, is enabled on the interface, the following notification will be displayed:

```
Failed to open sticky mac on interface [Interface name].
```

Common Errors

N/A

Platform Description

1.3 ipv6 verify source

Function

Run the **ipv6 verify source** command to enable IPv6 Source Guard on an interface or a VLAN.

Run the **no** form of this command to disable this feature.

IPv6 Source Guard is disabled on an interface or a VLAN by default.

Syntax

ipv6 verify source [**port-security**]

no ipv6 verify source

Parameter Description

port-security: Configures IPv6 Source Guard based on IPv6 address and MAC address.

Command Modes

VLAN configuration mode

Interface configuration mode

Default Level

14

Usage Guidelines

By enabling IPv6 Source Guard on an interface or a VLAN through this command, users can detect packets based on the IPv6 address or IPv6 address and MAC address.

This command can be configured only on L2 switching interfaces and L2 aggregation ports in interface configuration mode. When this command is configured on other types of interfaces, the configuration will fail.

Caution

Legitimate users of IPv6 Source Guard come from DHCPv6 Snooping/ND Snooping and static user configuration. If IPv6 Source Guard is enabled on an interface but no valid data source is configured, users who access the network through IPv6 cannot use the network normally.

Examples

The following example enables IPv6 Source Guard on GigabitEthernet 0/1 and detects packets only based on the IPv6 address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 verify source
```

The following example enables IPv6 Source Guard on GigabitEthernet 0/1 and detects packets based on the IPv6 address and MAC address.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 verify source port-security
```

The following example enables IPv6 Source Guard on VLAN 1 and detects packets only based on the IPv6 address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 1
Hostname(config-vlan)# ipv6 verify source
```

The following example enables IPv6 Source Guard on VLAN 1 and detects packets based on the IPv6 address and MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 1
Hostname(config-vlan)# ipv6 verify source port-security
```

The following example enables IP Source Guard on VLANs 2-5 and detects packets only based on the IPv6 address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan range 2-5
Hostname(config-vlan-range)# ipv6 verify source
```

The following example enables IP Source Guard on VLANs 2-5 and detects packets based on the IP address and MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan range 2-5
Hostname(config-vlan-range)# ipv6 verify source port-security
```

Notifications

When this command is configured on a DHCPv6 or an IPv6 Source Guard trusted interface, the following notification will be displayed:

```
% Failed to execute command, because of "Security config conflict".
```

Common Errors

- IPv6 Source Guard is enabled. However, the source of legitimate user records is not configured.
- IPv6 Source Guard is enabled on a VLAN. However, the uplink interface is not configured as a trusted interface.

Platform Description

Related Commands

N/A

1.4 ipv6 verify source permit link-local

Function

Run the **ipv6 verify source permit link-local** command to enable local link address release on an interface.

Run the **no** form of this command to disable this feature.

The local link address release function is disabled on an interface by default.

Syntax

ipv6 verify source permit link-local

no ipv6 verify source permit link-local

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When the local link address release function is enabled on an interface by running this command, packets with FE80::/10 or ::/128 as source addresses will not be checked.

When ND Snooping is disabled, entry addresses come from only DHCPv6 addresses and do not contain local link addresses. However, some terminals use local link addresses to access the gateway or other addresses in the same network segment. In addition, local link addresses are required for addressing, Duplicate Address Detection (DAD), and other operations before DHCPv6 exchange. Therefore, in DHCPv6 Snooping + IPv6 Source Guard scenarios, run the **ipv6 verify source permit link-local** command to release local link addresses (fe80::/10) and undefined addresses (::/128).

This command can be configured only on L2 switching interfaces and L2 aggregation ports.

Caution

The local link address release function needs to be configured only when both DHCPv6 Snooping and IPv6 Source Guard are enabled and ND Snooping is disabled. The configuration command for the local link address release function is independent of the DHCPv6 Snooping, IPv6 Source Guard, and ND Snooping commands.

Examples

The following example enables local link address release on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 verify source permit link-local
```

Notifications

When this command is configured on an AP member interface, the following notification will be displayed:

```
Configure is not supported on current interface.
```

1.5 ipv6 verify source trust

Function

Run the **ipv6 verify source trust** command to configure an interface as an IPv6 Source Guard trusted interface.

Run the **no** form of this command to remove this configuration.

No interface is configured as an IPv6 Source Guard trusted interface by default.

Syntax

ipv6 verify source trust

no ipv6 verify source trust

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When an interface is configured as an IPv6 Source Guard trusted interface, IPv6 Source Guard is not performed for the interface and packets through this interface are released directly.

This command can be configured on L2 switching interfaces and L2 aggregation ports (link aggregation).

Caution

This command is used only to enable IPv6 Source Guard for a VLAN.

Examples

The following example configures GigabitEthernet 0/1 as an IPv6 Source Guard trusted interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 verify source trust
```

Notifications

When this command is configured on an IPv6 Source Guard security interface, the following notification will be displayed:

```
% Failed to execute command, because of "Security configuration conflict ".
```

Common Errors

- An IPv6 Source Guard security interface is configured as an IPv6 Source Guard trusted interface.

1 SAVI Commands

Command	Function
savi ipv6 bind-source add	Configure the data sources of Source Address Validation Improvement (SAVI) binding entries.
savi ipv6 check permit link-local	Enable SAVI to permit local link addresses and undefined addresses.
savi ipv6 check source exclude-vlan	Configure excluded virtual local area networks (VLANs) for SAVI on an interface.
savi ipv6 check source ip-address	Enable IPv6 SAVI.
savi ipv6 station-move	Enable binding entry migration.
savi ipv6 source binding vlan	Add static user information to the IPv6 source address binding database.
show savi ipv6 check source	Display effective SAVI filtering entries.
show savi ipv6 source binding	Display binding entries learned by SAVI.

1.1 savi ipv6 bind-source add

Function

Run the **savi ipv6 bind-source add** command to configure the data sources of Source Address Validation Improvement (SAVI) binding entries.

Run the **no** form of this command to remove this configuration.

Binding entries generated during the stateless address autoconfiguration (SLAAC) and Dynamic Host Configuration Protocol version 6 (DHCPv6) processes are used as the sources of dynamic binding entries by default. Binding entries can also be statically configured.

Syntax

savi ipv6 bind-source add { **dhcp** | **slaac** }

no savi ipv6 bind-source add { **dhcp** | **slaac** }

Parameter Description

dhcp: Uses binding entries snooped during the DHCPv6 process as a source of SAVI binding entries.

slaac: Uses binding entries snooped during the SLAAC process as a source of SAVI binding entries.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Neighbor discovery (ND) Snooping is used to snoop the SLAAC process. When entries generated during ND Snooping are configured as a source of SAVI binding entries, ND Snooping needs to be enabled.

DHCPv6 Snooping is used to snoop the DHCPv6 process. When entries generated during DHCPv6 Snooping are configured as a source of SAVI binding entries, DHCPv6 Snooping needs to be enabled.

Examples

The following example cancels entries generated during SLAAC as a source of SAVI binding entries.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no savi ipv6 bind-source add slaac
```

1.2 savi ipv6 check permit link-local

Function

Run the **savi ipv6 check permit link-local** command to enable SAVI to permit local link addresses and undefined addresses.

Run the **no** form of this command to remove this configuration.

Permitting local link addresses and undefined addresses is not configured by default.

Syntax

savi ipv6 check permit link-local

no savi ipv6 check permit link-local

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After SAVI is enabled on an interface, SAVI checks the validity of source IPv6 addresses in IPv6 packets transmitted through the interface. After configuring this command, SAVI permits all IPv6 packets with fe80::/10 and ::/128 as source addresses.

Caution

Generally, this command is configured in a DHCPv6-only scenario. In this scenario, fe80::/10 address cannot be obtained through DHCPv6.

Examples

The following example enables SAVI to permit local link addresses and undefined addresses.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# savi ipv6 check permit link-local
```

1.3 savi ipv6 check source exclude-vlan

Function

Run the **savi ipv6 check source exclude-vlan** command to configure excluded virtual local area networks (VLANs) for SAVI on an interface.

Run the **no** form of this command to remove this configuration.

No excluded VLANs for SAVI are configured on an interface by default.

Syntax

savi ipv6 check source exclude-vlan *vlan-id*

no savi ipv6 check source exclude-vlan *vlan-id*

Parameter Description

vlan-id: VLAN for which SAVI is not performed. The value range is from 1 to 4094.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After SAVI is enabled, you can run this command to permit IPv6 packets from specified VLANs.

After SAVI is disabled, the specified excluded VLANs are deleted.

Examples

The following example configures excluded VLANs for SAVI on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# savi ipv6 check source ip-address
mac-address
Hostname(config-if-GigabitEthernet 0/1)# savi ipv6 check source exclude-vlan 1
```

1.4 savi ipv6 check source ip-address

Function

Run the **savi ipv6 check source ip-address** command to enable IPv6 SAVI.

Run the **no** form of this command to disable this feature.

IPv6 SAVI is disabled by default.

Syntax

savi ipv6 check source ip-address [**mac-address**]

no savi ipv6 check source

Parameter Description

mac-address: Enables media access control (MAC) address check at the same time. The filtering mode is set to IP address and MAC address.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can run this command on a DHCPv6 Snooping/ND Snooping untrusted interface to check the validity of source IPv6 addresses in IPv6 packets through the interface. If the filtering mode is set to IP address and MAC address, the validity of the source MAC address in the Ethernet header will also be checked.

Examples

The following example sets the filtering mode of IPv6 SAVI to IP address and MAC address on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# savi ipv6 check source ip-address
mac-address
```

Notifications

When a security mode conflict occurs, the following notification will be displayed:

```
% Failed to execute command, because of "Security config conflict".
```

1.5 savi ipv6 station-move

Function

Run the **savi ipv6 station-move** command to enable binding entry migration.

Run the **no** form of this command to disable this feature.

The binding entry migration function is disabled by default.

Syntax

savi ipv6 station-move

no savi ipv6 **station-move**

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the binding entry migration function is enabled, dynamic binding entries can be migrated to the corresponding VLANs and interfaces automatically based on changes of the MAC address table. In wireless scenarios, when a host does not re-obtain an IPv6 address after it roams, the access point (AP) after roaming does not match the SAVI binding entry. As a result, the host cannot access the network. When the binding entry migration function is enabled, SAVI can perceive host migration based on MAC address table changes and update SAVI binding entries.

SAVI binding entry migration is triggered by DHCPv6/ND Snooping binding entry migration.

Caution

After binding entry migration is enabled, security functions are weakened and forged MAC address communication by attackers cannot be prevented.

Examples

The following example enables binding entry migration.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# savi ipv6 station-move
```

1.6 savi ipv6 source binding vlan

Function

Run the **savi ipv6 source binding vlan** command to add static user information to the IPv6 source address binding database.

Run the **no** form of this command to remove this configuration.

No static user information is added by default.

Syntax

savi ipv6 source binding *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

no savi ipv6 source binding *mac-address* **vlan** *vlan-id ipv6-address* { **interface** *interface-type interface-number* | **ip-mac** | **ip-only** }

Parameter Description

mac-address: MAC address of a statically added user.

vlan-id: ID of the VLAN to which a statically added user belongs.

ipv6-address: IPv6 address of a statically added user.

interface-type interface-number: Type and number of the interface to which a statically added user belongs.

ip-mac: Specifies the IPv6 address and MAC address binding type.

ip-only: Specifies the IPv6 address binding type.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to permit packets from a specified user.

This command can be configured only on L2 switching interfaces, L2 aggregation ports (link aggregation), and encapsulation subinterfaces. When this command is configured on other types of interfaces, the configuration will fail.

Note

- A configured binding record takes effect either on the access interface or globally.
- When duplicate user records exist, attributes of the new record will overwrite those of the old record.

Examples

The following example adds a static user record to the IPv6 source address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IPv6 address is 1::1, and the interface is GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# savi ipv6 source binding 0000.0000.0001 vlan 1 1::1 interface
gigabitethernet 0/1
```

The following example adds a static user record to the IPv6 source address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IPv6 address is 1::1, and the filtering type is IPv6 address and MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# savi ipv6 source binding 0000.0000.0001 vlan 1 1::1 ip-mac
```

The following example adds a static user record to the IPv6 source address binding database. In the static user record, the MAC address is 0000.0000.0001, the VLAN ID is 1, the IPv6 address is 1::1, and the filtering type is IPv6 address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# savi ipv6 source binding 0000.0000.0001 vlan 1 1::1 ip-only
```

Notifications

When the **no** form of this command is run to delete static configuration and the entered parameters are different from those previously configured, the following notification will be displayed:

```
% Failed to execute command, because of "No such binding entry".
```

When a user record is configured and the entered wired access interface is not an L2 switching interface, L2 aggregation port, or encapsulation subinterface, the following notification will be displayed:

```
% Failed to execute command, because of "Configure is not supported on current interface"
```

1.7 show savi ipv6 check source

Function

Run the **show savi ipv6 check source** command to display effective SAVI filtering entries.

Syntax

show savi ipv6 check source [*ipv6-address* | **interface** *interface-type interface-number*]

Parameter Description

ipv6-address: IPv6 address whose filtering information is displayed.

interface-type interface-number: Interface whose effective binding entries are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays effective SAVI filtering entries.

```
Hostname> enable
Hostname# show savi ipv6 check source
Total entries found: 6
No.    Ipv6 Address                        Mac Address    VLAN Interface Filter

1.8 show savi ipv6 source binding

Function

Run the **show savi ipv6 source binding** command to display binding entries learned by SAVI.

Syntax

show savi ipv6 source binding [*ipv6-address*] [*mac-address*] [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [**type** { **dhcp** | **slaac** | **static** }]

Parameter Description

ipv6-address: IPv6 address whose binding entries are displayed.

mac-address: MAC address whose binding entries are displayed.

vlan *vlan-id*: Specifies the VLAN whose binding entries are displayed.

interface *interface-type interface-number*: Specifies the interface whose binding entries are displayed.

dhcp: Displays binding entries from the DHCPv6 process.

slaac: Displays binding entries from the SLAAC process.

static: Displays statically configured binding entries.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays SAVI-learned binding entries.

```
Hostname> enable
Hostname# show savi ipv6 source binding
Total entries found: 6
No.    Ipv6 Address                          Mac Address    VLAN Interface Type
0      2018:2::1                             8005.8820.182b 2    Gi0/1     SLAAC
1      2018:3::1                             8005.8820.182b 3    Gi0/1     SLAAC
2      2018:4::1                             8005.8820.182b 4    Gi0/1     SLAAC
3      fe80::8205:88ff:fe20:182b               8005.8820.182b 2    Gi0/1     SLAAC

1 ARP Check Commands

Command	Function
arp-check	Enable Address Resolution Protocol (ARP) Check.
show interfaces arp-check list	Display effective ARP Check entries on an interface.

1.1 arp-check

Function

Run the **arp-check** command to enable Address Resolution Protocol (ARP) Check.

Run the **no** form of this command to disable this feature.

ARP Check is disabled by default.

Syntax

arp-check

no arp-check

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Legitimate user information generated by security application modules is used to filter out invalid ARP packets in networks.

Examples

The following example enables ARP Check on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# arp-check

1 DAI Commands

Command	Function
ip arp inspection trust	Configure an L2 interface as a Dynamic APR Inspection (DAI) trusted interface.
ip arp inspection validate interface	Enable DAI to check interface information.
ip arp inspection vlan	Enable DAI on a VLAN.
show ip arp inspection vlan	Display the DAI status on a VLAN.
show ip arp inspection interface	Display the DAI trust status of an interface.

1.1 ip arp inspection trust

Function

Run the **ip arp inspection trust** command to configure an L2 interface as a Dynamic APR Inspection (DAI) trusted interface.

Run the **no** form of this command to remove this configuration.

L2 interfaces are DAI untrusted interfaces by default.

Syntax

ip arp inspection trust

no ip arp inspection trust

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To enable Address Resolution Protocol (ARP) packets received through an interface to pass DAI unconditionally, set the interface as a DAI trusted interface.

Examples

The following example configures GigabitEthernet 0/1 as a DAI trusted interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip arp inspection trust
```

Notifications

N/A

Common Errors

1.2 ip arp inspection validate interface

Function

Run the **ip arp inspection validate interface** command to enable DAI to check interface information.

Run the **no** form of this command to remove the configuration.

After DAI is enabled, interface information will be checked by default.

Syntax

ip arp inspection validate interface

no ip arp inspection validate interface

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command has been replaced by the **ip dhcp snooping station-move permit** command and is not recommended. Binding entry re-generation is supported in one virtual local area network (VLAN) and is not supported in sub VLANs.

Examples

The following example cancels interface information check by DAI.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ip arp inspection validate interface
```

Notifications

N/A

Common Errors

N/A

Platform Description

Related Commands

- **ip dhcp snooping station-move permit (IP Services/DHCP Snooping Commands)**

1.3 ip arp inspection vlan

Function

Run the **ip arp inspection vlan** command to enable DAI on a VLAN.

Run the **no** form of this command to disable this feature.

DAI is disabled on all VLANs by default.

Syntax

ip arp inspection vlan { *vlan-min* [*vlan-max*] | *vlan-range* }

no ip arp inspection vlan { *vlan- min* [*vlan-max*] | *vlan-range* }

Parameter Description

vlan-min: VLAN ID or the minimum value of a VLAN range for which DAI is performed. The value range is from 1 to 4094.

vlan-max: Maximum value of a VLAN range for which DAI is performed. The value range is from 1 to 4094.

vlan-range: VLAN range for which DAI is enabled. For example, 1, 3–5, 7, and 9–11.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To enable this command to take effect, enable ARP Check first.

Caution

Not all interfaces on a VLAN can be enabled with ARP Check. When an interface is a Dynamic Host Configuration Protocol (DHCP) Snooping trusted interface, no security check rule can be configured on the interface.

Examples

The following example enables DAI on VLAN 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip arp inspection
Hostname(config)# ip arp inspection vlan 1
```

anti-arp-spoofing ip	Enable gateway-targeted Address Resolution Protocol (ARP) spoofing prevention.
show anti-arp-spoofing	Display data on gateway-targeted ARP spoofing prevention on all interfaces.

1.1 anti-arp-spoofing ip

Function

Run the **anti-arp-spoofing ip** command to enable gateway-targeted Address Resolution Protocol (ARP) spoofing prevention.

Run the **no** form of this command to disable this feature.

Gateway-targeted ARP spoofing prevention is disabled by default.

Syntax

anti-arp-spoofing ip *ipv4-address*

no anti-arp-spoofing ip *ipv4-address*

Parameter Description

ipv4-address: IPv4 address of the gateway.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command can be configured only on L2 interfaces.

Examples

The following example enables gateway-targeted ARP spoofing prevention on GigabitEthernet 0/1 with the gateway IP address set to 192.168.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1

Examples

The following example clears the CPP statistics on GigabitEthernet 0/1.

```
Hostname> enable
```

```
Hostname# clear cpu-protect statistics interface gigabitethernet 0/1
```

1.4 cpu-protect type bandwidth

Function

Run the **cpu-protect type bandwidth** command to configure bandwidth for a specified packet type.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No bandwidth is configured for a specified packet type by default. Each type of packet has the default bandwidth value.

Syntax

cpu-protect type *packet-type* **bandwidth** *bandwidth-value*

no cpu-**protect type** *packet-type* **bandwidth**

default cpu-**protect type** *packet-type* **bandwidth**

Parameter Description

packet-type: Specified packet type.

bandwidth-value: Configured bandwidth value, in pps. The value range is from 0 to 3000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the bandwidth for BPDU packets to **200** pps.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cpu-protect type bpdu bandwitdth 200
```

1.5 cpu-protect cpu bandwidth

Function

Run the **cpu-protect cpu bandwidth** command to configure a bandwidth for a CPU port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The bandwidth for a CPU port is 2250 pps by default.

Syntax

cpu-protect cpu bandwidth *bandwidth-value*

no cpu-protect cpu

default cpu-protect cpu

Parameter Description

bandwidth-value: Configured bandwidth value, in pps. The value range is from 0 to 3000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the bandwidth for a CPU port to **3000** pps.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cpu-protect cpu bandwidth 3000
```

1.6 cpu-protect intf-statistics enable

Function

Run the **cpu-protect intf-statistics enable** command to enable the CPP statistics function for a port.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The CPP statistics function for any port is disabled by default.

Syntax

cpu-protect intf-statistics enable

no cpu-protect intf-statistics enable

default cpu-protect intf-statistics enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example enables the CPP statistics function on a port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cpu-protect intf-statistics enable
```

1.7 cpu-protect traffic-class bandwidth

Function

Run the **cpu-protect traffic-class bandwidth** command to configure a bandwidth for a queue.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No bandwidth is configured for a queue by default. Each queue has the default bandwidth value.

Syntax

cpu-protect traffic-class *traffic-class-number* **bandwidth** *bandwidth-value*

no cpu-protect traffic-class *traffic-class-number*

default cpu-protect traffic-class *traffic-class-number*

Parameter Description

traffic-class-number: Specified priority queue. The value range is from 0 to 7.

bandwidth-value: Configured bandwidth value, in pps. The value range is from 0 to 3000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the bandwidth for queue 5 to **2500** pps.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cpu-protect traffic-class 5 bandwidth 2500
```

1.8 cpu-protect type traffic-class

Function

Run the **cpu-protect type traffic-class** command to configure a priority queue for a specified packet type.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

Each packet type has the corresponding priority queue by default.

Syntax

cpu-protect type *packet-type* **traffic-class** *traffic-class-number*

no cpu-protect type *packet-type* **traffic-class**

default cpu-protect type *packet-type* **traffic-class**

Parameter Description

packet-type: Specified packet type.

traffic-class-number: Priority queue for a specified packet. The value range is from 0 to 7.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures priority queue 5 for BPDU packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cpu-protect type bpdu traffic-class 5
```

1.9 show cpu-protect

Function

Run the **show cpu-protect** command to display all the configurations and statistics of CPP.

Syntax

show cpu-protect [**device** *device-number*]

Parameter Description

device-number: Specified device number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays all the configurations and statistics of CPP.

```
Hostname> enable
Hostname# show cpu-protect

1.12 show cpu-protect statistics

Function

Run the **show cpu-protect statistics** command to display packet statistics.

Syntax

show cpu-protect statistics { **interface** *interface-type interface-number* | **type** *packet-type* }

Parameter Description

interface *interface-type interface-number*: Displays statistics of a specified interface.

type *packet-type*: Displays the statistics of a specified packet type.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the packet statistics on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show cpu-protect statistics interface gigabitethernet 0/1
Gi0/1
Packet Type        Rate(pps)  Drop(pps)  Total        Total Drop

1.14 show cpu-protect traffic-class

Function

Run the **show cpu-protect traffic-class** command to display the configurations and statistics of a priority queue.

Syntax

show cpu-protect traffic-class { **all** | *traffic-class-number* } [**device** *device-number*]

Parameter Description

all: Displays all priority queue information.

traffic-class-number: Information of a specified priority queue. The value range is from 0 to 7.

device *device-number*: Specifies the device number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the configurations and statistics of all priority queues on the master device.

```
Hostname> enable
Hostname# show cpu-protect traffic-class all
Traffic-class   Bandwidth(pps)  Rate(pps)      Drop(pps)
 0            8000          0             0
 1            8000          0             0
 2            8000          0             0
 3            8000          0             0
 4            8000          0             0
 5            3200          0             0
 6            8000          0             0
 7            8000          0             0
```

1.15 show cpu-protect type

Function

Run the **show cpu-protect type** command to display the configurations and statistics of a packet type.

Syntax

show cpu-protect type *packet-type* [**device** *device-number*]

Parameter Description

packet-type: Specified packet type.

device *device-number*: Specifies the device number.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the configurations and statistics of ICMP packets on the master device.

```
Hostname> enable
Hostname# show cpu-protect type icmp
```

```
Packet Type        Traffic-class  Bandwidth(pps)  Rate(pps)  Drop(pps)  Total
Total Drop
icmp               5              1500            50         0          10000    100
```

Table 1-7 Output Fields of the show cpu-protect type Command

1 NFPP Commands

Command	Function
all-guard enable	Enable all the basic types of global guard of Network Foundation Protection Policy (NFPP).
arp-guard attack-threshold	Configure the global attack threshold of ARP guard.
arp-guard enable	Enable the function of global ARP guard.
arp-guard isolate-forwarding enable	Enable the function of global isolation forwarding of ARP guard.
arp-guard isolate-period	Configure the global isolation time of ARP guard.
arp-guard monitored-host-limit	Configure the maximum number of monitored hosts of ARP guard in global configuration mode.
arp-guard monitor-period	Configure the monitoring time of ARP guard.
arp-guard rate-limit	Configure the global rate limiting threshold of ARP guard.
arp-guard ratelimit-forwarding enable	Enable the function of port-based rate limit forwarding of ARP guard.
arp-guard scan-threshold	Configure the global scanning threshold of ARP guard.
clear nfpp arp-guard hosts	Clear the monitored hosts of ARP guard.
clear nfpp arp-guard scan	Clear the scanning table of ARP guard.
clear nfpp define hosts	Clear the monitored hosts of the customized guard type.
clear nfpp dhcp-guard hosts	Clear the monitored hosts of DHCP guard.
clear nfpp dhcpv6-guard hosts	Clear the monitored hosts of DHCPv6 guard.
clear nfpp icmp-guard hosts	Clear the monitored hosts of ICMP guard.
clear nfpp ip-guard hosts	Clear the monitored hosts of IP guard.
clear nfpp log	Clear the log buffer of NFPP.
clear nfpp nd-guard hosts	Clear the monitored hosts of ND guard.
clear nfpp tcp-syn-guard hosts	Clear the monitored hosts of TCP-SYN guard.

define	Customize a guard type and enter the customized guard configuration mode of NFPP.
define enable	Enable the function of global customized guard.
dhcp-guard attack-threshold	Configure the global attack threshold of DHCP guard.
dhcp-guard enable	Enable the function of global DHCP guard.
dhcp-guard isolate-period	Configure the global isolation time of DHCP guard.
dhcp-guard monitored-host-limit	Configure the maximum number of monitored hosts of DHCP guard.
dhcp-guard monitor-period	Configure the monitoring time of DHCP guard.
dhcp-guard rate-limit	Configure the global rate limiting threshold of DHCP guard.
dhcpv6-guard attack-threshold	Configure the global attack threshold of DHCPv6 guard.
dhcpv6-guard enable	Enable the DHCPv6 guard function.
dhcpv6-guard monitored-host-limit	Configure the maximum number of monitored hosts of DHCPv6 guard.
dhcpv6-guard monitor-period	Configure the monitoring time of DHCPv6 guard.
dhcpv6-guard rate-limit	Configure the global rate limiting threshold of DHCPv6 guard.
global-policy	Configure the global rate limiting threshold and global attack threshold of the customized guard type.
icmp-guard attack-threshold	Configure the global attack threshold of ICMP guard.
icmp-guard enable	Enable the function of global ICMP guard.
icmp-guard isolate-period	Configure the global isolation time of ICMP guard.
icmp-guard monitored-host-limit	Configure the maximum number of monitored hosts of ICMP guard.
icmp-guard monitor-period	Configure the monitoring time of ICMP guard.
icmp-guard rate-limit	Configure the global rate limiting threshold of ICMP guard.
icmp-guard trusted-host	Configure the trusted hosts of ICMP guard.
ip-guard attack-threshold	Configure the global attack threshold of IP guard.

nfpp arp-guard scan-threshold	Configure the scanning threshold of ARP guard on an interface.
nfpp define enable	Enable the customized guard function on an interface.
nfpp define policy	Configure a local rate limiting threshold and a local attack threshold of customized guard on an interface.
nfpp dhcp-guard enable	Enable the DHCP guard function on an interface.
nfpp dhcp-guard isolate-period	Configure the local isolation time of DHCP guard on an interface.
nfpp dhcp-guard policy	Configure a local rate limiting threshold and a local attack threshold of DHCP guard on an interface.
nfpp dhcpv6-guard enable	Enable the DHCPv6 guard function on an interface.
nfpp dhcpv6-guard policy	Configure a local rate limiting threshold and a local attack threshold of DHCPv6 guard on an interface.
nfpp icmp-guard enable	Enable the ICMP guard function on an interface.
nfpp icmp-guard isolate-period	Configure the local isolation time of ICMP guard on an interface.
nfpp icmp-guard policy	Configure a local rate limiting threshold and a local attack threshold of ICMP guard on an interface.
nfpp ip-guard enable	Enable the IP guard function on an interface.
nfpp ip-guard isolate-period	Configure the local isolation time of IP guard on an interface.
nfpp ip-guard policy	Configure a local rate limiting threshold and a local attack threshold of IP guard on an interface.
nfpp ip-guard scan-threshold	Configure the local scanning threshold of IP guard on an interface.
nfpp nd-guard enable	Enable the ND guard function on an interface.
nfpp nd-guard policy per-port	Configure a local rate limiting threshold and a local attack threshold of ND guard on an interface.
nfpp tcp-syn-guard enable	Enable the TCP-SYN guard function on an interface.
nfpp tcp-syn-guard isolate-period	Configure the local isolation time of TCP-SYN guard on an interface.

nfpp tcp-syn-guard policy	Configure a local rate limiting threshold and a local attack threshold of TCP-SYN guard on an interface.
show nfpp arp-guard hosts	Display the monitored hosts of ARP guard.
show nfpp arp-guard scan	Display the scanning table of ARP guard.
show nfpp arp-guard summary	Display the configuration information of ARP guard.
show nfpp define hosts	Display the monitored hosts of a customized guard type.
show nfpp define summary	Display the configuration information of a customized summary type.
show nfpp define trusted-host	Display the trusted hosts of a customized guard type.
show nfpp dhcp-guard hosts	Display the monitored hosts of DHCP guard.
show nfpp dhcp-guard summary	Display the configuration information of DHCP guard.
show nfpp dhcpv6-guard hosts	Display the monitored hosts of DHCPv6 guard.
show nfpp dhcpv6-guard summary	Display the configuration information of DHCPv6 guard.
show nfpp icmp-guard hosts	Display the monitored hosts of ICMP guard.
show nfpp icmp-guard summary	Display the configuration information of ICMP guard.
show nfpp icmp-guard trusted-host	Display the trusted hosts of ICMP guard.
show nfpp ip-guard hosts	Display the monitored hosts of IP guard.
show nfpp ip-guard summary	Display the configuration information of IP guard.
show nfpp ip-guard trusted-host	Display the trusted hosts of IP guard.
show nfpp log buffer	Display the information in the log buffer of NFPP.
show nfpp log buffer statistics	Display the statistics about the log buffer of NFPP.
show nfpp log summary	Display the configuration information of NFPP logs.
show nfpp nd-guard hosts	Display the monitored hosts of ND guard.
show nfpp nd-guard summary	Display the configuration information of ND guard.
show nfpp tcp-syn-guard hosts	Display the monitored hosts of TCP-SYN guard.
show nfpp tcp-syn-guard summary	Display the configuration information of TCP-SYN guard.

show nfpp tcp-syn-guard trusted-host	Display the trusted hosts of TCP-SYN guard.
tcp-syn-guard attack-threshold	Configure the global attack threshold of TCP-SYN guard.
tcp-syn-guard enable	Enable the global TCP-SYN guard function.
tcp-syn-guard isolate-period	Configure the global isolation time of TCP-SYN guard.
tcp-syn-guard monitored-host-limit	Configure the maximum number of monitored hosts of TCP-SYN guard.
tcp-syn-guard monitor-period	Configure the monitoring time of TCP-SYN guard.
tcp-syn-guard rate-limit	Configure the global rate limiting threshold of TCP-SYN guard.
tcp-syn-guard trusted-host	Configure the trusted hosts of TCP-SYN guard.
trusted-host	Configure trusted hosts of a customized guard type.

1.1 all-guard enable

Function

Run the **all-guard enable** command to enable all the basic types of global guard of Network Foundation Protection Policy (NFPP).

Run the **no** form of this command to disable this feature.

Syntax

all-guard enable

no all-guard enable

Parameter Description

N/A

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

The preceding two commands cannot be displayed by running the **show running-config** command.

This global disabling/enabling command is supported on the basic types of global guard, including ARP guard, ICMP guard, TCP-SYN guard, DHCP guard, DHCPv6 guard, and ND guard.

This command is not supported on global customized guard types and does not affect the enabling status of the guard type in interface configuration mode.

This command cannot be saved, but its running result can be saved and take effect after device restart.

If you have configured the function of ARP source suppression and the isolation time for the IP guard function in global or interface configuration mode, an error is reported when you enable the IP guard function.

Examples

The following example disables all the basic types of global guard.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# no all-guard enable
```

Notifications

If you have configured the function of ARP source suppression, the following notification will be displayed when you configure isolation time for IP guard:

```
Configuration is prohibited, please disable the arp-guard suppression function first!
```

Common Errors

N/A

1.2 arp-guard attack-threshold

Function

Run the **arp-guard attack-threshold** command to configure the global attack threshold of ARP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global attack threshold of ARP guard for each interface is 200 pps, for each source IP address is 100 pps, and for each source MAC address is 100 pps.

Syntax

arp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* | **per-src-mac** *attack-threshold* }

no arp-guard attack-threshold { **per-port** | **per-src-ip** | **per-src-mac** }

default arp-guard attack-threshold { **per-port** | **per-src-ip** | **per-src-mac** }

Parameter Description

per-port *attack-threshold*: Configures an attack threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-ip *attack-threshold*: Configures an attack threshold for each source IP address, in pps. The value range is from 1 to 19999.

per-src-mac *attack-threshold*: Configures an attack threshold for each source MAC address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When packets are sent at a rate higher than the attack threshold, an attack occurs. The attack threshold must be equal to or greater than the rate limiting threshold.

Examples

The following example sets the global attack thresholds of ARP guard to **50** pps, **2** pps, and **3** pps for each interface, source IP address, and source MAC address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# arp-guard attack-threshold per-port 50
```

```
Hostname(config-nfpp)# arp-guard attack-threshold per-src-ip 2
Hostname(config-nfpp)# arp-guard attack-threshold per-src-mac 3
```

1.4 arp-guard isolate-forwarding enable

Function

Run the **arp-guard isolate-forwarding enable** command to enable the function of global isolation forwarding of ARP guard.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The function of global isolation forwarding of ARP guard is enabled by default.

Syntax

arp-guard isolate-forwarding enable

no arp-guard isolate-forwarding enable

default arp-guard isolate-forwarding enable

Parameter Description

N/A

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example enables the function of global isolation forwarding of ARP guard.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
```

```
Hostname(config-nfpp)# arp-guard isolate-forwarding enable
```

1.5 arp-guard isolate-period

Function

Run the **arp-guard isolate-period** command to configure the global isolation time of ARP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default global isolation time of ARP guard is **0**.

Syntax

arp-guard isolate-period { *interval* | **permanent** }

no arp-guard isolate-period

default arp-guard isolate-period

Parameter Description

interval: Isolation time, in seconds. The value is **0** or the value range is from 30 to 86400. The value **0** specifies no isolation.

permanent: Configures permanent isolation.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the global isolation time of ARP guard to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# nfpp
Hostname(config-nfpp)# arp-guard isolate-period 180
```

1.6 arp-guard monitored-host-limit

Function

Run the **arp-guard monitored-host-limit** command to configure the maximum number of monitored hosts of ARP guard in global configuration mode.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of monitored hosts of ARP guard in global configuration mode is **20000** by default.

Syntax

arp-guard monitored-host-limit *limit-number*

no arp-guard monitored-host-limit

default arp-guard monitored-host-limit

Parameter Description

limit-number: Maximum number of monitored hosts. The value range is from 1 to 4294967295.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When the number of monitored hosts reaches the default value **20000**, the monitored hosts are not automatically deleted if the administrator sets the maximum number of monitored hosts to a value smaller than 20000. An alarm message "%ERROR: The value that you configured is smaller than current monitored hosts 20000 (number of monitored hosts), please clear a part of monitored hosts." is printed to remind users of configuration failure and the need to clear some monitored hosts.

When the table of monitored hosts is full, the log "% NFPP_ARP_GUARD-SESSION_LIMIT: Attempt to exceed limit of ARP 20000 (number of monitored hosts) monitored hosts." is printed to remind the administrator.

Examples

The following example sets the maximum number of monitored hosts of ARP guard in global configuration mode to **200**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# arp-guard monitored-host-limit 200
```

Notifications

1.7 arp-guard monitor-period

Function

Run the **arp-guard monitor-period** command to configure the monitoring time of ARP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default monitoring time of ARP guard is **600** seconds.

Syntax

arp-guard monitor-period *interval*

no arp-guard monitor-period

default arp-guard monitor-period

Parameter Description

interval: Monitoring time, in seconds. The value range is from 180 to 86400.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When an attacker is detected, if the isolation time is 0, the attacker is monitored through software and the timeout time is the monitoring time. During software monitoring, when the isolation time is configured as a non-zero value, this function automatically isolates the attacker under software monitoring and the timeout time is configured as the isolation time. The monitoring time takes effect when the isolation time is 0.

If you change the isolation time to 0 from a non-zero value, the isolated attacker is directly deleted without monitoring the attacker through software.

Examples

The following example sets the monitoring time of ARP guard to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# arp-guard monitor-period 180
```

1.8 arp-guard rate-limit

Function

Run the **arp-guard rate-limit** command to configure the global rate limiting threshold of ARP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global rate limiting threshold of ARP guard for each interface is 128 pps, for each source IP address is 30 pps, and for each source MAC address is 30 pps.

Syntax

arp-guard rate-limit { **per-port** *rate-limit* | **per-src-ip** *rate-limit* | **per-src-mac** *rate-limit* }

no arp-guard rate-limit { **per-port** | **per-src-ip** | **per-src-mac** }

default arp-guard rate-limit { **per-port** | **per-src-ip** | **per-src-mac** }

Parameter Description

per-port *rate-limit*: Configures a rate limiting threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-ip *rate-limit*: Configures a rate limiting threshold for each source IP address, in pps. The value range is from 1 to 19999.

per-src-mac *rate-limit*: Configures a rate limiting threshold for each source MAC address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the global rate limiting thresholds of ARP guard to **50** pps, **2** pps, and **3** pps for each interface, source IP address, and source MAC address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# arp-guard rate-limit per-port 50
Hostname(config-nfpp)# arp-guard rate-limit per-src-ip 2

1.9 arp-guard ratelimit-forwarding enable

Function

Run the **arp-guard ratelimit-forwarding enable** command to enable the function of port-based rate limit forwarding of ARP guard.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The function of port-based rate limit forwarding of ARP guard is disabled by default.

Syntax

arp-guard ratelimit-forwarding enable

no arp-guard ratelimit-forwarding enable

default arp-guard ratelimit-forwarding enable

Parameter Description

N/A

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example enables the function of port-based rate limiting forwarding of ARP guard.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# arp-guard ratelimit-forwarding enable
```

1.10 arp-guard scan-threshold

Function

Run the **arp-guard scan-threshold** command to configure the global scanning threshold of ARP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The global scanning threshold of ARP guard is 100 packets per 10 seconds by default.

Syntax

arp-guard scan-threshold *scan-threshold*

no arp-guard scan-threshold

default arp-guard scan-threshold

Parameter Description

scan-threshold: Scanning threshold, in packets per 10 seconds. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

For the ARP packets received within 10 seconds beyond the scanning threshold, if the source MAC address is unchanged and the source IP address is changing on the link layer, or the source MAC address and source IP address on the link layer are unchanged but the destination IP address is changing, a scanning attack is suspected.

Examples

The following example sets the global scanning threshold of ARP guard to 20 packets per 10 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# arp-guard scan-threshold 20
```

1.11 clear nfpp arp-guard hosts

Function

Run the **clear nfpp arp-guard hosts** command to clear the monitored hosts of ARP guard.

Syntax

clear nfpp arp-guard hosts [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*ipv4-address* | *mac-address*]

Parameter Description

vlan *vlan-id*: Clears the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Clears the monitored hosts of a specified interface.

ipv4-address: Specified IPv4 address of a monitored host to be cleared.

mac-address: Specified MAC address of a monitored host to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

The isolated hosts must be released.

Examples

The following example clears the monitored hosts of ARP guard on VLAN 1 interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear nfpp arp-guard hosts vlan 1 interface gigabitethernet 0/1
```

1.13 clear nfpp define hosts

Function

Run the **clear nfpp define hosts** command to clear the monitored hosts of the customized guard type.

Syntax

clear nfpp define *define-name* **hosts** [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*ipv4-address* | *mac-address* | *ipv6-address*] *]

Parameter Description

define-name: Specified customized guard type.

vlan *vlan-id*: Clears the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Clears the monitored hosts of a specified interface.

ipv4-address: Specified IPv4 address of a monitored host to be cleared.

mac-address: Specified MAC address of a monitored host to be cleared.

ipv6-address: Specified IPv6 address of a monitored host to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

The isolated hosts must be released.

If this command is run without parameters, all monitored hosts of this customized type are cleared.

Examples

The following example clears the monitored hosts of the customized TCP guard type on VLAN 1 interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear nfpp define tcp hosts vlan 1 interface gigabitethernet 0/1
```

1.14 clear nfpp dhcp-guard hosts

Function

Run the **clear nfpp dhcp-guard hosts** command to clear the monitored hosts of DHCP guard.

Syntax

clear nfpp dhcp-guard hosts [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*mac-address*]

Parameter Description

vlan *vlan-id*: Clears the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Clears the monitored hosts of a specified interface.

mac-address: Specified MAC address of a monitored host to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If this command is run without parameters, all isolated hosts are cleared.

Examples

The following example clears the monitored hosts of DHCP guard on VLAN 1 interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear nfpp dhcp-guard hosts vlan 1 interface gigabitethernet 0/1
```

1.15 clear nfpp dhcpv6-guard hosts

Function

Run the **clear nfpp dhcpv6-guard hosts** command to clear the monitored hosts of DHCPv6 guard.

Syntax

clear nfpp dhcpv6-guard hosts [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*mac-address*]

Parameter Description

vlan *vlan-id*: Clears the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Clears the monitored hosts of a specified interface.

mac-address: Specified MAC address of a monitored host to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If this command is run without parameters, all isolated hosts are cleared.

Examples

The following example clears the monitored hosts of DHCPv6 guard on VLAN 1 interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear nfpp dhcpv6-guard hosts vlan 1 interface gigabitethernet 0/1
```

1.16 clear nfpp icmp-guard hosts

Function

Run the **clear nfpp icmp-guard hosts** command to clear the monitored hosts of ICMP guard.

Syntax

clear nfpp icmp-guard hosts [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*ipv4-address*]

Parameter Description

vlan *vlan-id*: Clears the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Clears the monitored hosts of a specified interface.

ipv4-address: Specified IPv4 address of a monitored host to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If this command is run without parameters, all monitored hosts are cleared.

Examples

The following example clears the monitored hosts of ICMP guard on VLAN 1 interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear nfpp icmp-guard hosts vlan 1 interface gigabitethernet 0/1

1.19 clear nfpp nd-guard hosts

Function

Run the **clear nfpp nd-guard hosts** command to clear the monitored hosts of ND guard.

Syntax

clear nfpp nd-guard hosts [**vlan** *vlan-id*] [**interface** *interface-type interface-number*]

Parameter Description

vlan *vlan-id*: Clears the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Clears the monitored hosts of a specified interface.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If this command is run without parameters, all monitored hosts are cleared.

If a host is configured with a rate limiting threshold by hardware, this configuration must be cleared.

Examples

The following example clears the monitored hosts of ND guard on VLAN 1 interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear nfpp nd-guard hosts vlan 1 interface gigabitethernet 0/1
```

1.20 clear nfpp tcp-syn-guard hosts

Function

Run the **clear nfpp tcp-syn-guard hosts** command to clear the monitored hosts of TCP-SYN guard.

Syntax

clear nfpp tcp-syn-guard hosts [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*ipv4-address*]

Parameter Description

vlan *vlan-id*: Clears the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Clears the monitored hosts of a specified interface.

ipv4-address: Specified IPv4 address of a monitored host to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

If this command is run without parameters, all monitored hosts are cleared.

Examples

The following example clears the monitored hosts of TCP-SYN guard on VLAN 1 interface GigabitEthernet 0/1.

```
Hostname> enable

1.22 define enable

Function

Run the **define enable** command to enable the function of global customized guard.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The function of global customized guard is disabled by default.

Syntax

define *define-name* **enable**

no define *define-name* **enable**

default define *define-name* **enable**

Parameter Description

define-name: Name of an enabled customized guard function.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

To validate the configuration of this command, you must configure the **match**, **rate-limit**, and **attack-threshold** parameters for this command.

Examples

The following example enables the global guard function of the TCP type.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# define tcp enable
```

1.23 dhcp-guard attack-threshold

Function

Run the **dhcp-guard attack-threshold** command to configure the global attack threshold of DHCP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global attack threshold of DHCP guard for each interface is 256 pps, and for each source MAC address is 10 pps.

Syntax

dhcp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-mac** *attack-threshold* }

no dhcp-guard attack-threshold { **per-port** | **per-src-mac** }

default dhcp-guard attack-threshold { **per-port** | **per-src-mac** }

Parameter Description

per-port *attack-threshold*: Configures an attack threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-mac *attack-threshold*: Configures an attack threshold for each source MAC address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When packets are sent at a rate higher than the attack threshold, an attack occurs.

Examples

The following example sets the global attack thresholds of DHCP guard to **200** pps and **15** pps for each interface and source MAC address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# dhcp-guard attack-threshold per-port 200
Hostname(config-nfpp)# dhcp-guard attack-threshold per-src-mac 15
```

1.25 dhcp-guard isolate-period

Function

Run the **dhcp-guard isolate-period** command to configure the global isolation time of DHCP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default global isolation time of DHCP guard is **0**.

Syntax

dhcp-guard isolate-period { *interval* | **permanent** }

no dhcp-guard isolate-period

default dhcp-guard isolate-period

Parameter Description

interval: Isolation time, in seconds. The value is **0** or the value range is from 30 to 86400. The value **0** specifies no isolation.

permanent: Configures permanent isolation.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

Isolation time of attackers falls into global isolation time and port-based isolation time (or local isolation time). If no port-based isolation time is configured for an interface, the global isolation time applies.

Examples

The following example sets the global isolation time of DHCP guard to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# dhcp-guard isolate-period 180
```

1.26 dhcp-guard monitored-host-limit

Function

Run the **dhcp-guard monitored-host-limit** command to configure the maximum number of monitored hosts of DHCP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of monitored hosts of DHCP guard is **20000** by default.

Syntax

dhcp-guard monitored-host-limit *number*

no dhcp-guard monitored-host-limit

default dhcp-guard monitored-host-limit

Parameter Description

number: Configured maximum number of monitored hosts. The value range is from 1 to 4294967295.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When the number of monitored hosts reaches the default value **20000**, the monitored hosts are not automatically deleted if the administrator sets the maximum number of monitored hosts to a value smaller than 20000. An alarm message "%ERROR: The value that you configured is smaller than current monitored hosts 20000 (number of monitored hosts), please clear a part of monitored hosts." is printed to remind users of configuration failure and the need to clear some monitored hosts.

When the table of monitored hosts is full, the log "% NFPP_DHCP_GUARD-SESSION_LIMIT: Attempt to exceed limit of DHCP 20000 monitored hosts." is printed to remind the administrator.

Examples

The following example sets the maximum number of monitored hosts of DHCP guard to **200**.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# dhcp-guard monitored-host-limit 200
```

Function

Run the **dhcp-guard monitor-period** command to configure the monitoring time of DHCP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default monitoring time of DHCP guard is **600** seconds.

Syntax

dhcp-guard monitor-period *interval*

no dhcp-guard monitor-period

default dhcp-guard monitor-period

Parameter Description

interval: Configured monitoring time, in seconds. The value range is from 180 to 86400.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When DHCP guard detects an attacker, if the isolation time is 0, this function monitors the attacker through software and the timeout time is the monitoring time. During software monitoring, when the isolation time is configured as a non-zero value, this function automatically isolates the attacker under software monitoring and the timeout time is configured as the isolation time. The monitoring time takes effect when the isolation time is 0.

If you change the isolation time to 0 from a non-zero value, the isolated attacker is directly deleted without monitoring the attacker through software.

Examples

The following example sets the monitoring time of DHCP guard to **180** seconds.

The following example sets the global rate limiting threshold of DHCPv6 guard to **100** pps and **8** pps for each interface and source MAC address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# dhcpv6-guard rate-limit per-port 100
Hostname(config-nfpp)# dhcpv6-guard rate-limit per-src-mac 8
```

1.34 global-policy

Function

Run the **global-policy** command to configure the global rate limiting threshold and global attack threshold of the customized guard type.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No global rate limiting threshold and global attack threshold of the customized guard type are configured by default.

Syntax

global-policy { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* | **per-src-mac** *rate-limit attack-threshold* }

no global-policy { **per-port** | **per-src-ip** | **per-src-mac** }

default global-policy { **per-port** | **per-src-ip** | **per-src-mac** }

Parameter Description

per-port: Performs rate statistics based on the physical port that receives packets.

per-src-ip: Performs rate statistics based on the source IP address, VLAN ID, and port that are used to identify hosts.

per-src- mac: Performs rate statistics based on the source MAC address, VLAN ID, and port that are used to identify hosts.

rate-limit: Configured rate limiting threshold, in pps. The value range is from 1 to 19999.

attack-threshold: Configured attack threshold, in pps. The value range is from 1 to 19999.

Command Modes

Customized configuration mode of NFPP

Default Level

14

Usage Guidelines

To create a customized guard type, you must specify rules of rate statistics classification for this type. You must identify hosts based on the source IP address and source MAC address, perform customized packet rate statistics based on the users, or perform rate statistics based on ports and specify rate limiting thresholds and attack thresholds for different classes of rate statistics. The attack threshold must be equal to or greater than the rate limiting threshold. When the rate exceeds the rate limiting threshold, packets of the customized type in this class are discarded. When the rate exceeds the attack threshold, an attack occurs, a log is printed, and a Trap message is sent.

Examples

The following example configures the customized guard type as TCP, sets the global rate limiting threshold and global attack threshold for each interface to **100** pps and **200** pps, and sets the global rate limiting threshold and global attack threshold for each source IP address to **10** pps and **20** pps respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# define tcp
Hostname(config-nfpp-define)# global-policy per-port 100 200
Hostname(config-nfpp-define)# global-policy per-src-ip 10 20
```

1.35 icmp-guard attack-threshold

Function

Run the **icmp-guard attack-threshold** command to configure the global attack threshold of ICMP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global attack threshold of ICMP guard for each interface is 400 pps, and for each source IP address is 300 pps.

Syntax

icmp-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

no icmp-guard attack-threshold { **per-port** | **per-src-ip** }

default icmp-guard attack-threshold { **per-port** | **per-src-ip** }

Parameter Description

per-port *attack-threshold*: Configures an attack threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-ip *attack-threshold*: Configures an attack threshold for each source IP address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the global attack thresholds of ICMP guard to **1200** pps and **600** pps for each interface and source IP address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# icmp-guard attack-threshold per-port 1200
Hostname(config-nfpp)# icmp-guard attack-threshold per-src-ip 600

1.37 icmp-guard isolate-period

Function

Run the **icmp-guard isolate-period** command to configure the global isolation time of ICMP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form this command to restore the default configuration.

The default global isolation time of ICMP guard is **0**.

Syntax

icmp-guard isolate-period { *interval* | **permanent** }

no icmp-guard isolate-period

default icmp-guard isolate-period

Parameter Description

interval: Isolation time, in seconds. The value is **0** or the value range is from 30 to 86400. The value **0** specifies no isolation.

permanent: Configures permanent isolation.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

Isolation time of attackers falls into global isolation time and port-based isolation time (or local isolation time). If no port-based isolation time is configured for an interface, the global isolation time applies.

Examples

The following example sets the global isolation time of ICMP guard to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# icmp-guard isolate-period 180
```

1.38 icmp-guard monitored-host-limit

Function

Run the **icmp-guard monitored-host-limit** command to configure the maximum number of monitored hosts of ICMP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of monitored hosts is **20000** by default.

Syntax

icmp-guard monitored-host-limit *number*

no icmp-guard monitored-host-limit

default icmp-guard monitored-host-limit

Parameter Description

number: Configured maximum number of monitored hosts. The value range is from 1 to 4294967295.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When the number of monitored hosts reaches the default value **20000**, the monitored hosts are not automatically deleted if the administrator sets the maximum number of monitored hosts to a value smaller than 20000. An alarm message "%ERROR: The value that you configured is smaller than current monitored hosts 20000 (number of monitored hosts), please clear a part of monitored hosts." is printed to remind users of configuration failure and the need to clear some monitored hosts.

When the table of monitored hosts is full, the log "% NFPP_ICMP_GUARD-SESSION_LIMIT: Attempt to exceed limit of ICMP 20000 (number of monitored hosts) monitored hosts." is printed to remind the administrator.

Examples

The following example sets the maximum number of monitored hosts of ICMP guard to **200**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# icmp-guard monitored-host-limit 200
```

1.39 icmp-guard monitor-period

Function

Run the **icmp-guard monitor-period** command to configure the monitoring time of ICMP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default monitoring time of ICMP guard is **600** seconds.

Syntax

icmp-guard monitor-period *interval*

no icmp-guard monitor-period

default icmp-guard monitor-period

Parameter Description

interval: Configured monitoring time, in seconds. The value range is from 180 to 86400.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When ICMP guard detects an attacker, if the isolation time is 0, this function monitors the attacker through software and the timeout time is the monitoring time. During software monitoring, when the isolation time is configured as a non-zero value, this function automatically isolates the attacker under software monitoring and the timeout time is configured as the isolation time. The monitoring time takes effect when the isolation time is 0.

If you change the isolation time to 0 from a non-zero value, the isolated attacker is directly deleted without monitoring the attacker through software.

Examples

The following example sets the monitoring time of ICMP guard to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# icmp-guard monitor-period 180
```

Function

Run the **icmp-guard rate-limit** command to configure the global rate limiting threshold of ICMP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global rate limiting threshold of ICMP guard for each interface is 250 pps, and for each source IP address is 200 pps.

Syntax

icmp-guard rate-limit { **per-port** *rate-limit* | **per-src-ip** *rate-limit* }

no icmp-guard rate-limit { **per-port** | **per-src-ip** }

default icmp-guard rate-limit { **per-port** | **per-src-ip** }

Parameter Description

per-port *rate-limit*: Configures a rate limiting threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-ip *rate-limit*: Configures a rate limiting threshold for each source IP address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the global rate limiting thresholds of ICMP guard to **800** pps and **500** pps for each interface and source IP address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# icmp-guard rate-limit per-port 800
Hostname(config-nfpp)# icmp-guard rate-limit per-src-ip 500
```

1.41 icmp-guard trusted-host

Function

Run the **icmp-guard trusted-host** command to configure the trusted hosts of ICMP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No host is configured as a trusted host by default.

Syntax

icmp-guard trusted-host *ipv4-address mask*

no icmp-guard trusted-host { *ipv4-address mask* | **all** }

default icmp-guard trusted-host

Parameter Description

ipv4-address mask: IPv4 address+mask. The mask is entered in dotted decimal mode.

all: Deletes the configuration of all trusted hosts when this parameter is used with the **no** parameter.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

To cancel the monitoring of a host, the administrator can run this command to configure the host as a trusted host. In this case, ICMP packets sent by this host can be forwarded to the CPU without rate limit or alarm. All hosts in a network segment can be configured as trusted hosts by configuring a mask.

A maximum of 500 trusted hosts can be configured.

Examples

The following example configures all hosts in the network segment 1.1.1.0/24 as trusted hosts of ICMP guard.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# icmp-guard trusted-host 1.1.1.0 255.255.255.0
```

1.42 ip-guard attack-threshold

Function

Run the **ip-guard attack-threshold** command to configure the global attack threshold of IP guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global attack threshold of IP guard for each interface is 200 pps, and for each source IP address is 100 pps.

Syntax

ip-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

no ip-guard attack-threshold { **per-port** | **per-src-ip** }

default ip-guard attack-threshold { **per-port** | **per-src-ip** }

Parameter Description

per-port *attack-threshold*: Configures an attack threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-ip *attack-threshold*: Configures an attack threshold for each source IP address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

The attack threshold must be equal to or greater than the rate limiting threshold.

IP guard is to solve IP attacks whose destination IP address is not a local IP address. If the destination IP address is a local IP address, the rates of IP packets are limited by the function of CPU protect policy (CPP).

Examples

The following example sets the global attack thresholds of IP guard to **50** pps and **2** pps for each interface and source IP address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# ip-guard attack-threshold per-port 50
Hostname(config-nfpp)# ip-guard attack-threshold per-src-ip 2
```

The default global isolation time of IP guard is **0**.

Syntax

ip-guard isolate-period { *interval* | **permanent** }

no ip-guard isolate-period

default ip-guard isolate-period

Parameter Description

interval: Isolation time, in seconds. The value is **0** or the value range is from 30 to 86400.

permanent: Configures permanent isolation.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

If you have configured the function of ARP source suppression, you are not allowed to configure the isolation function unless you disable the function of ARP source suppression.

Examples

The following example sets the global isolation time of IP guard to **180** seconds.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# ip-guard isolate-period 180
```

1.50 log-buffer enable

Function

Run the **log-buffer enable** command to enable the function of screen log output.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The function of screen log output is disabled by default and logs are saved in the buffer.

Syntax

log-buffer enable

no log-buffer enable

default log-buffer enable

Parameter Description

N/A

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

Full scanning table of ARP entries and session oversize are directly output on the screen without limit by the following rules.

When you configure the **log-buffer logs** command and set the value of the *message-number* parameter to **0**:

- If the **log-buffer enable** command is also configured, logs are output onto the screen without limit.
- If the **log-buffer enable** command is not configured, the logs related to isolation and port rate limit are output onto the screen without limit by the **log-buffer logs** command and other types of logs are stored in the log buffer without output. In this case, you can run the **show nfpp log buffer** command to display the logs.

When you configure the **log-buffer logs** command and set the value of the *message-number* parameter to **0** and the value of *interval* to a none-zero value: Logs are stored in the log buffer without output. In this case, you can run the **show nfpp log buffer** command to display the logs.

When you configure the **log-buffer logs** command and set the values of the *message-number* and *interval* parameters to none-zero values:

- If the **log-buffer enable** command is configured, logs are first stored in the log buffer and then output onto the screen regularly based on the *interval* configuration.
- If the **log-buffer enable** command is not configured, logs are first stored in the log buffer, and logs related to isolation and port rate limit are output onto the screen regularly based on the *interval* configuration.

When logs are first output onto the screen, the historical logs in the log buffer are output onto the screen. Before starting the configuration, you are advised to run the **clear nfpp log** command to clear the logs in the log buffer.

After active/standby switchover of a device, the device will clear logs in a buffer and record new logs again.

Examples

The following example enables the function of screen log output.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# log-buffer enable
```

1.52 log-buffer logs

Function

Run the **log-buffer logs** command to configure the rate of generating system messages from logs of the log buffer through NFPP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No rate of generating system messages from logs of the log buffer is configured through NFPP and NFPP logs are not written into the buffer by default.

Syntax

log-buffer logs *message-number* **interval** *interval*

no log-buffer logs

default log-buffer logs

Parameter Description

message-number: Number of system messages output in the specified *interval*, in pieces. The value range is from 0 to 1024. The value **0** specifies that logs are recorded in the special buffer without generating system messages.

interval: Time configured to generate *message-number* system messages, in seconds. The value range is from 0 to 86400. The value **0** specifies that logs are not written into the log buffer, but are used to immediately generate system messages.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When the values of *message-number* and *interval* are 0, logs are not written into the log buffer, but are used to immediately generate system messages.

The result of *message-number* divided by *interval* specifies the rate of generating system messages from logs of the log buffer.

When you configure the **log-buffer logs** command and set the value of the *message-number* parameter to 0:

- If the **log-buffer enable** command is also configured, logs are output onto the screen without limit.
- If the **log-buffer enable** command is not configured, the logs related to isolation and port rate limit are output onto the screen without limit by the **log-buffer logs** command and other types of logs are stored in the log buffer without output. In this case, you can run the **show nfpp log buffer** command to display the logs.

When you configure the **log-buffer logs** command and set the value of the *message-number* parameter to 0 and the value of *interval* to a none-zero value: Logs are stored in the log buffer without output. In this case, you can run the **show nfpp log buffer** command to display the logs.

When you configure the **log-buffer logs** command and set the values of the *message-number* and *interval* parameters to non-zero values:

- If the log-buffer enable command is configured, logs are first stored in the log buffer and then output onto the screen regularly based on the *interval* configuration.
- If the **log-buffer enable** command is not configured, logs are first stored in the log buffer, and logs related to isolation and port rate limit are output onto the screen regularly based on the *interval* configuration.

When logs are first output onto the screen, the historical logs in the log buffer are output onto the screen. Before starting the configuration, you are advised to run the **clear nfpp log** command to clear the logs in the log buffer.

Examples

The following example sets the system message generation rate to 2 logs per 12 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# log-buffer logs 2 interval 12
```

1.53 logging

Function

Run the **logging** command to configure NFPP to records the logs of a specified VLAN ID and a specified interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

NFPP records logs of all VLANs and interfaces by default.

Syntax

logging { **interface** *interface-type interface-number* | **vlan** *vlan-range* }

no logging { **interface** *interface-type interface-number* | **vlan** *vlan-range* }

default logging

Parameter Description

interface *interface-type interface-number*: Records only the NFPP logs of a specified interface.

vlan *vlan-range*: Records only the NFPP logs in the specified VLAN range. The value range is from 1 to 4095. The input format is as follows: 1-3, 5.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

This command can be used to filter logs and record the logs of a specified VLAN range or an interface. If the relationship of two log filtering configurations is OR, logs are recorded into the log buffer when one log filtering configuration is met.

Examples

The following example records the logs of VLAN 1, VLAN 2, VLAN 3, and VLAN 5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# logging vlan 1-3,5
```

The following example records the logs on interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# logging interface gigabitethernet 0/1
```

1.54 match

Function

Run the **match** command to configure the matched packet types of a customized guard type.

Syntax

match { **dst-ip** *destination-ipv4-address* [**dst-ip-mask** *mask*] | **dst-ipv6** *destination-ipv6-address* [**dst-ipv6-masklen** *prefix-length*] | **dst-mac** *destination-mac* [**dst-mac-mask** *destination-mac-mask*] | **dst-port** *port-number* | **etype** *type* | **protocol** *protocol* | **src-ip** *source-ip-address* [**src-ip-mask** *mask*] | **src-ipv6** *source-ipv6-address* [**src-ipv6-masklen** *prefix-length*] | **src-mac** *source-mac-address* | **src-port** *port-number* } *

Parameter Description

dst-ip *destination-ipv4-address*: Specifies a destination IPv4 address.

dst-ip-mask *mask*: Specifies a destination IPv4 address mask.

dst-ipv6 *destination-ipv6-address*: Specifies a destination IPv6 address.

dst-ipv6-masklen *prefix-length*: Specifies the length of a destination IPv6 address mask.

dst-mac *destination-mac*: Specifies a destination MAC address.

dst-mac-mask *destination-mac-mask*: Specifies a destination MAC address mask.

dst-port *port-number*: Specifies a destination port number on the transport layer.

etype *type*: Specifies an Ethernet link layer packet type.

protocol *protocol*: Specifies a protocol number.

src-ip *source-ip-address*: Specifies a source IPv4 address.

src-ip-mask *mask*: Specifies a source IPv4 address mask.

src-ipv6 *source-ipv6-address*: Specifies a source IPv6 address.

src-ipv6-masklen *prefix-length*: Specifies the length of a source IPv6 address mask.

src-mac *source-mac-address*: Specifies a source MAC address.

src-port *port-number*: Specifies a source port number on the transport layer.

Command Modes

Customized configuration mode of NFPP

Default Level

14

Usage Guidelines

After you create a customized guard type, you must specify packet fields to match this guard type.

Examples

The following example creates a customized TCP guard type and matches packets with **etype** being **0x0800** and **protocol** being **0x06**.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# nfpp
Hostname(config-nfpp)# define tcp
Hostname(config-nfpp-define)# match etype 0x0800 protocol 0x06
```

1.55 monitored-host-limit

Function

Run the **monitored-host-limit** command to configure the maximum number of monitored hosts of a customized guard type.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of monitored hosts is **20000** by default.

Syntax

monitored-host-limit *number*

no monitored-host-limit

default monitored-host-limit

Parameter Description

number: Configured maximum number of monitored hosts. The value range is from 1 to 4294967295.

Command Modes

Customized configuration mode of NFPP

Default Level

14

Usage Guidelines

When the number of monitored hosts reaches the default value **20000**, the monitored hosts are not automatically deleted if the administrator sets the maximum number of monitored hosts to a value smaller than 20000. An alarm message "%ERROR: The value that you configured is smaller than current monitored hosts 20000 (number of monitored hosts), please clear a part of monitored hosts." is printed to remind users of configuration failure and the need to clear some monitored hosts.

When the table of monitored hosts is full, the log "% NFPP_DEFINE_GUARD -SESSION_LIMIT: Attempt to exceed limit of name (name of a customized guard type)'s 20000 (number of monitored hosts) monitored hosts." is printed to remind the administrator.

Examples

The following example sets the maximum number of monitored hosts of the customized TCP guard type to **500**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# define tcp
Hostname(config-nfpp-define)# monitored-host-limit 500
```

1.56 monitor-period

Function

Run the **monitor-period** command to configure the monitoring time of a customized guard type.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default monitoring time of a customized guard type is **600** seconds.

Syntax

monitor-period *interval*

no monitor-period

default monitor-period

Parameter Description

interval: Configured monitoring time, in seconds. The value range is from 180 to 86400.

Command Modes

Customized configuration mode of NFPP

Default Level

14

Usage Guidelines

When customized guard detects an attacker, if the isolation time is 0, this function monitors the attacker through software and the timeout time is the monitoring time. During software monitoring, when the isolation time is configured as a non-zero value, this function automatically isolates the attacker under software monitoring and the timeout time is configured as the isolation time. The monitoring time takes effect when the isolation time is 0.

If you change the isolation time to 0 from a non-zero value, the isolated attacker is directly deleted without monitoring the attacker through software.

Examples

The following example sets the monitoring time of the customized TCP guard type to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# define tcp
Hostname(config-nfpp-define)# monitor-period 180
```

1.57 nd-guard attack-threshold per-port

Function

Run the **nd-guard attack-threshold per-port** command to configure the global attack threshold of ND guard.

Run the **no** form of command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global attack threshold of ND guard for NDSNP packets is 200 pps, for neighbor requests and advertisements is 100 pps, for route advertisements and redirection packets is 50 pps, and for route requests is 50 pps.

Syntax

nd-guard attack-threshold per-port { **ndsnp** *attack-threshold* | **ns-na** *attack-threshold* | **ra-redirect** *attack-threshold* | **rs** *attack-threshold* }

no nd-guard attack-threshold per-port { **ndsnp** | **ns-na** | **ra-redirect** | **rs** }

default nd-guard attack-threshold per-port { **ndsnp** | **ns-na** | **ra-redirect** | **rs** }

Parameter Description

ndsnp *attack-threshold*: Configures an attack threshold for NDSNP packets, in pps. The value range is from 1 to 19999. After the **ipv6 nd snooping enable** command is run in global configuration mode, all ND packets are NDSNP packets.

ns-na *attack-threshold*: Configures an attack threshold for neighbor requests and advertisements, in pps. The value range is from 1 to 19999.

ra-redirect *attack-threshold*: Configures an attack threshold for route advertisements and redirection packets, in pps. The value range is from 1 to 19999.

rs *attack-threshold*: Configures an attack threshold for route requests, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

The attack threshold must be equal to or greater than the rate limiting threshold.

Examples

The following example sets the global attack thresholds of ND guard to **10** pps, **20** pps, **10** pps, and **10** pps for NDSNP packets, neighbor requests and advertisements, route advertisements and redirection packets, and route requests respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# nd-guard attack-threshold per-port ndsnp 10
Hostname(config-nfpp)# nd-guard attack-threshold per-port ns-na 20

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No local rate limiting threshold or local attack threshold of DHCP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of DHCP guard are used.

Syntax

nfpp dhcp-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-mac** *rate-limit attack-threshold* }

no nfpp dhcp-guard policy { **per-port** | **per-src-mac** }

default nfpp dhcp-guard policy { **per-port** | **per-src-mac** }

Parameter Description

per-port: Configures a rate limiting threshold and an attack threshold for each interface.

per-src-mac: Configures a rate limiting threshold and an attack threshold for each source MAC address.

rate-limit: Configured rate limiting threshold, in pps. The value range is from 1 to 19999.

attack-threshold: Configured attack threshold, in pps. The value range is from 1 to 19999.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The attack threshold must be equal to or greater than the rate limiting threshold.

Examples

The following example sets the rate limiting threshold and attack threshold of DHCP guard to **50** pps and **100** pps for each interface on GigabitEthernet 0/1 and to **3** pps and **10** pps for each source MAC address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# nfpp dhcp-guard policy per-port 50 100
Hostname(config-if-GigabitEthernet 0/1)# nfpp dhcp-guard policy per-src-mac 3 10
```

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No local isolation time of ICMP guard is configured on an interface by default. The global isolation time of ICMP guard is used.

Syntax

nfpp icmp-guard isolate-period { *interval* | **permanent** }

no nfpp icmp-guard isolate-period

default nfpp icmp-guard isolate-period

Parameter Description

interval: Configured isolation time, in seconds. The value is **0** or the value range is from 30 to 86400. The value **0** specifies no isolation.

permanent: Configures permanent isolation.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the local isolation time of ICMP guard on GigabitEthernet 0/1 to **180** seconds.

```

1.75 nfpp icmp-guard policy

Function

Run the **nfpp icmp-guard policy** command to configure a local rate limiting threshold and a local attack threshold of ICMP guard on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No local rate limiting threshold or local attack threshold of ICMP guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ICMP guard are used.

Syntax

nfpp icmp-guard policy { **per-port** *rate-limit attack-threshold* | **per-src-ip** *rate-limit attack-threshold* }

no nfpp icmp-guard policy { **per-port** | **per-src-ip** }

default nfpp icmp-guard policy { **per-port** | **per-src-ip** }

Parameter Description

per-port: Configures a rate limiting threshold and an attack threshold for each interface.

per-src-ip: Configures a rate limiting threshold and an attack threshold for each source IP address.

rate-limit: Configured rate limiting threshold, in pps. The value range is from 1 to 19999.

attack-threshold: Configured attack threshold, in pps. The value range is from 1 to 19999.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The attack threshold must be equal to or greater than the rate limiting threshold.

Examples

The following example sets the rate limiting threshold and attack threshold of ICMP guard to **100** pps and **200** pps for each interface on GigabitEthernet 0/1 and to **5** pps and **10** pps for each source IP address.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# nfpp icmp-guard policy per-port 100 200

1.76 nfpp ip-guard enable

Function

Run the **nfpp ip-guard enable** command to enable the IP guard function on an interface.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

No IP guard function is configured on an interface by default. The global IP guard function is enabled.

Syntax

nfpp ip-guard enable

no nfpp ip-guard enable

default nfpp ip-guard enable

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The IP guard function on an interface takes precedence over the function of global IP guard.

If the function of ARP source suppression is enabled and the isolation time is configured for the IP guard function in global or interface configuration mode, an error is reported when you enable the IP guard function.

Examples

The following example enables the IP guard function on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# nfpp ip-guard enable
```

Notifications

No notification can be configured.

```
Configuration is prohibited, please disable the arp-guard suppression function first!
```

Common Errors

If the function of ARP source suppression is configured on an interface and the isolation time is configured for the IP guard function in global or interface configuration mode, an error is reported when you configure the IP guard function on this interface.

1.77 nfpp ip-guard isolate-period

Function

Run the **nfpp ip-guard isolate-period** command to configure the local isolation time of IP guard on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No isolation time of IP guard is configured by default. The global isolation time of IP guard is used.

Syntax

nfpp ip-guard isolate-period { *interval* | **permanent** }

no nfpp ip-guard isolate-period

default nfpp ip-guard isolate-period

Parameter Description

interval: Configured isolation time, in seconds. The value is **0** or the value range is from 30 to 86400. The value **0** specifies no isolation.

permanent: Configures permanent isolation.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If you have configured the function of ARP source suppression, you cannot configure the isolation time for the IP guard function.

Examples

The following example sets the local isolation time of IP guard on GigabitEthernet 0/1 to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# nfpp ip-guard isolate-period 180
```

Notifications

If you have configured the function of ARP source suppression, the following notification will be displayed when you configure isolation time for IP guard:

```
Configuration is prohibited, please disable the arp-guard suppression function first!
```

1.81 nfpp nd-guard policy per-port

Function

Run the **nfpp nd-guard policy per-port** command to configure a local rate limiting threshold and a local attack threshold of ND guard on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No local rate limiting threshold or local attack threshold of ND guard is configured on an interface by default. The global rate limiting threshold and global attack threshold of ND guard are used.

Syntax

nfpp nd-guard policy per-port { **ndsnp** *rate-limit attack-threshold* | **ns-na** *rate-limit attack-threshold* | **ra-redirect** *rate-limit attack-threshold* | **rs** *rate-limit attack-threshold* }

no nfpp nd-guard policy per-port { **ndsnp** | **ns-na** | **ra-redirect** | **rs** }

default nfpp nd-guard policy per-port { **ndsnp** | **ns-na** | **ra-redirect** | **rs** }

Parameter Description

ndsnp: Configures a rate limiting threshold and an attack threshold for NDSNP packets. After the **ipv6 nd snooping enable** command is enabled in global configuration mode, all ND packets are NDSNP packets.

ns-na: Configures a rate limiting threshold and an attack threshold for neighbor requests and advertisements.

ra-redirect: Configures a rate limiting threshold and an attack threshold for route advertisements and redirection packets.

rs: Configures a rate limiting threshold and an attack threshold for route requests.

rate-limit: Configured rate limiting threshold, in pps. The value range is from 1 to 19999.

attack-threshold: Configured attack threshold, in pps. The value range is from 1 to 19999.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The attack threshold must be equal to or greater than the rate limiting threshold.

Examples

The following example sets the local rate limiting threshold and local attack threshold of ND guard to **5** pps and **10** pps for NDSNP packets on interface GigabitEthernet 0/1, to **50** pps and **100** pps for neighbor requests and advertisements, to **10** pps and **20** pps for route advertisements and redirection packets, and to **10** pps and **20** pps for route requests.

1.85 show nfpp arp-guard hosts

Function

Run the **show nfpp arp-guard hosts** command to display the monitored hosts of ARP guard.

Syntax

show nfpp arp-guard hosts [**statistics** | [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*ipv4-address* | *mac-address*]]

Parameter Description

statistics: Displays the statistics about the monitored hosts.

vlan *vlan-id*: Displays the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Displays the monitored hosts of a specified interface.

ipv4-address: Specified IPv4 address of a monitored host to be displayed. Whether this parameter is supported depends on the actual product version.

mac-address: Specified MAC address of a monitored host.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the statistics about the monitored hosts of ARP guard.

```
Hostname> enable
```

```
Hostname# show nfpp arp-guard hosts statistics
success    fail    total
---    --    -------
100      20     120
```

Table 1-1 Output Field of the show nfpp arp-guard hosts statistics Command

Field	Description
Success	Number of isolated hosts
Fail	Number of hosts failed to be isolated
total	Number of monitored hosts

The following example displays the monitored hosts of ARP guard.

```
Hostname# show nfpp arp-guard hosts
If column 1 shows '*', it means "hardware do not isolate user" .
VLAN  interface IP address   MAC address     remain-time(s)
--  ----   ---    -----     -----
1     Gi0/1      1.1.1.1     -               110
2     Gi0/2      1.1.2.1     -               61
*3    Gi0/3      -           0000.0000.1111  110
4     Gi0/4      -           0000.0000.2222   61
Total: 4 hosts
```

Table 1-2 Output Field of the show nfpp arp-guard hosts Command

Field	Description
VLAN	VLAN ID of a host
interface	Interface name of a host
IP address	IP address of a host
MAC address	MAC address of a host
remain-time	Remaining isolation time
Total: *number* hosts	Total number of monitored hosts. *number* specifies the specific number of hosts.

1.86 show nfpp arp-guard scan

Function

Run the **show nfpp arp-guard scan** command to display the scanning table of ARP guard.

Syntax

show nfpp arp-guard scan [**statistics** | [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*mac-address*]]

Parameter Description

statistics: Displays the statistics about the scanning table.

vlan *vlan-id*: Displays the scanning table of a specified VLAN ID.

interface *interface-type interface-number*: Displays the scanning table of a specified interface.

mac-address: Specified MAC address of a scanning table.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the statistics about the scanning table of ARP guard.

```
Hostname> enable
Hostname# show nfpp arp-guard scan statistics
arp-guard scan table has 4 record(s).
```

Table 1-3 Output Field of the show nfpp arp-guard scan statistics Command

Field	Description
arp-guard scan table has *number* record(s).	Displays the number of records in the scanning table. *number* specifies the number of records in the scanning table.

The following example displays the scanning table of ARP guard. "timestamp" specifies the detection time of ARP scanning. For example, "2008-01-23 16:23:10" specifies that ARP scanning time is detected at 16:23:10 on January 23, 2008.

```
Hostname> enable
Hostname# show nfpp arp-guard scan
```

```
VLAN   interface   IP address   MAC address     timestamp
--   ----   ----  -----     ---
1       Gi0/1      -         0000.0000.0001   2008-01-23 16:23:10
2       Gi0/2      1.1.1.1     0000.0000.0002   2008-01-23 16:24:10
3       Gi0/3      -         0000.0000.0003   2008-01-23 16:25:10
4       Gi0/4      -         0000.0000.0004   2008-01-23 16:26:10
Total: 4 record(s)
```

Table 1-4 Output Field of the show nfpp arp-guard hosts Command

Field	Description
VLAN	VLAN ID of the ARP scanning information
interface	Interface name of the ARP scanning information
IP address	IP address of the ARP scanning information
MAC address	MAC address of the ARP scanning information
timestamp	Detection time of the ARP scanning
Total: *number* record(s)	Total number of records in the ARP scanning table. *number* specifies the specific number of records in the scanning table.

1.87 show nfpp arp-guard summary

Function

Run the **show nfpp arp-guard summary** command to display the configuration information of ARP guard.

Syntax

show nfpp arp-guard summary

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the configuration information of ARP guard.

```
Hostname> enable
Hostname# show nfpp arp-guard summary
(Format of column Rate-limit and  Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface  Status  Isolate-period Rate-limit Attack-threshold Scan-threshold
Global     Enable  300            4/5/60    8/10/100         15
Gi 0/1      Enable  180            5/-      8/-             -
Gi 0/2      Disable 200            4/5/60    8/10/100         20
Maximum count of monitored hosts: 1000
Monitor period: 300s
Suppress-mode: disable
Suppress-threshold: 5pps
Suppress-period: 5s
```

Table 1-5 Output Field of the show nfpp arp-guard summary Command

Field	Description
Interface	Interface. **Global** specifies global configuration.
Status	Whether the guard function is enabled: ● **Enable**: The function is enabled. ● **Disable**: The function is disabled.
Isolat-period	Isolation period configured in a policy, in seconds
Rate-limit	Rate limiting thresholds for a source IP address, source MAC address, and interface respectively
Attack-threshold	Attack thresholds for a source IP address, source MAC address, and interface respectively
Scan-threshold	Scanning threshold
Maximum count of monitored hosts	Maximum number of monitored hosts
Monitor period	Monitoring period, in seconds
suppress-mode	Whether the suppression mode is enabled: ● **Enable**: The mode is enabled.

Field	Description
	● **Disable**: The mode is disabled.
suppress-threshold	Suppression threshold, in pps
suppress-period	Suppression period, in seconds

1.88 show nfpp define hosts

Function

Run the **show nfpp define hosts** command to display the monitored hosts of a customized guard type.

Syntax

show nfpp define hosts *name* [**statistics** | [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*ipv4-address* | *mac-address* | *ipv6-address*]]

Parameter Description

name: Name of a specified customized guard type.

statistics: Displays the statistics about the monitored hosts.

vlan *vlan-id*: Displays the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Displays the monitored hosts of a specified interface.

ipv4-address: Specified IPv4 address of a monitored host to be displayed.

mac-address: Specified MAC address of a monitored host.

ipv6-address: Specified IPv6 address of a monitored host.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

Parameters can be configured in the command to filter unwanted monitored hosts.

Examples

The following example displays the monitored hosts of a customized TCP guard type.

```
Hostname> enable
Hostname# show nfpp define hosts tcp
If col_filter 1 shows '*', it means "hardware do not isolate host".
 VLAN    interface   MAC address    remain-time(s)
 --    ---   -----     ------
*1      Gi4/2      00d0.f822.33e5  592
Total: 1 host
```

Table 1-6 Output Field of the show nfpp define hosts Command

Field	Description
VLAN	VLAN ID of a host
interface	Interface name of a host
MAC address	MAC address of a host
remain-time	Remaining isolation time of a host, in seconds
Total: *number* hosts	Total number of monitored hosts. *number* specifies the specific number of hosts.

1.89 show nfpp define summary

Function

Run the **show nfpp define summary** command to display the configuration information of a customized summary type.

Syntax

show nfpp define summary [*name*]

Parameter Description

name: Name of a specified customized guard type.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the configuration information of the customized TCP guard type.

```
Hostname> enable
Hostname# show nfpp define summary abc
Define abc summary:
match etype 0x800 src-ip 1.1.1.1 src-ip-mask 255.255.255.255
Maximum count of monitored hosts: 20000
Monitor period:600s
(Format of column Rate-limit and  Attack-threshold is
per-src-ip/per-src-mac/per-port.)
Interface Status  Rate-limit     Attack-threshold
Global    Disable -/10/-         -/20/-
Gi4/1     Enable  -/-          -/-/-
```

Table 1-7 Output Field of the show nfpp define summary Command

Field	Description
Define *name* summary	Configuration of a specified customized guard type. *name* specifies the name of a customized guard type.
match etype *etype* src-ip *source-ipv4-address* src-ip-mask *source-mask*	Matched packet types of a customized guard type
Maximum count of monitored hosts	Maximum number of monitored hosts
Monitor period	Monitoring time, in seconds
Interface	Interface. **Global** specifies global configuration.
Status	Whether the guard function is enabled: ● **Enable**: The function is enabled. ● **Disable**: The function is disabled.
Rate-limit	Rate limiting thresholds for a source IP address, source MAC address, and interface respectively
Attack-threshold	Attack thresholds for a source IP address, source MAC address, and interface respectively

1.90 show nfpp define trusted-host

Function

Run the **show nfpp define trusted-host** command to display the trusted hosts of a customized guard type.

Syntax

show nfpp define trusted-host *name*

Parameter Description

name: Name of a customized guard type.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the trusted hosts of the customized TCP guard type.

```
Hostname> enable
Hostname# show nfpp define trusted-host tcp
Define tcp:
IP address     mask
---      -
1.1.1.0        255.255.255.0
1.1.2.0        255.255.255.0
Total: 2 record(s)
```

Table 1-8 Output Field of the show nfpp define trusted-host Command

Field	Description
Define *name*	Information of a specified customized guard type. *name* specifies the name of a customized guard type.
IP address	IP address of a trusted host
mask	Subnet mask of a trusted host

Field	Description
Total: *number* record(s)	Total number of trusted hosts. *number* -specifies the specific number of hosts.

1.91 show nfpp dhcp-guard hosts

Function

Run the **show nfpp dhcp-guard hosts** command to display the monitored hosts of DHCP guard.

Syntax

show nfpp dhcp-guard hosts [**statistics** | [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*mac-address*]]

Parameter Description

statistics: Displays the statistics about the monitored hosts.

vlan *vlan-id*: Displays the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Displays the monitored hosts of a specified interface.

mac-address: Specified MAC address of a monitored host.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the statistics about the monitored hosts of DHCP guard.

```
Hostname> enable
Hostname# show nfpp dhcp-guard hosts statistics
success   fail   total
---   --   --
100       20      120
```

Table 1-9 Output Field of the show nfpp dhcp-guard hosts statistics Command

Field	Description
success	Number of isolated hosts
Fail	Number of hosts failed to be isolated
total	Number of monitored hosts

The following example displays the monitored hosts of DHCP guard.

```
Hostname> enable
Hostname# show nfpp dhcp-guard hosts
If column 1 shows '*', it means "hardware failed to isolate host".
VLAN  interface   MAC address    remain-time(seconds)
--    ---    -----        ------
 1    gi0/2     0000.0000.0001   10

1.101 show nfpp log buffer

Function

Run the **show nfpp log buffer** command to display the information in the log buffer of NFPP.

Syntax

show nfpp log buffer

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

When the log buffer overflows, subsequent logs are discarded, and the log buffer displays an entry with attributes being "-". In this case, the administrator must increase the log buffer size or improve the generation rate of system messages.

The system message generated from logs of the log buffer carries the event timestamp, as shown below:

```
%NFPP_ARP_GUARD-DOS_DETECTED: Host<IP=N/A,MAC=0000.0000.0004,port=Gi4/1,VLAN=1>
was detected.(2009-07-01 13:00:00)
```

Examples

The following example displays the log buffer of NFPP.

```
Hostname> enable
Hostname# show nfpp log buffer

1.104 show nfpp nd-guard hosts

Function

Run the **show nfpp nd-guard hosts** command to display the monitored hosts of ND guard.

Syntax

show nfpp nd-guard hosts [**statistics** | [**vlan** *vlan-id*] [**interface** *interface-type interface-number*]]

Parameter Description

statistics: Displays the statistics about the monitored hosts.

vlan *vlan-id*: Displays the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Displays the monitored hosts of a specified interface.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the statistics about the monitored hosts of ND guard.

```
Hostname> enable
Hostname# show nfpp nd-guard hosts statistics
success    fail    total
---    --    --
10        2       12
```

Table 1-25 Output Field of the show nfpp nd-guard hosts statistics Command

Field	Description
success	Number of isolated hosts
fail	Number of hosts failed to be isolated
total	Number of monitored hosts

The following example displays the monitored hosts of ND guard.

```
Hostname> enable
Hostname# show nfpp nd-guard hosts
If col_filter 1 shows '*', it means "hardware do not isolate host".
 VLAN    interface   ND-guard          remain-time(s)
 --    ---   ----          ------
 -      Gi4/2      ns-na-guard        174
 -      Gi4/2      rs-guard          98
 -      Gi4/2      ra-redirect-guard   127
Total: 3 hosts
```

Table 1-26 Output Field of the show nfpp nd-guard hosts Command

Field	Description
VLAN	VLAN ID of a host

1.106 show nfpp tcp-syn-guard hosts

Function

Run the **show nfpp tcp-syn-guard hosts** command to display the monitored hosts of TCP-SYN guard.

Syntax

show nfpp tcp-syn-guard hosts [**statistics** | [**vlan** *vlan-id*] [**interface** *interface-type interface-number*] [*ipv4-address*]]

Parameter Description

statistics: Displays the statistics about the monitored hosts.

vlan *vlan-id*: Displays the monitored hosts of a specified VLAN ID.

interface *interface-type interface-number*: Displays the monitored hosts of a specified interface.

ipv4-address: Specified IPv4 address of a monitored host to be displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the statistics about the monitored hosts of TCP-SYN guard.

```
Hostname> enable
Hostname# show nfpp tcp-syn-guard hosts statistics
success    fail    total
---    --    ---
100        20       120
```

Table 1-28 Output Field of the show nfpp tcp-syn-guard hosts statistics Command

Field	Description
success	Number of isolated hosts
fail	Number of hosts failed to be isolated
total	Number of monitored hosts

The following example displays the monitored hosts of TCP-SYN guard.

```
Hostname> enable
Hostname# show nfpp tcp-syn-guard hosts
If column 1 shows '*', it means "hardware do not isolate host" .
VLAN  interface IP address   Reason     remain-time(s)
--  ----   ---   ---     -----
1     Gi0/1      1.1.1.1     ATTACK     110
2     Gi0/2      1.1.2.1     SCAN        61
Total: 2 host(s)
```

Table 1-29 Output Field of the show nfpp tcp-syn-guard hosts Command

Field	Description
VLAN	VLAN ID of a host
interface	Interface name of a host
IP address	IP address of a host
Reason	Reason for host monitoring: ● **ATTACK**: Specifies that TCP-SYN packets are sent at a rate higher than the attack threshold. ● **SCAN**: Specifies that a host is scanning a network segment.

Field	Description
remain-time	Remaining isolation time
Total: *number* hosts	Total number of monitored hosts. *number* specifies the specific number of hosts.

1.109 tcp-syn-guard attack-threshold

Function

Run the **tcp-syn-guard attack-threshold** command to configure the global attack threshold of TCP-SYN guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The global attack threshold of TCP-SYN guard for each interface is 200 pps and for each source IP address is 100 pps by default.

Syntax

tcp-syn-guard attack-threshold { **per-port** *attack-threshold* | **per-src-ip** *attack-threshold* }

no tcp-syn-guard attack-threshold { **per-port** | **per-src-ip** }

default tcp-syn-guard attack-threshold { **per-port** | **per-src-ip** }

Parameter Description

per-port *attack-threshold*: Configures an attack threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-ip *attack-threshold*: Configures an attack threshold for each source IP address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

The attack threshold must be equal to or greater than the rate limiting threshold.
TCP-SYN guard is to solve TCP-SYN attacks on the destination IP address, but not the local IP address. If the destination IP address is a local IP address, the rates of IP packets are limited by the function of CPU protect policy (CPP).

Examples

The following example sets the global attack thresholds of TCP-SYN guard to **50** pps and **2** pps for each interface and source IP address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# tcp-syn-guard attack-threshold per-port 50
Hostname(config-nfpp)# tcp-syn-guard attack-threshold per-src-ip 2
```

1.111 tcp-syn-guard isolate-period

Function

Run the **tcp-syn-guard isolate-period** command to configure the global isolation time of TCP-SYN guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default global isolation time of TCP-SYN guard is **0**.

Syntax

tcp-syn-guard isolate-period { *interval* | **permanent** }

no tcp-syn-guard isolate-period

default tcp-syn-guard isolate-period

Parameter Description

interval: Configured isolation time, in seconds. The value is **0** or the value range is from 30 to 86400.

permanent: Configures permanent isolation.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the global isolation time of TCP-SYN guard to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# tcp-syn-guard isolate-period 180
```

1.112 tcp-syn-guard monitored-host-limit

Function

Run the **tcp-syn-guard monitored-host-limit** command to configure the maximum number of monitored hosts of TCP-SYN guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of monitored hosts of TCP-SYN guard is **20000** by default.

Syntax

tcp-syn-guard monitored-host-limit *number*

no tcp-syn-guard monitored-host-limit

default tcp-syn-guard monitored-host-limit

Parameter Description

number: Configured maximum number of monitored hosts. The value range is from 1 to 4294967295.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When the number of monitored hosts reaches the default value **20000**, the monitored hosts are not deleted if the administrator sets the maximum number of monitored hosts to a value smaller than 20000. An alarm message "%ERROR: The value that you configured is smaller than current monitored hosts 20000 (number of monitored hosts), please clear a part of monitored hosts." is printed to remind users of configuration failure and the need to delete clear some monitored hosts.

When the table of monitored hosts is full, the log "% NFPP_TCP_SYN_GUARD-SESSION_LIMIT: Attempt to exceed limit of IP 20000 (number of monitored hosts) monitored hosts." is printed to remind the administrator.

Examples

The following example sets the maximum number of monitored hosts of TCP-SYN guard to **200**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# tcp-syn-guard monitored-host-limit 200
```

1.113 tcp-syn-guard monitor-period

Function

Run the **tcp-syn-guard monitor-period** command to configure the monitoring time of TCP-SYN guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default monitoring time of TCP-SYN guard is **600** seconds.

Syntax

tcp-syn-guard monitor-period *interval*

no tcp-syn-guard monitor-period

default tcp-syn-guard monitor-perio

Parameter Description

interval: Configured monitoring time, in seconds. The value range is from 180 to 86400.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

When TCP-SYN guard detects an attacker, if the isolation time is 0, this function monitors the attacker through software and the timeout time is the monitoring time. During software monitoring, when the isolation time is configured as a non-zero value, this function automatically isolates the attacker under software monitoring and the timeout time is configured as the isolation time. The monitoring time takes effect when the isolation time is 0.

If you change the isolation time to 0 from a non-zero value, the isolated attacker is directly deleted without monitoring the attacker through software.

Examples

The following example sets the monitoring time of TCP-SYN guard to **180** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# tcp-syn-guard monitor-period 180
```

1.114 tcp-syn-guard rate-limit

Function

Run the **tcp-syn-guard rate-limit** command to configure the global rate limiting threshold of TCP-SYN guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the global rate limiting threshold of TCP-SYN guard for each interface is 50 pps and for each source IP address is 20 pps.

Syntax

tcp-syn-guard rate-limit { **per-port** *rate-limit* | **per-src-ip** *rate-limit* }

no tcp-syn-guard rate-limit { **per-port** | **per-src-ip** }

default tcp-syn-guard rate-limit { **per-port** | **per-src-ip** }

Parameter Description

per-port *rate-limit*: Configures a rate limiting threshold for each interface, in pps. The value range is from 1 to 19999.

per-src-ip *rate-limit*: Configures a rate limiting threshold for each source IP address, in pps. The value range is from 1 to 19999.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the global rate limiting thresholds of TCP-SYN guard to **40** pps and **2** pps for each interface and source IP address respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# tcp-syn-guard rate-limit per-src-ip 2
Hostname(config-nfpp)# tcp-syn-guard rate-limit per-port 40

1.115 tcp-syn-guard trusted-host

Function

Run the **tcp-syn-guard trusted-host** command to configure the trusted hosts of TCP-SYN guard.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No host is configured as a trusted host of TCP-SYN guard by default.

Syntax

tcp-syn-guard trusted-host *ipv4-address mask*

no tcp-syn-guard trusted-host { *ipv4-address mask* | **all** }

default tcp-syn-guard trusted-host

Parameter Description

ipv4-address mask: IPv4 address+mask. The mask is entered in dotted decimal mode.

all: Deletes the configuration of all trusted hosts when this parameter is used with the **no** parameter.

Command Modes

NFPP configuration mode

Default Level

14

Usage Guidelines

To cancel the monitoring of a host, the administrator can run this command to configure the host as a trusted host. In this case, IP packets sent by this host can be forwarded to the CPU without rate limit or alarm.

A maximum of 500 trusted hosts can be configured.

Examples

The following example configures all hosts in the network segment 1.1.1.0/24 as trusted hosts of TCP-SYN guard.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# tcp-syn-guard trusted-host 1.1.1.0 255.255.255.0
```

1.116 trusted-host

Function

Run the **trusted-host** command to configure trusted hosts of a customized guard type.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No host is configured as a trusted host of the customized guard type by default.

Syntax

trusted-host { *ipv4-address mask* | *ipv6-address*/*prefix-length* | *mac-address mask* }

no trusted-host { *ipv4-address mask* | *ipv6-address*/*prefix-length* | *mac-address mask* | **all** }

default trusted-host

Parameter Description

ipv4-address mask: IPv4 address+mask. The mask is entered in dotted decimal mode.

ipv6-address/*prefix-length*: IPv6 address+prefix. The prefix starts with a slash (/).

Mac-address mask: MAC address and mask.

all: Deletes the configuration of all trusted hosts when this parameter is used with the **no** parameter.

Command Modes

Customized configuration mode of NFPP

Default Level

14

Usage Guidelines

To cancel the monitoring of a host, the administrator can run this command to configure the host as a trusted host. In this case, ICMP packets sent by this host can be forwarded to the CPU without rate limit or alarm. All hosts in a network segment can be configured as trusted hosts by configuring a mask.

A maximum of 500 trusted hosts can be configured.

The match type must be configured prior to the configuration of trusted hosts. If the matched packet type is IPv4, IPv6 addresses cannot be configured as trusted. If the matched packet type is IPv6, IPv4 addresses cannot be configured as trusted.

Examples

The following example configures the host 1.1.1.1 as a trusted host of the customized guard type.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# nfpp
Hostname(config-nfpp)# define tcp
Hostname(config-nfpp-define)# trusted-host 1.1.1.1 255.255.255.255
```

1 Storm Control Commands

Command	Function
show storm-control	Display storm control information.
storm-control	Enable packet storm control.

1.1 show storm-control

Function

Run the **show storm-control** command to display storm control information.

Syntax

show storm-control [*interface-type interface-number*]

Parameter Description

interface-type interface-number: Interface whose storm control information is displayed. If this parameter is not specified, storm control information of all interfaces is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays storm control information of GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show storm-control GigabitEthernet 0/1
Interface              Broadcast Control Multicast Control Unicast Control Action
------------------------ ----------------- ----------------- ---------------
--------
     GigabitEthernet 0/1       6400   pps       6400   pps     6400   pps    none
```

Table 1-1 Output Fields of the show storm-control Command

Field	Description
Interface	Interface name
Broadcast Control	Storm control settings for broadcast packets
Multicast Control	Storm control settings for multicast packets
Unicast Control	Storm control settings for unicast packets
Action	Action

Notifications

N/A

Platform Description

- **storm-control**

1.2 storm-control

Function

Run the **storm-control** command to enable packet storm control.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

Packet storm control is disabled by default.

Syntax

storm-control { **broadcast** | **multicast** | **unicast** } [**level** *percent* | **pps** *packets* | *rate*]

no storm-control { **broadcast** | **multicast** | **unicast** }

default storm-control { **broadcast** | **multicast** | **unicast** }

Parameter Description

broadcast: Enables storm control for broadcast packets.

multicast: Enables storm control for multicast packets.

unicast: Enables storm control for unicast packets.

level *percent*: Configures the allowed bandwidth percentage. The value range is from 1 to 100.

pps *packets*: Configures the allowed packet rate, in packets per second. The value range is from 2 to 1488095.

rate: Configures the allowed rate, in Kbit/s. The value range is from 64 to 1000000.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When excessive broadcast, multicast, or unknown unicast packets are received through a port, a data packet storm occurs, which slows down the network speed and increases the timeout probability of packet transmission. A storm may occur when topology protocol execution or network configuration is incorrect.

Storm control can be implemented to limit broadcast, multicast, or unknown unicast data flows. When receiving excessive broadcast, multicast, or unknown unicast packets, a device will temporarily forbid forwarding of packets of the same type until the data flows become normal.

Examples

The following example enables storm control for multicast packets on GigabitEthernet 0/1 and sets the allowed rate to 4 Mbit/s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# storm-control multicast 4096
```

1 uRPF Commands

Command	Function
clear ip urpf	Clear IPv4 Unicast Reverse Path Forwarding (uRPF) packet loss statistics.
ip verify unicast source reachable-via (Global configuration mode)	Enable IPv4 uRPF.
ip verify unicast source reachable-via (Interface configuration mode)	Enable uRPF on an interface.
ip verify urpf drop-rate compute interval	Configure the interval for calculating the uRPF IPv4/IPv6 packet loss rate.
ip verify urpf drop-rate notify	Enable uPRF packet loss information monitoring.
ip verify urpf drop-rate notify hold-down	Configure the alarm interval of the uRPF IPv4/IPv6 packet loss rate.
ip verify urpf notification threshold	Configure the threshold of the uRPF packet loss rate.
show ip urpf	Display the IPv4 uRPF configurations and statistics.

1.1 clear ip urpf

Function

Run the **clear ip urpf** command to clear IPv4 Unicast Reverse Path Forwarding (uRPF) packet loss statistics.

Syntax

clear ip urpf [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-name interface-number*: Specifies the interface whose statistics are cleared. If this parameter is not specified, statistics of all interfaces are cleared.

Command Modes

Privileged EXEC mode

Default Level

1

Usage Guidelines

N/A

Examples

The following example clears IPv4 uRPF packet loss statistics on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear ip urpf interface gigabitethernet0/1
```

The following example clears IPv4 uRPF packet loss statistics on all interfaces.

```
Hostname> enable
Hostname# clear ip urpf
```

Notifications

When IPv4 uRPF is not enabled on the specified interface, the following notification will be displayed:

```
% Interface GigabitEthernet 0/1 does not enable URPF function.
```

When no interface is specified and IPv4 uRPF is not enabled on the device, the following notification will be displayed:

```
% Device does not enable URPF function.
```

Platform Description

N/A

1.2 ip verify unicast source reachable-via (Global configuration mode)

Function

Run the **ip verify unicast source reachable-via** command to enable IPv4 uRPF.

Run the **no** form of this command to disable this feature.

IPv4 uRPF is disabled by default.

Syntax

ip verify unicast source reachable-via rx

no ip verify unicast

Parameter Description

rx: Configures the strict mode to perform a uRPF check. The strict mode requires that the outbound interface of the forwarding entry found in the forwarding table based on the source address of a received IP packet must match the inbound interface of the packet.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Based on the source address of a received IP packet, uRPF checks whether any route to the source address exists in the forwarding table and accordingly determines whether the packet is valid. If no forwarding entry is matched, the packet is determined as invalid.

You can enable uRPF in global configuration mode to perform a uRPF check for packets received on all interfaces of a device.

Only the uRPF strict mode can be configured in global configuration mode. If a matched equal-cost route is found for a packet, the packet will be processed according to the uRPF loose mode.

If uRPF is configured in global configuration mode, the default route cannot be used for a uRPF check.

uRPF cannot be configured in global configuration mode and interface configuration mode simultaneously.

Examples

The following example enables IPv4 uRPF.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip verify unicast source reachable-via rx
```

1.3 ip verify unicast source reachable-via (Interface configuration mode)

Function

Run the **ip verify unicast source reachable-via** command to enable uRPF on an interface.

Run the **no** form of this command to disable this feature.

uRPF is disabled for an interface by default.

Syntax

ip verify unicast source reachable-via { **any** | **rx** } [**allow-default**]

no ip verify unicast

Parameter Description

any: Configures the loose mode to perform a uRPF check. The loose mode only requires that a forwarding entry can be found in the forwarding table based on the source address of a received IP packet.

rx: Configures the strict mode to perform a uRPF check. The strict mode requires that the outbound interface of the forwarding entry found in the forwarding table based on the source address of a received IP packet must match the inbound interface of the packet.

allow-default: Allows to use the default route for a uRPF check. If this parameter is not specified, the default route is not used for a uPRF check.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is configured, a switch will perform a uRPF check on both IPv4 and IPv6 packets.

A switch supports configuration of uRPF on a routed port, a L3 aggregation port (AP) or a switch virtual interface (SVI).

Based on the source address of a received IP packet, uRPF checks whether any route to the source address exists in the forwarding table and accordingly determines whether the packet is valid. If no forwarding entry is matched, the packet is determined as invalid.

You can enable uRPF in interface configuration mode to perform a uRPF check for packets received on the interface.

The default route is not used for a uRPF check by default. You can use the **allow-default** keyword to use the default route for a URPF check if necessary.

- uRPF does not support association with the ACL option.
- uRPF does not support the use of IPv6 routes with a 65-bit to 127-bit prefix for a uRPF check.
- After uRPF is enabled on interfaces, a uRPF check is performed for all packets received on physical ports corresponding to these interfaces, which increases the scope of packets checked by uRPF. If a packet received on a tunnel port is also received on the preceding physical ports, the packet is also checked by uRPF. In such a scenario, be cautious in enabling uRPF.

- After uRPF is enabled, the route forwarding capacity of a device will be reduced by half.
- After the uRPF strict mode is enabled, if a packet received on an interface matches an equal-cost route during the uRPF check, the packet will be processed according to the URPF loose mode.
- If uRPF is configured in global configuration mode, the default route cannot be used for a uRPF check.
- uRPF cannot be configured in global configuration mode and interface configuration mode simultaneously.
- uRPF cannot be enabled on a range of interfaces.

Examples

The following example enables uRPF on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify unicast source reachable-via rx
```

1.4 ip verify urpf drop-rate compute interval

Function

Run the **ip verify urpf drop-rate compute interval** command to configure the interval for calculating the uRPF IPv4/IPv6 packet loss rate.

Run the **no** form of this command to remove this configuration.

The default interval for calculating the uRPF IPv4/IPv6 packet loss rate is **30** seconds.

Syntax

ip verify urpf drop-rate compute interval *interval*

no ip verify urpf drop-rate compute interval

Parameter Description

interval *interval*: Specifies the interval for calculating the uRPF packet loss rate, in seconds. The value range is from 30 to 300.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The interval for calculating the uRPF packet loss rate is configured in global configuration mode, which applies to the calculation of the uRPF packet loss rate globally and on each interface with uRPF enabled and takes effect to IPv4 and IPv6 uRPF.

Examples

The following example sets the interval for calculating the uRPF IPv4/IPv6 packet loss rate to 60 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip verify urpf drop-rate compute interval 60
```

1.5 ip verify urpf drop-rate notify

Function

Run the **ip verify urpf drop-rate notify** command to enable uPRF packet loss information monitoring.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

uRPF packet loss information monitoring is disabled by default.

Syntax

ip verify urpf drop-rate notify

no ip verify urpf drop-rate notify

default ip verify urpf drop-rate notify

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After uRPF packet loss information monitoring is enabled, a device can proactively send syslogs or trap messages to notify users of the packet loss information detected in the uRPF check so that the users can monitor the network status conveniently.

Examples

The following example enables uRPF packet loss information monitoring on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify

1.6 ip verify urpf drop-rate notify hold-down

Function

Run the **ip verify urpf drop-rate notify hold-down** command to configure the alarm interval of the uRPF IPv4/IPv6 packet loss rate.

Run the **no** form of this command to remove this configuration.

The default alarm interval for the uRPF IPv4/IPv6 packet loss rate is **300** seconds.

Syntax

ip verify urpf drop-rate notify hold-down *hold-down-time*

no ip verify urpf drop-rate notify hold-down

Parameter Description

hold-down *hold-down-time*: Specifies the alarm interval of the uRPF packet loss rate, in seconds. The value range is from 30 to 300.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The alarm interval of the uRPF packet loss rate is configured in global configuration mode, and applies to alarm reporting of the uRPF packet loss rate globally and on each interface with uRPF enabled and takes effect to IPv4 and IPv6 uRPF.

Examples

The following example sets the alarm interval of the uRPF IPv4/IPv6 packet loss rate to 60 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip verify urpf drop-rate notify hold-down 60

1.7 ip verify urpf notification threshold

Function

Run the **ip verify urpf notification threshold** command to configure the threshold of the uRPF packet loss rate.

Run the **no** form of this command to remove this configuration.

The default threshold of the uRPF packet loss rate is **1000** packets per second.

Syntax

ip verify urpf notification threshold *rate-value*

no ip verify urpf notification threshold

Parameter Description

threshold *rate-value*: Specifies the threshold of the uRPF packet loss rate, in packets per second. The value range is from 0 to 4294967295. If the threshold is **0**, a notification is sent for every packet that is discarded because it fails in the uRPF check.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the threshold of the uRPF packet loss rate to 10 packets per second on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet0/1
Hostname(config-if-GigabitEthernet 0/1)# ip verify urpf drop-rate notify

1.8 show ip urpf

Function

Run the **show ip urpf** command to display the IPv4 uRPF configurations and statistics.

Syntax

show ip urpf [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Specifies the interface whose configurations and statistics are displayed. If this parameter is not specified, configurations and statistics of all interfaces are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

N/A

Examples

The following example displays the uRPF configurations and statistics on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show ip urpf interface gigabitethernet0/1
IP verify source reachable-via RX
IP verify URPF drop-rate notify is disabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 2
```

The following example displays IPv4 uRPF configurations and statistics on all interfaces.

```
Hostname> enable
Hostname# show ip urpf
IP verify URPF drop-rate compute interval is 30s
IP verify URPF drop-rate notify hold-down is 300s
Interface GigabitEthernet 0/1
IP verify source reachable-via RX
IP verify URPF drop-rate notify is disabled
IP verify URPF notification threshold is 1000pps
Number of drop packets in this interface is 124
Number of drop-rate notification counts in this interface is 2
```

Table 1-1 Output Fields of the show ip urpf Command

Field	Description
IP verify URPF drop-rate compute interval is x	Interval for calculating the packet loss rate
IP verify URPF drop-rate notify hold-down is x	Alarm interval of the packet loss rate
Interface *interface-type interface-number*	Type and number of the interface whose uRPF configurations and statistics are displayed
IP verify source reachable-via *mode*	● When *mode* is set to **RX**, the uRPF strict mode is used. ● When *mode* is set to **ANY**, the uRPF loose mode is used.
IP verify URPF drop-rate notify *status*	Packet loss information monitoring status: ● When *status* is set to **enabled**, packet loss information monitoring is enabled. ● When *status* is set to **disabled**, packet loss information monitoring is disabled.
IP verify URPF notification threshold is *number*pps	Threshold of the uRPF packet loss rate
Number of drop packets in this interface is *number*	Number of lost packets
Number of drop-rate notification counts in this interface is *count*	Number of notifications for uRPF packet loss information monitoring

1 Security Log Auditing Commands

Command	Function
security-log audit-enable	Enable security log auditing.
security-log auto-vacuum-time	Configure the handling time of aged security logs.
security-log data-store-days	Configure the local storage time of security logs.
security-log data-store-items	Configure the local storage capacity for security logs.
security-log delete all	Clear logs for all key operations.
show security-log	Display all security logs.
show security-log config	Display security log configurations.
show security-log detail	Display detailed security log information.
show security-log detail export	Display detailed security log information.
show security-log detail stat	Display detailed security log statistics.
show security-log info	Display statistics during log processing.
show security-log statistics	Display security log statistics.

1.1 security-log audit-enable

Function

Run the **security-log audit-enable** command to enable security log auditing.

Run the **no** form of this command to disable this feature.

Security log auditing is enabled by default.

Syntax

security-log audit-enable

no security-log audit-enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

15

Usage Guidelines

After the security log auditing function is enabled, the device records logs for key operations, including account management, login events, system events, configuration file changes, and auditing events.

Examples

The following example enables security log auditing.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# security-log audit-enable
```

1.2 security-log auto-vacuum-time

Function

Run the **security-log auto-vacuum-time** command to configure the handling time of aged security logs.

The default handling time of aged security logs is **03:00:00** every day.

Syntax

security-log auto-vacuum-time *hh*:*mm*:*ss*

Parameter Description

hh:*mm*:*ss*: Handling time of aged security logs. Here, *hh* indicates the hour, *mm* indicates the minute, and *ss* indicates the second.

Command Modes

Global configuration mode

Default Level

15

Usage Guidelines

This command is used to configure the time for checking local logs. By default, the system checks whether any local logs have exceeded the storage time at 03:00:00 every day and deletes expired logs.

Examples

The following example sets the handling time for aged security logs to 05:05:00 every day.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# security-log auto-vacuum-time 05:05:00
```

1.3 security-log data-store-days

Function

Run the **security-log data-store-days** command to configure the local storage time of security logs.

The default local storage time of security logs is **65535** days.

Syntax

security-log data-store-days *data-store-time*

Parameter Description

data-store-time: Local storage time of security logs, in days. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

15

Usage Guidelines

- This command is used to configure the local storage time of security logs.
- The security logs for key operations are stored in the local database for **65535** days by default, and expired logs will be deleted.

Examples

The following example sets the local storage time of security logs to 300 days.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# security-log data-store-days 300
```

1.4 security-log data-store-items

Function

Run the **security-log data-store-items** command to configure the local storage capacity for security logs.

The maximum and minimum local storage capacity for security logs are **10000** and **500** (standard security requirements), respectively by default.

Syntax

security-log data-store-items *log-number*

Parameter Description

log-number: Local storage capacity for security logs. The value range is from 500 to 10000.

Command Modes

Global configuration mode

Default Level

15

Usage Guidelines

If the local storage space is insufficient, you can run this command to decrease the storage capacity for security logs.

Examples

The following example sets the local storage capacity for security logs to 5000.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# security-log data-store-items 5000
```

1.8 show security-log detail

Function

Run the **show security-log detail** command to display detailed security log information.

Syntax

show security-log detail { **all** | { **from** *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss* } } [**hostname** *hostname*] [**log-type** { **ACC_MNT** | **CONFIG** | **LOGIN** | **OTHER** | **SEC_LOG** | **SYS** }] [**peerinfo** *peerinfo*] [**user** *username*] { [**order-by** { **log-type** | **time** } { **asc** | **desc** } [**start-item** *start-item* **end-item** *end-item*]] }

Parameter Description

all: Displays all security logs.

from *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss*: Specifies the time range within which security logs are displayed. **from** specifies the start time, **to** specifies the end time, *YY* specifies the year, *MM* specifies the month, *DD* specifies the day, *hh* specifies the hour, *mm* specifies the minute, and *ss* specifies the second.

hostname *hostname*: Specifies the host name based on which security logs are displayed.

log-type: Specifies the log type based on which security logs are displayed. **SEC_LOG** specifies security log events, **ACC_MNT** specifies account management, **LOGIN** specifies login events, **SYS** specifies system events, **CONFIG** specifies configuration file changes, and **OTHER** specifies others.

peerinfo *peerinfo*: Specifies the terminal information based on which security logs are displayed. The terminal information can be the terminal name, terminal IP address, or both, such as vty0 (192.168.1.1).

user *username*: Specifies the user name based on which security logs are displayed.

order-by log-type: Orders logs by log type.

order-by time: Orders logs by log time.

asc: Orders logs in ascending mode.

desc: Orders logs in descending mode.

start-item *start-item*: Specifies the start position in the search result. The value range is from 1 to 10000.

end-item *end-item*: Specifies the end position in the search result. The value range is from 1 to 10000.

Command Modes

All modes except the user EXEC mode

Default Level

15

Usage Guidelines

This command is used to display detailed security log information, which can be filtered by time, log type, username, host name, and terminal information.

Examples

The following example displays all security logs.

```
Hostname> enable
Hostname# show security-log detail all
time, username, peerinfo, hostname, log-type: content
2019-10-22 10:00:02, admin, vty0(192.168.111.111), Hostname, SEC_LOG: SECURITY_LOG deleted all security log successfully
2019-10-22 10:00:02, admin, vty0(192.168.111.111), Hostname, SEC_LOG: SECURITY_LOG disabled security log audit configuration unsuccessfully
2019-10-22 10:00:03, -, console, Hostname, SEC_LOG: SECURITY_LOG enabled security log audit configuration successfully
……
```

1.9 show security-log detail export

Function

Run the **show security-log detail export** command to display detailed security log information.

Syntax

show security-log detail export { **all** | { **from** *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss* } } [**hostname** *hostname*] [**log-type** { **ACC_MNT** | **CONFIG** | **LOGIN** | **OTHER** | **SEC_LOG** | **SYS** }] [**peerinfo** *peerinfo*] [**user** *username*] { [**order-by** { **log-type** | **time** } { **asc** | **desc** } [**start-item** *start-item* **end-item** *end-item*]] }

Parameter Description

all: Exports all security logs.

from *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss*: Specifies the time range within which security logs are exported. **from** specifies the start time, **to** specifies the end time, *YY* specifies the year, *MM* specifies the month, *DD* specifies the day, *hh* specifies the hour, *mm* specifies the minute, and *ss* specifies the second.

hostname *hostname*: Specifies the host name based on which security logs are exported.

log-type: Specifies the log type based on which security logs are exported. **SEC_LOG** specifies security log events, **ACC_MNT** specifies account management, **LOGIN** specifies login events, **SYS** specifies system events, **CONFIG** specifies configuration file changes, and **OTHER** specifies others.

peerinfo *peerinfo*: Specifies the terminal information based on which security logs are exported. The terminal information can be the terminal name, terminal IP address, or both, such as vty0 (192.168.1.1).

user *username*: Specifies the user name based on which security logs are exported.

order-by log-type: Orders logs by log type.

order-by time: Orders logs by log time.

asc: Orders logs in ascending mode.

desc: Orders logs in descending mode.

start-item *start-item*: Specifies the start position in the export result. The value range is from 1 to 10000.

end-item *end-item*: Specifies the end position in the export result. The value range is from 1 to 10000.

Command Modes

All modes except the user EXEC mode

Default Level

15

Usage Guidelines

This command is used to export detailed security log information, which can be filtered by time, log type, username, host name, and terminal information.

You can run the **copy** command to download the exported file. The following shows an example.

```
Hostname# copy tmp:mng/security_log/export_file/log_20191022_110410_535250.csv
tftp://192.168.1.1/security_log.csv
```

Examples

The following example exports security logs of user A during the time range from 00:00:00 October 10, 2019 to 24:00:00 October 22, 2019.

```
Hostname> enable
Hostname# show security-log detail export from 2019 10 10 00:00:00 to 2019 10 22 23:59:59
user userA
Export file: tmp:mng/security_log/export_file/log_20191022_110410_535250.csv
```

1.10 show security-log detail stat

Function

Run the **show security-log detail stat** command to display detailed security log statistics.

Syntax

show security-log detail stat { **all** | { **from** *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss* } } [**hostname** *hostname*] [**log-type** { **ACC_MNT** | **CONFIG** | **LOGIN** | **OTHER** | **SEC_LOG** | **SYS** }] [**peerinfo** *peerinfo*] [**user** *username*]

Parameter Description

all: Displays all security logs.

from *YY//MM/DD hh*:*mm*:*ss* **to** *YY//MM/DD hh*:*mm*:*ss*: Specifies the time range within which security logs are displayed. **from** specifies the start time, **to** specifies the end time, *YY* specifies the year, *MM* specifies the month, *DD* specifies the day, *hh* specifies the hour, *mm* specifies the minute, and *ss* specifies the second.

hostname *hostname*: Specifies the host name based on which security logs are displayed.

log-type: Specifies the log type based on which security logs are displayed. **SEC_LOG** specifies security log events, **ACC_MNT** specifies account management, **LOGIN** specifies login events, **SYS** specifies system events, **CONFIG** specifies configuration file changes, and **OTHER** specifies others.

peerinfo *peerinfo*: Specifies the terminal information based on which security logs are displayed. The terminal information can be the terminal name, terminal IP address, or both, such as vty0 (192.168.1.1).

user *username*: Specifies the user name based on which security logs are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

15

Usage Guidelines

This command is used to display detailed security log statistics, which can be filtered by time, log type, username, host name, and terminal information.

Examples

The following example displays security log statistics of user A during the time range from 00:00:00 October 10, 2019 to 24:00:00 October 22, 2019.

```
Hostname# show security-log detail stat from 2019 10 10 00:00:00 to 2019 10 22 23:59:59
user userA
Count:555
```

1.11 show security-log info

Function

Run the **show security-log info** command to display statistics during log processing.

Syntax

show security-log info

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

15

Usage Guidelines

N/A

Examples

The following example displays security log statistics.

```
Hostname> enable
Hostname# show security-log info
Receive log count: 2000, err 1
Send syslog count: 1800
Current cached record count: 1999
Current store-in-flash record count: 5000
Historital sync flash count: 100, err 1
Reason for last sync failure: Failed to sync security logs to file database.
Next time to sync flash: 11:11:11
```

Table 1-4 Output Fields of the show security-log info Command

Field	Description
Receive log count	Number of successfully received logs (xxx) and number of logs failed to be received (xxx)
Current cached record count	Number of cached logs
Current store-in-flashrecord count	Number of logs stored in the flash memory
Historital sync flash count	Number of historical synchronization times to the flash memory (xxx) and number of failed synchronizations (xxx)
Reason for last sync failure	Reason for the last synchronization failure (which is displayed if a synchronization failure occurred and not displayed if no synchronization failure occurs)
Next time to sync flash	Next synchronization time to the flash memory, in HH:MM:SS format

1.12 show security-log statistics

Function

Run the **show security-log statistics** command to display security log statistics.

Syntax

show security-log statistics

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

15

Usage Guidelines

This command is used to display security log statistics, including the number of recorded logs and last deleted log. For details, see Table 1-5.

Examples

The following example displays security log statistics.

```
Hostname> enable
Hostname# show security-log statistics
Current storage record count: 9000
Historical record count: have written 11111, overwritten 1111
Aging record count: 1000
Last delete record: 2019-10-24 10:00:00 userA vty0(192.168.1.1) Hostname SEC_LOG:
SECURITY_LOG deleted all security log successfully
```

Table 1-5 Output Fields of the show security-log statistics Command

Field	Description
Current cache record count	Number of cached logs
Current storage record count	Number of locally stored logs
Historical storage record count	Number of historically stored logs in the local database, including the total number of stored logs (xxx) and the number of overwritten logs (xxx)
Aging record count	Number of aged logs in the local database
Last delete record	Last deleted log

Reliability Commands

1 REUP Commands

Command	Function
switchport backup interface	Configure a dual-link backup port of Rapid Ethernet Uplink Protection (REUP).
switchport backup interface preemption mode	Configure the link preemption mode of REUP.
switchport backup interface preemption delay	Configure the link preemption delay time of REUP.
mac-address-table update group	Configure a MAC address update group.
mac-address-table move update transit	Enable the function of sending MAC address update private multicast messages.
mac-address-table move update transit vlan	Configure the ID of a VLAN, in which a port sends MAC address update private multicast messages.
mac-address-table move update max-update-rate	Configure the maximum rate for sending MAC address update broadcast packets.
mac-address-table move update receive	Enable the function of receiving MAC address update private multicast messages.
mac-address-table move update receive vlan	Configure a VLAN ID range, in which MAC address update private multicast messages are received.
switchport backup interface prefer instance	Configure VLAN load balancing for a port with REUP dual-link backup enabled.
link state track	Enable a link state tracking group.
link state group	Add a port to a specified link state tracking group.
show interfaces switchport backup	Display the status information of a port with REUP dual-link backup enabled.
show mac-address-table update group	Display the information about a MAC address update group.
show mac-address-table move update	Display the statistics on the MAC address update private multicast messages sent by a port with REUP dual-link backup enabled.
show link state group	Display information about a link state tracking group.

1.1 switchport backup interface

Function

Run the **switchport backup interface** command to configure a dual-link backup port of Rapid Ethernet Uplink Protection (REUP).

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No REUP dual-link backup port is configured by default.

Syntax

switchport backup interface *interface-type interface-number*

no switchport backup interface *interface-type interface-number*

default switchport backup interface *interface-type interface-number*

Parameter Description

interface-type interface-number: Port type and number of the backup link.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When this command is configured, the port where the interface configuration mode is configured is the active port, and the port specified by the *interface-type interface-number* parameter is the backup port. When the active link corresponding to the active port is faulty, the backup port link is enabled to implement rapid recovery.

Examples

The following example configures the REUP dual-link backup function, and configures GigabitEthernet 0/1 as the active port and GigabitEthernet 0/2 as the backup port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2
```

Notifications

If a port is configured as the active port and backup port at the same time, the following notification will be displayed:

```
interface GigabitEthernet 0/1 can not backup itself.
```

If a configured active or backup port has been used to constitute another REUP pair, the following notification will be displayed:

```
interface GigabitEthernet 0/1 have already configured to another reup pair.
```

If the number of configured REUP port pairs reaches the maximum number, the following notification will be displayed:

```
Can not configure more than 16 pair.
```

Common Errors

- The configured active or backup port has been used to constitute another REUP pair.
- When the configured port is not an L2 physical port or L2 aggregate port (AP), this command is not supported.

Platform Description

N/A

Related Commands

N/A

1.2 switchport backup interface preemption mode

Function

Run the **switchport backup interface preemption mode** command to configure the link preemption mode of REUP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default link preemption mode of REUP is off mode.

Syntax

switchport backup interface *interface-type interface-number* **preemption mode** { **bandwidth** | **forced** | **off** }

no switchport backup interface *interface-type interface-number* **preemption mode**

default switchport backup interface *interface-type interface-number* **preemption mode**

Parameter Description

interface-type interface-number: Port type and number of the backup link.

bandwidth: Indicates the bandwidth mode, in which a port with a greater bandwidth is preferred for data transmission.

forced: Indicates the forced mode, in which the active port is preferred for data transmission.

off: Indicates the off mode, in which preemption is not performed.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When this command is configured, if no REUP backup port is configured for an active port, a backup port is automatically configured and added. When the **no** form of this command is run, the backup port is not deleted.

Examples

The following example configures the REUP dual-link backup function, specifies GigabitEthernet 0/1 as the active port and GigabitEthernet 0/2 as the backup port, and sets the link preemption mode of REUP to bandwidth mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2 preemption mode bandwidth
```

Notifications

If a port is configured as the active port and backup port at the same time, the following notification will be displayed:

```
interface GigabitEthernet 0/1 can not backup itself.
```

If a configured active or backup port has been used to constitute another REUP pair, the following notification will be displayed:

```
interface GigabitEthernet 0/1 have already configured to another reup pair.
```

Common Errors

- The configured active or backup port has been used to constitute another REUP pair.
- When the configured port is not an L2 physical port or L2 AP, this command is not supported.

Platform Description

N/A

Related Commands

- **switchport backup interface**

1.3 switchport backup interface preemption delay

Function

Run the **switchport backup interface preemption delay** command to configure the link preemption delay time of REUP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default preemption delay time of REUP is **35** seconds.

Syntax

switchport backup interface *interface-type interface-number* **preemption delay** *interval*

no switchport backup interface *interface-type interface-number* **preemption delay**

default switchport backup interface *interface-type interface-number* **preemption delay**

Parameter Description

interface-type interface-number: Port type and number of the backup link.

interval: Delay time for link preemption, in seconds. The value range is from 1 to 300.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Preemption delay indicates the delay time for link switching after a faulty link recovers.

It is effective only in bandwidth and forced preemption modes.

When this command is configured, if no REUP backup port is configured for an active port, a backup port is automatically configured and added. When the **no** form of this command is run, the backup port is not deleted.

Examples

The following example configures the REUP dual link backup function, specifies GigabitEthernet 0/1 as the active port and GigabitEthernet 0/2 as the backup port, and sets the link preemption mode of REUP to forced mode and the link preemption delay time to 40s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2 preemption mode forced
Hostname(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2 preemption delay 40
```

Notifications

If a port is configured as the active port and backup port at the same time, the following notification will be displayed:

```
interface GigabitEthernet 0/1 can not backup itself.
```

If a configured active or backup port has been used to constitute another REUP pair, the following notification will be displayed:

```
interface GigabitEthernet 0/1 have already configured to another reup pair.
```

Common Errors

- The configured active or backup port has been used to constitute another REUP pair.
- When the configured port is not an L2 physical port or L2 AP, this command is not supported.

Platform Description

N/A

Related Commands

1.4 mac-address-table update group

Function

Run the **mac-address-table update group** command to configure a MAC address update group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No MAC address update group is configured by default.

Syntax

mac-address-table update group [*group-id*]

no mac-address-table update group [*group-id*]

default mac-address-table update group [*group-id*]

Parameter Description

group-id: ID of a MAC address update group. The value range is from 1 to 8, and the default value is **1**.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To restore data transmission quickly after link switching, you can use the MAC address update advertising function. MAC address updates can cause massive broadcast packet flooding, which affects normal data transmission of the device. To prevent this consequence, you only need to add all ports in a switching path to the same MAC address update group so that the MAC address changes are synchronized in the group to achieve instant recovery.

Running the **no** and **default** forms of the command without specifying any parameters means that the configuration takes effect in all the update groups.

One port can belong to multiple MAC address update groups, and different types of ports can belong to the same MAC address update group.

Examples

The following example adds port GigabitEthernet 0/1 and GigabitEthernet 0/2 to MAC address update group 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface range gigabitethernet 0/1-2
Hostname(config-if-range)# mac-address-table update group 1
```

Notifications

If the number of member ports in a MAC address update group reaches the maximum value, the following notification will be displayed:

```
Can not configure more than 8 member for a flush group.
```

Common Errors

- The configured MAC address update group ID is not within the allowed value range.
- When the configured port is not an L2 physical port or L2 AP, this command is not supported.

1.5 mac-address-table move update transit

Function

Run the **mac-address-table move update transit** command to enable the function of sending MAC address update private multicast messages.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

No MAC address update private multicast message is sent by default.

Syntax

mac-address-table move update transit

no mac-address-table move update transit

default mac-address-table move update transit

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To reduce data loss in downstream data streams during link switching, you need to enable the function of sending MAC address update private multicast messages on the device where link switching occurs.

Examples

The following example enables the function of sending MAC address update private multicast messages.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mac-address-table move update transit
```

Notifications

N/A

Common Errors

1.6 mac-address-table move update transit vlan

Function

Run the **mac-address-table move update transit vlan** command to configure the ID of a VLAN, in which a port sends MAC address update private multicast messages.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the VLAN, in which a port sends MAC address update private multicast messages, is the default VLAN of the port.

Syntax

mac-address-table move update transit vlan *vlan-id*

no mac-address-table move update transit vlan

default mac-address-table move update transit vlan

Parameter Description

vlan-id: ID of a VLAN, in which a port sends MAC address update private multicast messages.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the REUP dual-link backup and the function of sending MAC address update private multicast messages have been configured on a device, when link switching is performed, the device sends the MAC address update private multicast message that carries a specified VLAN ID to the uplink device.

Examples

The following example sets the ID of a VLAN, in which port GigabitEthernet 0/1 sends MAC address update private multicast messages to 10.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# mac-address-table move update transit vlan 10
```

Notifications

If REUP is not configured for the local port, the following notification will be displayed:

```
Please enable REUP first.
```

Common Errors

- REUP is not configured for the local port.

Platform Description

N/A

Related Commands

- **switchport backup interface**

1.7 mac-address-table move update max-update-rate

Function

Run the **mac-address-table move update max-update-rate** command to configure the maximum rate for sending MAC address update broadcast packets.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default maximum rate for sending MAC address update broadcast packets is **150** packets/second.

Syntax

mac-address-table move update max-update-rate *packet-per-second*

no mac-address-table move update max-update-rate

default mac-address-table move update max-update-rate

Parameter Description

packet-per-second: Maximum rate for sending MAC address update broadcast packets, in packets per second. The value range is from 0 to 32000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If a device has been configured with REUP dual-link backup, when link switching is performed, a MAC address update broadcast packet is sent to the uplink device at the configured maximum rate to quickly recover downlink data transmission of the uplink device.

When the uplink device is another vendor's device (which does not support receiving MAC address update private multicast messages), the downlink device updates the MAC address by using the default policy (sending broadcast packets regularly), and this command is used to configure the maximum sending rate.

Examples

The following example sets the maximum rate for sending MAC address update packets to 20 packets/second.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mac-address-table move update max-update-rate 20
```

Notifications

1.8 mac-address-table move update receive

Function

Run the **mac-address-table move update receive** command to enable the function of receiving MAC address update private multicast messages.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

No MAC address update private multicast message is received by default.

Syntax

mac-address-table move update receive

no mac-address-table move update receive

default mac-address-table move update receive

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When link switching occurs on a device with REUP dual-link backup enabled, forwarding of the downstream data streams is interrupted because the MAC address table of the uplink device is not updated in time. To reduce the interruption time of L2 data streams, the MAC address table of the uplink device can be updated quickly to resume forwarding. Therefore, you need to enable the function of sending MAC address update private multicast messages on the device with dual-link backup enabled and enable the function of receiving MAC address update private multicast messages on the uplink device.

Examples

The following example enables the function of receiving MAC address update private multicast messages.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# mac-address-table move update receive
```

Notifications

N/A

Common Errors

N/A

Platform Description

1.9 mac-address-table move update receive vlan

Function

Run the **mac-address-table move update receive vlan** command to configure a VLAN ID range, in which MAC address update private multicast messages are received.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The MAC address update private multicast messages in all the VLAN ID ranges are received by default.

Syntax

mac-address-table move update receive vlan *vlan-range*

no mac-address-table move update receive [**vlan** *vlan-range*]

default mac-address-table move update receive [**vlan** *vlan-range*]

Parameter Description

vlan-range: String of the VLAN ID range, in which MAC address update private multicast messages are received. "-" indicates a continuous range, and "," indicates discrete values. The value range is from 1 to 4094.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be used to disable the function of receiving the MAC address update private multicast messages in some VLANs. For a VLAN with the function of receiving MAC address update private multicast messages disabled, MAC address update broadcast packets can be used to recover downlink transmission of the uplink device, but the convergence performance will be decreased in the case of link faults.

The VLAN ID range configured using this command is the incremental configuration. If you need to configure the function of receiving only the MAC address update private multicast messages of a certain VLAN range segment, delete all the VLAN range segments first, and then configure a new VLAN range segment.

Examples

The following example configures the function of receiving the MAC address update private multicast messages of VLAN 10 only.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no mac-address-table move update receive vlan 1-4094
Hostname(config)# mac-address-table move update receive vlan 10
```

Notifications

If the format of the entered VLAN is incorrect, the following notification will be displayed:

```
% Invalid input detected at '^' marker.
```

Common Errors

- The format of the entered VLAN is incorrect.

Platform Description

N/A

Related Commands

1.10 switchport backup interface prefer instance

Function

Run the **switchport backup interface prefer instance** command to configure VLAN load balancing for a port with REUP dual-link backup enabled.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no VLAN load balancing is configured for a port with REUP dual-link backup enabled.

Syntax

switchport backup interface *interface-type interface-number* **prefer instance** *instance-range*

no switchport backup interface *interface-type interface-number* **prefer**

default switchport backup interface *interface-type interface-number* **prefer**

Parameter Description

interface-type interface-number: Port type and number of the backup link.

instance-range: Range of instances with VLAN load balancing enabled.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can modify the mappings between instances and VLANs by using the instance mapping function of Multiple Spanning Tree Protocol (MSTP).

When this command is configured, if no REUP backup port is configured for an active port, a backup port is automatically configured and added. When the **no** form of this command is run, the backup port is not deleted.

Examples

The following example configures the REUP dual-link backup function, specifies GigabitEthernet 0/1 as the active port and GigabitEthernet 0/2 as the backup port, and configures VLAN load balancing on instance 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface GigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# switchport backup interface gigabitethernet
0/2 prefer instance 1
```

Notifications

If the port is not in the trunk/hybrid/uplink mode, the following notification will be displayed:

```
Reup vlan loadbalance only support interface on trunk, hybrid or uplink mode.
```

If a port is configured as the active port and backup port at the same time, the following notification will be displayed:

```
interface GigabitEthernet 0/1 can not backup itself.
```

If a configured active or backup port has been used to constitute another REUP pair, the following notification will be displayed:

```
interface GigabitEthernet 0/1 have already configured to another reup pair.
```

If the number of configured instances associated with MSTP reaches the maximum value, the following notification will be displayed:

```
Instance range error, right range is 0-64
```

Common Errors

- The command is configured in the trunk/hybrid/uplink mode on a non-L2 port.
- The number of instances associated with MSTP reaches the maximum value.

1.11 link state track

Function

Run the **link state track** command to enable a link state tracking group.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

All the link state tracking groups are disabled by default.

Syntax

link state track [*track-number* | **up-delay** *interval*]

no link state track [*track-number*]

default link state track [*track-number*]

Parameter Description

track-number: ID of a link state tracking group. The value range is from 1 to 2, and the default value is **1**.

up-delay *interval*: Configures the delay time for downlink recovery, in seconds. The value range is 0 to 300, and the default value is **0**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You must create a link state tracking group first and then add a port to the tracking group.

If no parameter is specified, the default link state tracking group 1 is enabled.

Examples

The following example enables link state tracking group 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# link state track 1
```

The following example enables link state tracking group 1, and configures the downlink to recover with a delay of 30s after the uplink recovers.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# link state track 1 up-delay 30
```

Function

Run the **link state group** command to add a port to a specified link state tracking group.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No port is added to a link state tracking group by default.

Syntax

link state group [*track-number*] { **upstream** | **downstream** }

no link state group

default link state group

Parameter Description

track-number: ID of a link state tracking group. The value range is from 1 to 2, and the default value is **1**. If this parameter is not specified, the link state tracking group ID is 1.

upstream: Configures an upstream port in the link state tracking group.

downstream: Configures a downstream port in the link state tracking group.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You must enable a link state tracking group and add a port to the tracking group before this command takes effect.

Examples

The following example enables link state tracking group 1, adds port GigabitEthernet 0/1 as an upstream port of link state tracking group 1 and port GigabitEthernet 0/2 as a downstream port of link state tracking group 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# link state track 1
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# link state group 1 upstream
Hostname(config-if-GigabitEthernet 0/1)# interface gigabitethernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# link state group 1 downstream
```

Notifications

If a port has been configured as a port of a link state tracking group, the following notification will be displayed:

```
Have configured a link state group for this interface GigabitEthernet 0/1.
```

If the number of upstream ports in a link state tracking group reaches the maximum value, the following notification will be displayed:

```
Can not configure more than 8 uplink member for lst group.
```

1.13 show interfaces switchport backup

Function

Run the **show interfaces switchport backup** command to display the status information of a port with REUP dual-link backup enabled.

Syntax

show interfaces [*interface-type interface-number*] **switchport backup** [**detail**]

Parameter Description

interface-type interface-number: Port type and number. After this parameter is specified, information about the REUP dual-link backup port of a specified port type and number is displayed.

detail: Displays the details of a port with REUP dual-link backup enabled. If this parameter is not specified, the brief information of a port with REUP dual-link backup enabled is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the brief information of all the ports with REUP dual-link backup enabled.

```
Hostname> enable
Hostname# show interfaces switchport backup

Switch Backup Interface Pairs:
Active Interface        Backup Interface       State
------------------------------------------------------------------------
Gi0/1                Gi0/2                Active Down/Backup Down
Gi0/3                Gi0/4                Active Down/Backup Down
Gi0/5                Ag1                 Active Down/Backup Down
```

The following example displays the details of all the ports with REUP dual-link backup enabled.

```
Hostname> enable
Hostname# show interfaces switchport backup detail

Switch Backup Interface Pairs:
Active Interface        Backup Interface       State
------------------------------------------------------------------------
Gi0/1                Gi0/2                Active Down/Backup Down
Gi0/3                Gi0/4                Active Down/Backup Down
Gi0/5                Ag1                 Active Down/Backup Down

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : off
Preemption Delay : 35 seconds
Bandwidth : Gi0/1(1000 Mbits), Gi0/2(1000 Mbits)
```

```
Interface Pair : Gi0/3, Gi0/4
Preemption Mode : forced
Preemption Delay : 120 seconds
Bandwidth : Gi0/3(1000 Mbits), Gi0/4(1000 Mbits)

Interface Pair : Gi0/5, Ag1
Preemption Mode : bandwidth
Preemption Delay : 180 seconds
Bandwidth : Gi0/5(1000 Mbits), Ag1(10000 Mbits)
```

The following example displays the details of port GigabitEthernet 0/1 with REUP dual-link backup enabled.

```
Hostname> enable
Hostname# show interfaces switchport backup detail

Switch Backup Interface Pairs:
Active Interface        Backup Interface        State
------------------------------------------------------------------------
Gi0/1                Gi0/2                Active Up/Backup Standby

Interface Pair : Gi0/1, Gi0/2
Preemption Mode : off
Preemption Delay : 50 seconds
Bandwidth : Gi0/1 (1000 Mbits), Gi0/2(1000 Mbits)
```

Table 1-1 Output Fields of the show interfaces switchport backup Command

Field	Description
Active Interface	Active port
Backup Interface	Backup port
State	Member port state (**Active** indicates an active port and **Backup** indicates a backup port): ● **Up**: Indicates the forwarding state. ● **Standby**: Indicates the blocked state. ● **Down**: Indicates that the port link is down. ● **Error**: Indicates unknown state.
Interface Pair	Member port list

Field	Description
Preemption Mode	Link preemption mode: ● **Forced**: Indicates forced mode, in which the active port is preferred for data transmission. ● **Bandwidth**: Indicates bandwidth mode, in which the port with a greater bandwidth is preferred for data transmission. ● **Off**: Indicates that the preemption mode is off, namely, no preemption is performed.
Preemption Delay	Link preemption delay, indicating the delay time for link switching after the faulty link recovers
Bandwidth	Bandwidth of the member port

1.14 show mac-address-table update group

Function

Run the **show mac-address-table update group** command to display the information about a MAC address update group.

Syntax

show mac-address-table update group [**detail**]

Parameter Description

detail: Displays the details of a MAC address update group.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the brief information of a MAC address update group.

```
Hostname>
Hostname# show mac-address-table update group

Mac-address-table Update Group:1
Member:Gi0/1, Gi0/2
```

The following example displays the details of a MAC address update group.

```
Hostname>
Hostname# show mac-address-table update group detail

Mac-address-table Update Group:1
Received mac-address-table update message count:0
Group member        Receive Count    Last Receive Switch-ID      Receive Time
Gi0/1               0              0000.0000.0000
Gi0/2               0              0000.0000.0000
```

Table 1-2 Output Fields of the show mac-address-table update group Command

Field	Description
Mac-address-table Update Group	ID of a MAC address update group
Received mac-address-table update message count	Number of the MAC address update private multicast messages received by the MAC address update group
Group member	Member port
Receive Count	Number of the MAC address update private multicast messages received by the member port
Last Receive Switch-ID	Device MAC address in the MAC address update private multicast message received by the member port last time
Receive Time	Time when the member port receives a MAC address update private multicast message last time

1.15 show mac-address-table move update

Function

Run the **show mac-address-table move update** command to display the statistics on the MAC address update private multicast messages sent by a port with REUP dual-link backup enabled.

Syntax

show mac-address-table move update

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the statistics on the MAC address update private multicast messages sent by a port with REUP dual-link backup enabled.

```
Hostname> enable
Hostname# show mac-address-table move update
Mac address table move update status:
Transit:enable
Receive:enable
Max-update-rate:150
Receive vlan:1-4094

Pair: Gi0/1,Gi0/2
Members            Status    Transit Count    Transit VLAN   Last Transit Time
-------------------------------------------------------------------------------
--------------
Gi0/1              Down      0
Gi0/2              Down      0
Pair: Ag1,Ag2
Members            Status    Transit Count    Transit VLAN   Last Transit Time
-------------------------------------------------------------------------------
--------------
Ag1                Down      0
Ag2                Down      0
Pair: Gi0/3,Ag3
Members            Status    Transit Count    Transit VLAN   Last Transit Time
```

```
--------------------------------------------------------------------------------
--------------
Gi0/3               Down      0
Ag3                 Down      0
```

Table 1-3 Output Fields of the show mac-address-table move update Command

Field	Description
Transit	Whether the function of sending MAC address update private multicast messages globally is enabled: ● **enable**: Indicates that the function is enabled. ● **disable**: Indicates that the function is disabled.
Receive	Whether the function of receiving MAC address update private multicast messages globally is enabled: ● **enable**: Indicates that the function is enabled. ● **disable**: Indicates that the function is disabled.
Max-update-rate	Maximum rate for sending MAC address update broadcast packets, in packets per second
Receive vlan	VLAN ID range for receiving MAC address update private multicast messages
Pair	REUP port pair
Members	Members of the REUP port pair
Status	Status of a member port: ● **Up**: Indicates the forwarding state. ● **Standby**: Indicates the blocked state. ● **Down**: Indicates that the port link is down. ● **Error**: Indicates unknown state.
Transit Count	Number of the MAC address update private multicast messages sent by the member port.
Transit VLAN	VLAN range, in which MAC address update private multicast messages are sent by the member port
Last Transit Time	Time when the member port sends a MAC address update private multicast message last time

1.16 show link state group

Function

Run the **show link state group** command to display information about a link state tracking group.

Syntax

show link state group

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays information about a link state tracking group.

```
Hostname> enable
Hostname# show link state group

Link State Group:1  Status: Enabled, Down
Up-delay (default 0s): 0(s)
Upstream Interfaces :Gi0/1(Down),Gi0/2(Down)
Downstream Interfaces :Gi0/3(Down)

Link State Group:2  Status: Disabled, Down
Up-delay (default 0s): 0(s)
Upstream Interfaces :
Downstream Interfaces :

(Up):Interface up   (Down):Interface Down   (Dis):Interface disabled
```

Table 1-4 Output Fields of the show link state group Command

Field	Description
Link State Group	ID of a link state tracking group

Field	Description
Status	Status of the link state tracking group: ● **Enabled**: Indicates that the link state tracking group is enabled. ● **Disabled**: Indicates that the link state tracking group is disabled. Working status of the link state tracking group: ● **Up**: Indicates that there is an upstream port with the link in the up status in the tracking group. ● **Down**: Indicates that there is no upstream port with the link in the up status in the tracking group.
Upstream Interfaces	Status of the upstream member port: ● **Up**: Indicates that the port link is in the up status. ● **Down**: Indicates that the port link is in the down status.
Downstream Interfaces	Status of the downstream member port: ● **Dis**: Indicates that the port is in error-disabled status. ● **Up**: Indicates that the port link is in the up status. ● **Down**: Indicates that the port link is in the down status. ● **ERROR**: Indicates that the port status is abnormal.

1 RLDP Commands

Command	Function
rldp detect-interval	Configure an interval for sending Rapid Link Detection Protocol (RLDP) packets by a port.
rldp detect-max	Configure the maximum detection count of RLDP.
rldp enable	Enable the global RLDP detection function.
rldp error-recover interval	Configure a time interval for RLDP to recover failed ports.
rldp neighbor-negotiation	Enable the neighbor negotiation function of RLDP.
rldp port	Enable RLDP detection on a port.
rldp reset	Recover all the failed RLDP ports and restart detection.
show rldp	Display the RLDP state information.
rldp detect-latency	Configure the loop detection latency interval of RLDP.

1.1 rldp detect-interval

Function

Run the **rldp detect-interval** command to configure an interval for sending Rapid Link Detection Protocol (RLDP) packets by a port.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default interval for sending RLDP packets by a port is **3** seconds.

Syntax

rldp detect-interval *interval*

no rldp detect-interval

default rldp detect-interval

Parameter Description

interval: Interval for sending RLDP packets by a port, in seconds. The value range is from 1 to 15.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The command takes effect for the probe packets and loop packets only.

If Spanning Tree Protocol (STP) has been enabled, you are advised to configure the command according to the rule that the total time calculated using the formula of [(Detection interval × Maximum detection count)] + 1 is smaller than the topology convergence time of STP.

Examples

The following example sets the interval for sending RLDP packets by a port to 5 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rldp detect-interval 5
```

1.2 rldp detect-max

Function

Run the **rldp detect-max** command to configure the maximum detection count of RLDP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default maximum detection count of RLDP is **2**.

Syntax

rldp detect-max *max-detect-number*

no rldp detect-max

default rldp detect-max

Parameter Description

max-detect-number: Maximum detection count of RLDP. The value range is from 2 to 10.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Maximum detection time = (Detection interval × Maximum detection count) + 1.

If a neighbor port still fails to respond when the maximum detection time expires, the link is diagnosed as a faulty link.

Examples

The following example sets the maximum detection count of RLDP to 5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rldp detect-max 5
```

1.3 rldp enable

Function

Run the **rldp enable** command to enable the global RLDP detection function.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The global RLDP detection function is disabled by default.

Syntax

rldp enable

no rldp enable

default rldp enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Only when the global RLDP detection function is enabled, can RLDP detection take effect on a port.

Examples

The following example enables the global RLDP detection function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rldp enable
```

Notifications

1.4 rldp error-recover interval

Function

Run the **rldp error-recover interval** command to configure a time interval for RLDP to recover failed ports.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No time interval for RLDP to recover failed ports regularly is configured by default.

Syntax

rldp error-recover interval *interval*

no rldp error-recover interval

default rldp error-recover interval

Parameter Description

interval: Time interval, in seconds. The value range is from 30 to 86400.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to recover failed ports regularly by RLDP.

When an RLDP port is in the error state, RLDP detection is started regularly on the port. If the error has been eliminated, the RLDP port is updated to the normal status; if the error still exists, RLDP detection is still effective on the port, and detection is restarted in the next cycle until the error is removed.

Examples

The following example sets a time interval for RLDP to recover failed ports to 600 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rldp error-recover interval 600
```

Notifications

1.5 rldp neighbor-negotiation

Function

Run the **rldp neighbor-negotiation** command to enable the neighbor negotiation function of RLDP.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The neighbor negotiation function is disabled by default.

Syntax

rldp neighbor-negotiation

no rldp neighbor-negotiation

default rldp neighbor-negotiation

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the negotiation function of RLDP is enabled, if a RLDP packet sent by a neighbor is successfully received, it is determined that the negotiation succeeds.

When the negotiation succeeds, the RLDP detection function is started on the port; otherwise, it is not started.

Examples

The following example configures the neighbor negotiation function during RLDP detection.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rldp neighbor-negotiation
```

Notifications

1.6 rldp port

Function

Run the **rldp port** command to enable RLDP detection on a port.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

RLDP detection is not configured on a port by default.

Syntax

rldp port { **bidirection-detect** | **loop-detect** | **unidirection-detect** } { **block** | **shutdown-port** | **shutdown-svi** | **warning** }

no rldp port { **bidirection-detect** | **loop-detect** | **unidirection-detect** }

default rldp port { **bidirection-detect** | **loop-detect** | **unidirection-detect** }

Parameter Description

bidirection-detect: Configures bidirectional link detection.

loop-detect: Configures loop detection.

unidirection-detect: Configures unidirectional link detection.

block: Disables the MAC address learning and forwarding functions on the port.

shutdown-port: Shuts down the port.

shutdown-svi: Shuts down the switch virtual interface (SVI) where the port is.

warning: Sends an alarm.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command can be configured on L2 and L3 physical ports.

Aggregate ports (APs) do not support this command, but the command can be configured on the member ports of an AP.

Examples

The following example enables RLDP detection on port GigabitEthernet 0/1, configures the loop detection type, and sets the failure handling method to block.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# rldp port loop-detect block
```

1.7 rldp reset

Function

Run the **rldp reset** command to recover all the failed RLDP ports and restart detection.

Syntax

rldp reset

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

2

Usage Guidelines

This command is used to restore the status of all failed ports, which can also be restored using the **errdisable recovery** command. For the introduction and specific configuration of the **errdisable recovery** command, refer to "Configuring Ethernet Interface" in *Interface Configuration Guide*.

Examples

The following example recovers all the failed RLDP ports and restarts detection.

```
Hostname> enable
Hostname# rldp reset
```

1.8 show rldp

Function

Run the **show rldp** command to display the RLDP state information.

Syntax

show rldp [**interface** *interface-type interface-number*]

Parameter Description

interface *interface-type interface-number*: Configures the RLDP port type and number. If this parameter is not specified, the RLDP state information of all the ports is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

2

Usage Guidelines

N/A

Examples

The following example displays the RLDP state information of all the ports.

```
Hostname> enable
Hostname# show rldp
rldp state       : disable
rldp hello interval: 3
rldp max hello    : 2
rldp local bridge  : 00d0.f822.37da
GigabitEthernet 0/1
port state     : normal
neighbor bridge : 0000.0000.0000
neighbor port   :
unidirection detect information:
    action: shutdown-port
    state : normal
bidirection detect information:
    action: shutdown-port
    state : normal
```

```
loop detect information:
    action: shutdown-port
    state : normal
```

Table 1-1 Output Fields of the show rldp Command

Field	Description
rldp state	State of the global RLDP function: ● **enable**: Indicates that the function is enabled. ● **disable**: Indicates that the function is disabled.
rldp hello interval	Interval for sending RLDP packets by a port, in seconds.
rldp max hello	Maximum detection count of RLDP.
rldp local bridge	MAC address of the local system. It is used to differentiate the local device from the neighbor device.
port state	Port state: ● **error**: Indicates that the link is abnormal. ● **normal**: Indicates that the link is normal.
neighbor bridge	MAC address of the neighbor system. It is used to differentiate the local device from the neighbor device.
neighbor port	Port that connects the neighbor device to the local device.
unidirection detect information	Unidirectional link detection information.
bidirection detect information	Bidirectional link detection information.
loop detect information	Loop detection information.
action	Handling policy after a link exception is detected.
state	RLDP detection state of the port: ● **error**: Indicates that the link is abnormal. ● **normal**: Indicates that the link is normal.

The following example displays the RLDP state information of port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show rldp interface gigabitethernet 0/1
port state     : normal
local bridge   : 00d0.f822.37da
neighbor bridge : 00d0.f823.37db
neighbor port   : GigabitEthernet 0/1
unidirection detect information:
    action: shutdown-port
    state : normal
```

```
bidirection detect information:
    action: shutdown-port
    state : normal
loop detect information:
    action: shutdown-port
    state : normal
```

Table 1-2 Output Fields of the show rldp interface Command

Field	Description
port state	Current state of the port: ● **Normal**: Indicates the normal state. ● **Error**: Indicates the failed state.
local bridge	MAC address of the local system. It is used to differentiate the local device from the neighbor device.
neighbor bridge	MAC address of the neighbor system. It is used to differentiate the local device from the neighbor device.
action	Handling policy after a link exception is detected.
state	RLDP detection state of the port: ● **error**: Indicates that the link is abnormal. ● **normal**: Indicates that the link is normal.

1.9 rldp detect-latency

Function

Run the **rldp detect-latency** command to configure the loop detection latency interval of RLDP.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default loop detection latency interval of RLDP is **0** seconds.

Syntax

rldp detect-latency *interval*

no rldp detect-latency

default rldp detect-latency

Parameter Description

interval: Loop detection latency interval of RLDP, in seconds. The value range is from 0 to 3600.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to suppress RLDP loop detection for core devices. Therefore, the selected latency interval is generally greater than the RLDP loop detection interval of the downlink aggregation device.

Examples

The following example sets the loop detection latency interval of RLDP to 2 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rldp detect-latency 2
```

1 DLDP Commands

Command	Function
clear dldp	Clear statistics on the link up/down counts of a Data Link Detection Protocol (DLDP) monitoring point.
dldp	Enable the DLDP detection function.
dldp passive	Set the DLDP detection mode of a port to passive mode.
dldp interval	Configure a global detection interval for DLDP detection.
dldp retry	Configure the number of global retransmission times for DLDP detection.
dldp resume	Configure the number of link recovery times for all the DLDP detection operations.
show dldp	Display the configuration or statistics of DLDP monitoring points.

1.1 clear dldp

Function

Run the **clear dldp** command to clear statistics on the link up/down counts of a Data Link Detection Protocol (DLDP) monitoring point.

Syntax

clear dldp [**interface** *interface-type interface-number* [*ipv4-address*]]

Parameter Description

interface *interface-type interface-number*: Configures the interface type and interface number.

ipv4-address: IP address of the peer device.

Command Modes

Privileged EXEC mode

Default Level

2

Usage Guidelines

DLDP records the statistics on link up/down counts. You can run this command to clear the statistics on link up/down counts of a specified monitoring point and restart counting.

You can specify an L3 port or device IP address to clear the statistics of all the monitoring points or a monitoring point on the specified L3 port. When no parameter is specified, the statistics of all the monitoring points are cleared.

Examples

The following example clears statistics on the link up/down counts of each DLDP monitoring point.

```
Hostname> enable
Hostname# clear dldp
```

The following example clears statistics on the link up/down counts of all the monitoring points on port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear dldp interface gigabitethernet 0/1
```

The following example clears statistics on the up/down counts of the link to 192.168.0.1 on port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# clear dldp interface gigabitethernet 0/1 192.168.0.1
```

1.2 dldp

Function

Run the **dldp** command to enable the DLDP detection function.

Run the **no** form of this command to disable this feature.

By default, the number of retransmission times of DLDP detection is **4**, the number of recovery times is **3**, and the detection interval is **1** second.

Syntax

dldp *ipv4-address* [*next-hop-ipv4-address*] [**mac-address** *mac-address*] [**interval** *tick-interval* | **resume** *resume-number* | **retry** *retry-number*]

no dldp *ipv4-address*

Parameter Description

ipv4-address: IP address of the peer device to be detected.

next-hop-ipv4-address: Next-hop IP address. If the peer device to be detected is in a different network segment, the next-hop IP address must be specified.

mac-address *mac-address*: Indicates the MAC address to be bound. If a next-hop IP address is specified, set this parameter to the MAC address of the next-hop device.

interval *tick-interval*: Configures the detection interval, in ticks (1 tick = 10 milliseconds). The value range is from 5 to 6000, and the value must be an integral multiple of 5.

resume *resume-number*: Configures the number of times for link recovery of the peer device to be detected, namely, the number of DLDP detection packets that need to be received consecutively before the link state changes from down to up. The value range is from 1 to 200.

retry *retry-number*: Configures the number of retransmission times. The value range is from 1 to 3600.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command is used to enable DLDP detection, to rapidly detect an Ethernet link failure.

DLDP can detect multiple IP addresses configured on an L3 port. DLDP sets the port to down when none of the IP addresses returns an ICMP reply. If one of the IP addresses resumes communication, DLDP sets the port to up.

Examples

The following example sets the IP address of port GigabitEthernet 0/1 to 192.168.0.1/24, enables DLDP detection on this port, and sets the IP address of the peer device to be detected to 192.168.0.2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet0/1)# no switchport
Hostname(config-if-GigabitEthernet0/1)# ip address 192.168.0.1 255.255.255.0
Hostname(config-if-GigabitEthernet0/1)# dldp 192.168.0.2
```

The following example sets the IP address of port GigabitEthernet 0/1 to 192.168.0.1/24, enables inter-network segment DLDP detection on this port, and sets the IP address of the peer device to be detected to 192.168.1.1 and the next-hop routing IP address to 192.168.0.2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet0/1)# no switchport
Hostname(config-if-GigabitEthernet0/1)# ip address 192.168.0.1 255.255.255.0
Hostname(config-if-GigabitEthernet0/1)# dldp 192.168.1.1 192.168.0.2
```

The following example disables DLDP detection for the peer IP address 192.168.0.2 on the port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet0/1)# no dldp 192.168.0.2
```

1.3 dldp passive

Function

Run the **dldp passive** command to set the DLDP detection mode of a port to passive mode.

Run the **no** form of this command to remove this configuration.

The default DLDP detection mode is active mode.

Syntax

dldp passive

no dldp passive

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If DLDP detection is enabled on the devices at both ends and both devices send ICMP echo packets to each other to realize connectivity detection, duplicate packets will exist. During DLDP detection, so long as the device at one end sends an ICMP echo packet and the peer device judges whether the packet can be received in time by using the same detection parameters, both devices can detect the link connectivity. In this way, DLDP detection saves bandwidth and CPU resources. Therefore, the device responsible for sending ICMP echo packets can be configured to work in active mode, and the device used for only receiving ICMP echo packets can be configured to work in passive mode.

When the passive mode is enabled, ensure that the time parameter configuration of the peer device is completely consistent with that of the local device so that the link detection state is synchronized. Otherwise, in the passive mode, the link state may be misjudged because the peer device fails to send packets synchronously.

Examples

The following example sets the DLDP detection mode to passive mode for port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet0/1)# dldp passive
```

1.4 dldp interval

Function

Run the **dldp interval** command to configure a global detection interval for DLDP detection.

Run the **no** form of this command to remove this configuration.

The default global detection interval of DLDP detection is **1** second.

Syntax

dldp interval *tick-interval*

no dldp interval

Parameter Description

tick- interval: Detection interval, in ticks (1 tick = 10 milliseconds). The value range is from 5 to 6000, and the value must be an integral multiple of 5.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The configuration of this command takes effect immediately for all DLDP detection operations.

When a network device does not receive any reply packet from the peer device within the period of the detection interval multiplied by the number of detection retransmission times, the device determines that the L3 port is down (despite the physical link reachable). When normal communication is resumed, the L3 port is up.

When adjusting this parameter, you need to take into account the number of DLDP sessions and the CPP bandwidth; otherwise the device performance is consumed, and misjudgment and network flapping can be caused easily. Generally, you are advised to use the default configuration. When the number of DLDP sessions exceeds 10, you are advised to configure a detection interval not less than 100 ticks.

Examples

The following example sets a global detection interval of DLDP detection to 200 milliseconds (200 ticks).

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dldp interval 20
```

1.5 dldp retry

Function

Run the **dldp retry** command to configure the number of global retransmission times for DLDP detection.

Run the **no** form of this command to remove this configuration.

The default number of global retransmission times of DLDP detection is **4**.

Syntax

dldp retry *retry-number*

no dldp retry

Parameter Description

retry-number: Number of retransmission times. The value range is from 1 to 3600.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The configuration of this command takes effect immediately for all DLDP detection operations.

Setting the number of retransmission times to 1 can easily lead to misjudgment and network flapping. You are advised to set the number of retransmission times to 2 at least.

Examples

The following example sets the number of retransmission times to 4 for all DLDP detection operations.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dldp retry 4
```

1.6 dldp resume

Function

Run the **dldp resume** command to configure the number of link recovery times for all the DLDP detection operations.

Run the **no** form of this command to restore the default configuration.

The default number of link recovery times of all DLDP detection operations is **3**.

Syntax

dldp resume *resume-number*

no dldp resume

Parameter Description

no dldp resume: Configures the number of times for link recovery for the peer device to be detected. This parameter specifies the number of DLDP detection packets that need to be received consecutively before the link state changes from down to up. The value range is 1 to 200.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The configuration of this command takes effect immediately for all DLDP detection operations.

Setting the number of recovery times to 1 can easily lead to misjudgment and network flapping. You are advised to set the number of recovery times to 2 at least.

Examples

The following example sets the number of link recovery times to 4 for all DLDP detection operations.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# dldp resume 4
```

1.7 show dldp

Function

Run the **show dldp** command to display the configuration or statistics of DLDP monitoring points.

Syntax

show dldp [**interface** *interface-type interface-number*] [**statistic**]

Parameter Description

interface *interface-type interface-number*: Configures the port type and number. If this parameter is not configured in the command, the related information of all ports is displayed.

statistic: Displays the statistics of DLDP monitoring points. If this parameter is not configured in the command, the configuration is displayed.

Defaults

N/A

Command Modes

All modes except the user EXEC mode

Default Level

2

Usage Guidelines

You can specify parameters of an L3 port to display the configuration and statistics of all the monitoring points on the port.

Examples

The following example displays the configuration of all the monitoring points of DLDP.

```
Hostname> enable
Hostname# show dldp
Interface  Type        Ip       Next-hop    Interval  Retry  Resume  State
Gi0/1      Active   192.168.0.1  192.168.1.2  100       4      3      Up
Gi0/2      Passive  192.168.2.1             100       4      3      Up
```

The following example displays the configuration of all the monitoring points on L3 port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show dldp intface gigabitethernet 0/1
Interface  Type        Ip       Next-hop    Interval  Retry  Resume  State
Gi0/1      Active   192.168.0.1  192.168.1.2  100       4      3      Up
```

Table 1-1 Output Fields of the show dldp Command

Field	Description
Interface	Name of a detected port.

Field	Description
Type	Detection mode.
Ip	IP address of the detected peer device.
Next-hop	Next-hop IP address for detection.
Interval	Detection interval.
Retry	Number of retransmission times.
Resume	Number of link recovery times.
State	Detection state.

The following example displays the statistics of all the monitoring points of DLDP.

```
Hostname> enable
Hostname# show dldp statistic
Interface  Type        Ip      record-time  Up-count  Down-count
Gi0/1     Active   192.168.0.1  2h34m5s     10       9
Gi0/2     Passive  192.168.2.1  1d2h3m52s    6        8
```

The following example displays the statistics of all the monitoring points on L3 port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show dldp interface gigabitethernet 0/1 statistic
Interface  Type        Ip      record-time  Up-count  Down-count
Gi0/1     Active   192.168.0.1  2h34m5s     10       9
```

Table 1-2 Output Fields of the show dldp statistic Command

Field	Description
Interface	Name of a detected port.
Type	Detection mode.
Ip	IP address of the detected peer device.
record-time	Time duration for collecting statistics on link up/down counts. The format of the displayed time duration is *y***d**h**m**s, where "y" indicates year, "d" indicates day, "h" indicates hour, "m" indicates minute, and "s" indicates second. Based on the values of the **Up-count** and **Down-count** parameters, you can know about the link up and down counts in this duration.
Up-count	Number of times that the protocol state is up, recorded for the corresponding monitoring point.
Down-count	Number of times that the protocol state is down, recorded for the corresponding monitoring point.

1 VRRP Commands

Command	Function
show vrrp	Display the information of a VRRP group.
show vrrp interface	Display the VRRP group information of a specified port.
show vrrp packet statistics	Display the statistics of VRRP packets.
vrrp ipv6 accept_mode	Enable the function of receiving packets whose destination addresses are the IPv6 address of a virtual router.
vrrp authentication	Enable the VRRP packet authentication function.
vrrp bfd (Global configuration mode)	Configure the global IPv4 VRRP bidirectional forwarding detection (BFD).
vrrp bfd (Interface configuration mode)	Configure BFD correlation for an IPv4 VRRP group.
vrrp delay	Configure a startup delay for a VRRP backup group.
vrrp description	Configure a name for a VRRP group.
vrrp detection-vlan	Configure a method of sending IPv4 VRRP packets on a super VLAN port.
vrrp mode dual-active	Configure an IPv4 VRRP group to run in dual-active mode.
vrrp ip	Configure an IPv4 VRRP backup group and specify a virtual IPv4 address.
vrrp ipv6	Configure an IPv6 VRRP backup group and specify a virtual IPv6 address.
vrrp preempt	Configure the preemption mode for a VRRP group.
vrrp priority	Configure a priority for a VRRP group.
vrrp timers advertise	Configure the interval for the master device in a VRRP group to send VRRP advertisements.
vrrp timers learn	Enable the timer learning function for a VRRP group.
vrrp track	Enable the port link or IP route accessibility tracking function of IPv4 VRRP.

vrrp ipv6 track	Enable the port link or IP route accessibility tracking function of IPv6 VRRP.
vrrp version	Configure the standard for sending VRRP multicast packets for IPv4 VRRP.

1.1 show vrrp

Function

Run the **show vrrp** command to display the information of a VRRP group.

Syntax

show [**ipv6**] **vrrp** [**brief** | *group-id*]

Parameter Description

ipv6: Indicates an IPv6 VRRP group. If this parameter is not specified, the information of an IPv4 VRRP group is displayed.

brief: Displays brief information of VRRP. If this parameter is not specified, the complete information is displayed.

group-id: ID of a VRRP group. The value ranges from 1 to 255. If this parameter is not specified, the information of all VRRP groups is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is specified, the details of all IPv4 VRRP groups are displayed.

Examples

The following example displays the details of all the IPv4 VRRP groups.

```
Hostname> enable
Hostname# show vrrp
GigabitEthernet 0/1 - Group 1
State is Backup
Virtual IP address is 192.168.201.1 configured
Virtual MAC address is 0000.5e00.0101
Advertisement interval is 3 sec
Preemption is enabled
min delay is 0 sec
Priority is 100
Master Router is 192.168.201.213 , priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.82 sec
GigabitEthernet 0/1 - Group 2
State is Master
Virtual IP address is 192.168.201.2 configured
Virtual MAC address is 0000.5e00.0102
Advertisement interval is 3 sec
```

```
Preemption is enabled
min delay is 0 sec
Priority is 120
Master Router is 192.168.201.217 (local), priority is 120
Master Advertisement interval is 3 sec
Master Down interval is 10.59 sec
```

The following example displays the details of all the IPv6 VRRP groups.

```
Hostname> enable
Hostname# show ipv6 vrrp
GigabitEthernet 0/13 - Group 1
  State is Master
  Virtual IPv6 address is as follows:
    FE80::2
    1::2
  Virtual MAC address is 0000.5e00.0201
  Advertisement interval is 1 sec
  Accept_Mode is enabled
  Preemption is enabled
    min delay is 0 sec
  Priority is 100
  Master Router is FE80::1 (local), priority is 100
  Master Advertisement interval is 1 sec
  Master Down interval is 3.60 sec
```

Table 1-1 Output Fields of the show vrrp Command

Field	Description
interface-type interface-number - Group *group-id*	• Backup group on a port. Here, *interface-type interface-number* indicates the type and number of the port, and *group-id* indicates the ID of the backup group.
State is *state*	The state of a VRRP group is *state*. Its value is as follows: • **Master**: Indicates the master state. • **Backup**: Indicates the backup state.
Virtual IP address is *ipv4-address* configured	Virtual IPv4 address of a backup group.
Virtual IPv6 address is as follows:*ipv6-address*	Virtual IPv6 address of a backup group.
Virtual MAC address is *mac-address*	Virtual MAC address of a backup group.
Advertisement interval is *interval* sec	The advertisement packet transmission interval is *interval* seconds.
Preemption is enabled	The preemption function of a backup group is enabled.

Field	Description
min delay is *min-delay* sec	The preemption delay of a backup group is *min-delay* seconds.
Priority is *priority*	The priority of a backup group is *priority*.
Master Router is *ipv4-address* (local), priority is *priority*	IP address and priority of a master router. Here, *ipv4-address* indicates an IPv4 address, and *priority* indicates a priority.
Master Advertisement interval is *interval* sec	The advertisement interval of a master router is *interval* second(s).
Master Down interval is *interval* sec	The interval for judging a failure of a master router is *interval* second(s).
Accept_Mode is enabled	The Accept_Mode of an IPv6 VRRP backup group is enabled.

The following example displays the brief information of all the IPv4 VRRP groups.

```
Hostname> enable
Hostname# show vrrp brief
Interface   Grp Pri timer   Own Pre State   Master addr     Group addr
Gi 0/1       1  100  10.82   -   P  Backup  192.168.201.213 192.168.201.1
Gi 0/1       2  120  10.59   -   P  Master  192.168.201.217 192.168.201.2
Hostname> enable
```

The following example displays the brief information of all the IPv6 VRRP groups.

```
Hostname# show ipv6 vrrp brief
Interface     Grp  Pri  timer  Own  Pre  State  Master addr  Group addr
Gi0/13        1    100  3.60   -    P    Master  FE80::1     FE80::2
```

Table 1-2 Output Fields of the show vrrp brief Command

Field	Description
Interface	Name of an Ethernet port.
Grp	ID of a VRRP backup group configured on a port.
Pri	Priority of a backup group.
timer	Interval for judging a failure of a master router, which is calculated by the backup group.
Own	Owner state of a backup group.
Pre	Preemption mode of a backup group.
State	State of a backup group.
Master addr	IP address of a master router.
Group addr	Primary virtual IP address of a backup group.

1.4 vrrp ipv6 accept_mode

Function

Run the **vrrp ipv6 accept_mode** command to enable the function of receiving packets whose destination addresses are the IPv6 address of a virtual router.

Run the **no** form of this command to disable this feature.

By default, an IPv6 VRRP group in the master state is not permitted to receive packets whose destination addresses are the IPv6 address of a virtual router, except the IPv6 VRRP group in owner state or the received NA/NS packets.

Syntax

vrrp ipv6 *group-id* **accept_mode**

no vrrp ipv6 *group-id* **accept_mode**

Parameter Description

group-id: ID of a VRRP group. The value ranges from 1 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command is configured on a network port and takes effect for a virtual router in master state.

You can configure this command for an IPv6 VRRP backup group only.

Examples

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, sets the ID of this IPv6 VRRP group to 1, and enables the function of receiving packets whose destination addresses are the IPv6 address of the virtual router on IPv6 VRRP group 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2001::1

Function

Run the **vrrp authentication** command to enable the VRRP packet authentication function.

Run the **no** form of this command to disable this feature.

The VRRP packet authentication function is disabled by default, and no authentication password is configured.

Syntax

vrrp *group-id* **authentication** *authentication-string*

no vrrp *group-id* **authentication**

Parameter Description

group-id: ID of a VRRP group. The value ranges from 1 to 255.

authentication-string: Authentication string for a VRRP group (it is a plaintext password of no more than eight bytes).

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The same authentication password must be configured for routers in the same VRRP group. The plaintext authentication password cannot guarantee security but only prevents or prompts wrong VRRP configurations. This command applies to VRRPv2 only.

Note

Authentication is abolished for VRRPv3 (IPv4 VRRP and IPv6 VRRP). If VRRPv2 is selected for an IPv4 VRRP group, the command is effective; if VRRPv3 is chosen, the command is ineffective.

Examples

The following example enables the IPv4 VRRP function on the port GigabitEthernet 0/1, sets the ID of this IPv4 VRRP group to 1, enables the VRRP packet authentication function on IPv4 VRRP group 1, and sets the authentication password to "x30dn78k".

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 authentication x30dn78k
```

Notifications

When the length of an entered authentication password exceeds eight bytes, the following notification will be displayed:

```
VRRP: Maximum authentication string length is 8.
```

Common Errors

- Different authentication modes are configured on the routers in the same VRRP group, resulting in multiple master routers in the group.
- Plaintext password authentication is configured in a VRRP group, but the authentication strings are inconsistent, which results in multiple master routers in the group.

Platform Description

N/A

- **show vrrp**

1.6 vrrp bfd (Global configuration mode)

Function

Run the **vrrp bfd** command to configure the global IPv4 VRRP bidirectional forwarding detection (BFD).

Run the **no** form of this command to remove this configuration.

The global IPv4 VRRP BFD is not configured by default.

Syntax

vrrp bfd *interface-type interface-number ipv4-address*

no vrrp bfd

Parameter Description

interface-type interface-number: Type and number of a port.

ipv4-address: Neighbor IPv4 address to be detected by BFD.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Configuring global IPv4 VRRP BFD deletes the local correlation with BFD configured for all the single IPv4 VRRP groups.

If global IPv4 VRRP BFD is configured, reconfiguring it overwrites the old global BFD configuration, that is, the old global BFD configuration is deleted automatically.

For the port, on which BFD correlation needs to be configured, you need to configure the IP address and BFD session parameters first.

This command is only applicable to an IPv4 VRRP virtual router composed of two devices.

Examples

The following example configures global IPv4 VRRP BFD, detects the forwarding path between the master and backup routers of SVI 1 through BFD, and sets the neighbor IP address to be detected by BFD to 192.168.1.100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vrrp bfd vlan 1 192.168.1.100
```

Notifications

When the specified BFD port is not an L3 port, the following notification will be displayed:

```
% Command is rejected because the interface should be a layer 3 interface.
```

When the specified IP address is not a valid IP address, the following notification will be displayed:

```
% Command is rejected because the IP address 127.0.0.1 is invalid.
```

When there is a separate BFD session in a VRRP backup group, the following notification will be displayed:

```
% All vrrp group bfd sessions were deleted because of global vrrp bfd was configured.
```

Common Errors

1.7 vrrp bfd (Interface configuration mode)

Function

Run the **vrrp bfd** command to configure BFD correlation for an IPv4 VRRP group.

Run the **no** form of this command to remove this configuration.

BFD correlation with an IPv4 VRRP group is not configured by default.

Syntax

vrrp *group-id* **bfd** *ipv4-address*

no vrrp *group-id* **bfd** *ipv4-address*

Parameter Description

group-id: ID of a VRRP group. The value ranges from 1 to 255.

ipv4-address: Neighbor IPv4 address to be detected by BFD.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If global IPv4 VRRP BFD is configured, BFD correlation with an IPv4 VRRP group is not allowed on a port.

Before configuring this command, make sure that the IP address and BFD session parameters have been configured for a port, on which BFD correlation needs to be configured.

Examples

The following example adds SVI 1 of device 1 and SVI 1 of device 2 to VRRP group 1, sets the IP addresses of SVI 1 to 1.1.1.2 and 1.1.1.3 respectively, sets the virtual IP address of the VRRP group to 1.1.1.1, and configures BFD correlation with the master and backup routes for VRRP backup group 1.

The configuration on device 1 is as follows:

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface vlan 1
Hostname(config-if-VLAN 1)# ip address 1.1.1.2 255.255.255.0
Hostname(config-if-VLAN 1)# bfd interval 50 min_rx 50 multiplier 3
Hostname(config-if-VLAN 1)# vrrp 1 ip 1.1.1.1
```

```
Hostname(config-if-VLAN 1)# vrrp 1 bfd 1.1.1.3
```

The configuration on device 2 is as follows:

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface vlan 1
Hostname(config-if-VLAN 1)# ip address 1.1.1.3 255.255.255.0
Hostname(config-if-VLAN 1)# bfd interval 50 min_rx 50 multiplier 3
Hostname(config-if-VLAN 1)# vrrp 1 ip 1.1.1.1
Hostname(config-if-VLAN 1)# vrrp 1 bfd 1.1.1.2
```

Notifications

When the specified IP address is not a valid IP address, the following notification will be displayed:

```
VRRP: 127.0.0.1 is not a valid host address.
```

When there is a global IPv4 VRRP BFD session, the following notification will be displayed:

```
% Command is rejected because global vrrp bfd[vrrp bfd VLAN 1 1.1.1.2] configured.
```

1.8 vrrp delay

Function

Run the **vrrp delay** command to configure a startup delay for a VRRP backup group.

Run the **no** form of this command to remove this configuration.

No startup delay is configured for a VRRP backup group by default.

Syntax

vrrp delay { **minimum** *min-seconds* | **reload** *reload-seconds* } *

no vrrp delay

Parameter Description

minimum *min-seconds*: Configures a startup delay for a VRRP backup group when a port changes to the active state, in seconds. The value range is from 0 to 60, and the default value is **0**.

reload *reload-seconds*: Configures a startup delay for a VRRP backup group when the system is started, in seconds. The value range is from 0 to 60, and the default value is **0**.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After a startup delay is configured for a VRRP group on a port, the VRRP backup group starts after the delay instead of starting immediately upon system startup or change of the port to the active state, to ensure that the non-preemption configuration takes effect. If the port receives a VRRP packet during the delay, the delay is canceled and VRRP is started immediately. This command configured on a network port is effective for both IPv4 VRRP and IPv6 VRRP.

Examples

The following example enables the IPv4 VRRP function on the port GigabitEthernet 0/1 of a router, and sets the IP address of the port to 10.0.1.2, the VRRP group ID to 1, the virtual IP address to 10.0.1.1, the VRRP group startup delay after system startup to 10 seconds, and the VRRP group startup delay when the port changes to the active state to 10 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# vrrp delay minimum 10 reload 10
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.2 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.1
```

1.9 vrrp description

Function

Run the **vrrp description** command to configure a name for a VRRP group.

Run the **no** form of this command to remove this configuration.

No VRRP group name is configured by default.

Syntax

vrrp [**ipv6**] *group-id* **description** *group-name*

no vrrp [**ipv6**] *group-id* **description**

Parameter Description

ipv6: Indicates an IPv6 VRRP group. If this parameter is not specified, a name is configured for an IPv4 VRRP group.

group-id: ID of a VRRP group. The value ranges from 1 to 255.

group-name: Name of the VRRP group.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Configuring a name for each VRRP group helps distinguish different VRRP groups.

Examples

The following example enables IPv4 VRRP on the port GigabitEthernet 0/1, and sets the group ID to 1 and group name to "BuildingA#", enables IPv6 VRRP on the port GigabitEthernet 0/2, and sets the group ID to 2 and group name to "BuildingB#".

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.2 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 description BuildingA#
Hostname(config-if-GigabitEthernet 0/1)# interface gigabitethernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# vrrp 2 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/2)# vrrp ipv6 2 description BuildingB#
```

Notifications

When the length of a configured VRRP group name exceeds 80 bytes, the following notification will be displayed:

```
% The length of description is up to 80!
```

1.10 vrrp detection-vlan

Function

Run the **vrrp detection-vlan** command to configure a method of sending IPv4 VRRP packets on a super VLAN port.

Run the **no** form of this command to restore the default configuration.

The IPv4 VRRP packets on a super VLAN port are sent to the first up sub VLAN only by default.

Syntax

vrrp detection-vlan { **first-subvlan** | *subvlan-id* }

no vrrp detection-vlan

Parameter Description

first-subvlan: Sends IPv4 VRRP packets only to the first up sub VLAN in a super VLAN.

subvlan-id: ID of a specified sub VLAN, to which IPv4 VRRP packets are sent. The value range is from 1 to 4094.

Command Modes

VLAN interface configuration mode

Default Level

14

Usage Guidelines

This command is configured on an SVI and effective only to super VLAN ports.

IPv4 VRRP packets can be sent in a super VLAN in three ways. Packets are sent to the first up sub VLAN in the super VLAN, or to a specified sub VLAN in the super VLAN, or to all the sub VLANs in the super VLAN. If VRRP and VRRP plus are both enabled on a super VLAN port, VRRP packets are sent to all the up sub VLAN ports of the super VLAN port.

Examples

The following example configures super VLAN 10 to send IPv4 VRRP packets to sub VLAN 2 only.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan range 2-10
Hostname(config-vlan-range)# interface vlan 10
Hostname(config-if-VLAN 10)# supervlan
Hostname(config-if-VLAN 10)# subvlan 2-9
Hostname(config-if-VLAN 10)# ip address 10.10.1.2 255.255.255.0
Hostname(config-if-VLAN 10)# vrrp 1 ip 10.10.1.1
Hostname(config-if-VLAN 10)# vrrp detection-vlan 2
```

1.11 vrrp mode dual-active

Function

Run the **vrrp mode dual-active** command to configure an IPv4 VRRP group to run in dual-active mode.

Run the **no** form of this command to restore the default configuration.

An IPV4 VRRP group runs in the master/backup mode by default.

Syntax

vrrp mode dual-active

no vrrp mode

Parameter Description

N/A

Command Modes

VLAN interface configuration mode

Default Level

14

Usage Guidelines

Configure this command on an SVI.

This command is used to configure the running mode of a VRRP group on an SVI. When **vrrp mode dual-active** is configured, the backup group runs in dual-active mode, in which the VRRP devices at both ends are in the master state. After the **no vrrp mode** command is configured, the master/backup mode is restored.

Examples

The following example configures a VRRP group on SVI 2 to run in the dual-active mode.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 2
Hostname(config-vlan)# interface vlan 2
Hostname(config-if-VLAN 2)# vrrp mode dual-active
```

1.12 vrrp ip

Function

Run the **vrrp ip** command to configure an IPv4 VRRP backup group and specify a virtual IPv4 address.

Run the **no** form of this command to remove this configuration.

No IPv4 VRRP backup group is configured by default.

Syntax

vrrp *group-id* **ip** *ipv4-address* [**secondary**]

no vrrp *group-id* **ip** *ipv4-address* [**secondary**]

Parameter Description

group-id: ID of a VRRP group. The value ranges from 1 to 255.

ipv4-address: Virtual IPv4 address of an IPv4 VRRP backup group.

secondary: Configures the secondary IPv4 address for the virtual IP address of an IPv4 VRRP backup group.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the **secondary** parameter is not specified, the configured IP address becomes the primary IP address of a VRRP backup group.

Examples

The following example enables the VRRP function on the port GigabitEthernet 0/1, and sets the ID of this VRRP group to 1, the primary IP address of the VRRP backup group to 10.0.1.20, and the secondary IP address to 10.0.2.20.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.2.1 255.255.255.0 secondary
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.2.20 secondary
```

Notifications

When the **no** form of this command is configured on a port but there is no backup group of the specified backup group ID on this port, the following notification will be displayed:

```
VRRP:there is not ipv4 group 1 on interface Vl10.
```

When the specified virtual IP address is not a valid IP address, the following notification will be displayed:

```
VRRP:127.0.0.1 is not a valid host address.
```

When a virtual IP address is configured on a port, the port is bound to the multi-protocol virtual routing and forwarding (VRF) instance, but the VRF instance is not configured with an IPv4 address family, the following notification will be displayed:

```
VRRP: VLAN 10 is linked to a VRF. Enable IPv4 on that VRF first.
```

When the configured virtual IP address overlaps with the IP address of another port in the same VRF instance, the following notification will be displayed:

```
VRRP: 192.168.23.160 overlaps with other interface's address.
```

When the configured virtual IP address is a subnet address or broadcast address on the port, the following notification will be displayed:

```
VRRP: IP address 192.168.23.0 cannot be equal to interface broadcast or subnet address.
```

When a backup group is not configured with a primary virtual IP address but configured with a secondary virtual IP address directly, the following notification will be displayed:

```
VRRP: the first address assigned to IPv4 virtual router must be primary address!
```

When the **no** form of this command is configured to delete a secondary virtual IP address, but the secondary virtual IP address is not configured on the backup group, the following notification will be displayed:

```
VRRP: 192.168.23.162 is not secondary virtual IP address of ipv4 group 1 on interface
vl2.
```

When the **no** form of this command is configured to delete a primary virtual IP address but the primary virtual IP address is not configured on the backup group, the following notification will be displayed:

```
VRRP: 192.168.23.160 is not primary virtual IP address of ipv4 group 2 on interface
vl2.
```

When the **no** form of this command is configured to delete a primary virtual IP address but a secondary virtual IP address is configured on the backup group, the following notification will be displayed:

```
VRRP: all secondary addresses must be deleted before deleting primary address.
```

Common Errors

- Different virtual IP addresses are specified for the routers in the same VRRP backup group, resulting in multiple master routers in the group.

1.13 vrrp ipv6

Function

Run the **vrrp ipv6** command to configure an IPv6 VRRP backup group and specify a virtual IPv6 address.

Run the **no** form of this command to remove this configuration.

No IPv6 VRRP backup group is configured by default.

Syntax

vrrp *group-id* **ipv6** *ipv6-address*

no vrrp *group-id* **ipv6** *ipv6-address*

Parameter Description

group-id: ID of a VRRP group. The value ranges from 1 to 255.

ipv6-address: Virtual IPv6 address of an IPv6 VRRP backup group.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

The IPv6 VRRP groups and IPv4 VRRP groups share the group ID range from 1 to 255. One VRRP backup group ID is applicable to an IPv4 VRRP backup group and an IPv6 VRRP backup group configured on the same port.

The first configured address must be a link local address, which can be deleted only after other virtual addresses are deleted.

Examples

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, and sets the ID of this VRRP group to 1 and the virtual IPv6 addresses to FE80::1 and 2001::1 respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)#ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)#ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)#vrrp 1 ipv6 2001::1
```

Notifications

When the **no** form of this command is configured on a port but there is no backup group of the specified backup group ID on this port, the following notification will be displayed:

```
VRRP:there is not ipv6 group 1 on interface vl2.
```

When the specified virtual IP address is not a valid IPv6 address, the following notification will be displayed:

```
VRRP:::1 is not a valid host address.
```

When a virtual IP address is configured on a port, the port is bound to a multi-protocol VRF instance, but the VRF instance is not configured with an IPv6 address family, the following notification will be displayed:

```
VRRP: VLAN 2 is linked to a VRF. Enable IPv6 on that VRF first.
```

When the configured virtual IP address overlaps with the IP address of another port in the same VRF instance, the following notification will be displayed:

```
VRRP: 2001::66 overlaps with other interface's address.
```

When the first virtual IP address configured for the backup group is not a link local address, the following notification will be displayed:

```
VRRP: the first address assigned to IPv6 virtual router must be link-local address.
```

When the **no** form of this command is configured to delete a virtual IP address, but the virtual IP address is not configured on the backup group, the following notification will be displayed:

```
VRRP: FE80::66 is not virtual IPv6 address of ipv6 group 1 on interface vl2.
```

When the **no** form of this command is configured to delete a link local address, but there is also a non-link local address, the following notification will be displayed:

```
VRRP: link-local address must be deleted at last.
```

Common Errors

- Different virtual IP addresses are specified for the routers in the same VRRP backup group, resulting in multiple master routers in the group.

Platform Description

1.14 vrrp preempt

Function

Run the **vrrp preempt** command to configure the preemption mode for a VRRP group.

Run the **no** form of this command to remove this configuration.

The VRRP backup group function is disabled by default. If the VRRP function is enabled, a VRRP backup group runs in preemption mode, and the master state is advertised without a delay.

Syntax

vrrp [**ipv6**] *group-id* **preempt** [**delay** *delay-seconds*]

no vrrp [**ipv6**] *group-id* **preempt** [**delay**]

Parameter Description

ipv6: Indicates an IPv6 VRRP group. If this parameter is not specified, this command configures the preemption mode for an IPv4 VRRP group.

group-id: ID of a VRRP group. The value ranges from 1 to 255.

delay-seconds: Delay time for advertising the master state, in seconds. The value range is from 0 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If a VRRP group runs in preemption mode, a higher priority router takes the place of the lower priority master router. If a VRRP group runs in non-preemption mode, a router with a priority higher than that of the master router remains in backup state.

If the virtual IP address of a VRRP group is the same as the IP address of the port (in the owner state), the configured preemption mode is not effective, because the VRRP backup group of the port has the maximum priority 255, and automatically becomes the master device in the VRRP group.

Examples

The following example enables the IPv4 VRRP function on the port GigabitEthernet 0/1 of a router, sets the ID of this IPv4 VRRP group to 1, and configures the router to preempt to become the master device after waiting for 15 seconds if the router judges that its priority (200) is higher than that of the current master device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 preempt delay 15
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 priority 200
```

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, sets the ID of this IPv6 VRRP group to 1, and configures the router to preempt to become the master device after waiting for 15 seconds if the router finds that its priority (200) is higher than that of the current master device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2001::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 preempt delay 15
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 priority 200
```

1.16 vrrp timers advertise

Function

Run the **vrrp timers advertise** command to configure the interval for the master device in a VRRP group to send VRRP advertisements.

Run the **no** form of this command to restore the default configuration.

The VRRP function is disabled by default. If the VRRP function is enabled, the interval for the master device to send advertisements is 1 second.

Syntax

vrrp [**ipv6**] *group-id* **timers advertise** { *advertise-interval* | **csec** *centisecond-interval* }

no vrrp [**ipv6**] *group-id* **timers advertise**

Parameter Description

ipv6: Indicates an IPv6 VRRP group. If this parameter is not specified, this command configures the interval for a device in an IPv4 VRRP group to send VRRP advertisements.

group-id: ID of a VRRP group. The value ranges from 1 to 255.

advertise-interval: Interval for sending VRRP advertisements, in seconds. The value range is from 1 to 255.

csec *centisecond-interval*: Specifies the interval for the master device in a backup group to send VRRP packets, in centiseconds. The value is an integer in the range from 50 to 99. No default value is provided. The command is only effective to VRRPv3 packets. If it is configured for VRRPv2, the default interval is **1** second for the master device.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

If the current device is elected as the master device in a VRRP group, it sends VRRP advertisement packets at the set interval to advertise its VRRP state, priority, and other information.

According to the RFC standard, the maximum interval for advertising multicast packets is **40** seconds. Therefore, if the advertisement interval configured is longer than 40 seconds, the maximum advertisement interval is applied, though the configuration is effective.

Examples

The following example enables the VRRP function on the port GigabitEthernet 0/1, and sets the ID of the backup group to 1 and the interval for sending IPv4 VRRP advertisements to 4 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 timers advertise 4
```

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, and sets the ID of the IPv6 VRRP group to 1 and the interval for sending IPv6 VRRP advertisements to 4 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2001::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 timers advertise 4
```

The following example enables the VRRP function on the port GigabitEthernet 0/1, and sets the ID of the backup group to 1 and the interval for sending IPv4 VRRP advertisements to 50 centiseconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
```

```
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 version 3
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 timers advertise csec 50
```

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, and sets the ID of the IPv6 VRRP group to 1 and the interval for sending IPv6 VRRP advertisements to 50 centiseconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2001::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 timers advertise csec 50
```

Notifications

When an IPv4 VRRP or IPv6 VRRP group is configured to adopt VRRPv3 for sending multicast packets, if the configured interval for sending advertisements exceeds 40 seconds, the following notification will be displayed:

```
VRRP: The Maximum adver time of VRRPv3 Packet is 40s.
```

1.17 vrrp timers learn

Function

Run the **vrrp timers learn** command to enable the timer learning function for a VRRP group.

Run the **no** form of this command to disable this feature.

The timer learning function of a VRRP group is disabled by default.

Syntax

vrrp [**ipv6**] *group-id* **timers learn**

no vrrp [**ipv6**] *group-id* **timers learn**

Parameter Description

ipv6: Indicates an IPv6 VRRP group. If this parameter is not specified, the timer learning function of an IPv4 VRRP group is enabled by default.

group-id: ID of a VRRP group. The value ranges from 1 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When the timer learning function is enabled on a backup router, it learns the VRRP advertisement transmission interval from the master device and calculates the interval for determining the failure of the master device if no packet is received from the master device, instead of using the locally configured VRRP advertisement transmission interval for calculation.

This command achieves synchronization of the VRRP advertisement transmission timer between the master and backup routers.

Examples

The following example enables the IPv4 VRRP function on the port GigabitEthernet 0/1 of a router, sets the ID of this IPv4 VRRP group to 1, and enables the timer learning function on IPv4 VRRP group 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 timers learn
```

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, sets the ID of this IPv6 VRRP group to 1, and enables the timer learning function on IPv6 VRRP group 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2001::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 timers learn
```

Notifications

N/A

Common Errors

- Different VRRP advertisement transmission intervals are configured in a VRRP group and the timer learning function is not configured, resulting in multiple master routers in the group.

Platform Description

N/A

Related Commands

1.18 vrrp track

Function

Run the **vrrp track** command to enable the port link or IP route accessibility tracking function of IPv4 VRRP.

Run the **no** form of this command to disable this feature.

The IPv4 VRRP tracking function is disabled by default.

Syntax

vrrp *group-id* **track** { **bfd** *interface-type interface-number ipv4-address* | *interface-type interface-number* | *ipv4-address* [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] } [*Priority*]

no vrrp *group-id* **track** { *interface-type interface-number* | **bfd** *interface-type interface-number ipv4-address* | *ipv4-address* }

Parameter Description

group-id: ID of a VRRP group. The value ranges from 1 to 255.

bfd *interface-type interface-number ipv4-address*: Tracks the neighbor IPv4 address of a specified port through BFD.

interface-type interface-number: Type and number of the monitored port.

ipv4-address: IPv4 address to be monitored.

interval *interval-value*: Configures the interval for sending detection packets, in seconds. The value range is from 1 to 3600. The default value is **3**.

timeout *timeout-value*: Configures the timeout time of waiting for a response to a sent detection packet, in seconds. If no response is received when the timeout time is up, it is determined that the destination is inaccessible once. The value range is from 1 to 60. The default value is **1**.

retry *retry-value*: Configures the number of retries. If no response is received for consecutive *retry-value* times, it is determined that the tracking status is inaccessible. The value range is from 1 to 60. The default value is **3**.

priority: VRRP priority change value when a monitored port link state or IP route accessibility state changes (for example, when the link is disconnected, the priority is reduced; when the link recovers, the priority is restored). The value range is from 1 to 255, and the default value is **10**.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can use this command to monitor the egress link state and route accessibility state. A monitored port must be a routable L3 logical port (for example: a routed port, an SVI, a loopback port, or a tunnel port).

To monitor a host, specify its IPv4 address.

If a VRRP group uses the actual IP address of an Ethernet port, the group priority is 255, and the monitored IP address or port can be configured, but the priority of the VRRP group is not changed.

Examples

The following example enables the IPv4 VRRP function on the port GigabitEthernet 0/1 of a router, sets the ID of this IPv4 VRRP group to 1, and configures VRRP group 1 to monitor GigabitEthernet 0/1. In this case, if the GigabitEthernet 0/1 link is disconnected, the priority of the VRRP group is reduced by 30; after the link of GigabitEthernet 0/1 is restored, the priority of VRRP group 1 is restored.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 priority 254
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 track GigabitEthernet 0/1 30
```

The following example enables the IPv4 VRRP function on the port GigabitEthernet 0/1 of a router, sets the ID of this IPv4 VRRP group to 1, configures VRRP group 1 to track the port GigabitEthernet0/1 through BFD, and sets the tracked neighbor IP address to 192.168.1.3. In this case, if the BFD tracking result is inaccessible, the priority of the VRRP group is reduced by 30; when the tracking result is accessible again, the priority of VRRP group 1 is restored.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 192.168.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# bfd interval 50 min_rx 50 multiplier 3
Hostname(config-if-GigabitEthernet 0/1)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 192.168.201.17 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 priority 120
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 192.168.201.1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 track bfd gigabitethernet 0/1
192.168.1.3 30
```

Notifications

When the monitored port is not an L3 port, the following notification will be displayed:

```
VRRP: tracked interface must be a Layer 3 interface.
```

When the monitored IP address is not a valid IP address, the following notification will be displayed:

```
VRRP: 127.0.0.1 is not a valid host address.
```

When interval-value of the monitored address configured is smaller than timeout-value, the following notification will be displayed:

```
VRRP: interval must not be less than timeout.
```

When a specified VRRP group is configured to track a specified neighbor through BFD and the tracked port is not an L3 interface, the following notification will be displayed:

```
VRRP: tracked interface must be a Layer 3 interface.
```

When a specified VRRP group is configured to track a specified neighbor through BFD, but the neighbor address is not a valid address, the following notification will be displayed:

```
VRRP: 127.0.0.1 is not a valid host address.
```

1.19 vrrp ipv6 track

Function

Run the **vrrp ipv6 track** command to enable the port link or IP route accessibility tracking function of IPv6 VRRP.

Run the **no** form of this command to disable this feature.

The IPv6 VRRP tracking function is disabled by default.

Syntax

vrrp ipv6 *group-id* **track** { *interface-type interface-number* | { *ipv6-global-address* | *ipv6-linklocal-address interface-type interface-number* } [**interval** *interval-value*] [**timeout** *timeout-value*] [**retry** *retry-value*] | **bfd** *interface-type interface-number peer-ipv6-address* } [*Priority*]

no vrrp ipv6 *group-id* **track** { *interface-type interface-number* | *ipv6-global-address* | *ipv6-linklocal-address interface-type interface- number* | **bfd** *interface-type interface-number peer-ipv6-address* }

Parameter Description

group-id: ID of a VRRP group. The value ranges from 1 to 255.

interface-type interface-number: Type and number of the monitored port.

ipv6-global-address: IPv6 global unicast address.

ipv6-linklocal-address: IPv6 link local address.

interval *interval-value*: Configures the interval for sending detection packets, in seconds. The value range is from 1 to 3600. The default value is **3**.

timeout *timeout-value*: Configures the timeout time of waiting for a response to a sent detection packet, in seconds. If no response is received when the timeout time is up, it is determined that the destination is inaccessible once. The value range is from 1 to 60. The default value is **1**.

retry *retry-value*: Configures the number of retries. If no response is received for consecutive *retry-value* times, it is determined that the tracking status is inaccessible. The value range is from 1 to 60. The default value is **3**.

priority: VRRP priority change value when a monitored port link state or IP route accessibility state changes (for example, when the link is disconnected, the priority is reduced; when the link recovers, the priority is restored). The value range is from 1 to 255, and the default value is **10**.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You can use this command to monitor the egress link state and route accessibility state. A monitored port must be a routable L3 logical port (for example: a routed port, an SVI, a loopback port, or a tunnel port).

To monitor a host, only specify its IPv6 address.

If a tracked host IP address is a link local address, specify a network port.

If a VRRP group uses the actual IP address of an Ethernet port, the group priority is 255, and the monitored IP address or port can be configured, but the priority of the VRRP group is not changed.

Examples

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, sets the ID of this IPv6 VRRP group to 1, and configures VRRP group 1 to track whether the host 1000::1 is accessible. If it is inaccessible, the priority of the VRRP group is reduced to the default value **10**. After the accessibility recovers, the priority is restored.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2001::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 priority 254
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 track 1000::1
```

The following example enables the IPv6 VRRP function on the port GigabitEthernet 0/1 on a router, sets the ID of this IPv6 VRRP group to 1, configures VRRP group 1 to track whether the host FE80::2 on SVI 1 is accessible, and reduces the priority of the VRRP group to 20 when the host is accessible. After the accessibility recovers, the priority is restored.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 enable
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2001::2/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2001::1
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 priority 254
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 track fe80::2 vlan 1 20
```

Notifications

When the monitored port is not an L3 port, the following notification will be displayed:

```
VRRP: tracked interface must be a Layer 3 interface.
```

When the monitored IP address is not a valid IP address, the following notification will be displayed:

```
VRRP: 127.0.0.1 is not a valid host address.
```

When interval-value of the monitored address configured is smaller than timeout-value, the following notification will be displayed:

```
VRRP: interval must not be less than timeout.
```

1.20 vrrp version

Function

Run the **vrrp version** command to configure the standard for sending VRRP multicast packets for IPv4 VRRP.

Run the **no** form of this command to restore the default configuration.

The default standard for sending IPv4 VRRP packets is VRRPv2 on a port.

Syntax

vrrp *group-id* **version** { **2** | **3** }

no vrrp *group-id* **version**

Parameter Description

group-id: ID of a VRRP group. The value range is from 1 to 255.

version 2: Uses the VRRPv2 standard to send multicast packets.

version 3: Uses the VRRPv3 standard to send multicast packets.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

This command applies to IPv4 VRRP only.

For IPv4 VRRP, to meet the requirements of the VRRPv2 and VRRPv3 switching scenario, you can specify a standard for sending VRRP packets based on the actual network condition. The VRRPv2 standard is based on RFC 3768, while the VRRPv3 standard is based on RFC 5798.

Examples

The following example enables the IPv4 VRRP function on the port GigabitEthernet 0/1 of a router, sets the ID of the IPv4 VRRP group to 1, and configures IPv4 VRRP group 1 to use VRRPv3 to send multicast packets.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ip address 10.0.1.1 255.255.255.0
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 10.0.1.20
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 version 3
```

1 VRRP Plus Commands

Command	Function
show vrrp balance	Display the information of a Virtual Router Redundancy Protocol Plus (VRRP Plus) group.
show vrrp balance interface	Display the information of a VRRP Plus group on a specified interface.
vrrp balance	Enable the VRRP Plus function.
vrrp forwarder preempt	Enable the forwarding preemption function for a VRRP Plus backup group.
vrrp load-balancing	Configure a load balancing policy for a VRRP Plus group.
vrrp timers redirect	Configure the redirection interval and timeout time for a proxy virtual MAC address of a VRRP Plus backup group.
vrrp weighting	Configure the weight and upper and lower thresholds for a VRRP Plus backup group.
vrrp weighting track	Configure the track object for adjusting the weight for a VRRP Plus backup group.

1.1 show vrrp balance

Function

Run the **show vrrp balance** command to display the information of a Virtual Router Redundancy Protocol Plus (VRRP Plus) group.

Syntax

show [**ipv6**] **vrrp balance** [**brief** | *group-id*]

Parameter Description

ipv6: Indicates an IPv6 VRRP Plus group. If this parameter is not specified, the information of an IPv4 VRRP Plus group is displayed.

brief: Displays brief information of a VRRP Plus group. If this parameter is not specified, the detailed information of a VRRP Plus group is displayed.

group-id: ID of a VRRP Plus group. The value range is from 1 to 255.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

If no parameter is specified, the detailed information of all the VRRP Plus groups is displayed.

Examples

The following example displays the detailed information of all the IPv4 VRRP Plus groups.

```
Hostname> enable
Hostname# show vrrp balance
VLAN 1 - Group-id 1
  State is BVG
  Virtual IP address is 192.168.1.54
  Hello time 1 sec, hold time 3 sec
  Load balancing: host-dependent
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 90 (configured 100), thresholds: lower 1, upper 100
    Track object 1, state: down, decrement weight: 10
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0101
    Owner ID is 00d0.f822.33ab
  Forwarder 2
    MAC address:
      001a.a916.0201
```

```
Owner ID is 00d0.f822.8800
```

The following example displays the detailed information of all the IPv6 VRRP Plus groups.

```
Hostname> enable
Hostname# show ipv6 vrrp balance
VLAN 2 - Group-id 1
  State is BVG
  Virtual IPv6 address is as follows:
    FE80::8
    2000::8
  Hello time 2 sec, hold time 6 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0201
    Owner ID is 00d0.f822.33f5
    Preemption disabled (BVG cannot be preempted)
  Forwarder 2
    MAC address:
      1414.4b72.7701
    Owner ID is 00d0.f822.33b9
Preemption enabled
```

Table 1-1 Output Fields of the show vrrp balance Command

Field	Description
interface-type interface-number - Group *group-id*	Backup group on a port. Here, *interface-type interface-number* indicates the type and number of the port, and *group-id* indicates the ID of the backup group.
State is *role*	The role of the device in VRRP Plus is *role*, which can be set to the following values: ● **BVG**: Indicates the balancing virtual gateway. ● **BVF**: Indicates a balancing virtual forwarder.
Virtual IP address is *ipv4-address*	The virtual IPv4 address of the VRRP Plus group is *ipv4-address*.
Virtual IPv6 address is as follows: *ipv6-address*	The virtual IPv6 address of the IPv6 VRRP Plus group is *ipv6-address*.
Hello time *hello-time* sec	The interval at which the BVG sends keepalive packets is *hello-time* seconds.
hold time *hold-time* sec	The waiting time for a device to switch from the BVF role to the BVG role is *hold-time* seconds.

Field	Description
Load balancing:*loading-policy*	The type of the load balancing policy enabled on the VRRP Plus group is *loading-policy*, which can be set to the following values: ● **host-dependent**: Indicates the host-dependent load balancing policy. ● *round-robin*: Indicates the round-robin policy. ● *weighted*: Indicates the weighted policy.
Redirect time *redirect-time* sec, forwarder time-out *time-out* sec	Redirection time and timeout time of a proxy virtual MAC address. Here, *redirect-time* indicates the redirection time; and *time-out* indicates the timeout time.
Weighting *weight* (configured *configured-weight*), thresholds: lower *lower-threshold*, upper *upper-threshold*	Current weight, configured weight, upper threshold for weight, and lower threshold for weight of the device. Here, *weight* indicates the current weight; *configured-weight* indicates the configured weight; *upper-threshold* indicates the upper threshold for weight; and *lower-threshold* indicates the lower threshold for weight.
Track object *object*, state: *state*, decrement weight: *decrement-weight*	Object tracked by the track module and its state, as well as the weight decrement when the state is down. Here, *object* indicates the object tracked by the track module; *state* indicates the current state; and *decrement-weight* indicates the weight decrement when the state is down.
Forwarder *forwarder-number*	Forwarder of the VRRP Plus group. Here, *forwarder-number* indicates the forwarder number.
MAC addresss:*mac-address*	The virtual MAC address allocated to the device by the BVG is *mac-address*.
Owner ID is:*mac-address*	The real MAC address of the device is *mac-address*.
Preemption enabled	The forwarding preemption function is enabled for the VRRP Plus backup group.

The following example displays the brief information of a VRRP Plus group.

```
Hostname> enable
Hostname# show vrrp balance brief
Interface     Grp   State     Group-id Addr      MAC addr
VLAN 1         1    BVG       192.168.1.1        0000.5e00.0101
```

The following example displays the brief information of all the IPv6 VRRP Plus groups.

```
Hostname> enable
Hostname# show ipv6 vrrp balance brief
Interface            Grp   State     Group-id Addr       MAC addr
VLAN 2               1     BVG       FE80::8             0000.5e00.0201
```

Table 1-2 Output Fields of the show vrrp balance brief Command

Field	Description
Interface	Interface with VRRP Plus enabled.
Grp	ID of a VRRP group.
State	Role of the device in the VRRP Plus group, which can be set to the following values: ● **BVG**: Indicates the balancing virtual gateway. ● **BVF**: Indicates a balancing virtual forwarder.
Group-id Addr	Virtual IP address of the VRRP group.
MAC addr	Virtual MAC address of the device.

The following example displays the detailed information of an IPv4 VRRP Plus group on the Ethernet port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# show vrrp balance interface gigabitethernet 0/1
GigabitEthernet 0/1 - Group-id 1
  State is BVG
  Virtual IP address is 192.168.1.54
  Hello time 1 sec, hold time 3 sec
  Load balancing: host-dependent
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 90 (configured 100), thresholds: lower 1, upper 100
    Track object 1, state: down, decrement weight: 10
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0101
    Owner ID is 00d0.f822.33ab
  Forwarder 2
    MAC address:
      001a.a916.0201
Owner ID is 00d0.f822.8800
```

The following example displays the detailed information of an IPv6 VRRP Plus group on the Ethernet port GigabitEthernet 0/2.

```
Hostname> enable
Hostname# show ipv6 vrrp balance interface gigabitethernet 0/2
GigabitEthernet 0/2 - Group-id 1
  State is BVG
  Virtual IPv6 address is as follows:
    FE80::8
    2000::8
  Hello time 1 sec, hold time 3 sec
  Load balancing: weighted
  Redirect time 300 sec, forwarder time-out 14400 sec
  Weighting 100 (configured 100), thresholds: lower 1, upper 100
  There are 2 forwarders
  Forwarder 1 (local)
    MAC address:
      0000.5e00.0201
```

```
   Owner ID is 00d0.f822.33f5
   Preemption disabled (BVG cannot be preempted)
 Forwarder 2
   MAC address:
     1414.4b72.7701
   Owner ID is 00d0.f822.33b9
Preemption enabled
```

Table 1-3 Output Fields of the show vrrp balance interface Command

Field	Description
interface-type interface-number - Group *group-id*	Backup group on a port. Here, *interface-type interface-number* indicates the type and number of the port, and *group-id* indicates the ID of the backup group.
State is *role*	The role of the device in VRRP Plus is *role*, which can be set to the following values: **BVG**: Indicates the balancing virtual gateway. **BVF**: Indicates a balancing virtual forwarder.
Virtual IP address is *ipv4-address*	The virtual IPv4 address of the VRRP Plus group is *ipv4-address*.
Virtual IPv6 address is as follows: *ipv6-address*	The virtual IPv6 address of the IPv6 VRRP Plus group is *ipv6-address*.
Hello time *hello-time* sec	The interval at which the BVG sends keepalive packets is *hello-time* seconds.
hold time *hold-time* sec	The waiting time for a device to switch from the BVF role to the BVG role is *hold-time* seconds.
Load balancing:*loading-policy*	The type of the load balancing policy enabled on the VRRP Plus group is *loading-policy*, which can be set to the following values: ● **host-dependent**: Indicates the host-dependent load balancing policy. ● *round-robin*: Indicates the round-robin policy. ● *weighted*: Indicates the weighted policy.
Redirect time *redirect-time* sec, forwarder time-out *time-out* sec	Redirection time and timeout time of a proxy virtual MAC address. Here, *redirect-time* indicates the redirection time; and *time-out* indicates the timeout.
Weighting *weight* (configured *configured-weight*), thresholds: lower *lower-threshold*, upper *upper-threshold*	Current weight, configured weight, upper threshold for weight, and lower threshold for weight of the device. Here, *weight* indicates the current weight; *configured-weight* indicates the configured weight; *upper-threshold* indicates the upper threshold for weight; and *lower-threshold* indicates the lower threshold for weight.

Field	Description
Track object *object*, state: *state*, decrement weight: *decrement-weight*	Object tracked by the track module and its state, as well as the weight decrement when the state is down. Here, *object* indicates the object tracked by the track module; *state* indicates the current state; and *decrement-weight* indicates the weight decrement when the state is down.
Forwarder *forwarder-number*	Forwarder of the VRRP Plus group. Here, *forwarder-number* indicates the forwarder number.
MAC addresss:*mac-address*	The virtual MAC address allocated to the device by the BVG is *mac-address*.
Owner ID is:*mac-address*	The real MAC address of the device is *mac-address*.
Preemption enabled	The forwarding preemption function is enabled for the VRRP Plus backup group.

1.3 vrrp balance

Function

Run the **vrrp balance** command to enable the VRRP Plus function.

Run the **no** form of this command to disable this feature.

The VRRP Plus function is disabled by default.

Syntax

vrrp [**ipv6**] *group-id* **balance**

no vrrp [**ipv6**] *group-id* **balance**

Parameter Description

ipv6: Indicates an IPv6 VRRP Plus group. If this parameter is not specified, an IPv4 VRRP Plus group is configured.

group-id: ID of a VRRP group. The value of the parameter ranges from 1 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

To enable the VRRP Plus function, you need to first configured a VRRP group.

Examples

The following example enables the VRRP Plus function on the L3 port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 192.168.1.1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 balance
```

The following example enables the IPv6 VRRP Plus function on the L3 port GigabitEthernet 0/2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/2
Hostname(config-if-GigabitEthernet 0/2)# vrrp 1 ipv6 fe80::8
Hostname(config-if-GigabitEthernet 0/2)# vrrp 1 ipv6 2000::8
Hostname(config-if-GigabitEthernet 0/2)# vrrp ipv6 1 balance
```

1.4 vrrp forwarder preempt

Function

Run the **vrrp forwarder preempt** command to enable the forwarding preemption function for a VRRP Plus backup group.

Run the **no** form of this command to disable this feature.

The forwarding preemption function is enabled for a VRRP Plus backup group by default.

Syntax

vrrp [**ipv6**] *group-id* **forwarder preempt**

no vrrp [**ipv6**] *group-id* **forwarder preempt**

Parameter Description

ipv6: Indicates an IPv6 VRRP Plus group. If this parameter is not specified, the forwarding preemption function is enabled for an IPv4 VRRP Plus group.

group-id: ID of a VRRP Plus group. The value range is from 1 to 255.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

1.5 vrrp load-balancing

Function

Run the **vrrp load-balancing** command to configure a load balancing policy for a VRRP Plus group.

Run the **no** form of this command to remove this configuration.

The default load balancing policy of a VRRP Plus group is round robin mode.

Syntax

vrrp [**ipv6**] *group-id* **load-balancing** { **host-dependent** | **round-robin** | **weighted** }

no vrrp [**ipv6**] *group-id* **load-balancing** { **host-dependent** | **round-robin** | **weighted** }

Parameter Description

ipv6: Indicates an IPv6 VRRP Plus group. If this parameter is not specified, the load balancing policy is configured for an IPv4 VRRP Plus group.

group-id: ID of a VRRP Plus group. The value range is from 1 to 255.

host-dependent: Indicates the host-dependent load balancing policy. In this policy, different virtual MAC addresses are used to respond to ARP requests from different hosts.

round-robin: Indicates the round-robin load balancing policy. In this policy, different virtual MAC addresses are used to respond to host ARP requests in turn.

weighted: Indicates the weighted load balancing policy. In this policy, ARP replies are given based on weight values of devices in a backup group.

Command Modes

Interface configuration mode

Default Level

1.6 vrrp timers redirect

Function

Run the **vrrp timers redirect** command to configure the redirection interval and timeout time for a proxy virtual MAC address of a VRRP Plus backup group.

Run the **no** form of this command to restore the default configuration.

The default redirection interval of proxy virtual MAC addresses of a VRRP Plus backup group is **300** seconds and the default redirection timeout time is **14400** seconds.

Syntax

vrrp [**ipv6**] *group-id* **timers redirect** *redirect-interval redirect-timeout*

no vrrp [**ipv6**] *group-id* **timers redirect**

Parameter Description

ipv6: Indicates an IPv6 VRRP Plus group. If this parameter is not specified, the redirection interval and redirection timeout time are configured for a proxy virtual MAC address of an IPv4 VRRP Plus group.

group-id: ID of a VRRP Plus group. The value range is from 1 to 255.

redirect-interval: Redirection interval, in seconds. The value range is from 0 to 3600.

redirect-timeout: Redirection timeout, in seconds. The value range is from (*redirect-interval*+600) to 64800.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You must enable the VRRP Plus function before configuring the redirection interval and timeout time for a proxy virtual MAC address of a VRRP Plus backup group.

Examples

The following example sets the redirection interval for a proxy virtual MAC address of VRRP Plus group 1 to **300** seconds and the redirection timeout time to **6000** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 192.168.1.1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 balance
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 timers redirect 300 6000
```

The following example sets the redirection interval for a proxy virtual MAC address of IPv6 VRRP Plus group 1 to **300** seconds and the redirection timeout time to **6000** seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::8
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2000::8
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 balance
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 timers redirect 300 6000
```

1.7 vrrp weighting

Function

Run the **vrrp weighting** command to configure the weight and upper and lower thresholds for a VRRP Plus backup group.

Run the **no** form of this command to restore the default configuration.

The default weight, default upper threshold, and default lower threshold of a VRRP Plus backup group are **100**, **1**, and **100** respectively.

Syntax

vrrp [**ipv6**] *group-id* **weighting** *weight-limit* [**lower** *min-weight-value*] [**upper** *max-weight-value*]

no vrrp [**ipv6**] *group-id* **weighting**

Parameter Description

ipv6: Indicates an IPv6 VRRP Plus group. If this parameter is not specified, the weight and upper and lower thresholds are configured for an IPv4 VRRP Plus group.

group-id: ID of a VRRP Plus group. The value range is from 1 to 255.

weight-limit: Weight value. The value range is from 2 to 254.

lower *min-weight-value*: Indicates the lower threshold of the weight. The value range is from 1 to (*weight-limit* - 1).

upper *max-weight-value*: Indicates the upper threshold of the weight. The value range is from *min-weight-value* to *weight-limit.* That is, the value is between the minimum value of the weight (*min-weight-value*) and the maximum value of the weight (*weight-limit*).

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

You must enable the VRRP Plus function before configuring the weight and upper and lower thresholds for a VRRP Plus backup group.

Examples

The following example sets the weight of VRRP Plus group 1 to **50**, and the lower threshold and upper threshold of weight to **30** and **50** respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 192.168.1.1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 balance
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 weighting 50 lower 30 upper 50
```

The following example sets the weight of IPv6 VRRP Plus 1 to **50**, and the lower threshold and upper threshold of weight to **30** and **50** respectively.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::8
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2000::8
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 balance
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 weighting 50 lower 30 upper 50
```

1.8 vrrp weighting track

Function

Run the **vrrp weighting track** command to configure the track object for adjusting the weight for a VRRP Plus backup group.

Run the **no** form of this command to restore the default configuration.

This command is not configured by default.

Syntax

vrrp [**ipv6**] *group-id* **weighting track** *object-number* [**decrement** *value*]

no vrrp [**ipv6**] *group-id* **weighting track** *object-number*

Parameter Description

ipv6: Indicates an IPv6 VRRP Plus group. If this parameter is not specified, the track object for adjusting the weight is configured for an IPv4 VRRP Plus group.

group-id: ID of a VRRP Plus group. The value range is from 1 to 255.

object-number: Number of the track object created by the track module. The value range is from 1 to 700.

value: Weight decrement when the track object is down. The value range is from 1 to 255. The default value is **10**.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the track object for adjusting the weight for VRRP Plus group 1, configures the group to track the port GigabitEthernet 0/2, and sets the weight decrement when the track object is down to 50.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 1 interface gigabitethernet 0/2 line-protocol
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ip 192.168.1.1
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 balance
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 weighting track 1 decrement 50
```

The following example configures the track object for adjusting the weight for IPv6 VRRP Plus group 1, configures the group to track the port GigabitEthernet 0/2, and sets the weight decrement when the track object is down to 50.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 1 interface gigabitethernet 0/2 line-protocol
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# ipv6 address 2000::1/64
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 fe80::8
Hostname(config-if-GigabitEthernet 0/1)# vrrp 1 ipv6 2000::8
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 balance
Hostname(config-if-GigabitEthernet 0/1)# vrrp ipv6 1 weighting track 1 decrement 50
```

1 BFD Commands

Command	Function
bfd interval	Configure bidirectional forwarding detection (BFD) session parameters.
bfd bind peer-ip	Associate the interface status with the BFD sessions status.
bfd cpp	Enable BFD protection.
bfd echo	Enable the echo mode.
bfd slow-timer	Configure the slow timer time in the echo mode.
bfd up-dampening	Configure a delay for status change advertisement, after which BFD informs an associated application.
sbfd reflector discriminator	Configure a seamless bidirectional forwarding detection (SBFD) reflector discriminator.
show bfd neighbors	Display the information of a BFD session.
show sbfd reflector discriminator	Display the information of an SBFD reflector discriminator.
show sbfd reflector initiator-mapping	Display the mappings between the SBFD reflector and the initiator.

1.1 bfd interval

Function

Run the **bfd interval** command to configure bidirectional forwarding detection (BFD) session parameters.

Run the **no** form of this command to remove this configuration.

Bidirectional forwarding detection (BFD) session parameters are not configured by default..

Syntax

bfd interval *send-interval* **min_rx** *receive-interval* **multiplier** *multiplier-value*

no bfd interval

Parameter Description

interval *send-interval*: Configures the interval of sending BFD control packets to a neighbor of a BFD session, which is also the interval of echo packets. The value ranges from 50 to 999, in milliseconds.

min_rx *receive-interval*: Configures the interval for the local device of a BFD session to receive BFD control packets from a neighbor. The value ranges from 50 to 999, in milliseconds.

multiplier-value: Maximum number of BFD control packets from the peer end that can be discarded within the negotiation interval. The value range is from 3 to 50.

Command Modes

Interface configuration mode

BFD template configuration mode

Default Level

14

Usage Guidelines

You are advised to keep the parameter configuration consistent at both ends of a BFD session. The purpose is to ensure that the application protocols associated with BFD take effect simultaneously and prevent occurrence of one-way forwarding path due to different dampening time at both ends.

Transmission bandwidth differences of different interfaces need to be taken into account during parameter configuration. If the configured minimum Tx interval and minimum Rx interval are very small, BFD may occupy excessive bandwidth and affect data transmission.

When a session negotiation is not completed on a port during command execution, the system prompts that a session negotiation is in progress and returns a configuration failure.

Examples

The following example configures the BFD session parameters for the L3 port GigabitEthernet0/1, and sets the interval of sending BFD packets to **100** ms, the interval of receiving BFD packets to **100** ms, and the maximum number of packets that can be discarded to **3**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
```

```
Hostname(config-if-GigabitEthernet0/1)# bfd interval 100 min_rx 100 multiplier 3
```

The following example configures the BFD session parameters for the template template1, and sets the interval of sending BFD packets to **100** ms, the interval of receiving BFD packets to **100** ms, and the maximum number of packets that can be discarded to **3**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bfd-template multi-hop template1
Hostname(config-bfd)# bfd interval 100 min_rx 100 multiplier 3
```

1.2 bfd bind peer-ip

Function

Run the **bfd bind peer-ip** command to associate the interface status with the BFD sessions status.

Run the **no** form of this command to remove this configuration.

No interface status is associated with the BFD sessions status by default.

Syntax

bfd bind peer-ip *ipv4-address* [**source-ip** *ipv4-address*] **process-pst**

no bfd bind peer-ip *ipv4-address*

Parameter Description

peer-ip *ipv4-address*: Configures the peer IP address for detection. It must be set to the address of a directly connected L3 interface.

source-ip *ipv4-address*: Configures the source IP address for sending BFD packets. The source IP address is specified to ensure that packets are not discarded by the unicast reverse path forwarding (URPF) when BFD is used together with URPF and other functions. The default source IP address is **0**, and the source IP address is learned through BFD session negotiation.

process-pst: Associates the session with the BFD state of an L3 interface.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Configure this command on an L3 interface and make sure that the detected peer IP address is the address of the directly connected interface.

Examples

The following example enables BFD on the L3 port GigabitEthernet 0/1, and sets the peer IP address to 192.168.0.2, and associates the interface with the BFD state of the interface.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet0/1)# ip address 192.168.0.1 255.255.255.0
Hostname(config-if-GigabitEthernet0/1)# bfd bind peer-ip 192.168.0.2 source-ip
192.168.0.1 process-pst
```

Notifications

When the memory is insufficient during the execution of this command and the configuration fails, the following notification will be displayed:

```
no enough memory for this config.
```

Common Errors

1.3 bfd cpp

Function

Run the **bfd cpp** command to enable BFD protection.

Run the **no** form of this command to disable this feature.

BFD protection is enabled by default.

Syntax

bfd cpp

no bfd cpp

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The BFD protocol is very sensitive. If a BFD-enabled device is attacked, BFD protection can be enabled to provide protection.

If both BFD and BFD protection are enabled, the device discards the BFD packets received from the previous-hop device, which affects the establishment of a BFD session between the previous-hop device and other devices.

Examples

The following example enables BFD protection.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bfd cpp
```

1.4 bfd echo

Function

Run the **bfd echo** command to enable the echo mode.

Run the **no** form of this command to disable this feature.

The echo mode is disabled for a BFD session by default.

Syntax

bfd echo [**one-arm**]

no bfd echo

Parameter Description

one-arm: Indicates a one-armed echo mode.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

By default, when BFD session parameters are configured, the system automatically enables the asynchronous mode, and disables the one-armed echo mode.

The minimum TX interval and minimum RX interval of echo packets adopt the **Interval** *send-interval* and **min_rx** *receive-interval* parameters of a session.

Before enabling the echo mode or one-armed echo mode of BFD, run the **no ip redirects** command on the neighbors of a BFD session to disable the function of sending ICMP redirection packets, and run the **no ip deny land** command to disable the distributed denial of service (DDoS) function to prevent the land-based attack.

The echo mode takes effect only after it is enabled at both ends of a BFD session.

The one-armed echo mode takes effect when it is enabled at one end of a BFD session.

In the process that the forwarding plane of the peer device returns echo packets transmitted by the local end to the local end, the echo packets may be lost due to congestion of the peer device, causing a session detection failure. In this case, you need to configure a quality of service (QoS) policy to ensure that echo packets are processed preferentially or disable the echo function.

Examples

The following example enables the echo mode on the L3 port GigabitEthernet0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet0/1)# bfd echo
```

The following example enables the one-armed echo mode on the L3 port GigabitEthernet0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
Hostname(config-if-GigabitEthernet0/1)# bfd echo one-arm
```

Notifications

When the memory is insufficient during the execution of this command and the configuration fails, the following notification will be displayed:

```
no enough memory for this config.
```

When the interface line bandwidth is insufficient during the execution of this command and the configuration fails, the following notification will be displayed:

1.5 bfd slow-timer

Function

Run the **bfd slow-timer** command to configure the slow timer time in the echo mode.

Run the **no** form of this command to restore the default configuration.

The default slow timer time in the echo mode is **2000** milliseconds.

Syntax

bfd slow-timer [*interval*]

no bfd slow-timer

Parameter Description

interval: Slow timer time of BFD, in milliseconds. The value range is from 1000 to 30000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the slow timer time in the echo mode to **14000** milliseconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# bfd slow-timer 14000
```

1.6 bfd up-dampening

Function

Run the **bfd up-dampening** command to configure a delay for status change advertisement, after which BFD informs an associated application.

Run the **no** form of this command to restore the default configuration.

The default delay for status change advertisement, after which BFD informs an associated application of BFD up is **0** seconds.

Syntax

bfd up-dampening *interval*

no bfd up-dampening

Parameter Description

interval: Required delay for status change advertisement, after which BFD informs an associated application of BFD up, in milliseconds. The value range is 0 to 300000. When the parameter is set to **0**, the associated application is informed immediately when the session state is switched from down to up.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

Enable this function only when the link is unstable.

If a BFD session does not frequently switch between the down and up states, configuring this command will delay notifying an associated application of BFD up.

Examples

The following example sets the delay for status change advertisement, after which BFD informs an associated application of BFD up, to **60,000** milliseconds on the port GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitethernet 0/1
```

```
Hostname(config-if-GigabitEthernet0/1)# bfd up-dampening 60000
```

Notifications

When the memory is insufficient during the execution of this command and the configuration fails, the following notification will be displayed:

```
no enough memory for this config.
```

When the interface line bandwidth is insufficient during the execution of this command and the configuration fails, the following notification will be displayed:

```
no enough bandwidth for this config.
```

1.7 sbfd reflector discriminator

Function

Run the **sbfd reflector discriminator** command to configure a seamless bidirectional forwarding detection (SBFD) reflector discriminator.

Run the **no** form of this command to remove this configuration.

No SBFD reflector discriminator is configured by default.

Syntax

sbfd reflector discriminator { *unsigned-integer-descriptor* | *ipv4-address* }

no sbfd reflector discriminator { *unsigned-integer-descriptor* | *ipv4-address* }

Parameter Description

unsigned-integer-descriptor: Discriminator of the integer type. The value range is from 16777216 to 4294967295.

ipv4-address: IPv4 address, in dotted decimal notation.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Like BFD sessions, SBFD sessions also distinguish different sessions through My Discriminator and Your Discriminator. Since the reflector of SBFD does not perceive the detection service and is responsible for only

looping back packets, only a reflector discriminator needs to be configured by running the **reflector discriminator** command at the reflector. This discriminator is Your Discriminator for the initiator.

In a network, one initiator can be deployed to map to multiple reflectors, and multiple reflector discriminators can be configured for one reflector. All the reflector discriminators in the network must be globally unique.

Examples

The following example sets the SBFD reflector discriminator to 16777216.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sbfd reflector discriminator 16777216
```

- **show sbfd reflector discriminator**

1.8 show bfd neighbors

Function

Run the **show bfd neighbors** command to display the information of a BFD session.

Syntax

show bfd neighbors [**vrf** *vrf-name*] [**client** { **ap** | **bgp** | **isis** | **ospf** | **ospfv3** | **rip** | **vrrp** | **static-route** | **pbr** | **vrrp-balance** | **bgp-lsp** | **ldp-lsp** | **static-lsp** | **backward-lsp-with-ip** | **pst** | **dhcp** | **openflow** | **pimdm** | **pimsm** | **pimsmv6** | **srp** }] [**ipv4** *ipv4-address* | **ipv6** *ipv6-address*] [**details**] [**parm-consult** [*interface-type interface-number*]]

Parameter Description

vrf *vrf-name*: Specifies the name of a virtual routing forwarding (VRF) instance, to which a neighbor belongs. The global VRF instance is displayed by default.

client: Displays a specified application protocol. All the application protocols are displayed by default.

ap: Displays the information of a BFD session associated with an L3 aggregate port (AP) member port.

bgp: Displays the information of a BFD session associated with Border Gateway Protocol (BGP).

isis: Displays the information of a BFD session associated with Intermediate System to Intermediate System (IS-IS).

ospf: Displays the information of a BFD session associated with Open Shortest Path First (OSPF).

ospfv3: Displays the information of a BFD session associated with OSPFv3.

rip: Displays the information of a BFD session associated with Routing Information Protocol (RIP).

vrrp: Displays the information of a BFD session associated with Virtual Router Redundancy Protocol (VRRP).

static-route: Displays the information of a BFD session associated with static routing.

pbr: Displays the information of a BFD session associated with policy-based routing (PBR).

vrrp-balance: Displays the information of a BFD session associated with VRRP Plus.

bgp-lsp: Displays the information of a BFD session associated with BGP label switched paths (LSPs).

ldp-lsp: Displays the information of a BFD session associated with Label Distribution Protocol (LDP) LSPs.

backward-lsp-with-ip: Displays the information of a BFD session associated with IP addresses of reverse LSPs.

static-lsp: Displays the information of a BFD session associated with static LSPs.

pst: Displays the information of a BFD session associated with an L3 interface.

dhcp: Displays the information of a BFD session associated with Dynamic Host Configuration Protocol (DHCP).

openflow: Displays the information of a BFD session associated with open flow.

pimdm: Displays the information of a BFD session associated with Protocol Independent Multicast-Dense Mode (PIM-DM).

pimsm: Displays the information of a BFD session associated with Protocol Independent Multicast-Sparse Mode (PIM-SM).

pimsm: Displays the information of a BFD session associated with PIM-SMv6.

srp: Displays the information of a BFD session associated with SRP.

ipv4 *ipv4-address*: Displays the information of a specific IPv4 session. The information of all the sessions is displayed by default.

ipv6 *ipv6-address*: Displays the session information of a specific IPv6 neighbor. The information of all the sessions is displayed by default.

details: Displays the details. The brief information is displayed by default.

parm-consult: Displays the number of BFD sessions that have completed negotiation.

parm-consult *interface-type interface-number*: Displays the number of BFD sessions that have completed negotiation on a specified port.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

In the information displayed by running the **show bfd neighbors** command, "OurAddr" indicates the source address of a session. When it is displayed as "-", no source address is specified. For example, the command is run on a BFD session associated with IP addresses of reverse LSPs. "Int" indicates the interface information of a session. When it is displayed as "-", no interface is specified. For example, the command is run on a session

associated with a protocol that does not carry interface information, and the system prompt logs of the session do not contain the interface information.

Examples

The following example displays the basic information of BFD sessions.

```
Hostname> enable
Hostname# show bfd neighbors
IPV4 sessions: 1, UP: 1
IPV6 sessions: 0, UP: 0
OurAddr       NeighAddr     LD/RD      RH/RS    Holdown(mult)  State  Int
192.168.24.2   192.168.24.1   8192/8192    Up     0(3   )       Up
GigabitEthernet 0/1
```

The following example displays the details of BFD sessions.

```
Hostname> enable
Hostname# sh bfd neighbors details
IPV4 sessions: 1, UP: 1
IPV6 sessions: 0, UP: 0
OurAddr       NeighAddr     LD/RD      RH/RS    Holdown(mult)  State  Int
192.168.24.2   192.168.24.1   8192/8192    Up     0(3   )       Up
GigabitEthernet 0/1
Session state is Up and using echo function with 50 ms interval.
Local Diag:   0,       Demand mode:   0,      Poll bit:   0
MinTxInt: 3000000,         MinRxInt: 3000000,          Multiplier:   3
Received MinRxInt 3000000, Multiplier: 3
Holdown (hits): 9000(0), Hello (hits): 3000(36)
Rx Count: 127, Rx Interval (ms) min/max/avg: 40/999/999
Tx Count: 135, Tx Interval (ms) min/max/avg: 1000/1000/999
Registered protocols: VRRP
Uptime: 0:01:19
Last packet:
 Version         :        1               - Diagnostic    : 0
 State bit       :       Up               - Demand bit    : 0
 Poll bit        :        0               - Final bit     : 0

 Min tx interval  :   3000000               - Min rx interval: 3000000
 Min Echo interval:    50000
```

The following example displays the information about a BFD session associated with the L3 AP application.

```
Hostname> enable
Hostname# show bfd neighbors client ap
IPV4 sessions: 1, UP: 0
IPV6 sessions: 0, UP: 0
OurAddr       NeighAddr      LD/RD     RH/RS   Holdown(mult) State  Int
192.168.23.1   192.168.23.2    8192/0    Admin    0(3   )      Down   GigabitEthernet
0/2 (AP 1)
```

The following example displays the number of BFD sessions that have completed negotiation.

```
Hostname> enable
Hostname# show bfd neighbors parm-consult
IPV4 sessions: 1, UP: 1  consult-Finish: 1
IPV6 sessions: 0, UP: 0  consult-Finish: 0
OurAddr       NeighAddr      LD/RD     RH/RS   Holdown(mult) State  Int
192.168.23.1   192.168.23.2    8192/8192  UP     0(3   )      UP    GigabitEthernet
0/2 (AP 1)
```

Table 1-1 Output Fields of the show bfd neighbors Command

Field	Description
IPV4 sessions	Total number of IPv4 BFD sessions and number of up sessions.
IPV6 sessions	Total number of IPv6 BFD sessions and number of up sessions.
OurAddr	Local IP address of a session.
NeighAddr	Neighbor IP address of the session.
LD/RD	Local and remote discriminators of the session.
RH/RS	Current state of the session's peer end.
Holdown(mult)	Time when the local end of the session fails to receive hello packets and number of session detection timeout times.
State	Current state of the session.
Int	ID of the interface where the session is.
Session state is UP and using echo function with 50 ms interval	Whether the session is in the echo mode and the time interval of sending echo packets (the information is displayed only in the echo mode).
Local Diag	Diagnostic information of the session.
Demand mode	Whether the session query mode is activated.
Poll bit	Whether the configuration of the session is modified.
MinTxInt	Minimum Tx interval configured at the local end of the session.
MinRxInt	Minimum Rx interval configured at the local end of the session.
Multiplier	Number of detection timeout times configured at the local end of the session.
Received MinRxInt	Minimum Tx interval configured at the remote end of the session.
Received Multiplier	Number of detection timeout times configured at the remote end of the session.

Field	Description
Holdown (hits)	Session detection time and the number of detected timeout times.
Hello (hits)	Minimum interval of receiving hello packets after session negotiation.
Rx Count	Number of BFD packets received by the local end of the session.
Rx Interval (ms) min/max/avg	Minimum interval, maximum interval, and average interval of receiving packets at the local end of the session.
Tx Count	Number of BFD packets sent at the local end of the session.
Tx Interval (ms) min/max/avg	Minimum interval, maximum interval, and average interval of transmitting packets at the local end of the session.
Registered protocols	Type of the application protocol registered to the session.
Uptime	Up time of the session.
Last packet	Information of the last BFD packet received at the local end of the session.
consult-Finish	Statistics of the sessions that have completed negotiation.

1.9 show sbfd reflector discriminator

Function

Run the **show sbfd reflector discriminator** command to display the information of an SBFD reflector discriminator.

Syntax

show sbfd reflector discriminator

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

To display the reflector information of SBFD, run the **show sbfd reflector discriminator** command.

Examples

The following example displays the information of an SBFD reflector discriminator.

```
Hostname> enable
Hostname# show sbfd reflector discriminator
Reflec-Discr(INT)    Reflec-Discr(IP)             State          CreateType
16777216             1.0.0.0                     Active         Integer
Total Discriminator Num : 1
```

Table 1-2 Output Fields of the show sbfd reflector discriminator Command

Field	Description
Reflec-Discr(INT)	SBFD reflector discriminator of the integer type.
Reflec-Discr(IP)	IP address of the SBFD reflector.
State	Status of the SBFD reflector.
CreateType	Character type of the SBFD reflector.
Total Discriminator Num	Number of SBFD reflector discriminators.

1.10 show sbfd reflector initiator-mapping

Function

Run the **show sbfd reflector initiator-mapping** command to display the mappings between the SBFD reflector and the initiator.

Syntax

show sbfd reflector initiator-mapping

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

To display the information of the initiator associated with a reflector, run the **show sbfd reflector initiator-mapping** command.

Examples

The following example displays the mappings between the SBFD reflector and the initiator.

```
Hostname> enable
Hostname# show sbfd reflector initiator-mapping
Reflec-Discr        Initia-Discr        Int
16777216            10000               Gi1/0/5
16777216            10001               Gi1/0/5
16777216            10002               Gi1/0/5
16777216            10003               Gi1/0/6
16777216            10004               Gi1/0/6
16777216            10005               Gi1/0/6
Total Initiator-mapping Num : 6
```

Table 1-3 Output Fields of the show sbfd reflector initiator-mapping Command

Field	Description
Reflec-Discr	SBFD reflector discriminator of the integer type.
Initia -Discr	SBFD initiator discriminator of the integer type.
Int	Outbound interface of SBFD reflector response packets.
Total Initiator-mapping Num	Total number of mappings between the SBFD reflector and the initiator.

1 Track Commands

Command	Function
delay	Configure the delay for notifying the status change of a track object.
dhcp	Create a reliable network service (RNS) test of Dynamic Host Configuration Protocol (DHCP) type.
dns	Create an RNS test of DNS type.
frequency	Configure a test interval.
icmp-echo	Create an RNS test of ICMP echo type.
ip rns	Define a track operation object.
ip rns reaction-configuration	Configure the proactive threshold monitoring and triggering mechanism for a test.
ip rns reaction-trigger	Trigger another test in pending state to activate when the monitoring threshold exceeds the expectation during a test.
ip rns reset	Clear the configurations of all tests.
ip rns restart	Restart a test.
ip rns schedule	Configure the scheduling policy of a test.
ip rns-server udp-echo	Configure the IP RNS server to provide server functions for the test of UDP echo type.
object	Configure a member object for a track list object.
request-data-size	Configure the protocol payload size of a test.
show ip rns-server	Display the configuration information of an RNS server object.
show ip rns configuration	Display the configuration information of a track object.
show ip rns collection-statistics	Display the detailed statistics of a test.
show ip rns operational-state	Display the current status of a test.
show ip rns reaction-configuration	Display the proactive threshold monitoring information of a test.

show ip rns reaction-trigger	Display the test trigger information of a test.
show ip rns statistics	Display the brief statistics of a track object.
show track	Display the statistics of a track object.
tag	Configure a tag for an IP test.
tcp-connect	Configure a TCP test.
threshold	Configure the upper threshold of a test.
timeout	Configure the timeout interval of a test.
tos	Configure the type of service (TOS) field in the IPv4 packet of a test.
track interface line-protocol	Configure a track object, which is used to track the link status of an interface.
track list	Configure a track object for tracking the status of a track list.
track rns	Configure a track object, which is used to track the test result of a track instance.
track rns-list	Configure a track object, which is used to track the test result of an rns-list instance.
udp-echo	Configure a test object of UDP echo type.
vrf	Configure the VRF of a test.

1.1 delay

Function

Run the **delay** command to configure the delay for notifying the status change of a track object.

Run the **no** form of this command to restore the default configuration.

No delay is set by default for notifying the track object status change from up to down or from down to up.

Syntax

delay { **up** *interval* [**down** *interval*] | **down** *interval* [**up** *interval*] }

no delay

Parameter Description

up *interval*: Specifies the delay for notifying the status change of a track object from down to up, in seconds. The value range is from 0 to 180.

down *interval*: Specifies the delay for notifying the status change of a track object from up to down, in seconds. The value range is from 0 to 180.

Command Modes

Track configuration mode

Default Level

1

Usage Guidelines

When the status of a track object frequently changes, the status of the client that uses the track object will frequently change as well.

Run this command to delay the notification of the status change of a track object. For example, if the status of a track object changes from up to down, and the **delay down** command is configured, the down status of the track object is notified 10s later. If the status of the track object changes to up again within this period of time, no notification is sent. Therefore, the status of the track object is always up on the client that uses this track object.

Examples

The following example configures track object 5 for tracking track instance 10. When the status of the track object changes from down to up, the notification is delayed for 30 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 5 rns 10
Hostname(config-track)# delay up 30
```

Notifications

When no track object is configured, the following notification will be displayed:

```
set delay error.
```

Common Errors

N/A

Platform Description

N/A

Related Commands

N/A

1.2 dhcp

Function

Run the **dhcp** command to create a reliable network service (RNS) test of Dynamic Host Configuration Protocol (DHCP) type.

No RNS test of DHCP type is created by default.

Syntax

dhcp *destination-ipv4-address* **out-interface** *interface-type interface-number* **next-hop** *next-ipv4-address*

Parameter Description

destination-ipv4-address: Destination host IP address for testing.

out-interface interface-type interface-number: Specifies the outbound interface for test packets.

next-hop *next-ipv4-address*: Specifies the next hop IP address for test packets.

Command Modes

IP RNS configuration mode

Default Level

1

Usage Guidelines

The RNS test of DHCP type supports the IPv4 network only.

After an RNS test of DHCP type is started, the system sends a DHCP packet to test whether the network of the target host is connected, and whether the destination host has the function of DHCP service. After an RNS test of DHCP type is created, the system enters the IP RNS DHCP mode.

You need to configure the test type, such as Internet Control Message Protocol (ICMP) echo or domain name server (DNS), before configuring its specific parameters. To modify the type of a test instance, delete the instance by running the **no ip rns** command in global configuration mode.

Examples

The following example creates test instance 1 of DHCP type. The instance requests the DHCP service of 172.30.30.3 through the GigabitEthernet 0/1 interface and the next hop address 172.30.31.1.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# dhcp 172.30.30.3 out-interface GigabitEthernet 0/1 next-hop
172.30.31.1
Hostname(config-ip-rns-dhcp)#
```

Notifications

When you want to create a test of DHCP type, if the memory allocation fails, the configuration fails and the following notification will be displayed:

```
rns object rns-dhcp create fail
```

Common Errors

- When a test of DHCP type is created, the DHCP service is not enabled on the server.
- When a test of DHCP type is created, no IP address is configured for the outbound interface of the client.

Platform Description

N/A

Related Commands

N/A

1.3 dns

Function

Run the **dns** command to create an RNS test of DNS type.

No RNS test of DNS type is created by default.

Syntax

dns { **oob** *destination-hostname* **name-server** *ipv4-address* [**source-ipaddr** *ipv4-address*] **via** *interface-type interface-number* **next-hop** *ipv4-address* } | { *destination-hostname* **name-server** *ipv4-address* [**source-ipaddr** *ipv4-address*] [

[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*]] }

dns *destination-hostname* **name-server** *ipv4-address* [**source-ipaddr** *ipv4-address*] [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*]]

Parameter Description

oob: Indicates the test on the MGMT port.

destination-hostname: Destination host name. The maximum length is 127 characters, and the excess part is truncated automatically.

name-server *ipv4-address*: Indicates the IP address of the DNS server.

source-ipaddr *ipv4-address*: Indicates the source IP address.

out-interface *interface-type interface-number*: Specifies the outbound interface (not the MGMT port) for test packets.

af-direct: Indicates that packets are received and sent without passing through the protocol stack in the test.

via *interface-type interface-number*: Specifies the MGMT port as the egress interface for the test packets.

next-hop *ipv4-address*: Indicates the next hop IP address when the outbound interface is specified.

Command Modes

IP RNS configuration mode

Default Level

1

Usage Guidelines

The RNS test of DNS type supports the IPv4 network only.

After an RNS test of DNS type is started, the system sends a DNS parsing request packet to test whether the device is connected to the target host. After an RNS test of DNS type is created, the system enters the IP RNS DNS mode.

You need to configure the test type, such as Internet Control Message Protocol (ICMP) echo or domain name server (DNS), before configuring its specific parameters. To modify the type of a test instance, delete the instance by running the **no ip rns** command in global configuration mode.

Examples

The following example creates test instance 1 of DNS type. The DNS server address configured for this instance is 61.154.22.41, and the IP address of the domain name www.abc.com is requested.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# dns www.abc.com name-server 61.154.22.41
Hostname(config-ip-rns-dns)#
```

Notifications

When you want to create a test of DNS type, if the memory allocation fails, the configuration fails and the following notification will be displayed:

```
rns object dns create fail
```

Common Errors

- When you want to create a test of DNS type, the memory allocation fails.
- When you want to create a test of DNS type, the maximum length of the destination host name consists of 127 characters, and the excess part is truncated automatically.

Platform Description

N/A

Related Commands

N/A

1.4 frequency

Function

Run the **frequency** command to configure a test interval.

Run the **no** form of this command to remove this configuration.

The default test interval is **60** seconds.

Syntax

frequency *interval*

no frequency

Parameter Description

interval: Packet transmission interval, in milliseconds. The value range is from 10 to 604800000. The maximum duration is 1 week.

Command Modes

IP RNS DNS configuration mode

IP RNS ICMP-Echo configuration mode

IP RNS TCP configuration mode

IP RNS UDP-Echo configuration mode

Default Level

1

Usage Guidelines

In the lifetime of a test, the test is conducted periodically. Run the **frequency** command to specify the test interval. The configuration must comply with the following formula to ensure correct test calculation.

(**frequency** *interval*) > (**timeout** *interval*) ≥ (**threshold** *interval*)

Examples

The following example configures test instance 1 of ICMP echo type, and sets the test destination IP address of this instance to 192.168.21.1, the test frequency to 30 seconds, the timeout to 8000 milliseconds, and the threshold to 6000 milliseconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 192.168.21.1
Hostname(config-ip-rns-icmp-echo)# frequency 30000
Hostname(config-ip-rns-icmp-echo)# timeout 8000
Hostname(config-ip-rns-icmp-echo)# threshold 6000
```

Notifications

When you configure a test repeat interval shorter than the timeout interval, the configuration fails and the following notification will be displayed:

```
Illegal Value: Cannot set Frequency to be less than Timeout
```

Common Errors

- The configured test repeat interval is shorter than the timeout interval.

Platform Description

N/A

Related Commands

N/A

1.5 icmp-echo

Function

Run the **icmp-echo** command to create an RNS test of ICMP echo type.

No RNS test of ICMP echo type is created by default.

Syntax

icmp-echo { **oob** { *destination-ipv4-address* | *destination-hostname* [**name-server** *ipv4-address*] } [**source-ipaddr** *ipv4-address*] **via** *interface-type interface-number* **next-hop** *ipv4-address* } | { { *destination-ipv4-address* | *destination-hostname* [**name-server** *ipv4-address*] } [**source-ipaddr** *ipv4-address* | **source-interface** *interface-type interface-number*] [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*]] }

icmp-echo { *destination-ipv4-address* | *destination-hostname* [**name-server** *ipv4-address*] } [**source-ipaddr** *ipv4-address* | **source-interface** *interface-type interface-number*] [[**af-direct**] **out-interface** *interface-type interface-number* [**next-hop** *ipv4-address*]]

Parameter Description

oob: Indicates the test on the MGMT port.

destination-ipv4-address: Destination IPv4 address.

Destination-hostname: Destination host name. The maximum length is 127 characters, and the excess part is truncated automatically.

name-server *ipv4-address*: Specifies the DNS server when the destination host name is configured. By default, the DNS server configured by running the **ip name-server** command is used for address resolution.

source-ipaddr *ipv4-address*: Indicates the source IPv4 address.

source-interface *interface-type interface-number*: Specifies the source interface type and number.

out-interface *interface-type interface-number*: Specifies the outbound interface (not the MGMT port) for test packets.

af-direct: Indicates that packets are received and sent without passing through the protocol stack in the test.

via *interface-type interface-number*: Specifies the MGMT port as the egress interface for the test packets.

next-hop *ipv4-address*: Indicates the next hop IPv4 address when the outbound interface is specified.

Command Modes

IP RNS configuration mode

Default Level

1

Usage Guidelines

After an ICMP echo test is started, the system sends an ICMP echo request packet to test whether the device is connected to the target host. After an ICMP echo test instance is created, the system enters the IP RNS ICMP echo mode. The default protocol payload size of an ICMP echo request packet is **36** bytes. Run the **request-data-size** command to change the packet size. You need to configure the test type, such as Internet Control Message Protocol (ICMP) echo or domain name server (DNS), before configuring its specific parameters. To modify the type of a test instance, delete the instance by running the **no ip rns** command in global configuration mode.

You are not advised to use the **name-server** parameter, but use **ip name-server** to configure a DNS.

Examples

The following example configures IP test instance 1 of ICMP echo type, and sets the destination IP address of this instance to 10.1.1.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 10.1.1.1
Hostname(config-ip-rns-icmp-echo)#
```

Notifications

When you want to create a test of ICMP echo type, if the memory allocation fails, the configuration fails and the following notification will be displayed:

```
rns object icmp-echo create fail.
```

Common Errors

N/A

Platform Description

N/A

Related Commands

No test

1.6 ip rns

Function

Run the **ip rns** command to define a track operation object.

Run the **no** form of this command to remove this configuration.

No track operation object is created by default.

Syntax

ip rns *operation-number* [{ **dns** *destination-hostname* **name-server** *ipv4-address* | **icmp-echo** *destination-ipv4-address* | **tcp-connect** *destination-ipv4-address port-number* } [**frequency** *interval*] [**timeout** *interval*] [**threshold** *interval*]]

no ip rns *operation-number*

Parameter Description

operation-number: Track operation number. The value range is from 1 to 500.

dns *destination-hostname* **name-server** *ipv4-address*: Briefly configures a DNS test.

destination-hostname: Destination host name. The maximum length is 127 characters, and the excess part is truncated automatically.

name-server *ipv4-address*: Indicates the IPv4 address of the DNS server.

icmp-echo *destination-ipv4-address*: Briefly configures an ICMP echo test.

destination-ipv4-address: Destination IPv4 address.

tcp-connect *destination-ipv4-address port-number*: Briefly configures a Transmission Control Protocol (TCP) connect test.

destination-ipv4-address: Destination IPv4 address.

port-number: TCP port to be tested.

frequency *interval*: Indicates the test repeat interval.

timeout *interval*: Configures the timeout interval of an IP test.

threshold *interval*: Configures the upper threshold of an IP test.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

Currently, only IPv4-related tests are supported, but IPv6-related tests are not supported. At most 500 tests can be configured, depending on the performance of devices. The test function is only a value-added function. When a large number of tests are configured and consume a lot of system resources, the test function may be temporary disabled to ensure normal operation of core services, such as route forwarding.

Detailed configuration (executing mandatory items of **ip rns** *operation-number*): Run this command and enter the IP RNS mode. In this mode, you can define various test types. If the test type is not configured, the track object is not created. After configuring a test, you must run the **ip rns** *operation-number* command to configure its scheduling startup policy; otherwise, the test cannot be conducted.

After configuring the type of a test, you can run the **ip rns** command to enter the configuration mode of the corresponding test type. To modify the type of a test, you must first delete the test by running the **no ip rns** command in global configuration mode.

Brief configuration (executing the subsequent optional test items of **ip rns**): After optional items are executed, it is equivalent that **ip rns** *operation-number*, **ip rns schedule**, detailed test configuration (such as the ICMP

echo test), **frequency**, **timeout**, and **threshold** are executed according to the logical sequence. Among these commands, the **ip rns schedule** command is executed to start a test by using the *start-time now life forever* parameter. For details about restrictions of other configuration items, see the related description in the detailed configuration.

Similarly, to modify a briefly configured test, you need to first delete this test by running the **no ip rns** command in global configuration mode before re-configuration.

Examples

The following example defines test instance 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)#
```

The following example defines test instance 1 of ICMP echo type, and sets the test destination IP address of this instance to 10.1.1.1, the threshold to 10 seconds, the timeout interval to 20 seconds, and the test frequency to 30 seconds.

```
Hostname(config)# ip rns 1 icmp-echo 10.1.1.1 threshold 10000 timeout 20000 frequency
30000
```

Notifications

When you define a track operation object, if the operation object ID is already configured and the object is running, you will enter the IP RNS mode and the following notification will be displayed:

```
Entry already running and cannot be modified
(only can delete (no) and start over)
(check to see if the probe has finished exiting)
```

Common Errors

- When you run the **ip rns** command, if the corresponding test is already configured and is running, you cannot enter the mode corresponding to the test type. To modify the test configuration, you must first delete the scheduling configuration by running the **no ip rns schedule** command.

Platform Description

1.7 ip rns reaction-configuration

Function

Run the **ip rns reaction-configuration** command to configure the proactive threshold monitoring and triggering mechanism for a test.

Run the **no** form of this command to remove this configuration.

The proactive threshold monitoring and triggering mechanism is not configured for the test by default.

Syntax

ip rns reaction-configuration *operation-number* **react** { **allfail** | **rtt** | **timeout** } [**action-type track**] [**threshold-type** { **average** [*number-of-measurements*] | **consecutive** [*occurrences*] | **immediate** | **never** | **xofy** [*x-value y-value*] }] [**threshold-value** *max-threshold min-threshold*]

no ip rns reaction-configuration *operation-number* [**react** *monitored-element*]

Parameter Description

operation-number: Track operation number. The value range is from 1 to 500.

react { **allfail** | **rtt** | **timeout** }: Specifies the monitored test information element (*monitored-element*). **allfail** indicates that monitoring all elements fails, and only correlation with track is supported. **rtt** indicates that the packet round trip time is not within the threshold range. **timeout** indicates timeout in either direction.

action-type { **track | trigger** }: Indicates the action taken after the test is triggered. Only correlation with trigger or track is supported. Correlation with the track action is allowed only when the monitored test information element is **allfail**. This parameter is not configured by default, namely, no action is taken.

average [*number-of-measurements*]: Indicates that the test is triggered if the average of number-of-measurements of the monitored element exceeds the threshold. For example, set the value of number-of-measurements to 3, upper threshold to 5000, and lower threshold to 4000. If the values of three consecutive tests are 6000, 6000, and 5000 respectively, their average is (6000 + 6000 + 5000)/3 = 5667, exceeding the upper threshold 5000. The value range of number-of-measures is from 1 to 16, and the default value is **5**.

consecutive [*occurrences*]: Indicates that the action is triggered if the number of consecutive occurrences of the monitored element exceeds the threshold. The value range of occurrences is from 1 to 16. The default value is **5**.

immediate: Indicates that the action is triggered immediately after the monitored element exceeds the threshold.

never: Indicates that the action is never triggered.

xofy [*x-value y-value*]: Indicates that results of X tests exceed the threshold in the last Y tests. The value ranges of both X and Y are from 1 to 16. The default values of X and Y are both **5**.

threshold-value *max-threshold min-threshold*: Indicates the upper and lower thresholds. When the monitored test information element is **rtt**, the thresholds indicate time, in milliseconds, and the value range is from 0 to 60000. For default values, see *Usage Guidelines*. When the monitored test information element is **timeout**, the **threshold-vaule** parameter does not need to be configured.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

You can configure multiple thresholds for one test to monitor different elements. The following table lists the mappings between test types and monitored elements.

Table 1-1 Mapping Table of Test Types and Monitored Elements

monitored-element	icmp-echo	dns	tcp-connect	udp-echo
timeout				
rtt				

The following table lists the default thresholds of each monitored element.

Table 1-2 Mapping Table of Monitored Elements and Default Thresholds

monitored element	Upper Threshold	Lower Threshold
timeout	-	-
rtt	5000 ms	0 ms

Examples

The following example configures to trigger the action when the monitored element of test instance 1 times out in any direction and the timeout exceeds the threshold range, and supports correlation with trigger only.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns reaction-configuration 1 react timeout threshold-type
immediate action-type trigger
```

Notifications

When you configure the proactive threshold for the test of a track instance, if creation of a react variable memory fails, the configuration will fail and the following notification will be displayed:

```
rns react malloc fail
```

When the configured information type of monitored test element is not supported, the configuration will fail and the following notification will be displayed:

```
rns entry %d detect not support this react_type %s [reacttype name]
```

Common Errors

- The configured information type of the monitored test element is not supported.

Platform Description

1.8 ip rns reaction-trigger

Function

Run the **ip rns reaction-trigger** command to trigger another test in pending state to activate when the monitoring threshold exceeds the expectation during a test.

Run the **no** form of this command to remove this configuration.

The trigger mechanism when the monitoring threshold exceeds the expectation is not configured for the test by default.

Syntax

ip rns reaction-trigger *source-operation-number target-operation-number*

no ip rns reaction-trigger *source-operation-number target-operation-number*

Parameter Description

source-operation-number: Number of the source operation triggering the action. The value range is from 1 to 500.

target-operation-number: Number of the triggered target operation. The value range is from 1 to 500.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

The trigger function is generally used in network fault diagnosis scenario. In a common scenario, you do not need to configure the trigger function.

Examples

The following example triggers to activate track instance 2 in pending state when the monitoring threshold of test instance 1 exceeds the expectation.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns reaction-trigger 1 2
```

Notifications

When you configure a test trigger object, if the memory allocation for the trigger object fails, the configuration will fail and the following notification will be displayed:

```
rns trigger malloc fail
```

1.9 ip rns reset

Function

Run the **ip rns reset** command to clear the configurations of all tests.

Syntax

ip rns reset

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

Run this command to clear all the track configurations. This command is used only in extreme cases, for example, when a lot of track tests are configured but the configurations are found incorrect.

Examples

The following example clears all the test configurations.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns reset
```

Notifications

The following notification will be displayed when you run **ip rns reset** to clear all the track configurations, and you need to confirm the operation. The default value is **no**.

```
WARNING: rns reset will remove all rns configurations, continue? (y/n) [no]
```

If a track instance is being tested, you will be prompted to confirm the deletion. The default value is **no**.

```
rns 1 schedule is running, confirm to delete?(y/n) [no]
```

Common Errors

N/A

Platform Description

N/A

1.10 ip rns restart

Function

Run the **ip rns restart** command to restart a test.

Syntax

ip rns restart *operation-number*

Parameter Description

operation-number: Track operation number. The value range is from 1 to 500.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

This command restarts an ip rns test for which the scheduling policy is configured and is in pending state of scheduling. This command is invalid for a test for which the scheduling policy is not configured.

Examples

The following example restarts test instance 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns restart 1
```

Notifications

If the specified test is not configured, the test will fail to restart and the following notification will be displayed:

```
rns operate has not define
```

If the specified test is not configured with rns schedule, the test will fail to restart and the following notification will be displayed:

```
% rns 2 schedule is not configured.
```

If the specified test is running, the test will fail to restart and the following notification will be displayed:

```
rns 1 schedule is active state.
```

Common Errors

- The specified test is not configured.
- The rns schedule configuration is not configured.
- The specified test is running.

Platform Description

1.11 ip rns schedule

Function

Run the **ip rns schedule** command to configure the scheduling policy of a test.

Run the **no** form of this command to remove this configuration.

No scheduling policy is configured for the test by default.

Syntax

ip rns schedule *operation-number* [**life** { **forever** | *period* }] [**start-time** { *hh*:*mm* [:*ss*] [*month day* | *day month*] | **pending** | **now** | **after** *hh*:*mm*:*ss* }] [**recurring**]

no ip rns schedule *operation-number*

Parameter Description

operation-number: Track operation number. The value range is from 1 to 500.

life forever: Indicates that the life of RNS operation is always valid.

life *period*: Indicates the life period of the ip rns test. That is, after the test starts at the configured start-time, the test stops in the time set for *period***.**

hh:*mm* [:*ss*]: Accurate operation start time, in a 24-hour system.

month: Month in which the operation starts. The default value is the current month. The format is the English abbreviation or full name of January to December.

day: Date on which the operation starts. The default value is the current day. The value range is from 1 to 31.

pending: Indicates that the start time of the operation is not defined, and the default value is used.

now: Indicates that the operation start time is now and the operation will start immediately.

after *hh*:*mm*:*ss*: Indicates that the operation starts after a delay of hh:mm:ss.

recurring: Indicates that the operation starts at the same time every day.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

If a test of scheduling policy has been configured by running the **ip rns schedule** command and the test has started, the test parameters cannot be modified. To modify the configuration, you need to first run the **no ip rns schedule** command to delete the scheduling configuration.

Examples

The following example configures to start test instance 1 immediately and makes it permanently valid.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns schedule 1 start-time now life forever
```

The following example makes the test unmodifiable after a scheduling policy is configured. The test can be modified after the scheduling policy is deleted.

```
Hostname(config)# ip rns 1
Entry already running and cannot be modified
       (only can delete (no) and start over)
       (check to see if the probe has finished exiting)
Hostname(config)# no ip rns schedule 1
Hostname(config)# ip rns 1
Hostname(config-ip-rns-icmp-echo)# exit
```

Notifications

When you configure the scheduling policy of a test, if memory allocation fails, configuration of the scheduling policy will fail and the following notification will be displayed:

```
ip rns malloc rns schedule fail
```

When the schedule object is already configured and being tested, the configuration will fail and the following notification will be displayed:

```
Cannot modify schedule. Operation may have started.
```

Common Errors

- The **ip rns schedule** object is already configured and running.

1.12 ip rns-server udp-echo

Function

Run the **ip rns-server udp-echo** command to configure the IP RNS server to provide server functions for the test of UDP echo type.

Run the **no** form of this command to remove this configuration.

The server for UDP echo test is not configured by default.

Syntax

ip rns-server udp-echo *port-number*

no ip rns-server udp-echo

Parameter Description

udp-echo: Configures the server for the UDP echo test.

port-number: Number of the port monitored by the UDP service on the RNS server. The value range is from 1025 to 65535.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

If the RNS type is UDP echo, the RNS server must be enabled on the peer end to process the test packet.

Examples

The following example configures the IP RNS server to provide server functions for the UDP echo test, and configures the port for UDP service monitoring as 1025.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns-server udp-echo 1025
```

1.13 object

Function

Run the **object** command to configure a member object for a track list object.

Run the **no** form of this command to delete a track member.

No member object is configured by default.

Syntax

object *object-number* [**not**]

no object *object-number*

Parameter Description

object-number: Number of a track object. The value range is from 1 to 700.

Command Modes

Track configuration mode

Default Level

1

Usage Guidelines

Run this command to configure a member object for a track list. The number of track list members that can be configured is restricted by the capacity of track objects only.

If the status of the track object is consistent with that of the member object, only when the member object is in the up status, can the track object be in the up status.

If the status of the track object is contrary to that of the member object, only when the member object is in the down status, can the track object be in the up status.

Configure this command only when the track object is in the track mode of list.

A track object cannot track itself.

Track objects cannot track each other. For example, if Track A tracks Track B, Track B cannot track Track A in reverse. Otherwise, the statuses of Track A and Track B may change frequently.

Examples

The following example configures track object 4. When the status of track object 1 is up, the status of track object 2 is down, and the status of track object 3 is up, track object 4 is up.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 4 list boolean and
Hostname(config-track)# object 1
Hostname(config-track)# object 2 not
Hostname(config-track)# object 3
```

Notifications

When no track object is configured or the configuration fails, the following notification will be displayed if you configure this **object** command:

```
set object error.
```

If a configured member object is the track object itself, the configuration will fail and you will be prompted that the track object cannot track itself.

```
track can not track itself.
```

If the configured member object has tracked this track object, the configuration will fail and the following notification will be displayed:

```
object xx is already tracking track yy.
```

1.14 request-data-size

Function

Run the **request-data-size** command to configure the protocol payload size of a test.

Run the **no** form of this command to restore the default configuration.

The default protocol payload sizes of both the ICMP echo test and UDP echo test are **36**.

Syntax

request-data-size *bytes*

no request-data-size

Parameter Description

bytes: Number of bytes in the payload of the test packet. The minimum/maximum bytes are different for respective tests. The value range of the ICMP echo test and the UDP echo test is from 36 to 1472.

Command Modes

IP RNS ICMP Echo configuration mode

IP RNS UDP Echo configuration mode

Default Level

1

Usage Guidelines

This command is used to stuff some bytes in the test packet so that large packets can be used for the test.

Examples

The following example configures test instance 1 of ICMP echo type, and sets the test destination address to 10.1.1.1 and the protocol load size to 50.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 10.1.1.1
Hostname(config-ip-rns-icmp-echo)# request-data-size 50
```

1.15 show ip rns-server

Function

Run the **show ip rns-server** command to display the configuration information of an RNS server object.

Syntax

show ip rns-sever udp-echo

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the configuration information of an RNS server object. The configuration information varies with packet types.

Examples

The following example displays the configuration information of ip rns-server udp.

```
Hostname> enable
Hostname# show ip rns-server udp-echo
   UDP-Echo-Server: 0.0.0.0:1026
   Receive packets number: 0
   Reflect packets success number: 0
Reflect packets fail number: 0
```

Table 1-3 Output Fields of the show ip rns-server udp-echo Command

Field	Description
UDP-Echo-Server	Server address of the UDP echo test, including the server IP address and port information
Receive packets number	Number of received packets
Reflect packets success number	Number of response packets that are sent successfully

Field	Description
Reflect packets fail number	Number of response packets that cannot be sent

1.16 show ip rns configuration

Function

Run the **show ip rns configuration** command to display the configuration information of a track object.

Syntax

show ip rns configuration [*operation-number*]

Parameter Description

operation-number: Track operation number. The value range is from 1 to 500. If this parameter is not specified, all the tests are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the configuration information of a test. The configuration information varies with packet types.

Examples

The following example displays the configuration information of ip rns 1.

```
Hostname> enable
Hostname# show ip rns configuration 1
Entry number: 1
Tag: Hostname555
Type of operation to perform: icmp-echo
Operation timeout (milliseconds): 5000
Operation frequency (milliseconds): 10000
Threshold (milliseconds): 5000
```

```
Recurring (Starting Everyday): FALSE
Life (seconds): 3500
Next Scheduled Start Time:Start Time already passed
Target address/Source address: 2.2.2.3/0.0.0.0
Request size (ARR data portion): 36
```

Table 1-4 Output Fields of the show ip rns configuration Command

Field	Description
Entry number	Track operation index
Tag	Instance tag
Type of operation to perform	Test type
Operation timeout (milliseconds)	Timeout duration
Operation frequency (milliseconds)	Test repeat interval
Threshold (milliseconds)	Threshold
Recurring (Starting Everyday)	Whether to start repeatedly
Life (seconds)	Time to live
Next Scheduled Start Time	Start time of the next test scheduling
Target address/Source address	Destination/source address
Request size (ARR data portion)	Size of the request packet data

1.17 show ip rns collection-statistics

Function

Run the **show ip rns collection-statistics** command to display the detailed statistics of a test.

Syntax

show ip rns collection-statistics [*operation-number*]

Parameter Description

operation-number: Track operation number. The value range is from 1 to 500. If this parameter is not specified, all the RNS operation objects are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the result statistics of a test.

Examples

The following example displays the result statistics of all the tests (the ICMP echo test type is taken as an example).

```
Hostname> enable
Hostname# show ip rns collection-statistics 1
Entry number: 1
Start Time Index: *2014-03-20 19:53:51
Last receive time Index: *2020-11-08 06:13:42
Number of successful operations: 919
Number of operations over threshold: 0
Number of failed operations due to a Disconnect: 0
Number of failed operations due to a Timeout: 2
Number of failed operations due to a Busy: 0
Number of failed operations due to a No Connection: 0
Number of failed operations due to an Internal Error: 2
Number of failed operations due to a Sequence Error: 0
Number of failed operations due to a Verify Error: 0
Last packet sent sequence: 5

RTT Values:
RTTAvg: 18      RTTMin: 16      RTTMax: 37
NumOfRTT: 919    RTTSum: 16654      RTTSum2: 302786
jitter of operations: 0.000000
Lost packet ratio :0.0000%
```

Table 1-5 Output Fields of the show ip rns collection-statistics Command

Field	Description
Entry number	Track operation index
Start Time Index	Actual test start time (scheduling start time)
Number of successful operations:	Number of successful tests

Field	Description
Number of operations over threshold:	Number of operations over the configured threshold
Number of failed operations due to a Disconnect:	Number of disconnections
Number of failed operations due to a Timeout:	Number of failed operations due to timeout
Number of failed operations due to a Busy:	Number of failed operations because the peer is busy after a packet is sent to the test destination address
Number of failed operations due to a No Connection:	Number of failed operations due to a connection failure
Number of failed operations due to an Internal Error:	Number of failed operations due to an internal error
Number of failed operations due to a Sequence Error:	Number of failed operations due to a sequence error
Number of failed operations due to a Verify Error:	Number of failed operations due to a verification error
RTT Values	Round trip time (RTT) value
RTTAvg:	RTT average of the test
RTTMin:	RTT minimum value of the test
RTTMax:	RTT maximum value of the test
NumOfRTT:	Number of times of counting RTT
RTTSum:	RTT sum of the test
RTTSum2:	RTT square sum of the test
jitter of operations:	Jitter value during the test
Lost packet ratio	Packet loss rate, with four decimal places reserved

1.18 show ip rns operational-state

Function

Run the **show ip rns operational-state** command to display the current status of a test.

Syntax

show ip rns operational-state [*operation-number*]

Parameter Description

operation-number: Track operation number. The value range is from 1 to 500. If this parameter is not specified, all the tests are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the current status of a test.

Examples

The following example displays the current status information of all the tests.

```
Hostname> enable
Hostname# show ip rns operational-state
Entry number: 1
Modification time: *2014-01-10 10:26:14
Current seconds left in Life: Forever
Operational state of entry: Active
Number of Octets Used by this Entry: 2272
Number of operations attempted: 232
Number of operations skipped: 0
Connection loss occurred: FALSE
Timeout occurred: FALSE
Over thresholds occurred: FALSE
Latest RTT (milliseconds): 4
Latest operation start time: 2014-01-10 10:26:55
Latest operation return code: OK
```

Table 1-6 Output Fields of the show ip rns operational-state Command

Field	Description
Entry number	Track operation index
Modification time	Re-counting time of test results (the results are re-counted after one scheduling starts)
Number of Octets Used by this Entry	Total number of packet bytes sent by the instance
Number of operations attempted	Total number of operations attempted
Number of operations skipped	Total number of operations skipped
Current seconds left in Life	Remaining life of the test
Operational state of entry	Current status (Active or Disactive) of the test
Connection loss occurred	Whether disconnection occurred during the test
Timeout occurred	Whether timeout occurred
Over thresholds occurred	Whether the test result exceeds the threshold
Latest RTT (milliseconds)	RTT of the latest test
Latest operation start time	Latest operation start time
Latest operation return code	Latest operation return code

Notifications

When the IP track instance is not configured, the following notification will be displayed:

```
rns operate has not define
```

Platform Description

N/A

1.19 show ip rns reaction-configuration

Function

Run the **show ip rns reaction-configuration** command to display the proactive threshold monitoring information of a test.

Syntax

show ip rns reaction-configuration [*operation-number*]

Parameter Description

operation-number: Number of an IP RNS operation object. The value range is from 1 to 500. If this parameter is not specified, all the RNS operation objects are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the proactive threshold monitoring information of a test.

Examples

The following example displays the proactive threshold monitoring information of all the tests.

```
Hostname> enable
Hostname# show ip rns reaction-configuration
Entry number: 1
Reaction: rtt
Threshold Type: Never
Rising (milliseconds): 5000
Falling (milliseconds): 3000
Threshold Count: 5
Threshold Count2: 5
Action Type: trigger
Entry number: 2
Reaction: timeout
Threshold Type: Never
Threshold Count: 5
Threshold Count2: 5
Action Type: trigger
```

Table 1-7 Output Fields of the show ip rns reaction-configuration Command

Field	Description
Entry number	Track operation index
Reaction	Threshold monitoring object, such as RTT or timeout
Threshold Type	Threshold trigger action type
Rising (milliseconds)	Upper threshold
Falling (milliseconds)	Lower threshold
Threshold Count	x value when threshold-type is xofy or the average number of times when threshold-type is average
Threshold Count2	y value when threshold-type is xofy or the number of consecutive times when threshold-type is consecutive
Action Type	Action type

Notifications

When the IP track instance is not configured, the following notification will be displayed:

```
rns operate has not define.
```

Platform Description

1.20 show ip rns reaction-trigger

Function

Run the **show ip rns reaction-trigger** command to display the test trigger information of a test.

Syntax

show ip rns reaction-trigger [*operation-number*]

Parameter Description

operation-number: Number of an IP RNS operation object. The value range is from 1 to 500. If this parameter is not specified, all the RNS operation objects are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the test trigger information of a test.

Examples

The following example displays the test trigger information of all the tests.

```
Hostname> enable
Hostname# show ip rns reaction-trigger
Entry number: 1
Target rns index: 2
Status of Entry: active
Operational State: pending
```

Table 1-8 Output Fields of the show ip rns reaction-trigger Command

Field	Description
Entry number	Track operation index

Field	Description
Target rns index	Triggered track index value
Status of Entry	rns_entry status
Operational State	Current trigger status

Notifications

When the IP track instance is not configured, the following notification will be displayed:

```
rns operate has not define
```

Platform Description

1.21 show ip rns statistics

Function

Run the **show ip rns statistics** command to display the brief statistics of a track object.

Syntax

show ip rns statistics [*operation-number*]

Parameter Description

operation-number: Number of an IP RNS operation object. The value range is from 1 to 500. If this parameter is not specified, all the RNS operation objects are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the brief statistics of a track object. The statistics vary with packet types.

Examples

The following example displays the brief statistics of ip rns 1.

```
Hostname> enable
Hostname# show ip rns statistics 1
Entry number: 1
Operation time to live: forever
```

```
Latest RTT: 1
Latest operation start time: 2020-07-31 14:59:07
Latest operation return code: NoConnection/Busy/Timeout
Number of successes: 16
Number of failures: 49
Jitter of rtt time: 2
```

Table 1-9 Output Fields of the show ip rns statistics Command

Field	Description
Entry number	RNS index ID
Operation time to live	Remaining life of the current test
Latest RTT	RTT of the latest test
Latest operation start time	Latest operation start time
Latest operation return code	Latest operation return code (such as ok, timeout, and noconnection)
Number of successes	Number of successful tests
Number of failures	Number of failed tests

Notifications

When the IP track instance is not configured, the following notification will be displayed:

```
rns operate has not define
```

1.22 show track

Function

Run the **show track** command to display the statistics of a track object.

Syntax

show track [*object-number*]

Parameter Description

object-number: Number of a track object. The value range is from 1 to 700. If this parameter is not specified, all the track objects are displayed.

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

Run this command to display the statistics of a track object.

Examples

The following example displays the statistics of all the track objects.

```
Hostname> enable
Hostname# show track
Track 1
  Reliable Network Service 1
  The state is Up
    1 change, current state last: 120 secs
  Delay up 30 secs, down 50 secs
Track 2
  Interface GigabitEthernet 0/1
  The state is Down
    3 change, current state last: 300 secs
  Delay up 60 secs, down 60 secs
Track 4
  rns-list 1-2 and
  The state is Down
    3 change,current state last:5 secs
  Delay up 0 secs,down 0 secs
```

Table 1-10 Output Fields of the show track Command

Field	Description
Track x	Number of the track object
Reliable Network Service x	Track RNS object
The state is x	Track object state
x change	Number of state change times of the track object
current state last: x secs	Duration of the current track object state
Delay up x secs, down x secs	Delay attribute of the track object
Interface x x	Track interface information
The state is x, delayed y (c secs remaining)	Indicates that the current track object state is x and changes to y after c seconds.

Field	Description
List boolean and	Indicates that the result of the track object is accessed from the AND operation result of all the members.
Object x	Indicates that the meeting condition of member x is its up state.
Object x not	Indicates that the meeting condition of member x is its down state.

Notifications

When the specified track object for display is not configured, the following notification will be displayed:

```
Illegal Value: the track object does not exist.
```

1.23 tag

Function

Run the **tag** command to configure a tag for an IP test.

Run the **no** form of this command to remove this configuration.

No test tag is configured by default.

Syntax

tag *tag-name*

no tag

Parameter Description

tag-name: Test tag. The value is a string consisting of a maximum of 79 characters.

Command Modes

IP RNS DNS configuration mode

IP RNS ICMP-Echo configuration mode

IP RNS TCP configuration mode

IP RNS UDP-Echo configuration mode

Default Level

1

Usage Guidelines

This command specifies a tag for a test, which is often used to indicate the function of the test. When the tag character length exceeds 79, the excess part is automatically truncated.

Examples

The following example configures test instance 1 of ICMP echo type, and sets the test destination IP address of this instance to 10.1.1.1 and tag to telecom_gateway.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 10.1.1.1
Hostname(config-ip-rns-icmp-echo)# tag telecom_gateway
```

1.24 tcp-connect

Function

Run the **tcp-connect** command to configure a TCP test.

No test of TCP type is configured by default.

Syntax

tcp-connect { *destination-ipv4-address* | *destination-hostname* [**name-server** *ipv4-address*] } *port-number* [**source-ipaddr** *ipv4-address*] [[**af-direct**] **out-interface** *interface-type interface-number* **next-hop** *ipv4-address*]

Parameter Description

destination-ipv4-address: Destination IPv4 address.

destination-hostname: Destination host name. The maximum length is 127 characters, and the excess part is truncated automatically.

name-server *ipv4-address*: Indicates the IPv4 address of the DNS server. By default, the DNS server configured by running the **ip name-server** command on the device is used for resolution.

port-number: TCP port to be tested. The value range is from 1 to 65535.

source-ipaddr *ipv4-address*: Indicates the source IPv4 address.

af-direct: Indicates that packets are received and sent without passing through the protocol stack in the test.

out-interface *interface-type interface-number*: Specifies the outbound interface type and number for test packets.

next-hop *ipv4-address*: Indicates the next hop IPv4 address when the outbound interface is specified.

Command Modes

IP RNS configuration mode

Default Level

1

Usage Guidelines

After a TCP test is started, the system sets up a TCP connection to test whether the device is connected to the target host. After a TCP IP test is created, the system enters the IP RNS TCP mode.

The TCP test is used to test the performance of establishing a connection with a TCP server. When there is no corresponding TCP server at the peer end, you can start the RNS server on the peer device to complete the test.

Examples

The following example configures test instance 1 of TCP type, and sets the test destination address to www.123.com, DNS server address to 1.1.1.1, and the test TCP port to 999.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config)# tcp-connect www.123.com name-server 1.1.1.1 999
```

Notifications

When you configure a test of TCP type, if the memory allocation fails, the configuration fails and the following notification will be displayed:

```
rns object tcp create fail
```

When you configure a TCP test, if the destination host name exceeds 63 characters, the configuration fails and the following notification will be displayed:

```
rns domain name too long
```

When you configure an incorrect tcp-connect destination host name, the configuration fails and the following notification will be displayed:

```
dns domain name to ip faild
```

Common Errors

- The configured tcp-connect destination host name is incorrect.

Platform Description

1.25 threshold

Function

Run the **threshold** command to configure the upper threshold of a test.

Run the **no** form of this command to restore the default configuration.

The default upper threshold of test is **5** seconds.

Syntax

threshold *interval*

no threshold

Parameter Description

interval: Upper threshold of a test, in milliseconds. The value range is from 0 to 60000.

Command Modes

IP RNS DNS configuration mode

IP RNS ICMP-Echo configuration mode

IP RNS TCP configuration mode

IP RNS UDP-Echo configuration mode

Default Level

1

Usage Guidelines

The configured threshold must be less than or equal to timeout. For the configuration relationship between timeout, frequency, and threshold, see the usage guidelines for frequency.

Examples

The following example configures test instance 1 of ICMP echo type, and specifies the test destination address as 10.1.1.1. The upper threshold of test is set to 8000 milliseconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 10.1.1.1
Hostname(config-ip-rns-icmp-echo)# threshold 8000
```

Notifications

When the configured threshold is greater than timeout, the following notification will be displayed:

```
Illegal Value: Cannot set Threshold to be greater than Timeout.
```

Common Errors

N/A

Platform Description

N/A

Related Commands

N/A

1.26 timeout

Function

Run the **timeout** command to configure the timeout interval of a test.

Run the **no** form of this command to restore the default configuration.

The default timeout interval of a test is **5** seconds.

Syntax

timeout *interval*

no timeout

Parameter Description

interval: Timeout interval of the test, in milliseconds. The value range is from 10 to 604800000.

Command Modes

IP RNS DNS configuration mode

IP RNS ICMP-Echo configuration mode

IP RNS TCP configuration mode

IP RNS UDP-Echo configuration mode

Default Level

1

Usage Guidelines

The configured timeout interval must be greater than or equal to the configured threshold. For the configuration relationship between timeout, frequency, and threshold, see the usage guidelines for frequency.

Examples

The following example configures test instance 1 of ICMP echo type, specifies the test destination IP address as 10.1.1.1, and sets the timeout interval to 10000 milliseconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 10.1.1.1
Hostname(config-ip-rns-icmp-echo)# timeout 10000
```

Notifications

When you configure a timeout interval greater than the frequency value, the configuration fails and the following notification will be displayed:

```
Illegal Value: Cannot set Timeout to be greater than Frequency.
```

When you configure a timeout interval smaller than the threshold value, the configuration fails and the following notification will be displayed:

```
Illegal Value: Cannot set Timeout to be less than Threshold.
```

Common Errors

- The configured timeout interval is greater than the frequency value.
- The configured timeout interval is smaller than the threshold value.

Related Commands

N/A

1.27 tos

Function

Run the **tos** command to configure the type of service (TOS) field in the IPv4 packet of a test.

Run the **no** form of this command to remove this configuration.

The default TOS value for IPv4 packet of the test is **0**.

Syntax

tos *tos-value*

no tos

Parameter Description

tos-value: TOS field in the IPv4 packet of a test. The value range is from 0 to 255.

Command Modes

IP RNS DNS configuration mode

IP RNS ICMP-Echo configuration mode

IP RNS TCP configuration mode

IP RNS UDP-Echo configuration mode

Default Level

1

Usage Guidelines

TOS is an 8-bit field in the IPv4 packet header. You can set the TOS field to control the priority of the test packet. For different TOS fields, the processing priorities are different on the intermediate devices.

Examples

The following example configures an ICMP echo test, specifies the destination address of the test as 10.1.1.1, and sets the TOS value in IPv4 test packet header to 128.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 10.1.1.1
Hostname(config-ip-rns-icmp-echo)# tos 128
```

1.28 track interface line-protocol

Function

Run the **track interface line-protocol** command to configure a track object, which is used to track the link status of an interface.

Run the **no** form of this command to remove this configuration.

The function of clearing all the tests is not configured by default.

Syntax

track *object-number* **interface** *interface-type interface-number* **line-protocol**

no track *object-number*

Parameter Description

object-number: Number of a track object. The value range is from 1 to 700.

I*nterface-type interface-number*: Type and number of the interface.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

Run this command to configure a track object for tracking the link status of an interface. When the link status of the interface is up, the status of the corresponding track object is also up.

Examples

The following example configures track object 3, which is used to track the link status of the interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 3 interface GigabitEthernet 0/1 line-protocol
```

Notifications

When a track object is configured, if the resource on the device is insufficient, the following notification will be displayed:

```
Failed to create track obj, no resource.
```

When you run the **no track** command to delete a specified track object, if the track object is not configured on the device, the following notification will be displayed:

```
the track object does not exist.
```

Common Errors

- The track object for tracking the link status of an interface is configured, but the corresponding interface is not configured.

Platform Description

N/A

Related Commands

N/A

1.29 track list

Function

Run the **track list** command to configure a track object for tracking the status of a track list.

Run the **no** form of this command to remove this configuration.

No status is configured for a track list by default.

Syntax

track *object-number* **list boolean** { **and** | **or** }

no track *object-number*

Parameter Description

object-number: Number of a track object. The value range is from 1 to 700.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

Run this command to configure a track object for tracking the status of a track list. The result can be the AND or OR operation result of all member status.

track *object-number* **list boolean and**: Configures a track object to track the status of a track list. The result is the AND operation result of all member status.

track *object-number* **list boolean or**: Configures a track object to track the status of a track list. The result is the OR operation result of all member status.

Examples

The following example configures track object 4, which is used to track the status of a track list. The result is the AND operation result of all member status.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 4 list boolean and
```

Related Commands

Run the **show track** command to display the statistics of a track object.

Notifications

When a track object is configured, if the resource on the device is insufficient, the following notification will be displayed:

```
Failed to create track obj, no resource.
```

When you run the **no track** command to delete a specified track object, if the track object is not configured on the device, the following notification will be displayed:

```
the track object does not exist.
```

Common Errors

- The track object for tracking the status of a track list is configured, but no member of the track list is configured.

Platform Description

N/A

Related Commands

N/A

1.30 track rns

Function

Run the **track rns** command to configure a track object, which is used to track the test result of a track instance.

Run the **no** form of this command to remove this configuration.

No track test result is configured by default.

Syntax

track *object-number* **rns** *entry-number*

no track *object-number*

Parameter Description

object-number: Number of a track object. The value range is from 1 to 700.

entry-number: Track operation number. The value range is from 1 to 500.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

Run this command to configure a track object for tracking the test result of a track instance. When the track instance test succeeds, the corresponding track object is in up status.

Examples

The following example configures track object 5 for tracking track instance 7.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 5 rns 7
```

Notifications

When a track object is configured, if the resource on the device is insufficient, the following notification will be displayed:

```
Failed to create track obj, no resource.
```

When you run the **no track** command to delete a specified track object, if the track object is not configured on the device, the following notification will be displayed:

```
the track object does not exist.
```

Common Errors

- The track object for tracking an RNS test is configured, but the corresponding track instance is not configured.

Platform Description

N/A

Related Commands

N/A

1.31 track rns-list

Function

Run the **track rns-list** command to configure a track object, which is used to track the test result of an rns-list instance.

Run the **no** form of this command to remove this configuration.

No object of track test result is configured by default.

Syntax

track *object-number* **rns-list** *men-list* { **and** | **or** }

no track *object-number*

Parameter Description

object-number: Number of a track object. The value range is from 1 to 700.

men-list: Tracked RNS list. Here, men-list can be an RNS test instance or a series of RNS test instances. If men-list is a series of RNS IDs, the format is as follows: Minimum RNS ID-Maximum RNS ID, for example, 10-20. The value range of RNS ID is from 1 to 500.

Command Modes

Global configuration mode

Default Level

1

Usage Guidelines

Run this command to configure a track object for tracking the status of an RNS list. The result can be the AND or OR operation result of all member status.

track object-number rns-list men-list and: Configures a track object to track the status of a track list. The result is the AND operation result of all member status.

track *object-number* **rns-list** *men-list* **or**: Configures a track object to track the status of an RNS list. The result is the OR operation result of all member status.

Examples

The following example configures track object 5 for tracking track instances 1, 2-5, and 8.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# track 5 rns-list 1,2-5,8 and
```

Notifications

When a track object is configured, if the resource on the device is insufficient, the following notification will be displayed:

```
Failed to create track obj, no resource.
```

When you run the **no track** command to delete a specified track object, if the track object is not configured on the device, the following notification will be displayed:

```
the track object does not exist.
```

Common Errors

- The track object for tracking rns-list is configured, but the corresponding track instance is not configured.

Platform Description

N/A

Related Commands

N/A

1.32 udp-echo

Function

Run the **udp-echo** command to configure a test object of UDP echo type.

No test object of UDP echo type is configured by default.

Syntax

udp-echo { **oob** *destination-ipv4-address port-number* [**via** *interface-type interface-number* **next-hop** *next-hop-ip*] | *destination-ipv4-address port-number* [**out-interface** *interface-type interface-number* **next-hop** *next-hop-ip*] }

udp-echo *destination-ipv4-address port-number* [**out-interface** *interface-type interface-number* **next-hop** *next-hop-ip*]

Parameter Description

oob: Indicates the test on the MGMT port.

destination-ipv4-address: Destination IP address.

port-number: Destination port.

out-interface *interface-type interface-number*: Specifies the outbound interface (not the MGMT port) for test packets.

next-hop *next-hop-ip*: Indicates the next hop IP address.

via *interface-type interface-number*: Specifies the outbound interface (MGMT port) for the test packets.

Command Modes

IP RNS configuration mode

Default Level

1

Usage Guidelines

You must enable the RNS server at the peer end of the test to implement a UDP echo test.

The value of *port-number* must be consistent with the port number configured for the RNS server.

Examples

The following example configures test instance 1 of UDP echo type.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# udp-echo 10.10.10.1 1025
Hostname(config-ip-rns-udp-echo)#
```

Notifications

When you configure a test of UDP echo type, if the memory allocation fails, the configuration fails and the following notification will be displayed:

```
rns object entry %d create fail
```

Common Errors

- The configured udp-echo destination host name is incorrect.

Platform Description

N/A

Related Commands

N/A

1.33 vrf

Function

Run the **vrf** command to configure the VRF of a test.

Run the **no** form of this command to remove this configuration.

No VRF name is configured for the test by default.

Syntax

vrf *vrf-name*

no vrf

Parameter Description

vrf-name: Virtual routing and forwarding (VRF) name.

Command Modes

IP RNS DNS configuration mode

IP RNS ICMP-Echo configuration mode

IP RNS TCP configuration mode

IP RNS UDP-Echo configuration mode

Default Level

1

Usage Guidelines

This command specifies the VRF of the test packet.

Examples

The following example configures test instance 1 of ICMP echo type, and specifies the test destination address as 10.1.1.1 and the VRF of the test as VPN1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ip rns 1
Hostname(config-ip-rns)# icmp-echo 10.1.1.1
Hostname(config-ip-rns-icmp-echo)# vrf VPN1
```

Notifications

When the specified VRF name is invalid, the configuration fails and the following notification will be displayed:

```
no vrf named.
```

Common Errors

- The specified VRF name is invalid.

1 IP Event Dampening Commands

Command	Function
dampening	Enable the function of IP Event Dampening.
show dampening interface	Display the statistics about interfaces with IP Event Dampening.
show interfaces dampening	Display IP Event Dampening configurations on an interface.

1.1 dampening

Function

Run the **dampening** command to enable the function of IP Event Dampening.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The function of IP Event Dampening is disabled for a routing interface by default.

Syntax

dampening [*half-life-period* [*reuse-threshold suppress-threshold max-suppress* [**restart** [*restart-penalty*]]]]

no dampening

default dampening

Parameter Description

half-life-period: Half-life period in seconds. The value range is from 1 to 30. The default value is **5**.

reuse-threshold: Reuse threshold. The value range is from 1 to 20000. The default value is **1000**.

suppress-threshold: Suppress threshold. The value range is from 1 to 20000. The default value is **2000**.

max-suppress: Maximum suppress time. The value range is 1 to 255. The default value is four times that of *half-life-period*.

restart *restart-penalty*: Specifies the initial penalty. The value range is from 1 to 20000. The default value is **2000**.

Command Modes

Interface configuration mode

Default Level

2

Usage Guidelines

Configuring the function of IP Event Dampening affects the functions of associated modules (direct routes, host routes, static routes, dynamic routes, and Virtual Router Redundancy Protocol (VRRP)).

When an interface is suppressed based on the configured criteria of the command, the associated modules determine the interface as Down and thus delete corresponding routes. This interface does not receive and send any data.

When the **dampening** command is reconfigured on an interface configured with this command, the dampening information on the interface is cleared, but the flap count is retained, unless you run the **clear counters** command to clear the interface statistics.

Examples

The following example enables IP Event Dampening on interface GigabitEthernet0/1, and sets the half-time period to 30s, the reuse threshold to 1500, the suppress threshold to 10,000, and the maximum suppress time to 100s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# dampening 30 1500 10000 100
```

Notifications

When the configured maximum suppress time (*max-suppress*) is so small that the maximum penalty is smaller than the suppress threshold, the interface is never suppressed. When such a configuration error occurs, the following notification will be displayed:

```
% Maximum penalty (10) is less than suppress penalty (2000). Increase maximum suppress time
```

When the **damening** command is configured and the available system memory is insufficient to save the configuration, the following notification will be displayed:

```
% No memory, configure dampening fail!
```

Common Errors

- The configured maximum suppress time (*max-suppress*) is too small.
- IP Event Dampening is configured on an non-L3 interface.

Platform Description

This command is supported on only L3 devices.

When a routed interface is converted into a switching interface, the **dampening** command configured on the interface is deleted.

IP Event Dampening cannot be configured on **virtual templates**.

Related Commands

- **show dampening interface**
- **show interfaces dampening**

1.2 show dampening interface

Function

Run the **show dampening interface** command to display the statistics about interfaces with IP Event Dampening.

Syntax

show dampening interface

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

2

Usage Guidelines

This command is used to display statistics about interfaces with IP Event Dampening.

Examples

The following example displays statistics about interfaces with IP Event Dampening.

```
Hostname> enable
Hostname# show dampening interface
1 interfaces are configured with dampening.
No interface is being suppressed.
```

Table 1-1 Output Fields of the show dampening interface Command

Field	Description
interfaces are configured with dampening	Number of interface configured with Event Dampening
interface is being suppressed	Number of the suppressed interfaces

Notifications

N/A

Common Errors

N/A

Platform Description

N/A

Related Commands

- **show interfaces dampening**

1.3 show interfaces dampening

Function

Run the **show interfaces dampening** command to display IP Event Dampening configurations on an interface.

Syntax

show interfaces [*interface-type interface-number*] **dampening**

Parameter Description

interface-type interface-number: Interface type and interface number. If this parameter is not specified, information about all interfaces is displayed.

Command Modes

All modes except the user EXEC mode

Default Level

2

Usage Guidelines

N/A

Examples

The following example displays IP Event Dampening configurations.

```
Hostname> enable
Hostname# show interfaces dampening
GigabitEthernet 0/1
  Flaps Penalty Supp    ReuseTm HalfL   ReuseV  SuppV   MaxSTm  MaxP    Restart
  0     0       FALSE   0       30      1500    10000   100     15119   0
```

Table 1-2 Output Fields of the show interfaces dampening Command

Field	Description
Flaps	Number of flaps of an interface
Penalty	Current penalty value
Supp	Whether an interface is suppressed
ReuseTm	Remaining time for an interface to be reused in seconds
HalfL	Half-life period
ReuseV	Reuse threshold
SuppV	Suppress threshold
MaxSTm	Maximum suppress time
MaxP	Maximum penalty
Restart	Initial penalty

1 HAM Commands

Command	Function
ham single-process-ha auto-restart enable	Enable the high availability (HA) service of one frequently restarting process.

1.1 ham single-process-ha auto-restart enable

Function

Run the **ham single-process-ha auto-restart enable** command to enable the high availability (HA) service of one frequently restarting process.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The HA service of one frequently restarting process is enabled by default.

Syntax

ham single-process-ha auto-restart enable

no ham single-process-ha auto-restart enable

default ham single-process-ha auto-restart enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Before a patch upgrade, you can disable the HA service of one frequently restarting process. After a patch upgrade, you can enable the HA service of one frequently restarting process when confirming that no process restarts frequently.

Caution

If you disable the HA service of one frequently restarting process by running a command, services may not be automatically restored to normal because some processes frequently restart due to no automatic restarting of the device. As a result, failure time prolongs. Therefore, you are advised to enable the configuration in scenarios other than patch upgrades.

Examples

The following example disables the HA service of one frequently restarting process.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ham single-process-ha auto-restart enable
```

Network Management and Monitoring Commands

1 Network Connectivity Test Commands

Command	Function
clear rping table	Clear the remote Ping (Rping) table entries.
ping ip	Check whether the specified IPv4 address is reachable and output the related information.
ping ipv6	Check whether the specified IPv6 address is reachable and output the related information.
show rping detail	Display the details about Rping table entries.
traceroute ip	Display the routing devices through which IPv4 packets are sent from the source address to the destination address.
traceroute ipv6	Display the gateways through which IPv6 packets are sent from the source address to the destination address.

1.1 clear rping table

Function

Run the **clear rping table** command to clear the remote Ping (Rping) table entries.

Syntax

clear rping table { **all** | **ping-object** *owner-index test-index* | **trace-object** *owner-index test-index* }

Parameter Description

all: Deletes all entries of the Rping table.

owner-index: Index of a user.

test-index: Index of a test.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

After this command is executed, Rping table entries are deleted based on the specified parameters.

The Rping table stores the results of Ping tests executed by users through Simple Network Management Protocol (SNMP).

Examples

The following example clears all entries of the Rping table.

```
Hostname> enable
Hostname# clear rping table all
```

The following example clears the Rping table entry where the user index is **user** and the test index is **Hostname**.

```
Hostname> enable
Hostname# clear rping table user Hostname
```

Notifications

When no specified entry exists on the device, the following notification will be displayed:

Platform Description

N/A

Related Commands

N/A

1.2 ping ip

Function

Run the **ping ip** command to check whether the specified IPv4 address is reachable and output the related information.

By default, five 100-byte packets are sent to the specified IP address within two seconds.

Syntax

ping [**ip** | **vrf** *vrf-name*] { *hostname* | *ipv4-address* } [**data** *data* | **detail** | **df-bit** | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **validate**] *

ping oob { *hostname* | *ipv4-address* } [**data** *data* | **detail** | **df-bit** | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **validate** | **via** *mgmt-name*] *

Parameter Description

vrf *vrf-name*: Specifies a VRF. If this parameter is not specified, the public network instance is used.

hostname: Destination host name.

ipv4-address: Destination IPv4 address.

data *data*: Specifies the padding data of the packet. The format is a string of 1 to 255 characters. By default, **abcd** is padded.

detail: Configures whether to display the detailed information. By default, only the exclamation mark (!) and period (.) are displayed.

df-bit: Configures the DF bit of the IP address. If the DF bit is set to 1, the packet is not segmented. The default value is 0.

interval *interval*: Specifies the interval between the Ping packets, in milliseconds. The value range is from 50 to 300000, and the default value is **100**.

length *length*: Specifies the length of the padding section in the sent packet, in bytes. The value range is from 36 to 18024, and the default value is **100**.

ntimes *times*: Specifies the number of sent packets. The value range is from 1 to 4294967295. The default value is **5**.

out-interface *interface-type interface-number*: Specifies the type and number of the outbound interface used to send the packets.

next-hop *next-hop*: Specifies the IPv4 address of the next hop of the outbound interface used to send the packets.

source *interface-type interface-number*: Specifies the type and number of the source interface of the packets.

source *source-ipv4-address*: Specifies the source IPv4 address or source interface of the packets. A loopback interface, for example, 127.0.0.1, cannot be configured as the source address.

timeout *time*: Specifies the timeout, in seconds. The value range is from 1 to 10, and the default value is **2**.

validate: Configures whether to verify the response packet.

oob: Indicates that an out-of-band channel is used. This parameter is mandatory if the MGMT interface is configured as the source interface.

via *mgmt-name*: Specifies the outbound MGMT interface of packets where the Ping operation is performed.

Command Modes

Privileged EXEC mode

Default Level

0

Usage Guidelines

After this command is executed, the related response information is printed and then the statistical information is output.

To use the domain name function, you must first configure the domain name server (DNS). For details, see "Configuring DNS" in "IP Service Configuration Guide."

Examples

The following example checks whether the IPv4 address 192.168.21.26 is reachable.

```
Hostname> enable
Hostname# ping 192.168.21.26
Sending 5, 100-byte ICMP Echoes to 192.168.21.26, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The following example checks whether the IPv4 address 192.168.21.26 is reachable. The sent packet length is 1500 bytes, the number of sent packets is 10, the timeout is 3 seconds, the packet padding data is ffff, and the source IP address is 192.168.21.99.

```
Hostname> enable
Hostname# ping 192.168.21.26 length 1500 ntimes 10 data ffff source 192.168.21.99
timeout 3 detail
Sending 20, 1500-byte ICMP Echoes to 192.168.21.26, timeout is 3 seconds:

1.3 ping ipv6

Function

Run the **ping ipv6** command to check whether the specified IPv6 address is reachable and output the related information.

By default, five 100-byte packets are sent to the specified IPv6 address within two seconds.

Syntax

ping [**ipv6** | **vrf** *vrf-name*] { *hostname* | *ipv6-address* } [**data** *data* | **detail** | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time*] *

ping oob { *hostname* | *ipv6-address* } [**data** *data* | **detail** | **interval** *interval* | **length** *length* | **ntimes** *times* | **out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time* | **validate** | **via** *mgmt-name*] *

Parameter Description

vrf *vrf-name*: Specifies a VRF. If this parameter is not specified, the public network instance is used.

hostname: Destination host name.

ipv6-address: Destination IPv6 address.

data *data*: Specifies the padding data of the packet. The format is a string of 1 to 255 characters. By default, **abcd** is padded.

detail: Configures whether to display the detailed information. By default, only the exclamation mark (!) and period (.) are displayed.

interval *interval*: Specifies the interval between the Ping packets, in milliseconds. The value range is from 50 to 300000, and the default value is **100**.

length *length*: Specifies the length of the sent packet, in bytes. The value range is from 16 to 18024, and the default value is **100**.

ntimes *times*: Specifies the number of sent packets. The value range is from 1 to 4294967295. The default value is **5**.

out-interface *interface-type interface-number*: Specifies the type and number of the outbound interface used to send the packets.

next-hop *next-hop*: Specifies the IPv6 address of the next hop of the outbound interface used to send the packets.

source *interface-type interface-number*: Specifies the type and number of the source interface of the packets.

source *source-ipv6-address*: Specifies the source IPv6 address or source interface of the packets. A loopback interface, for example, ::1, cannot be configured as the source address.

timeout *time*: Specifies the timeout, in seconds. The value range is from 1 to 10, and the default value is **2**.

oob: Indicates that an out-of-band channel is used. This parameter is mandatory if the MGMT interface is configured as the source interface.

via *mgmt-name*: Specifies the outbound MGMT interface of packets where the Ping operation is performed.

Command Modes

Privileged EXEC mode

Default Level

0

Usage Guidelines

After this command is executed, the related response information is printed. If the data in the response is inconsistent with the data in the request, "Request receive error" is displayed, and then the statistical information is output.

To use the domain name function, you must first configure the domain name server (DNS). For details, see "Configuring DNS" in "IP Service Configuration Guide."

Examples

The following example checks whether the IPv6 address 2001::5 is reachable.

```
Hostname> enable
Hostname# ping ipv6 2001::5
Sending 5, 100-byte ICMP Echoes to 2001::5, timeout is 2 seconds:
< press Ctrl+C to break >
!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/2/10 ms
```

The following example checks whether the IPv6 address 2001::5 is reachable. The sent packet length is 1500 bytes, the number of sent packets is 10, the timeout is 3 seconds, the packet padding data is ffff, and the source IP address is 2001::9.

```
Hostname> enable
Hostname#ping 2001::5 length 1500 ntimes 10 data ffff source 2001::9 timeout 3
Sending 10, 1500-byte ICMP Echoes to 2001::5, timeout is 3 seconds:
  < press Ctrl+C to break >
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms
```

```
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms
Reply from 2001::5: bytes=1500 time=1ms

1.4 show rping detail

Function

Run the **show rping detail** command to display the details about Rping table entries.

Syntax

show rping detail

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

You can use this command to view the number of users and the number of tests in the Rping table on a device.

Examples

The following example displays detailed information of Rping table entries.

```
Hostname> enable
Hostname# show rping detail
Total owner number: 2
Total test number: 4
owner: user1
   test name: taget_1        storage type: volatile
```

```
test name: taget_2        storage type: nonVolatile
owner: user2
  test name: taget_1        storage type: permanent
test name: taget_2        storage type: readOnly
```

Table 1-1 Output Fields of the show rping detail Command

Field	Description

1.5 traceroute ip

Function

Run the **traceroute ip** command to display the routing devices through which IPv4 packets are sent from the source address to the destination address.

By default, the timeout is **3** seconds, the number of sent probe packets is **3**, the minimum TTL is **1**, and the maximum TTL is **255**.

Syntax

traceroute [**ip** | **vrf** *vrf-name*] { *hostname* | *ipv4-address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **ttl** *minimum maximum*] *

traceroute oob { *hostname* | *ipv4-address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv4-address*] | **timeout** *time* | **ttl** *minimum maximum* | **via** *mgmt-name*] *

Parameter Description

vrf *vrf-name*: Specifies a VRF. If this parameter is not specified, the public network instance is used.

hostname: Destination host name.

ipv4-address: Destination IPv4 address.

out-interface *interface-type interface-number*: Specifies the type and number of the outbound interface used to send the packets.

next-hop *next-hop*: Specifies the IPv4 address of the next hop of the outbound interface used to send the packets.

probe *probe*: Specifies the number of sent probe packets. The value range is from 1 to 255, and the default value is **3**.

source *interface-type interface-number*: Specifies the type and number of the source interface of the packets.

source *source-ip-address*: Specifies the source IPv4 address or source interface of the packets. A loopback interface, for example, 127.0.0.1, cannot be configured as the source address.

timeout *time*: Specifies the timeout, in seconds. The value range is from 1 to 10, and the default value is **3**.

ttl *minimum maximum*: Specifies the minimum and maximum TTL values. The value range is from 1 to 255. By default, the minimum TTL is **1**, and the maximum TTL is **255**.

oob: Indicates that an out-of-band channel is used. This parameter is mandatory if the MGMT interface is configured as the source interface.

via *mgmt-name*: Specifies the outbound MGMT interface of packets where the Traceroute operation is performed.

Command Modes

Privileged EXEC mode

Default Level

0

Usage Guidelines

You can run this command to check the network connectivity, and accurately determine the location of a network fault when the fault occurs.

To use the domain name function, you must first configure the domain name server (DNS). For details, see "Configuring DNS" in "IP Service Configuration Guide."

Examples

The following example displays the gateways through which IPv4 packets are sent from the source address to the destination address 61.154.22.36.

```

1.6 traceroute ipv6

Function

Run the **traceroute ipv6** command to display the gateways through which IPv6 packets are sent from the source address to the destination address.

By default, the timeout is **3** seconds, the number of sent probe packets is **3**, the minimum TTL is **1**, and the maximum TTL is **255**.

Syntax

traceroute [**ipv6** | **vrf** *vrf-name*] { *hostname* | *ipv6-address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time* | **ttl** *minimum maximum*] *

traceroute oob { *hostname* | *ipv6-address* } [**out-interface** *interface-type interface-number* [**next-hop** *next-hop*] | **probe** *probe* | [**source** *interface-type interface-number* | **source** *source-ipv6-address*] | **timeout** *time* | **ttl** *minimum maximum* | **via** *mgmt-name*] *

Parameter Description

vrf *vrf-name*: Specifies a VRF. If this parameter is not specified, the public network instance is used.

hostname: Destination host name.

ipv6-address: Destination IPv6 address.

out-interface *interface-type interface-number*: Specifies the type and number of the outbound interface used to send the packets.

next-hop *next-hop*: Specifies the IPv6 address of the next hop of the outbound interface used to send the packets.

probe *probe*: Specifies the number of sent probe packets. The value range is from 1 to 255, and the default value is **3**.

source *interface-type interface-number*: Specifies the type and number of the source interface of the packets.

source *source-ipv6-address*: Specifies the source IPv6 address or source interface of the packets. A loopback interface, for example, ::1, cannot be configured as the source address.

timeout *time*: Specifies the timeout, in seconds. The value range is from 1 to 10, and the default value is **3**.

ttl *minimum maximum*: Specifies the minimum and maximum TTL values. The value range is from 1 to 255. By default, the minimum TTL is **1**, and the maximum TTL is **255**.

oob: Indicates that an out-of-band channel is used. This parameter is mandatory if the MGMT interface is configured as the source interface.

via *mgmt-name*: Specifies the outbound MGMT interface of packets where the Traceroute operation is performed.

Command Modes

Privileged EXEC mode

Default Level

0

Usage Guidelines

You can run this command to check the network connectivity, and accurately determine the location of a network fault when the fault occurs.

To use the domain name function, you must first configure the domain name server (DNS). For details, see "Configuring DNS" in "IP Service Configuration Guide."

Examples

The following example displays the gateways through which IPv6 packets are sent from the source address to the destination address 3004::1.

```
Hostname> enable
Hostname# traceroute ipv6 3004::1
  < press Ctrl+C to break >
Tracing the route to 3004::1
1     3000::1        0 msec  0 msec  0 msec

1 Tech-Support Commands

Command	Function
debug support	Enter the debug support mode.
execute diagnose-cmd	Run the diagnose command.
tech-support package	Collect the detailed fault information of the device.
@@@@f	Collect the detailed fault information of the device by using the hotkey.

1.1 debug support

Function

Run the **debug support** command to enter the debug support mode.

Syntax

debug support

Parameter Description

N/A

Command Modes

Privileged EXEC mode

Default Level

15

Usage Guidelines

This command is used to enter the debug support mode. You can run the Tech-Support commands only in debug support mode.

Examples

The following example enters the debug support mode.

```
Hostname> enable
Hostname# debug support
%Warning: Enter debug support mode, all commands in this mode are used to diagnose system hardware and software.
        Misuse of these commands will affect system performance. Therefore, use these commands under the guidance of Ruijie Networks engineers.

1.2 execute diagnose-cmd

Function

Run the **execute diagnose-cmd** command to run the diagnose command.

Syntax

execute diagnose-cmd { [**device** *device-id*] [**slot all** | **slot** *slot-id* }] [**chip** *chip-id*] *shell-command* | **help** }

Parameter Description

device *device-id*: Indicates the ID of a device.

slot all: Indicates that the diagnose command is executed on all cards.

slot *slot-id*: Indicates that the diagnose command is executed on the specified board. **m*** indicates the management engine, **fe*** indicates the switch fabric module, and 1~* indicates the service interface board. * indicates a positive integer number.

chip *chip-id*: ID of a chip. The value range is from 0 to 7.

shell-command: String of the shell command to be executed. For details about the command string, see Table 1-1.

help: Displays a list of executable *shell commands.*

Command Modes

Debug support mode

Default Level

15

Usage Guidelines

Table 1-1 Description of shell Command Strings

Command	Description
at	**at** diagnose command. Whether the **at** diagnose command is supported depends on the actual product.
copy	Copies files.
delete	Deletes files.
df	Displays the disk space usage.
dir	Displays the file list of the directory.
dmesg	Displays the core logs.
du	Displays the space usage of the file system.
echo	Saves data to a target file.
fdisk	Displays the partitioning information of a device.

Command	Description
hexdump	Displays the file information in hexadecimal format.
kill	Sends a signal to a specified process.
md5sum	Calculates and checks the MD5 message digest.
mkdir	Creates a directory.
more	Displays the file information.
mount	Displays the mounted file system.
process	Stops, starts, or restarts a process or a kernel module with the startup script.
ps	Displays information of the current process.
redis-cli	Database diagnose command
rmdir	Deletes an empty directory.
sdk	sdk diagnose command ● If the chip field is entered, only the sdk command can be executed. ● If the chip field is not entered, the sdk command is executed and the chip value is 0 by default.
sh	Runs the module diagnose shell command.
stat	Displays the file or file system status.
sync	Updates the file system cache.
tftp-tipc	Transfers files through TFTP TIPC between different devices or cards.
tipc-config	Displays the TIPC neighbor node information.
top	Displays the process information.
touch	Creates an empty file or changes the timestamp of a file.
zlog	Displays the zlog file information. For details about the zlog command format, see Table 1-2.

Table 1-2 zlog Command Format

Command	Description
module-name process-name { **debug** | **error** | **fatal** | **info** | **notice** | **warn** }	Displays different levels of log files of a process on a module. Parameter description: ● *module-name*: Name of a module ● *process-name*: Name of a process ● **debug**: Debug level ● **error**: Error level ● **fatal**: Fatal level ● **info**: Information level ● **notice**: Notification level ● **warn**: Warning level

Examples

The following example displays the device configuration file.

```
Hostname> enable
Hostname# debug support
Hostname(support)#execute diagnose-cmd more /data/config.text
```

Notifications

When the diagnosed slot ID is not configured, the following notification will be displayed:

```
% Execute command fail, because tipc connect fail!
```

When the diagnosed chip is not configured, the following notification will be displayed:

```
RG_AT command execute begin.
Chip id is invalid in this device, Please check the chip id!
RG_AT command execute end.
```

When the diagnosed device is not configured, the following notification will be displayed:

```
% Execute command fail, because tipc connect fail!
```

1.3 tech-support package

Function

Run the **tech-support package** command to collect the detailed fault information of the device.

Syntax

tech-support package [*component-name* | **basic**]

Parameter Description

component-name: Specified component whose fault information is to be collected.

basic: Collects the basic fault information of the device.

Command Modes

Debug support mode

Default Level

14

Usage Guidelines

- This command is used to collect the detailed real-time fault information of each service component and dump file registered with the TECH-SUPPORT framework, and save them in a fault information compressed package. The compressed package name indicates the VSD for which the fault information is collected.
- The fault information compressed package is stored in the descending order of USB flash drive, **Flash:/**, and **Tmp:/**. Before running this command, you are advised to insert the USB flash drive to avoid information loss. You can use the TFTP function to transfer the compressed packages of the final fault information to a PC.
- To prevent excessive consumption of space on the storage media after the fault information is collected for multiple times, a maximum of three compressed packages of fault information can be stored on the same storage medium.
- The compressed packages of fault information are stored as follows:
  - USB flash drive

    If a USB flash drive is inserted into the device, the compressed packages are stored in the root directory of the USB flash drive. You can run the **dir usb0:** command to view these compressed packages.
  - Flash directory

    If no USB flash drive is inserted into the device, the compressed packages are preferentially stored in the Flash directory. You can run the **dir flash:** command to view these compressed packages.
  - **Tmp** directory (memory)

    If no USB flash drive is inserted into the device and the Flash has insufficient space, the compressed packages are stored in the **Tmp** directory. You can run the **dir tmp:** command to view these compressed packages.

Examples

The following example collects the detailed fault information of the device.

```
Hostname> enable
```

```
Hostname# debug support
Hostname(support)# tech-support package
```

Notifications

- When the fault information of VSD 0 is successfully collected and packaged, the following notifications will be displayed, depending on the type of the storage medium:

  If the fault information compressed package is stored on the USB flash drive of VSD 0, run the **dir usb0:** command to view the package.

  ```
  Tech-support package success, the package file is
  /mnt/usb0/tech_vsd0_20140825164828.tar.gz.
  ```

  If the fault information compressed package is stored in the Flash directory on VSD 0, run the **dir flash:** command to view the package.

  ```
  Tech-support package success, the package file is
  /data/tech_vsd0_20140825164828.tar.gz.
  ```

  If the fault information compressed package is stored in the **Tmp** directory on VSD 0, run the **dir tmp:** command to view the package.

  ```
  Tech-support package success, the package file is
  /tmp/tech_vsd0_20140825164828.tar.gz.
  ```

- When the fault information of VSD 1 is successfully collected and packaged, the following notifications will be displayed, depending on the type of the storage medium:

  If the fault information compressed package is stored on the USB flash drive of VSD 1, run the **dir usb0:** command to view the package.

  ```
  Tech-support package success, the package file is
  /mnt/usb0/tech_vsd1_20140825164829.tar.gz.
  ```

  If the fault information compressed package is stored in the Flash directory on VSD 1, run the **dir flash:** command to view the package.

  ```
  Tech-support package success, the package file
  is/data/var/run/vsd/1/tech_vsd1_20140825175652.tar.gz.
  ```

  If the fault information compressed package is stored in the **Tmp** directory on VSD 1, run the **dir tmp:** command to view the package.

  ```
  Tech-support package success, the package file is
  /tmp/vsd/1/tech_vsd1_20140825164828.tar.gz.
  ```

- When the fault information is successfully collected but fails to be packaged, the following notification will be displayed:

  ```
  Tech-support package failed, the dump file is in dir: /data/tech_vsd0.
  ```

Common Errors

If the storage medium has insufficient space, information fails to be collected in the Tech-Support operation.

Platform Description

N/A

Related Commands

- **debug support**

1.4 @@@@f

Function

Run the @@@@**f** command to collect the detailed fault information of the device by using the hotkey.

Syntax

@@@@**f**

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

N/A

Usage Guidelines

This command is used to collect the detailed fault information of the device by using the hotkey. The @@@@**f** hotkey operation is often performed when the console crashes. The fault information is packaged in a way similar to the **tech-support package** command. The fault information is stored in the descending order of USB flash drive, **Flash:/**, and **Tmp:/**. Before running this command, you are advised to insert the USB flash drive to avoid information loss.

This command takes effect only when the device is connected to the console port, and is invalid for remote connections, for example, Telnet or SSH connection.

Examples

The following example collects the detailed fault information of a management board by using the hotkey.

You only need to press "@@@@f" on the console to trigger the information collection.

Notifications

When the fault information is successfully collected but fails to be packaged, the following notification will be displayed:

```
Tech-support package failed, the dump file is in directory: /data/tech_vsd0.
```

Common Errors

If the storage medium has insufficient space, information fails to be collected in the Tech-Support operation.

1 SPAN Commands

Command	Function
default monitor session	Delete all switch port analyzer (SPAN) sessions.
destination ip address	Configure the destination IP address when the encapsulation type is GRE.
ip dscp	Configure the DSCP value for an encapsulated IP packet.
ip ttl	Configure the TTL value for an encapsulated IP packet.
mac-loopback	Enable the MAC loopback function of an interface.
monitor session destination interface	Configure a destination port for a local SPAN session.
monitor session destination remote vlan interface	Configure an output port on an RSPAN source device or a destination port on an RSPAN destination device for an RSPAN session.
monitor session erpsan-source	Create an ERSPAN session.
monitor session filter vlan	Exclude one or more VLANs as the data source of SPAN.
monitor session remote-source	Configure the source device for an RSPAN session.
monitor session remote-destination	Configure a destination device for an RSPAN session.
monitor session source interface	Configure the source port for a local SPAN session.
monitor session source vlan	Specify a VLAN as the data source of SPAN.
no monitor session	Delete all SPAN sessions.
remote-span	Configure a remote VLAN.
origin ip address	Configure a source IP address for GRE encapsulation.
show monitor	Display the SPAN sessions.
source interface	Configure a source port for ERSPAN.
shutdown	Shut down an ERSPAN session.
vrf	Associate a VRF with ERSPAN.

1.1 default monitor session

Function

Run the **default monitor session** command to delete all switch port analyzer (SPAN) sessions.

Syntax

default monitor session { *session-number* | **all** }

Parameter Description

session-number: ID of a SPAN session. The value range is from 1 to 4.

all: Indicates all SPAN sessions.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays SPAN sessions configured on the device.

```
Hostname> enable
Hostname# show running-config | include monitor session
monitor session 1 remote-source
monitor session 1 destination remote vlan 10 interface GigabitEthernet 0/1
monitor session 1 filter vlan 3 rx
```

The following example removes all the SPAN sessions from the device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# default monitor session all
Hostname(config)# exit
Hostname# show running-config | include monitor session
```

1.2 destination ip address

Function

Run the **destination ip address** command to configure the destination IP address when the encapsulation type is GRE.

Run the **no** form of this command to remove this configuration.

By default, no destination IP address is configured when the encapsulation type is GRE.

Syntax

destination ip address *ipv4-address*

no destination ip address

Parameter Description

ipv4-address: Destination IP address when the encapsulation type is GRE.

Command Modes

ERSPAN configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the destination IP address to 10.1.1.2 when the SPAN encapsulation type is GRE.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 2 erspan-source
Hostname(config-mon-erspan-src)# destination ip address 10.1.1.2
```

Notifications

When the entered IP address is invalid, the following notification will be displayed:

```
Invalid ip address
```

Platform Description

N/A

Common Errors

1.3 ip dscp

Function

Run the **ip dscp** command to configure the DSCP value for an encapsulated IP packet.

Run the **no** form of this command to restore the default DSCP value.

The default DSCP of the encapsulated IP packet is **0**.

Syntax

ip dscp *dscp-value*

no ip dscp

Parameter Description

dscp-value: DSCP value of the encapsulated IP packet. The value range is from 0 to 63.

Command Modes

ERSPAN configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the DSCP of the encapsulated IP packet to 56.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 2 erspan-source
Hostname(config-mon-erspan-src)# ip dscp 56
```

1.4 ip ttl

Function

Run the **ip ttl** command to configure the TTL value for an encapsulated IP packet.

Run the **no** form of this command to restore the default TTL value.

The default TTL of the encapsulated IP packet is **64**.

Syntax

ip ttl *ttl-value*

no ip ttl

Parameter Description

ttl-value: TTL value of the encapsulated IP packet. The value range is from 1 to 255.

Command Modes

ERSPAN configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the TTL of the encapsulated IP packet to 65.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 2 erspan-source
Hostname(config-mon-erspan-src)# ip ttl 65
```

Notifications

1.5 mac-loopback

Function

Run the **mac-loopback** command to enable the MAC loopback function of an interface.

Run the **no** form of this command to disable this feature.

By default, MAC loopback is disabled for an interface.

Syntax

mac-loopback

no mac-loopback

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

When configuring one-to-many SPAN, you need to use this command to enable the MAC loopback function of an interface.

Do not add other configurations for this interface.

To save port resources, you are advised to configure a port in Down state as the MAC loopback port.

Examples

The following example configures the remote VLAN 10.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 100
Hostname(config-vlan)# remote-span
Hostname(config-vlan)# exit
```

The following example configures a source device and configures GigabitEthernet 0/1 as the source port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 1 remote-source
Hostname(config)# monitor session 1 source interface gigabitEthernet 0/1 both
```

The following example configures GigabitEthernet 0/2 as the destination port, and enables the MAC loopback function on this port. (You can see that the state of GigabitEthernet 0/2 changes to Up instantly.)

```
Hostname(config)# monitor session 1 destination remote vlan 100 interface
gigabitEthernet 0/2 switch
Hostname(config)# interface gigabitEthernet 0/2
```

```
Hostname(config-if-GigabitEthernet 0/2)# switchport access vlan 100
Hostname(config-if-GigabitEthernet 0/2)# mac-loopback
```

The following example adds GigabitEthernet 0/3-4 to remote VLAN 100.

```
Hostname(config)# interface range gigabitEthernet 0/3-4
Hostname(config-if-range)# switchport access vlan 100
```

1.6 monitor session destination interface

Function

Run the **monitor session destination interface** command to configure a destination port for a local SPAN session.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no destination port is configured for a local SPAN session.

Syntax

monitor session *session-number* **destination interface** *interface-type interface-number* [**switch**]

no monitor session *session-number* **destination interface** *interface-type interface-number* [**switch**]

default monitor session *session-number* **destination interface** *interface-type interface-number* [**switch**]

Parameter Description

session-number: ID of a SPAN session.

interface-type interface-number: Type and number of the source or destination port.

switch: Configures the switching function of the destination port.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/AExamples

The following example configures GigabitEthernet 0/1 as the source port and GigabitEthernet 0/2 as the destination port for SPAN session 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 1 source interface gigabitEthernet 0/1
Hostname(config)# monitor session 1 destination interface gigabitEthernet 0/2
```

Notifications

On some devices that do not support configuration of SPAN for AP member ports, if you try to configure an AP member port as the source or destination port for SPAN, the following notification will be displayed:

```
Set fail on ap member.
```

Common Errors

N/A

Platform Description

1.7 monitor session destination remote vlan interface

Function

Run the **monitor session destination remote vlan interface** command to configure an output port on an RSPAN source device or a destination port on an RSPAN destination device for an RSPAN session.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no output port on the RSPAN source device or no destination port on the RSPAN destination device is configured.

Syntax

monitor session *session-number* **destination remote vlan** *remote-vlan-id* **interface** *interface-type interface-number* [**switch**]

no monitor session *session-number* **destination remote vlan** *remote-vlan-id* **interface** *interface-type interface-number* [**switch**]

default monitor session *session-number* **destination remote vlan** *remote-vlan-id* **interface** *interface-type interface-number* [**switch**]

Parameter Description

session-number: ID of a SPAN session.

interface-type interface-number: Type and number of the source or destination port.

remote-vlan-id: ID of a remote VLAN.

vlan-id-list: VLAN list (containing common VLANs instead of remote VLANs).

switch: Configures the switching function of the destination port.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures GigabitEthernet 0/1 as the output port on the source device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 1 remote-source
Hostname(config)# monitor session 1 destination remote vlan 10 interface
gigabitEthernet 0/1
```

Notifications

On some devices that do not support configuration of SPAN for AP member ports, if you try to configure an AP member port as the source or destination port for SPAN, the following notification will be displayed:

```
Set fail on ap member.
```

If the VLAN specified by remote-vlan-id does not exist or is not a remote VLAN, the following notification will be displayed:

```
vlan 1 doesn't exist or it isn't remote span vlan.
```

Common Errors

Common Errors

N/A

Platform Description

N/A

Related Commands

N/A

1.9 monitor session filter vlan

Function

Run the **monitor session filter vlan** command to exclude one or more VLANs as the data source of SPAN.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no VLAN is excluded as the data source of SPAN.

Syntax

monitor session *session-number* **filter vlan** *vlan-id-list* **rx**

no monitor session *session-number* **filter vlan** *vlan-id-list* **rx**

default monitor session *session-number* **filter vlan** *vlan-id-list* **rx**

Parameter Description

session-number: ID of a SPAN session.

vlan-id-list: VLAN list (containing common VLANs instead of remote VLANs).

rx: **rx** indicates that only received packets are mirrored.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command must be configured together with the **monitor session source interface** command.

If you add or delete a VLAN source port to or from an effective SPAN session, you need to re-apply the entire SPAN session. Therefore, a few existing mirrored packets may be lost.

Examples

The following example excludes the RX direction of VLAN 2 as the data source of SPAN.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 1 filter vlan 2 rx
```

1.12 monitor session source interface

Function

Run the **monitor session source interface** command to configure the source port for a local SPAN session.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no source port is configured for a local SPAN session.

Syntax

monitor session *session-number* **source interface** *interface-type interface-number* [**both** | **rx** [**acl** { *acl-name* | *acl-number* }] | **tx**]

no monitor session *session-number* **source interface** *interface-type interface-number* [**both** | **rx** [**acl** { *acl-name* | *acl-number* }] | **tx**]

default monitor session *session-number* **source interface** *interface-type interface-number* [{ **both** | **rx** [**acl** { *acl-name* | *acl-number* }] | **tx**]

Parameter Description

session-number: ID of a SPAN session.

interface-type interface-number: Type and number of the source port.

both: Indicates that both the received and sent packets are mirrored.

rx: Indicates that only the received packets are mirrored.

tx: Indicates that only the sent packets are mirrored.

acl { *acl-name* | *acl-number* }: Indicates that only packets that match ACL rules are mirrored. *acl-name*: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters. *acl-number*: Number of an ACL. For a standard IP ACL, the value range is from 1 to 99 and from 1300 to 1999. For an extended IP ACL, the value range is from 100 to 199 and from 2000 to 2699. For a MAC ACL, the value range is from 700 to 799.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- If you do not specify **both**/**rx**/**tx** when configuring a source port, **both** is used by default. If the direction is specified, only packets in the specified direction are mirrored.

Examples

The following example configures GigabitEthernet 0/1 as the source port for SPAN session 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 1 source interface gigabitEthernet 0/1
```

Notifications

On some devices that do not support configuration of SPAN for AP member ports, if you try to configure an AP member port as the source port for SPAN, the following notification will be displayed:

```
Set fail on ap member.
```

Function

Run the **monitor session source vlan** command to specify a VLAN as the data source of SPAN.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no VLAN is specified as the data source of SPAN.

Syntax

monitor session *session-number* **source vlan** *vlan-list* **rx**

no monitor session *session-number* **source vlan** *vlan-list* **rx** [**both** | **rx** | **tx**]

default monitor session *session-number* **source vlan** *vlan-list* **rx**

Parameter Description

session-number: ID of a SPAN session.

vlan-list: VLAN list (containing common VLANs instead of remote VLANs).

rx indicates that only received packets are mirrored.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If you add or delete a VLAN source port to or from an effective SPAN session, you need to re-apply the entire SPAN session. Therefore, a few existing mirrored packets may be lost.

Examples

The following example configures the RX direction of VLAN 2 as the data source of SPAN session 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 1 source vlan 2 rx
```

1.14 no monitor session

Function

Run the **no monitor session** command to delete all SPAN sessions.

Syntax

no monitor session { *session-number* | **all** }

Parameter Description

session-number: ID of a SPAN session. The value range is from 1 to 4.

all: Indicates all SPAN sessions.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays SPAN sessions configured on a device.

```
Hostname> enable
Hostname# show running-config | include monitor session
monitor session 1 remote-source
monitor session 1 destination remote vlan 10 interface GigabitEthernet 0/1
monitor session 1 filter vlan 3 rx
```

The following example deletes all SPAN sessions from the device.

```
Hostname# configure terminal
Hostname(config)# no monitor session all
Hostname(config)# exit
Hostname# show running-config | include monitor session
```

1.15 remote-span

Function

Run the **remote-span** command to configure a remote VLAN.

Run the **no** form of this command to remove this configuration.

By default, no remote VLAN is configured.

Syntax

remote-span

no remote-span

Parameter Description

N/A

Command Modes

VLAN configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures VLAN 100 as the remote VLAN.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# vlan 100
Hostname(config-vlan)# remote-span
```

Notifications

If this VLAN is already a remote VLAN, the following notification will be displayed when you run the **remote-span** command:

```
RSPAN vlan can't be set as remote span vlan.
```

1.16 origin ip address

Function

Run the **origin ip address** command to configure a source IP address for GRE encapsulation.

Run the **no** form of this command to remove this configuration.

By default, no source IP address is configured for GRE encapsulation.

Syntax

origin ip address *ipv4-address*

no origin ip address

Parameter Description

ipv4-address: Source IP address specified for GRE encapsulation.

Command Modes

ERSPAN configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the source IP address of an IP packet to 11.1.1.2 when the ERSPAN encapsulation type is GRE.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 2 erspan-source
Hostname(config-mon-erspan-src)# origin ip address 11.1.1.2
```

1.17 show monitor

Function

Run the **show monitor** command to display the SPAN sessions.

Syntax

show monitor session *session-number*

Parameter Description

session *session-number*: Specifies the ID of a SPAN session.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays all the SPAN sessions.

```
Hostname> enable
Hostname# show monitor
sess-num: 1
span-type: LOCAL_SPAN
src-intf:
GigabitEthernet 0/2     frame-type Both
dest-intf:
GigabitEthernet 0/3
sess-num: 3
span-type: ERSPAN_SOURCE
src-intf:
```

```
 AggregatePort 1           frame-type: Both      TX status: Inactive   RX status:
Inactive
original ip address: 1.1.1.1
destination ip address: 1.1.1.2
status: disable
ip ttl: 64
ip dscp: 0
vrf: global-vrf
```

The following example displays the specified SPAN session.

```
Hostname> enable
Hostname# show monitor session 1
sess-num: 1
span-type: LOCAL_SPAN
src-intf:
GigabitEthernet 0/2     frame-type Both
dest-intf:
GigabitEthernet 0/3
```

Table 1-1 Output Fields of the show monitor Command

Field	Description
sess-num	ID of a SPAN session
span-type	SPAN type
src-intf	Source interface of the SPAN session
frame-type	Direction of streams to be mirrored
TX/RX status	Connectivity status of the route to the destination IP address when the ERSPAN session is valid (that is, the session is complete and not shut down): ● **Active**: The route to the destination IP address is reachable, and the ERSPAN session is active. ● **Inactive**: The route to the destination IP address is unreachable, and the ERSPAN session is inactive.
dest-intf	Destination interface of the SPAN session
original ip address	Source IP address for ERSPAN
destination ip address	Destination IP address for ERSPAN
status	Availability status of the ERSPAN session: ● **disable**: When the **shutdown** command is configured, the status is displayed as disable, and the session is unavailable. ● **enable**: The session is available.
ip ttl	TTL value of the encapsulated IP packet
ip dscp	DSCP value of the encapsulated IP packet

Field	Description
vrf	VRF information of the ESPAN session

1.18 source interface

Function

Run the **source interface** command to configure a source port for ERSPAN.
Run the **no** form of this command to remove this configuration.
By default, no source port is configured for ERSPAN.

Syntax

source interface *interface-type interface-numbere* [{ **both** | **rx** [**acl** { *acl-name* | *acl-number* }] | **tx**]

no source interface *interface-type interface-number* [{ **both** | **rx** [**acl** { *acl-name* | *acl-number* }] | **tx**]

Parameter Description

interface-type interface-number: Type and number of the source port.

both: Indicates that both the received and sent packets are mirrored.

rx: Indicates that only received packets are mirrored.

tx: Indicates that only the sent packets are mirrored.

acl-name: Name of an ACL. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an ACL. For a standard IP ACL, the value range is from 1 to 99 and from 1300 to 1999. For an extended IP ACL, the value range is from 100 to 199 and from 2000 to 2699. For a MAC ACL, the value range is from 700 to 799.

Command Modes

ERSPAN configuration mode

Default Level

14

Usage Guidelines

- When a sub-interface is configured as the source port, mirroring is supported only in the inbound direction.
- If you do not specify **both**/**rx**/**tx** when configuring a source port, **both** is used by default. If the direction is specified, only packets in the specified direction are mirrored.

Examples

The following example configures GigabitEthernet 0/1 as the source port for a stream-based ERSPAN session, and mirrors packets that match ACL 90.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# monitor session 2 erspan-source
Hostname(config-mon-erspan-src)# source interface gigabitEthernet 0/1 rx acl 90
```

1 sFlow Commands

Command	Function
sflow agent	Configure the sFlow Agent address.
sflow collector destination	Configure the sFlow Collector address.
sflow collector max-datagram-size	Configure the maximum size of an output sFlow packet.
sflow counter collector	Configure the ID of the sFlow Collector for sFlow counter sampling.
sflow counter interval	Configure the interval for sFlow counter sampling.
sflow enable	Enable the sFlow function on an interface.
sflow flow collector	Configure the ID of the sFlow Collector for sFlow flow sampling.
sflow flow max-header	Configure the maximum length of the packet header copied during sFlow flow sampling.
sflow sampling-rate	Configure the sFlow flow sampling rate.
sflow source	Configure the source address of output sFlow packets.
show sflow	Display the sFlow configurations.

1.1 sflow agent

Function

Run the **sflow agent** command to configure the sFlow Agent address.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No sFlow Agent address is configured by default.

Syntax

sflow agent { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **interface** [**ipv6**] *interface-type interface-number* }

no sflow agent { **address** | **interface** }

default sflow agent { **address** | **interface** }

Parameter Description

address { *ipv4-address* | **ipv6** *ipv6-address* }: Configures an IP address as the sFlow Agent address.

Here, *ipv4-address* indicates the IPv4 address of the sFlow Agent. **ipv6** *ipv6-address* indicates the IPv6 address of the sFlow Agent.

interface [**ipv6**] *interface-type interface-number*: Configures an interface as the sFlow Agent address.

Here, *interface-type interface-number* indicates the type and number of an interface configured with the IPv4 address. **ipv6** *interface-type interface-number* indicates the type and number of an interface configured with the IPv6 address.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the **Agent ip address** field in an output packet. If the sFlow Agent address is not configured, the packet cannot be output. The address must be a host IP address. If it is set to a non-host IP address, for example, a multicast or broadcast address, a notification indicating the configuration error is displayed. It is recommended that the IP address of the sFlow Agent device be configured as the sFlow Agent address.

Examples

The following example sets the sFlow Agent address to 192.168.2.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sflow agent address 192.168.2.1
```

Notifications

If an invalid address is configured, the following notification will be displayed:

```
invalid host address.
```

Common Errors

N/A

Platform Description

N/A

Related Commands

N/A

1.2 sflow collector destination

Function

Run the **sflow collector destination** command to configure the sFlow Collector address.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

No sFlow Collector address is configured by default.

Syntax

sflow collector *collector-id* **destination** { *ipv4-address* | **ipv**6 *ipv6-address* } *udp-port-number* [**vrf** *vrf-name*] [**description** *collector-description*]

no sflow collector *collector-id* **destination** { *ipv4-address* | **ipv6** *ipv6-ddress* } *udp-port-number* [**vrf** *vrf-name*] [**description** *collector-name*]

default sflow collector *collector-id* **destination** { *ipv4-address* | **ipv6** *ipv6-address* } *udp-port-number* [**vrf** *vrf-name*] [**description** *collector-description*]

Parameter Description

collector-id: ID of the sFlow Collector. The value range is from 1 to 2.

ipv4-address: IPv4 address of the sFlow Collector.

ipv6 *ipv6-address*: Specifies the IPv6 address of the sFlow Collector.

udp-port-number: Number of a UDP port. The value range is from 1 to 65535.

vrf *vrf-name*: Specifies the name of a VRF instance.

description *collector-description*: Specifies the description of the sFlow Collector.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- The sFlow Agent address must be a valid address. That is, the sFlow Agent address cannot be a multicast or broadcast address. It is recommended that the IP address of the sFlow Agent device be used.

- The sFlow Collector intercepts sFlow packets on the configured port.
- When the **vrf** parameter is configured, the corresponding VRF instance must be configured. If you configure a VRF instance for an sFlow Collector address and later remove this VRF instance, the sFlow Collector address will be removed as well.

Examples

The following example sets the address of sFlow Collector 1 to 192.168.2.100, listen port to 6343, and VRF instance name to vpn1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sflow collector 1 destination 192.168.2.100 6343 vrf vpn1
```

Notifications

If an invalid address is configured, the following notification will be displayed:

```
invalid host address.
```

If the VPN is not configured, the following notification will be displayed:

```
vpn is not exist
```

1.3 sflow collector max-datagram-size

Function

Run the **sflow collector max-datagram-size** command to configure the maximum size of an output sFlow packet.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the maximum size of the output sFlow packet is **1400**.

Syntax

sflow collector *collector-id* **max-datagram-size** *datagram-size*

no sflow collector *collector-id* **max-datagram-size**

default sflow collector *collector-id* **max-datagram-size**

Parameter Description

collector-id: ID of the sFlow Collector. The value is 1 or 2.

max-datagram-size *datagram-size*: Specifies the maximum size of an output sFlow packet. The value range is from 200 to 9000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the maximum size of an output sFlow packet to 1000 bytes for sFlow Collector 1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sflow collector 1 max-datagram-size 1000
```

1.4 sflow counter collector

Function

Run the **sflow counter collector** command to configure the ID of the sFlow Collector for sFlow counter sampling.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no ID of the sFlow Collector is configured for sFlow counter sampling.

Syntax

sflow counter collector *collector-id*

no sflow counter collector

default sflow counter collector

Parameter Description

collector-id: ID of the sFlow Collector. The value range is from 1 to 2.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

- You must configure an IP address for the sFlow Collector before the sFlow packets can be output.

Examples

The following example outputs the sFlow counter sampling packets on the port GigabitEthernet 0/1 to sFlow Collector 2.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# sflow counter collector 2
```

1.5 sflow counter interval

Function

Run the **sflow counter interval** command to configure the interval for sFlow counter sampling.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default interval for sFlow flow sampling is **30** seconds.

Syntax

sflow counter interval *sampling-interval-time*

no sflow counter interval

default sflow counter interval

Parameter Description

sampling-interval-time: Sampling interval, in seconds. The value range is from 3 to 2147483647.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the global interval for sFlow counter sampling. This configuration applies to all interfaces.

Examples

The following example sets the global interval for sFlow counter sampling to 60s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sflow counter interval 60
```

1.6 sflow enable

Function

Run the **sflow enable** command to enable the sFlow function on an interface.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The sFlow function is disabled by default.

Syntax

sflow enable [{ **ingress** | **egress** }

no sflow enable [{ **ingress** | **egress** }

default sflow enable [{ **ingress** | **egress** }

Parameter Description

ingress: Specifies inbound direction.

egress: Specifies outbound direction.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

- This command can be configured on a physical or an aggregation port.
- If the direction is not specified, flow sampling is enabled in both the inbound and outbound directions.
- The counter sampling and flow sampling functions are enabled concurrently. Counter sampling is enabled when flow sampling is enabled in any direction of an interface.
- You must configure an IP address for the sFlow Collector before the sFlow packets can be output.
- The following configuration is not recommended because flow sample statistics may be inaccurate (for example, the configuration may not take effect, or statistics of an interface is displayed on another interface):
  - Flow sampling is enabled on an aggregation port and its member port.

Examples

The following example enables the sFlow function on the GigabitEthernet 0/1 port.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# sflow enable
```

1.8 sflow flow max-header

Function

Run the **sflow flow max-header** command to configure the maximum length of the packet header copied during sFlow flow sampling.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the maximum length of the packet header copied during sFlow flow sampling is **64**.

Syntax

sflow flow max-header *sampling-length*

no sflow flow max-header

default sflow flow max-header

Parameter Description

sampling-length: Maximum length of the packet header copied, in bytes. The value range is from 18 to 256.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the maximum number of bytes that can be copied from the header of the original packet. The copied content is recorded in the generated sample. The protocol requires byte alignment during packet encapsulation, that is, the actual length of a sent packet is a multiple of 4. Therefore, the length of a collected packet may exceed the configured length. For example, when the maximum length is set to any of 21, 22, 23, and 24, the actual output packet length is 24.

Examples

The following example sets the maximum length of the packet header copied during sFlow flow sampling to 128 bytes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sflow flow max-header 128
```

Function

Run the **sflow sampling-rate** command to configure the sFlow flow sampling rate.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default sFlow flow sampling rate is 65536.

Syntax

sflow sampling-rate *sampling-rate*

no sflow sampling-rate

default sflow sampling-rate

Parameter Description

sampling-rate: sFlow flow sampling rate, which indicates that a packet is sampled from every *sampling-rate* packets. The value is 65536.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the global flow sampling rate. This configuration applies to all interfaces.

Examples

The following example sets the sFlow flow sampling rate to **4096**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sflow sampling-rate 4096
```

1.10 sflow source

Function

Run the **sflow source** command to configure the source address of output sFlow packets.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the source address of output sFlow packets is the local device IP address which is used to ping the destination IP address.

Syntax

sflow source { **address** { *ipv4-address* | **ipv6** *ipv6-address* } | **interface** [**ipv6**] *interface-type interface-number* }

no sflow source { **address** | **interface** }

default sflow source { **address** | **interface** }

Parameter Description

address { *ipv4-address* | **ipv6** *ipv6-address* }: Configures an IP address as the sFlow source address.

Here, *ipv4-address* indicates the IPv4 address of the sFlow source, which is not configured by default. **ipv6** *ipv6-address* indicates the IPv6 address of the sFlow source, which is not configured by default.

interface [**ipv6**] *interface-type interface-number*: Configures an interface as the sFlow source address.

interface-type interface-number indicates the type and number of an interface configured with the IPv4 address. **ipv6** *interface-type interface-number* indicates the type and number of an interface configured with the IPv6 address.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command is used to configure the source IP address of output packets.
- By default, the source address of output sFlow packets is the local device IP address which is used to ping the destination IP address.
- If the source interface is specified, the primary address (or the first global IPv6 address if any) of the interface is the source IP address of output packets.
- If the source interface is not specified, the default source address is used.

Examples

The following example sets the sFlow source address to 192.168.2.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sflow source address 192.168.2.1
```

Notifications

If an invalid address is configured, the following notification will be displayed:

```
invalid host address.

1 NTP Commands

Command	Function
no ntp	Disable the NTP synchronization with the time server, and clear all NTP configurations.
ntp access-group	Configure the NTP access control rights.
ntp authenticate	Configure the NTP global authentication mechanism.
ntp authentication-key	Configure an NTP global authentication key for the NTP service.
ntp disable	Disable the function of receiving NTP packets on an interface.
ntp discard	Configure the minimum packet request interval and average packet request interval allowed by NTP. The actual effective value is a power of 2.
ntp interval	Configure the interval for clock synchronization between the NTP client and NTP server.
ntp master	Configure the local clock as the NTP master clock to provide synchronization time for other devices.
ntp server	Specify an NTP server for an NTP client.
ntp service disable	Disable the NTP time synchronization service provided for other devices.
ntp trusted-key	Configure a key corresponding to an ID as a globally trusted key.
ntp update-calendar	Enable the NTP client to periodically update the hardware clock of the device using the clock synchronized from an external clock source.
show ntp server	Display the NTP server information.
show ntp status	Display the NTP information.
show ntp packets	Display information about the received and sent NTP packets.

1.1 no ntp

Function

Run the **no ntp** command to disable the NTP synchronization with the time server, and clear all NTP configurations.

The NTP service is disabled by default.

Syntax

no ntp

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The NTP service is disabled by default. It is enabled only when the NTP server or NTP master clock is configured.

Examples

The following example disables the NTP service.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ntp
```

Notifications

1.2 ntp access-group

Note

Whether a device supports this command depends on the ACL configuration.

Function

Run the **ntp access-group** command to configure the NTP access control rights.

Run the **no** form of this command to remove this configuration.

No NTP access control rule is configured by default.

Syntax

ntp access-group { **limited** | **peer** | **query-only** | **serve** | **serve-only** } *acl-number* | *acl-name* [**kod**]

no ntp access-group { **limited** | **peer** | **query-only** | **serve** | **serve-only** } *acl-number* | *acl-name*

Parameter Description

limited: Allows time request and control query for local NTP services, but limits the sending interval of request packets.

peer: Allows time request and control query for local NTP services, and allows a local device to synchronize time with a remote system (full access rights).

query-only: Allows only control query for local NTP services.

serve: Allows time request and control query for local NTP services, but does not allow a local device to synchronize time with a remote system.

serve-only: Allows only time request for local NTP services.

acl-number: Number of an IP ACL. The value range is from 1 to 99 and from 1300 to 1999.

acl-name: Name of an IP ACL.

kod: If the KoD function is enabled in **limited** mode, the NTP server sends the corresponding KoD packet to the client.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command is used to configure the NTP access control rights of the local device. Access control provides a minimum security measure. A more secure method is to use the NTP authentication mechanism.
- When an access request arrives, the NTP service matches rules in the sequence from the minimum access restriction to the maximum access restriction and uses the first matched rule. The matching sequence is limited, peer, serve, serve-only, and query-only.
- If no access control rule is configured, all accesses are allowed. If any access control rule is configured, only accesses allowed by the rule can be implemented.
- The system currently does not support the access control query function. Though rule matching is implemented in the preceding sequence, no request related to control query is supported.

Examples

The following example allows only the device with the IP address 192.168.1.1 to send a time request to a local device.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# access-list 1 permit 192.168.1.1
Hostname(config)# ntp access-group serve-only 1
```

The following example configures the NTP server, limits the request packet interval of the client, and sends KoD packets.

```
Hostname(config)# ip access-list standard limited 1
Hostname(config-std-nacl)# 10 permit any
Hostname(config-std-nacl)# exit
Hostname(config)# ntp access-group limited limited1 kod
Hostname(config)# ntp discard min-spacing 5 avg-spacing 5
Hostname(config)# ntp master
```

1.3 ntp authenticate

Function

Run the **ntp authenticate** command to configure the NTP global authentication mechanism.

Run the **no** form of this command to remove this configuration.

The NTP global authentication mechanism is disabled by default.

Syntax

ntp authenticate

no ntp authenticate

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

If no global security authentication mechanism is configured, synchronization communication is not encrypted. Encrypted communication with the server is initiated only when the global security authentication mechanism is enabled and the global key is configured.

Examples

The following example configures a global authentication key with the ID set to 6 and MD5 set to wooooop, specifies it as a globally entrusted key, and then enables the global authentication mechanism.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp authentication-key 6 md5 wooooop
Hostname(config)# ntp trusted-key 6
Hostname(config)# ntp authenticate
```

Notifications

1.4 ntp authentication-key

Function

Run the **ntp authentication-key** command to configure an NTP global authentication key for the NTP service.

Run the **no** form of this command to remove this configuration.

No authentication key is configured by default.

Syntax

ntp authentication-key *authentication-key-id* **md5** *authentication-key-string* [**0** | **7**]

no ntp authentication-key key-id

Parameter Description

authentication-key-id: ID of the key. The value range is from 1 to 4294967295.

authentication-key-string: Key string in text format. The maximum length of the key string is 31 bytes when the key is not encrypted, and 64 bytes when the key is encrypted.

0 | **7**: Indicates whether the key is encrypted. Here, **0** indicates no encryption, and **7** indicates simple encryption. The default value is **0**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command is used to configure a global authentication key and use MD5 for encryption. Each key has a unique key-id. You can run the **ntp trusted-key** command to configure a key corresponding to key-id as a globally trusted key.
- You can configure up to 1024 keys, but a server supports only one key.

Examples

The following example configures an authentication key with the ID set to 6 and MD5 set to wooooop.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp authentication-key 6 md5 wooooop
```

1.5 ntp disable

Function

Run the **ntp disable** command to disable the function of receiving NTP packets on an interface.

The function of receiving NTP packets on an interface is enabled by default.

Syntax

ntp disable

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

- By default, NTP packets received on any interface can be provided for the client for clock adjustment. By configuring this command, you can disable the function of receiving NTP packets on the related interface to shield these packets.
- You can configure this command only on an interface that can be configured with an IP address.

Examples

The following example enables the function of receiving NTP packets on the interface GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# no ntp disable
```

1.6 ntp discard

Function

Run the **ntp discard** command to configure the minimum packet request interval and average packet request interval allowed by NTP. The actual effective value is a power of 2.

Run the **no** form of this command to remove this configuration.

By default, the minimum packet request interval allowed by NTP is 2s, and the average packet request interval is 8s.

Syntax

ntp discard min-spacing *discard-min-spacing-interval* **avg-spacing** *avg-spacing-interval*

no ntp discard

Parameter Description

discard-min-spacing-interval: Minimum interval at which the NTP client is allowed to send the request packet, in seconds. The actual interval is 2 to the power of *discard-min-spacing-interval*. The value range is from 1 to 8. The default value is **1**.

avg-spacing-interval: Average interval at which the NTP client is allowed to send the request packet, in seconds. The actual interval is 2 to the power of *avg-spacing-interval*. The value range is from 3 to 10. The default value is **3**.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command must be used together with the **ntp access-group** { **limited** | **peer** | **serve** | **serve-only** | **query-only** } *acl-number* | *acl-name* [**kod**] command.
- The configured *discard-min-spacing-interval* and *avg-spacing-interval* are a power of 2, in seconds. For example, if *avg-spacing-interval* is set to 5, the actual average interval is 2 to the 5th power, that is, 32 seconds, instead of 5 seconds.
- When a KoD-enabled NTP device acts as a client, it reduces the rate after receiving a KoD packet. A KoD-disabled device does not reduce the rate.
- KoD cannot be triggered by specifying the interval in the **ntp interval** command.

Examples

The following example sets the minimum packet request interval allowed by NTP to 32s, and the average packet request interval to 32s.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp discard min-spacing 5 avg-spacing 5
```

1.7 ntp interval

Function

Run the **ntp interval** command to configure the interval for clock synchronization between the NTP client and NTP server.

Run the **no** form of this command to remove this configuration.

The interval for clock synchronization between the NTP client and NTP server is 64s by default.

Syntax

ntp interval *synchronization-interval-time*

no ntp interval

Parameter Description

synchronization-interval-time: Interval for clock synchronization, in seconds. The value range is from 10 to 2592000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- The interval configured by this command does not take effect immediately. If you need this configuration to take effect immediately, enable NTP before configuring the interval.
- If the NTP client has not successfully synchronized the time, it quickly synchronizes the time at an interval of 5s. After the successful synchronization, the NTP server synchronizes the time at the configured interval.

Examples

The following example sets the interval for clock synchronization between the NTP client and NTP server to 1 hour.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp interval 3600
```

1.8 ntp master

Caution

Use this command with caution. After a local clock is configured as the master clock (especially when a clock with a lower stratum is specified), a real effective clock source may be overwritten. If this command is used for

multiple devices in a network, the clock difference between the devices may cause unstable time synchronization of the network.

Function

Run the **ntp master** command to configure the local clock as the NTP master clock to provide synchronization time for other devices.

Run the **no** form of this command to remove this configuration.

The NTP master clock is disabled by default.

Syntax

ntp master [*stratum*]

no ntp master

Parameter Description

stratum: Stratum of the local clock. The value range is from 1 to 15. The default value is 8.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- Before this command is configured, if this system never synchronizes time with an external clock source, you may need to manually calibrate the system clock to ensure that there is no excessive difference.
- When the local system cannot synchronize time with the external clock source due to a network connection failure or other reasons, you can use this command to configure the local clock as the NTP master clock to provide synchronization time for other devices.
- After this command is executed, the system does not synchronize with a clock source with a higher stratum.

Examples

The following example configures the local clock as the NTP master clock and sets its stratum to 12.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp master 12
```

1.9 ntp server

Function

Run the **ntp server** command to specify an NTP server for an NTP client.

Run the **no** form of this command to remove this configuration.

No NTP server is configured by default.

Syntax

ntp server [**oob** | **vrf** *vrf-name*] { *ipv4-address* | *ipv6-address* | *peer-hostname* | **ip** *domain* | **ipv6** *domain* } [**key** *keyid*] [**prefer**] [**source** *interface-type interface-number*] [**version** *version*] [**via** *mgmt-name*]

no ntp server [**oob** | **vrf** *vrf-name*] { *ipv4-address* | *ipv6-address* | **ip** *domain* | **ipv6** *domain* }

Parameter Description

oob: Accesses the NTP server through the MGMT port. By default, the local device does not access the NTP server through the MGMT port.

vrf *vrf-name*: Specifies the name of the VRF instance used to access the NTP server. By default, the VRF is not used to access the NTP server.

ipv4-address: IPv4 address of the NTP server.

ipv6-address: IPv6 address of the NTP server.

peer-hostname: Name of the server.

ip *domain*: Specifies the IPv4 domain name of the NTP server.

ipv6 *domain*: Specifies the IPv6 domain name of the NTP server.

key *keyid*: Specifies the key used for encrypted communication with the peer. The value range is from 1 to 4294967295. By default, the communication is not encrypted.

prefer: Specifies a server as the preferred server. No server is configured as the preferred server by default.

source *interface-type interface-number*: Specifies the type and number of the source interface (L3 interface) for sending the NTP packets. By default, a route is selected by the forwarding plane.

version *version*: Specifies the NTP version. The value range is from 1 to 4. By default, NTPv4 is used.

via *mgmt-name*: Specifies the egress port of packets in **oob** mode as the MGMT port.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- The device supports up to 20 synchronization servers.
- You need to first configure a global encryption key and a globally trusted key, and then specify the keys as

the server trusted keys before the local device can initiate encrypted communication with the server. To implement encrypted communication with the server, ensure that the server has the same global encryption key and globally trusted key as the local device.

- If the precision is the same, the clock of the preferred server is selected for synchronization.
- When configuring the source interface for sending NTP packets, ensure that this interface is already configured with an IP address and can communicate with the corresponding NTP server.

Examples

The following example configures a device with the IP address 192.168.210.222 in the network as the NTP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp server 192.168.210.222
```

1.10 ntp service disable

Function

Run the **ntp service disable** command to disable the NTP time synchronization service provided for other devices.

Run the **no** form of this command to remove this configuration.

The NTP time synchronization service is enabled by default.

Syntax

ntp service disable

no ntp service disable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- If NTP works in client/server mode, after the NTP device synchronizes time from an external reliable clock source, the device acts as the time server to provide the time synchronization service for other devices. If you want the NTP device to act simply as a client, configure this command to disable the NTP time synchronization service.
- This command is mutually exclusive with the **ntp master** command. If the **ntp master** command is configured, the device acts as the server and the NTP time synchronization service cannot be disabled. If this command is configured, the **ntp master** command cannot be executed to configure the local clock as the NTP master clock.

Examples

The following example disables the NTP time synchronization provided for other devices.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp service disable
```

1.11 ntp trusted-key

Function

Run the **ntp trusted-key** command to configure a key corresponding to an ID as a globally trusted key.

Run the **no** form of this command to remove this configuration.

No globally trusted key is configured by default.

Syntax

ntp trusted-key *trusted-key-id*

no ntp trusted-key *trusted-key-id*

Parameter Description

trusted-key-id: ID of a globally trusted key. The value range is from 1 to 4294967295.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

During NTP communication, two parties must use the same trusted key. To improve security, the key itself is not transmitted. Therefore, it is necessary to find the key based on the ID of the globally trusted key.

Examples

The following example configures an authentication key 6 as the key trusted by the corresponding server.

```
Hostname(config)# ntp authentication-key 6 md5 wooooop
Hostname(config)# ntp trusted-key 6
Hostname(config)# ntp server 192.168.210.222 key 6
```

1.12 ntp update-calendar

Function

Run the **ntp update-calendar** command to enable the NTP client to periodically update the hardware clock of the device using the clock synchronized from an external clock source.

Run the **no** form of this command to remove this configuration.

By default, automatic update of the hardware clock is not configured on the NTP client.

Syntax

ntp update-calendar

no ntp update-calendar

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The hardware clock of the device can continue to work even when the device is shut down or reset.

Examples

The following example configures automatic update of the hardware clock by the NTP client.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ntp update-calendar
```

1.3 sntp server

Function

Run the **sntp server** command to configure an SNTP server.

Run the **no** form of this command to remove this configuration.

No SNTP server is configured by default.

Syntax

sntp server [**oob**] { *ipv4-address* | *domain* } [**source** *ipv4-address*] [**via** *mgmt-name*]

no sntp server

Parameter Description

oob: Accesses the SNTP server through the MGMT port. By default, the local device does not access the SNTP server through the MGMT port.

ipv4-address | *domain*: SNTP server. Here, *ipv4-address* indicates the IP address of the SNTP server, and *domain* indicates the domain name of the SNTP server.

source *ipv4-address*: Specifies the source IP address of SNTP.

via *mgmt-name*: Specifies the egress port of packets in oob mode as the MGMT port.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Since SNTP is fully compatible with NTP, the SNTP server can be configured as a public NTP server on the Internet.

Examples

The following example configures the device with the IP address 192.168.4.12 as an SNTP server in the network.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# sntp server 192.168.4.12

1 FTP Server Commands

Command	Function
clear ftp-server block-list	Clear the user lock entries in the FTP lock list.
ftp-server enable	Enable the FTP server.
ftp-server login timeout	Configure the FTP login timeout.
ftp-server login times	Configure the FTP login times.
ftp-server login permission enable	Enable read/write permission control of FTP users.
ftp-server login ip-block disable	Disable the IP address lock function.
ftp-server login username-block disable	Disable the username lock function.
ftp-server login silence-time	Configure the FTP lock time.
ftp-server login max-block-limit	Configure the maximum number of IP addresses that can be locked.
ftp-server topdir	Configure the top-level directory under which the FTP client can read and write files.
ftp-server timeout	Configure the idle timeout of an FTP session.
ftp-server username password	Configure the username and password for login to the FTP server.
ftp-server authentication	Enable AAA on the FTP server.
ftp-server max-sessions	Configure the maximum number of FTP sessions.
show ftp-server	Display status information of the FTP server.
show ftp-server list	Display the status information of FTP lock entries.

1.1 clear ftp-server block-list

Function

Run the **clear ftp-server block-list** command to clear the user lock entries in the FTP lock list.

Syntax

clear ftp-server block-list [**all** | **ip-address** { *ipv4-address* | *ipv6-address* } [**vrf** *vrf_name*] | **username** *user*]

Parameter Description

all: Clears all user lock entries in the FTP lock list.

ip-address: Clears a specified user lock entry based on the IP address.

ipv4-address: IPv4 address.

ipv6-address: IPv6 address.

vrf *vrf-name*: Specifies a VRF instance. If this parameter is not specified, the public network instance is used.

username *user*: Clears a specified user lock entry based on the username.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

After the lock function is enabled, if a user has been locked because the number of his/her login failures reaches the upper limit, a lock entry is generated. This command can be used to delete a specified entry based on the IP address or username, or delete all lock entries.

When both the IP address lock and username lock functions are enabled, if you want to unlock a locally configured username, check whether the IP address is also locked. If the IP address is also locked, unlock the IP address as well so that the user can log in to the FTP server normally.

Examples

The following example clears specified lock entries based on the IPv4 address 1.1.1.1 and VRF name ftp-vrf.

```
Hostname> enable
Hostname# clear ftp-server lock-list ip-address 1.1.1.1 vrf ftp-vrf
```

The following example clears specified lock entries based on the username admin.

```
Hostname> enable
Hostname# clear ftp-server lock-list username admin
```

The following example clears all lock entries.

```
Hostname> enable
Hostname# clear ftp-server lock-list username all
```

1.2 ftp-server enable

Function

Run the **ftp-server enable** command to enable the FTP server.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

The FTP server is disabled by default.

Syntax

ftp-server enable

no ftp-server enable

default ftp-server enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the FTP server is enabled, you can connect to the FTP server through the FTP client and perform operations such as file upload or download.

The FTP client can access files on the FTP server only after this command and **ftp-server topdir** are configured.

Examples

The following example enables the FTP server, and allows the client to access only the **syslog** sub-directory.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server topdir /syslog
Hostname(config)# ftp-server enable
```

The following example disables the FTP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server enable
```

1.3 ftp-server login timeout

Function

Run the **ftp-server login timeout** command to configure the FTP login timeout.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the FTP login timeout is 2 minutes.

Syntax

ftp-server login timeout *time*

no ftp-server login timeout

default ftp-server login timeout

Parameter Description

time: FTP login timeout, in minutes. The value range is from 1 to 30.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The login timeout refers to the maximum time that the user can stay online after the username and password are verified. If the username and password are not verified again before login timeout, the session will be terminated to ensure that other users can log in to the FTP server.

Examples

The following example sets the FTP login timeout to 5 minutes.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# ftp-server login timeout 5
```

The following example restores the default FTP login timeout to 2 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server login timeout
```

1.4 ftp-server login times

Function

Run the **ftp-server login times** command to configure the FTP login times.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the FTP login times is 3.

Syntax

ftp-server login times *times*

no ftp-server login times

default ftp-server times

Parameter Description

times: FTP login times. The value range is from 1 to 10.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The FTP login times refers to the maximum number of times that the user's account and password can be verified during FTP login. By default, the FTP login times is 3, that is, a session will be terminated once you enter an incorrect username or password so that other users can go online.

Examples

The following example sets the FTP login times to 5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server login times 5
```

The following example restores the default FTP login times to 3.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server login times
```

1.5 ftp-server login permission enable

Function

Run the **ftp-server login permission enable** command to enable read/write permission control of FTP users.

Run the **no** form of this command to disable this feature.

Run the **default** form of this command to restore the default configuration.

By default, read/write permission control of FTP users is disabled.

Syntax

ftp-server login permission enable

no ftp-server login permission enable

default ftp-server login permission enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the read/write permission control function is enabled, the configured FTP user levels or AAA username levels can be used to control read/write permissions. For details about user levels and corresponding permissions, refer to the **ftp-server username password** command.

By default, all users have the read/write permissions. After permission control is enabled, if the user level is not configured, it is set to 1 by default and the user has only the read permission, that is, the user can only download data. You can configure FTP users of different levels as required for read/write permission control.

Examples

The following example enables read/write permission control of FTP users.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server login permission enable
```

The following example disables read/write permission control of FTP users.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server login permission enable
```

1.6 ftp-server login ip-block disable

Function

Run the **ftp-server login ip-block disable** command to disable the IP address lock function.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The IP address lock function is enabled by default.

Syntax

ftp-server login ip-block disable

no ftp-server login ip-block disable

default ftp-server login ip-block disable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the IP address lock function is enabled, if the cumulative number of login failures caused by entry of the incorrect username or password reaches the configured upper limit, the FTP session is terminated and the user's IP address is locked. In addition, all users cannot log in to the FTP server properly using this IP address or username.

Examples

The following example disables the IP address lock function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server login ip-block disable
```

The following example enables the IP address lock function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server login ip-block disable
```

1.7 ftp-server login username-block disable

Function

Run the **ftp-server login username-block disable** command to disable the username lock function.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The username lock function is enabled by default.

Syntax

ftp-server login username-block disable

no ftp-server login username-block disable

default ftp-server login username-block disable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the username lock function is enabled, if the cumulative number of login failures caused by entry of the incorrect password reaches the configured upper limit, the FTP session is terminated and the username is locked. The user cannot log in to the FTP server, but other users are not affected.

After the username lock function is enabled, only a locally configured FTP username can be locked. If the entered username is not configured, the IP address is locked instead.

Examples

The following example disables the username lock function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server login username-block disable
```

The following example enables the username lock function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server login username-block disable
```

1.8 ftp-server login silence-time

Function

Run the **ftp-server login silence-time** command to configure the FTP lock time.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the FTP lock time is 5 minutes.

Syntax

ftp-server login silence-time *time*

no ftp-server login silence-time

default ftp-server login silence-time

Parameter Description

time: FTP lock time, in minutes. The value range is from 1 to 30.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The FTP lock time refers to the duration that a user needs to wait for automatic unlocking after the user is locked because the number of the user's login failures reaches the upper limit. The locked user can log in to the FTP server only after the login silence time expires.

Examples

The following example sets the FTP lock time to 15 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server login silence-time 15
```

The following example restores the default FTP login timeout to 5 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server login silence-time
```

1.9 ftp-server login max-block-limit

Function

Run the **ftp-server login max-block-limit** command to configure the maximum number of IP addresses that can be locked.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, up to 30 IP addresses can be locked.

Syntax

ftp-server login max-block-limit *limit*

no ftp-server login max-block-limit

default ftp-server login max-block-limit

Parameter Description

limit: Maximum number of IP addresses that can be locked. The value range is from 1 to 100.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the IP address lock function is enabled, if the number of locked IP addresses reaches the upper limit, the full lock function is enabled. By then, the FTP server no longer accepts the connection request from any user until the number of locked IP addresses is smaller than the upper limit.

Examples

The following example sets the maximum number of IP addresses that can be locked to 50.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server login max-block-limit 50
```

The following example restores the default maximum number of IP addresses that can be locked to 30.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server login max-block-limit
```

1.10 ftp-server topdir

Function

Run the **ftp-server topdir** command to configure the top-level directory under which the FTP client can read and write files.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no top-level directory under which the FTP client can read and write files is configured, that is, the client is prohibited from accessing any directory on the FTP server.

Syntax

ftp-server topdir { *directory* | **flash:** *directory* | **tmp:** *directory* | **usb0:** *directory* }

no ftp-server topdir

default ftp-server topdir

Parameter Description

directory: Top-level directory under which the FTP client can perform read/write operations.

flash: *directory*: Specifies the directory of the Flash memory.

tmp: *directory*: Specifies the directory of the temporary memory.

usb0: *directory*: Specifies the directory of the USB memory.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The top-level directory of the FTP server limits the range of directories that can be accessed by the FTP client after login. You must specify the correct top-level directory so that the FTP client can access files on the FTP server.

If this command is not configured, the FTP client cannot access any files or directories on the FTP server.

Examples

The following example limits the top-level directory under which the FTP client can read and write files, and allows the FTP client to access only the **syslog** sub-directory.

```
Hostname> enable
```

```
Hostname# configure terminal
Hostname(config)# ftp-server enable
Hostname(config)# ftp-server topdir /syslog
```

The following example prohibits the FTP client from accessing any files on the FTP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server topdir
```

Notifications

When no directory is configured, the following notification will be displayed:

```
%FTPSRV-USER: Haven't config topdir!
```

When a non-existing directory is configured, the following notification will be displayed:

```
Hostname(config)#ftp-server topdir ab
folder /ab don't exist!
```

Common Errors

- An invalid directory is configured.
- No directory is configured.

1.11 ftp-server timeout

Function

Run the **ftp-server timeout** command to configure the idle timeout of an FTP session.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the idle timeout of an FTP session is 10 minutes.

Syntax

ftp-server timeout *time*

no ftp-server timeout

default ftp-server timeout

Parameter Description

time: Idle timeout, in minutes. The value range is from 1 to 3600.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to configure the FTP session idle timeout. If no operation is performed on the current session within the specified time (that is, the session is idle), the FTP server considers that the connection has failed and therefore releases the connection with the user.

The session idle timeout refers to the time from the completion of the last FTP operation to the start of the next FTP operation in an FTP session. After the server responds to an FTP client command (for example, after a file is completely transferred), the server starts to count the idle time again, and stops counting when the next FTP client command arrives. Therefore, the configuration of the idle timeout does not affect time-consuming file transfer operations.

Examples

The following example sets the idle timeout to 5 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server timeout 5
```

The following example restores the default FTP login timeout to 10 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server timeout
```

1.12 ftp-server username password

Function

Run the **ftp-server username password** command to configure the username and password for login to the FTP server.

Run the **no** form of this command to lift the restrictions on users who log in to the FTP server.

Run the **default** form of this command to restore the default configuration.

By default, no username and password are configured for login to the FTP server, that is, no login users are restricted.

Syntax

ftp-server username *username* [**privilege** *level*] **password** [*type*] *password*

no ftp-server username *username*

default ftp-server username *username*

Parameter Description

username: Username used for login. The value is a case-sensitive string of 1 to 64 characters, and no space is allowed in the middle of the string. The username may contain English letters, half-width numbers, and half-width symbols.

password: Password used for login. The password must contain letters or numbers. Spaces can appear before or after the password, but will be ignored. Spaces in the middle of the password are regarded as part of the password. A plain-text password is a string of 1 to 25 characters, and a cipher-text password is a string of 4 to 52 characters.

privilege *level*: Specifies the level of the login user, which is used to control the read/write permissions of the user. The value range is from 0 to 15, and the default value is **1**. The levels are consistent with those defined by AAA. The range from 0 to 5 indicates read only, the range from 6 to 10 indicates write only, and the range from 11 to 15 indicates read and write.

type: 0 indicates not encrypted, and 7 indicates encrypted.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

You must configure a username and password for login to the FTP server to authenticate the client. The password and the user must be in one-to-one correspondence. The FTP server does not support login of anonymous users. If the username configuration is cleared, the FTP client cannot pass the authentication of the FTP server. The FTP client must provide both the correct username and password to log in to the FTP server.

You can configure at most 10 users for an FTP server.

A user with the read-only permission can only download files from the FTP server. A user with the write-only permission can only upload files to the server. A user with both the read and write permissions can upload and download files to or from the FTP server.

Examples

The following example sets the username to **user** and password to **pass** to log in to the FTP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server username user password pass
```

The following example lifts the restrictions on users who log in to the FTP server.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# no ftp-server username user
```

The following example sets the username to **user**, password to **pass**, and user level to **11**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server username user privilege 11 password pass
```

Notifications

When a user tries to log in to the FTP server before a username is configured on the server, the following notification will be displayed:

```
%FTPSRV-USER: Haven't config username!
```

When the configured username is too long, the following notification will be displayed:

```
Hostname(config)#$sssssssssssssssssssssssssssssssssddddddddddddddd
Username abcdefghjijklnn,sssssssssssssssssssssssssssssssssssddddddddddddddd is
NULL or too long, max length is 64.
```

When a user tries to log in to the FTP server before a password is configured on the server, the following notification will be displayed:

```
%FTPSRV-PASS: Haven't config password!
```

When the configured cipher-text password is too short, the following notification will be displayed:

```
Hostname(config)#ftp-server username user password 7 2
Invalid encrypted password, min length is 4, max length is 52.
```

When the configured plain-text password is too long, the following notification will be displayed:

```
Hostname(config)#ftp-server username user password abcdefghijklmnopqrstuvwxyz
% Password is too long, max length is 25
```

Common Errors

- The configured username contains invalid characters, or is too long.
- A user tries to log in to the FTP server before a username is configured on the server.
- A user tries to log in to the FTP server before a password is configured on the server.
- The configured password is too short or too long.
- The password contains invalid characters.

Function

Run the **ftp-server authentication** command to enable AAA on the FTP server.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, FTP does not support AAA login authentication.

Syntax

ftp-server authentication { **default** | *name* }

no ftp-server authentication

default ftp-server authentication

Parameter Description

default: Uses the default authentication mode in the AAA configuration.

name: Specified name in the AAA configuration.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command takes effect only after FTP is enabled.

Enable the AAA function before configuring this command.

Examples

The following example enables AAA on the FTP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server enable
Hostname(config)# ftp-server topdir tmp:
Hostname(config)# ftp-server authentication 111
Hostname(config)# aaa new-model

1.14 ftp-server max-sessions

Function

Run the **ftp-server max-sessions** command to configure the maximum number of FTP sessions.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, the maximum number of FTP sessions is 20.

Syntax

ftp-server max-sessions *session*

no ftp-server max-sessions

default ftp-server max-sessions

Parameter Description

session: Maximum number of user connections allowed. The value range is from 1 to 20.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The maximum number of FTP sessions refers to the maximum number of users that can be concurrently connected to the FTP server. The default value is 20. That is, if the number of FTP sessions reaches 20, no more user can log in to the FTP server unless a session is closed.

Examples

The following example sets the maximum number of FTP sessions to 5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-server max-sessions 5
```

The following example restores the default maximum number of FTP sessions to 20.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no ftp-server max-sessions
```

1.16 show ftp-server list

Function

Run the **show ftp-server list** command to display the status information of FTP lock entries.

Syntax

show ftp-server { **ip-block** | **username-block** } **list**

Parameter Description

ip-block: Displays the IP address of the lock entry.

username-block: Displays the username of the lock entry.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

FTP lock entries are classified into two types:

- IP address lock entries, which contain the following information: locked IP address, VRF name, and remaining time for unlocking.
- Username lock entries, which contain the following information: locked username and remaining time for unlocking.

Examples

The following example displays the IP address lock entries.

```
Hostname> enable
Hostname# show ftp-server ip-block list
---------------------------------------
Address                                              VRF Name
Unlock Interval(seconds)
---------------------------------------
172.30.33.50                                          default
1720
```

Table 1-2 Output Fields of the show ftp-server ip-block list Command

Field	Description
Address	Locked IP address
VRF Name	Name of the VRF where the locked IP address resides. The default value is **default**.
Unlock Interval(seconds)	Remaining time for unlocking, in seconds

The following example displays the username lock entries.

```
Hostname> enable
Hostname# show ftp-server username-block list
------------------------------
Username                                          Unlock Interval(seconds)
------------------------------
admin                                            1720
```

Table 1-3 Output Fields of the show ftp-server username-block list Command

1 FTP Client Commands

Command	Function
ftp-client ascii	Set the FTP transmission mode to ASCII.
ftp-client disable-size-check	Disable the size check of files downloaded from the FTP server.
ftp-client port	Set the FTP data connection mode to PORT.
ftp-client source	Bind a source IP address to the FTP client.
copy ftp	Use the FTP client to download files from the FTP server to the local device.
copy flash	Use the FTP client to upload files from the local device to the server.
show ftp-client	Display information about the FTP client.

1.1 ftp-client ascii

Function

Run the **ftp-client ascii** command to set the FTP transmission mode to ASCII.

Run the **no** form of this command to set the FTP transmission mode to Binary.

Run the **default** form of this command to restore the default configuration.

The default FTP transmission mode is Binary.

Syntax

ftp-client [**vrf** *vrf-name*] **ascii**

no ftp-client [**vrf** *vrf-name*] **ascii**

default ftp-client [**vrf** *vrf-name*]

Parameter Description

vrf *vrf-name*: Specifies a VRF instance. If this parameter is not specified, it indicates the public network instance.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

To specify the **vrf** *vrf-name* parameter, configure the VRF first. For details about the VRF, see *Configuring VRF*.

Caution

When the **default ftp-client** command is configured, all the configurations of the FTP client are restored to the default configurations. That is, the data connection mode is PASV, the FTP transmission mode is Binary, and the client is not bound to any source IP address.

Examples

The following example sets the FTP transmission mode to ASCII.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-client ascii
```

Notifications

If the configuration succeeds, no notification will be displayed.

If the specified *vrf-name* is not configured on the local device, the following notification will be displayed:

```
% VPN Routing/Forwarding instance name error
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **ip vrf** (IP routing/VRF)

1.2 ftp-client disable-size-check

Function

Run the **ftp-client disable-size-check** command to disable the size check of files downloaded from the FTP server.

Run the **no** form of this command to enable size check of files downloaded from the FTP server.

Run the **default** form of this command to restore the default configuration.

By default, the sizes of files downloaded from the FTP server are checked.

Syntax

ftp-client disable-size-check

no ftp-client disable-size-check

default ftp-client disable-size-check

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

When the FTP client downloads a file, it checks the file size by default to detect file transfer errors (if any). You can also disable the file size check when downloading files from FTP servers that cannot reply to FTP clients with file sizes.

Examples

The following example disables the size check of files downloaded from the FTP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-client disable-size-check
```

Notifications

If the configuration succeeds, no notification will be displayed.

1.3 ftp-client port

Function

Run the **ftp-client port** command to set the FTP data connection mode to PORT.

Run the **no** form of this command to set the FTP data connection mode to PASV.

Run the **default** form of this command to restore the default configuration.

The default FTP data connection mode is PASV.

Syntax

ftp-client [**vrf** *vrf-name*] **port**

no ftp-client [**vrf** *vrf-name*] **port**

default ftp-client [**vrf** *vrf-name*]

Parameter Description

vrf *vrf-name*: Specifies a VRF instance. If this parameter is not specified, it indicates the public network instance.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be used to set the FTP connection mode to PORT, in which the FTP server initiates a connection request to the client.

To specify the **vrf** *vrf-name* parameter, configure the VRF first. For details about the VRF, see "Configuring VRF" in "IP Routing."

Caution

When the **default ftp-client** command is configured, all the configurations of the FTP client are restored to the default configurations. That is, the data connection mode is PASV, the FTP transmission mode is Binary, and the client is not bound to any source IP address.

Examples

The following example enables the FTP client to set up the data connection in PORT mode based on vrf-name.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-client vrf vrf-name port
```

Notifications

If the configuration succeeds, no notification will be displayed.

If the specified *vrf-name* is not configured on the local device, the following notification will be displayed:

```
% VPN Routing/Forwarding instance name error
```

Common Errors

N/A

Platform Description

N/A

Related Commands

- **ip vrf** (IP routing/VRF)

1.4 ftp-client source

Function

Run the **ftp-client source** command to bind a source IP address to the FTP client.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no source IP address is bound to the FTP client. Instead, a source IP address is selected based on the route.

Syntax

ftp-client [**vrf** *vrf-name*] **source** { *ipv4-address* | *ipv6-address* | *interface-type interface-number* }

no ftp-client [**vrf** *vrf-name*] **source**

default ftp-client [**vrf** *vrf-name*]

Parameter Description

vrf *vrf-name*: Specifies a VRF instance. If this parameter is not specified, it indicates the public network instance.

ipv4-address: Source IP address of the client.

ipv6-address: Source IPv6 address of the client.

interface-type interface-number: Type and number of the source interface of the client.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to bind a source IP address to the FTP client so that the client can use this IP address to communicate with the server.

To specify the **vrf** *vrf-name* parameter, configure the VRF first. For details about the VRF, see "Configuring VRF" in "IP Routing."

Caution

When the **default ftp-client** command is configured, all the configurations of the FTP client are restored to the default configurations. That is, the data connection mode is PASV, the FTP transmission mode is Binary, and the client is not bound to any source IP address.

Examples

The following example binds the source IP address 192.168.23.236 to the FTP client vrf-name.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-client vrf vrf-namesource 192.168.23.236
```

The following example binds the IP address of the source interface tenGigabitEthernet 1/0/1 to the FTP client vrf-name.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# ftp-client source tengigabitethernet 1/0/1
```

Notifications

If the configuration succeeds, no notification will be displayed.

If the bound IP address is not a local address, the following notification will be displayed:

```
Bind failed: the specified source address is non-local ip
```

If the specified *vrf-name* is not configured on the local device, the following notification will be displayed:

```
% VPN Routing/Forwarding instance name error
```

Common Errors

N/A

Platform Description

N/A

Related Commands

1.5 copy ftp

Function

Run the **copy ftp** command to use the FTP client to download files from the FTP server to the local device.

Syntax

copy { **ftp: | oob_ftp:** } ***//****username****:****password****@****destination-ip-address* [***/****remote-directory*] ***/****remote-file* **flash:** [*local-directory****/***] *local-file*

Parameter Description

oob_ftp: Transfers files through the MGMT port.

username: Username for login to the FTP server. It is a string of 1 to 64 characters. The value cannot contain characters such as colon (:), at sign (@), slash (/) and spaces, and must be specified.

password: Password for login to the FTP server. It is a string of 1 to 64 characters. The value cannot contain characters such as colon (:), at sign (@), slash (/) and spaces, and must be specified.

destination-ip-address: IP address of the FTP server.

remote-directory: Directory on the FTP server, which is optional. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters. If this parameter is left empty, the current working path of the FTP server is used.

remote-file: File name on the remote server. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters.

flash: Indicates flash memory.

local-directory: Directory on the local device, which is optional. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters. To specify a directory, ensure that the directory is already created. This command does not support automatic creation of a directory. If this parameter is left empty, the current directory of the device is used.

local-file: Name of the file on the local device. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

You can run the **dir** command to check whether the downloaded file is configured on the local device. If the file is configured, the download is successful; otherwise, the download fails.

Examples

The following example uses the username **user** and password **pass** to log in to the FTP server, downloads the **remote-file** file from the **root** directory of the FTP server with the IP address 192.168.23.69 to the **home** directory of the local device, and renames this file **local-file**.

```
Hostname> enable
Hostname# copy ftp://user:pass@192.168.23.69/root/remote-file flash:home/local-file
```

Notifications

If the download succeeds, the following notification will be displayed:

```
success
```

If the download fails, you can find the corresponding error message after running the **debug ftp-client** command.

Common Errors

1.6 copy flash

Function

Run the **copy flash** command to use the FTP client to upload files from the local device to the server.

Syntax

copy flash: [*local-directory***/**] *local-file* { **ftp: | oob_ftp:** } ***//****username***:***password@destination-ip-address* [***/****remote-directory*] ***/****remote-file*

Parameter Description

local-directory: Directory on the local device, which is optional. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters. To specify a directory, ensure that the directory is already created. This command does not support automatic creation of a directory. If this parameter is left empty, the current directory of the device is used.

local-file: Name of the file on the local device. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters.

oob_ftp: Transfers files through the MGMT port.

username: Username for login to the FTP server. It is a string of 1 to 64 characters. The value cannot contain characters such as colon (:), at sign (@), slash (/) and spaces, and must be specified.

password: Password for login to the FTP server. It is a string of 1 to 64 characters. The value cannot contain characters such as colon (:), at sign (@), slash (/) and spaces, and must be specified.

destination-ip-address: IP address of the FTP server.

remote-directory: Directory on the FTP server, which is optional. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters. If this parameter is left empty, the current working path of the FTP server is used.

remote-file: File name on the remote server. It is a string of 1 to 255 characters, and cannot contain spaces or Chinese characters.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

During file transfer, do not insert or remove a storage medium or transmission medium to or from the device to avoid transmission errors.

You can run the **dir** command to check whether the uploaded file is configured on the FTP server. If the file is configured, the upload is successful; otherwise, the upload fails.

Examples

The following example uses the username **user** and password **pass** to log in to the FTP server, uploads the **local-file** file in the **home** directory of the local device to the **root** directory of the FTP server with the IP address 192.168.23.69, and renames the file **remote-file**.

```
Hostname> enable
Hostname# copy flash:home/local-file ftp://user:pass@192.168.23.69/root/remote-file
```

Notifications

If the upload succeeds, the following notification will be displayed:

```
success
```

If the upload fails, you can find the corresponding error message after running the **debug ftp-client** command.

Common Errors

1 TFTP Server Commands

Command	Function
tftp-server enable	Enable the TFTP server.
tftp-server topdir	Configure the top-level directory under which the TFTP client can read and write files.
show tftp-server	Display the configurations of the current TFTP server.
show tftp-server updating-list	Display the file download progress of the current TFTP client.

1.1 tftp-server enable

Function

Run the **tftp-server enable** command to enable the TFTP server.

Run the **no** form of this command to disable the TFTP server.

The TFTP server is disabled by default.

Syntax

tftp-server enable

no tftp-server enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After the TFTP server is enabled, files can be transmitted only through the MGMT port.

The TFTP client can access files on the TFTP server only after this command and **tftp-server topdir** are configured.

The TFTP server can connect to a maximum of 10 clients concurrently.

Examples

The following example enables the TFTP server.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tftp-server enable
```

Common Errors

N/A

Platform Description

1.2 tftp-server topdir

Function

Run the **tftp-server topdir** command to configure the top-level directory under which the TFTP client can read and write files.

Run the **no** form of this command to restore the default configuration.

Run the **default** form of this command to restore the default configuration.

By default, the TFTP client can read and write files in the Flash directory.

Syntax

tftp-server topdir *directory*

no tftp-server topdir

default tftp-server topdir

Parameter Description

directory: Top-level directory under which the TFTP client can perform read/write operations. Here, a slash (/) indicates the root directory.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The top-level directory of the TFTP server limits the range of directories that can be accessed by the TFTP client after login. You must specify the correct top-level directory so that the TFTP client can access files on the TFTP server.

Examples

The following example enables the TFTP server, and allows the client to access only the **Syslog** sub-directory.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tftp-server topdir /syslog
Hostname(config)# tftp-server enable
```

Notifications

When a non-existing directory is configured, the following notification will be displayed:

```
% topdir /ab don't exist!
```

When an invalid directory is configured, the following notification will be displayed:

```
% Root dir too long, max length is 64.
```

Common Errors

- A non-existing directory is configured.

- An invalid directory is configured.

1 TFTP Client Commands

Command	Function
tftp-client source	Bind a source IP address to the TFTP client.
copy tftp	Use the TFTP client to download files from the TFTP server to the local device.
copy flash	Use the TFTP client to upload files from the local device to the server.

1.1 tftp-client source

Function

Run the **tftp-client source** command to bind a source IP address to the TFTP client.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

By default, no source IP address is bound to the TFTP client. Instead, a source IP address is selected based on the route.

Syntax

tftp-client source { **ip** *ipv4-address* | **ipv6** *ipv6-address* | *interface-type interface-number* }

no tftp-client source

default tftp-client source

Parameter Description

ipv4-address: IPv4 address.

ipv6-address: IPv6 address.

interface-type interface-number: Interface type and interface number.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to bind a source IP address to the TFTP client so that the client can use this IP address to communicate with the server.

Examples

The following example binds the source IP address 192.168.23.236 to the TFTP client.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# tftp-client source ip 192.168.23.236

1 SNMP Commands

Command	Function
clear snmp locked-ip	Clear the list of source IP addresses that are locked after Simple Network Management Protocol (SNMP) authentication fails consecutively.
no snmp-server	Disable the SNMP agent function of a device.
show snmp	Display the SNMP status.
snmp trap link-status	Send a Link Trap message through an interface.
snmp-server authentication attempt	Configure the maximum number of consecutive SNMP authentication failures and specify the corresponding processing actions.
snmp-server chassis-id	Configure a system serial number.
snmp-server community	Configure an authentication name and access permission.
snmp-server contact	Configure a system contact mode.
snmp-server enable secret-dictionary-check	Configure password dictionary check for communities and users.
snmp-server enable traps	Enable the agent to actively send Trap messages to the NMS.
snmp-server enable version	Configure an SNMP version.
snmp-server flow-control pps	Configure SNMP traffic control.
snmp-server group	Configure an SNMP user group.
snmp-server host	Configure NMS host addresses for the agent to send messages.
snmp-server inform	Configure Inform message sending attempts and timeout time.
snmp-server location	Configure a system location.
snmp-server logging	Enable the SNMP logging function.
snmp-server net-id	Configure NE code information of a device.
snmp-server packetsize	Configure the maximum packet length of the SNMP agent.

snmp-server queue-length	Configure the queue of the Trap messages.
snmp-server source-interface	Configure the source port of a device to receive SNMP packets.
snmp-server system-shutdown	Enable the SNMP system reboot notification function.
snmp-server trap-format private	Include private fields in SNMP Trap messages.
snmp-server trap-source	Configure a source address for sending Trap messages.
snmp-server trap-timeout	Configure the timeout time of Trap message re-sending.
snmp-server udp-port	Configure the ID of a port that receives SNMP packets.
snmp-server user	Configure an SNMP user.
snmp-server view	Configure an SNMP view.

1.1 clear snmp locked-ip

Function

Run the **clear snmp locked-ip** command to clear the list of source IP addresses that are locked after Simple Network Management Protocol (SNMP) authentication fails consecutively.

Syntax

clear snmp locked-ip [**ipv4** *ipv4-address* | **ipv6** *ipv6-address*]

Parameter Description

ipv4 *ipv4-address*: Specifies the source IPv4 address to be cleared.

ipv6 *ipv6-address*: Specifies the source IPv6 address to be cleared.

Command Modes

Privileged EXEC mode

Default Level

14

Usage Guidelines

- This command is used to manually clear source IP addresses that are locked after authentication fails consecutively. A list of source IP addresses or a specific source IP address can be cleared.
- After a source IP address is cleared, a request to authenticate the IP address can be initiated when SNMP access packets from this cleared IP address are received.

Examples

The following example clears the list of source IP addresses that are locked after SNMP authentication fails consecutively.

```
Hostname> enable
Hostname# clear snmp locked-ip
```

1.2 no snmp-server

Function

Run the **no snmp-server** command to disable the SNMP agent function of a device.

The SNMP agent function is enabled by default.

Syntax

no snmp-server

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- The SNMP agent function is enabled by default. When SNMP agent parameters (for example, Network Management System (NMS) host address, authentication name, and access permission) are configured, the SNMP agent service is automatically enabled. This command can be used to disable the agent service of all SNMP versions supported on a device.
- This command must be used with the **enable service snmp-agent** command to make the SNMP agent service take effect. Otherwise, the SNMP agent service will not take effect.
- After this command is run, all SNMP agent service configurations are shielded. In this case, running the **show running-config** will not display the configurations. The configurations can be restored after the SNMP agent service is enabled again. Running the **no enable service snmp-agent** will not shield the SNMP agent configurations.

Examples

The following example disables the SNMP agent service function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no snmp-server
```

1.3 show snmp

Function

Run the **show snmp** command to display the SNMP status.

Syntax

show snmp [**group** | **host** | **locked-ip** | **mib** | **process-mib-time** | **user** | **version** | **view**]

Parameter Description

group: Displays SNMP user group information.

host: Displays user configuration information.

locked-ip: Displays source IP address that is locked after consecutive SNMP authentication failure.

mib: Displays SNMP management information base (MIB) information supported in the system.

process-mib-time: Displays the MIB node with the longest processing time.

user: Displays SNMP user information.

version: Displays SNMP version.

view: Displays SNMP view information.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays SNMP statistics.

```
Hostname> enable
Hostname# show snmp
Chassis: 60FF60
0 SNMP packets input
       0 Bad SNMP version errors
       0 Unknown community name
       0 Illegal operation for community name supplied
       0 Encoding errors
       0 Number of requested variables
       0 Number of altered variables
       0 Get-request PDUs
       0 Get-next PDUs
```

```
       0 Set-request PDUs
0 SNMP packets output
       0 Too big errors (Maximum packet size 1472)
       0 No such name errors
       0 Bad values errors
       0 General errors
       0 Response PDUs
       0 Trap PDUs
SNMP global trap: disabled
SNMP logging: disabled
SNMP agent: enabled
```

Table 1-1 Output Fields of the show snmp Command

Field	Description
Chassis	System serial number
SNMP packets input	Total number of input packets
Bad SNMP version errors	Total number of packets with version error
Unknown community name	Total number of packets in which an unknown community name is used for access
Illegal operation for community name supplied	Total number of packets in which the community name is used for override operations
Encoding errors	Total number of packets with encoding error
Number of requested variables	Total number of read MIB objects
Number of altered variables	Total number of set MIB objects
Get-request PDUs	Total number of Get request packets
Get-next PDUs	Total number of Get-next request packets
Set-request PDUs	Total number of Set request packets
SNMP packets output	Total number of output packets
Too big errors (Maximum packet size 1472)	Total number of excessively long packets (more than 1,472 bytes)
No such name errors	Total number of packets that contains the no such name error
Bad values errors	Total number of packets that contains the bad values error
General errors	Total number of packets that contains the general error
Response PDU	Total number of packets that are normally returned
Trap PDUs	Total number of sent Trap packets

Field	Description
SNMP global trap	Global Trap enabling/disabling status
SNMP logging	Global SNMP log enabling/disabling status
SNMP agent	Global SNMP agent enabling/disabling status

1.4 snmp trap link-status

Function

Run the **snmp trap link-status** command to send a Link Trap message through an interface.

Run the **no** form of this command to disable this function.

The Link Trap message sending function is enabled on an interface by default.

Syntax

snmp trap link-status

no snmp trap link-status

Parameter Description

N/A

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

After this command is run, the SNMP sends a Link Trap message if the link status on the interfaces (Ethernet interface, AP interface, and SVI interface) changes. Otherwise, the SNMP does not send the message.

Examples

The following example disables the Link Trap sending function on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-if-GigabitEthernet 0/1)# no snmp trap link-status
```

1.5 snmp-server authentication attempt

Function

Run the **snmp-server authentication attempt** command to configure the maximum number of consecutive SNMP authentication failures and specify the corresponding processing actions.

Run the **no** form of this command to remove this configuration.

The SNMP attack prevention and detection function is disabled by default.

Syntax

snmp-server authentication attempt *attempt-times* **exceed** { **lock** | **lock-time** *lock-time* | **unlock** }

no snmp-server authentication attempt *times* **exceed** { **lock** | **lock-time** *lock-time* | **unlock** }

Parameter Description

attempt-times: Maximum number of SNMP authentication failures. The value range is from 1 to 10.

exceed: Specifies the actions taken after the SNMP authentication failures exceed the threshold.

lock: Permanently forbids this source IP address from authentication. After this source IP address is placed on the blacklist, the administrator needs to manually unlock the IP address.

lock-time *lock time*: Specifies the lock time of a source IP address after this source IP address is forbidden from authentication, in minutes. The value range is from 1 to 65535.

unlock: Allows a user to log in though the user fails the authentication.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

After a source IP address fails the SNMP authentication, the system adds the source IP address to the blacklist. When the number of consecutive authentication failures exceeds the limit, the system restricts subsequent access authentication of this source IP address based on the configured processing actions.

- The permanently forbidden source IP addresses can be authenticated for access again only after the administrator manually unlocks the IP addresses.
- The source IP addresses that are forbidden in a period of time can be authenticated again after the period expires or after the administrator manually unlocks the IP addresses.
- Unrestricted source IP addresses can be authenticated again based on the correct community name (for SNMPv1 and SNMPv2c) or username (for SNMPv3) so long as users access authentication again.

Examples

The following example sets the consecutive authentication failures of SNMP to 4 and IP address lock time to 30 minutes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server authentication attempt 4 exceed lock-time 30
```

Notifications

After the SNMP attack prevention and detection function is enabled, if a source IP address is locked because an incorrect community name or username is used for access authentication, the following notification will be displayed.

1.6 snmp-server chassis-id

Function

Run the **snmp-server chassis-id** command to configure a system serial number.

Run the **no** form of this command to restore the default configuration.

The default system serial number is **60FF60**.

Syntax

snmp-server chassis-id *chassis-id-text*

no snmp-server chassis-id

Parameter Description

chassis-id-text: Text of the system serial number, which may be digits or characters. The maximum length is 255.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

In general, the device serial number is used as the SNMP serial number to facilitate identification of the device. The system sequence number can be displayed by running the **show snmp** command.

Examples

The following example sets the system serial number of SNMP to 123456.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server chassis-id 123456
```

1.7 snmp-server community

Function

Run the **snmp-server community** command to configure an authentication name and access permission.

Run the **no** form of this command to remove this configuration.

The default access permission of all communities is read-only.

Syntax

snmp-server community [**0** | **7** | **secret** [**0** | **8**]] *community-string* [**view** *view-name*] [**ro** | **rw**] [**host** *ipv4-address* | **host** *ipv6-address*] [**ipv6** *ipv6-acl-name*] [*acl-name* | *acl-number*]

no snmp-server community [**0** | **7** | **secret** [**0** | **8**]] *community-string*

Parameter Description

0: Indicates that the input community string is a plaintext string.

7: Indicates that the input community string is a ciphertext string.

secret [**0** | **8**]: Indicates that the input community string is encrypted. **0** indicates that the input community string is a plaintext string and is encrypted with the default algorithm. **8** indicates that the input community string is a ciphertext string and is encrypted with the SHA256 algorithm. The default encryption algorithm is SHA256.

community-string: Community string. This parameter is case sensitive and does not support special characters or Chinese characters. The maximum length is 32. It is equivalent to the communication password used between the NMS and SNMP agent.

view *view-name*: Specifies a view name for view-based management.

ro: Specifies that the NMS can only read variables of the MIB.

rw: Specifies that the NMS can read and write variables of the MIB.

host *ipv4-address*: Configures IPv4 host address of SNMP.

host *ipv6-address*: Configures IPv6 host address of SNMP.

ipv6 *ipv6-acl-name*: Specifies the name of a list of IPv6 addresses and the range of the addresses that are allowed to access the MIB.

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an ACL. The value range of the ACL list of standard IP addresses is from 1 to 99 or from 1300 to 1999. The value range of the ACL list of extended IP addresses is from 100 to 199 or from 2000 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command is used to enable the SNMP agent function. It specifies community attributes and NMS scope that is allowed to access the MIB.
- Run the **no snmp-server** command to disable the SNMP agent function.

Examples

The following example allows the NMS to access the MIB with the read-only permission using the SNMP community string named public1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server community public1 ro
```

1.8 snmp-server contact

Function

Run the **snmp-server contact** command to configure a system contact mode.

Run the **no** form of this command to remove this configuration.

The contact mode of the system is empty by default.

Syntax

snmp-server contact *contact-text*

no snmp-server contact

Parameter Description

contact-text: String that describes the system contact mode. This parameter is case sensitive and does not support Chinese characters. The maximum length is 255.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the system contact mode to i-net800@i-net.com.cn.

```
Hostname> enable
Hostname# configure terminal

1.9 snmp-server enable secret-dictionary-check

Function

Run the **snmp-server enable secret-dictionary-check** command to configure password dictionary check for communities and users.

Run the **no** form of this command to remove this configuration.

No password dictionary check is configured for communities and users by default.

Syntax

snmp-server enable secret-dictionary-check

no snmp-server enable secret-dictionary-check

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command must be used with the **password policy** command in global configuration mode.

Examples

The following example sets the password length to be no less than six characters and configures password dictionary check for communities.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# password policy min-size 6
Hostname(config)# snmp-server enable secret-dictionary-check
Hostname(config)# snmp-server community abc12
% The community(abc12) is a weak community!

1.10 snmp-server enable traps

Function

Run the **snmp-server enable traps** command to enable the agent to actively send Trap messages to the NMS.

Run the **no** form of this command to disable this function.

The SNMP agent is forbidden to send Trap messages to the NMS by default.

Syntax

snmp-server enable traps [*notification-type*]

no snmp-server enable traps

Parameter Description

notification-type: Type of Trap messages that are actively sent. The following types of Trap messages are supported:

authentication: Enables Trap notification for authentication events.

bgp: Enables Trap notification for Border Gateway Protocol (BGP) events.

bridge: Enables Trap notification for bridge events.

entity: Enables Trap notification for entity events.

isis: Enables Trap notification for intermediate system to intermediate system (ISIS) events.

mac-notification: Enables Trap notification for MAC events.

nfpp: Enables Trap notification for Network Foundation Protection Policy (NFPP) events.

ospf: Enables Trap notification for Open Shortest Path First (OSPF) events.

snmp: Enables Trap notification for SNMP events.

urpf: Enables Trap notification for unicast reverse path forwarding (URPF) events.

vrrp: Enables Trap notification for Virtual Router Redundancy Protocol (VRRP) events.

web-auth: Enables Trap notification for Web authentication events.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command must be used with the **snmp-server host** command so that Trap messages can be sent.

- If no Trap type is specified, all types of Trap messages are sent.

Examples

The following example configures the function of actively sending Trap messages for SNMP events.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server enable traps snmp
```

1.12 snmp-server flow-control pps

Function

Run the **snmp-server flow-control pps** command to configure SNMP traffic control.

Run the **no** form of this command to restore the default configuration.

About 300 SNMP request packets are processed every second by default.

Syntax

snmp-server flow-control pps *packet-count*

no snmp-server flow-control pps

Parameter Description

packet-count: Number of SNMP request packets processed per second. The value range is from 50 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the number of SNMP request packets processed per second to 200.

```
Hostname> enable

1.13 snmp-server group

Function

Run the **snmp-server group** command to configure an SNMP user group.

Run the **no** form of this command to remove this configuration.

No user group is configured by default.

Syntax

snmp-server group *group-name* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } } [**read** *readview*] [**write** *writeview*] [**access** { [**ipv6** *ipv6-acl-name*] *acl-name* | *acl-number* }]

no snmp-server group *group-name* { **v1** | **v2c** | **v3** { **auth** | **noauth** | **priv** } }

Parameter Description

group-name: Name of a user group.

v1: Uses SNMPv1.

v2c: Uses SNMPv2c.

v3: Uses SNMPv3.

auth | **noauth** | **priv**: Configures the security level of SNMPv3 users. **auth** indicates that the messages transmitted by users in this group need authentication but the data does not need encryption. **noauth** indicates that the messages transmitted by users in this group do not need authentication and the data does not need encryption. This security level is valid for SNMPv3 only. **priv** indicates that the messages transmitted by users in this group need authentication and the data needs encryption. This security level is valid for SNMPv3 only.

read *readview*: Associates a read-only view.

write *writeview*: Associates a read/write view.

ipv6 *ipv6-acl-name*: Specifies the name of a list of IPv6 addresses and the range of the addresses that are allowed to access the MIB.

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an ACL. The value range of the ACL list of standard IP addresses is from 1 to 99 or from 1300 to 1999. The value range of the ACL list of extended IP addresses is from 100 to 199 or from 2000 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures a user group with the name mib2user.

```
Hostname> enable

1.14 snmp-server host

Function

Run the **snmp-server host** command to configure NMS host addresses for the agent to send messages.

Run the **no** form of this command to remove this configuration.

No SNMP host address is configured by default.

Syntax

snmp-server host [**oob**] { *ipv4-addrress* | **ipv6** *ipv6-address*

| **domain** *domain-name*

} [**vrf** *vrf-name*] [**informs** | **traps**] [**version** { { **1** | **2c** } [**0** | **7**] *community* | **3** { **auth** | **noauth** | **priv** } *username* }] [**udp-port** *port-number*] [**via** *mgmt-name*] [*notification-type*]

no snmp-server host [**oob**] { *ipv4-address* | **ipv6** *ipv6-address*

| **domain** *domain-name*

} [**vrf** *vrf-name*] [**informs** | **traps**] [**version** { { **1** | **2c** } [**0** | **7**] *community* | **3** { **auth** | **noauth** | **priv** } *username* }] [**udp-port** *port-numer*] [**via** *mgmt-name*]

Parameter Description

oob: Specifies out-of-band communication for the alarm server (sending logs to the alarm server through the management interface).

ipv4-address: IPv4 address of the SNMP host.

ipv6 *ipv6-address*: Specifies the IPv6 address of the SNMP host.

domain *domain-name*: Domain name of the SNMP host.

vrf *vrf-name*: Configures the name of the VRF forwarding table.

informs: Configures the host to send Inform messages.

traps: Configures the host to send Trap messages.

v1: Uses SNMPv1.

v2c: Uses SNMPv2c.

0: Indicates that the input community string is a plaintext string.

7: Indicates that the input community string is a ciphertext string.

community: Community string.

v3: Uses SNMPv3.

auth | **noauth** | **priv**: Configures the security level of SNMPv3 users. **auth** indicates that the messages transmitted by users in this group need authentication but the data does not need encryption. **noauth** indicates that the messages transmitted by users in this group do not need authentication and the data does not need encryption. This security level is valid for SNMPv3 only. **priv** indicates that the messages transmitted by users in this group need authentication and the data needs encryption. This security level is valid for SNMPv3 only.

username: Username used in SNMPv3 configuration.

udp-port *port-number*: Configures the port ID of the SNMP host. The value range is from 0 to 65535.

via *mgmt-name*: Specifies a management port when OOB is configured. *mgmt-name* indicates the name of the management port.

notification-type: Type of Trap packets, for example, SNMP.

Note

Parameter **0** is not supported if SNMPv3 is used.

Parameter **7** is not supported if SNMPv3 is used.

If no Trap type is specified for the *notification-type* parameter, all types of Trap messages are sent.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command is used with the **snmp-server enable traps** command to actively send Trap messages to the NMS.
- Multiple SNMP hosts can be configured to receive Trap messages. A host can combine different types of Trap messages, ports, and VRF forwarding tables. If a host is configured with the same port and VRF in multiple configurations, the last configuration is combined with the previous configurations. To send different Trap messages to the same host, configure different types of Trap messages each time. These configurations are finally combined.
- Note: The **via** parameter can be specified only when **oob** is enabled in the command. In this case, the VRF parameter is unavailable.

Examples

The following example sets the SNMP host address to 192.168.12.219 and the community name to public1 and receives Trap messages for SNMP events.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server host 192.168.12.219 public1 snmp
```

1.17 snmp-server logging

Function

Run the **snmp-server logging** command to enable the SNMP logging function.

Run the **no** form of this command to disable this function.

By default, the SNMP logging function is disabled.

Syntax

snmp-server logging { **get-operation** | **set-operation** | **trap-info** }

no snmp-server logging { **get-operation** | **set-operation** | **trap-info** }

Parameter Description

get-operation: Enables the Get and Get-Next operation logging function.

set-operation: Enables the Set operation logging function.

trap-info: Enables the Trap message logging function

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- After this command is run, the NMS Get, Get-Next, and Set operations on the SNMP agent are logged. When the Get and Get-Next operations are performed, the agent records the IP address of the NMS user, operation type, and OID of the operation node. When the Set operation is performed, the agent records the IP address of the NMS user, operation type, OID of the operation node, and set value.
- Normally, you are advised to disable the SNMP logging function to avoid large amount of logs from affecting device performance.

Examples

The following example enables the Get operation logging function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server logging get-operation
```

The following example performs Get, Get-Next, and Set operations on the sysname node (.1.3.6.1.2.1.1.5.0) through the NMS and prints the following log information on the console:

```
Hostname#*Feb  7 15:31:16: %SNMP-GET_OPER: NMS source-ip(13.12.11.7) operation(GET)
object(id=1.3.6.1.2.1.1.5.0)
Hostname#*Feb  7 15:32:16:%SNMP-GETN_OPER: NMS source-ip(13.12.11.7)
operation(GET-NEXT) object(id=1.3.6.1.2.1.1.5.0)
Hostname#*Feb  7 15:33:23: %SNMP-SET_OPER: NMS source-ip(13.12.11.7) operation(SET)
object(id=1.3.6.1.2.1.1.5.0, value=Hostname)
```

The following example disables the Get and Set operation logging function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no snmp-server logging get-operation
Hostname(config)# no snmp-server logging set-operation
```

Run the **snmp-server packetsize** command to configure the maximum packet length of the SNMP agent.

Run the **no** form of this command to restore the default configuration.

The maximum packet length of the SNMP agent is 1,472 bytes by default.

Syntax

snmp-server packetsize *packetsize*

no snmp-server packetsize

Parameter Description

packetsize: Packet size, in bytes. The value range is from 484 to 17876.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the maximum SNMP packet size to 1,492 bytes.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server packetsize 1492
```

1.20 snmp-server queue-length

Function

Run the **snmp-server queue-length** command to configure the queue of the Trap messages.

Run the **no** form of this command to restore the default configuration.

The default queue length of the Trap messages is **100**.

Syntax

snmp-server queue-length *queue-length*

no snmp-server queue-length

Parameter Description

queue-length: Queue length. The value range is from 1 to 1000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

Adjust the size of the message queue to control the message sending speed.

Examples

The following example sets the queue length of Trap messages to 100.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server queue-length 100
```

1.21 snmp-server source-interface

Function

Run the **snmp-server source-interface** command to configure the source port of a device to receive SNMP packets.

Run the **no** form of this command to restore the default configuration.

The source port of a device with a valid IP address is used to receive SNMP packets by default.

Syntax

snmp-server source-interface *interface-type interface-number*

no snmp-server source-interface

Parameter Description

interface-type interface-number: Interface type and interface number of the source port of a device that receives SNMP packets.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures the source port of a device to receive SNMP packets as Mgmt 0.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server source-interface Mgmt 0
```

1.22 snmp-server system-shutdown

Function

Run the **snmp-server system-shutdown** command to enable the SNMP system reboot notification function.

Run the **no** form of this command to disable this function.

The SNMP system reboot notification function is disabled by default.

Syntax

snmp-server system-shutdown

no snmp-server system-shutdown

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command is used to enable the SNMP system reboot notification function. The system sends Trap messages to the NMS to notify system reboot before reboot of the device.

Examples

The following example enables the SNMP system reboot notification function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server system-shutdown
```

1.23 snmp-server trap-format private

Function

Run the **snmp-server trap-format private** command to include private fields in SNMP Trap messages.

Run the **no** form of this command to restore the default configuration.

SNMP Trap messages do not include private fields by default.

Syntax

snmp-server trap-format private

no snmp-server trap-format private

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

- This command is used to include private fields in Trap messages. The supported private field is the alarm generation time. For the specific data types and data ranges of the fields, see the RUIJIE-TRAP-FORMAT-MIB.mib file.
- When SNMPv1 is used to send Trap messages, this configuration does not take effect.

Examples

The following example includes private fields in SNMP Trap messages.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server trap-format private
```

1.24 snmp-server trap-source

Function

Run the **snmp-server trap-source** command to configure a source address for sending Trap messages.

Run the **no** form of this command to restore the default configuration.

The IP address of the interface that sends SNMP packets is used as the source address by default.

Syntax

snmp-server trap-source *interface-type interface-number*

no snmp-server trap-source

Parameter Description

interface-type interface-number: Interface type and interface number of the source port of a device that sends Trap messages.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

By default, the IP address of an interface that sends SNMP packets is used as the source address of the SNMP packets. To manage and identify the source address, you can run this command to configure a fixed local IP address as the source address of the SNMP packets.

Examples

The following example configures the IP address of GigabitEthernet 0/1 as the source address of Trap messages.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server trap-source gigabitEthernet 0/1
```

1.25 snmp-server trap-timeout

Function

Run the **snmp-server trap-timeout** command to configure the timeout time of Trap message re-sending.

Run the **no** form of this command to restore the default configuration.

The Trap messages are resent with a timeout time of 300 milliseconds by default.

Syntax

snmp-server trap-timeout *trap-timeout-time*

no snmp-server trap-timeout

Parameter Description

trap timeout-time: Timeout time of Trap message re-sending, in 10 milliseconds. The value range is from 1 to 1000.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the timeout time of Trap message re-sending to 60 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server trap-timeout 60
```

1.26 snmp-server udp-port

Function

Run the **snmp-server udp-port** command to configure the ID of a port that receives SNMP packets.

Run the **no** form of this command to restore the default configuration.

The default UDP port ID of the SNMP service is **161**.

Syntax

snmp-server udp-port *port-number*

no snmp-server udp-port

Parameter Description

port-number: ID of a port that receives SNMP packets. The value range is from 1 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the ID of the UDP port that receives SNMP packets to 15000.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server udp-port 15000
```

1.27 snmp-server user

Function

Run the **snmp-server user** command to configure an SNMP user.

Run the **no** form of this command to remove this configuration.

No SNMP user is configured by default.

Syntax

snmp-server user *username group-name* { **v1** | **v2c** | **v3** [**encrypted** | **interactive**] [**auth** { **md5** | **sha** | **sha2-256** | **sha2-512** } *auth-password*] [**priv** { **des56 | acs128** } *priv-password*] } [**access** { [**ipv6** *ipv6-acl-name*] *acl-name* | *acl-number* }]

no snmp-server user *username group-name* { **v1** | **v2c** | **v3** }

Parameter Description

username: Username.

group-name: Name of the user group to which this user belongs.

v1: Uses SNMPv1.

v2c: Uses SNMPv2c.

v3: Uses SNMPv3.

encrypted: Ciphertext input as the password input mode. Otherwise, plaintext is used for input. If ciphertext input is selected, enter a key consisting of continuous hexadecimal digits. An MD5 authentication key consists of 16 bytes and an SHA authentication key consists of 20 bytes. Two characters stand for one byte. Encrypted keys are valid for this engine only.

interactive: Uses the interactive method to configure the authentication and encrypted password string.

auth { **md5** | **sha** | **sha2-256** | **sha2-512** } *auth-password*: Specifies a protocol used for user authentication when an SNMPv3 user is configured.

md5 indicates that MD5 is used for authentication, **sha** indicates that SHA is used for authentication, **sha2-256** indicates that 256-bit SHA2 is used for authentication, **sha2-512** indicates that 512-bit SHA2 is used for authentication, and *auth-password* indicates a password string that is used for authentication protocol configuration. The value range is from 1 to 32 characters. The system converts the passwords into the corresponding authentication keys.

priv { **des56 | acs128** } *priv-password*: Specifies an encryption protocol when an SNMPv3 user is configured.

des56 indicates that 56-bit DES encryption protocol is used, **acs128** indicates that 128-bit ACS encryption protocol is used, and *priv-password* indicates a password string used for encryption. The value is a string of 1 to 32 characters. The system converts the password into the corresponding encryption key.

ipv6 *ipv6-acl-name*: Associates a specified list of IPv6 addresses and specifies the range of the IPv6 NMS addresses that are allowed to access the MIB.

acl-name: ACL name. The value is a case-sensitive string of 1 to 99 characters.

acl-number: Number of an ACL. The value range of the ACL list of standard IP addresses is from 1 to 99 or from 1300 to 1999. The value range of the ACL list of extended IP addresses is from 100 to 199 or from 2000 to 2699.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example creates an SNMPv3 user user-2 and configures MD5 as an authentication protocol and DES as an encryption protocol.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server user user-2 mib2user v3 auth md5 authpassstr priv des56
despassstr
```

The following example creates an SNMPv3 user in interaction mode and configures MD5 as an authentication protocol DES and DES as an encryption protocol.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# snmp-server user mib2user mib2group v3 interactive auth md5 priv
des56

1.28 snmp-server view

Function

Run the **snmp-server view** command to configure an SNMP view.

Run the **no** form of this command to remove this configuration.

The default view allows access to all MIB objects.

Syntax

snmp-server view *view-name oid-tree* { **exclude** | **include** }

no snmp-server view *view-name* [*oid-tree*]

Parameter Description

view-name: View name.

oid-tree: MIB objects associated with a view, which are displayed as an MIB subtree.

exclude: Indicates that the MIB object subtree is not included in the view.

include: Indicates that the MIB object subtree is included in the view.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures a view named mib2 and includes all MIB-2 subtrees with OID 1.3.6.1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# snmp-server view mib2 1.3.6.1 include

1 RMON Commands

Command	Function
rmon alarm	Configure the Remote Network Monitoring (RMON) alarm function.
rmon collection history	Configure the history statistics function on an Ethernet interface.
rmon collection stats	Configure the statistics function on an Ethernet interface.
rmon event	Configure an RMON event.
show rmon	Display all RMON information.
show rmon alarm	Display the alarm table information.
show rmon event	Display the event table information.
show rmon history	Display the history table information.
show rmon statistics	Display the Ethernet statistics information.

1.1 rmon alarm

Function

Run the **rmon alarm** command to configure the Remote Network Monitoring (RMON) alarm function.

Run the **no** form of this command to remove this configuration.

The RMON alarm function is not configured by default.

Syntax

rmon alarm *alarm-table-index alarm-variable sampling-interval* { **absolute** | **delta** } **rising-threshold** *ampling-rising-threshold-value* [*event-number*] **falling-threshold** *falling-threshold-value* [*event-number*] [**owner** *owner-name*]

no rmon alarm *alarm-table-index*

Parameter Description

alarm-table-index: Index number of an alarm table. The value range is from 1 to 65535.

alarm-variable: Alarm variable. The value is a string of 1 to 255 characters and is represented in the format of entry.integer.instance, for example, 1.3.6.1.2.1.2.1.10.1.

sampling-interval: Collection interval, in seconds. The value range is from 1 to 2147483647.

absolute | **delta**: Configures a collection type. **absolute** indicates absolute value sampling. That is, variable values are extracted directly when sampling starts. **delta** indicates changing value sampling. That is, changing values are extracted in the sampling interval when sampling starts.

rising-threshold *sampling-rising-threshold-value*: Configures an upper limit of sampled objects. The value range is from -2147483648 to 2147483647.

event-number: Index number of an event whose event number is *event-number* when the upper or lower limit is reached. The value range is from 1 to 65535.

falling-threshold *falling-threshold-value*: Configures a lower limit to sampled objects. The value range is from -2147483648 to 2147483647.

owner *owner-name*: Configures an entry creator. The value is a case-sensitive string of 1 to 63 characters.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be used to modify parameters of configured alarm entries, including alarm variable, sampling type, entry creator, sampling interval, upper/lower limit, and event.

Examples

The following example monitors the management information base (MIB) variable instance **ifInNUcastPkts.6**, sets the sampling interval to 60 seconds, and triggers event 1 when the variable value reaches the upper limit 20 or lower limit 10.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rmon alarm 10 1.3.6.1.2.1.2.2.1.12.6 60 delta rising-threshold 20
1 falling-threshold 10 1 owner UserA
```

Notifications

- If the configuration you delete is not configured, the following notification will be displayed.
- If the upper limit is smaller than or equal to the lower limit, the following notification will be displayed.
- If the entered object OID is not improper, the following notification will be displayed.
- If the number of configured entries reaches the upper limit, the following notification will be displayed.
- If a memory application failed, the following notification will be displayed.

Common Errors

- The entered object OID is improper. For example, the variable corresponding to this OID is not configured or the OID type is not an integer or unsigned integer.
- The upper limit is smaller than or equal to the lower limit.

Platform Description

1.2 rmon collection history

Function

Run the **rmon collection history** command to configure the history statistics function on an Ethernet interface.

Run the **no** form of this command to remove this configuration.

The history statistics function is not configured on an Ethernet interface by default.

Syntax

rmon collection history *collection-history-table-index* [**buckets** *bucket-number*] [**interval** *period-time*] [**owner** *owner-name*]

no rmon collection history *collection-history-table-index*

Parameter Description

collection-history-table-index: Index number of a history control table. The value range is from 1 to 65535.

owner *owner-name*: Configures an entry creator. The value is a case-sensitive string of 1 to 63 characters.

buckets *bucket-number*: Configures the capacity of a history statistics table. The value range is from 1 to 65535. Actually, only 10 history entries are configured.

interval *period-time*: Configures a collection period, in seconds. The value range is from 1 to 3600, and the default value is **1800**.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

- It is not allowed to modify parameters of the configured history control entries.
- It is not allowed to delete history statistics entries configured on another interface on the local interface.

Examples

The following example configures the history statistics function on GigabitEthernet 0/1 and sets the capacity of the history statistics table to 5 and collection period to 60 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-GigabitEthernet0/1)# rmon collection history 1 owner UserA buckets
5 interval 60
```

Notifications

- If the configuration you delete is not configured, the following notification will be displayed.
- If you modify parameters of the configured history control entries, the following notification will be displayed.
- If the number of configured entries reaches the upper limit, the following notification will be displayed.
- If a memory application failed, the following notification will be displayed.

Common Errors

The parameters of configured history control entries are reconfigured or modified.

1.3 rmon collection stats

Function

Run the **rmon collection stats** command to configure the statistics function on an Ethernet interface.

Run the **no** form of this command to remove this configuration.

The Ethernet statistics function is not configured on an Ethernet interface by default.

Syntax

rmon collection stats *collection-stats-table-index* [**owner** *owner-name*]

no rmon collection stats *collection-stats-table-index*

Parameter Description

collection-stats-table-index: Index number of a statistics entry. The value range is from 1 to 65535.

owner *owner-name*: Configures an entry creator. The value is a case-sensitive string of 1 to 63 characters. Space is not supported.

Command Modes

Interface configuration mode

Default Level

14

Usage Guidelines

- It is not allowed to modify parameters of configured statistics entries.
- It is not allowed to delete history statistics entries configured on another interface on the local interface.

Examples

The following example configures the statistics function on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# interface gigabitEthernet 0/1
Hostname(config-GigabitEthernet0/1)# rmon collection stats 1 owner UserA
```

Notifications

- If the configuration you delete is not configured, the following notification will be displayed.
- If you modify parameters of the configured statistics entries, the following notification will be displayed.
- If the number of configured entries reaches the upper limit, the following notification will be displayed.
- If a memory application failed, the following notification will be displayed.

Common Errors

The parameters of configured statistics entries are reconfigured or modified.

Platform Description

1.4 rmon event

Function

Run the **rmon event** command to configure an RMON event.

Run the **no** form of this command to remove this configuration.

No RMON event is configured by default.

Syntax

rmon event *event-table-index* [**description** *description-string*] [**log**] [**owner** *owner-name*] [**trap** *community*]

no rmon event *event-table-index*

Parameter Description

event-table-index: Index number of an event table. The value range is from 1 to 65535.

description d*escription-string*: Configures description of an event. The value is a string of 1 to 127 characters.

log: Specifies a log event. When a log event is triggered, the system generates a record in the log. The default number of log records is 10. If a new record is generated, the earliest record is deleted.

owner *owner-name*: Configures an entry creator. The value is a case-sensitive string of 1 to 63 characters.

trap *community*: Specifies a Trap event. When a Trap event is triggered, the system sends a Trap message with the community name *community*.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

This command can be used to modify parameters of configured event entries, including event table type, community name, creator, and description.

Examples

The following example defines actions of an event: generating an event record "ifInNUcastPkts is abnormal" and sending a Trap message with the community name being public.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# rmon event 1 log trap public description "ifInNUcastPkts is abnormal"
owner UserA
```

Notifications

- If the configuration you delete is not configured, the following notification will be displayed.
- If the number of configured entries reaches the upper limit, the following notification will be displayed.
- If a memory application failed, the following notification will be displayed.

Syntax

show rmon history

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays the history group information.

```
Hostname> enable
Hostname# show rmon history
rmon history control table:
                index = 1
                interface = GigabitEthernet 0/1
                bucketsRequested = 5
                bucketsGranted = 5
                interval = 60
                owner = UserA
                stats = 1
rmon history table:
                index = 1
                sampleIndex = 2485
                intervalStart = 7d:22h:56m:38s
                dropEvents = 0
                octets = 5840
                pkts = 27
                broadcastPkts = 0
                multiPkts = 0
                crcAlignErrors = 0
                underSizePkts = 0
                overSizePkts = 0
                fragments = 0
                jabbers = 0
                collisions = 0
                utilization = 0
```

Table 1-3 Output Fields of the show rmon history Command

Field	Description
rmon history control table	History statistics control table
index	Index of a history statistics control table
interface	Interface name
bucketsRequested	Number of requests
bucketsGranted	Capacity of history entries allowed

Field	Description
interval	Sampling interval
owner	Entry creator
stats	Entry state
rmon history table	History statistics table
sampleIndex	Index of a history table
intervalStart	Generation time
dropEvents	Number of received packets that are lost due to insufficient resources
octets	Number of received bytes
pkts	Number of received packets
broadcastPkts	Number of received broadcast packets
multiPkts	Number of received multicast packets
crcAlignErrors	Number of packets with CRC errors
underSizePkts	Number of packets in the correct format and with a length being less than 64 bytes
overSizePkts	Number of packets in the correct format and with a length being more than 1,518 bytes
fragments	Number of packets with a length being less than 64 bytes and with CRC or alignment errors
jabbers	Number of packets with a length being more than 1,518 bytes and with CRC or alignment errors
collisions	Total number of conflicts
utilization	Network utilization

1 CWMP Commands

Command	Function
acs password	Configure an ACS password for CWMP connection.
acs url	Configure an ACS URL for CWMP connection.
acs username	Configure an ACS username for CWMP connection.
cpe back-up	Enable the backup and restoration function of the CPE main program or configuration file.
cpe inform	Enable the periodic Inform function of the CPE.
cpe source interface	Obtain an IP address through the specified interface and configure a CPE URL for CWMP connection. based on the IP address.
cpe password	Configure a CPE password for CWMP connection.
cpe url	Configure a CPE URL for CWMP connection.
cpe username	Configure a CPE username for CWMP connection.
cwmp	Enable the CWMP function and enter the CWMP configuration mode.
disable download	Disable the management function of receiving any main program and configuration file delivered by the ACS.
disable upload	Disable the management function of uploading any main program, configuration file and log file to the ACS.
show cwmp configuration	Display the current configuration of the CWMP function.
show cwmp status	Display the current running status of CWMP.
timer cpe-timeout	Configure the CPE timeout time in the case of no ACS response.

1.1 acs password

Function

Run the **acs password** command to configure an ACS password for CWMP connection.

Run the **no** form of this command to remove this configuration.

No ACS password is configured for CWMP connection by default.

Syntax

acs password { **0** *encryption-type* | **7** *encrypted-password* | *password* }

no acs password

Parameter Description

0 *encryption-type*: Specifies a plaintext password as the password encryption type.

7 *encrypted-password*: Specifies a cyphertext string. The cyphertext encrypted using encryption algorithms must be legal, for example, it must be an even number and less than or equal to 256 characters.

password: ACS password for CWMP connection.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

When an ACS password is configured for CWMP connection, the encryption type does not need to be entered. If an encrypted password is copied and pasted, the encryption type must be entered. A valid password should meet the following format requirements:

- Contain letters or digits.
- Trailing and middle spaces are a part of the password.

Examples

The following example sets the ACS password for CWMP connection to 123user_1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# acs password 123user_1
```

Notifications

If the entered password is cyphertext and it is not an even number or its length is less than 2 characters or more than 254 characters, the following notification will be displayed:

```
Invalid Encrypted Password
```

If the entered password is plaintext and longer than 126 characters, the following notification will be displayed:

```
The Length of ACS's Password is Too Long
```

If the entered password is plaintext and contains invalid characters, the following notification will be displayed:

```
Password String Include Invalid Characters!
```

Common Errors

1.2 acs url

Function

Run the **acs url** command to configure an ACS URL for CWMP connection.

Run the **no** form of this command to remove this configuration.

No ACS URL is configured for CWMP connection by default.

Syntax

acs url *url*

no acs url

Parameter Description

url: ACS URL for CWMP connection.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

If the ACS URL is not manually configured but a dynamic ACS URL is obtained through DHCP, this dynamic ACS URL is used to initiate a connection to the ACS. Ensure that UDP port 7547 on the CPE is unused. This port is used for Simple Traversal of UDP over NATs (STUN) port listening. The ACS URL must meet the following format requirements:

- Follow the format of http://ip[:port]/path.
- Contain 255 characters at most.

Examples

The following example sets the ACS URL for connection with the CPE to http://10.10.10.1:7547/acs.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
```

```
Hostname(config-cwmp)# acs url http://10.10.10.1:7547/acs
```

Notifications

If the ACS URL is null, the following notification will be displayed:

```
input acs attribute parameter is null
```

Common Errors

N/A

Platform Description

N/A

Related Commands

N/A

1.3 acs username

Function

Run the **acs username** command to configure an ACS username for CWMP connection.

Run the **no** form of this command to remove this configuration.

No ACS username is configured for CWMP connection by default.

Syntax

acs username *username*

no acs username

Parameter Description

username: ACS username for CWMP connection.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

N/A

Examples

The following example sets the ACS username for CWMP connection to **admin**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# acs username admin
```

Notifications

If the ACS username is null, the following notification will be displayed:

```
input acs attribute parameter is null
```

Common Errors

N/A

Platform Description

N/A

Related Commands

1.4 cpe back-up

Function

Run the **cpe back-up** command to enable the backup and restoration function of the CPE main program or configuration file.

Run the **no** form of this command to disable this function.

The backup and restoration function of the main program or configuration file is disabled by default.

Syntax

cpe back-up [**delay-time** *time*]

no cpe back-up

Parameter Description

time: Delay for backup and restoration of the CPE main program or configuration file, in seconds. The value range is from 30 to 1000, and the default value is **60**.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

After the backup and restoration of the main program or configuration file is enabled on the CPE in the case of an abnormality, the CPE can restore its abnormal main program or configuration file to their previous states in time when the CPE fails to connect to the ACS and breaks away from the management center after the main program or configuration file upgrade. The ACS is restored to manage the CPE. This abnormality is generally caused by delivery of an incorrect main program version or configuration file.

Examples

The following example configures the backup and restoration function of the CPE main program or configuration file.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# cpe back-up
```

Common Errors

1.5 cpe inform

Function

Run the **cpe inform** command to enable the periodic Inform function of the CPE.

Run the **no** form of this command to disable this function.

The periodic Inform function of the CPE is disabled by default.

Syntax

cpe inform [**interval** *interval*] [**start-time** *hh:mm:ss MM/DD/YY*]

no cpe inform

Parameter Description

interval *interval*: Configures the periodic Inform interval of the CPE, in seconds. The value range is from 30 to 3600, and the default value is **600**.

start-time *hh:mm:ss MM/DD/YY*: Configures the start time of periodic Inform. *hh* indicates hour. *mm* indicates minute. *ss* indicates second. *MM* indicates month. *DD* indicates day. *YY* indicates year.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

- The shorter the CPE periodic Inform interval is, the more timely the ACS traces the latest status of the CPE. More CPE-ACS sessions consume more resources. Users must configure a proper interval based on the current network status and ACS performance configuration.
- If no Inform start time is configured, from the Inform enabling time, Inform is performed once every default

Inform interval.

- If the Inform start time is configured, periodic Inform starts at the specified start time. For example, if the Inform interval is set to 60 seconds and the start time is 12:00 a.m. next day, periodic Inform will start at 12:00 a.m. next day and be performed once every 60 seconds.

Examples

The following example sets the periodic Inform interval of the CPE to 60 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# cpe inform interval 60
```

Common Errors

1.6 cpe source interface

Function

Run the **cpe source interface** command to obtain an IP address through the specified interface and configure a CPE URL for CWMP connection. based on the IP address.

Run the **no** form of this command to remove this configuration.

No IP address is obtained through the specified interface and used to configure a CPE URL for CWMP connection by default.

Syntax

cpe source interface *interface-type interface-number* [**port** *port-number*]

no cpe source interface

Parameter Description

interface-type interface-number: Type and number of the port of CPE URL for CWMP connection.

port *port-number*: Specifies a port number. The value range is from 1 to 65535, and the default value is **7547**.

Command Modes

CWMP configuration mode

Default Level

14

Usage Guidelines

- This command and the **cpe url** command cannot be configured at the same time. If either command is configured, the other command must not be configured or must be deleted. If the two commands are not configured, the CPE automatically selects its URL based on the ACS URL.
- The interface name of the CPE must be the full name of the interface and can be automatically filled when a CLI command is entered.
- If no port ID is configured, the default port ID 7547 is used.

Examples

The following example configures a CPE URL for CWMP connection and sets the CPE port ID to 7547 on GigabitEthernet 0/1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# cpe source interface GigabitEthernet 0/1 port 7547
```

Notifications

If the name of the entered interface is incorrect, the following notification will be displayed:

```
% Invalid input detected at '^' marker.
```

If an IP address is configured using the **cpe url** command, the following notification will be displayed:

```
Cpe url have been set by command cpe url, please clear it.
```

Common Errors

N/A

Platform Description

If this command is configured on the CPE, running the **show cwmp configuration** command displays one more record, which is the full name of the interface. If this command is not configured on the CPE, running the **show cwmp configuration** command displays no information.

```
Hostname> enable

1.7 cpe password

Function

Run the **cpe password** command to configure a CPE password for CWMP connection.

Run the **no** form of this command to remove this configuration.

No CPE password is configured for CWMP connection by default.

Syntax

cpe password { **0** *encryption-type* | **7** *encrypted-password* | *password* }

no cpe password

Parameter Description

0 *encryption-type*: Specifies a plaintext password as the password encryption type.

7 *encrypted-password*: Specifies a cyphertext string. The cyphertext encrypted using encryption algorithms must be legal, for example, it must be an even number and less than or equal to 256 characters.

password: CPE password for CWMP connection.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

When a CPE password is configured for CWMP connection, the encryption type does not need to be entered. If an encrypted password is copied and pasted, the encryption type must be entered. A valid password should meet the following format requirements:

- Contain 1 to 26 characters including uppercase letters, lowercase letters, and digits.
- Leading spaces will be ignored, while the trailing and middle spaces are valid.

Examples

The following example sets the CPE password for CWMP connection to 123user_1.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# cpe password 123user_1
```

Notifications

If the entered password is cyphertext and it is not an even number or its length is less than 2 characters or not more than 254 characters, the following notification will be displayed:

```
Invalid Encrypted Password
```

If the entered password is plaintext and longer than 126 characters, the following notification will be displayed:

```
The Length of ACS's Password is Too Long
```

If the entered password is plaintext and contains illegal characters, the following notification will be displayed:

```
Password String Include Invalid Characters!
```

1.8 cpe url

Function

Run the **CPE url** command to configure a CPE URL for CWMP connection.

Run the **no** form of this command to remove this configuration.

No CPE URL is configured for CWMP connection by default.

Syntax

cpe url *url*

no cpe url

Parameter Description

url: CPE URL for CWMP connection.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

If the CPE URL is not manually configured, a CPE URL is automatically selected based on the ACS URL. The CPE URL format must meet the following requirements:

- Follow the http://ip [: port]/ format.
- Contain 255 characters at most.

Examples

The following example sets the CPE URL for CWMP connection to http://10.10.10.1:7547/.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# cpe url http://10.10.10.1:7547/

Examples

The following example displays the current configuration of the CWMP function.

```
Hostname> enable
```

```
Hostname# show cwmp configuration
CWMP Status                  : enable
ACS URL                     : http://www.Hostname.com.cn/acs
ACS username                 : admin
ACS password                 : ******
CPE source interface name      :
CPE URL                     : http://10.10.10.2:7547/
CPE username                 : Hostname
CPE password                 : ******
CPE inform status             : disable
CPE inform interval           : 60s
CPE inform start time         : 0:0:0 0 0 0
CPE wait timeout             : 50s
CPE download status           : enable
CPE upload status            : enable
CPE back up status            : enable
CPE back up delay time         : 60s
CPE STUN port-adaptive         : disable
CPE STUN probe nat agingtime    : disable
CPE STUN port                : 3478
CPE STUN max-period           : 60s
CPE STUN min-period           : 20s
```

Table 1-1 Output Fields of the show cwmp configuration Command

Field	Description
CWMP Status	Enabling status of the CWMP function
ACS URL	ACS URL for CWMP connection
ACS username	ACS username for CWMP connection
ACS password	ACS password for CWMP connection
CPE source interface name	CPE URL port for CWMP connection
CPE URL	CPE URL for CWMP connection
CPE username	CPE username for CWMP connection
CPE password	CPE password for CWMP connection
CPE inform status	Periodic Inform status of CPE
CPE inform interval	Periodic Inform interval of CPE
CPE wait timeout	CPE session timeout time
CPE inform start time	Start time of periodic Inform of CPE
CPE download status	Whether to download any main program and configuration file from the ACS

Field	Description
CPE upload status	Whether to upload any main program and configuration file and log file to the ACS
CPE back up status	Whether to enable restoration of the main program and configuration file
CPE back up delay time	Delay for restoration of the main program and configuration file
CPE STUN port-adaptive	Whether to enable STUN port auto-adaption: ● **disable**: Disables the STUN port auto-adaption function. ● **enable**: Enables the STUN port auto-adaption function.
CPE STUN probe nat agingtime	Whether to enable the STUN NAT age time probe function: ● **disable**: Disables the STUN NAT age time probe function. ● **enable**: Enables the STUN NAT age time probe function.
CPE STUN port	STUN server port
CPE STUN max-period	Maximum keep-alive time of STUN packets
CPE STUN min-period	Minimum keep-alive time of STUN packets

1.14 show cwmp status

Function

Run the **show cwmp status** command to display the current running status of CWMP.

Syntax

show cwmp status

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

1

Usage Guidelines

N/A

Examples

The following example displays the current running status of CWMP.

```
Hostname> enable
Hostname# show cwmp status
CWMP Status                  : enable
Session status               : Close
Last success session         : Unknown
Last success session time    : Thu Jan  1 00:00:00 1970
Last fail session            : Unknown
Last fail session time       : Thu Jan  1 00:00:00 1970
Session retry times          : 0
```

Table 1-2 Output Fields of the show cwmp status Command

Field	Description
CWMP Status	Enabling status of the CWMP function
Session status	Status of the current session between the CPE and ACS
Last success session	Type of the last successful session
Last success session time	End time of the last successful session
Last fail session	Type of the last failed session
Last fail session time	End time of the last failed session
Session retry times	Retry times of the current session

1.15 timer cpe-timeout

Function

Run the **timer cpe-timeout** command to configure the CPE timeout time in the case of no ACS response.

Run the **no** form of this command to remove this configuration.

The default CPE timeout time is **30** seconds in the case of no ACS response.

Syntax

timer cpe-timeout *tiemout*

no timer cpe-timeout

Parameter Description

timeout: Timeout time, in seconds. The value range is from 10 to 600.

Command Modes

CWMP configuration mode

Default Level

1

Usage Guidelines

This command is used to configure the CPE timeout time in the case of no ACS response. This CPE timeout time refers to the maximum delay of a session when the CPE fails to receive ACS response due to an exception, for example, network disconnection.

Examples

The following example sets the CPE timeout time to 50 seconds in the case of no ACS response.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# cwmp
Hostname(config-cwmp)# timer cpe-timeout 50
```

1 SEM Commands

Command	Function
action cli	Configure a policy by running a specified command line.
action counter	Configure an action for a policy by operating a specified SEM naming counter.
action exit	Configure an action for a policy by terminating a policy script and exiting the current status.
action reload	Configure an action for a policy by restarting a device.
action set	Configure an action for a policy by setting local variables.
action syslog	Configure an action of logging.
action wait	Configure an action for a policy by pausing a policy script.
commit	Submit policy configuration.
description	Configure the description of an SEM policy.
event tag counter	Configure a counter monitoring event.
event tag interface	Configure an interface monitoring event.
event tag syslog	Configure a log monitoring event.
event tag timer	Configure a timer monitoring event.
event tag track	Configure a track monitoring event.
list-config	Display the current policy configuration.
policy record	Enable the function of recording CLI command output and configure output size.
rollback	Roll back the current policy configuration.
show smart manager detector	Display detector information.

show smart manager history events	Display event history information.
show smart manager policy all	Display all policies and their submission information.
show smart manager policy registered	Display registered policies.
show smart manager version	Display SEM versions.
smart manager applet	Create an SEM policy.
smart manager detector event-number	Configure upper limits of SEM detector parameters.
smart manager global-variant number	Configure the maximum number of global variables of SEM.
smart manager policy	Configure upper limits of SEM policy parameters.
smart manager record	Configure upper limits of SEM policy instance parameters.
smart manager schdulr	Configure upper limits of SEM policy scheduler parameters.

1.1 action cli

Function

Run the **action cli** command to configure a policy by running a specified command line.

Run the **no** form of this command to remove this configuration.

No action is configured for a policy by default.

Syntax

action *action-label* **cli command** *cli-string* [**pattern** *pattern-string*]

no action *action-label*

Parameter Description

action-label: Label of an action.

command *cli-string*: Specifies the command content to be run.

pattern *pattern-string*: Specifies the interaction reply content of a command.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

- The *pattern-string* parameter separates multiple interaction replies with space. If a reply contains space, the double quotes ("") are used for discrimination.
- Command output of a policy can be recorded to the file system of a device. The **policy record** command is run to enable the recording function and configure file size, and the **smart manager policy record clean** command is run to clear command output records. For more information, see **policy record**.

Examples

The following example runs the **enable**, **clear arp-cache**, and **clear ip route *** commands for the none events in the clear_cache policy.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet clear_cache
Hostname(config-applet)# event tag monitor_cmd none
Hostname(config-applet)# action 00 cli command "enable"
Hostname(config-applet)# action 10 cli command "clear arp-cache"
Hostname(config-applet)# action 20 cli command "clear ip route *"
```

```
Hostname(config-applet)# commit
```

1.2 action counter

Function

Run the **action counter** command to configure an action for a policy by operating a specified SEM naming counter.

Run the **no** form of this command to remove this configuration.

No action is configured for a policy by default.

Syntax

action *action-label* **counter name** *counter-name* **value** *counter-value* **op** { **dec** | **inc** | **nop** | **set** }

no action *action-label*

Parameter Description

action-label: Label of an action.

name *counter-name*: Specifies the name of a counter to be operated.

value *counter-value*: Specifies a value used by an operation. The value range is from -2147483648 to 2147483647.

op { **dec** | **inc** | **nop** | **set** }: Specifies a method used by an operation. **dec** indicates a decrement of the counter value based on the value of **value** *counter-value*. **inc** indicates an increment of the counter value based on the value of **value** *counter-value*. **nop** indicates the reading of the counter value, and **set** specifies the counter value.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures a log monitoring policy Test_1 and sets the action of the policy to increase the value of the Authenticate_Faile counter by 1 when the content "login faile" is detected in the log.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag monitor_log syslog pattern "login faile"
Hostname(config-applet)# action 00 counter name Authenticate_Faile op inc
value 1
Hostname(config-applet)# commit
```

Notifications

Related Commands

- **smart manager applet**

1.3 action exit

Function

Run the **action exit** command to configure an action for a policy by terminating a policy script and exiting the current status.

Run the **no** form of this command to remove this configuration.

The value **1** is returned by default when a policy is run to the end.

Syntax

action *action-label* **exit** [*result*]

no action *action-label*

Parameter Description

action-label: Label of an action.

result: Returned value of **exit**. The value range is from 0 to 2147483647. The default value is **1**.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

In the synchronous mode, the operation that triggers a policy will wait for the policy to complete and determine whether to continue running the policy based on the returned value of the policy. If the returned value is 0, the policy stops running. If the returned value is another value, the policy continues running.

Examples

The following example configures a policy Test_1 to monitor the command lines in the synchronous mode and forbids user operation and displays a notification when the user enters "write memory".

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag monitor_cli cli pattern "write memory"
sync yes
Hostname(config-applet)# action 00 puts "can not do this"
Hostname(config-applet)# action 10 exit 0
Hostname(config-applet)# commit
```

1.4 action reload

Function

Run the **action reload** command to configure an action for a policy by restarting a device.

Run the **no** form of this command to remove this configuration.

No action is configured for a policy by default.

Syntax

action *action-label* **reload**

no action *action-label*

Parameter Description

action-label: Label of an action.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures a policy Test_1 to restart a device when the total memory of the device is less than 20 MB.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag monitor_memory sysmon memory scope
system-free entry-op lt entry-val 20000
Hostname(config-applet)# action 00 reload
Hostname(config-applet)# commit
```

1.5 action set

Function

Run the **action set** command to configure an action for a policy by setting local variables.

Run the **no** form of this command to remove this configuration.

No local variable of SEM is configured by default.

Syntax

action *action-label* **set** *variable-name variable-value*

no action *action-label*

Parameter Description

action-label: Label of an action.

variable-name: Name of a local variable.

variable-value: Value of a local variable.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

A configured local variable can have the same name as a global variable. If the configured local variable has the same name as a global variable, the local variable takes priority over the global variable when this variable name is used to visit a variable.

Examples

The following example configures a policy Test_1, sets variables in the policy of the none event type, and sends the variables to a log.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag none_event none
Hostname(config-applet)# action 00 set var_for_test "Test_1 running"
Hostname(config-applet)# action 10 syslog msg "$var_for_test"
Hostname(config-applet)# commit
```

1.6 action syslog

Function

Run the **action syslog** command to configure an action of logging.

Run the **no** form of this command to remove this configuration.

No action is configured for a policy by default.

Syntax

action *action-label* **syslog** [**facility** *mnemonics*] **msg** *syslog-message* [**priority** *priority-level*]

no action *action-label* **syslog**

Parameter Description

action-label: Label of an action.

facility *mnemonics*: Specifies the mnemonic of a log.

msg *syslog-message*: Specifies log content.

priority *priority-level*: Sets the priority of a log.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

The mnemonic of a log must consist of uppercase letters and underline, with a length of 4 to 32 characters. If the configured mnemonic exceeds the specified range, the **Action syslog** command fails.

Examples

The following example configures an action Test_2 for logging when the CPU usage of an entire device exceeds 95%.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_2
Hostname(config-applet)# event tag monitor_cpu sysmon cpu scope system
entry-op gt entry-val 95
Hostname(config-applet)# action 00 syslog msg "system busy !"
Hostname(config-applet)# commit
```

1.7 action wait

Function

Run the **action wait** command to configure an action for a policy by pausing a policy script.

Run the **no** form of this command to remove this configuration.

No action is configured for a policy by default.

Syntax

action *action-label* **wait** *wait-time*

no action *action-label* **wait**

Parameter Description

action-label: Label of an action.

wait-time: Wait time, in seconds. The value range is from 1 to 180.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example configures a policy Test_1 by waiting for five seconds before running the **show arp** command.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag monitor_cli cli pattern "show arp" sync
yes
Hostname(config-applet)# action 00 cli command "enable"
Hostname(config-applet)# action 10 wait 5
Hostname(config-applet)# action 20 exit 1

1.10 event tag counter

Function

Run the **event tag counter** command to configure a counter monitoring event.

Run the **no** form of this command to remove this configuration.

No counter monitoring event is configured by default.

Syntax

event tag *event-name* [**correlate** { **and** | **andnot** | **or** }] **counter name** *counter-name* **entry-op** *operator* **entry-val** *entry-value* **exit-op** *operator* **exit-val** *exit-value*

no event tag *event-name*

Parameter Description

event-name: Name of an event.

correlate { **and** | **andnot** | **or** }: Specifies the conditional relationship between the current event and the combination of all other events. **and** indicates a logical AND relation. **andnot** indicates a logical AND NOT relation. **or** indicates a logical OR relation.

name *counter-name*: Specifies the name of a monitored counter.

entry-op *operator*: Triggers a method used for comparison.

exit-op *operator*: Restores a comparison method.

operator indicates a method used for comparison. The value **eq** indicates equal. The value **ge** indicates greater than or equal to. The value **gt** indicates greater than. The value **le** indicates less than or equal to. The value **lt** indicates less than. The value **ne** indicates unequal to.

entry-val *entry-value*: Triggers a value used for comparison. The value range is from -2147483648 to 2147483647.

exit-val *exit-value*: Restore a value used for comparison. The value range is from -2147483648 to 2147483647.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

- This command is used to configure a naming counter for SEM monitoring. The **action counter** command is run to modify the value of the naming counter.
- The **exit-op** and **exit-val** parameters are used to suppress frequent triggering of events. When an event is triggered, it becomes ineffective. If the comparison between the value of the naming counter and the value of the combination of the **exit-op** and **exit-val** parameters complies with the comparison method, the event is restored to effective status and can be triggered again.
- **correlate andnot** indicates a logical AND NOT relationship. For example, x **andnot** y means compliance with x but noncompliance with y.

Examples

The following example configures a counter monitoring policy Test_1 to trigger logging when the value of Test_Counter is greater than or equal to 10 and sets Test_Counter to 0 so that monitoring is restored when the value of Test_Counter is greater than 5.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag monitor_counter counter name
Test_Counter entry-op ge entry-val 10 exit-op gt exit-val 5
```

```
Hostname(config-applet)# action 10 counter name Test_Counter op set value
0
Hostname(config-applet)# commit
```

1.11 event tag interface

Function

Run the **event tag interface** command to configure an interface monitoring event.

Run the **no** form of this command to remove this configuration.

No interface monitoring event is configured by default.

Syntax

event tag *event-name* [**correlate** { **and** | **andnot** | **or** }] **interface name** *interface-type interface-number* **parameter** { **link_down** | **link_up** }

no event tag *event-name*

Parameter Description

event-name: Name of an event.

correlate { **and** | **andnot** | **or** }: Specifies the conditional relationship between the current event and the combination of all the preceding events. **and** indicates a logical AND relation. **andnot** indicates a logical AND NOT relation. **or** indicates a logical OR relation.

interface-type interface-number: Interface type and interface number of a monitoring interface.

parameter { **link_down** | **link_up** }: Specifies the status of a monitoring interface. **link_down** indicates a down interface and **link_up** indicates an up interface.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

correlate andnot indicates a logical AND NOT relation. For example, x **andnot** y means compliance with x but noncompliance with y.

Examples

The following example configures logging when the status of GigabitEthernet0/1 changes to up.

```
Hostname> enable
Hostname(config)# smart manager applet Test_1
Hostname(config)# event tag monitor_interface interface parameter link_up
name GigabitEthernet0/1
Hostname(config-applet)# action 00 syslog msg "$_interface_name up"
Hostname(config-applet)# commit
Hostname(config-applet)# exit
```

1.12 event tag syslog

Function

Run the **event tag syslog** command to configure a log monitoring event.

Run the **no** form of this command to remove this configuration.

No log monitoring event is configured by default.

Syntax

event tag *event-name* [**correlate** { **and** | **andnot** | **or** }] **syslog** [**occurs** *num-occurrences*] **pattern** *regular-expression* [**period** *period-value*] [**priority** *priority-level*] [**skip** { **no** | **yes** }]

no event tag *event-name*

Parameter Description

event-name: Name of an event.

correlate { **and** | **andnot** | **or** }: Specifies the conditional relationship between the current event and the combination of all configured events. **and** indicates a logical AND relation. **andnot** indicates a logical AND NOT relation. **or** indicates a logical OR relation.

occurs *num-occurrences*: Specifies the number of occurrences that trigger an event. The value range is from 1 to 2147483647. The default value is **1**.

pattern *regular-expression*: Specifies a string for pattern match of log content.

period *period-value*: Specifies the expiry time of **occurs** in a command. An **occurs** operation that lasts for more than *period-value* times out. When the value of **occurs** is 1, this parameter is invalid, in seconds. The value range is from 1 to 2147483647. The default value is **30**.

priority *priority-level*: Sets the priority of a matched log.

skip { **no** | **yes** }: Specifies whether to ignore syslog. If the value is set to **yes**, a matched log is ignored. The default value is **no**.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

- **correlate andnot** indicates a logical AND NOT relation. For example, x **andnot** y means compliance with x but noncompliance with y.
- To avoid event loop, logs sent by SEM, including logs suspended by the SEM scheduler and logs sent by Action Syslog, are ignored by the syslog detector without checking.
- Due to the limited space of a command line, the regular expression in the **pattern** parameter cannot include a question mark (?). To input, display and save configuration, use the ampersand and slash (&/) to replace the question mark (?) and use two ampersands (&&) to replace the ampersand (&). For example, a&/bc&&d represents a?bc&d.
- The **pattern** parameter can be used to add a sub-string of an event variable with the name pattern_name and the value regex in the (?<pattern_name>regex) format. The **pattern** parameter supports a maximum number of 16 sub-strings.

Examples

The following example configures a log monitoring event Test_1 to forcibly perform active/standby switchover of a device when "memory fail" is detected in the monitored log.

```
Hostname> enable
Hostname# configure terminal
```

```
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag monitor_log syslog pattern "memory fail"
Hostname(config-applet)# action 00 switchover
Hostname(config-applet)# commit
```

1.13 event tag timer

Function

Run the **event tag timer** command to configure a timer monitoring event.

Run the **no** form of this command to remove this configuration.

No timer monitoring event is configured by default.

Syntax

event tag *event-name* [**correlate** { **and** | **andnot** | **or** }] **timer countdown time** *countdown-timer*

no event tag *event-name*

Parameter Description

event-name: Name of an event.

correlate { **and** | **andnot** | **or** }: Specifies the conditional relationship between the current event and the combination of all the preceding events. **and** indicates a logical AND relation. **andnot** indicates a logical AND NOT relation. **or** indicates a logical OR relation.

countdown time *countdown-timer*: Configures a time point when events can be triggered. *time-value* indicates the duration in which events can be triggered, in seconds. The value range is from 1 to 2147483.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

- **correlate andnot** indicates a logical AND NOT relation. For example, x **andnot** y means compliance with x but noncompliance with y.

Examples

The following example configures a time point when an event Test_3 can be triggered: the duration in which the event can be triggered is 10 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_3
Hostname(config-applet)# event tag monitor_timer timer countdown time 10
Hostname(config-applet)# action 00 cli command "enable"

1.14 event tag track

Function

Run the **event tag track** command to configure a track monitoring event.

Run the **no** form of this command to remove this configuration.

No track monitoring event is configured by default.

Syntax

event tag *event-name* [**correlate** { **and** | **andnot** | **or** }] **track** [**state** { **down** | **up** }] [*track-id*]

no event tag *event-name*

Parameter Description

event-name: Name of an event.

correlate { **and** | **andnot** | **or** }: Specifies the conditional relationship between the current event and the combination of all the preceding events. **and** indicates a logical AND relation. **andnot** indicates a logical AND NOT relation. **or** indicates a logical OR relation.

state { **down** | **up** }: Specifies the status of a tracked entity. If this parameter is ignored, a tracked entity in the up or down status can trigger an event.

track-id: ID of a tracked entity. If this variable is ignored, all tracked entities are monitored.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

- **correlate andnot** indicates a logical AND NOT relation. For example, x **andnot** y means compliance with x but noncompliance with y.
- Track-based events are categorized into the following types:
  - Monitoring the up or down status of a tracked object
  - Monitoring the up or down status of all tracked objects
  - Monitoring the up and down statuses of a tracked object
  - Monitoring the up and down statuses of all tracked objects
- Before a tracked object is monitored, this object must be configured in advance. Otherwise, users are notified of undetected object when SEM configures an event.

Examples

The following example configures an event Test_1 to print "track 1 up." when the status of tracked object 1 changes to up.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag track_1 track 1 state up
Hostname(config-applet)# action 00 syslog msg "track 1 up."
```

1.16 policy record

Function

Run the **policy record** command to enable the function of recording CLI command output and configure output size.

Run the **no** form of this command to remove this configuration.

The recording function is not enabled for CLI command action output by default.

Syntax

policy record [**per-instance** *record-size-per-policy*] [**per-policy** *record-size-per-policy*]

no policy record

Parameter Description

per-instance *record-size-per-policy*: Configures the size of CLI command output recorded each time a policy is triggered, in thousand bytes. The value range is from 1 to 50. The default value is **50**.

per-policy *record-size-per-policy*: Configures the total size of all CLI command output recorded when a policy is triggered, in thousand bytes. The value range is from 1 to 1024. The default value is **1000**.

Command Modes

SEM configuration mode

Default Level

14

Usage Guidelines

- CLI command output is not recorded by default. After the **policy record** command is run, CLI command output will be recorded to the file system of a device. The output is recorded to the file /sem_record/policy_name/yyyy-mm-dd_hh-mm-ss_mspolicytriggerid.txt.
    - /sem_record/ is the general directory of all CLI command output and located in the root directory of the file system.
    - policy_name indicates the name of the policy and resides in the /sem_record/ directory. Each policy corresponds to a separate directory.
    - yyyy-mm-dd_hh-mm-ss_mspolicytriggerid.txt indicates the file name. The file name consists of the recording time and the ID of the triggered policy.

- The **more** command is run to display recorded content.
- When the size of the CLI command output generated during policy running exceeds the configured value of the **per-instance** *record-size-per-policy* parameter, the CLI command output starts to override the file from the header of the file.
- When the total size of the CLI command output files generated during running of a specific policy exceeds the configured value of the **per-policy** *record-size-per-policy* parameter, the earliest files start to be cleared until the total size of the CLI command output files complies with the configured value of **per-policy** *record-size-per-policy* parameter.
- The **smart manager policy record clean** command is run to clear CLI command output files in the file system.

Examples

The following example configures a Test_1 policy and records the CLI action output of the **enable** and **show arp** commands.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_1
Hostname(config-applet)# event tag none-event none
Hostname(config-applet)# action 00 cli command "enable"
Hostname(config-applet)# action 10 cli command "show arp"
Hostname(config-applet)# policy record
Hostname(config-applet)# commit
Hostname(config-applet)# exit
Hostname(config)# exit
Hostname# more /sem_record/Test_1/2010-01-01_01-00-00_1001.txt
                    SEM CLI RECORD FILE
SEM policy name: Test_1
SEM policy trigger id :1
SEM policy cli record time : Fri Jan 01 01:00:00 2010
=================================================
Hostname# enable

1.23 smart manager applet

Function

Run the **smart manager applet** command to create an SEM policy.

Run the **no** form of this command to remove this configuration.

No SEM policy is created by default.

Syntax

smart manager applet *applet-name*

no smart manager applet *applet-name*

Parameter Description

applet-name: Name of an SEM policy. A policy name must consist of digits, letters, and underline.

Command Modes

Global configuration mode

Default Level

15

Usage Guidelines

- A policy includes the following configurations:
  - One or more events
  - One or more actions
  - Description of the policy
  - Trigger control information of the policy
- The **smart manager applet** command is run to enter the SEM configuration mode. In this mode, users can complete the following operations:
  - Configure events of the policy.

    Each event must be given a unique name based on the **tag** parameter. SEM arranges the events in the alphabetical order of the **tag** parameter.

- Configure actions of the policy.

  Each action must be given a unique label as well. SEM arranges the actions in the alphabetical order of the *label* parameter. When the policy is triggered, the actions are taken in the alphabetical order of the *label*.

- Configure description of the policy.
- Configure trigger control parameters of the policy.
- Submit the policy configuration.
- Roll back the policy configuration.
- Display the current policy configuration.

- In the SEM configuration mode, users can use environmental variables in the actions of the policy. The variables are divided into two types:
  - Global variable
  - Local variable

    The global variables can be defined by an event detector when an event occurs.

    The local variables can be defined based on actions during policy running.

Note

- Each policy corresponds to a class. The default class is **default**. Multiple policies can belong to the same class. A class is used to allocate thread resources to policies in the class and specify priorities of the policies in the class.
- Policy configuration cannot take effect immediately and must be submitted by running the **commit** command in the SEM configuration mode.
- When the policy configuration is submitted, their validity is checked. If the checking fails, the policy configuration fails to be submitted. In this case, the policy is not registered.
- If no event is configured for the policy, the policy cannot pass the validity check and the policy submission fails.
- If no action is configured for the policy, the policy can pass the validity check. However, no action is taken when the policy is triggered. Therefore, a warning is given during the policy submission.
- If users want to quit the changes to the policy configuration, run the **rollback** command to roll back the policy configuration.
- When multiple events are configured for a policy, the events are automatically arranged in the alphabetical order of tags and the events are juxtaposed. Other events, except the first event, are used as additional conditions of the first event. Except the first event, the relationship of the current event with the combination of all preceding events is referred to as the relationship of other events. The juxtaposition of the first event is ignored, and the default value of the juxtaposition is **and**.

Examples

The following example creates a CLI based policy and names the policy Test_A.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# smart manager applet Test_A
Hostname(config-applet)#
```

1.24 smart manager detector event-number

Function

Run the **smart manager detector event-number** command to configure upper limits of SEM detector parameters.

Run the **no** form of this command to remove this configuration.

By default, the maximum number of events configured for the counting detector, that of events for the interface detector, and that of events configured for the timer detector are 256, respectively.

Syntax

smart manager detector { **counter** | **interface** | **timer** | **track**} **event-number** *detector-number*

no smart manager detector { **counter** | **interface** | **timer** } **event-number**

Parameter Description

counter event-number *detector-number*: Configures the maximum number of events for a counter detector. The value range is from 1 to 256.

interface event-number *detector-number*: Configures the maximum number of events for an interface detector. The value range is from 1 to 256.

timer event-number *detector-number*: Configures the maximum number of events for a timer detector. The value range is from 1 to 256.

track event-number *detector-number*: Configures the maximum number of events for a track detector. It is not configured by default. The value range is from 1 to 128.

Command Modes

1.26 smart manager policy

Function

Run the **smart manager policy** command to configure upper limits of SEM policy parameters.

Run the **no** form of this command to remove this configuration.

By default, the maximum number of actions in a policy is 64; the maximum numbers of policy detectors and registered policies are 128, respectively; and the maximum numbers of configured policies and policy delayed triggers are 256, respectively.

Syntax

smart manager policy { **action-number** *policy-number* | **config-number** *policy-number* | **event-number** *policy-number* | **register-number** *policy-number* | **trigger-delay-number** *policy-number* }

no smart manager policy { **action-number** | **config-number** | **event-number** | **register-number** | **trigger-delay-number** }

Parameter Description

action-number *policy-number*: Configures the maximum number of actions in a policy. The value range is from 1 to 64.

config-number *policy-number*: Configures the maximum number of policies. The value range is from 1 to 256.

event-number *policy-number*: Configures the maximum number of events that are detected by detectors. The value range is from 1 to 128.

register-number *policy-number*: Configures the maximum number of registered policies. The value range is from 1 to 128.

trigger-delay-number *policy-number*: Configures the maximum number of policy delayed triggers. The value range is from 1 to 256.

1 Intelligent Monitoring Commands

Command	Function
show fan	Display the fan information of a chassis.
show power	Display the power supply information.
show temperature	Display device temperature and threshold configuration.

1.1 show fan

Function

Run the **show fan** command to display the fan information of a chassis.

Syntax

show fan [[[*device-id*] *fan-id*] **detail** | **version**]

Parameter Description

device-id: Chassis ID of the fan tray to be displayed. This parameter is available only in VSU mode.

fan-id: ID of the fan tray to be displayed. IDs of all fan trays are displayed by default. In VSU mode, if a fan tray is specified but *device-id* is not specified, fans of the current chassis are displayed by default.

detail: Displays detailed information of fans. Except the content displayed by the **show fan** command, the rotating speed of the fans in each fan tray is displayed. For a faulty fan, its detailed fault information is displayed. The detailed information of all fan trays is displayed by default. If a fan tray ID is specified, only the detailed information of the specified fan tray is displayed.

version: Displays the version of a fan.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display fan information. If no parameter is specified in the **show fan** command, the model, serial number, operating status, and fan speed adjustment mode of all fan trays are displayed.
If a fan tray is faulty, the **show fan detail** command can be run to display fault cause of the fan tray.

Examples

The following example displays fan information.

```
Hostname> enable
Hostname# show fan
Fan id Type           Status    Hardware Version Serial Number
------ ---------------- ---------- ---------------- ---------------
1     M1SFAN I-F      ok        1.00           5555555555555
2     M1SFAN I-F      ok        1.00           6666666666666
```

Table 1-1 Output Fields of the show fan Command

Field	Description
Fan id	ID of a fan tray
Type	Fan type

Field	Description
Status	Status of a fan tray. A fan can be in one of the following statuses: ● **ok**: A fan runs normally. ● **no-present**: A fan tray is not in position. ● **fail**: At least one sub-fan stops rotating. ● **line fail**: Communication fails. ● **N/A**: Other errors.
Hardware-Version	Hardware version
Serial Number	Serial number of a fan

The following example displays detailed information of a fan.

```
Hostname> enable
Hostname# show fan detail
Card-type: RG-S6120-20XS4VS2QXS-L
Fan-id: 1
   Status:        ok
   Mode:          normal
   Fan-type:      M1SFAN I-F
   Serial Number:  5555555555555

   sub-fan-id  status  speed(rpm)  speed-level
   ----------  ------  ----------  ----------
   1          ok     7830       118
Fan-id: 2
   Status:        ok
   Mode:          normal
   Fan-type:      M1SFAN I-F
   Serial Number:  6666666666666

   sub-fan-id  status  speed(rpm)  speed-level
   ----------  ------  ----------  ----------
   1          ok     7980       118
---------
```

The following example displays detailed information of fan 1.

```
Hostname> enable
Hostname# show fan 1 detail
Chassis-type: S6120-20XS4VS2QXS
Fan-id: 1
   Status:        ok
   Mode:          normal
   Fan-type:      M1SFAN I-F
   Serial Number:  5555555555555
```

1          ok     7125       108
```

Table 1-2 Output Fields of the show fan detail Command

Field	Description
Chassis-type	Device type
Fan id	ID of a fan tray
Status	Status of a fan tray. A fan can be in one of the following statuses: ● **ok**: A fan runs normally. ● **no-present**: A fan tray is not in position. ● **fail**: At least one sub-fan stops rotating. ● **line fail**: Communication fails. ● **N/A**: Other errors.
Mode	Fan mode. A fan can be in one of the following modes: ● **quiet**: Quiet mode. The rotating speed of a fan in the normal mode is higher than that of a fan in the quiet mode at the same level. ● **defined**: User-defined mode. The rotating speed of fans can be customized. ● **normal**: Normal mode.
Fan-type	Fan-type
Serial Numbe	Serial numbe of a fan
sub-fan-id	ID of a sub-fan
Status	Status of a sub-fan. A sub-fan can be in one of the following statuses (if there are multiple sub-fans, the corresponding fan tray fails when one sub-fan fails). ● **ok**: A sub-fan runs normally. ● **fail**: A sub-fan stops rotating.
speed(rpm)	Rotating speed, in revolutions per minute.
speed-level	Level of a rotating speed. The value range is from 1 to 255. A higher level indicates a greater rotating speed.

1.2 show power

Function

Run the **show power** command to display the power supply information.

Syntax

show power [**version**]

Parameter Description

version: Displays serial number, hardware version No., and software version No. of each power supply.

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example displays basic power supply information.

```
Hostname> enable
Hostname# show power
Power-id Power-type         Status    Hardware-Version Serial
Supply(W)
-------- -------------------- ---------- ----------------
------------------------------ ---------
1       RG-PA150I-F         ok        1.3            R253H1942130110
150
2       N/A               no-present N/A            N/A                          N/A
```

Table 1-3 Output Fields of the show power Command

Field	Description
Power-id	ID of a power supply

Field	Description
Power-type	Power supply type
Status	Status of a power supply: ● **no-present**: The power supply is not in position. ● **ok**: The power supply works normally. ● **off**: The power supply is powered off. ● **fail**: The power supply fails. ● **line-fail**: Communication fails.
Supply(W)	Power, in Watt
Hardware-Version	Hardware version
Serial	Serial number of a power supply

The following example displays power supply version information.

```
Hostname> enable
Hostname# show power version
Card-type: RG-S6120-20XS4VS2QXS-L
Power-id: 1
   Serial Number:     R253H1942130110
   Type:             RG-PA150I-F
   Hardware Version:   1.3
   Software Version:   N/A
   Temperature(C):    N/A
Power-id: 2
   Status:        no-present
```

Table 1-4 Output Fields of the show power version Command

Field	Description
Card-type	Device type
Power-id	ID of a power supply
Serial Number	Serial number of a power supply
Type	Power supply type
Hardware Version	Hardware version
Software Version	Software version
Temperature	Temperature of a power supply

1.3 show temperature

Function

Run the **show temperature** command to display device temperature and threshold configuration.

Syntax

show temperature

Parameter Description

N/A

Command Modes

All modes except the user EXEC mode

Default Level

14

Usage Guidelines

This command is used to display current temperature and temperature thresholds of a device.

Temperature thresholds include alarm threshold and hazard threshold.

- Alarm threshold: When the temperature of a device exceeds the alarm threshold, the active supervisor module generates a Syslog message and the alarm indicator on the panel turns yellow.
- Hazard threshold: It indicates the power-off temperature. When the temperature of a device exceeds the hazard threshold, the device is powered off automatically. In addition, the active supervisor module generates a Syslog message and the alarm indicator on the panel turns red.

Examples

The following example displays temperature and temperature thresholds of all devices.

```
Hostname> enable
Hostname# show temperature
Temperature:
-------------------------------------------------------------------------------
Slot    Temp_name    Warning       Shutdown      Current      Status
```

```
                  (Celsius)       (Celsius)     (Celsius)
-------------------------------------------------------------------------------
0       air_inlet       55             72             32          ok
0       board           60             77             39          ok
0       switch          90             102            55          ok
```

Table 1-5 Output Fields of the show temperature Command

Field	Description
Slot	Slot ID of a device
Temp_name	Name corresponding to a temperature point
Warning	Warning level of temperature, in °C
Shutdown	Critical level of temperature, in °C. This is the hazard threshold and power-off temperature of a device.
Current	Temperature value corresponding to this temperature, in °C
Status	Status of a temperature. A temperature can be in one of the following statuses: ● **ok**: Current temperature is within the normal range. ● **fail**: A temperature sensor fails. ● **warning**: Current temperature exceeds the alarm threshold of the warning level. ● **critical**: Current temperature exceeds the alarm threshold of the shutdown level.

1 NETCONF Commands

Command	Function
netconf enable	Enable the NETCONF function.
netconf max-sessions	Configure the maximum number of session connections supported by NETCONF.
netconf port	Configure the port ID of the NETCONF server.
netconf timeout	Configure the timeout time of the Edit-config operation in a NETCONF session.
netconf yang multi-revision	Enable the YANG module multi-version notification function of NETCONF.
show netconf session	Display all current session information of NETCONF.
show netconf statistics	Display global statistics of NETCONF.
show netconf yang file	Display all YANG files supported by a device.
show netconf yang node-path	Display all node paths supported by a device.
show netconf yang tree	Display all YANG model trees supported by a device.

1.1 netconf enable

Function

Run the **netconf enable** command to enable the NETCONF function.

Run the **no** form of this command to disable this function.

Run the **default** form of this command to restore the default configuration.

The NETCONF function is enabled by default.

Syntax

netconf enable

no netconf enable

default netconf enable

Parameter Description

N/A

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example disables the NETCONF function.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# no netconf enable
```

1.2 netconf max-sessions

Function

Run the **netconf max-sessions** command to configure the maximum number of session connections supported by NETCONF.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The maximum number of session connections supported by NETCONF is **5** by default.

Syntax

netconf max-sessions *max-sessions-numbers*

no netconf max-sessions

default netconf max-sessions

Parameter Description

max-sessions *max-sessions-numbers*: Configures the maximum number of session connections supported by NETCONF. The value range is from 1 to 36.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the maximum number of session connections supported by NETCONF to **10**.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# netconf max-sessions 10
```

1.3 netconf port

Function

Run the **netconf port** command to configure the port ID of the NETCONF server.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default port ID of the NETCONF server is **830**.

Syntax

netconf port *port-number*

no netconf port

default netconf port

Parameter Description

port-number: Port ID of the NETCONF server. The value range is from 1025 to 65535.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

N/A

Examples

The following example sets the port ID of the NETCONF server to 5000.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# netconf port 5000
```

1.4 netconf timeout

Function

Run the **netconf timeout** command to configure the timeout time of the Edit-config operation in a NETCONF session.

Run the **no** form of this command to remove this configuration.

Run the **default** form of this command to restore the default configuration.

The default timeout time of the Edit-config operation in a NETCONF session is **120** seconds.

Syntax

netconf timeout *timeout*

no netconf timeout

default netconf timeout

Parameter Description

timeout: Timeout time, in seconds. The value range is from 50 to 1200.

Command Modes

Global configuration mode

Default Level

14

Usage Guidelines

The timeout time configured in this command for the Edit-config operation is not the duration between the delivery of an XML packet and the return of a reply. This timeout time counts from the completed processing of the XML packet is processed in NETCONF and the start of the business interaction.

Examples

The following example sets the timeout time of the Edit-config operation in a NETCONF session to 60 seconds.

```
Hostname> enable
Hostname# configure terminal
Hostname(config)# netconf timeout 60
```

Session unsupport      : 0
Session lock_or_unlock  : 0
```

```
==============================================================
```

Table 1-1 Output Fields of the show netconf session Command

Field	Description
Session count	Total number of current sessions
Session ID	Session ID defined internally
Session version	Current NETCONF version No.
Session transport	Transmission protocol used in the current NETCONF connection. At present, only SSH is supported.
Session login IP	IP address of the connected objects in the current session
Session login time	Login time of the current session
Session in rpcs	Total number of correct RPC requests sent in the current session
Session in bad rpcs	Total number of incorrect RPC requests sent in the current session
Session out rpc errors	Total number of RPC replies with error returned in the current session
Session out notification	Total number of notifications output in the current session
Session out rpcs	Total number of RPC replies with success returned in the current session
Session out send fail	Total number of replies that failed to be sent in the current session
Session get	Total number of Get operations in the current session
Session get config	Total number of Get-Config operations in the current session
Session edit config	Total number of Edit-Config operations in the current session
Session copy config	Total number of Copy-Config operations in the current session
Session delete config	Total number of Delete-Config operations in the current session
Session close session	Total number of Close-Session operations in the current session
Session unsupport	Total number of requests unsupported in the current session
Session lock_or_unlock	Total number of Lock and Unlock operations in the current session
